   I could continue this list. Take the categorical aspect of the old Moore-Seiberg work and all the subsequent papers in that frame of mind (most recently the Fuchs-Runkel-Schweigert etc. work). It is a good illustration of the present Zeitgeist that papers which develop these issues from an entirely physical spacetime perspective (as e.g. the paper of Rehren and myself on Einstein Causality and Artin Braids which appeared at the same time and several subsequent papers in this conceptual line) are hardly noticed outside a small community which has not suffered from that grand rupture in particle physics. Or take the recent works on n-categories (see the blogs in the string coffee table). The oldest and physically best motivated work on such issue (it shows you how hard the AQFTists worked in order to find a structural entrance to gauge theories) by John Roberts is not even mentioned!
   The situation reminds me of a newspaper report I red a long time ago in the US. It said that a catchup factory had to close down because the taste of their product was too

natural i.e. too close to real tomatos (not the plastic stuff which you find often in supermarkets in Europe and the US); most of the costumers already got to like the type which is mixed with pineapple and a lot of other less healthy things. Physicists only accept mathematical products if the underlying concepts have a certain distance from physics!

Reading the recent blogs on Dan Freed's work, I also learned to appreciate the subtle (but I still think unintended) humor of Lubos Motl. He is of course right in pointing out the metaporical link between those combining and splitting Euclidean waterhoses which Dan Freed and string theory share (I seriously hope that Freed does not require do interpret them the same way). Lubos Motl plays the (in modern times often missing) role a jester of the string community, a kind of supreme Lord of Misrule. If they have any sense of humor they would support his tenure at Harvard. His role of a jester also works perfectly with repect to the climate change issue. By carrying rightwing propaganda to its extremes, he creates a relaxed cabaret atmosphere which has the opposite effect from what it purpots to do, a perfect Lord of Misrule!

7. **Bert Schroer**
   May 9, 2006

   Peter
   This morning there was a post of Motl in this series of posts. My last remaks refer to this post and without is some part of my comments on string theory& Dan Freeds mathematical work runs into the void. Peter, did you loose your humor? There was no peronal attack in that one which could have annoyed you. Maybe we can ask him to re-import it.

8. **woit**
   May 9, 2006

   Bert,

   I certainly did not delete any comment of Lubos's here intentionally. If any recent comments in this thread disappeared, I don't know how it happened.

Revealing the Hidden Nature of Space and Time

April 26, 2006
Categories: Uncategorized

The EPP2010 report by the Committee on Elementary Particle Physics in the 21st Century is out today, and it is entitled Revealing the Hidden Nature of Space and Time. This committee was convened to recommend priorities for high energy physics in the U.S. over the next 15 years. Its membership included non-physicists and it was chaired by economist and ex-president of Princeton Harold Shapiro. The inclusion of people from outside the field emphasized the need for wide support for funding of U.S. particle physics if it is to remain healthy. The latest issue of Nature contains an article about the report entitled US particle physics fights for survival, and an editorial Making collider endorsement count. A press release about the report is here.

At the press conference announcing the report (which was webcast), Shapiro emphasized that the non-physicists on the committee had not been fully aware of the difficult situation US particle physics was in. They were very sobered by the state of US HEP, which he described as facing a serious danger that it would be half its size in 4-5 years, as current programs ended without a compelling follow-on program. The most important recommendation of the committee was that construction of the ILC in the US, probably at Fermilab, be vigorously pursued and that:

The United States should announce its strong intent to become the host country for the ILC and should undertake the necessary work to provide a viable site and mount a compelling bid.

Constructing the ILC in the US would require an increase beyond the rate of inflation in HEP funding, and the committee considered a scenario of budget increases of 2-3%per year that would probably be required, although solid numbers for what the cost of the ILC would be are still not yet available. Emphasizing the ILC in this way was described as a "high-risk, high-reward" strategy, and that taking these risks was necessary for US HEP to retain any leadership role in the field.

More specifically, the committee recommended six action items, ranked by priority:

1. Realize the physics potential of the LHC experimental program.

2. Launch a major program of R and D for the ILC, significantly expanding current expenditures on this.

3. Announce US intent to become the host country for the ILC.

4. Increase the current share of the HEP budget devoted to studying dark matter, the CMB and dark energy.

5. Develop a staged program, with international cooperation, of neutrino experiments, with emphasis on neutrinoless double-beta decay, accelerator based experiments, and search for possible charge-parity violation. This last might involve large detectors that could also be used to search for proton decay.

6. Support (especially if they're not very expensive) high-precision experiments that probe beyond the Standard Model physics, such as a future B factory, lepton-flavor violation and rare-decay studies, searches for electric dipole moments, and precision measurements of muon g-2.

The committee did a very good job of recognizing the difficult situation of US HEP, and coming up with a plausible strategy for how to make the best of it. I have my doubts about whether it's really a good idea to sell this as "Revealing the Hidden Nature of Space and Time", since it's not especially likely that that is what is going to happen. There's no particularly good reason to believe that extra dimensions will show up at the LHC or ILC energy scales, so over-selling this is dangerous. I do understand that it's a lot harder to get people excited about the new physics that this is likely to really all be about: understanding the nature of electro-weak symmetry breaking.

This was a study of what to do about experimental HEP, so the problems of theoretical HEP were not addressed. Unfortunately, besides the usual arguments for supersymmetry, over-hyped ideas about string theory make an appearance as the committee calls for "Improved tests of general relativity to search for effects of extra dimensions or string theory" and "Measuring time variation of physical constants with spectroscopy of distant objects to search for effects of extra dimensions and string theory", without noting that string theory makes no predictions about either of these. One other thing included in the report is new, improved verbiage about the status of string theory. In Witten's biographical sketch, it is described as "one of the leading candidates for the grand unified theory of elementary particle physics", which seems to me to be a downgrade from the phrase "the leading candidate" which until recently was often used to describe the status of the theory.

Update: More about this from Chad Orzel, Lubos, Clifford Johnson at Cosmic Variance, Tommaso Dorigo and The New York Times.

Update: Also from Alexey Petrov, who in a comment at Cosmic Variance links to a very different point of view about prospects for constructing the ILC in the near term: a recent resignation letter from Bill Foster, who was the Proton Driver project leader at Fermilab (the Proton Driver would be a high-luminosity, lower energy accelerator, useful for, among other things, producing a more intense neutrino beam).

Update: More from JoAnne Hewett at Cosmic Variance.

Comments

1. **michael**
   April 26, 2006

   It's difficult to comprehend extending our pocketbooks in favor of such laboratories while the NCI budget (i.e. applicable, translational research) is drying up. What is so pressing about understanding the fundamentals of symmetry breaking when troves of Americans are dying daily from the toxicity associated with underdeveloped cancer treatments?

2. **Who**
   April 26, 2006

   it is possible that you mean "droves" of Americans and not "troves".

   My dictionary says trove (as in "treasure-trove") is a thing found, from the old French word *to find*.

3. **michael**
   April 26, 2006

   Yes…even probable. Perhaps you could just talk Dr. Woit into building a grammar check into the 'submit comment' section?

4. **Peter Woit**
April 26, 2006

Michael,

There were long discussions of this over at Cosmic Variance. I think the relevant point is that each year the federal government is spending about 2500 billion, of which .7 billion is going to particle physics. This .03 percent of the budget isn't what is crowding out money for the purpose you mention (or any other purpose), much less the incremental amount over this that the ILC would cost.

5. **anon**
April 27, 2006

Peter, could you clarify for us what your problems with electroweak symmetry breaking are. The jargon probably puts laymen like me off. Perhaps I can explain what I've picked up on the subject.

My understanding is there are four electroweak gauge bosons, the photon and the massive but uncharged Z, plus two massive charged (W+ and W-).

All four have been detected at CERN in 1983, which validated electroweak theory.

The problem I think is why of the four only the photon has no rest mass and infinite range at low energy, while the Z, W+ and W- all have very short ranges (giving the weak force which controls the decay of neutrons into protons, etc.).

The mainstream mechanism is that a Higgs vacuum field gives mass to the Z, W+ and W- bosons at low energies, in some way. At higher energy, ie at the energy of electroweak unification, these bosons are no longer attenuated (or whatever) by the Higgs field, and their range becomes infinite.

The photon is able to go an infinite distance because it has no rest mass. The Higgs field gives rise to all inertial masses. It hasn't been detected directly. Is this a reasonable summary?

6. **sunderpeeche**
April 27, 2006

The EPP report was dedicated to experimental HEP, and it makes no difference if there are a few statements about string theory (or any other theory). The decision to fund the ILC etc will be based on criteria far removed from "will this validate string theory or not".

7. **Tony Smith**
April 27, 2006

Peter said "… The … report by the Committee on Elementary Particle Physics in the 21st Century … was a study of what to do about experimental HEP … the problems of theoretical HEP were not addressed …".
sunderpeeche said "… The EPP report was dedicated to experimental HEP, and it makes no difference if there are a few statements about string theory (or any other theory). …".

anon said "… CERN in 1983 … validated electroweak theory …".

A generation ago, high energy physics experiment and theory were so closely linked that you could not really discuss one without the other, leading to results such as validation of electroweak theory.

The fact that the EPP report is about experiment and "… it makes no difference if there are a few statements about … theory …",
is a clear condemnation of the present-day state of conventional theoretical high energy physics = superstring theory, and of this generation of conventional high energy physics theorists.

That condemnation is emphasized by the fact that "… The principal charge to the Committee on Elementary Particle Physics in the 21st Century was to recommend priorities for the U.S. particle physics program for the next 15 years …", which charge was to study ALL of Elementary Particle Physics.
That the EPP report was "dedicated to experimental HEP" is a de facto statement by the committee that present-day conventional theory = superstring theory is irrelevant. (It would be nice to be able to say that irrelevance = mostly harmless, but unfortunately that is not the case.)

Tony Smith
http://www.valdostamuseum.org/hamsmith/

8. **sunderpeeche**
April 27, 2006

Bravo Tony Smith! A condemnation of current theory … I hadn't really thought of it that way … but still.

However, the fact is also that (as has been noted in this blog before), expt HEP simply hasn't (definitively) found anything beyond SM since the mid-1970's. The new machines simply *have* to be search-and-discovery machines, not linked to tests/validations of any theory
— and this is *not* the fault of string theory. (FWIW it's not the fault of any theory or expt. Nobody knows the mass scale of the next discovery.) Note that in 1950-60's there were competing theories, and many expt puzzles. Machines were built to find new things, not always guided by any theory — but there were plenty of questions to ponder, no need to "set priorities".

The committee might officially be for all HEP, but theory (apart from supercompters?) doesn't need (much?) capital infrastructure. No need for a committee.

9. **SomeBody**
April 27, 2006

A billion here, a billion there, soon you're starting to talk real money:

The Gross National Debt

10. **JoAnne**
April 27, 2006

Peter, thanks for providing a good summary of the contents and the purpose of this report. Alot of people worked very hard to get the non-HEP scientists and non-scientists on this panel excited about our science. It seemed to have worked and the positive statements in this report have the potential to do HEP a tremendous amount of good.

11. **Peter Woit**
April 27, 2006

Thanks Joanne,

Good luck with the hard work over the next few years that will be needed to convince people to support US HEP. There are very good reasons for people to be interested in this kind of science and want to see it supported, the report does a good job of explaining this.

12. **steve**
April 27, 2006

From a political point of view, I question putting all the eggs in the international basket. Americans tend not to support large-scale collaborations of this type (with the unfortunate exception of the space station), and given current international opinion I think it could be hard to get foreign countries to agree to a US site.

It might make more sense to stoke insecurities about falling behind foreign countries in HEP. Americans respond better to a chance to compete and win. There's a big psychological difference between a) inviting collaboration from all over the world on a mostly-US project and b) fighting to get permission from foreign countries to host an international project. The latter smacks a bit too much of cities bidding for the Olympics, which is also often unpopular. It may seem stupid, but I think wanting to stay ahead of other countries is a pretty strong motivator for funding of basic research. Even when we do it by attracting people from other countries.

13. **sunderpeeche**
April 27, 2006

The opening sentence of the EPP Executive Summary talks of "US global leadership in science, technology…" Next para "By recognizing the need for US leadership in particle physics…" Third para "… US tradition of leadership in the field is not secure" (tradition? post-WW2 maybe)

Language like this is not going to impress foreign collaborators (for ILC). Why would Japan/China/Europe/… collaborate to establish (or perpetuate) "US leadership"? On the other hand, the US Congress is unlikely to fund a project not sited in the USA. Not so simple. US may have to be prepared to fund entire "I"LC.

14. **Tommaso Dorigo**
April 28, 2006

My two pence on the "US leadership" issue:

I think the attitude of us non-americans working in HEP would improve a lot if the US stopped talking about themselves as the owners of the field.

A committee of americans talking about how to steer US HEP into a leadership role is fine – nothing to object. But it should not be a public document, as if seeking agreement from international collaborators. It is slightly annoying since it gives the -IMO wrong- idea that the US has entered the LHC experiments in forces to do science there for a long time to come, bringing experience and money, but with the secret aim of finding the right moment to stab their collaborators on the back, win support for an american ILC, and march back home triumphantly.

Why can't we form a committee who deals with a more important issue: how to dodge the need to tickle the ego of a few dumb congressmen in order to survive ?
I am sure 90% of US scientists would be happy to live without having to be the kings of the hill in HEP. Let me rephrase it: without the need to put "leadership" as a deliverable in all their requests for funding…

15. **Tony Smith**
April 28, 2006

Tommaso Dorigo, about EPP2010 and ILC, said "… I think the attitude of us non-americans working in HEP would improve a lot if the US stopped talking about themselves as the owners of the field. …".

I completely agree. That was one of the two major factors that killed the SSC (the other being failure to honestly state and control costs). Back in the SSC days a German friend of mine said something like:
"… The Americans expect us to put a lot of money into the SSC, but they want every proton in the SSC to carry a little American flag. …".

Tony Smith
http://www.valdostamuseum.org/hamsmith/

16. **sunderpeeche**
April 28, 2006

About the SSC, absolutely yes. (My friend wasn't German, but no matter.) The machine was conceived (after the cancellation of ISABELLE) to "bring back the lead the US", "highest energy particle accelerator back in the US". Why would foreigners support such a project (as they were later asked to do)? If the ILC is also to "maintain/restore US leadership in HEP" why will others support it?

17. **SomeBody**
April 28, 2006

Isn't the best location for the ILC, should it really be built, the most successful, most international particle physics lab on the planet ever? I.e. CERN? There's much to be said for the Swiss hosts, not least their lack of interest in claiming world leadership based on physical location of this or that machine or building. And there are some pretty good restaurants in Geneva, too.

18. **from EU**
April 29, 2006

The ILC collider employs the standard accelerator technique and aims at reaching an energy of 0.5 TeV around 2020. This would be a poor improvement over the LEP collider, that reached 0.2 TeV in 2000.

Even if LHC will indicate that 0.5 TeV is enough to access new physics, and even if US particle physics needs ILC to survive, it would be better to wait until a linear collider can be built starting a new, more promising, technique (e.g. CERN is trying to develope CLIC).

19. **sunderpeeche**
May 1, 2006

The ILC does not employ “standard” accelerator technology, as if were off-the-shelf stuff. It is very demanding technically. Still a challenge to figure out how to deal with the heat load, radiation hazards etc. A brief history (which anyone is free to dispute): after the SLC was the idea for a 1 TeV x 1 TeV linear collider (TLC = TeV Linear Collider). This proved too ambitious, scaled to 0.5 x 0.5 TeV (TLC = TeV c-o-m linear collider). This was mooted for a while, evolved to NLC (Next Linear Collider), whatever might be achievable/fundable ~ 250 x 250 GeV (these were all pure US projects). Japan developed idea for JLC (you figure it out). CERN worked on CLIC, others on TESLA (~TeV Superconducting Linear Acc). The various ideas (maybe not CLIC) merged into ILC, which is 0.5 TeV c-o-m ~ NLC. But still many unsolved technical challenges.

20. **from EU**
May 1, 2006

dear sunderpeeche,

the German, US and Japanese projects are “standard” in the sense that they all aim at an acceleration gradient of “only” about 20 MeV/meter, such that an “ultimate” linear accelerator (about 2 x 30 km long) is needed to reach 500 GeV.

If we hope to someday reach larger energies, we should start trying a shorter accelerator with a larger gradient. CLIC aims at about 150 MeV/meter: even if CLIC will not seem faster nor cheaper than ILC, I would consider CLIC as the most promising option.

21. **sunderpeeche**
May 1, 2006

Tell that to the designers of the ILC. People have been trying to design a next-generation linear collider for ~ 20 years now. I expect that if they could do better than 20 MeV/m they would.

22. **sunderpeeche**
May 1, 2006

It’s not exclusively a matter of the accelerating gradient. The positron source is another problem. Typically one smashes an electron beam onto a target, and positrons come out (along with junk). Usual target choice is copper (dissipates heat well) or tungsten (v high melting point), but for ILC requirements all known solutions will melt. Current thinking (as far as I know) is to spray a mercury jet across the e- beam, collect the spent mercury — it is a liquid — and recycle it (via heat exchanger or something). Raises safety/health problems with mercury vapor leakage etc. Not clear the idea will work. Never been done. Don’t know if prototype exists.

Yuval Ne'eman 1925-2006

April 27, 2006
Categories: Obituaries

Yuval Ne'eman died yesterday, from a brain hemorrhage caused by a recent fall. Science magazine has a story about this.

Together with Murray Gell-Mann, in 1961 Ne'eman co-discovered the SU(3) classification of strongly interacting particles. At the time he was both an Israeli military attache in London, as well as a graduate student of Abdus Salam (who was a devout Muslim). For some amusing stories of that period, see this web-page of fellow student Ray Streater.

In later years Ne'eman continued his research in theoretical physics, was president of Tel Aviv University, played an active role in the Israeli nuclear weapons program, and was the head of a far-right political party. He was definitely one of the most colorful characters in particle theory during the second half of the last century.

Update: There's an obituary from the AP in the New York Times. It's only comment about Ne'eman's work in particle theory is that:

The Technion credited Dr. Ne'eman with discovering the principles of tiny subatomic particles, called quarks, although another scientist received the Nobel Prize for that discovery.

Ne'eman and Gell-Mann both realized that mesons and baryons could be classified as representations of SU(3), and some of the physics of the strong interactions could be understood this way. Gell-Mann won the Nobel because he later identified the fundamental representation of SU(3) with new particles, quarks.

Comments

1. **Arun**
   April 27, 2006

   "Abdus Salam (who was a devout Muslim)" – since you brought up religion, I think the following is pertinent:

   Abdus Salam belonged to a sect called "Ahmaddiya" which has been deemed non-Muslim by Abdus Salam's native country, Pakistan. The following is an excerpt of a law that went into effect in 1984:

   > Any person of the Quadiani group or the Lahori group (who call themselves 'Ahmadis' or by any other name), who, directly or indirectly, poses himself as Muslim, or calls, or refers to, his faith as Islam, or preaches or propagates his faith, or invites others to accept his faith, by words, either spoken or written, or by visible representations, or in any manner whatsoever outrages the religious feelings of Muslims, shall be punished with imprisonment of either description for a term which may extend to three years and shall also be liable to fine."

2. **knotted string**
   April 27, 2006

   Yuval Ne'eman certainly stands out as a an interesting character, because he was prepared to do what he felt was for the best. I'm glad that the assassination attempts failed.

   It's fascinating to read in the Science story that he inspired the spy Ne'eman in Frederick Forsythe's novel The Odessa File. I know Einstein was once offered the Presidency of Israel, but he declined it.

   The page Science links to, explaining the eightfold way, is nicely illustrated: http://fafnir.phyast.pitt.edu/particles/conuni6.html

   A link from there has a nice history of the Standard Model http://fafnir.phyast.pitt.edu/particles/smt.html which ends in 1995:

   'After eighteen years of searching at many accelerators, the CDF and D0 experiments at Fermilab discover the top quark at the unexpected mass of 175 GeV. No one understands why the mass is so different from the other five quarks.'

   It's sad that the subject has become so stagnant since 1995.

3. **MathPhys**
   April 27, 2006

   Abdus Salam was not a devout Muslim. In his later years, he put on the devout Muslim thing, but surely not when he was a young professor at Imperial College, which is the time when Ne'eman became his student.

4. **Subhash**
   April 27, 2006

   I apologize for not sticking to the main subject of this post, but since Abdus Salam, Ne'eman's supervisor, has been mentioned in two comments with different assessments, perhaps this column on him would be of interest:

5. **D R Lunsford**
   April 27, 2006

   A great physicist. And don't forget George Zweig.

   -drl

6. **Tony Smith**
   April 27, 2006

   Yuval Ne'eman (with Yoram Kirsch) wrote a book, The Particle Hunters (Massada 1983, Cambridge 1986 and second Cambridge edition 1996), intended to provide a text on particle research for non-professionals.
   The preface to the second edition says "… we were encouraged by warm responses of readers from all over the world, who have read the book either in English or …

Spanish, Italian, Japanese, or Hebrew … A poet sent us a poem in which she recounted dreams she had after finding out what the world is made of … Their … comments made them partners in creating this revised edition. …".
Having had the pleasure of meeting with Yuval Ne'eman some years ago, that passage reinforces my feeling that he was a genuine humanitarian in the deepest sense.

As to the subject matter of this blog, the book is not silent, saying:
"… The enthusiasm …[for]… superstring theories … cooled off … when the theory was taken from ten dimensions down to our prosaic four-dimensional world. It turns out that this can be done in myriads of ways, each yielding a different GUT, in contrast to the uniqueness of the E(8)xE(8) which had impressed physicists so much. It means that one can put almost anything into the six dimensions (out of ten) which have to fold up. Thus, the theory seems to contain a correct formulation of quantum gravity and to fit the requirements of a TOE, but is much too flexible and therefore has very little predictive power.
The hope is that an equation for all possible superstring theories can be formulated, and that it will single out one specific theory, as the TOE selected by nature to describe our physical world. Several theorists have expressed the hope that this theory, if found, would be the ultimate and final theory of physics. The authors of this book hold a different view. We think that Hamlet's words 'There are more things in Heaven and Earth, Horatio, than are dream't of in our Philosophy' (I, v. 167) are closer to the lessons of the past. …".

As to policies for the future of particle physics, the book concludes by saying:
"… In the beginning of this book we mentioned the atomic theory of Democritus, who lived in the Greek city of Abdera in the fifth century BC. The citizens of Abdera awarded Democritus with five hundred talents of gold for his idea, as if their eyesight could sense the view at a distance of twenty five centuries and see the atomic theory in its glory. Can we afford to be less far-seeing? …".

Tony Smith
http://www.valdostamuseum.org/hamsmith/

7. **sunderpeeche**
April 28, 2006

Democritus expounded the atomic hypothesis (5th century BC?), but he had no testable predictions to back it up. Even in the 19th century people like Ernst Mach disputed the atomic hypothesis. (Ludwig Boltzmann had trouble his whole life convincing people about the existence of atoms.) Surely, then, Democritus' idea of atoms was not even wrong?

8. **knotted string**
April 28, 2006

Democritus' atom was predicted to be impenetrable and unsplittable. Hence it was wrong in detail. (But so were later efforts, eg Dalton's atomic explanation of chemistry was ridiculed for the non-integer mass numbers of elements, because he didn't know about isotopes or binding mass-energy effects.) The Greek atomic concept was grossly oversimplified, which is the exact opposite of the problem with string theory today…

9. **Jack Sarfatti**
April 30, 2006

I met Yuval Ne-eman with Max Jammer in 1980 at the Fairmont Hotel at a Reverend Moon Unity in Science Conference. Henry Stapp was at this conference. Ne-eman spent at least 10 minutes lecturing me on the importance of my name "Sarfatti" to Jewish History via Rabbi Rashi de Troyes 1040-1105 AKA "Solomon ha-Sarfatti." Murray Gell-Mann also had some obscure things to say about my name in Jewish thought at a Santa Fe Complexity fund-raiser at the San Francisco Ferry Building. Murray was attracted to the woman I was with who had no idea who he was and this got Murray even more interested.

10. **MathPhys**
May 1, 2006

Jack,

When was that encounter with Gell-Mann that you mentioned? What year?

11. **Eluard**
May 1, 2006

"Democritus' atom was predicted to be impenetrable and unsplittable. Hence it was wrong in detail."

This should be called the Spinal Tap the-amp-goes-to-11 fallacy. Why not just think that the real atoms are the fundamental particles? What does it matter that someone jumped the gun and called the wrong things 'atoms'?

12. **Anonymoose**
May 1, 2006

I think I've heard of Abdus Salam before. It was column about how many scientists manage to remain strict followers of a particular religion, yet peacefully reconcile their faith with their work in science. Salam mentioned how there was no necessary conflict with his Islamic faith and scientific exploration, but I wonder what it was like for Yuval Ne'eman, given his Zionist background. This could provide interesting feedback on Muslim-Israeli relations.

13. **Jose N. Pecina-Cruz**
May 7, 2006

Today, May 8, 2006 I read that Yuval Ne'eman passed away. Last time I contacted him, we agreed on writing a book on General Lie Invariants (beyond of those called Casimirs). I had the pleasure of being one of his students. In an attempt to quantize gravity (Gauge Affine Theory) Ne'eman and I came to the discovery of a general method to calculate Lie invariants. Because his oustanding work in other areas this work is barely known. Yuval and I had nice expectations on writing the best book on Lie Invariants. Rutwig Campoamor from The Universidad Complutense of Madrid planned to join us on this task. Rutwig and I will pursue this titanic task to honor the memory of this great physicist and dear friend.

Scientists Speak Out About Guantánamo

May 1, 2006
Categories: Uncategorized

I've been thinking there's too much politics on this blog recently, and yet I still think the political activities of well-known theorists are worth noting here. As commenter Arun pointed out, this Sunday's New York Times has a letter to the editor criticizing the human rights violations at Guantanamo, signed by many prominent particle theorists, including Susskind (whose name comes first, perhaps he's the organizer), Bjorken, Deser, Dyson, Gaillard, Gross, Polchinski, Schwarz, Wilczek, Witten and Zumino.

Over at the science policy blog Prometheus, Roger Pielke has a posting called A Very Bad Dream Indeed, in which he strongly criticizes the authors of this letter for writing such a letter that has nothing to do with science policy. He seems to be worried about these scientists "transforming their privilege in the scientific domains into authority in non-scientific domains." Somehow, I just don't see the possibility of theoretical physicists grabbing political power and ramrodding through policies they support as being something much worth worrying about. My reaction to this particular letter was not "who do these people think they are to do this?", but rather "how come everyone else isn't doing this?" The situation at Guantanamo is a disgrace to this country and that the courts allow it to continue is shocking.

More about this at No Se Nada, the blog of Kevin Vranes.

OK, now, no more about politics for a while. I promise….

Comments

   Book! Book!

3. **Yuri**
   May 1, 2006

   You right 1000 times!
   No needs use this room for politics.
   There are many other places for it.

4. **woit**
   May 1, 2006

   DB,
   My book? Last Thursday I got one of the first copies off the press of the British edition in the mail. Quite something to finally see the thing in print as a real book. Publication date is still one month from now, June 1 in Britain. Working this week on going through the newly copy-edited American version, that's still set for September sometime.

5. **absolutely**
   May 1, 2006

   Guantánamo sours my otherwise sweet memory of the few years I spent in the US and the warm and enlightened folk I met there. That my government (Australian) should be so complicit and gutless in condoning it really heavies my heart.

6. **Chris Oakley**
   May 1, 2006

   I just don't get it … sunny climate, high-fashion orange suits, being fed and watered at the US taxpayers' expense … no doubt Cuban cigars and rum freely available as well, especially to Muslims. And of course the most meticulous trial procedure ever, i.e.

   George W Bush: "These are bad people".

   What's all the fuss about?

7. **Dumb Biologist**
   May 1, 2006

   OK, sorry to get so egregiously off topic. Thanks for the update!

8. **Lubos Motl**
   May 1, 2006

   Roger Zielke's name is Roger Pielke, and he definitely knows what he talks about.

9. **woit**
   May 1, 2006

   Thanks Lubos, I fixed his name. He does seem to be your kind of guy.

10. **Tommaso Dorigo**
    May 2, 2006

    Hi Peter,

I totally agree with what you said.

I see nothing wrong if anybody who sees something wrong happening, and who enjoys attention of the media, uses the media to denounce it. It is part of the game. I don't particularly like the game, sure. But anybody who cares for civil rights should think about the horror of american prisons in Guantanamo and Iraq, and the indecence of Defence Ministers covering it instead than putting an end to it.

Let's stop this horror, and let's not be afraid to use any possible venue and means to denounce it. The US have been entangled with regimes that tortured and killed thousands of innocents in the past. Sure, other countries have too. But if the US wants people in the world to look at it as an example of a free, civil country, they need to change the way they act abroad.

I love the US, as I love my country, but both have lots to change for the better.

T.

11. **ObsessiveMathsFreak**
May 2, 2006

Einstein's letter to Roosevelt comes to mind as an example of the weight scientists hold with politicians when they stay within their field of competance. His lobbying for a world government after the second world war, comes to mind as an example of the lack of weight scientist's views carry once they stray outside their field of competance.

12. **SomeBody**
May 2, 2006

I note that pointing out the hypocritical behaviour and dishonorable political affiliation of a certain serial US basher posting here is frowned upon by the management. May I ask why?

13. **woit**
May 2, 2006

Ad hominem, personal attacks are definitely frowned upon by the management and will virtually always be deleted (although I often leave up the ones by string theorists attacking me). Also strongly discouraged are attempts to start up off-topic political battles here. Your comment qualified for deletion on both counts, so I deleted it and the responses it immediately started generating.

14. **SomeBody**
May 2, 2006

I see the delete button is working overtime today. 😉

I disagree with your characterization of my post, but it's your blog. Peace.

15. **Benjamin**
May 2, 2006

I don't want to promote the politics that Peter Woit doesn't want here, but I do want to make a comment that I think would be beneficial to those on the 'left'. I am in the center, not in favor of the Iraq war, but not willing to call Bush a Nazi or anything like that. I agree that Abu Ghraib and Guantanamo were wrong and hurt America's image badly. What I can't understand is how the 'left' gets obsessed with this and ignores all the terrorism, often in the name of Islam, the bombings, decapitations, human rights abuses, etc. It's not that America should never be criticized, but it seems that there is a lack of proportion. Abu Ghraib and Guantanamo, for all their horror and humiliation, are still much less 'evil' than pedestrians being blown to pieces in Israeli pizza parlors. If the left seemed more balanced, it would have much more credibility, but the same can be said of the right of course. You really need to think about how you sound to the mainstream, or you are self-defeating. All this partisan hypocrisy and stupidity from both sides needs to stop in favor of a fair and balanced view. I'm surprised that even smart physicists fall for far-left rhetoric. Don't erase this; it's really worth thinking about. No need to discuss further.

16. **woit**
May 2, 2006

OK Benjamin, I'll leave your comment as having some relevance to the topic. However, please, everyone, take any arguments about who is more or less evil than whom elsewhere.

17. **knotted string**
May 2, 2006

It's a shame they do the torture behind closed doors, in a democracy it should be done openly. I humbly offer the suggestion that torture is done democratically:

The person to be tortured should be web-cast live, and U.S. viewers should be in control. Electric shocks can be administered automatically after every fixed number of internet votes. (1) This will really deter terrorists. (2) This will save a small number of professional torturer's feeling bad about their work. (3) It will give everyone an elated sense of justice and moral ethics.

18. **Chris Oakley**
May 2, 2006

Knotted String,

I think that you have a great idea there, and I have to say, I prefer it to your ideas about physics.

What I like best is that because we live in a free society, it will be all the sadistic muthas who will choose to log on to this web site to administer tortures to terrorists. I am no expert on psychology, but I am sure that people will be much more sincerely nasty if they are doing it as a recreation rather than a boring old nine to five job.

19. **steve**
May 2, 2006

It is disappointing that scientists who would insist on precision in distinguishing one phenomenon from another in their own fields have no compunctions about tossing out a word like "Guantanamo" without crucial distinctions being made. There are big differences in the morality and prudence and remedies for a) the detention of illegal combatants for the duration of hostilitles, b) the detention of people incorrectly believed to be illegal combatants, c) the authorized use of aggressive interrogation tactics against presumed illegal combatants, d) the unauthorized use of aggressive tactics to gratify individual power-lust, e) the authorized use of torture for interrogation, f) the unauthorized use of torture for interrogation, and g) the unauthorized use of torture for personal gratification.

Some of these may be acceptable, some of them call for systemic reform, some of them call for allowing the existing disciplinary structures to function (e.g. the Abu Ghraib abuses were uncovered by the military itself; the media found out months later). The kind of lazy thinking displayed in using “Guantanamo” as some sort of shorthand for evil is discouraging in a group that prides itself on its analytical acumen and clarity of thought.

20. **Eli Rabett**
May 2, 2006

Ben and Lubos only believe in or not and.

One can be against all groups who practice deceit, kill and torture. It is ethically more important to oppose those closest to you who do this. Even as a practical matter this is vital so that you may have allies in your struggle.

21. **Michael Kellman**
May 6, 2006

Like it or not, this is the policy of the elected government of the United States. Congress has the power to stop it if it judges such to be warranted. It apparently doesn’t.

Is it really such a good idea for scientists — physicists — qua scientists and physicists — to set themselves up in opposition to American foreign policy?

Perhaps the message received will be that science does not support America as represented by its elected government.

And perhaps that a reconsideration is in order as to whether it is such a good idea for America to support science?

22. **Santo D'Agostino**
May 7, 2006

To Michael Kellman:

Of course it is a good idea for citizens of a purportedly free democracy to speak freely, whether or not they support the current government. Numerous American leaders over the years (the current president, with his “You’re either with us or against us,” being a prime example) have very effectively confused people into thinking that criticizing the U.S. government is being anti-American. On the contrary, it is a DUTY of citizenship to speak out against immoral and criminal behavior, especially when it is committed by a country’s leaders.

The ideas behind your last sentence are repellent, both for its implication that scientists should experience repercussions (What did you have in mind? That they lose their jobs? That they lose their research funding?) for exercising their rights as American citizens, and for its counter-productive vindictiveness. A decrease in support for American science harms all Americans, not just the scientists directly involved.

Santo D’Agostino

23. **Bert Schroer**
May 7, 2006

I suppot D’Agostino’s statement. As a non US citizen I have no influence on the US policies through a vote, but as a member of the western civilization I suffer all the consequences of the tension and hightened danger created by such an uncivilized action; so my democratic rights have been considerably reduced (despite all the propaganda about strengthening democracy in this world) by Guantanamo, Abu Graib and the CIA torture flights using European airspace. There are numerous past precedents of such actions by the scientific elite of a country, some of them even successful as the anti-nuclear campaign of the Goettingen 18 (Born, Heisenberg,….)

24. **Michael Kellman**
May 7, 2006

D’Agostino and Schroer have every right to call our elected governors “immoral”, “criminal”, “uncivilized”. Witten et al. have a right to criticize the government as a group of scientists. (Why anyone should especially care what a group of scientists thinks about foreign policy is beyond me.)

But the public who elected the government has a right to draw its own conclusions. I’m not suggesting that anyone should lose their job (as a possibility the notion that IAS is going to fire Witten for this is pretty preposterous). I’m not suggesting that anyone should lose a grant.

But the public has a right to draw its own conclusions. Perhaps people will think that the scientists’ judgement about science is as unproductive as their judgement about foreign policy.

There is no law of nature that “a decrease in support for American science harms all Americans”.

Science also no natural right or entitlement to support.

I notice that U.S. high energy physics is looking for support for new experiments. Many people may conclude that if it’s a choice between backing what the country is doing in war and backing high energy physics, that they prefer the latter.

The scientists have every right to set themselves up as sceintists in opposition to our elected government.

But personally, I don’t think it’s too smart.

25. **SomeBody**
May 8, 2006

Now I’m really puzzled. Why was my latest post in this thread deleted? Surely it contained nothing which could be labeled as either ad hominem or off topic (if anything, it pointed out the topic of the thread). More and more peculiar…

26. **Bert Schroer**
May 8, 2006

The answer is very simple: it is because my post was deleted. Its democracy in practice and this time I even agree with it.

27. **woit**
    May 8, 2006

    I’ve deleted a lot of comments from this thread, both from people submitting political rants, as well as those responding to them. If you want to spend your time doing things like attributing straw-man arguments to people and then vigorously attacking them as foolish and immoral, or if you enjoy responding to this kind of thing, do it elsewhere, not here.

28. **woit**
    May 8, 2006

    Bert,

    Actually it’s more of a benevolent dictatorship in practice…

29. **Bert Schroer**
    May 8, 2006

    I meant that the dictatorship is at least administered democratically.

Hype from the Swampland

May 1, 2006
Categories: Swampland

Over the last twenty years there has been an endless stream of hype about "tests of string theory", pretty much all of it complete nonsense. For some examples just from the first few months of this year, see here, here, and here. Most of these examples seem to have been generated by confused PR people who misunderstood carefully worded comments by various physicists about the relation of their work to string theory. The average person just finds it hard to believe that it really could be true that there is no way to test a theory that has gotten so much attention for so long from so many prominent people.

Today there's new nonsensical hype about testing string theory, but this time it's due not to a clueless press relations person, but to several physicists, including the one who decides what gets into the hep-th arXiv and what doesn't. The hype isn't buried in the article somewhere, it's in the title: Falsifying String Theory Through WW Scattering. In their abstract, the authors claim to derive a bound on coefficients of operators in the effective electroweak Lagrangian such that "a measured violation of the bound would falsify string theory."

The first striking thing about this paper that purports to show that string theory is falsifiable is that there's actually nothing about string theory in it. It's only four pages long, and the first three pages consist of an introduction followed by some calculations in the non-linear sigma model one might want to use as an effective low-energy theory of pions. This is just a warm-up exercise for the real calculation that the authors want to make some claims about, which involves the low energy effective action for a non-linear sigma-model coupled to gauge fields. This is the model that one expects to describe the low-energy behavior of the Higgs field coupled to electroweak gauge fields, if one takes the Higgs mass to be very large.

The authors go on to just copy the terms in the relevant Lagrangian down from a 1993 paper by Appelquist and Wu, then stop and promise to actually calculate the relevant bounds in a forthcoming paper. Unless one wants to try and sit down and do oneself the calculation the authors haven't done yet, it's hard to know what these bounds will actually say and whether they will really be non-trivial. It's also unclear to me exactly how all of this depends on the Higgs mass, which I guess is being assumed to very high, thus violating the known indirect experimental bounds from precision electroweak measurements (which assume the standard model). Very hard to tell about any of this, since it's dealt with in a paragraph with no equations.

It turns out that the author's proposal isn't a proposal to falsify string theory at all, but a proposal to falsify the idea that physics satisfies Lorentz invariance, analyticity and unitarity at high energies. This would falsify our standard ideas about QFT, but it wouldn't falsify current ideas about string theory. The authors don't define what they mean by "string theory", but presumably they mean some version of perturbative string theory. This involves a divergent series (even granting the conjecture that one can make sense of these amplitudes at more than two loops), so it's unclear how one is going to "falsify" that. Standard ideology about non-perturbative string theory ("M-theory") is that it will involve some new ideas about space and time, so I don't see how one can assume that it won't violate the analyticity and Lorentz invariance properties characteristic of QFT in flat space-time. I'm not convinced that the author's proposal will falsify anything, but if it does, it will be QFT that is falsified, not string theory. After all, this paper is a QFT calculation (or, more accurately, a promise to do a QFT calculation), not a string theory calculation.

The authors note the problems of non-predictivity generated by the Landscape, and in the first version of the paper write:

Moreover, even if it is found to be difficult to generate the proper model from string theory, one would sooner accept the notion that it is the theorist's imaginations which are insufficient than conclude that string theory has been falsified.

In the second version of the paper, they seem to realize that this attitude of "one" is kind of unscientific, and they change it to

Moreover, even if it is found to be difficult to generate the proper model from string theory, some would sooner accept the notion that it is the theorist's imaginations which are insufficient than conclude that string theory has been falsified.

This new version leaves it unclear who this unscientific "some" is. In both versions they note correctly that:

This line of reasoning has resulted in sharp criticism of the theory.

This paper is motivated by the "swampland" program of trying to find effective field theories that can't be the low energy limits of a string theory. I've written about the problems with this elsewhere, and blog postings by Distler have amply embodied what some of them are. In his first posting on the Swampland he gave as an example of a low energy effective theory that couldn't come from string theory one with only one or two generations, only to be told by a commenter how to construct such things from string theory. He has a more recent blog posting called Avatars of Nonlocality? about the swampland work of Arkani-Hamed and collaborators that motivated this new paper. In a comment there, Arkani-Hamed takes him to task:

This post is a great illustration of what I dislike about blogs and more specifically trackbacks. As I explained to you when you were visiting Harvard last week, your first point about the RG running is standard effective field theory (with an abbreviated discussion in our paper because it is fairly common knowledge–read Georgi's book). I of course don't object to your writing a paper to clarify these points to yourself or others. But this is minor. More importantly, as I also explained to you both in email and in person, what you write about the DGP model is totally wrong…

Now, in general I don't care about what is said on blogs, as I believe they largely fulfill the primate desire to look and see what the other monkeys are doing, and I think they are a big waste of time. But I do object to having a trackback, linked from my paper, to a post about it that claims that one of the central claims is wrong, when a 45 second computation, even done for the reader's convenience in the paper itself, refutes the argument.

This whole subject really is a swamp, if you ask me, and has nothing at all to do with physics, including nothing to do with the supposed "falsifiability of string theory". It will be interesting to see if a referee thinks otherwise.

Update: It has been pointed out to me that I'm being a bit unfair to the authors in characterizing the calculation in this paper as a "warm-up exercise", since they claim that it is a correct first approximation to the actual calculation that they intend to do.

Comments

1. **Benni**
   May 1, 2006

   you can congratulate yourself. You have Distler made to write a paper with your blog.
   One might imagine how long he thought about the problem of falsifying string theory and how desperate some scientists are, when they begin to publish such nonsense.

2. **MathPhys**
   May 2, 2006

It’s all very sad. I sometimes think that if these guys (many of whom are brilliant) took a break from string theory and started thinking about something else (perturbative QCD, collider physics, whatever), they may actually get inspired and find a way to revive strings.

3. **anonymous**
May 2, 2006

The analogous constraints, in the simpler case where the Higgs exists and is light (as data indirectly suggest), had been studied in section 5 of http://arxiv.org/abs/hep-ph/0604111.

4. **justin**
May 2, 2006

Dear Peter,

Isn’t this what you would want… papers at least attempting to falsify string theory, on general grounds?

5. **Alejandro Rivero**
May 2, 2006

Hmm I supposse this is a falsify argument both for string theory and QFT, but at least it aim to proof that the scenary where QFT is falsifyed and string theory remains is unlikely.

6. **woit**
May 2, 2006

Justin,

This isn’t a paper that gives a plausible way to falsify string theory and get rid of it, it’s a paper trying to claim that string theory is in principle falsifiable.

The whole issue of whether string theory is falsifiable, and thus a part of conventional science, is an absolutely crucial one that people are now debating. As far as I can tell, all evidence at the moment is that it is not falsifiable. This paper makes a dramatic claim, in its title, that string theory actually is falsifiable by looking at relatively low energy WW scattering amplitudes. My posting explains why this claim is simply incorrect.

7. **Dick Thompson**
May 2, 2006

You said:
“It turns out that the author’s proposal isn’t a proposal to falsify string theory at all, but a proposal to falsify the idea that physics satisfies Lorentz invariance, analyticity and unitarity at high energies”

In my reading the paper says no such thing. Rather it says that IF there is no light Higgs, AND the calculated bounds are found to be violated THEN EITHER SST is false OR one or more of Analycity, Unitarity, and Lorentz Invariance is false. It is up to the experimenters to determine which is the case. Quoting one sentence out of context does not invalidate this conclusion.

8. **Elliot Stern**
May 2, 2006

I’m not a scientiest, but I think the argument that string theory is not science because it is not falsifiable is a red herring. String theorists don’t claim that they understand string theory, let alone that it is a full fledged scientific theory. If and when string theory develops into a full scientific fledged theory, it will no doubt make many predictions and some will be falsifiable. It seems to me that if you want to attack string theory, you need to argue that it is a dead end, and that there is little or no hope that it will ever develop into a full fledged scientific theory. If you can’t make that argument, you have nothing worthwhile to say.

9. **woit**
May 2, 2006

Elliot,

I have been making pretty much that argument, here and elsewhere (at most length in my book).

10. **Ira**
May 2, 2006

I am honestly not a fan of blogs, but I cant help but just make a short comment about the paper. The paper just points out that there are bounds on gauge bosons scattering which, if violated, would mean that the underlying theory violates one of the assumptions stated in the paper. Namely, unitarity, analyticity and Lorentz invariance. If one assumes that string theory obeys these assumptions, then string theory, is falsifiable.
The most intriguing part of the paper is that we can perform a low energy experiment which probes the complete UV theory. This is what makes this test truly interesting. It also opens the possibility for other such tests which allow us in practice to test certain assumptions we make about the what lies beneath the standard model.

The title could have just as easily been, “Falsifying …….. using W Scattering”, where in the blank you could put in your favorite “theory of everything” which is suppose to obey these mathematical assumptions. Note that the blank could not have been filled with Loop Quantum Gravity, since (see Smolin)it has been conjectured to violate Lorentz invariance in the UV. So that just leaves string theory, defined with those above assumptions.

Now whether or not this is the “working def” of string theory should be discussed. Certainly perturbatively its true and its true non-perturbatively its true in AdS. So it seems reasonable to assume it true
in Minkowski. But…. I believe its fair to say that If the bound were violated it would certaintly mean that we would have to rethink string theory.

If I were a betting man, Id bet the bounds wont be violated but, as I said, the point of the paper was to point out that this kind of bound is
possible at all.

11. **Chris W.**
May 2, 2006

Elliot,

It is very late in the game to be allowing that "string theorists don't claim that they understand string theory, let alone that it is a full fledged scientific theory, " given much of the rhetoric that has surrounded the subject.

At this stage it seems quite likely that genuine understanding will require such a profound shift of perspective and approach that it will amount to a repudiation of much of string theory as a research program, and will be perceived as such by most string theorists, even if some important formal features of string theory are clearly related to elements of the new perspective. (The latter is almost guaranteed to be true; such is the nature of mathematics.) Vital physical ideas are missing, and it doesn't seem likely that they will discovered by continuing to wallow in a vast morass of formalism.

12. **Tony Smith**
May 2, 2006

The paper of Distler et al at hepph0604225 says:
"… Analyticity: the cuts lie on the real axis … with no singularities on the physical sheet off the real axis.
Unitarity: the discontinuity in the forward scattering amplitude across the cuts is given by the total cross section.
Lorentz invariance: the amplitude can only depend upon the three invariants.
Most importantly, these assumptions must be obeyed for arbitrarily short distances.
String theory, which is designed to be valid at all distance scales, is constructed to produce an S-matrix with precisely these properties. …".

It seems that they are saying that, for example, obersvation of ANY Lorentz violation, no matter how small, would falsify conventional superstring theory.

Do other conventional superstring theorists agree ?

David Mattingly at UC Davis has written a review "Modern Tests of Lorentz Covariance" at http://relativity.livingreviews.org/Articles/lrr-2005-5/ in which he says:
"… Currently, we have no experimental evidence that Lorentz symmetry is not an exact symmetry in nature.
The only not fully understood experiments where Lorentz violation might play a role is in the (possible) absence of the GZK cutoff and the LSND anomaly.
New experiments such as AUGER, a cosmic ray telescope, and MiniBooNE, a neutrino oscillation experiment specifically designed to test the LSND result, may resolve the experimental status of both systems and allow us to determine if Lorentz violation plays a role. …".

Would all conventional superstring theorists agree to give up their virtual monopoly on USA high energy theory jobs and grants if Lorentz violation were observed by means described by Mattingly (for example, if the GZK cutoff is seen to be absent due to Lorentz violation) ?

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – By associating conventional superstring theory with such well tested (at presently accessible energies) principles as analyticity, unitarity, and Lorentz invariance, Distler et al seem to be trying to make it appear to be a respectable physical theory.
If it really were respectable, then (after a generation of hard work by many smart people) it ought to be able to predict something like particle masses, force strengths, KM matrix parameters, etc, that are more easily tested than tiny (perhaps Planck-scale) violations of analyticity, unitarity, or Lorentz invariance.
In fact, Lubos Motl has said (reference frame 21 March 2006) "… particular string models predict the exact masses of all particles …".
Such a spectrum of "exact masses of all particles" would be much easier to test expermentally.
Why don't Motl, Distler, et al write a paper setting out such a spectrum, and saying that if such a spectrum disagrees with experiment, then they will consider conventional superstring theory to have been falsified ?

PPS – I am not asking them to do anything that I have not already done with my own physics model, so I think that it is, coming from me, a fair request.

13. **Tony Smith**
May 2, 2006

The Distler et al paper is at hepph0604255,
not at hepph0604225 which is where my typo in a preceding comment put it.
Since it was a reference number, I am making this correction.
My apologies for all of my many typos, for most of which I just leave uncorrected hoping that people will understand that my fingers don't always type what my mind thinks.
Tony Smith
http://www.valdostamuseum.org/hamsmith/

14. **Brett**
May 3, 2006

With respect to the question of whether Lorentz violation would automatically falsify string theory, I would like to point out that the modern study of Lorentz violation began with the discovery that string theories might contain spontaneous breaking of Lorentz symmetry.

Of course, there are caveats. What was discovered was a Lorentz-violating local minimum of the potential in bosonic string field theory. This is not superstring theory, and, at least for the models studied, this does not appear to be the global minimum. The theories are actually unstable at tree level, and the true vacuum is only stabilized by quantum corrections. The fact that these quantum corrections are involved makes the question of whether the lowest-energy state is Lorentz invariant or not a (difficult) quantitative question, not an obvious qualitative one. I don't know of any general feature of the theory that would ensure that the Lorentz-invariant minimum is the true vacuum; this can only be verified, so far, by computation.

In fact, there are a number of string theorists interested in possible Lorentz violations in the context of string theory, so it seems difficult to believe that the discovery of Lorentz violation would be followed by any repudiation of string theory.

15. **Not a Nobel Laureate**
May 3, 2006

Let's if their forthcoming calculation fares better than the QM version of Feynman + Wheeler's "action at a distance" model.

Wheeler JA, Feynman RP. 1945. Rev. Mod. Phys. 17:156

Where's a guy like Pauli when he's really needed.

It's funny, in a pathetic way, reading all the theoretical pontifications about the Swampland and the nature of space and time on the Planck scale when theorists can't even explain the structure and mass of the proton.

But then acual theories about the latter are subject to annoying and inconvenient experimental tests.

re: recent Happex results.

16. **Tony Smith**
May 3, 2006

Brett says "… In fact, there are a number of string theorists interested in possible Lorentz violations in the context of string theory …".

That is a clear contradiction to the statement of Distler et al hepph0604255:
"… Analyticity … Unitarity … Lorentz invariance …
Most importantly, these assumptions must be obeyed for arbitrarily short distances.
String theory, which is designed to be valid at all distance scales, is constructed to produce an S-matrix with precisely these properties. …".

Such a contradiction shows that either:
1 – the attempt of Distler et al to associate conventional superstring theory with the principles of analyticity, unitarity, and Lorentz violation is incorrect (at best mistaken, at worst dishonest);
or
2 – the "number of string theorists" cited by Brett do not understand the fundamental basis of string theory (as described by Distler et al).

I would be interested in seeing some discussion between Brett and Distler et al about that.

Since I am not a conventional superstring theorist, I really don't care who wins that argument.

With respect to unitarity (in particular, the Higgs unitarity bounds mentioned in the Distler et al paper), there is a lot of indirect Standard Model type evidence that the Higgs probably exists and is between 115 GeV (the upper limit of Fermilab's search) and 200 GeV, so the chance of the LHC finding unitarity violation due to absence of such a light Higgs is probably very small.
My guess is that Distler et al are of the same opinion, and that the title of their paper "Falsifying String Theory Through WW Scattering" was a set-up for a sequel "LHC Confirms String Theory" when the LHC finds that there is no Higgs unitarity violation.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

17. **Tony Smith**
May 3, 2006

My apologies for yet another bad typo. I typed "violation" when should have typed "invariance".
What I should have written above was:

Such a contradiction shows that either:
1 – the attempt of Distler et al to associate conventional superstring theory with the principles of analyticity, unitarity, and Lorentz invariance is incorrect (at best mistaken, at worst dishonest);
or
2 – the "number of string theorists" cited by Brett do not understand the fundamental basis of string theory (as described by Distler et al).

21. **Brett**
May 4, 2006

Based on what I know, I suspect that string theory is inconsistent with any explicity violations of Lorentz symmetry in the Lagrangian. However, spontaneous Lorentz violation is probably more interesting anyway. Off the top of my head, there are four ways that a general symmetry can be broken: explicitly, spontaneously, anomalously, and by boundard conditions. That Lorentz symmetry is anomalous is also possible in certain spacetime configurations, and we know that that boundary conditions of our universe break boost invariance quite strongly. For a theory of everything (especially one where the underlying equations of motion are not known explicitly), it may not be possible to disentangle violations of Lorentz invariance due to the fact that the universe is expanding from violations of other origins.

22. **Peter**
May 4, 2006

Man, this blog attracts some very, very bizarre things….

I think the Distler et. al. paper is clear enough, and one of the authors (Ira) emphasizes the point here, about what its technical claim really is. They are deriving bounds on electroweak scattering amplitudes based on assuming analyticity, Lorentz invariance and unitarity. It's highly unlikely these bounds are violated in the real world, but certainly would be very interesting if they are.

These three properties are properties of Minkowski space perturbative string theory amplitudes, and that's what the authors base their "falsifiability of string theory" claims on. I think this claim is unwise, for two reasons

1. These aren't distinctive properties of perturbative string theory, they're also shared by QFT itself.

2. They just refer to "string theory", without defining what they mean by it. This leaves the implication that their results are relevant to the falsifiability of the general idea of string theory as a unified theory of gravity and particle physics, something which is not the case. Current hopes for connecting up string theory with real world particle physics involve branes and other aspects of a conjectural non-perturbative theory, and since no one knows exactly what this theory is, it is not at all certain that it has the three properties at issue.

Unitarity is something that one presumably won't give up, but analyticity is not so clear.

Brett Altschul wrote in about the Lorentz invariance issue, but didn't mention that he has a new paper today on the arXiv about this: http://www.arxiv.org/abs/hep-th/0605044

There's also something on the topic from Cohen and Glashow: http://www.arxiv.org/abs/hep-ph/0605036

23. **Ira**
May 4, 2006

Thanks Peter for clarifying this. Just one last comment. I dont think anyone can rule out "string theory" given its enormous extent and the many forms it may take, many of which are not really understood. However, the canonical forms of the theory (even including non-perturbative objects such as branes) do have all the properties assumed in the paper. Thus, a violation of the bound would falsify this class/definition of string theory. As brett states the possbility of a Lorentz violating background has not been ruled out, though I am not sure if anyone has found such a solution. I believe it is fair to say that if a violation of the bound were found, then string theory would have to be reshaped in a highly non-trivial way.

24. **Thomas Larsson**
May 5, 2006

Ira, how about the following way to falsify string theory as a theory of QG in 4D?

In section 6.1 [hep-th/0501114](hep-th/0501114), Nicolai, Peeters and Zamaklar point out that the free string is quantum gravity in 2D, and that the only non-trivial thing about this model is that the constraint algebra admits anomalies. Assuming that the only non-trivial thing about 2D gravity generalizes to 4D (why on earth would they bring it up otherwise?), the constraint algebra of 4D gravity must admit anomalies. However, there are no diff anomalies in 4D, neither in string theory nor in LQG. Hence both theories are wrong.

25. **Juan R.**
May 5, 2006

Ira,

The problem with "string theory" is it does not exist (there is not theory just a goulash of conjetures, hypotesis, and views). The problem is also that stringers use "string theory" in many ways including incompatible ones (probably because marketing purposes).

There are not "canonical forms of the theory" as you say, just historical development. Let me take the concept of "string theory" in a broad sense.

There are versions of string theories are unitary, and versions are not unitary. E.g. Nanopoulos non-critical string theory introduces a kind of local nonunitarity that he claims (is not true) can solve the measurement problem of quantum mechanics. There are some versions of D0-brane theory are not Lorentz invariant (it is not known is at what extension effects can be detected at low energies), etc.

After of near 40 years, the main postulate of string theory, that the theory is compatible with anything and the contrary of anything, continues being true. But that is not physics.

That I really find unethical of all this are the two main points "always" present in many stringers discourses:

1) Claims about next verification of string theory are not novel (are 20 years old). It is unethical to offer to non-expertises that kind of belief when expertises know what can or cannot be tested in that "theory".

I can understand that after 40 years of continous failure to test the theory (or to fix main properties or even to check basic promises: e.g. quantization of gravity derivation of SM parameters…) stringers are more desesperate that when Glasgow wrote his critical paper decades ago. But forcing an unnatural survival of string theory between mass media and non-expertises via preprints as this.

2) During decades, violation of LI were studied in other theories as LQG. Then the only version of string theory was LI, therefore stringers rudely critized loop theorists. I heard many things including aberrations such as that loop theorists did not understand Einstein (however M-theory proves just the inverse) and that LQG was a kind of absurd ether theory violating all our knowledge about nature (stringers' claim was more absurd still).

I heard that whereas string theory was a beatiful unification of SM with full relativity, LQG would be considered as a kind of ugly 19th century approach and, therefore, abandoned…

It is interesting to see how many string theorists agree on maybe LI is not exact now. History is fascinating.

May 5, 2006

To Juan R.
One can be much more specific in criticizing string theory.
On the historical side the strongest criticism comes right from its confused start from the remnants of the S-matrix bootstrap program. It substituted the crossing property of on-shell quantities of QFT for the S-matrix and formfactors (for a recent review B. S, Ann. of Phys.319, (2005) 48), which is a deep (and admittedly somewhat mysterious) property up to this date, by what was later called duality, namely the saturation of crossing by infinite one-particle towers (the physical reading of the beta and gamme function properties used by Veneziano). This had no conceptual backing from QFT whatsoever (in QFT crossing is a delicate interplay between a finite number of one-particle states and their multi-particle cuts). It so happened that there was an extremely strong prodding for such a situation from phenomenologists of strong-interaction dispersion theory (especially from a Swiss phenomenologist named (?). Schmidt who was criticized by Res Jost). The phenomenologists really got what they wanted, but a short time later when the first results on high momentum transfer scattering came in, they got completely disillusioned with the duality idea. Without this support the idea was theoretical blue yonder in its purest form but it led to rich mathematical structures; we all know the rest of the story.
Physics would be more healthy if string theorists could be forced to compete on the same level as alternative ideas, but their hegemonial grip on power led to a sociological situation (physics/0603112) in which they are in firm economical control of the market (remember Marx: the existence preceeds consciousness which Brecht succeeded to put into a more popular form).
On the purely scientific side, particle physics incorporates two type of arguments: metaphorical ones and autonomous ones. QFT sometimes uses metaphorical arguments but as one can show in detail at least in the setting of QFT they can always be backed up by (often conceptually and mathematically more demanding) autonomous arguments. These words can be given an extraordinarily precise physical meaning (there is yet no reference, I am presently working on these ideas).
It turns out that string theory is totally metaphorical. Take for example the claim that QFT is originating from string theory in the low energy limit. Such scale-sliding arguments are only worthy if the structural relation between the two settings does not permit their application. The most important and characteristic property of QFT is vacuum polarization through localization. This is the reason why QFT goes significantly beyond quantum mechanics in producing thermal manifestations of localizations which go significantly beyond the uncertainty relations of QM (B.S. http://www.lqp.uni-goettingen.de/papers/06/04/). But string theory has no autonomously fluctuating quantum matter on its target space, its only knows quantum fluctuations which come from the (conformal) two-dimensional source space! Whereas autonomous vacuum polarization may get lost in “scale sliding” (see transition from QFT to nonrelativistic QM), it never can be created, i.e. Lambshift is not created through scale sliding, it has to be there before!
One can continue this list of autonomous versus metaphorical reality.
I do not know about you, but I often wondered why string theory appears so extraordinarily eerie and surreal, like a dreamworld. I finally found the answer in the total metaphorical nature of its arguments.

28. **Mentos**
May 5, 2006

What is this “scale-sliding” that you refer to (and seem to very much dislike)?
The Renormalization Group?

Does Bert Schroer not believe in the Renormalization Group in QFT?

29. **Bert Schroer**
May 5, 2006

No, the RG, if it is correctly implemented, is done on the solution (quite a demanding task!) whereas scale sliding is that rapid kinematical argument (directly done on the Lagrangian/action) by which e.g. people convince themselves that nonrelativistic QM emerges from QFT for small energies (which I called metaphoric).
Since I do not have messianic expectations in particle physics, I would like to leave “beliefs” to people who like to find them there.

30. **Chris Oakley**
May 5, 2006

Bert,

Since no-one has signed up to my particular take on QFT I am in no position to pontificate here, but despite having been a researcher in QFT for a while I cannot say that I have understood much of your 09:13 post. I might add that it may well be possible that one of the reasons why the *Feldverein* remains a small and exclusive club is that a lot of the rest of the world does not know what you (= ihr, (would that English had a 2nd person plural)) are talking about. Of course, the same criticism can be levelled at Superstringers, but then they seem to be calling the shots at the moment, whereas you guys are not.

Or, to put it another way, your comment looked interesting, please expand/explain …

31. **Mentos**
May 5, 2006

“No, the RG, if it is correctly implemented, is done on the solution (quite a demanding task!) whereas scale sliding is that rapid kinematical argument (directly done on the Lagrangian/action)”

What do those words mean?

Wilson’s renormalization group is a transformation on the action (in response to an infinitesimal change in the cutoff).

Are you saying there is something wrong with Wilson’s renormalization group?

32. **Bert Schroer**
May 5, 2006

Chris,
what I said this morning among other things is that Veneziano duality in contast to the crossing property of on-shell objects (S-matrix, formfactors) of QFT is a new postulate which without the phenomenological support from strong interaction, which however only had a shelf life of less than two years, would never have come into being; the mathematical content alone would not have been strong enough.
Do you not understand the logical content of this statement or are you worried of how to prove it? In the latter case I cannot help you in this blog (because of thematic restrictions), but I gave you a referemce which may be at least of some help.

33. **Bert Schroer**
May 5, 2006

Mentos
I told you what I meant by scale sliding, whereas you want me to enter the swampland of the renormalization group which I am perfectly prepared to do, but not in this blog, since it is not its topic and also since people don't use this sort of argument when they say that QFT follows from string theory (the present knowledge of string theory is not sufficient to do something like this).
Let me again try by analogy try to get my point (about a structural comparison which has to precede scale-sliding) across. Suppose you would live in a 2+1 dimensional world where the locality principle allows for braid group statistics. Maintaining the approriate relation between spin and statistics in the process of energy becoming small compared with the mass, you would never recover quantum mechanics but always end up with a nonrelativistic QFT (vacuum polarization would be persistent). On the other hand in d=3+1 where plektons cannot exist, the Bosons/Fermions allow for a relativistic free field realization in which the one-field state contains no admixture of vacuum polarization. This makes the physical relevance of QM possible because now there is at least no structural obstacle against "scale sliding" or if you want the somewhat more sophisticated RG arguments (I think by now you know what I mean without having to enter any additional controvery). Conversely the nonexistence of autonomous vacuum polarization of quantum matter on target space (fluctuations only take place in the 2-dim conformal field theory which defines source=worldsheet space) in string theory makes it structurally impossible to recover anything like Lambshift. I know that you are willing to sacrifices a lot of things from the past in getting some messianic string ideas ideas going. But do you really want to sacrifice also Lambshift?

34. **Mentos**
May 5, 2006

"I told you what I meant by scale sliding, whereas you want me to enter the swampland of the renormalization group…"

I didn't understand what you meant by "scale sliding", which is why I asked for clarification.

I take it, from your use of the word "swampland" to describe it, that you don't like Wilson's Renormalization Group very much.

"Conversely the nonexistence of autonomous vacuum polarization of quantum matter on target space …"

One-loop vacuum polarization computations in string theory look like fancy generalizations of the corresponding field theory computations (minus the UV divergences).

I don't understand your comment about "sacrificing the Lambshift."

35. **Bert Schroer**
May 5, 2006

My question to you: does quantum matter on string target space have vacuum polarization (on target space and not on the 2-dimensional worldsheet!)? I agree that some perturbative expression have a vague resemblence but this is a structural question! (and by the way QFT is not about taming ultraviolet infinities but rather about finding autonomous finite parametric subspaces in an apparently infinite parametric space of coupling strengths); either there is a target vacuum polarization (e.g. on the bondaries of localization of quantum matter on target space) or there is not. This is not a quantitative matter in the same vein as it is meaningless to take about "being a little bit pregnant".
As far as my underlying philosophy of QFT goes it is Wilsonian and not TOEian. But Euclidean field theory is primarily statistical mechanics (following Osterwalder and Schrader, for a recent review see hep-th/0603118) and its use should be limited to structural arguments in (real time) QFT (because of the extremely subtle reflection positivity).
If you are so convinced to know what a cutoff is then please tell me what I have to do in any of those infinite families of two dimensional factorzing models (the Sine-Gordon/massive Thirring being the oldest one) in order to introduce a cutoff into their known formfactors or correlation functions; its not a retorical question, I honestly do not know how to do that. I of course know what a cutoff is in a Feynman integral but I am already lost if I should do something like this on a functional integral and even if I succeed how do I convince myself that I preserved the all-important reflection positivity which is my only assurance that I am still within quantum physics? I think if you ever seriously confront these question you will come to the conclusion that it is mathematically (and conceptually) easier to formulate and control local QFT than nonlocal (cutoff etc.) ones in which the nonlocality results from momentum space manipulations. Particle physics is not about attending holy cows; it is of pivotal importance to re-investigate old problems if there are new conceptual tools to do this.

36. **Mentos**
May 5, 2006

"I agree that some perturbative expression have a vague resemblence but this is a structural question!"

I don't understand your structural question, nor what you mean by the statement that the resemblance of the two perturbation expansions is only a "vague" one. Sure there are important differences, but none of them have anything to do with low-energy physics like the Lambshift.

"As far as my underlying philosophy of QFT goes it is Wilsonian…"

If your philosophy of QFT is Wilsonian, why do you call the Wilsonian Renormalization Group "the swampland"?

"If you are so convinced to know what a cutoff is …"

The presence of a cutoff is absolutely central to the Wilsonian approach to field theory. So your distrust of cutoffs is more than a little puzzling for someone whose underlying philosophy of QFT is "Wilsonian."

How do you feel about a lattice cutoff?

37. **Chris Oakley**
May 5, 2006

Hi Bert,

No, I think I got the first bit.

> On the purely scientific side, particle physics incorporates two type of arguments: metaphorical ones and autonomous ones.

So "autonomous" here just means "not metaphorical"?

> The most important and characteristic property of QFT is vacuum polarization through localization.

What? The most important and characteristic property of QFT is that it is quantum mechanics wherein particles can be created and destroyed.

> This is the reason why QFT goes significantly beyond quantum mechanics in producing thermal manifestations of localizations which go significantly beyond the uncertainty relations of QM (B.S. http://www.lqp.uni-goettingen.de/papers/06/04/).

This is AQFT jargon that means nothing to me.

> But string theory has no autonomously fluctuating quantum matter on its target space, its only knows quantum fluctuations which come from the (conformal) two-dimensional source space! Whereas autonomous vacuum polarization may get lost in "scale sliding" (see transition from QFT to nonrelativistic QM), it never can be created, i.e. Lambshift is not created through scale sliding, it has to be there before!
> One can continue this list of autonomous versus metaphorical reality.

I expect that there are a whole swathe of papers I need to read before I can understand this (& I wonder whether any of them actually calculate cross sections).

38. **Bert Schroer**
May 5, 2006

A lattice cutoff would perfectly satisfy me but please tell me how you introduce any cutoff in a model whose rigorous construction principles are not following the Lagrangian quantization logic. You do not seem to be aware of the explicit existence of a large class of strictly local 2-dim. QFT which owe their existence to completely different ideas than those of Lagrangian actions and Wilsonian RGs. This is a class where not only the old bootstrap idea about the S-matrix works, but there exists in addition a QFT which is uniquely associated with this S-matrix (the formfactor part of the formfactor-bootstrap program). The point is that any introduction of a cutoff in any form would totally wreck this constructive approach by which they have been manufactured (I don't think Lagrangian quantization will ever lead to such explicit constructions even in those case where the models may be baptized with a Lagrangian name). The cozy conceptual security in which you seem to live (and of course not only you personally) has been already seriously undermined apparently without you being aware to live in an undermined world. Of course you may want to execrate this reality by claiming that these models are irrelevant for TOE fans but it certainly will not go away but rather will grow stronger. It looks that this is just the first glimpse of a new way of entering QFT and a new way to look at QFT, and it is far away from the swampland entries.

39. **Arun**
May 5, 2006

So "autonomous" here just means "not metaphorical"?

What I have gathered from the conversation so far is that autonomous means standing on its own, not needing a reference to something else.

40. **Bert Schroer**
May 5, 2006

Sorry, I give up. Please don't think that I am arrogant and I want to put you down. In reality am sad about this situation. The schism in particle physics generated by more than 30 years of string-induced metaphorical (as opposite to autonomous) thinking (string theory is only the culmination of something which already started before) has led to a situation where a genuine dialog is estremely difficult. I agree with Smolin that the physics discourse is on the verge of breaking down, but not only between string theory and LQG but also between advanced QFT and attempts at TOEs.
I don't think it is my ignorance because I have followed the development of string theory form its cradle and I have a certain sympathy for the more conservative aim of LQG (which unfortunetly gets into a false recent competition with ST which forces it to occupy territories which are outside its conceptual range). But the fact that I understand what other people are doing is of little help here if it remains one-sided.
Chris, I am disappointed that you ask that abominable question. Of course I can calculate cross section and they would be the same as everybody else's. Pointlike fields are singular generators of algebras and perturbative interactions are formulated by polynomial invariant couplings of free fields. Of the infinitely many forms for (m,s) free fields (see Weinberg) you can use any you want in doing causal perturbation theory. In case you have a Lagrange-Euler description which generically is the exception rather than the rule (for low spin fields such free field representations are known) you can also use the functional integral approach but why should I put this restriction on myself? Local quantum physics is an extension and not a narrowing down and if you define QFT through functional integrals you are narrowing it. Renormalized causal perturbation theory is the most general framework based on pointlike free fields and it is totally mathematically rigorous (in the sense of formal power series just as the formal algebraist like Drinfeld treat Kac-Moody representations or vertex algebras)but of course not in the sense of convergent sums which are formally representing the would be operators in Hilbert space.
Let us never come back an loose time on re-hashing such questions over and over again.

41. **Bert Schroer**
May 5, 2006

To Arun
Autonomous means that it contains its interpretation i.e. there is no freedom to add anything from outside, and the terminology metaphorical is used if the interpretation has to be added from the outside. Observe that metaphorical does not mean wrong, of course you make sure that you do not add something which creates an inconsistency (it is similar to Goedels situation in the theory of logic).
In QFT one often uses metaphorical arguments but thanks to vacuum polarization which distinguishes QFT significantly from any kind of relativistic QM matephorical arguments in QFT can always be replaced by (generally more deep and demanding) autonomous ones. I discuss such situations in connection with thermal manifestations of localization in QFT (for example the entropy problem) in
http://www.lqp.uni-goettingen.de/papers/06/04/
although I did not yet use this terminology in those papers. The usual thermodynamic limit approach in thermal QFT is metaphorical but there exists an open system formulation based on the so-called "split property" (which makes essential use of vacuum polarization) which converts the sequence of finite systems into a sequence of genuine inclusions which are all subsystems of an open system. In Haag's book it is referred to as the statistical mechanics of open quantum systems. Without quantum matter which reacts to the process of localizing it by producing vacuum fluctuations on the causal horizon you cannot get to the autonomous formulation of open systems. QM and string theory do not have that vacuum polarization you need. Wheras this lack of autonomy does no harm to QM, it makes string theory (because it is supposed to contain autonomous QFT) look very eerie, more like a surreal painting of Dali than a realistic theory of quantum matter.

42. **Mentos**
May 5, 2006

"You do not seem to be aware of the explicit existence of a large class of strictly local 2-dim. QFT which owe their existence to completely different ideas than those of Lagrangian actions and Wilsonian RGs."

Almost all nontrivial 2D CFTs are non-Lagrangian. Most of the known integrable 2D QFTs are constructed as relevant deformations of a 2D CFT, and so are non-Lagrangian as well.

The same is true in higher dimensions. Nontrivial interacting fixed points generically have no useful Lagrangian formulation. (Sometimes such theories can be realized as the IR limits of a weakly-coupled Lagrangian field theory. Sometimes they can be realized as the limit of a family of Lagrangian field theories.)

There are even (thanks to string theory constructions) examples of nontrivial interacting QFTs in 5 and 6 dimensions. These, of course, are also non-Lagrangian.

"QM and string theory do not have that vacuum polarization you need."

In the case of QM, you are, of course correct. In the case of string theory, you seem to have gotten a wrong impression somewhere along the line …

43. **Bert Schroer**
May 5, 2006

No, I think we are living in different conceptual realms. When you say you can construct you mean that you can make a mental picture but not anything which a mathematician or a mathematical physicist would call a construction or a proof of existence. There is not a single construction or existence prove in higher dimensional QFT with or without the RG, not to mention string theory. In string theory, unlike QFT one does nor even know any intrinsic characterization one only has some recipes. If the word construction would still have a mandatory engaging meaning which it used to have before the new barbarians appeared on the scene, we would never enter such futile arguments.
And finally: why do you think there are these trillions of vacua which do not communicate; in a theory with vacuum fluctuations caused by local quantum matter this would not happen, they would all communicate and not live separate lives as in a classical theory.
If somebody would have frozen me at a time when particle physics was still healthy and woken me up in the present, I would feel like in one of Kafka's short stories: eerie and surreal.

44. **Mentos**
May 5, 2006

"There is not a single construction or existence prove in higher dimensional QFT with or without the RG, not to mention string theory."

That's right.

By your criterion, QCD does not exist.

"If somebody would have frozen me at a time when particle physics was still healthy and woken me up in the present, I would feel like in one of Kafka's short stories: eerie and surreal."

Nonsense.

No one believed that the limited class of field theories, constructible by the techniques of Constructive Quantum Field Theory, were the only things that existed back then either.

Essentially all progress back then came from what you call a "different conceptual realm." And that continues to be true to this day.

If anything, the set of rigorous results in 2D (the only dimension where CQFT/AQFT ever had any traction anyway) coming from other approaches is vastly greater now than it was then.

As to dimensions above 2 (like, for instance, 4 dimensions, where we happen to live), life goes on, despite the utter lack of progress from Constructive/Algebraic Quantum Field Theory approaches.

If you want to spend your time working on rigorous approaches to 2D QFTs, that's fine. But don't pretend to be surprised at other people's lack of fascination in your progress.

Only in your fevered imagining is that a sign of the sickness of high energy theoretical physics. The center of attention has always been elsewhere and, for intellectually-sound reasons, remains elsewhere today.

45. **Chris Oakley**
May 6, 2006

> Let us never come back and lose time on re-hashing such questions over and over again.

Just this once:
The cross section calculation in 3+1 dimensions you refer to is I assume based on the Epstein/Glaser causal perturbation theory as outlined in (e.g.) Scharf's *Finite Quantum Electrodynamics*. I bought a copy of the latter a while back and have a made a mental note of going through the arguments it in detail, but have not done so yet for the following reason: it just looks like good old renormalizing Feynman-Dyson perturbation theory in elegant clothes. Cutoffs are a crude way of "dealing with" theories that give unwanted infinite results, but not the only one. One may also introduce other kinds of spurious degrees degrees of freedom and take spurious limits and although I will grant that what is done here is better than cutoffs or dimensional regularization it still seems to amount to the same thing.

46. **Bert Schroer**
May 6, 2006

Yes Chris, everything of a systematic nature which you can do with functional integrals you can also do within the causal perturbation setting and much more (the perturbation theory in CST can only be done in cp and the resulting local covariance principle of Hollands, Wald, Brunetti, Fredenhagen and Verch is truely something which shows the vibrancy of modern QFT and there are several other startling results outside of the radar screen of string theory; but fortunately the relevance of some discovery for physics is not determined by Gallup polls among string theorists).

47. **JC**
May 6, 2006

Bert,

Have you thought about writing your own textbook on quantum field theory, emphasizing the aspects which you feel are being neglected in modern textbooks treatments (ie. Peskin & Schroder, Zee, etc …)?

48. **Chris Oakley**
May 6, 2006

Peter's opponents apparently in a more conciliatory mood:

http://www.careerbuilder.com/monk-e-mail/?mid=8823799

49. **Bert Schroer**

May 6, 2006

JC,
yes I have, but there are certain problems which I want to see solved before. I probably would not do this on my own because it is not enough to have new ideas (including of course new ideas on old open problems), one also needs a critical counterpart. Presently advanced QFT is too much in an upheaval, maybe in two years from now some of the dust will have settled. There are very astonishing structures in QFT which could not have been noticed with the old conceptual apparatus. The local operator algebras in QFT are all of one kind, i.e. if you have seen one, you know them all (just like points in geometry) and the richness of QFT, including its inner symmetries and its (noncompact) spacetime symmetries, is all contained in the relative position of a finite number of copies of this "monade" (explicitly: hyperfinite Type III_1 von Neumann algebras, Ed Witten may pardon me) which are placed in terms of modular algebraic concepts with geometry being the result and not the input (note the difference to Atiyah-Witten). The setting resembles that of Vaughn Jones's inclusion theory but the monades used here lead to modular inclusions and they lead to spacetime, whereas the Jones inclusions are limited to only notice a left-right distiction (braid groups, topological field theory). The concepts and mathematics are clear and rigorous, what is completely open is the range of physical content.
I do not complain that the small dedicated group of people who are engaged in this project do not get enough attention, since I am convinced that real progress will not result from those globalized monocultures: there seems to be a critical size just as in the theory of traffic collapses. But of course on the other hand I am afraid that we will be left with near zero new blood at a time when it would be really important because the ball of local quantum physics seems to be rolling again. My polemic article was not written for the sake of polemics but mainly to let those many physicists who have doubts about how particle physics is administrated by string theorists know that there is another world. We are in a situation in particle physics which never was confronted before and which definitely cannot be explained without taking sociological aspects into consideration.
I think Arun makes a serious mistake if he thinks that this eerie and surreal appearance of string theory is my personal problem; he would be surprized how many particle theorists have a similar impression; in fact hep-th/ has in the eyes of most particle physicists become a site of messianic TOE expectations.
My question to Arun about the structural status of vacuum polarization was carefully chosen because the very nature of those above mentioned monade algebras already incorporates the vacuum polarization and thermal properties in their algebraic structure (these algebras have no pure states at all!). They are the heart of local quantum physics (much more basic than the use of particular field coordinatizations) and it would be interesting and important to know what string theory puts in their place. What is somewhat depressing is not that Arun does not know the answer, but that he gave the impression that it is not worthwhile to know the answer; for him it is only a minority interest of some isolated individuals who do their little thing and are detached from the great design of a final TOE. Although I live in a completely different conceptual realm than Peter or Lee Smolin (whose worries about a falling apart basis of communication within particle physics I however share) I never have the impression that they are dismissive about different views or that they have hegemonic ambitions.

50. **Bert Schroer**
May 6, 2006

With all appologies to Arun, I mean Mentos.
These pseudonyms add an impersonal flair. I think their original purpose is to further the course of democracy so that somebody, who wants to discuss with a bigshot, does not have to be inhibited or afraid of his reactions; but on the other hand they should not be used denigrate somebody who signs with his name and takes the responsibility for what he writes. Up to now I did not have the impression that such an abuse occurred with respect to my contribution.

51. **Mentos**
May 6, 2006

"What is somewhat depressing is not that [Mentos] does not know the answer, but that he gave the impression that it is not worthwhile to know the answer…"

I am sorry if I gave that impression. It's not that I don't think the answer is interesting. It's that I don't understand the question.

As to the status of CQFT/AQFT as a "minority interest of a few individuals," you seem to be arguing that, in some past golden age, that was not the case. The fact is that it was always a minority interest.

That's not a criticism of AQFT. It's simply a statement of reality, and important to repeat for those too young to remember the "golden age."

"…they should not be used denigrate somebody who signs with his name and takes the responsibility for what he writes."

Which is not my intention either.

52. **Bert Schroer**
May 6, 2006

Mentor,
"As to the status of CQFT/AQFT as a "minority interest of a few individuals," you seem to be arguing that, in some past golden age, that was not the case. The fact is that it was always a minority interest."
That is certainly true, but this was a democratic choice and if one made that choice and had some innovative ideas there was no problem, it was the quality on the level of the state of art of an area which determined careers. There was no need for a hegemonial control through citation indicees in which mathematical physics fares less well so AQFT also could profit from the "golden age".

"That's not a criticism of AQFT. It's simply a statement of reality, and important to repeat for those too young to remember the "golden age.""
I meant "golden age" for particle physics not for AQFT, although as I said AQFT did not fare badly.
Now that we are in tune again, I could try once more to get to that question of intrinsicness (autonomy) with respect to string theory across. Let's forget the vacuum polarization aspect and explore that intrinsicness in a more specific context of the free 10-dim. superstring (to avoid tachyons) in the covariant gauge (conformal formalism, BRSTetc.). We probably can rapidly agree that if one applies the free string field operator once to the vacuum (the "one-field state") and descends via BRST cohomology to the physical subspace, one obtains a highly reducible unitary Poincare representation which describes a mass tower. Take it from me (we can argue about this separatly, this is where I use modular localization) that the two point function which is a function of center of mass X and internal dynamical variables is point-localized in X and hence the physical projection of that free string field inherits this localization. If that field would have been string-localized it would have shown up right here in a reduced spacelike (anti)commutativity where the geometry of the string would be plainly visible (if one string comes into the timelike causal shadow of the other). It does't, and so you could get the impression that the situation is indistinguishable from a pointlike infinite component free field. But I am almost certain (I have not done the computation) that the result will have a much better spacelike commutativity than one can get in infinite component QFT (and in any QFT for that matter): depending on the excitations of the internal degrees of freedom the situation will be "supercausal" i.e. the (anti)commutator will continue to vanish up into the timelike region (inclusing lightlike distances) below a certain timelike distance which varies with the internal excitation state. This then may be considered as an intrinsic characterization of a free string versus an infinite component free field. I is certainly independent on all the words which went into its manufacturing (conformal QFT, BRST, reparametrization and gauge aspects etc.). In other words the question is which property distinguishes the string mass tower from a generic infinite component tower. I do not know the answer, but would you agree that this at least is a way for aiming at an intrinsic meaning?

53. **Mentos**
May 6, 2006

No, let's stick with vacuum polarization.

Maybe what we need is an example of the kind of explanation that would satisfy you.

Consider Lattice Gauge Theory. What “structural property” of Lattice Gauge Theory ensures that it has vacuum polarization?

54. **Ming**
May 6, 2006

Sorry this is off-topic, but I’m wondering what’s happening to Peter Woit’s book “Not Even Wrong”. I thought it should have been published in April (according to one listing in amazon), but apparently not. And another listing in amazon says it won’t be published till 9/30/06. Just want to get a more definite answer from the author. Thanks.

55. **Bert Schroer**
May 6, 2006

Mentos,
Unfortunatly nothing, you just do not get those nice monades which structurally encapsulate and bind together(modular) localization, vacuum polarization, thermal manifestation of localization in the vacuum etc.
I would not know how to rewrite my papers on localization entropy on the Goettingen AQFT server in terms of a lattice model.
It seems to me that the lattice is good for nonperturbative approximations but not for structural problems, in fact it is particularly efficient if you do not yet understand the conceptual structure of a problem. In the present case one really knows a lot about the QFT structure, and that analytic insight should not be vasted by returning to a lattice (I do not know how the lattice works for string theory).
In principle one should find an answer somewhere, but it is too much buried in details. Just as in QM, vacuum polarization is not structurally forced upon you. In QM and lattice theory you always have factorization between the Hilbert space of a region and its complement (and the cacuum factorizes trivially), whereas in QFT there is never a factorization between the subspace of localized states and that of states belonging to the spacelike disjoint region. In fact you can only create such a tensorproduct factorization if you allow for a “collar” region which separates a localization region from its causal disjoint; but even if you do this “splitting” you will not loose the thermal aspects of the vacuum (which are never there in QM and lattice theory unless you introduce a heatbath by hand).
With other words it would be a terrible mess if you were to describe the Hawking radiation phenomenon on a lattice. For this reason you have to be satisfied with my other more pedagogical example; try to look at it, it is not so bad for getting the structural point of “intrinsicness” across.

56. **Who**
May 6, 2006

there is a logical point about testing scientific theories that in the long run is probably more important than some particular paper about a particular theory. it is illustrated by this post:

“…it says that IF there is no light Higgs, AND the calculated bounds are found to be violated THEN EITHER SST is false OR one or more of Analyticity, Unitarity, and Lorentz Invariance is false. It is up to the experimenters to determine which is the case.”

Something worries me about this. suppose the conclusion were
“(EITHER SST is false OR General Relativity is false)” And suppose the conclusion were “It is up to the experimenters to determine which is the case.”

This is not a possible way to falsify SST, because logically in order to do that one would have to prove that General Relativity is TRUE. but that is, in principle, impossible. One cannot show that a scientific theory is true one can only continue to test it.

One can not put up to experimenters the job of proving a theory true.

But in order to function as a falsification of SST one would have to do just that. therefore the logical scheme presented here UNSATISFACTORY as a proposed falsification. (this is not a Distler issue or a SST issue, it transcends the immediate circumstances and involves our understanding of how theories can be tested)

The scheme would only work marginally in a context where all educated people of good faith accept Gen Rel without question. As an unquestioned premise that is not felt to need experimental support.

But in our particular case here, “Analyticity, Unitarity, Lorentz Invariance” is very far from being such an unquestioned premise. I see indications of widespread skepticism that nature conforms to those three rules. As the poster indicated, we could NOT take it on faith but would have to hand over the job of verifying it to experimentalists. They, however, would be logically incapable of verifying these as features of nature, and could at best falsify them.

The Distler et al paper, it seems, could serve a textbook example of how NOT show the falsifiability of a theory (because it illustrates this simple, but easily overlooked logical point.)

57. **Mentos**
May 6, 2006

Schroer said:

“Unfortunatly nothing, you just do not get those nice monades which structurally encapsulate and bind together(modular) localization, vacuum polarization, thermal manifestation of localization in the vacuum etc.”

Well, if lattice gauge theory does not have the requisite “structural properties” that you require, then I am sure that nothing I can think of will either.

QCD, for you, is a nonexistent quantum field theory.

The problem lies not in string theory, but in all of the “quantum field theories” of moderm particle physics. Even the best of them is not defined in a fashion that satisfies your requirements.

Who wrote:

““‘…it says that IF there is no light Higgs, AND the calculated bounds are found to be violated THEN EITHER SST is false OR one or more of Analyticity, Unitarity, and Lorentz Invariance is false.”

I don’t think that is what their paper says.

They argue that IF there is no light Higgs, AND the calculated bounds are found to be violated THEN one or more of Analyticity, Unitarity, and Lorentz Invariance is false. Since SST incorporates the properties of Analyticity, Unitarity, and Lorentz Invariance, then IT, TOO, must be false.

That’s quite different from the logical syllogism you propose. Perhaps it has its own flaws, but not the ones you claim.

58. **Who**
May 6, 2006

thanks for the reaction Mentos. I am glad you have a different interpretation, this gives more of a chance for Distler et al work to exhibit genuine falsifiability.

I have three questions for you.

what does it mean to assert that “Analyticity is false” ?

what does it mean to assert that “Unitarity is false” ?

what does it mean to assert that “Lorentz invariance is false”?

Perhaps as you suggest, your version of the syllogism has its own flaws, such as the flaw that these statement are meaningless. What is your view?
Personally I cannot imagine attributing a meaning for these statements unless we venture into the realm of metaphysics and make normative statements restricting the mathematical content of physical models—i.e. stop judging theories on the basis of their performance.

Metaphysical statements such as (“mathematical functions used in modeling should be expandable in power series”) are not, I believe, empirically testable—-they concern human conventions and not the physical world. How does one falsify a metaphysical principle,
or a normative injunction about conventions?
And then if you DO falsify it, or at least contradict it, you get something like (“it is OK for mathematical functions to be expandable in power series but also OK if they are not, maybe they dont even all have to be differentiable, whatever works!”) And then how does that falsify SST?

It seems to me that “Analyticity is false” merely enlarges the range of theories that the maker of the statement is willing to consider and test. SST would still be required to make predictions and be judged on its merits, whatever be the field of competitors.

Something fishy about Distler et al claim to show falsifiability, I suspect. Can’t get a paraphrase of the argument that means anything. If you have one, I’d be very glad to hear it.

59. **Mentos**
May 6, 2006

Saying that one of these properties is false is simply to say that the fundamental theory at very short distances does not possess this property. Perhaps, like LQG, the fundamental theory is not Lorentz-invariant at short distances. Or, perhaps one of the other properties does not hold.

Anyway, the dispersion-relation bounds of Distler et al are derived assuming that these properties hold to arbitrarily short distances in the fundamental underlying theory (whatever it is). If the bounds are found to fail experimentally, then these assumptions about the short distance theory must be false.

Perhaps, in that case, the true short distance theory is LQG. In any case (they say) it isn’t string theory.

60. **Bert Schroer**
May 7, 2006

To Who says,
I have the same problems with the paper. Analyticity is not a physical principle and Lorentz invariance may refer to the fact that string theory among other things permits also a Poincare-invariant solution. As it stands it implies a somewhat uninteded cabaret interpretation of the word “theory of everything”. Nevertheless it may indicate a deep desire to bring the discussion back to a more conceptual level. A characteristic aspect of the mentioned “golden age” is that it brought the conceptual dialogue to an art form and this has been lost and we probably must re-learn it.
Presently many works place calculations directly next to sophisticated mathematics without a mediating conceptual link. I am very suspicious when I see all that high powered and from a physical viewpoint amok-running mathematics (differential- and algebraic- geometry, Langlands etc) being juxtaposed to supersymmetry, e-m symmetry and other unfulfilled physical pleas to nature over and over again, although the D-J-R paper cannot be accused of duing that. But a first swallow does not yet make a spring and one has to wait and see whether this indicates a trend.

61. **Adrian Heathcote**
May 7, 2006

Bert

I’ve been finding your posts very interesting — and engagingly frank. My own interest is perhaps a very small subset of yours. I’m interested in the possibility of solving some of the interpretative/foundational problems with QM (not QFT) by looking more closely at the algebraic structure — in particular what happens when you couple systems together either in measurement situations or in EPR-type ensembles. It seems to me that some subtleties have been glossed over in traditional presentations: it is for example usually ignored that there are a very large number of tensor products that may describe a coupled system, and this range, in a sense, represents a physically determinable aspect of coupled systems that has not been looked at.

I’ve always thought that this aspect of QM (entanglement etc) must really get its fullest exposure in QFT and have always been quite dissapointed with what I’ve found. (Let alone what is in string theory.)

Is this an aspect of AQFT that you can comment upon? Particularly as many people think that AQFT ‘s local nature precludes it from saying anything about this from the outset.

62. **Arun**
May 7, 2006

Bert:

If you’re not writing a textbook right now, could you outline a reading program? Let the starting point be a grad student who has had a first course in QFT.

Thanks in advance!

63. **Bert Schroer**
May 7, 2006

Concerning basic advanced structures in QM off hand I would recommend Claas Landsman's homepage. I have seen a link in Peter's homepage. The issue of entaglement etc. is a bit more demanding in QFT as a result of the ubiquitous vacuum polarization.
Also the second addition of Haag's book on QFT has some nice material on the measurement which is presented in an interesting personal flair. More advanced topics on ERP and Bell in the context of QFT you find on Steve Summers homepage.
http://www.math.ufl.edu/~sjs/
Very interesting and highly recommendable are also publications of the University of Pittsburgh Philosophy department. These people really know what they are talking about. I had many interesting email exchanges with Rob clifton and I was deeply saddened when I heard about his early death a couple of year ago. Hans Halverson, who is now in Princeton is a very worthy successor (he actually was his student). Apparently because of its rich conceptual structure AQFT has a very strong attraction to philosophers of science. Without knowing a little bit on the mathematical side one may feel lost in their articles, but I think they have also supplied some more pedagogical articles.
Articles of Halverson you can also find on
http://www.lqp.uni-goettingen.de/
Arun
Since I have my reservation about recent literatur on QFT, I still would recommend Haag (not so much as a textbook to learn tools of the trade, more to get a conceptual overview), also Streater-Wightman and Jost are still good in what they cover (and there are many important things they do not cover). For scattering theory, which is a cornerstone of AQFT, there is also a recent little book by Araki. For the tools of the trade Itzykson-Zuber is still good. With all those antidotes I think you can also get sum honey from Peskin-Schroeder since you can then easily spot the weak part where they allowed the string theoretical carricature of QFT to take over.

64. **Mork**
May 7, 2006

>With all those antidotes I think you can also get sum honey from Peskin-Schroeder since you can then easily spot the weak part where they allowed the string theoretical carricature of QFT to take over.

That must be the best 1-line book review ever!

Any choice words on other popular QFT texts (Weinberg, Srednicki, …)?

65. **Alejandro Rivero**
May 7, 2006

Bert, speaking of weakness, what do you think of Doplicher's quantum area in the context of AQFT? Does it implies that the net of observable algebras contains a minimum algebra? Is it in contradiction with some fundamental issue of AQFT?

(and yep, I join in recommending the reading of Haag's in paralell with P&S. I "stole" (xeroxcopied) Haag's draft when in display at Leipzig IAMP meeting, and then I went straigh for the full book when it appeared at the bookstores).

66. **Bert Schroer**
May 7, 2006

Alejandro Rivero,
"Bert, speaking of weakness, what do you think of Doplicher's quantum area in the context of AQFT? Does it implies that the net of observable algebras contains a minimum algebra? Is it in contradiction with some fundamental issue of AQFT?"
If your question is what I think about Sergio Doplicher's contributions to QFT, my answer is that I am impressed by them. The deepest work (in collaboration with John Roberts and in part Rudolf Haag) is the derivation of the structure of charge sectors, their statistics and the inner symmetry (in 4-dim. always a compact symmetry group) as well as the construction of the charge-carrying field algebra from basically the causality and spectrum structure of local observables. This is like Marc Kac's "how to hear the shape of a drum" where the ear is the observable algebra and the shape of the drum is the field algebra i.e. the field algebra including its particle statistics and its inner symmetry is constructed from its observable shadow (the observable algebra), a marvelous conceptual achievment. You cannot do such things in the Lagrangian setting where the structure of the field algebra is assumed ab inicio.
Sergio (together with Roberts and Fredenhagen) also worked on "noncommutative QFT" with Quantum Gravity in mind (although what they actually do is noncommutative QFT in Minkowski spacetime). Despite their "good physical intentions" they arrive pretty much at those problems which other people many years afterwards also found with less good physical motivations (a L-invariance breaking "aether", only partially solved problems with unitarity, no complete improvement of short-distance properties etc.)
In my view (AOP 319 (2005) 92) the most serious problems (in addition to unitarity) which the present generation of physicists are generally overlooking is the question of whether some sort of macro-causality (no timelike precursors, spacelike cluster properties) can be maintained. As I explained in my review, an earlier generation of physicists (in the 50-70ies) who studied the feasibility of nonlocal QFT really payed attention to this point and ended in failure (wrong in a sense which Pauli would have deeply appreciated!); this was at a time of honesty in particle physics when people did not published positive results and surpressed negative ones even though they came from the same assumptions.
I know that there is presently only one setting which fulfills all the assumptions (including cluster properties) the "direct particle interaction" of Coester and Polyzou, but the profound work of these nuclear physicists seem to remain unnoticed among particle physicists. When I mentioned this in a blog last month there came a very interesting reaction from Eugene Stefanovich pointing out that there are other attempts which use a more field theoretic presentation, but I did not yet find the time to look at them (they may very well also treat that macrocausality requirement correctly, but since this is a very delicate conceptual point, I prefer to look at this before I say something).
I have a question to all of you, can anybody provide me with a reference where the cluster factorization property of the string S-matrix was shown?

67. **Mentos**
May 7, 2006

"I have a question to all of you, can anybody provide me with a reference where the cluster factorization property of the string S-matrix was shown?"

We went through the same problem with respect to vacuum polarization.

At the end of the day, you insisted that Lattice Gauge Theory (the only rigorous (some might say, not yet rigorous enough) definition of an interacting 4D field theory, that currently exists) does not have the requisite "structural properties" for vacuum polarization.

Can you point to a rigorous proof of cluster factorization in a 4D interacting field theory, as a model of a proof that you would consider satisfactory in the string case?

68. **Bert Schroer**
May 7, 2006

Of course, the derivation of cluster properties as a structural consequence on the same conceptual level as TCP, spin&statistics is a consequence of the principles of local causality and positivity of energy. Have done this for the correlation functions the Haag-Ruelle scattering theory carries it to the S-matrix. Prooving it for a concrete model amounts to checking these two properties and this is extremely simple and in all models which have been constructed in any mathematical rogorous sense and in those

models which only have a Lagrangian name but are not yet mathematically born it is guarantied by the fact that causal locality and positive energy-momentum spectrum are formal properties of the Larangian quantization setting which become rigorous as soon as you are able to fill this Lagrangian name with a mathematical content. It is of course true in every order of perturbation theory.
In string theory the conceptual position of the S-Matrix is totally different; instead of being the crown of an underlying theory it is the result of a yet mathematically (outside that genus perturbation theory) not secured cooking recipe which comes from a theoretical blue yonder attempt and therefore there is really something to prove here. But in my question I would be satisfied with an answer in lowest nontrivial order in fact I would already be satisfied if one can see that the 4-particle amplitude (the one which comes from that two tubes joining and splitting) goes to zero if you remove the center of wave packets to infinity in spacelike direction (but of course without any additional approximation of the amplitude). I am not so familiar with the analytical form of these amplitudes, otherwise I would have done it myself.
The important point is that whereas in QFT you get it for free (from other well-known properties), in string theory you have to prove something (asymptotic properties of presumably quite complicated function). I would find it very strange if this has not been done in G-S-W or Polchinski's book.
Since I would except perturbation theory, there is no reason to take refuge to a lattice.

69. **Mentos**
May 7, 2006

You may find the discussion in Polchinski's book (for the bosonic string) satisfactory.

In general, there is an intricate mapping between properties of the 2-dimensional world sheet theory and analytic structure of the spacetime S-matrix.

(A word of caution, since in your question, you seem to blur the distinction between S-matrix elements and off-shell Green's functions: conventional string perturbation theory does not attempt to produce expressions for the latter. Only S-matrix elements are defined, but the poles and cuts of the perturbative S-matrix do satisfy all the usual axioms – something that was not guaranteed in a quantum theory of gravity.)

70. **Bert Schroer**
May 8, 2006

Sorry for the several typos in my posting from yesterday, but since I think that they did not impede the understanding of the content.
Yesterday I left my cottage in Arraial do Cabo (160 km north of Rio de Janeiro, lovely micro climate caused by a passing cold Patagonian current) and went to the nearby Cabo Frio to interrupt my temporary self-chosen solitude. I went to a Chorinho Club. Chorinho is probably the result of the oldest musical encounter between African and European traditions. It is approximately of the same age as as ragtime and New Orleans jazz. The melodic lines (guitar, flute or clarinet) are rich and complex and they are all written down (like ragtime) and hard to improvise on. Everybody in the older generation knows them. The freedom of improvisation is mainly on the side of the rythm which is created by a pandeiro and a cavaquinho. There were many old couples and some "coroas", widows or divorcees of African (probably the strongest ethnic component around Rio), Arabian and European descend. I did not know that Brazil received so many immigrants from the time when the Otoman empire fell apart. The coroas had extravagant very light clothes with a lot of gold rings around their arms, ornamental belts and impressive trappings around their neck. Their vibrant way of dancing encapsulated memories of past beauty and art de vivre. It reminded me of Wim Wenders social club.
I always have been attracted by the originality and richness of Brazilian popular music inasmuch as I liked jazz (when I was at Princeton in the early 60ies I went down to East Village several times to listen to Art Blakey and many other jazzists. While in Pittsburgh I once met a Brazilian au pair girl who aquainted me with the music of Chico Buarque de Hollanda, Gilberto Gil and other Brazilian composers. So when I finally went down there for the first time in 1968 at the invitation of Jorge Andre Swieca, I was not totally unprepared about Brazilean popular culture. The country was in the grip of a military dictatorship but the popular culture was flourishing. Several compositions of Chico were banned by the military and Gil and Caetano Veloso had to flee to London. The censureship was quite severe and many concert and theatre productions were forbidden. This often had the effect of refining the style (one had to avoid addressing problems directly) and significantly enhanced the artistic value (with all apologies to the aficionados of political correctness), an effect which my colleagues from the former Soviet Union probably also experienced. I perfectly understood why Feynman during his more than on year stay in Rio de Janeiro was so much taken in that he did not only become a honorary member in one of Rio's famous Samba school, but he was an activel participant of the batucada section (he played the frigideira a small frying-pan-shaped piece of metal which requires a very high playing speed).
When I came home I had to listen to some Brazilian form of hiphop because the young guys park their ghettoblaster cars near my living place. What a difference to what I had heard before and the high quality popular music which used to be deeply appreciated by all strata of Brazilean society (remember the maid in Pittsburgh I mentioned before)! Brazilian hiphop (at least the one I have heard) is primitive on the musical side and usually pornographic in its lyrics. How can such a rich popular culture fall into such gaping cultural hole within only two generations?
But isn't the history of particle physics physics very similar? Did't we hit the rock bottom in past years? Take a central issue as scattering theory. The S-matrix wasn't the result of a prescription, but the proud crown resulting from underlying spacetime properties (the LSZ-Haag-Ruelle scattering theory). Because of this you did not have to worry about properties which you may have forgotten to impose. But look at what string theory made of this once proud object. If you want to know the counterpart of the Brazilian hiphop, well it is Kakuism, and I am not sure if even a car-dealer would like this kind of hiphop.
Mentos,
I really meant the on-shell S-matrix and not some off-shell extrapolation. It is precisely for that reason that LSZ and HR had to work on top of the (already at that time known) cluster properties of correlation functions.

71. **Juan R.**
May 8, 2006

Bert Schroer,

Of course, that one can be much more specific in criticizing string theory, but in my personal opinion it is a waste of time, because most of stringers are so arrogant that do not even heard or read their colleagues. This is the main reason of failure ot string theory as working theory.

I find amazing the history of the subject, with almost all of past stringers' claims recently proven to be false or considered today to be not so obvious.

From a historical point of view I find history of the variation of the number of dimension or the recent formulation of M(atrix) theory as a theory of pointlike particles two funny points. Maybe the biggest historical error is, in my opinion, the generalized belief between string theorists that a perturbative theory with a spin-two quantum field was a theory of quantum gravity. It was not, therein the need for the unknown M-theory.

Regarding your S-matrix question i never saw a full proof. In fact, would it exists?

The cluster decomposition principle is a hint of QFT (has anyone measured particles infinitely separated?) due to non-existence of full bounded states (only free fields are well-defined).

String theory borns from particle physics, therefore, it copies most of concepts and methods. However, string theory cannot ignore gravitatory effects (as QFT does) and in the large scale, you may include several effects as a cosmological event horizon or the dynamical expansion of universe. Standard string theory (e.g. bosonic version cited above) deals with a classical fixed predefined infinite background. In the generic case there is not factorization and the full string theory scattering perturbative approach breaks down.

Then what? A Hawking $-matrix like approach? I doubt.

The problem with QFT and string theory is that both admit S-matrix as the fundamental observable. Original criticism by Dirac or Landau whereas ignored by mainstream continues holding.

Juan R.

Center for CANONICAL |SCIENCE)

72. **Bert Schroer**
May 8, 2006

Juan R.
Objection your honor, the S-matrix is not a fundamental (but extremely) object of QFT, rather it is the crown/roof of an edifice which is founded on localization and stability principles. The fact that with more recent insights (coming from modular localization theory) the S-matrix also reveals some information about wedge-localization does not really change its role as the honey glaze on top of the cake.
QFT also cannot deliver an intrinsic distinction between bound and elementary particle states; it rather implements full nuclear democracy being only moderated by a hierarchy between fundamental and fused superselected charges (and the cluster factorization property takes this nuclear democracy fully into account). A particular model may invite you to think of some particle state as being a bound version involving other ones, there is nothing wrong with this. But in many cases you find another description which shows that what you considered as elementary permits also a composite interpretation and there is nothing wrong with this either; this is just the consequence of the ubiquitious vacuum polarization. Only in QM such a distiction has an intrinsic meaning. Many of the things which appear intrinsic are not, e.g. the gauge theoretical setting to characterize a theory.
The S-matrix setting is valid precisely as long as the Wigner particle picture is relevant and of course in CST it is not applicable. For this reason Fredenhagen and Haag have based their derivation of Hawking radiation for a collapsing star on registration rates of radiation-counters (they define what this means) and not on Wigner particles (see also Walds comments in his reviews of this issue).

73. **Bert Schroer**
May 8, 2006

Sorry in the previous post it should read: extremely useful, and in one of my earlier posts the incomplete phrase
"but since I think that they did not impede the understanding of the content"
should be completed by: I did not bother to correct them.

74. **Juan R.**
May 10, 2006

Bert Schroer,

I know experimental success of field theory and also some of attempts to provide a more solid foundation to the whole issue.

I was saying is that QFT (and standard string theory) assumes that S-matrix is a fundamental observable. This cannot be true and reason for improvement from several schools and authors.

The theorems on localization, stability et cetera are not convincing when one checks mathematical details. This is reason that people as Dirac, Landau, Wheeler, or Feynman (I am citing only great past guys) knew of those limitations and took QFT as a first step in the formulation of a complete and consistent relativistic quantum theory.

They failed in their respective attempts but at least recognized the problem. Usual QFT textbooks simply ignore the difficulties with QFT, with others -such as recent Weinberg manual- going beyond and attempting to present us the discipline in an "axiomatic way" as if QFT were a well-founded subject!

Most of supposed rigor of QFT breaks down when one studies details of the formalism. For example, it is not difficult prove that a quantum field does not fit inside a pure Hilbert space structure and one may go beyond usual framework, for example via a Rigged structure [Phys. Rev. A 1996, 53(6), 4075]. This is especially true when one try to obtain rigorous descriptions of instable particles, or of non-equilibrium thermal states between others. Another example is thermal phenomena. The irrelevant attempts to study thermal phenomena using QFT showed the lack of a rigorous and full foundation for standard thermal QFT and finalized in a new approach TFD from the particle physics community and alternative (more solid still) approaches from the statistical mechanics community (there are some attempts to improve TFD from ideas developed in the latter). Maybe I would remember here that already the original TFD is based in at least 5 new postulates modifying the most basic of QFT: Hilbert space, state vectors, Hamiltonian, operators, etc.

Another difficulty with the S-matrix approach is that derivation of master formulae is not mathematical or physically founded. I wrote a paper just on this topic has been submitted and accepted. The fundamental idea is that if Hamiltonian unitarity is true, then there is not possibility for a rigorous one-to-one mapping to experimental data (master formula) and if you map to experimental data then unitarity is not true. For illustration, I checked "derivation" of S-matrix in Weinberg manual (1st volume) and showed it contains at least three mathematical errors and two external assumptions (of course Weinberg received a draft copy of manuscript ;-). Van Kampen called "mathematical funambulism" to derivations of that kind! That is true.

When remarking QFT is a free field theory I (as others) did mean that exists not full satisfactory relativistic theory for bounded states. That is the reason that only asymptotic states can be rigorously studied with no possibility for studying intermediate states [Phys. Rev. A 1996, 53(6), 4075].

You can -at least formally- write a Schrodinger-like equations for a single electron but you cannot write a full equation for a two electron system and people use partial mixed approaches such as a double Dirac equation with non-field 16 component spinors and interaction potentials derived from QED but complemented with ad hoc procedures before implementation in bound states (continuum dissolution problem, and rest of trouble)…

It is true that QFT lets us to study some properties of bound states via formal scattering processes |12> —> |1>|2> but that is very different from deriving properties for the real bound state |12>. Dirac was very clear in the incompatibility of QFT with QM in his last works.

The vacuum polarization is just a mathematical artifact arising in QFT when one does *certain assumptions*. Already Feynman explained in his book on statistical mechanics why the usual methodology in QFT and atomic/nuclear QM was not rigorous and one would see what happens when one reintroduces the effects of taking the response of the rest of universe in the model. The picture is then very different (see his famous article with Wheeler on the so-called Universe response theory).

One of the interesting point you are missing is that one can obtain same kind of effects usually ascribed to a "vacuum polarization" in field theory without vacuum. Advantages of this new approach are a more solid foundation and that one can also compute another things cannot be computed from a field-theoretic approach [Rev. Mod. Phys. 1995, 67(1), 113].

And all those without including well-known inconsistencies of CED are not solved by QED. In fact, modern textbooks carefully avoid the topic.

Wald and others' thoughts regarding particles in curved spacetimes are not concluding (and some thoughts are simply wrong). See above reference for remarks on a theory of particles in curved spacetimes and how it has been applied to description of cosmological models without initial singularities.

There is more interesting stuff to be discussed here, but sincerely I have no time.

Categories: Uncategorized

I've been much too busy the past few days, so haven't had time to write anything new here. One thing that has been keeping me busy is going over the copy-edited version of the American edition of my book, which will be published in September by Basic Books. The British edition, published by Jonathan Cape, should be available June 1, both in Britain and Canada, and presumably one can order it from the British or Canadian versions of Amazon. The American version will have a somewhat different preface, and has been separately copy-edited, so there will be minor changes (beyond just changing British spellings back to the American ones I first wrote down…). Late last week I was sent an early copy of the British version of the book itself, and I'm very happy with how it looks.

Last week I also spent a significant amount of time at my colleague John Morgan's 60th birthday conference, which was held here in the math department. Morgan is one of the leading figures in topology, and over the years has worked on a wide range of different kinds of mathematics, often bringing the subject together with other very different parts of mathematics. At the moment he's involved in at least two projects, one involving Calabi-Yaus with Chuck Doran, another an ambitious attempt with Gang Tian to work out the details of Perelman's proof of the Poincare conjecture. He's also doing a stellar job as chair of our department.

Morgan has collaborated with and interacted significantly with Witten over the years, and Witten gave a wonderful talk at the conference on Gauge Theory and the Geometric Langlands Program. This was really just a taste aimed at mathematicians of his recent work on geometric Langlands and gauge theory. He explained some of the history of Montonen-Olive duality, some of the relevance of supersymmetry to mathematics, and then explained what an 't Hooft operator in gauge theory is, and that it is related to the Hecke operators studied in geometric Langlands.

Here are some quick links to interesting things I've run across recently:

John Baez has a new edition of his proto-blog "This Week's Finds in Mathematical Physics". It contains a beautiful exposition of the circle of very different sorts of mathematics that all gets related via Dynkin diagrams.

Greg Moore and his recently graduated student Dmitriy Belov had a beautiful new paper on self-dual field theory in 4l+2 dimensions.

Christianity Today has an article entitled Science in Wonderland, which mentions Susskind and string theory and notes:

This theory has not met with, shall we say, universal approbation, not least because it can't be empirically tested. You could even say it's not science, and some have said that, but they don't hiss the way they do when they talk about Intelligent Design.

The AMS has a new web-site devoted to Mathematical Imagery.

In the comment section here, Bert Schroer pointed to some web-sites I wasn't aware of that contain all sorts of links to various material related to the algebraic approach to QFT. These include the home page of Stephen Summers and the Local Quantum Physics Crossroads" hosted at Gottingen.

Update: If you want to know why the mathematics associated with Dynkin diagrams can't be usefully explained or viscerally understood without string theory, as well as why John Baez is a proto-human, you can consult the blog of a prominent Harvard faculty member. He also notes that

Peter Woit is another proto-human who eats everyone who dares to look in between the clouds. Be afraid. Be very afraid.

and explains in great detail why

it is important not only to learn string theory well but also to emphasize that and explain why people like Peter Woit are intellectual barbarian cannibals. 😉

1. **Deane**
   May 7, 2006

   Peter,

   Did you notice this:

   http://www.intlpress.com/AJM/p/2006/10_2/AJM-10-2-165-498-Abstract.pdf

   Zhu spent last year at Harvard working through all of this in a weekly seminar run by Yau.

   Regards,
   Deane

2. **knotted string**
   May 7, 2006

   June 1 is a Thursday, the traditional book publishing day in England. Is Jonathan Cape making a real marketing effort for NOT EVEN WRONG?

   Can you give anti-stringy interviews on TV when the book comes out? Or is it just going to be a case it going quietly on to bookshelves, largely unnoticed. I suppose you should have an agent for a book for publicity bearing in mind it isn't a textbook.

   The girls who do the marketing just post off a few complimentary copies of the book to magazines, who rarely review them.

   Really you should be granted some interest from the media on this. What you're doing is defending the right to argue that the mainstream is headed down a blind alley. Any string theorist who takes offense or makes a show of 'getting angry' needs to grow up.

   Is there going to be any publishing party in London or New York? Invite your fellow Princeton student Brooke Shields along, that will help attract the media. Seriously, I hope you are not going to be a loser with this book. (You face the risk of getting a bad reputation if it doesn't sell, which may stop you publishing any other book.)

   The basic facts are free on here on the internet. Hence the book isn't something to be guilty about, it's democracy in action – in the bookstore. The expert case against extra dimensional speculation must be studied carefully by string fanatics, it can't be ignored.

3. **Thomas Love**
May 7, 2006

I don't know about the accuracy of that Christianity Today report.
I hiss about String Theory in the same Tones I use for "Intelligent Design".

4. **MathPhys**
May 7, 2006

Every time I glance at Greg Moore's most recent paper, I seem to think that he works in 41 space and 2 time dimensions.

5. **woit**
May 7, 2006

Deane,

Thanks for pointing that out, I had heard rumors about it. Do you know if it has been refereed, and if it is now publicly available.

6. **Richard**
May 7, 2006

What is the current status of Perelman's proof of the Poincaré conjecture? Is he essentially, at this point, leaving it to others to complete his work?

7. **woit**
May 7, 2006

Richard,

As far as I know, Perelman has moved on to other things and seems to have no intention of writing down the details of a proof. The Cao-Zhu work Deane mentions and the Morgan-Tian work underway are two projects I'm aware of to write out a detailed proof.

At this point, I think most people believe that Perelman's outline of a proof can be turned into a real proof, since no serious problems in doing this are known to have turned up. Once one or more detailed proofs have appeared in print, and experts have had a chance to examine these carefully, then it should be well-accepted that the Poincare conjecture has been proved.

And then the Clay Foundation can start trying to figure out who if anyone get the million bucks. Supposedly Perelman doesn't really want it….

8. **Richard**
May 7, 2006

Peter,

I suspected that he may have gotten bored and moved on to other things. Still … how can he leave his baby to others to raise? How could we have produced someone with this brilliance who apparently does not apparently understand the craft (and satisfaction) of bringing theory to complete and completely rigorous presentation and fruition? None of us will always do the latter with brilliance, but to not even try is [fill in the blanks].

9. **Deane**
May 7, 2006

Peter,

As far as I know, the full Cao-Zhu paper will only be available when it is published. I have not seen any preprint. I don't know anything about how it was refereed. I was up at Harvard last week and did talk to Yau about it. Yau now also believes that the Hamilton-Perelman program does yield a complete proof of Thurston's conjecture. Yau says that not only does the Cao-Zhu paper fill in all the details of the program, it also fixes errors that he says are in Perelman's work.

May 8, 2006

http://www.amazon.co.uk/exec/obidos/ASIN/0224076051/

11. **SomeBody**
May 8, 2006

Richard, it is not unreasonable for somebody truly brilliant to consider it more interesting to look for big new ideas, point out overall directions and then leave it to the so-called rank and file to work out the details while they move on. It's just efficient distribution of labor. Perhaps if there were more such people and a little fewer navel gazing nitpickers in physics we wouldn't be stuck you-know-where…

12. **anon**
May 8, 2006

What Oh! No Lubos review yet at amazon uk of Not Even Wrong? C'est pas possible. I think Lubos must be getting old. His response times are slowing down.

13. **sunderpeeche**
May 8, 2006

If the book is not yet on public sale (~June 1) and you do not have an advance copy, how do you review the book? Chris Oakley evidently received an advance copy, and reviewed it, and his review is available for all to read.

FWIW, in French the "ne" is mandatory to indicate negation. "Ce n'est pas possible", "Ce n'est rien", "Je n'ai jamais visite' Paris" …..

14. **Chris Oakley**

May 8, 2006

Well actually, Sunderpeeche, my review was based on a January 2005 copy of the manuscript that Peter gave me when I visited him at Columbia (my visit being funded by the Illuminati and the Freemasons as part of their campaign to destroy Superstring theory). He may have completely re-written the book since, but if so, he never told me.

15. **Chris Oakley**
May 8, 2006

    I should add that when I last saw the Grand Imperial Wizard of the Illuminati and Senior Master JCB Driver of the Freemasons, they were well pleased with Lubos. They noted that the number of hits on Peter's weblog always goes through the roof when he posts comments here, and that most people would not even be aware of the issue but for his invective.
    Personally, I kind of like him. Having had a lot of experience of mealy-mouthed academics with zero moral courage I find it quite refreshing to discover someone so apparently unconstrained by the normal rules of the game. I am sure that they will eventually take steps to shut him up, but I think that in the meantime, we should all just enjoy it.

16. **Deane**
May 8, 2006

    …"FWIW, in French the "ne" is mandatory to indicate negation. "Ce n'est pas possible", "Ce n'est rien", "Je n'ai jamais visite' Paris" ….."

    In proper written French, yes. However, in French spoken by the natives, it is practically impossible to hear the "n'". Some of us suspect it's not even pronounced by the natives and therefore used to detect foreigners in their midst. The extreme example is "Je ne said pas", which the natives pronounce as "chez pas" (at least to my non-French ears). So "C'est pas possible" may look incorrect, but it sounds correct.

17. **Who**
May 8, 2006

    anon: C'est pas possible.

    I believe this is ordinary vernacular. anon sounds like he knows idiomatic French.
    sunderpeeche correction "FWIW, in French the "ne" is mandatory to indicate negation. "Ce n'est pas possible", "Ce n'est rien", "Je n'ai jamais visite' Paris" ….." is textbook correct. but I think in French streets or movies they don't always talk like that.

    Chris, it takes courage to be a mealy-mouthed academic. And screw the Grand Imperial Wizard of the Illuminati.

18. **sunderpeeche**
May 8, 2006

    If we're going to get into the business of idiomatic French, I suggest you drop the French altogether and go stand in the middle of Times Square NYC and listen to the Queen's English and submit it in your next essay in English Lit class. See what happens.

19. **me**
May 8, 2006

    > If the book is not yet on public sale and you do not have an advance copy, how do you review the book?

    In the past Lubos had no problem reviewing books he did not read.

20. **sunderpeeche**
May 8, 2006

    Let's not be stupid about this. Amazon will exercise some quality control to maintain the integrity of the reviews on its web page. If a review is written (without reading the book) and posted on a blog, then that's something else. But Amazon needs to turn a profit, hence it needs to be credible, hence it cannot (overall, anyway) allow nonsense.

21. **John A**
May 8, 2006

    I think you should know Peter, that I don't agree with Lubos describing you and John Baez as "proto-human". I think its beneath contempt to use such language between two very intelligent people, and I've said so on his blog. Lubos goes on to talk about the "explanatory power of string theory" to explain the linkages between concepts in physics but nowhere does he establish uniqueness of string theory as the only way those linkages can be made.

    To describe string theory as a "proto-science" is nothing more than a statement about where string theory is in relation to experimental physics. It might predict an unambiguous experimental result one day and then you'll have to change the name of your blog.

    I'd have to say that I wait for that day before I commit mental energy to the string hypothesis. Experimental falsifiability is a key concept for me. Mathematical consistency is not enough.

22. **JC**
May 8, 2006

    I wonder what would happen if Harvard decides to award Lubos with a tenured professor job. 😉

23. **Lord**
May 8, 2006

    String theory may not be science, but it would still be math, which is a lot more than one can say for ID.

24. **Ryan**
May 8, 2006

    sunderpeeche… Apparently you have never seen [David Hasselhoff – The Very Best Of](#).

25. **woit**
May 8, 2006

Sunderpeeche,

I haven't looked at many Amazon reviews, but there are some pretty weird things there. They do seem to have a policy of mostly deleting one-star reviews. Lubos is well aware of this (he's been involved in a campaign to get one-start reviews of a crackpot physics book allowed), so when he wants to attack something he gives it two stars. Check out his review of Lawrence Krauss's recent book that was critical of string theory. I believe it was the first one posted.

String theory doesn't make any predictions, but I can make one: Lubos will be among the first reviewers of my book on Amazon, and I'll get two stars.

John A. and Lord,

No, string theory on the whole is not math and it's not mathematically consistent. Some work on string theory has led to important new ideas about mathematics, but those parts of string theory that try and connect up to the real world generally haven't, and much of them is not even mathematically consistent. The "Landscape" is even less mathematics than it is physics.

26. **Chris W.**
May 8, 2006

Learned and leisurely hospitality is the only antidote to the stance of deadly cleverness that is acquired in the professional pursuit of objectively secured knowledge. I remain certain that the quest for truth cannot thrive outside the nourishment of mutual trust flowering into a commitment to friendship.

— [Ivan Illich]

27. **anon**
May 8, 2006

Lubos seems to have edited the mean personal comments a bit:

"A mathematician who thinks about the ADE classification without string theory is like a proto-human who knows something about the summer and the winter but who can't understand why the seasons change because he does not want to look in the skies and see the motion of the Sun. In this metaphor, an anti-string-theory blogger is another proto-human who eats everyone who dares to look in between the clouds. Be afraid. Be very afraid. :-)" [http://motls.blogspot.com/2006/05/ade-classification-mckay.html]

So "Peter Woit" has been edited to "an anti-string-theory blogger". 😉

28. **woit**
May 8, 2006

Glad to see that Lubos doesn't believe in personal attacks. I wonder what "anti-string-theory blogger" he has in mind?

29. **Michael**
May 8, 2006

"I've been much too busy the past few days"

Publishing too much these days, I guess!? 😆

30. **woit**
May 8, 2006

Question of the day: Are all string theory partisans moronic assholes, or it's just the ones who post things on the internet?

At least one of them, Michael the anonymous coward from suburban Boston never seems to tire of this.

31. **Michael**
May 8, 2006

Better an asshole than a proto-human… 😆

I live near Needham, Massachusetts, know lots more about string theory than stupid people like you, and Lubos Motl is my hero. I think he's almost as cool as Spiderman.

32. **Michael**
May 8, 2006

"I live near Needham, Massachusetts"
not quite, but my ISP does. 😉

"know lots more about string theory than stupid people like you"
That's for sure.

"and Lubos Motl is my hero. I think he's almost as cool as Spiderman."
Spiderman is *way* cooler!

33. **Arun**
May 8, 2006

If string theory had even one connection to physical reality, it wouldn't be necessary for Motl to tear down Woit at every opportunity.

34. **sunderpeeche**
May 8, 2006

I notice that many of these posts degenerate into idiotic polemics to/from/about Lubos, whether written in idiomatically correct French or otherwise. It's just foolish. (I looked up Motl's website about twice, decided it was rubbish, and haven't been back. Proto-human? I wouldn't even have known if the matter had not been repeated on this blog.)

Amazon/David Hasselhoff? No, I hadn't seen it before. Amazon has to cater to many tastes, and I expect those who like DH will like those reviews. Lawrence Krauss book? I saw reviews by Tom Appelquist and PW, in addition to LM. It's impossible to tell if LM (or anyone else) actually read the book. I do not doubt (and I do not care) if LM publishes a bad review of NEW. But to try and publish a review BEFORE the book goes on sale, and without an advance copy, that would raise a red flag.

I guess nobody has anything to say about John Morgan. As for myself, I've never heard of him. John Baez/TWF has some nice stuff, and the AMS Mathematical Imagery is also worth further attention. Such is the life I choose to lead. You'll forgive me (or not, as the case may be) if I have no interest in nonsense.

35. **David**
May 8, 2006

Peter,
Please don't let the level of discourse on this blog drop. The distinguished faculty member suggested that I can't tell an electron from a dog when I tried to suggest that some biology articles are worth reading even if they might not support your favorite newspaper report about global warming or your view on how climate science should be done. Thus, I will spend less time over there. Your blog offers interesting and useful discussions of topics I'm interested in. Keep up the good work.
From a proto-proto-human,
David

36. **Thomas Love**
May 9, 2006

It occured to me as I read the above comments that Motl posts a lot. That would indicate that he has nothing better to do, which is proof that there is no substance to string theory. If there were substance to sting theory, he would be working on it rather than posting absurd comments. Back to work.

37. **secret milkshake**
May 9, 2006

Lubos likes to spread visceral understandig by disembowling his oponents.

38. **You**
May 9, 2006

I bet the last five comments were from the same person.

39. **woit**
May 9, 2006

You,

How much do you want to bet? If it's enough to make it worthwhile, I'll put you in touch with all five of them so you can write them a check. One of them is using his full, real name and I've corresponded with him via e-mail. The others have valid, different e-mail addresses, and are accessing the blog from very different locations.

That's the story of the last few Lubos critics. Lubos supporters like "You" seem to prefer anonymity like "Michael", who didn't leave an e-mail address, but splits his time between his home in suburban Boston, the HEP group at Brandeis, and the HEP group at UMass Amherst. Probably anyone who cared could figure out who he is.

40. **Who**
May 12, 2006

we didn't yet get any comment on the paper that Peter pointed to by Freidel Minic Leigh about 4D Yang Mills
http://arxiv.org/abs/hep-th/0604184
Towards a solution of pure Yang-Mills theory in 3+1 dimensions
someone mentioned possible relevance to the megadollar Clay Prize
so far on this thread we are getting mostly technical discussion of assholes by Michael and others whether they are better or worse than proto-protos etc. and about the Harvard Ranter and so on. this is OK but it might also be interesting if someone explained the interest of Freidel Minic Leigh if any.

Simons Donation to Stony Brook

May 9, 2006
Categories: Uncategorized

Stony Brook [announced yesterday] that Jim Simons will be making a $25 million dollar donation to the university, focused in the area of mathematics and physics. This is a great deal of money for a math or physics department, and it is the largest single cash donation ever made to any of the SUNY institutions.

Simons was responsible for building up the Stony Brook math department, which he joined as chair in 1968. About his hopes for what his donation will do, he says:

During the past thirty years mathematics and physics have grown increasingly intertwined. This is particularly true in the cases of string theory, quantum field theory and cosmology, which have all depended upon and stimulated advanced work in geometry and topology. Buttressed by its close relationship with Brookhaven National Laboratory and building on a fine faculty already in place we believe our gift can help propel Stony Brook into the very top rank in these central fields.

Comments

1. **sunderpeeche**
   May 9, 2006

   I read this in the newspaper yesterday. Good for Simons. I have no millions to donate. If he has a vision that it will help propel SUNY-SB to the top in string theory, QFT and cosmology (and links between physics + mathematics), and that doesn't suit the tastes of anyone else at this blog, no matter.

   Fiat Lux.

2. **Who**
   May 9, 2006

   partisan gloating aside, that kind of private support for mathematics and physics is thrilling.
   I saw Simons out here at the dedication of the Chern auditorium and MSRI expansion, some of which he funded. His brief remarks ahead of the featured talk by Penrose were modest and genuinely funny.
   Never saw a smarter or more gracious donor.

3. **was just wondering**
   May 9, 2006

   is this the Simons from Chern + Simons

   http://en.wikipedia.org/wiki/James_Harris_Simons

4. **woit**
   May 9, 2006

   Yes. I should have added an explanatory link to some of the other postings here about Simons, such as

   http://www.math.columbia.edu/~woit/wordpress/?p=299

   And I should also point out that I think it is quite reasonable for Simons to list string theory as a topic that has brought together mathematics and physics. It certainly has done that, to good effect.

   By the way, I was a postdoc at the Institute for Theoretical Physics at Stony Brook for three years (back when Yang was the director, and it wasn't yet named after him). I enjoyed interacting with the people there and with many of the people in the math department. My best wishes to them all in figuring out what to do with the new resources that Simons is providing.

5. **Bert Schroer**
   May 9, 2006

   Peter,
   I think you mean "physicists" and not physics, unless Lubos has convinced you that string theory is physics.

6. **woit**
   May 9, 2006

   Bert,

   I did really have in mind that string theory has brought together mathematicians and physicists, but I don't think the way that I expressed this is really inaccurate. "String theory", "mathematics" and "physics" are all not very well-defined terms…

7. **sunderpeeche**
   May 9, 2006

   Once again the silliness about Lubos … why not stick to the good that Simons is doing with his money? We shall see if things spiral downhill from here…..

8. **Bert Schroer**
   May 9, 2006

   To Peter,
   objection you honor, these days physics and what physicists are doing is not the same.

9. **sunderpeeche**
   May 9, 2006

Ach du lieber.

Pardon the non-idiomatic non-French.

10. **Bert Schroer**
May 9, 2006

The expression “that what physicists are doing” instead of physics is not my invention. It was used by Hirzebruch when he was talking about the Atiyah-Witten ideas and I some of my colleagues found this impressingly careful and farsighted. In fact it has entered my way of looking at things so profoundly that I will always remember it.

11. **Simon**
May 9, 2006

I love the fact that Simons used his considerable math skills to make lots of money to put back into math and phys.
My only worry is that this might encourage governments to rely even more on private funding for fundamental research

12. **sunderpeeche**
May 9, 2006

Govt funding for research is mainly a post-WW2 thing. Millikan for example had to get private funding for Caltech. The various large telescopes (Yerkes, Hale etc) were all privately funded. The Manhattan Project changed all that. Physicists (nuclear phycists anyway) were perceived as good for making bombs (also ICBMs). The sociology may not be as simple as that, but anyway, govt funding for science is not some long-standing tradition. Funding for fundamental research has traditionally been difficult.

13. **was just wondering**
May 10, 2006

maybe it’s time that we define what ‘physics’ means.

Dibner Institute Closes

May 9, 2006
Categories: Uncategorized

The Dibner Institute and Burndy Library at MIT will soon be closing, with the Burndy collection moving to the Huntington Library in California near Caltech. The Dibner Institute is devoted to research in the history of science and technology, and I mentioned it a couple years ago here. Among the interesting things the Dibner has on-line are copies of lecture notes on quantum electrodynamics from Freeman Dyson in 1951 and Fritz Rohrlich in 1953.

Comments

1. **D R Lunsford**
   May 9, 2006

   The notes by Rohrlich are priceless! What a find!

   -drl

2. **Bert Schroer**
   May 9, 2006

   Is Fritz Rohrlich still alive? Did he invite Jauch, who probably was in Geneva during the war, to come over and collaborate with him? Why did both change the area of interests years after having written that influential textbook? My main association with the two names is related to the book.

3. **Brett**
   May 9, 2006

   I'm sorry to see the Dibner Institute disappear. They brought in interesting people to talk about the history of science, and I enjoyed occasionally attending the lectures. However, I am not too surprised that this has happened. Although I naturally never knew anything about the Institute's finances, I always had the impression that they were probably overspending themselves, on publicity and other things.

4. **D R Lunsford**
   May 9, 2006

   Yes, he's alive, at least as of November when he told me to (paraphrasing) "get some experimental backup or it's just speculation!" 🙂

   He's one of a vanishing breed, no doubt.. "Classical Charged Particles" was – is still – a great read. So was "Theory of Photons and Electrons", one of the best QED books ever..

   -drl

5. **Alejandro Rivero**
   May 10, 2006

   Is the website going down?

6. **woit**
   May 10, 2006

   No idea, you'd have to contact them to find out what their plans are.

7. **Alejandro Rivero**
   May 10, 2006

   Hmm I tried but the email address for ashrafi@mit.edu fails, so the website is already obsolete…

   The interviews in the website are also of some value, and interesting to read. Visitors can enjoy a remark from KG Wilson:

   The U.S. had a period in the 1960s when it was a buyer's market for positions in academe, and so a lot of people had this kind of opportunity. But at the same time, you look at how people struggled at the time of Kepler, at the kind of struggles he went through in order to be able to continue for twenty years, and it's clear there are many more people who, if they're willing to engage in the kind of struggle that Kepler did, can do it and not starve. A lot of people complain today that the conditions are tight, you have to toe the line and everything, but the people who are like Kepler are going just as stubborn today as Kepler was, as far as I can see.

Discovering the Quantum Universe

May 9, 2006
Categories: Uncategorized

HEPAP today released a new publication designed to convey to the general public excitement about prospects for particle physics in the coming years. It's entitled Discovering the Quantum Universe, and it has a companion web-site. Both the web-site and the document itself are beautiful and impressive productions. The web-site also contains the earlier 2004 HEPAP report Quantum Universe, which was mentioned in one of the earliest posts of this blog. The newer document is based on an earlier version from last summer, and one of its main goals is to make the case for a linear collider. In some sense this is promotional material for the conclusions recently reached by the EPP2010 panel. Also part of the promotional activity today is a briefing for members of Congress that will include a talk by my colleague Brian Greene.

While I hope that this all has the intended effect of getting the public, the Congress and the Administration excited about particle physics and willing to support it at the level necessary to fund a new generation of machines and experiments, as you might guess I have my doubts about the wisdom of some of the material included in this report. Unlike the EPP2010 report, which oversold string theory a bit, this report oversells it a lot, with language like:

…preliminary studies have looked at the ability of linear collider experiments to detect the telltale harmonies of strings. Here linear collider precision is essential, since the string effects appear as small differences in the extrapolated values of the superpartner parameters. A combined analysis of simulated LHC and ILC data shows it may be possible to match the fundamental parameters of the underlying string vibrations.

The inclusion of this kind of language seems to me to be misleading and irresponsible. Ten years from now when we have real LHC data, know that the ILC can't tell us anything about string theory, and are asking the US government to put up large sums to finish the ILC, we'll have to hope that the relevant decision makers didn't get convinced by this report that the ILC is a machine designed to get information about string theory.

Update: More about this at Cocktail Party Physics.

Comments

1. **Chris Oakley**
   May 9, 2006

   I agree. How about re-wording it like this:

   …preliminary studies have looked at the ability of linear collider experiments to detect particle interactions that probably have nothing to do with the telltale harmonies of strings. Here linear collider precision is essential, in spite of the fact that string effects somebody probably once guessed may appear as small differences in the extrapolated values of the superpartner parameters, have nothing to do with it. A combined analysis of simulated LHC and ILC data shows it may be possible to advance understanding of the underlying physics even though there are probably no underlying string vibrations with which we may match the fundamental parameters.

2. **sunderpeeche**
   May 9, 2006

   Most successful particle accelerators + detectors achieved their fame for reasons having nothing to do with their originally intended mission. The AGS at BNL produced 3 NP-winning expts, none of which were foreseen — J/psi, CP violation, 2 neutrino species.
   Sam Ting's expt was proposed to discover vector mesons to test Vector Meson Dominance, not to discover the charmed quark. While the Bevatron was built to produce the antiproton (which it did, leading to NP), it really became famous for the resonances ("Bump hunting") discovered with the Alvarez bubble chamber. Gargamelle discovered weak neutral currents, which were not even mentioned in the proposal (if I recall correctly from The Second Creation.) The proton decay underground water tanks have turned out to be better suited for neutrino astronomy.

   For that matter Columbus proposed to sail to China, discovered America (Erik the Viking might disagree), claimed to have landed in India, and after all that people still call him a hero.

   PEP, PETRA, TRISTAN were all built to find the top quark (which IS part of the SM), and all failed. This did admittedly lead to subsequent funding difficulties. If indeed LHC/ILC produce new physics beyond SM, the string theory stuff will be forgotten/ignored. The real hope is that the new machines will find *something* never mind why they were proposed.

3. **Bert Schroer**
   May 9, 2006

   But I guess Peter is afraid that too much hype may create a backlash. In all those cited cases they were looking with much less hype for something and they found something else which was at least as interesting. Now they have to find something which has to go beyond all this messianic hype, a pretty difficult task.

4. **sunderpeeche**
   May 9, 2006

   The real backlash problem is that so many machines have been built and have found no new physics beyond SM. If yet another generation of machines fails to produce physics beyond SM, then it will get even harder to justify further machines. At a minimum the next generation machines really MUST find the Higgs. Although the Higgs is part of SM, it will still be a major finding and will serve as a boost to obtain funding for future machines. If LHC/ILC do not find the Higgs, it will get really hard to get more money. (Unfortunately nobody can guarantee where/how the Higgs will appear, just as with the top quark.) String theory or any other theoretical motivation ("hype") is not the critical issue.

5. **woit**
   May 9, 2006

   One different aspect of this situation is that the ILC will not really be exploring a completely new energy range, since the LHC actually will have higher energy. By the time the ILC construction decision is ready to be made, I suspect the LHC data will have given strong indications that there is no supersymmetry/higher dimensions/string theory at energies accessible to the ILC. That's why using these ideas to sell the ILC now may be a mistake.

   Hopefully the LHC will find some new and unexpected physics that explains electroweak symmetry breaking and the ILC will have enough energy to study it. If so, there will be a very good case to be made to build the ILC, but much of this report will have to be explained away.

6. **sunderpeeche**

May 9, 2006

Historically, e+e- colliders have not had the energy to go beyond the mass reach of hadron machines. As powerful as LEP was, the W and Z were first produced in hadron machines. LEP was designed for precision studies of particles of known mass. Even SPEAR, when it produced the psi, the J had been produced at the AGS. If, as one hopes, the LHC produces the Higgs, the ILC will promptly become a Higgs factory. Its design parameters will be adjusted (if necessary) to optimize Higgs production. It will simply be unnecessary to explain away the string theory or any other prior motivation/hype. It is in the nature of scientific discovery that this is so.

7. **woit**
May 9, 2006

Sunderpeeche,

I hope you're right about not needing to explain away the hype. But I personally wouldn't want to be the physicist testifying before Congress in 2012 trying to answer questions from congressmen about why the US should spend billions on something that's not even going to help discover those strings and extra dimensions.

8. **sunderpeeche**
May 9, 2006

If the LHC produces the Higgs, the physicists will testify "the Higgs has been found, the ILC will be a unique precision tool to study it, anything else will be a bonus". It was not so different for LEP, the W and Z had been found, anything else would be a bonus (except that LEP was proposed AFTER the W and Z were found). Unfortunately the design and construction timescales are now so long that ILC planning must start now, before LHC data is in. If LHC finds nothing, ILC will have to be sold as a pure search and discovery machine. This is difficult, and not the fault of ST. PEP, PETRA and TRISTAN were all built to find a particle which really does exist, but the SM gave no clue as to its mass. Physics can be and is unkind.

Really, the difficulty is that in the good old days (those wonderful times before the internet, cell phones and blogs … one hankers for the simple life) each new generation of machines produced new physics discoveries beyond the theories of the day. That has not happened for ~30 years. One simply does not know the mass scale of the new physics. And that is not the fault of ST. No theory — including QED — has given the mass scale of the next generation of particles. The expts must find something, then one can say "these particles are part of a family, search for the next one (like the Omega-)".

9. **Tony Smith**
May 9, 2006

On page 13 of the pdf, "Discovering the Quantum Universe" says:
"… According to our present understanding, the Higgs particle itself should have a mass a trillion times beyond the Terascale. …".
I thought that the Standard Model would be happy with a Higgs in the 110 to 200 GeV range, and that was such a generally accepted view that Fermilab thought that it might have seen the Higgs at around 115 GeV. To what "present understanding" are they referring ?

On page 18 they list the following potential LHC discoveries:
A Higgs particle
Superpartner particles
Evidence for extra dimensions
Missing energy from a weakly interacting heavy particle
Heavy charged particles that appear to be stable
A Z-prime particle, representing a previously unknown force of nature
Superpartner particles matching the predictions of supergravity

If the Standard Model continues to hold up, as it has so far,
so that there are
no superstring-type superpartners,
no superstring-type extra dimensions,
no WIMP,
no heavy charged stable particle,
no Z-prime, and
no supergravity-type superpartners
then
the LHC might see nothing much beyond a 115-200 GeV Higgs,
plus better luminosity of the sort of signals already seen at Fermilab.

Does the USA high energy physics community have a plan for such a contingency ?

If not, is it such a contingency really so remote that there is no need to plan for it ?

Tony Smith
http://www.valdostamuseum.org/hamsmith/

10. **Aaron Bergman**
May 10, 2006

Does the USA high energy physics community have a plan for such a contingency ?

Yes. We all give up and go home. Not just the USA, pretty much everyone. People have nightmares about the LHC only seeing a Higgs. Maybe you can justify the ILC to probe the electroweak symmetry breaking sector, but if everything fits a single Higgs doublet and nothing else, I'm not sure I see the point.

11. **Tony Smith**
May 10, 2006

Aaron Bergman said that "… if the LHC only see[s] a Higgs … We all give up and go home …".

That sounds sad to me, when such things as the values of the Standard Model parameters are not explained by conventional models (unless you accept anthropic landscape models as being both conventional and explanatory).

If it is a contingency that is sufficiently likely to cause nightmares, wouldn't it be nice to have a contingency plan other than "give up and go home"? Has much effort been put in trying to develop such a plan, or is that contingency being ignored as being incompatible with a united USA lobby for ILC ?

Tony Smith
http://www.valdosamuseum.org/hamsmith/

12. **Aaron Bergman**
May 10, 2006

Has much effort been put in trying to develop such a plan, or is that contingency being ignored as being incompatible with a united USA lobby for ILC ?

You don't seem to understand. At that point, there's pretty much nothing left to do. You can measure the standard model parameters to a ridiculously high precision, I suppose, and hope that you can get the theory down well enough to look for small discrepancies, but that's not particularly sexy. You're just going to have a damned hard time convincing anyone to spend ten or so billion dollars on an accelerator after the previous one bored us all to tears.

Maybe someone will have some clever idea for accelerating subatomic particles cheaply, but until then, I'd guess the contingency plan for a lot of people would be to start contemplating the Black-Scholes equation.

13. **Thomas Larsson**
May 10, 2006

IIRC, you once guaranteed that there must be new physics at the LHC, because of the Landau pole. So if LHC sees nothing new, except perhaps for a standard Higgs, there is something seriously flawed about our understanding of QFT?

14. **Tony Smith**
May 10, 2006

Aaron Bergman said, replying to me about the contingency in which the LHC only sees a 110 to 200 GeV Higgs, plus events similar to those already seen at Fermilab:
"… You don't seem to understand. At that point, there's pretty much nothing left to do. …".

I can see that might be the case for superstring theoretical physics, which would be invalidated by lack of conventional supersymmetry,
but
is it really futile to search for a non-superstring theory that might explain the parameters of the Standard Model etc,
in which case further detailed study of Fermilab/LHC type data might be useful in distinguishing among such types of models, and in examining their consequences ?

Has high energy theoretical physics become such a monoculture of superstrings that the community feels that it is preferable to "give up and go home" rather than work on non-superstring models ?

From another point of view, if LHC sees only non-supersymmetric Higgs plus similar-to-Fermilab events, thus invalidating superstring theory,
would the USA superstring community (with 90% of USA theoretical hep funding and jobs) prefer to
take their ball and go home (giving up that funding and jobs to non-hep things)
rather than
see non-superstring theoretical hep have a chance to succeed where they failed ?

Tony Smith
http://www.valdostamuseum.org/hamsmith/

15. **woit**
May 10, 2006

Thomas,

The argument that you have to have "new physics" at the LHC just is that you have to either see a Higgs or something else new.

16. **Disgusted**
May 10, 2006

It is not only a matter of strings. Selling theoretical speculations in this way, a few years before LHC, seems either useless or suicidal.

More in general, this and other similar presentations look like a show for a big bureaucratical enterprise ("we must discover the Higgs / extra dimensions / …"). In my opinion emphasizing the points made by sunderpeeche (#2) would be not only more honest, but also more attractive.
But I am only a physicist, not an expert of outreach.

17. **Thomas Larsson**
May 10, 2006

Peter, I should have addressed my comment to Aaron, who I think issued this guarantee on some occation. I'm no expert, but I don't think that the Landau pole becomes safe if you only add a Higgs.

18. **anonymous**
May 10, 2006

preliminary studies have looked at the ability of linear collider experiments to detect the telltale harmonies of strings.

!!! A reference here would be interesting. Or at least amusing.

19. **woit**
May 10, 2006

Thomas,

There's a Landau pole problem for non-asymptotically free couplings. It's there for the U(1) gauge coupling, but only occurs at exponentially high energies (not at the TeV scale). All it says is that at short enough distances the effective coupling will get large and perturbation theory will break down.

The Higgs quartic coupling also has this problem, and it is this coupling that determines the mass of the physical Higgs particle. If the Higgs particle is low enough mass, the quartic coupling at the TeV scale is small, and again its blowing up only is a problem of principle at short distances. If you try and push the Higgs mass up in the standard model, you are pushing up this quartic coupling. At some point it gets large and perturbation theory breaks down.

The reason you get a guarantee at the Tev-scale isn't really the Landau pole issue: it's just that either you'll see a Higgs particle (small enough quartic coupling), or whatever is causing the Higgs phenomenon is something inherently non-perturbative and completely new physics.

20. **Aaron Bergman**
May 10, 2006

Has high energy theoretical physics become such a monoculture of superstrings that the community feels that it is preferable to "give up and go home" rather than work on non-superstring models ?

Must you see everything through these silly string wars? This has nothing to do with that. Theorists can go on speculating about whatever they want. It won't matter. If you've been reading what I've been saying, this is about *experiment*.

The reason you have to see something is that otherwise WW scattering (I think) becomes nonunitary. If you believe in unitarity, then something better fix that. A simple doublet Higgs solves that problem, however, and it's perfectly consistent for that to be all there is until the Planck scale.

21. **Eugene Stefanovich**
May 10, 2006

Aaron Bergman said that "… if the LHC only see[s] a Higgs … We all give up and go home …".

I may agree that in these circumstances there will be no compelling reason to build even bigger accelerators. However, I do not agree that theorists should give up. There are quite a few fundamental problems that are not addressed by current theories at all. Some of them were mentioned in Chris Oakley's posts:

1. What about divergences in QFT? Will we ever get them from "under the rug" and honestly examine? Or the current consensus is that divergences are ultimately related to the (currently unknown) Planck-scale physics, and we can do nothing about them?

2. There seems to be no satisfactory resolution of the bound state problem in QFT. We learned how to calculate the S-matrix to high precision. So, we can get the energies of bound states as poles of the S-matrix (e.g., the Lamb shifts). However, there is no well-defined Hamiltonian in QFT, so the radiative corrections to the wave functions of bound states cannot be calculated within QFT.

3. Without well-defined Hamiltonian, I don't see how one can address the time evolution of wave functions in QFT.

The experimental support for problems 2. and 3. above does not require smashing of particles with TeV energies. It would rather need precise time-resolved observations of dynamics of low-energy systems, such as excited states of atoms. This may be not as sexy as building multi-billion dollar monsters, but the insight gained from these low-energy experiments could be just as fundamental.

22. **Shantanu**
May 10, 2006

Talking about searching for the unexpected, have a look at the bets amde at
Richard Arnowitt festschrift almost 10 years ago.
http://faculty.physics.tamu.edu/allen/fest/bets.html
Unfortunately , still none of the above have been discovered. Would people here want to take stabs at the same bet?

23. **Aaron Bergman**
May 10, 2006

QFT is a much better theory than you think, as has been gone over repetitively on spr.

24. **woit**
May 10, 2006

Please, all, spare us the bickering about the status of QFT. This is way off topic.

25. **John F. McGowan**
May 10, 2006

Is this wise? The only major linear collider ever built, the Stanford Linear Collider (SLC) , experienced extensive startup problems lasting for many years. For example, the initial scheduled run in the summer of 1988 yielded not a single Z boson. This was followed by several years of very disappointing performance, numerous technical problems, and considerable acrimony. The accelerator and asociated experiments (Mark II and SLD) were largely eclipsed by LEP. As far as I know, no one has built a similar machine since. Does the knowledge and expertise really exist to build an even more ambitious linear collider?

26. **sunderpeeche**
May 11, 2006

"As far as I know, no one has built a similar machine since." The SLC is the only linear collider ever built. For the pedants, it was not a true linear collider because it used only one linac (for both e+ and e-) and routed them through 2 arcs to a detector (Mk II, later SLD). It experienced all of the teething problems of an untested technology ("path breaking" … you choose the description). Its luminosity was far below expectations. It should have produced Z's before LEP and it did not. I don't know about the acrimony.

The ILC will be a true linear collider (2 linacs). I have no doubt it will also experience teething problems. The proponents admit there are significant R+D issues to solve. I have heard several people say it is unwise to put all the eggs in such a basket.

The SSC got cancelled. A muon collider is also untested technology, even more far future than ILC. Have you any better ideas?

27. **better ideas?**
May 11, 2006

Futuristic techniques could increase the acceleration gradient by up to 3 orders of magnitude. This would allow to shorten a linear collider by 3 orders of magnitude. It would have true practical applications, giving cheap sources of synchrotron radiation.

Unfortunately this kind of activity does not receive the attention and manpower that it deserves, proposing theoretical speculations is more rewarding, and with some propaganda we can maybe get the 5 or 10 Giga$ needed for a ILC.

PS: I am a theorist.

28. **sunderpeeche**
May 11, 2006

People have been trying futuristic ideas for > 20 years (30 years) ~ plasma accelerators etc. Still far future.

Read here for info about SLC. Reasonably honest, not too boring.
http://www-sldnt.slac.stanford.edu/sldbb/SLD%2010-01.pdf

29. **David**
May 11, 2006

I just thought I would add a few comments to this. Before it was called ILC it was known as NLC (Next Linear Collider) and there has been a tremendous amount of work that has been done on trying to realize such a big project. Experimentally there was the NLCTA (Next Linear Collider Test Accelerator) that ran at SLAC as well as much research into higher frequency klystrons. It was basically a normal conducting X-band (11.424 GHz) accelerator. Going to higher frequencies and higher energies is a tremendous effort because of the impediments of reaching higher gradients due to effects like RF breakdown. When I was a grad student there I actually worked on the effect of pulsed heating that occurs on the interior copper surfaces from the eddy currents due to high magnetic fields. The heating happens so quickly the copper has no time to expand which causes stress on the surface. This repeated cyclic stress can be enough to cause microcracking over some period of time. This degrades the Q of the cavity and also causes thermal runaway (not to mention leading to RF breakdown). This all means if you are not careful and actually build an accelerator that can deliver the gradients you want, you might destoy it over not so long of a time. This leads into material science and surface science. So there are just an incredible amount of things to look at to realize something like the ILC. Superconducting accelerators do not have the pulsed heating issue but they do suffer from wakefields due to the high Q's of the cavities. Trying to realize an ILC machine has not been done for the lack of trying, but it will still require great efforts moving forward.

30. **wab**
May 11, 2006

Something better? We could return to the idea of the VLHC (>100 TeV @ 10^34 luminosity). The Fermilab design study of a few years ago shows that we do know how to build such a machine technically. Managerially the jury is out; but the LHC construction trials are valuable and relevant experience.

31. **sunderpeeche**
May 12, 2006

I mentioned in an earlier post that after SLC there was TLC (1 TeV x 1 TeV), this was too demanding, it became TLC (1 TeV c-o-m), eventually NLC (achieve whatever is feasible ~ 250 GeV x 250 GeV), evolved into international project = ILC. Very demanding technically.

VLHC? The technology + knowhow already exists to build SSC, VLHC and other conventional storage rings (a super LEP if desired). But the size and cost is very large. SSC did not survive the politics. (ILC may not either.)

32. **Tony Smith**
May 12, 2006

The 27 April 2006 issue of Nature said some interesting things about the ILC.

1 – The lead editorial (unsigned) (page 1089) had a favorable subhead, saying "There is broad backing for a US bid to build the International Linear Collider".

2 – That same editorial also said "… Germany, Japan, and CERN itself may also bid to host the project … the insistence of CERN … that decisions about the siting of the ILC be delayed until an accelerator technology … is ready, strikes some in the community as unnecessary and self-serving …".

3 – A News article by Geoff Brumfiel (pages 1094-1095) said "… Russia, Japan, and China have all expressed interest in hosting it …".

4 – That same News article also said "… Mike Lubell, head of public affairs for the American Physical Society in Washington DC, cautions that the collider – estimated to cost at least $6 billion – still faces an uphill battle …".

5 – The above-mentioned editorial also said "… political backing for the deal is likely to come from friends of Fermilab … Fermilab … is looking to its supporters, such as House Speaker Dennis Hastert (Republican, Illinois) …".

I see some similarities to the SSC situation.

A – Rivalries about siting (in the ILC case, USA v. CERN, Japan, China, etc…).

B – Rushing to get commitments before technology is demonstrated (maybe this is related to remarks by G. William Foster in his 19 February 2006 resignation letter "… it has been impossible to elicit any honest public discussion of a technically defensible schedule for the ILC from the leadership of HEP. This is not an academic exercise or an empty political game, since unrealistic schedules for the ILC are being used to destroy prospects for any feasible mid-scale near term program in U.S. HEP. … our steamship seems to have a committee of captains who believe that the ductility of carbon steel rivets at freezing temperatures is just a political problem …").

C – The $6 billion dollar figure for ILC (when the DOE estimate is $12 billion) may be an effort, a la SSC, to lock in the project with an unrealistic low-ball cost estimate, which is bound to unravel sooner or later.

D – If the Democrats win the House in 2006, then Illinois Republican Dennis Hastert will not be Speaker of the House. The current Democrat Minority Leader is Nancy Pelosi of California. Recall that the straw that broke the SSC's back was the defeat of Republican Texas-SSC supporter Bush I by Democrat Clinton, who, although he had paid lip service to the SSC, refused to go to the mat to fight for it, and was quite OK to let it die.
If Pelosi succeeds Hastert, and follows the Clinton pattern, she will tell all the ILC lobbyists/physicists how she is strongly in favor of the ILC at Fermilab, but when it comes time to cast the votes, she won't crack the Speaker's disciplinary whip, and will watch the vote kill the ILC, and say something like "Gee, I tried, but times are tough and too many people wanted to use that money for what they see as more pressing things" – (her web page emphasizes Energy, Medicare, Gas Prices, etc).

Tony Smith
http://www.valdostamuseum.org/hamsmith/

33. **sunderpeeche**
May 12, 2006

The ILC is far from a done deal. The technology to build it, the siting (will the US pull out if ILC not in USA?), a timeline and cost estimate — all are unknown. Not to mention a change of administration and/or party control of Congress. It isn't always Democrats who kill Republican-sponsored programs. (BTW do the Reps really support ILC?) The Apollo project was initiated by Kennedy, killed off by Nixon.

34. **Tony Smith**
May 13, 2006

sunderpeeche said “It isn’t always Democrats who kill Republican-sponsored programs.”

sunderpeeche is correct.
It is just accidental/coincidental that Texas’s Bush I who supported SSC and Illinois’s Hastert who supports ILC are both Republicans,
and
that they were (or may be) succeeded in power by Democrats Clinton (no big allegiance to Texas) and Pelosi (no big allegiance to Illinois).

sunderpeeche also asks “BTW do the Reps really support ILC?”.
No, not in general.
It is just an accident of geography that Hastert of Illinois is Republican Speaker of the House, and as Republican Speaker he has a lot of power to whip all House Republicans (now a majority) into line.
If a non-Illinois Republican were Speaker, the Republican Majority would probably not be a coherent block in favor of the ILC.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – If Dirksen had not been an influential Senator years ago, Fermilab might not be in Illinois. Dirksen’s party was much less relevant than his influence used on behalf of his constituents in Illinois.

PPS – As to my personal political party bias, in the last 4 USA elections, I voted Perot, Perot, Libertarian, Libertarian. I don’t have much of any preference between the Republican and Democrat parties.

35. **Tony Smith**
May 13, 2006

sunderpeeche said “… after SLC there was TLC (1 TeV x 1 TeV), this was too demanding, it became TLC (1 TeV c-o-m), eventually NLC (achieve whatever is feasible ~ 250 GeV x 250 GeV), evolved into international project = ILC …”.

An ILC operating up to sqrt(s) = 500 GeV should be able to “… effectively perform top quark measurements in an almost background free environment …” and study the “… The top-Higgs Yukawa coupling …”, as stated in a Fermilab document at http://www.fnal.gov/pub/news05/TTTPosterSession/TTT-ILC.pdf.

Since it is very likely that LHC will see Higgs at 115 – 200 GeV, it is also very likely that ILC could be very useful to study the Higgs – T-quark system.

I am puzzled why the USA HEP community fails to emphasize such a very likely useful symbiotic relation of ILC and LHC,
but instead
emphasizes speculative things like superstring-relatd supersymmetry, which might well be ruled out by LHC before the ILC is completed.

Why take a Russian Roulette chance of getting ILC killed by LHC seeing only Higgs at 115 – 200 GeV (plus stuff similar to that already seen at Fermilab),
when
a case can be made that the ILC and LHC are both needed to fully understand how the T-quark and Higgs work within the Standard Model ?

For example, in “Discovering the Quantum Universe” the only mention I recall of studying quark interaction with Higgs is on page 14 (page 18 of the pdf) with respect to the possibility that LHC might find a Z-prime.

Why not play up T-quark interactions with Higgs ?

Not only is it almost certain to be seen at LHC, and therefore real,
but also
there are interesting possibilities that could be publicized.
For one example, look at the T-quark condensate work of Yamawaki et al (hep-ph/0508065 and hep-ph/0311165 etc). In addition to being interesting, it might be nice for the USA HEP people to put some emphasis on non-USA work such as that at Nagoya.

Tony Smith

36. **sunderpeeche**
May 13, 2006

Indeed it would make sense to emphasize/advertise the Higgs and T-quark sectors. The T has already been found, ~ ” tentative evidence for a Higgs at 114 GeV was found at CERN, a more comprehensive search can be made at ILC, including precision studies of its properties” ….. certainly in this regard the extra dimensions stuff is hype.

37. **Alejandro Rivero**
May 15, 2006

That sounds sad to me, when such things as the values of the Standard Model parameters are not explained by conventional models

This happened already from the instant we accepted the view of QFTs as a chain of effective theories because then we bought also the asumption that any unnatural mass (in the sense of t’Hooft naturality) shall come via renormalization group from the GUT scale, and then we will never be able to predict his mass with experimental certainess because we will not have enough loops to run the renormalization group downwards with high precision. Of course this is not the whole history, because even with effective theories we can exploit some formulae coming from fixed points; but in general it is true one has surrendered to the string-gut-planck scale.

38. **sunderpeeche**
May 15, 2006

Let us not get carried away with silliness, just because of the overabundance of (presumed to be) vacuous theories. What did Max Planck predict when he fitted the blackbody spectrum in 1900? To Planck the energy partition into finite cells was a book-keeping device which he could not avoid. It was Einstein who took the existence of light quanta as particles seriously, in 1905. When Dirac first published his equation, his paper had no predictions of new phenomena. It gave a “natural” explanation of spin 1/2 (and a value g=2), but it was already known (but not explained) that an electron has s=1/2 and g=2. Dirac had no immediate explanation for the negative energy states. The realization that the union of relativity and QM requires the existence of antimatter came later (as did the realization that the Dirac eq must be formulated as a second-quantized field operator equation).

Pauli did indeed hew to the principles 1 and 2 above, and dismissed just about any new idea as rubbish. He initially opposed the notion that an electron could have an intrinsic angular momentum, he later rejected Yang-Mills theories (because a nonzero bare mass for the gauge bosons destroys renormalizability). He opposed many other good ideas (including the work of Stuckelberg). Not really a good role model to follow.

39. **anon**
May 15, 2006

Wolfgang Pauli's letter of Dec 4, 1930 to a meeting of beta radiation specialists in Tubingen:

'Dear Radioactive Ladies and Gentlemen, I have hit upon a desperate remedy regarding … the continous beta-spectrum … I admit that my way out may seem rather improbable a priori … Nevertheless, if you don't play you can't win … Therefore, Dear Radioactives, test and judge.'

(Quoted in footnote of page 12, http://arxiv.org/abs/hep-ph/0204104)

40. **Alejandro Rivero**
May 16, 2006

Note that the events related to Spin happened very fast during the years 1921-1929 or even a narrow interval (1923-25?). From the empirical work of Lande, on J^2 terms, Pauli was in the belief that angular momentum had an intrisic bi-valuedness of mathematical origin, and then he rejected the need of the notion of a new physical angular momentum in the electron; initially he was looking for the answer in total angular momentum itself. He suggested that it was possible that angular momentum had a minimum interval to be integrated upon (so \int j^{-2} dj produces 1/j – 1/(j-1) or even that any derivative of functions f(j) was forced to be discrete (so d/dj 1/j gives the term 1/j – 1/j-1). This was in 1923. Then Born-Jordan mechanics showed that quantisation of angular momentum was in multiples of h/2, while Schroedinger mechanics showed that it is in multiples of h. Dirac comes to the rescue giving a wave equation (thus Schroedinger like) that provides the h/2. And from both ways it is clear that the j(j+1) terms in angular momentum are coming from the indeterminacy principle but not from the bivaluation; thus Pauli accepts the electron 1/2 as a separate idea: the bivaluation of the electron (that at the end comes because SO(3) is covered by SU(2)) separated from the fact that J^2 has eigenvalue j (j+1).

41. **sunderpeeche**
May 16, 2006

I am much edified. My previous post was however in response to a preceding utterly foolish comment (now deleted). The fact remains that a new idea frequently offers no clue as to the consequences it will lead to. And one cannot demand that it do so.

42. **Alejandro Rivero**
May 16, 2006

I agree; and in fact we still do not know where the idea of fermions will lead us to. Look at susy, for instance.

If you just can't get enough of pictures of mathematicians, head over to the [Oberwolfach Photo Collection]. This is a huge collection, which I recently ran across when trying to locate something by [Graeme Segal]. It also includes a photo of a [frequent contributor here].

The AMS has put quite a few whole books on-line. Recently they added the three-volume set *A Century of Mathematics in America* [here], [here], and [here]. Another interesting volume is [Mathematics into the Twenty-First Century], which includes some wonderful survey articles, including a very long series on Lie theory by Roger Howe, and one on [Geometry and Quantum Field Theory] by Witten.

Terrance Tao has a sort of [research blog].

In the category of interesting-looking work that I haven't yet had time to read carefully and think about, here are two papers on an approach to studying pure Yang-Mills theory, by [Freidel] and [Freidel and collaborators].

Update: A correspondent suggests I mention another [famous mathematician] whose photo is on the Oberwolfach site.

   May 11, 2006

   Speaking of Ted Kaczynski, anybody have a clue as to why he left math in the first place? (Of all the articles and books I've read about him over the years, I haven't been able to find an explicit reason as to why he left math).

   If I had to guess, maybe Ted got bored of math?

2. **Deane**
   May 11, 2006

   Great stuff!

3. **Michael**
   May 11, 2006

   There's been some legitimate and constructive criticism of the recent work on 2+1d YM. Some people, whom I consider experts in "ordinary" QCD — including but not limited to the authors of recent Pomeron research –, have raised some questions that ought to be answered before relying on those results as a starting point for new research.

4. **Lubos Motl**
   May 11, 2006

   JC: according to Wikipedia, he just wanted to live as a hermit – which is not a bad idea after all.

   And he was preparing his anti-technological revolution.

   I did not know this guy until 30 minutes ago. Interesting. A few minutes ago, I just tried to solve the quiz "Gore or Kaczynski"

   http://www.crm114.com/algore/quiz.html

   and got exactly 50 percent of the answers right, which is exactly what one gets by guessing. Can you do better?

   Although I have some compassion and understanding for Unabomber, it is rather clear that our colleague Bill Cottrell probably has much more understanding. 😉

5. **jayhog**
   May 11, 2006

   Ted Kaczynski is a hero, a man of honor and courage.

6. **jayhog**
   May 11, 2006

   Ted Kaczynski is also a true freedom fighter.

7. **Sakura-chan**
   May 11, 2006

   I'm sure you said that with a very straight face jay. 😉

8. **jayhog**
   May 11, 2006

   lubos, some of Ted Kaczynski's ideas may seem to similar to that of Al Gore's, but they are really quiet different. You should read his manifesto at http://www.thecourier.com/manifest.htm

9. **Pindare**
   May 12, 2006

Tao’s habit of commenting each new paper is nice and I hope it will generalize (I know a few other interesting examples), instead of just putting a kind of in-your-face dense list of papers.

The latter may impress grant-related committees, but it’s of little use for the would-be grad student, and for colleagues as well…

10. **knotted string**
May 12, 2006

‘… according to Wikipedia, he just wanted to live as a hermit – which is not a bad idea after all.

‘And he was preparing his anti-technological revolution.’ – Lubos Motl

Dear Lubos,

have you any plans to follow in Kaczynski’s footsteps?

🙂

11. **Lubos Motl**
May 12, 2006

Dear knotted string,

I happen to have the opposite opinions about technology than Kaczynski, and if I am tempted to send someone mail bomb, it’s the people who say that the technological progress destroys the ecosystem – people like Al Gore. I say Al Gore instead of Unabomber because Unabomber is already arrested which is OK with me.

Let me emphasize that I have no short term or long term plans to send mail bombs. 😉

Dear jayhod, Kaczynski was almost certainly a more courageous character than Al Gore, but let me stay away from the fan clubs of both of these Gentlemen if it’s OK with you.

All the best
Lubos

12. **A.J.**
May 12, 2006

Just for the record (since Lubos is a bit vague about this), Billy Cottrell was a vandal, not a murderer. He does not deserve to be compared with the likes of Kaczynski.

13. **Lubos Motl**
May 12, 2006

Dear A.J.,

no doubt that there is a difference but you can see that even Kaczynski has his own admirers here. 😉

All the best
Lubos

14. **sunderpeeche**
May 12, 2006

Witten is not in the photo collection. Having a Fields Medal is not enough to get oneself into the collection, I guess.

15. **jayhog**
May 12, 2006

Al Gore is not really anti-technology, after all, he’s on the board of Apple Computers. Al Gore’s a pro-technology green. Ted Kaczynski’s criticism of technology is not limited to its effect on nature, but also its effects on human, for example he disliked genetic engineering because it’s potential to change what it means to be human. Ted Kaczynski’s a neo-luddite.

16. **Who**
May 12, 2006

has anybody read the paper by Freidel Minic and Leigh that Peter linked to in the initial post?

17. **Eli Rabett**
May 14, 2006

Try Thoreau or Kaszinski instead

18. **Who**
May 14, 2006

Try Thoreau or Kaszinski instead
Sorry to be grouchy, Eli. BTW I liked your translation of the article in Die Zeit.

there’s all kinds of atavism in the world—lots of ways to be luddy-minded—some trash technology and some sabotage their own or their neighbor’s mental faculties

I want to know by how far Freidel missed the Clay million.

19. **anonymous**
May 14, 2006

Why is *Freidel* the only one you're mentioning? This is just an attempt to extend the interesting work of Leigh, Minic, and Yelnikov in the 2+1 dimensional case, which is in turn an outgrowth of work by Karabali and Nair. But of course readers of this blog seize on the one person who has worked on "alternative" approaches to quantum gravity as the person to mention and ignore the contributions of others. In any case, it is clearly not yet very close to being what the Clay Institute wants.

20. **Who**
May 14, 2006

thanks, why is it not yet close? what remains to do (if not too much bother to summarize briefly)?

Let's call it the work of Minic Leigh and Freidel, simply changing to reverse alphabetic order.
The interest from a quantum gravity viewpoint is that there are some papers by F. and Sean Majid, by Baratin and F., and by F. and Livine that get some results in 2+1 dimensions certain parts of which are said to be extendable to 3+1: a problem being presently addressed. there may be some common element in how they try jacking up the dimension in both cases from 3d to 4. I don't know that there is, but the possibility seemed there.

21. **woit**
May 14, 2006

anonymous,

The reason for mentioning it has nothing to do with Freidel's work on quantum gravity and everything to do with the fact that it's in 3+1, not 2+1 dimensions. The Karabali + Nair and later work in 2+1 d is quite interesting, but 3+1 d is very different and personally I was always dubious that you could do anything in 3+1 d with their methods. If Freidel and collaborators actually can, that will be very exciting. I just haven't had the time to read their papers carefully enough to see exactly how far they've managed to get. Like Who, I'd be interested to hear from someone who has carefully read and understood these papers (but not interested in hearing from people whose reaction is just to dismiss Freidel's work because he also works on an alternative to string theory).

22. **anonymous**
May 14, 2006

Well, we're more or less in agreement: (3+1)d is indeed very different, and it would in fact be very exciting if a result is achieved. Here's my understanding of the current status.

One defines a set of variables as follows. For a given point "x", one takes Wilson lines extending along one of the axes from infinity in to x, and then along a different axis from x out to infinity. This provides a set of local, gauge-invariant operators. They have some nice properties related to holomorphy in 2D, and in 3D they satisfy some identity H_{ij}H_{jk}H_{ki}=1 (and can also be formulated in a somewhat holomorphic way).

Next one shows that there is a nice Hamiltonian approach to studying the theory in terms of these operators and some associated currents. There are some subtleties about regularizing in the right way but they seem to have addressed these.

The next problem is to construct the vacuum wave functional. In (2+1)d there turned out to be a simple analytic solution in the large N limit. In (3+1)d, it is not nearly so simple, and they seem to have currently only some wishful thinking. In the UV they find that a free-field ansatz seems to work (it had better!), and in the IR something with a mass scale might work. But the detailed form of the solution is completely mysterious.

Unfortunately, that mass scale is just added by hand (effectively, it's a cutoff) and so far there is no connection of UV to IR in which we can see that it really is the QCD scale and is related to logarithmic running. They hope to find some self-consistent solution showing there really is a nonzero mass. To do this would certainly be a major breakthrough, and I hope it can be done, but it hasn't yet.

If all of this works it's at best a solution at large N, but that would still be very exciting. However, the current status reminds me of some old work of Migdal on solving the loop equations; there are tantalizing hints that there is something deep there, but no one ever seemed to know quite what to do with it. (In fact, you might think of this more recent approach as working with a subset of the loop variables, namely those loops that go through the "point at infinity" and remain parallel to one of the axes at all times.)

23. **Bert Schroer**
May 15, 2006

To Peter and anonymous:
with all caution I would like to take the following optimistic view on the Freidel et al work.
It should be viewed as being connected with Stanley Mandelstam's old program (Ann. of Phys. 19 (1962)) of substituting gauge theory by a formulation in terms of field strength. This old idea has received a significant conceptual underpinning through our recent work on semiinfinite spacelike string-localization derived within the new powerful setting (Mund, Schroer, Yngvason in print in CMP, math-ph/0511042) of modular localization. In that setting the family of massless finite helicity=s Wigner representations have pointlike field strength but (in the same Hilbert space, hence no ghosts!) covariant semiinfinite spacelike localization. As a result the the associated quantum potentials A(x,e) fluctuate in both the Minkowski space x and the De Sitter e (unit spacelike string direction) which leads to an improved short distance behavior (scaling dimension 1 independent of s). These objects are not Lagrangian fields but the properly adjusted (to strings instead of pointlike fields) Epstein-Glaser approach seems to work. For s=1 the string-independent subalgebra corresponds to the gauge invariant observables. But for s=2 (Gravitation, dimg(metric potential)=1) this is virgin territory since there does not seem to exist any gauge setting in terms of unphysical pointlike potentials. If the calculations continue to live up to our expectations we should have in due time a "renormalizable" setting for gravitation (where renormalizable means that from an infinite parametric universal Bogoliuvov-Shorkov-Epstein-Glaser matrix S(couplings) we are able to filter out a finite parametric set). This together with the strong arguments bu Brunetti and Fredenhagen that the perturbation can be arranged in such a way that (using their quantum local covariance principle) that a perturbative version of background independence results.
Maybe I project too much into Freidel et al ideas, as with any computational work whose conceptual basis is yet nebulous I may have taken an overly optimistic interpretation.
Woudn't it be ironic if string-localization (not at all related to string theory) achieves what string theory promised?
Question to Peter: suppose what I described can be in due time converted into hard facts, what would you thing string theorists will do if they loose their only supporting argument?

24. **Bert Schroer**
May 15, 2006

small correction to an important statement in my text
"In that setting the family of massless finite helicity=s Wigner representations have pointlike field strength but (in the same Hilbert space, hence no ghosts!) covariant semiinfinite spacelike" localized potentials.

25. **woit**
May 16, 2006

anonymous,

Thanks for the very informative comments on the Freidel et.al. work!

Bert,

If the scenario you describe pans out, string theorists will announce that it is part of “string theory”, closely related to what they had in mind all along, and proclaim victory.

26. **Bert Schroer**
May 16, 2006

What a coincidence, given their hegemonic all-devouring sociological situation this is precisely what I also expected!
In this case the word “string-localized” would make it quite easy for them (the fact that its conceptual meaning is lightyears apart from string theory would be no obstacle for people who live in a conceptual twilight zone).

27. **Aaron Bergman**
May 16, 2006

Don’t forget the pony.

28. **woit**
May 16, 2006

Great idea Aaron, let’s add “and a pony” to all string theory papers coming out these days. Would be highly appropriate…

29. **Aaron Bergman**
May 16, 2006

Just the ones that don’t calculate anything.

30. **knotted string**
May 16, 2006

What % is that?

31. **woit**
May 16, 2006

Since 0% of string theory papers calculate anything that can be compared to the real world, I guess he means ones that calculate something, with the hope that someday it will lead to some calculation that can be compared to the real world. These papers deserve “and a pony” as much (and often, more) than any others.

32. **Aaron Bergman**
May 16, 2006

The least you can do when you don’t have any hope of comparing with the real world is to calculate something. Otherwise you get “wouldn’t it be nice if…” papers. Wouldn’t it be nice if we all had a pony?

33. **woit**
May 16, 2006

Just doing random, pointless calculations doesn’t make you a scientist. If you want to claim that your calculation is part of science, you have to be able to show that it has some hope of being related to the real world. Right now, just about all string theory calculations are motivated by “wouldn’t it be nice if” hopes. Some of them very bizarre, e.g. “wouldn’t it be nice if the world were some random point in some horrifically complicated space and we could never predict anything…”

34. **Thomas Love**
May 16, 2006

I enjoyed browsing through the pix, but they’re not well catalogued. There’s an entry for Marsden, Jerry and for Marsden, Jerrold E. ; Singer, I. and Singer, Isadore. Several photos are only labeled by last name. One I am curious about was “Love”, it isn’t me (of course) and it’s too recent to be AEH Love.

35. **Aaron Bergman**
May 16, 2006

We all know you dislike string theory, Peter.

36. **woit**
May 16, 2006

One reason being that string theorists, lacking any real arguments, can’t stop themselves from descending to ad hominem ones

37. **Alejandro Rivero**
May 16, 2006

You could perhaps enjoy messages 16, 28 and 29 in this thread:

http://www.physicsforums.com/showthread.php?t=120192&page=2

one can use math a lot simpler than string theoretists and still come to results of fuzzy and membranous interpretation.

38. **Aaron Bergman**
May 16, 2006

I glad you kept that in such general terms because I haven’t made any ad hominem remarks in this comment thread. Nonetheless, as enjoyable as this exchange has been, I’ll bow out now unless something new happens to come up.

arXiv Weirdness

May 16, 2006
Categories: Uncategorized

Some rather strange things are going on at the arXiv, especially in the hep-th section:

Besides the usual string theory papers, which just get more and more pointless as time goes on, some very weird things have started to appear on hep-th. Last night, there was a new paper entitled [Amplitude for existence of spacetime points]() that makes no sense to me. It's by Monica Dance, who seems to have no academic affiliation, but does have a Hotmail account. Not clear why the hep-th moderator allows this kind of thing. One explanation would be that earlier this year she put [Symmetry limitations on quantum mechanical observers, and conjectured link with string theory]() on hep-th, an equally nonsensical document which presumably was all right because it had "string theory" in the title. Maybe once you get one paper about "string theory" on hep-th, you become an "active researcher" and can put whatever you want there.

Actually, to get to be an "active researcher" according to the arXiv, as long as you're studying string theory, you don't need to even ever have written a paper at all. Recall that arXiv trackbacks to this blog have been banned on the grounds that I'm not an "active researcher" (for more about this, go [here]()). But [this hep-th paper]() has a trackback to [this blog entry]() by Nicola Ambrosetti. Ambrosetti's blog contains some fine entries and having trackbacks to it makes good sense, but he appears to be a student at Neuchatel who has never written a paper, so I would have guessed that according to arXiv standards he wasn't yet an "active researcher". Maybe standards are different when your blog entries have titles like [Barton Zwiebach Rules!]().

Over the last few months I've written quite a few blog postings that discuss arXiv papers. In many cases I happen to think that either the posting or the discussion in the comment section is something that someone interested in the paper might find worthwhile. In the case of postings about string theory papers ([here]() and [here]()), [non-string theory papers](), and [non-string theory papers claiming to be string theory papers](), no trackbacks to my blog were allowed. This is what I expected, but for some mysterious reason, a trackback to [this blog entry]() about a [paper critical of string theory]() was allowed. So, it seems that the arXiv is allowing trackbacks to my blog entries only when they are about papers criticizing string theory.

None of this makes any sense to me, so I tried politely writing to the arXiv person at Cornell that my logs showed had examined my blog entry just before their trackback system generated a trackback to it, asking about what was going on. No response to that inquiry, as to all my other inquiries about arXiv trackback policy. To find out what their policy now is, I guess I'll just have to wait for the relevant authorities to get around to posting a blog entry or writing a comment at some blog somewhere, since that seems to be their preferred manner of dealing with this issue.

Update: I did get an e-mail response from someone at Cornell about my enquiry about trackbacks. It didn't address the question of how hep-th trackbacks are now being moderated, but did point out that the trackback system is still in an experimental state, that they have recently had significant personnel changes, and that sorting out the trackback system hasn't been one of their highest priorities.

Update: Lubos is even more out there than usual with his [comments on this](). It seems that my objections to the Dance paper are an example of sexism.

Comments

1. **Todd**
   May 17, 2006

   Doing a quick search I found that Monica Dance's first paper posted on the arXiv was listed under quant-ph in 2004 using the name M. C. Dance. It apparently had something to do with the Holographic Principle. It also appears that she is a policy analyst for the EECA (Energy Efficiency and Conservation Authority) in New Zealand.

2. **Aaron Bergman**
   May 17, 2006

   She was apparently at Auckland physics if [this post]() is accurate.

3. **Peter Erwin**
   May 17, 2006

   I think you may be conflating the nebulous (and poorly defined) "active researcher" status, which is apparently necessary for your blog posts to be linked (except when it isn't), with the ability to submit papers, for which all you need is: a) to have registered with the arXiv before they introduced their "endorsement" system; or b) to have been endorsed after that time by someone with the endorsement ability.

   So there's no a priori requirement, however well or poorly defined, to be an "active researcher" in order to submit papers anywhere in the arXiv.

4. **Charlie Dance**
   May 17, 2006

   > A simple possibility might be that spacetime points x have an amplitude of existence $E(x)$ consistent with this. The magnitude of $E(x)$ might be greater or less than 1 at any point x; or the relative values of $E(x)$ might be what matters. In a classical limit, a function like $E(x)$ might give the effect of a gravitational metric.

   This seems perfectly reasonable to me. Can anybody here explain why $E(x)$ isn't likely to give the effect of a gravitational metric? Couldn't the gravitational metric, m, have an amplitude of existence, $E(m)$? Particles have amplitudes of existence, and they even have different amplitudes depending on whether you're accelerating. Wouldn't that explain the standard model?

5. **Chris Oakley**
   May 17, 2006

   Charlie,

   A couple of wacky ideas turned out to be fruitful, namely special relativity and quantum mechanics, and many people have concluded from this that if an idea is wacky enough then it must be correct.

   I do not agree with this. The idea that spacetime points may or may not exist according to some probability amplitude is certainly wacky, but without some examples of how the idea clarifies that which was unclear before, one has to put it in the same category as those insights into the nature of the universe which are gained when under the influence of recreational chemicals.

6. **absolutely**
May 17, 2006

I think Charlie was attempting humour, or else he's the actor of same name genre-hopping.

7. **Ali Yegulalp**
May 17, 2006

Sometimes the web can be a very small place…

Monica Dance was a physics graduate student at Princeton in the early 90's (same time as me). She went back home to New Zealand after about 3 years without finishing the PhD program, started studying medicine, and then I don't know what happened after that. I knew her quite well in Princeton, but I haven't heard from her in years.

8. **abc**
May 17, 2006

> Maybe once you get one paper about 'string theory' on hep-th, you become an 'active researcher' and can put whatever you want there.

If this is the case the String Illuminati failed.

Judging from the references given by M. Dance it seems that as far as this is nonsense it is nonsense inspired by alternatives-to-string-theory (TM).

Which may happen…

9. **anon**
May 17, 2006

"In this model, the closer an object is to a mass or energy source, the more paths through spacetime might be available to the object in the direction of the mass/energy, or the higher the amplitude associated with such paths." – Monica Dance

What part of this doesn't make sense to you? Bring two objects together and anybody can see there is more space between and around them for path integrals.

It is not as if bringing things closer together will reduce the space for interactions … (I'm being sarcasm)

(I've got my own personal pet theory that is just slightly more radical. Perhaps if I FIRST write a positive constructive stringy paper on arxiv, they won't delete a second later paper on the topic?)

[extensive off-topic material deleted]

10. **Steve Myers**
May 17, 2006

Quick respone to Monica Dance's paper: it's a joke, right? She's showing the Arxiv will print anything (almost). As for $E(x)$?! Come on.

11. **Sam**
May 17, 2006

Oh no! Not another former Princeton Physics graduate student gone bad? Let's all pile on about how stupid she is.

12. **sunderpeeche**
May 17, 2006

I was going to suggest that the Monica Dance paper may be a practical joke.

13. **woit**
May 17, 2006

Steve + sunderpeeche,

The problem with the idea that this is a joke is that it's not funny.

Peter Erwin,

I was using "active researcher" in the arXiv sense of the term. They have announced that it doesn't mean "active in research", but is a term that cannot be defined (attempts to define it foundered when it turned out the hep-th moderator didn't qualify as one). In practice it seems to mean "someone the hep-th moderator approves of", and that's how I was using it.

I'm well aware that there's supposed to be a difference between the endorsement system for papers and the "active researcher" standard for trackbacks. The "active researcher" term is a piece of dishonesty created by the hep-th moderator, who announced that the usual endorsement system could not be used for trackbacks, since Peter Woit would "game the system" by getting endorsed. His other justification for this was that unlike papers, blog entries could not be individually moderated. The Monica Dance papers evidently were individually moderated and approved.

14. **Sam**
May 17, 2006

It's not just hep-th. All the archives are drowning in trash papers. Look at hep-ph or gr-qc.

Clearly, their moderation system is a failure.

15. **woit**
May 17, 2006

Sam,

I think you're right. Part of the problem is that when leading figures in theoretical physics start writing pseudo-science (e.g. the anthropic string theory landscape), it becomes impossible to have any rational standard that will allow them to keep publishing, but keep out other crackpot papers.

16. **Sam**
May 17, 2006

“Part of the problem is that when leading figures in theoretical physics start writing pseudo-science …. it becomes impossible to have any rational standard that will allow them to keep publishing, but keep out other crackpot papers.”

Yes, like the bird flu, string theory has destroyed, not just hep-th, but all branches of theoretical physics.

17. **Lubos Motl**
May 17, 2006

Nothing against Monica Dance personally, but I am pretty certain that these papers are completely nonsensical. Whether or not such papers or the previous papers by the same authors have “string theory” anywhere in the abstract is unphysical. (Lee Smolin’s also have “string theory” in them.) What matters is the content. The content is not string theory. It is an alternative to string theory – the kind of hypothetical stuff that Peter Woit and Lee Smolin call far.

Stuff that does not exist, and even if it exists, it is impossible to see it from the current state of knowledge.

The main message is that even in periods when progress is slow, it is very important to distinguish papers that are based on knowledge of existing phenomena and theories and that want to explain more about them, and papers that don’t. Dance’s paper is an example of the latter category, much like Sundance’s papers (with or without Lee Smolin).

People in theoretical physics must still learn quantum field theory and the non-phenomenological ones also string theory. If the community allows physics to be developed in the direction of these alternatives, it could be a real end of it, after a few years (one year is one decreasing e-folding once these mechanisms win).

18. **sunderpeeche**
May 17, 2006

A system like the ArXiv with moderators is prone to self-serving rubbish. Not all jokes are laugh-out-loud funny. Poor quality jokes (or poorly written jokes) can be very unfunny. Don’t give the paper more publicity than it deserves.

19. **Sam**
May 17, 2006

“A system like the ArXiv with moderators is prone to self-serving rubbish.”

Clearly, that’s what’s happened here.

“Don’t give the paper more publicity than it deserves.”

What? No more blog posts about stupid papers on hep-th?

20. **woit**
May 17, 2006

sunderpeeche,

As physics I don’t think the paper deserves to be publicized, but the fact that the arXiv moderation system is breaking down needs to be discussed and addressed by the particle theory community. This kind of breakdown already was becoming clear with the Bogdanov papers, but no one seemed very interested in addressing it at that time. It has just gotten much worse since then.

21. **sunderpeeche**
May 17, 2006

“What? No more blog posts about stupid papers on hep-th?”

Why do you want to waste your time on nonsense? Indeed, why am I writing this? Time to quit this thread and wait for something more sensible to be displayed on the blog.

22. **Sam**
May 17, 2006

“[T]he fact that the arXiv moderation system is breaking down needs to be discussed and addressed by the particle theory community. This kind of breakdown already was becoming clear with the Bogdanov papers…”

Bogdanov papers? On the archives? That’s terrible.

No wonder the archives are drowning in crap.

23. **woit**
May 17, 2006

Sam,

The Bogdanov papers were not posted on the arXiv. As far as I know they didn’t even submit them to the arXiv. They were published in several peer-reviewed journals, after gettting positive referee’s reports, and it was that breakdown in the refereeing system that I was referring to. That was a different case, but one root cause of the problem is the same.

24. **woit**
May 17, 2006

OK Lubos, the approval of the Dance papers is the fault of me and Lee Smolin. That makes perfect sense…

25. **anonymous**

May 17, 2006

You’re all missing the *real* point: her name is M.C. Dance! How awesome is that?

Seriously though, the arXiv is a *pre-print* server. Not everything there has to pass peer review. As long as the system works well enough to keep it from being completely overrun with crackpots, I would say it’s not a big concern.

26. **Sam**
May 17, 2006

“OK Lubos, the approval of the Dance papers is the fault of me and Lee Smolin. That makes perfect sense…”

Just like the idea that the crap papers all over the archives (not to mention the refereed physics literature) are the fault of the landscapeologists.

27. **Peter Erwin**
May 17, 2006

A couple of points:

I’d hesitate to conclude that *all* of the arXiv is “drowning in crap”; I wouldn’t say that’s the case for astro-ph, for example. Of course, almost all submissions to astro-ph come with self-labeled quality indicators: either it’s something presented at a conference (possibly interesting, but not well vetted), or it’s been submitted to a journal (potentially OK, but hasn’t been through peer review yet), or it’s already accepted by a journal (better chance of being OK). I admit to a certain bemusement when I glance over hep-th listings and see that the majority have no indication of whether there’s any connection to a journal or peer-review process.

Re Bogdanov and oddball papers showing up in arXiv: the problem is to figure out if there’s more at work than just the Recency Illusion and its cousin, the Frequency Illusion (see here for a discussion in the context of linguistics).

In other words, is there solid evidence that peer review, in general, is letting more nonsense through? Were there cases like the Bogdanov papers in the past, that have been conveniently forgotten?

28. **Jimbo**
May 17, 2006

I usually side with Peter on most of the topix discussed herein, but me thinks Prof. Woit is sulking a bit about his `inactive researcher’ status/stigma by the admins at ArXiv, and lashing out.
True, Ms. Dance may not have her PhD (neither does Freeman Dyson nor former Livermore NIF chief scientist Michael Cambell, nor many others), but neither PhD nor academic address implies scientifically viable work.
Hep-th needs novel ideas, apart from the standard schlock of mathematical masturbations, devoid of physical relevance, which regularly inundate its nightly postings.

29. **woit**
May 17, 2006

Jimbo,

Whether or not this author has a Ph.D. or not is thoroughly irrelevant, and not something that I raised. The problem with these papers is that they’re nonsense, not the qualifications or lack thereof of the author.

Yes, hep-th needs novel ideas. But it also needs a moderator who can recognize utter nonsense for what it is.

And no, I don’t think “sulking” is quite the right word to describe how I’m responding to the behavior of the arXiv hep-th moderators. It’s not like I’m not saying loudly and publicly what I think about this…

30. **Sam**
May 17, 2006

“But it also needs a moderator who can recognize utter nonsense for what it is.”

Was he the referee on the Bogdanov papers, too?

That would explain everything.

31. **woit**
May 17, 2006

Sam,

No, the problem is not one person.

32. **Lubos Motl**
May 17, 2006

Dear Peter,

of course that it is your fault and fault of Lee Smolin. It’s two of you, among others, who have been fighting for years to replace string theorists with crackpots. By “original independent ideas” which is how you call these cranks. Accepting papers of the same quality as Monica Dance’s paper or the paper about trinions has always been one of your main political goals.

The staff or arxiv.org accepted these papers to make two of you happier. You don’t like it either. You will complain until the end of your life but the real problem is that first of all, you have absolutely nothing to offer, and second of all, you discourage people from doing serious work.

Best
Lubos

33. **Alejandro Rivero**

May 17, 2006

I have not objection to bad papers in the arxiv. I have some about *repeated* papers, and worse if they are bad papers. Most emptypots do not innovate and thus the "version replacement" utility of the arxiv is handy to control it, instead of censorship.

34. **Shantanu**
May 17, 2006

Peter, let's forget such papers. any comments on hep-ph/0605119
and gr-qc/0602086(which is discussed in http://www.world-science.net/othernews/060514_bouncefrm.htm)

35. **SteveM**
May 17, 2006

The arxiv really needs to stop accepting papers that are just empty or vague waffle, wishful thinking, philosophising and handwaving. That's fine for coffee breaks or cocktail parties. Hard concrete and rigorous calculations that actually calculate or rigorously prove some very specific result or important /interesting point are becoming harder to find, and are actually difficult to produce–but that is why physics is hard! Even if you are into the mathematical side of things you still have to come up with some result or theorem or proof.A lot of people talk a good theory in english but then never really put anything into concrete mathematical terms or actually calculate anything; or else they make some general mathematical statements then go on about what they would like to be able to do, like to be able to calculate etc., but it never happens. A minimum criterion for acceptance should be that it contains an interesting result or concrete calculation.

36. **Alejandro Rivero**
May 17, 2006

Coffee break conversations are important. The path integral was developed as a follow-up of a coffee table conversation at Princeton (I never remember the name of the pub, it was an exotic island or so). Perhaps the physics/ cathegory should be better place than hep, but a lot of people tries first hep because moderators usually forbid cross-announcements (not really cross-posting) from physics to hep-yyy listings.

The use of diverse bulletins plus personal options in the listings (show/not show cross-posting, show/notshow replacements, filter, etc) could do better work. Also note than a lot of arxiv navigation is via SPIRES (or citebase) reference linking.

37. **woit**
May 17, 2006

Shantanu,

Sorry, but I'm no cosmologist and this isn't a cosmology blog. Better to look for such a discussion at another place (e.g. CosmoCoffee).

38. **Peter Shor**
May 17, 2006

Alejandro Rivero's comment seems to contain the germ of an idea for eliminating crank/vague/philosophical/handwaving papers posted to the arxiv. Somehow direct them to a separate category. (I will hereby preempt the smart aleck who is going to propose that we name it hep-no, short for nonsense, and put all landscape papers in it.)

39. **Nigel**
May 17, 2006

Can anyone define crank/vague/philosophical/handwaving without behaving like a crank, being vague, being philosophical and doing a lot of handwaving? And can you define these in such a way that they allow today's 10/11-d string theory as not being crank, etc.

Kelvin's vortex atom is the best good precedent for string theory. It was full of ad hoc predictions, but couldn't do anything useful like predict subsequent discoveries. It might have been retained forever if radioactivity and nuclear physics hadn't been discovered.

40. **Lubos Motl**
May 17, 2006

Dear Nigel,
google for *crackpot errors* and pick the first reference:

http://www.google.com/search?q=crackpot+errors

This could answer your question.

Best wishes
Lubos

41. **Carl**
May 17, 2006

They must be getting loose at arXiv because they asked me to resubmit my crank paper that predicts the neutrino masses to 6 decimal places (LOL):
http://brannenworks.com/MASSES2.pdf

But they want it in "physics" instead of "hep-ph". I would guess that the reason for the liberality was that my paper was referenced by this paper:
http://www.arxiv.org/abs/hep-ph/0605074

Carl

42. **Shantanu**
May 17, 2006

Peter, point noted. However the first one hep-ph/0605119 is about collider particle physics and technicolor and has nothing to do with cosmology.

43. **A.Torok**
May 17, 2006

I support Lobus(seriously).

44. **A Different Peter**
May 17, 2006

Distinguishing cranky nonsense from genuine work is difficult for several reasons. One is that genuine, correct, work can appear to be gibberish if one is not intimately familiar with the topic involved. Another is that genuine researchers and Nobel Prize winners are not unknown to issue communications which appear to be just as incomprehensible and radical as the statements of certified crackpots. Another is that those who have made conceptual mistakes, and are now presenting some ridiculous assertion as a result, will defend their assertion for as long as they can, just as any competent physicist presenting a counter-intuitive but correct theory would.

A part of the problem is that physicists today do not have the time to devote to the unrewarding task of examining the claims of everybody who thinks they have a great idea about physics. Without investing this time and effort, it will be impossible to distinguish crackpots from undiscovered geniuses. It will not be possible to simultaneously satisfy those who want to ethnically cleanse the crackpots and those who want a source of original ideas. If you want to keep out the crackpots without being prepared to talk to the crackpots and discover exactly why they're wrong, then you're going to have to reject all ideas which aren't part of the mainstream.

So the choices are:

1. A slow and tedious process of carefully examining every claim and checking the validity of every argument. This is peer review.
2. Let the crackpots through the filter and some good ideas might come through as well. This is what the arxiv has always been, but it was better when fewer crackpots knew about it.
3. Accept what's mainstream and reject everything else, Lubos style. If you want to do this, string theory is the theory for you.

Any other ideas?

45. **Tony Smith**
May 17, 2006

Carl said "… arXiv … asked ..[him]… to resubmit …[his]… crank paper that predicts the neutrino masses …".

Did arXiv ask by sending an e-mail, or how?

Carl may be right that arXiv changed its mind because his "… paper was referenced by
http://www.arxiv.org/abs/hep-ph/0605074 …", which is a paper by Yoshio Koide of the University of Shizuoka, "supported in part by the … Ministry of Education, Science and Culture, Japan …".

Is this the first case of arXiv's blacklisting causing it to be embarrassed
when the work that arXiv blacklisted as crank
is found to be useful
(in this case, by non-USA Japanese who are outside the USA physics establishment and its consensus-enforcement mechanisms) ?

Tony Smith
http://ww.valdostamuseum.org/hamsmith/

46. **Richard**
May 17, 2006

Peter Shor said — "Alejandro Rivero's comment seems to contain the germ of an idea for eliminating crank/vague/philosophical/handwaving papers posted to the arxiv. Somehow direct them to a separate category."

I recently received an arXiv math daily title/abstract distribution email with a reference to a paper entitled A Concise and Direct Proof of "Fermat's Last Theorem" (listed as 4 pages long). It was placed into the General Mathematics category.

47. **LDM**
May 17, 2006

Is it Ms Dance's paper and its content, or its acceptance by arXiv, that is the problem here…or both?

Ultimately,you are known by your work, and if you want to publish scientific rubbish, then that is the scientific reputation you will develop…

I would suggest http://compbiol.plosjournals.org/perlserv/?request=get-document&doi=10.1371/journal.pcbi.0010057 as an excellent guide to temper overly enthusiastic journal submissions, with emphasis on point 10.

However, I disagree with Woit's claim, that the article is nonsensical.

I would rather make the objection that the ideas in this paper are so underdeveloped and so loose, that it is not appopriate for a scientific paper…and that this type of communication should continue to be confined to private correspondence (or even blogs)

48. **Chris Oakley**
May 18, 2006

I would rather make the objection that the ideas in this paper are so underdeveloped and so loose, that it is not appopriate for a scientific paper…and that this type of communication should continue to be confined to private correspondence (or even blogs)

Right. Here is a wacky idea. The author needs to do more to convince us that it is worth taking seriously. Even that wacky idea Superstrings can point to the possibility that they might be able to reproduce GR (although I am still not sure of the situation there).

49. **Nigel**
May 18, 2006

Dear Lubos,

Kelvin's 'crackpot errors' in predicting the vortex atom are just the same as string theory's. There were NO testable predictions. (Radioactivity and nuclear structure were totally unexpected, and disproved the vortex atom.) More on grand mainstream cranks:

Helge Kragh, 'The Vortex Atom: A Victorian Theory of Everything', Centaurus 44 (1-2), 32-114.

'Each atom, pictured as a ring with some set of possible oscillations …

'Here in principle, Thomson [Lord Kelvin] asserted, was the foundation of what we might now call a grand unified theory of light and matter. "Helmholtz's rings are the only true atoms," Thomson confidently declared.' – http://fermat.nap.edu/books/0309090733/html/266.html

50. **phenomenologist**
May 18, 2006

Motl: "People in theoretical physics must still learn quantum field theory and the non-phenomenological ones also string theory"

What a claim! Is finally lubos accepting string theory has nothing to do with the phenomenological world ???
Or is he promoting a new role for physics?
I wonder what does he consider himself…

51. **Bert Schroer**
May 18, 2006

"of course that it is your fault and fault of Lee Smolin. It's two of you, among others, who have been fighting for years to replace string theorists with crackpots. By "original independent ideas" which is how you call these cranks."
these are words from the mouth of the Lord of Misuse in the Hegemon´s service. Like in the case of climate change they create that relaxed atmosphere which reminds the rest of us that it took a never before seen lowering of standards emenating from string theory to convert large parts of particle physics into a metaphorical messianic enterprize in which everything goes as long as it does not hamper this path. The priority-fight around the antropic trashcan (using the fight between dogs around trashcans which one sees in the morning here in Brazil as a metaphor) is an excellent illustration of where the hegemon wants us to go.

52. **B**
May 18, 2006

The easiest way would be to allow registered users of the arxiv to review papers, maybe similar to reviews at amazon.com. Such a review process is not perfect, and the standard below peer review in journals, but it will give the inexperienced user a rough quality estimate on the papers posted. It might even provide valuable feedback to the author. Also, it would be useful to search papers according to some importance or impact criteria based on that. Say, if you are a newcomer in some field, it takes some while to figure out which are the relevant and important contributions.

Discussing papers in blogs and allowing trackbacks already leads into this direction, but it could be made more easy by directly having reviews on the arxiv.

See also my blog entry Peer Review II. Best,

B.

53. **anon**
May 18, 2006

When hundreds of papers are published in the arxiv, that contain no more substance than an air-pillow, what harm can Monica Dance's paper make? She at least has the courage to be original, unlike the above mentioned authors who hide their non-contributions to physics in the cover of mainstream physics and academic affilations.

54. **woit**
May 18, 2006

anon,

There are lots of not very good papers on the arXiv, but up until now I have not seen ones that at a glance are obviously nonsense like the Dance one. I'm sure that there is a long history of such things being submitted to the arXiv, and being rejected by their moderation system. I'm just wondering why their moderation system broke down in this case.

It's certainly bad enough how many not very good papers are posted on the arXiv, but if the thing becomes dominated by complete nonsense papers, that will be a lot worse, and a very, very bad sign for theoretical physics.

Originality is good and desperately needed, but the open problems in this field are very difficult and originality without competence is useless and just pollutes the field with more noise.

55. **D R Lunsford**
May 18, 2006

I have submitted a new paper to arxiv, "New Results in Gravitational Chess". In this paper, it is shown that when a bishop strikes through a square adjoining the queen, the path is deflected and it actually starts attacking squares of the other color! Now here is what is interesting: when it attacks past the *opponent's* queen, the path is deflected *the other way*. This was a totally unexpected new result and one must read my earlier papers on gravitational chess with this in mind. In particular, my earlier treatment of the Cosmological Constant Gambit is shown to be unsound.

Some will complain that my paper contains no games and not even any meaningful diagrams. I can only say that publishing costs prohibit me from introducing such minutiae that would only distract the reader from my main result in any case.

I hope to extend these results to rooks if my busy gardening and carpentry schedule permits. However, I feel that my legacy is secure, thanks to arxiv.org.

-drl

56. **sunderpeeche**
May 19, 2006

Gravitational Chess exists, believe it or not

http://play.chessvariants.org/erf/Gravitat.html

and yes, I will thoroughly approve if this post is deleted

57. **D R Lunsford**
May 19, 2006

ROFL! It’s so hard to do anything new 🙂

-drl

Priority for the Landscape

May 17, 2006
Categories: Uncategorized

The string theory anthropic landscape point of view has now become so widely accepted and entrenched in the particle theory community that various people are making their claims about having had the idea first. The standard first paper that people generally reference is Leonard Susskind's February 2003 [The Anthropic landscape of string theory](), which now has 243 citations. Susskind claims credit at least for the "Landscape" terminology in his recent book.

Last month Dutch string theorist Bert Schellekens posted a paper on the arXiv entitled [The Landscape "avant la lettre"](), in which he claims credit to some extent for the idea. He is quite enthusiastic about the Landscape as a paradigm shift and a new way of doing physics:

…I think even today we are only in an intermediate stage of a very slow shift of opinions regarding the objectives of our field. Although landscape ideas and even the anthropic principle are now at least discussed, it seems to me that the importance of the landscape is still severely underrated. I have tried to express my enthusiasm about the recent progress during seminars, but apparently with little success.

Schellekens claims that:

My own thoughts in this direction started around 1987. The year before I had published a paper with Wolfgang Lerche and Dieter Lust. Like other authors at the time, we found large numbers of four-dimensional chiral string theories, but much more than others we made a point of strongly emphasizing the non-uniqueness of the result.

He goes on to say that already back then it was clear to him that string theory was sending the message "if we find one vacuum we are going to find a huge number of them." He recalls that when he was working at CERN in the years before 1992 he was promoting the anthropic string theory landscape idea and encountering a lot of resistance, often from people who now tell him that they had always been saying this kind of thing.

In 1998, at the occasion of his inauguration at the University of Nijmegen he gave a speech on this subject in Dutch. In the arXiv preprint Schellekens reproduces the Dutch text of his speech, together with an English translation. He notes that he used the Dutch word "landschap" in the text, although he mostly referred to the landscape using the Dutch word for a "mountain range".

Schellekens admits that string theory may not be correct, but he says that string theory implies the landscape, so for string theory to be correct the landscape must exist. His only comment indicating that this might be a problem for string theory is that

…the unexpectedly huge size of the landscape is making it a lot harder to convince ourselves of that.

He does admit that back in 1998 he expected the size of the landscape to be much smaller than it now appears to be, smaller than the 10^{80} vacua that, uniformly distributed, could cover all possible values of the standard model parameters to the accuracy that we can measure them. So he expected that one would be able to somehow check string theory by seeing if one of the vacua agreed with the real world. Now that the number of vacua seems to be vastly greater than this, eliminating any reasonable hope of checking string theory this way, for some unfathomable reason his enthusiasm for the idea is undiminished if not intensified.

If you just can't get enough of landscape discussion, there are recent blog entries on the topic by [Sabine Hossenfelder]() and [Alejandro Satz]().

Update: The last-gasp hope for getting a prediction out of the landscape is that there is some useful structure in the landscape, so that it doesn't densely cover all possible standard model parameters. Washington Taylor and Michael Douglas have been looking for such a thing amongst vacua, trying to find some correlations between properties of these vacua. For more about this, see [Taylor's web-page](). Lubos has a [blog posting]() about all this, in which Taylor explains the philosophy:

If we find 5 models with features X and Y of the standard model which all have feature Z which is not yet observed it is not very definitive. If we look in different parts of the string theory landscape and find that all 10^{20} models we know how to construct with features X and Y of the standard model have feature Z also it begins to carry some weight as a possible prediction.

So far, as you might expect, since there is no known reason for such correlations, they haven't found any. Lubos reports:

Wati's result in his particular examples was that there was virtually no information in the correlations: the difference was one bit and the distributions of different quantities were essentially independent Gaussians.

and goes on to rant:

Surely the physicists have not been working for 30 years to extract 1 bit of information – whose probability of being correct is moreover 50 percent. Even if there were any correlation, I would probably find such a correlation physically uninteresting. We know for sure that some of these correlations would agree with those observed in the real world, and some of them would not.

What will you do with this probable outcome? Will you overhype the "successful" patterns as evidence that the landscape reasoning is good, while you will be silent about the "unsuccessful" ones? I would count this activity as a part of astrology or catastrophic global warming theory, not physics. It's frustrating to see that this is what is apparently being intended.

I wonder whether the people who were producing the very convoluted microscopic theories of the luminiferous aether in the 19th century really believed that this was the way to say anything new about physics – or whether most of them did these things just to do something and keep their jobs. Einstein took over in 1905 and showed not only that the aether was a ludicrous fantasy – but moreover, the absence of the aether is one of the basic principles that underlies his relativistic revolution in physics. Today, all of us – except for those in loop quantum gravity – know that the aether is a silliness that is not realized physically and that was never well motivated.

My feeling about the random model building and random model guessing is somewhat analogous to the random construction of the aether from gears and wheels. We're missing something and we should not fool ourselves into thinking that we're not.

Update: The Harvard physics department seems to be having quite a few seminars on the Landscape, and one participant [reports]():

A funny aspect of these discussions is that one can't quite distinguish which of the considerations are jokes and which of them are meant seriously. At least I can't distinguish them.

Comments

1. **Lubos Motl**

May 17, 2006

It’s our friends’ internal problem to decide who should be credited. I think that it’s some priests in the Catholic Church who should be credited for having discovered the idea a long time ago. At any rate, I don’t think that the originator of the anthropic idea has anything to be proud about, so it is not quite clear to me why anyone should be bitter about not being the first one who discovered this “great” idea.

2. **lmot**
May 17, 2006

One man’s junk is another man’s treasure.

3. **JC**
May 17, 2006

From a historical perspective, how fast did the aether idea fall out of favor a century ago? Was it dropped like a rock suddenly by many physicists, or did it gradually fade away slowly into irrelevance over many years?

4. **Chris Oakley**
May 17, 2006

In this case, Lubie’s junk is also my junk.

Q: Why did the chicken cross the road?

Anthropic answer: In the other 10^500-1 universes it did not, but we happen to live in the universe where it did, even though we have no idea why.

5. **Thomas Love**
May 17, 2006

JC asked when ether theory went out of favor. Basically when Einstein introduce SR. But Einstein himself reintroduced the ether in GR. Read “Einstein and the Ether” from Aperion Pub.

The ether is still being worked on actively, especially in Russia and China.

6. **lmot**
May 17, 2006

Actually Chris, that’s not the Anthropic principle, it’s the closely related Pouletropic principle. It subject of an upcoming paper by Dimopoulos and Arkani-Hamed that purports to solve the chicken-egg paradox.

7. **MathPhys**
May 17, 2006

Peter,

One can argue that the first glimpse of the landscape is in Narain continuous infinity of heterotic string compactifications.

When was Narain’s paper? 1985? 1986? That is definitely before Schellekens paper.

Narain does not talk about a landscape, but it was very clear (at least to me) that there were infinitely many string theories in 4 dimensions.

8. **Thomas Love**
May 17, 2006

I should have left an example:

http://redshift.vif.com/JournalFiles/V13NO2PDF/V13N2DMI.pdf

9. **woit**
May 17, 2006

Please, no more about current theories of the aether. The landscape is depressing enough.

10. **rof**
May 17, 2006

The chicken-egg “paradox” ways always trivial to solve. The egg came first. Dinosaurs laid eggs.

11. **LDM**
May 17, 2006

Lubus: I would hope you have enough knowledge of PHYSICS to realize your statement: “Today, all of us – except for those in loop quantum gravity – know that the aether is a silliness that is not realized physically and that was never well motivated” is just nonsense.

If , as in those days, you believed in Maxwell and the wave equation, it was a VERY well motivated question to ask ‘what is it that is waving’ when light waves (not photons) propagate.

Einstein realized that in General Relativity, the notion of an aether was perhaps not so simple and not so easily dismissed.

But, out repect for Woit’s request for no more aether discussion, you will have to excercise your own initiative to discover what Einstein thought in that regard.

12. **priority**
May 18, 2006

dear Schellekens, Woit and Susskind,

I realized that string theory is useless when I was a student. My priority is clearly proofed by the fact that I do not have any stringy publication, not even a blog.

13. **Thomas Larsson**
May 18, 2006

    The Michelson-Morley experiment was performed in 1887, and Einstein formulated SR in 1905. However, H A Lorentz kept believing in the aether long after that.

    Even if LHC becomes the Michelson-Morley experiment of supersymmetry, many people will continue to believe in SUSY and strings for the rest of their lives. (Note: a real prediction 🙂)

14. **The Great Landscaper**
May 18, 2006

    Lubos: your agreement with Woit denotes deviationism. In order to save you from becoming the Gorbachev of String Theory, you are transferred from Harvard. Your next position will be in Kolyma, Siberia.

15. **Lubos Motl**
May 18, 2006

    LDM: "If, as in those days, you believed in Maxwell and the wave equation, it was a VERY well motivated question to ask 'what is it that is waving' when light waves (not photons) propagate."

    Dear LDM,

    my feeling is that I have explained rather clearly something that everyone in the field knows anyway – that the question "what is waving" was NEVER motivated and only the people who misunderstand not only relativity but also the rudimentary philosophy of physics can say otherwise in 2006.

    The aether is a gigantic hoax, nonsense, and it has always been one. The only positive thing about the aether is that some of the people who believed it in the 19th century have also done some extremely serious physics, unlike most of their followers in the 20th and 21st century.

    The reality of Nature is encoded in the set of mathematical equations – Maxwell's equations in this case – and they are the full story. Naive mechanistic ways to imagine "what is waving" should only be created for children in the kindergarden or other people who have some intellectual limitations that prevent them from understanding that equations themselves can be and are fundamental and that fields can live in empty vacuum. Yes, there are gummi bears everywhere that are waving. The gummi bears must be there because some kids can't live without them.

    Adult physicists should be able to live without gummi bears. The electric and magnetic vectors exist directly at each point of vacuum, without any substrate, and it must be so, otherwise the basic postulates of special relativity would be compromised.

    Dear Landscaper, your landscape is far from being the only reason why I plan something along your lines.

    All the best
    Lubos

16. **Bert Schroer**
May 18, 2006

    What about the return of the aether in the veil of a "noncommutative" selection of a particular spacetime reference frame?

17. **urs**
May 18, 2006

    A simple change of terminology can affect the way we think about one and the same issue.

    The term "space of CFTs (with certain properties)" hardly induces the same passion as "landscape of vacua (with certain properties)" does, does it?

    At some point it would be great if we really knew what the "space of CFTs" actually is.

    For the baby example of rational CFTs we sort of do.

    Choosing deliberately unusual terminology we can reformulate a well known result as follows.

    The landscape of rational CFTs is the category of lax functors from quivers into modular tensor categories.

18. **woit**
May 18, 2006

    Any more of this and I put the word "aether" in the kill-file that will automatically delete any comment containing this word…

19. **woit**
May 18, 2006

    Urs,
    Mystifying with obscure mathematical terminology the fact that string theory has failed as an idea about unification because it is compatible with anything is not going to improve the situation.

20. **Lubos Motl**
May 18, 2006

    Dear Bert,

    the noncommutative parameter may break the Lorentz symmetry, like aether. It also breaks the rotational symmetry, unlike aether. Noncommutativity carries no entropy, unlike aether. It has no nontrivial microscopic structure, unlike aether. A noncommutative parameter may be viewed as a spontaneous symmetry violation in a theory that preserves the symmetry – and the original theory already carries all the excitations, unlike the space without aether.

To summarize: noncommutativity is not aether.

Let me be more general about the unmotivated ideas that can be classified as sick philosophical preconceptions. Take the sound and light. Sound is made of waves in the air. Is it natural to expect the same thing from light?

The answer is No. We only conjectured that there was a material that is waving – whenever there is sound – because we wanted to be able to:

* explain that sound can have different speed and other properties in different environments and different inertial frames; the extra material whose properties can change helps

* unify sound with some previous physical theories that rely on the concept of the air, such as the theory of breathing and the theory of winds 😉

Neither of these motivations existed in the case of light. Light has the same properties in each point of vacuum, and as one can figure out by analyzing Maxwell's equations, it has also the same properties in all inertial reference frames.

The second point is not applicable either because there is no other experimental reason to think that there exists something such as the aether; for example, there is no aether wind. To summarize, the aether does not explain anything and it violates the knowledge of physics at the end of 19th century. It was never motivated. It was always a philosophical dogma – a stupidity.

Something that Einstein realized pretty well which allowed him to overcome the limitations of other physicists of his time and the limitations of crackpots.

The same thing holds for dozens of other fantasies that billions of people believe for purely irrational reasons. For example, hidden variables. Much like the case of the aether, there are absolutely no indications that the correct predictions need some extra garbage (hidden variables) or that they depend on some additional assumptions that could depend on the position in space. Quantum mechanics works the same way in the whole Universe.

In both cases, we have some obviously universal laws – Maxwell's equations with the principle of relativity and the probabilistic character of physical predictions – that seem to hold in the same Universe. This always strongly indicated, to any rational person, that it was a very bad idea to try to find a more "microscopic mechanism" for these phenomena. Any new structure that one adds beneath these systems – Maxwell's equations or the probabilistic structure of quantum mechanics – will ruin the universal validity of these laws.

Of course, today we have much more specific ways to prove that hidden variables can't exist (unless we want to believe that locality is just a gigantic cosmic hoax and unexplainable conspiracy) – but the previous paragraph was meant to settle down the fact that aether or hidden variables were never motivated by scientific arguments – they were always stupid dogmas of philosophers who wanted to impose their naive ideas on Nature.

But she can make fun out of all people, not just the simpletons. It is scientists' task to listen to Her and see how She really looks like.

Best wishes
Lubos

21. **Lubos Motl**
May 18, 2006

Dear Peter Woit,

you have been saying these stupidities about the hypothetical "problems" in string theory for more than 20 years. You have been predicting that theoretical physics can be done without string theory for more than 20 years. Is not it time for you to admit that your predictions – and not only predictions, for that matter – have been a gigantic failure? How many more years do you need to see that what you keep on writing is just a pile of idiocies and that string theory is absolutely essential for any conceptual theoretical physics beyond the framework of quantum field theory? A century? A millenium?

Best wishes
Lubos

22. **woit**
May 18, 2006

Lubos,

Quite the opposite of what you say, I find more and more people all the time agreeing with my point of view about the problems of string theory and its failure as an idea about unification. My predictions about this failure made many years ago are in the process of coming true and being widely recognized.

23. **urs**
May 18, 2006

> Mystifying with obscure mathematical terminology the fact that string theory has failed as an idea about unification because it is compatible with anything is not going to improve the situation.

In contrast, the mystification is due to the fact that nobody really knows what the space of all CFTs is like in detail.

That's different for the rational case, and there what looks like obscure mathematical terminology to people unfamiliar with it is actually the lingua franca which makes things transparent.

24. **Thomas Love**
May 18, 2006

Sorry, but I must use the verboten word one last time. String theory has a very strong resemblance to the 19th century theory of vortex filaments in the e….

25. **Bert Schroer**
May 18, 2006

The descending back into chiral QFT (that is what Urs probably means by conformal QFT) does not give any autonomous support of the metaphorical interpretation of string theoretical target space. It is however true that the adaptation of the old Nelson-Symanzik duality to the chiral realm permits to demonstrate the existence of a temperature duality relation between a chiral thermal theory and its dual (which is also a thermal chiral theory of the same kind) of which the Verlinde relations are a special case (thermal duality of the zero-point function). Whereas in the case of Nelson-Symanzik the rigorous framework for duality was the Osterwalder-Schrader Euclideanization, the chiral situation (as a consequence of braid group statistics) requires a new more noncommutative Euclideanization (done in the setting of Tomita-

Takesaki modular operator theory). In this case one can even show that the temperature spacetime permits a spacetime interpretation (but not that in terms of a torus as a living space of a chiral theory, that remains metaphorical).
None of these new deep insights gives any support for the target space interpretation in string theory (basically because string theory only inherits those vacuum fluctuations from the lower dimensional source theory and has no autonomous target vacuum fluctuations). And this, Urs, is precisely the reason why string theory appears so metaphoric and eerie to your QFT colleagues (and to me) at the University of Hamburg.

26. **fh**
May 18, 2006

"string theory is absolutely essential for any conceptual theoretical physics beyond the framework of quantum field theory"

-LM

Whether or not it will be essential remains to be seen, as for now LQG provides an example of a (mathematically) well defined construction of alternative QFTs that in certain simple cases have been shown to be a generalization of flat spacetime QFT.

Whether or not you believe these extensions to be physically relevant is one thing, but it's simply incorrect that String theory is the only known way to go beyonf QFT. It's certainly the most advanced and has revealed the richest structures, but it's not the only option anymore.

27. **Bert Schroer**
May 18, 2006

To Lubos,
thanks for this nice semantic attempt.

28. **Lubos Motl**
May 18, 2006

Dear Peter,

you find more and more people because your blog attracts crackpots and people with serious intellectual limitations. There are roughly 4 billion people in the world who have no chance to comprehend anything that goes beyond classical physics. You're finding an increasing percentage of these 4 billion limited people because you are falling deeply in between average peasants in Namibia yourself. The more you will be falling, the more counterparts you will be meeting.

But that's not the community I am talking about.

I am reporting about real physics as done now in 2006, with which you have almost absolutely nothing to do. It is now clear that string theory as a framework is the only way how to transcend the limitations of GR and quantum field theories. Informed people know it, ignorants don't. Of course that the number of ignorants in the world exceeds the number of informed people, much like in the case of Darwin's evolution which – as you should already know by now – is completely analogous to string theory, but science is not democracy. Evolution and string theory are "must" despite billions of people who find the theories troubling.

Physicists who matter don't waste time with you and people who agree with you. Only I do because I was born into an even more ordinary anti-academic environment, compared to which you are relatively informed in theoretical physics, which is why I have the natural temptation to communicate these things because I am indeed troubled by the gap between actual science and what regular people think about it.

My goal was always to make not just myself but also everyone else to be more able to understand the right thinking that is necessary for science and that normally distinguishes scientists from laymen. Your goal has always been the opposite one: to confirm laymen that they're not missing anything and they should not learn anything, and even to transform relatively intelligent people into hopeless laymen who can't comprehend even things as elementary as the fact that quantum gravity can't be done without string theory.

Best
Lubos

29. **Dick Thompson**
May 18, 2006

****
the 10^80 vacua that, uniformly distributed, could cover all possible values of the standard model parameters to the accuracy that we can measure them.
****

Is this a recent way of expressing the problem? Can anyone give an online cite for it? Thanks.

30. **woit**
May 18, 2006

Lubos,

My blog isn't at all aimed at laymen, and I suspect a much smaller fraction of its readership is laymen than yours. The majority of connections to it come from academic machines with names like *.physics.wellknowninstitution.edu, often with "string" somewhere in the wild-card. The people who are reading it and sometimes agreeing, sometimes not, are your colleagues at Harvard, MIT, BU, Brandeis, etc., etc.

Virtually nobody in the physics community except you and a few other fanatics thinks that string theory and the theory of evolution are analogous.

Dick,

The number comes from Schellekens article, quoting Douglas, and it's probably in one of his landscape papers. It's a rough estimate, just taking all the parameters of the standard model and looking at the accuracy to which they are known.

31. **Krotos**
May 18, 2006

——-
"you find more and more people because your blog attracts crackpots and people with serious intellectual limitations. ——-
Is this what passes for scientific discourse in the string theory community?

Glad I stayed in astrophysics.

32. **Johan Richter**
May 18, 2006

While I can not evaluate your general criticism of string theory,I think you are absolututely right to call the "anthropic" idea pseudo-science, Peter.

What percentage of string theorists do estimate share your and Lubos' view on that matter? Part of the problem seams to be that some legitimate science is also called "antropic". For example Weinbergs "prediction" of the CC seams to be legitimate science to me (as an uninformed layman), but as an empirical measurement and not as a theoretical prediction.

33. **Lubos Motl**
May 18, 2006

It's ridiculous that you have a higher percentage of academic physics readers. Last 100 visits (domains) from the last 80 minutes follow.

34. **woit**
May 18, 2006

Johan,

Based on anecdotal data and public votes at Strings 2005, I'd guess that older, more established string theorists split 50/50 pro and anti anthropic landscape, while younger people starting out are 4-5 to 1 against the landscape.

My take on the difference is that older string theorists who have worked on this for a while realize that there is no way to get a unique answer out of string theory, have given up on this, and realize that string theory implies the landscape and they have to accept it. Younger people who have swallowed lots of propaganda and not had enough time to learn just how bad the situation is, are still more optimistic about evading the landscape.

35. **Sam**
May 18, 2006

Schroer says:

"The descending back into chiral QFT (that is what Urs probably means by conformal QFT)"

No, Urs meant CONFORMAL QFT, specifically, rational conformal QFT.

"And this, Urs, is precisely the reason why string theory appears so metaphoric and eerie…"

Ooooooooh! Scary!

Oooooooooooh. Make it go away!

36. **Lubos Motl**
May 18, 2006

Dear Peter,

there exists no background for your unusual statements about the generation gap. But even if there were any generation gap like this, it's not terribly important. There have been many generation gaps in the past – and incidentally the younger generation was right in many cases, in sharp contradiction with your silly suggestion that the more old or senile someone is, the more likely is she to be right.

What's more important is that Nature is whatever She is. If a careful analysis of the physical laws implies that certain phenomena have a unique and deep justification, then we have to accept such a justification. If a careful analysis of Nature leads to the insight that some things in the Universe are essentially random, then they're random, and the opinion of Peter Woit and hundreds of those readers who can be counted as limited simply can't change this fact.

The only framework how we can ask these deep questions scientifically is the framework of string theory and everyone who knows something about insights of theoretical physics of the last 30 years, instead of just being brainwashed by low-brow weblogs of science-haters, realizes it very well.

This is the basic point about science that you are apparently uncapable to realize. You can't order Nature to look the way you would like. If you don't like quantum mechanics or string theory, it's your problem. If you really hate the idea that the world according to everything we can say follows these laws, that's too bad. Try to move into another Universe.

Best
Lubos

37. **urs**
May 18, 2006

> The descending back into chiral QFT (that is what Urs probably means by conformal QFT) does not give any autonomous support of the metaphorical interpretation of string theoretical target space

I mean full 2D CFT.

The landscape is nothing but the space of all 2D CFTs (with certain properties). This space is not well understood in detail. Except in the rational case. There we have a powerful theorem that tells us precisely what this space really is.

Concerning metaphorics: Target space is indeed metaphoric, in some sense, in perturbative string theory.

String Field Theory is an attempt to formulate the theory on target space. Some day people might find out how to rigorously formulate quantum SFT. Maybe. Currently all work in SFT is classical. (It's "first quantized", but classical at the "second quantized" level.)

When you demand rigorously constructed theories, string field theory does not exist for practical purposes.

But this is not what the discussion here is about. The discussion here is about the idea that correlators in certain CFTs are a "good" approximation to certain scattering amplitudes. (That's the premise of perturbative string theory – be that right or wrong).

38. **Bert Schroer**
May 18, 2006

These days the extremely special case of 2-dim. conformal QFT (and its two chiral components) is often called conformal QFT which leads to confusione with higher dimensional conformal QFT. Whereas it is true that one knows less about higher dimensional conformal QFT, it is in no way less important/interesting.
The Maldacena conjecture starts with a alleged 4-dim. conformal QFT (to be more precise beta=0, which is the prerequisite (necessary, but not sufficient) for CQFT). There are by now convincing arguments that the landscape (the old fashioned meaning) of higher-dimensional QFT is at least as rich as that for 2.dim. (Todorov, Rehren, Nicolov…) and of course each one of those models has an interesting AdS counterpart. The correct reading of Maldacenas conjecture is not that SuSyYM has a AdS encoding, since there is a structural theorem that this is the property of any CQFT. The sociological anomaly which lead to those thousands of papers is that he specifically claims that that rather simple encoding has anything to do with gravity.
Sam, I am not holding you back to feel cozy with string theory but there are people who know a lot more than you who do not share your feelings.

39. **Lubos Motl**
May 18, 2006

Dear Bert,

whoever claims to be a theoretical physicist in 2006 and who simultaneously believes that conformal field theories are not related to gravity in anti de Sitter space is a crackpot, and thousands of laymen who try to pretend that he's not a crackpot can't change the fact that he is a crackpot.

http://www.slac.stanford.edu/spires/find/hep?c=00203,2,231

Could you also find a technical problem with any of the 4000 papers that show that your idea is an undefendable one? Or do you realize that your "arguments" are only good for listeners who have no idea about physics?

Best wishes
Lubos

40. **Bert Schroer**
May 18, 2006

Urs
using your terminology "space", the space of any QFT is not understood, and among all such non-understood spaces (I would prefer the word models) the one of the 2-dim. CQFT setting is relatively well understood.
Let me also say that I appreciate your honest and on the whole correct answer.
But I honestly do not understand to which scattering amplitudes you are referring to (probably not those which Veneziano tried to understand with his dual model and which were abandoned by phenomenologists when it contradicted the data).

41. **Juan R.**
May 18, 2006

Lubos motl said,

“It is now clear that string theory as a framework is the only way how to transcend the limitations of GR and quantum field theories.”

That is partially true! In physics, string theory is so boring and ineffective that even cannot offer results offered from GR and QFT. In fact, string theory is useless for physical predictions. Moreover, it “predicts” tons of unobserved properties for Universe and is based in “many” incorrect technical points.

Where string theory goes beyond GR and QFT, in no doubt, is in marketing purposes, positions in academia, best-sellers for public, TV, interviews, grants…

String theory is also very useful in exoteric fields: multidimensions, aliens, time travelling, exotic brain behavior, telekinese, multiuniverses, God…

The contributions to marketing and exoteric fields is inversely proportional to contributions of string theory to real physics.

It is a kind of duality 😉

Juan R.

May 18, 2006

Dear Lubos,
I am a healthy sinner against the metaphorical messianic way in which you defend your beliefs.

43. **woit**
May 18, 2006

Lubos,

Yes, from your data, I do have a higher percentage of academic readers. During the last 80 minutes, they have come from three different machines in physics.harvard.edu, so my readers this hour include two of your colleagues.

The whole list is too long to include here, but the past 80 minutes include connections from (besides the harvard ones, and often there are multiple machines connecting from some of these domains)

Urs: "The landscape is nothing but the space of all 2D CFTs (with certain properties). This space is not well understood in detail. Except in the rational case. There we have a powerful theorem that tells us precisely what this space really is."

That's exactly off the point – this is how CFT people like you see the world 😉 The landscape is more than CFT (= perturbative string theory), because it encompasses also non-perturbative vacua, for which there is no world-sheet definition at all. For example, F-theory vacua form a very large class of vacua; those are intrinsically non-perturbative as the coupling constant varies over the internal space; I wouldn't know of any world-sheet like formulation! Similar for M-theory.

On the other hand, vacua based on completely different world-sheet theories (like heterotic, type II and type I strings), can give identical space-time theories… so in order to understand the nature of the landscape of string vacua (should it exist at all non-perturbatively), it is essential to step beyond string perturbation theory (=CFT) and especially rational CFT!

45. **Lubos Motl**
May 18, 2006

No, Peter, you can't prove anything about the percentage by choosing the academic connections only. What you're doing is not science.

Even in absolute terms, I have more visitors in the category in the last 80 minutes than you have.

My list only includes the first unique visitors per day. Here are those added in the last 60 minutes to the previous list. Also, if you look carefully at the lists, you will see that I got more harvard.edu visitors (5) in the same period, despite the fact that my counter only counts the first visitors per day.

46. **Bert Schroer**
May 18, 2006

The insinuation I intended with my remark about the missing autonomous vacuum polarization was among other things to blame those string vacua which do not communicate on this crucial but unfortunately missing property (with other words this is the limit of the metaphor).

47. **Lubos Motl**
May 18, 2006

Dear MoveOn,

I agree with you. There are many points in the configuration space of string theory that can't be uniquely reached from a perturbative description – from a 2D CFT. In this sense, the perturbative string theories described by CFT are just 5/6 of the boundary of the landscape, while the bulk of the landscape contains extra points. The fraction 5/6 is meant to convey the fact that M-theory with 11 large dimensions may be viewed as a boundary of the moduli space that has no description in terms of strings.

From the text above, one can argue that even if you include M-theory and F-theory vacua, you don't quite have the full "bulk" of the configuration space of the theory – all these things are just ways to approach the bulk from a kind of "boundary". The bulk contains points where all perturbative expansions are strongly coupled, the space is non-geometric, Planck/string-sized, and so on.

Best wishes
Lubos

48. **Anon-e-mus**
May 18, 2006

Great list, Lubos, but my **ck is still twice as long as yours! Get a life, kids. There are better things to argue about than “whose readers have bigger brains”.

49. **urs**
May 18, 2006

> The landscape is more than CFT (= perturbative string theory), because it encompasses also non-perturbative vacua, for which there is no world-sheet definition at all.

True. But that’s even less well understood.

(For sure, I wish I better understood it…)

One of the points I tried to make is that everybody is getting heated about the “landscape”, while its true nature is pretty elusive.

For instance, correct me if I am wrong, but isn’t it true that the tadpole cancellation conditions that are routinely checked in order to see if a background is consistent only guarantee a consistent effective field theory, not necessarily a consistent full worldsheet CFT with that target?

> it is essential to step beyond string perturbation theory (=CFT) and especially rational CFT!

No doubt. On the other hand, for doing the next step it is always helpful to have fully understood the previous one. The joy of toy examples, you know.

To be more precise, given that a full 2D TFT is the same thing as a Frobenius algebra in Vect, and given that full rational CFT is the same as a Frobenius algebra internal to a modular tensor category, it is not too daring to extrapolate and guess that, in the end, general full 2D CFT will be found to be the same as Frobenius algebras internal to something still a little more sophisticated.

50. **urs**
May 18, 2006

> using your terminology “space”, the space of any QFT is not understood,

For rational 2D CFT you should assume that space to have discrete topology, if that’s what you are alluding to. The deformation of any rational 2D CFT is non-rational, so all points in the “landscape of rational 2D CFTs” are isolated.

And we do understand what the nature of this space is like. Which of course does not mean we know precisely how to navigate it.

> But I honestly do not understand to which scattering amplitudes you are referring to (probably not those which Veneziano tried to understand with his dual model and which were abandoned by phenomenologists when it contradicted the data).

The basic premise of perturbative string theory is that you compute the scattering amplitude for incoming particles a,b,c and outgoing particles c,d,e by computing CFT correlators with insertions being some states corresponding to a,b,c and c,d,e. That’s what I mean.

51. **Bert Schroer**
May 18, 2006

Urs, but to call something an S-matrix, the least it has to deliver is the validity of cluster properties. Heisenberg’s 1943 proposal failed exactly on this point, the multi-particle scattering amplitudes from his S-operator model did not fulfill the asymptotic multiparticle cluster factorization. Any S-matrix, independent of whether it comes from QFT, string theory or any other physically interpretable particle physics theory, must fulfill this property. For the S-matrices coming from QFT it is easy to see that this property holds.
The other day I was asking for a proof in the setting of string theory and got no answer. Can you give me an answer?

52. **Mentos**
May 18, 2006

“The other day I was asking for a proof in the setting of string theory and got no answer.”

You got an answer. You just didn’t like it.

The tree level N-particle S-matrix has only simple poles, whose residues are given by products of lower-point tree level S-matrices. At loops, you start getting cuts, and unstable resonances develop finite widths. And, again, in appropriate limits, the g-loop S-matrices factorize onto lower-point (and lower-loop) S-matrices.

All of these reproduce precisely the required analytic properties of the perturbative N-particle S-matrix. And they follow from axiomatic properties of 2D CFT (+ BRST invariance and the Frenkel-Garland-Zuckerman version of the No-Ghost Theorem).

If you find those arguments unsatisfactory, you have a simple opportunity to DISPROVE string theory by finding a counterexample. Compute, say, the 1-loop bosonic string N-particle S-matrix element for some process and show that it fails to have the required properties.

Since you seem to know so much about the subject, that should be easy for you …

And your “insinuation … about the missing autonomous vacuum polarization” makes as little sense now as it did then.

53. **Bert Schroer**
May 18, 2006

Mentos,
the one-particle structure (residua of poles) are related to the Stueckelberg causal rescattering and I appreciate your remark that there are at least some indications for this kind of timelike macrocausality (no timelike pre-cursors). But it is not addressing the cluster factorisation. And believe me I do not plan any sinister attack on string

theory, I genuinely want to know.
Concerning the lack of communication between the different string vacua, I made a suggestion (which, if I would work on string theory I probably could prove, it should not be too difficult to understand the consequences of the absence of direct target vacuum polarizations). But I just do not have enough physical confidence in order to work on problems on which string theorists failed to do their homework. Do you have an argument why against all physical intuition one acquired in particle physics this is so?
And let me add, I do not quite share Peter's belief that the present crisis can be all blamed on string theory; the latter is rather the most visible sign of a degeneration process in particle physics and a fundamental critique of the present situation must include those developments which prepared the fertile ground for the reception of string theory.

54. **Mentos**
May 18, 2006

"But it is not addressing the cluster factorisation."

Aside from the analyticity, crossing, and factorization properties, what property of the S-matrix are you worried about?

"Concerning the lack of communication between the different string vacua,…"

I'm not sure what you mean by that. One of the things KKLT did was estimate the tunnelling rate between the metastable de Sitter vacua they found. They required (among other things) that the lifetime be comparable to or longer than the age of the universe.

For stable (supersymmetric) string vacua, there is, of course, no tunnelling.

But we don't have to go to string theory to see that you seem to have some confusion on this point.

Consider Seiberg-Witten theory: N=2 supersymmetric SU(2) Yang Mills Theory. This theory has a 1-complex dimensional moduli space of vacua. Is there "communication between the different vacua" in that theory? And, if not, what does that have to do with vacuum polarization?

Now turn on a mass for the adjoint chiral multiplet, breaking N=2 supersymmetry down to N=1. Whereas, formerly, there was a continuous infinity of vacua, now there are just two isolated vacua. Is there "communication between the two vacua" in that theory? And, if not, what does that have to do with vacuum polarization?

55. **Johan Richter**
May 18, 2006

One thing I have been wondering about is how much the average string theorist knows about the competeing alternatives. How many have themselves determined that string theory is the most promising approach and how many have simply trusted others opion?

56. **Bert Schroer**
May 18, 2006

O.K. Mentos,
I think the clustering of the string S-matrix can be achieved by definition. You simply use those pictures of those tubes and define disconnected amplitudes. There is still the problem to show that what you interpret the connected part really goes to zero when the wave packets of the particles become asymptotically spacelike separated. This is indeed a analytic property and what you say about tree diagrams has at least a certain plausibility.
Heisenberg's S-matrix models where given by a closed operator expression (the exponential of i times an hermitian operator which was a finite power series in free fields). In that case the cluster factorization failed (and probably cannot be obtaines by any such finite series). Lets hope that this will be argued in some future book on string theory but let us not come back to it in this blog.
Concerning the question of vacuum degeneracy you raised, I have no problem of understanding this issue in connection with spontaneaous symmetry breaking. In that case the theory can be decomposed so that the vacuum is unique and all the irreducible components are identical physical theories, i.e. if you have seen one you know them all. The case of the Schwinger-Higgs breaking which may lead to the Theta vacua is similar. In fact whenever you have several translation invariant states (vacua) you can without loss of generality reduce the situation to a theory with a unique vacuum. Is that what you mean "moduli"? This seems to be an expression which comes from a geometrical metaphoric picture of QFT to which I have no intrinsic access. Is there any way to understand this in QFT concepts without referring to big names?

57. **Mentos**
May 18, 2006

"Concerning the question of vacuum degeneracy you raised, I have no problem of understanding this issue in connection with spontaneaous symmetry breaking."

No.

In the Seiberg-Witten example, the different vacua corresponding to different points in the u-plane are inequivalent. This is not like spontaneous symmetry-breaking, where all of the vacua lead to equivalent physics.

"Is there any way to understand this in QFT concepts without referring to big names?"

You could start by reading their paper, where they solve the low-energy dynamics of this QFT. Or one of the many good reviews on the subject (which, of course, has many generalizations to other gauge groups and the addition of matter hypermultiplets in various representations of the gauge group).

58. **LDM**
May 18, 2006

Lubos:
Most of us are also familiar with the view you have expressed (Feynman was a proponent, maybe you got it from him, I don't know) that the mathematics — or the equations — are the full story. Einstein would probably not have believed this view.

Feynman also shares your disdain for hidden variables. (cf. Vol 3, Feynman Lectures, page 1-10 "Suppose we were to assume that inside the electron, there is some kind of machinary that determines where it is going to end up" etc)

However, you better be pretty sure that Feynman (or whoever it was you read or heard these ideas from) is actually right before you subscribe such absolute certaintity to these views, or as a scientitst, you may find that you miss out on some very interesting possible theories…just because you stopped looking deeper.

T' Hooft just 2 weeks ago published a very elegant hidden variable theory :
http://www.arxiv.org/quant-ph/0604008

Perhaps you can explain to T' Hooft that he is a crackpot…
Anyway Lubos, you will never become a physicist until you start to think for yourself.

59. **Bert Schroer**
May 18, 2006

Before I retire for today one last question which originates in Urs's claims.
On classyifying 2-dim QFT one certainly can have different settings. My favorite one is the theorem (Guido-Longo-Wiesbrock math-ph/9703129) that the physical classification of chiral conformal QFT (including the localizable "meat" and not just the topological "bones" and also not only the rational ones) is "isomorphic to the isomorphism classes of standard modular inclusions" (modular in the sense of Tomita-Takesaki modular theory and not in the sense of modular forms), the latter being a clealy defined mathematical problem.
Your Frobenius algebra classification may achieve the same thing. But I fail to see any indication of a unifying universal "space". Are you thinking of an analogon of a regular representation for compact groups? What brings an expert of classification of chiral theories to believing in the existence of such a universal object? Please help me, I am completely lost.

60. **woit**
May 18, 2006

LDM,
Please discuss Lubos's views about things like hidden variables that have nothing to do with the posting with him over at his blog, not here.

61. **LDM**
May 18, 2006

Woit,

If one cannot have some reasonable freedom to discuss or intelligently pursue the ideas that are naturally part of a discussion or blog… because it is not exactly coincident with the original posting…well, it seems like an artificial restriction…but then again, it is your blog, and you can enforce any policies you like.

I will therefore honor your request and not be posting further on your site.

62. **anon**
May 18, 2006

Lubos has a hilarious account of a talk on the landscape by Vilenkin at Harvard.

Lubos:"Vilenkin said that by this single sentence, Nima has essentially scooped the speaker and presented the rest of the talk as Vilenkin planned it."

Vilenkin and Nima sound like two naked emperors flattering each other. "Nima, your new garments look so good on you". "Yours do too, Vilenkin"

63. **dan**
May 19, 2006

Peter, I am sympathetic to your concerns, that string theory suffers from problems, such as extracting predictions, and that too much of particle physics has been engrossed in this seemingly unpromising approach, but I am curious as to what research programs particle physicists and theoretical particle physics are pursuing that go beyond the standard model, but do not involve SUSY or string theory or higher dimensions, programs that are academic respectable, and not "crackpots". by "beyond the standard model" one example is what sort of unification do you prefer, as SUSY-string theory approach you reject, and other models, such as SU(5) which predict proton decay and magnetic monopoles, seemingly is contradicted by experiment and observation. other examples of going beyond the standard model might be predictions for high-energy physics, dark matter candidates, etc. do you think the graviton is a part of particle physics and if so, what are non-string methods of studying it?

64. **tsg**
May 19, 2006

"string theory is absolutely essential for any conceptual theoretical physics beyond the framework of quantum field theory"
"quantum gravity can't be done without string theory."

Lubos, can you post (or link to) some justification of these assertions — in terms that a typical physics grad student (not in high energy) could understand? Or is that impossible?

I don't have a dog in this fight, but so far in this discussion I haven't seen any justification for these claims — just the assertion that they're obvious.

65. **Aether**
May 19, 2006

To Thomas Larsson: LHC can kill more than supersymmetry; it can disproof the theoretical prejudice that the SM must be replaced by a theory that makes the Higgs mass naturally small. If LHC does so, some people will still study supersymetry, but no longer as a solution to the hierarchy problem.

Hopefully this will be faster than in the analogous case of the aether: one century ago there were no blogs ranting that ether dragging is not even wrong. (Sorry for having used the word aether)

66. **MathPhys**
May 19, 2006

I believe that W Taylor's attempts to extract information from the Landscape goes against the general picture that's very naturally emerging from string theory, namely that string theory makes no predictions at all.

67. **knotted string**
May 19, 2006

tsg,

Since Lubos can't or won't give a link to back up his assertion "quantum gravity can't be done without string theory," can I suggest he is referring to:

http://arxiv.org/abs/physics/0601218

Hope this is useful. 😉 Also, I want to say Peter is not trying to replace you with a crackpot, Lubos! He is just trying to stop you being one to save you wasting your life on pseudoscience. The same goes for other string theorists. 🙂

68. **anonymous**
May 19, 2006

tsg,

Jacques Distler wrote a nice post about the difficulties of quantum gravity a while back:

http://golem.ph.utexas.edu/~distler/blog/archives/000639.html

I'm not sure it meets your criterion "a typical physics grad student (not in high energy) could understand"; the requirement is that you at least understand the renormalization group.

The Reuter approach to QG, looking for a UV fixed point, makes sense from this point of view but is really difficult. I have no idea how LQG fits into this story.

69. **Mentos**
May 19, 2006

knotted string:

Somehow, I doubt Lubos was referring to a crackpot paper on the physics arxiv.

tsg:

Distler's post is better, and he has another one where he discusses Reuter et al (maybe the best hope for a quantum field theoretic approach to QG).

Bert Schroer wrote (in http://www.math.columbia.edu/~woit/wordpress/?p=392#comment-10888)

> Before I retire for today one last question which originates in Urs's claims.
>
> […]

From the way the question is stated it seems to me that there is some sort of misunderstanding involved.

The theorem I was referring to says that a full rational 2D CFT is the same thing as a special symmetric Frobenius algebra object internal to the representation category of a chiral vertex algebra.

The claim is that this is the complete solution of the problem of solving the sewing constraints, given any chiral algebra and the spaces of conformal blocks obtained from these.

So, to say that again, the "space of rational 2D CFTs" is precisely the space of Morita classes of algebras internal to modular tensor categories. Since every perturbation of rational theories leads to a
a non-rational theory all the points in this space are isolated.

Therefore, as long as we are not talking about moduli stacks of RCFTs, we can pretty much think "set" instead of "space" here.

I have a more detailed discussion of the FRS theorem here:

http://golem.ph.utexas.edu/string/archives/000813.html

71. **Lee Smolin**
May 19, 2006

Dear Peter,

If i can return this thread to its original subject, the earliest discussion of a crisis in predictibility from a vast proliferation of string vacua that I am aware of is in the conclusion of a 1986 paper by Strominger, in which he says, in part

"the class of supersymmetric superstring compactifications has been enormously enlarged…..it does not seem likely that [these] solutions……can be classified in the foreseeable future. … All predictive power seems to have been lost."

– A. Strominger, "Superstrings with Torsion," Nuclear Physics B, 274(2):253-284 (1986).

This is a highly cited paper, which makes it curious that its main conclusion was ignored.

As far as the concept and the term of a landscape of theories, to my knowledge, they originated in my papers in the 1990's on cosmological natural selection, and my 1997 book, Life of the Cosmos. For example gr-qc/9505022 and Classical and Quantum Gravity 9 (1992) 173-191. I do not take credit for the anthropic version, the whole point of my idea was to solve the crisis of too many string vacua that was apparent already then by inventing a falsifiable scenario that avioded the anthropic principle (which it was clear then could only lead to a dead end.) I chose the term "landscape" to allude to the well known biological term "fitness landscape" in order to make the point that the resolution of the crisis has to follow the methology used in biology-of being based on a mechanism that makes our universe a typical member of the ensemble- if it were to be testible scientifically. I find it bizzare that people have taken the term, and used it both without proper attribution and without recognition of its connotations- which were exactly to avoid the use of the anthropic argument.

Thanks,

Lee

72. **Thomas Larsson**
May 19, 2006

Two comments:

In an early discussion on sps, before that newsgroup effectively died, Wolfgang Lerche also seemed to claim anthropic credit for the Lerche-Lust-Schellenkens papers from around 1987.

I read a preprint by Schellenkens in the early 1990s, maybe on Leech or Nijmeier lattices, whose beginning I still remember (roughly): "It is clear that string theory contains all of mathematics. The only question is whether it also contains all of physics." Positively Motlerian.

73. **island**
May 19, 2006

> Lee Smolin said:
> I find it bizzare that people have taken the term, and used it both without proper attribution and without recognition of its connotations-which were exactly to avoid the use of the anthropic argument.

Didn't you know, Lee?… the landscape is now synonymous with the anthropic principle and has been ever since Lenny's book came out.

Lumo:
At any rate, I don't think that the originator of the anthropic idea has anything to be proud about…

Duh… that would be, Brandon Carter, after a bunch of respectable physicists independently came to a similar conclusion after running into the same brick wall that stops science dead in it's tracks to this day…

OHhhhhhhh… you meant the Stringy Anthropic Landscape Principle… Sorry, I forgot that you take string theory for granted without justification, like any good crackpot would.

~

Thankyou, Lee… I thought that I was going to burst…

74. **Bert Schroer**
May 19, 2006

It seems that these days the priority fights in particle physics are increasing in intensity the closer they are to trash-cans. Its pathetic!

75. **JC**
May 19, 2006

It would be interesting to see if there were other episodes in physics history, where there were heated priority fights over a "trash can".

76. **hack**
May 19, 2006

Funny, just before reading the above I was tossing around this image in my head of Susskind and Schellekens as two bums fighting over a cardboard box.

77. **JLM**
May 19, 2006

>Funny, just before reading the above I was tossing around this image in my head of Susskind and Schellekens as two bums fighting over a cardboard box.

Funny, really, that a bunch of people with little or no awareness or appreciation of his many contributions to physics (Kogut-Susskind fermions, technicolor, the Fischler-Susskind mechanism, black hole complementarity, the holographic principle, Matrix Theory, …) should be busying themselves making fun of Susskind.

Pretty much sums up everything wrong with so-called "physics blogs."

Lubos Motl wrote:

"Could you also find a technical problem with any of the 4000 papers that show that your idea is an undefendable one?"

Science is not a democracy, the laws of nature are not determined by popular vote.

79. **Not a Nobel Laureate**
May 19, 2006

These arguments about string theory are no different than the arguments of warring priest during the Reformation and Counter-Reformation.

With string theory I predict that we're seeing the birth of a new type of religion,
a meta-mathetical theology.

80. **Neubrain**
May 19, 2006

Lubos and Peter,

it's amusing how you both rush headfirst into infantile disputes about web statistics when about 99.95% of the web fares better than both of your sites combined. Seriously, how can you call yourselves scientists and willingly engage in these childish internet shenanigans? Have you no shame or common sense? Shouldn't you be spending your time more productively, like on your research? Do yourselves a favor and unplug your internet connection for like a week and see how much work you can get done. Who knows, you might even fix string theory or show that it has an ounce of predictive value.

81. **Mentos**
May 19, 2006

” ‘Could you also find a technical problem with any of the 4000 papers that show that your idea is an undefendable one?’
Science is not a democracy, the laws of nature determined by popular vote. ”

No, it’s not.

Nor does it amount to mere he said/she said.

Do you have a single rational argument why Maldacena/Witten/Gubser-Klebanov-Polyakov and all of the various people who have checked, rechecked, generalized and extended their calculations are wrong and Bert Schroer is right?

This isn’t about a head count. It’s about the results of detailed calculations (by a host of very smart people).

Why don’t you sit down with Berenstein, Maldacena and Nastase’s paper (for instance), and figure out where the flaw is. That might give a little bit more force to your argument.

82. **MoveOnOrStayBehind**
May 20, 2006

Mateos:
“Consider Seiberg-Witten theory: N=2 supersymmetric SU(2) Yang Mills Theory. This theory has a 1-complex dimensional moduli space of vacua. Is there “communication between the different vacua” in that theory?”
..

“Why don’t you sit down with Berenstein, Maldacena and Nastase’s paper (for instance), and figure out where the flaw is.”

The kind of people you try to argue against here would not accept SYM as well-defined theory to start with. They even do not consider QCD as a well-defined or meaningful theory. It is completely pointless to fight with them about string theory – they are against everything that has happened after their own PhD thesis in the 50’s. They use this silly anti-string club here as a platform to propagate their dislike of what they since ever failed to grasp.

Fortunately, no serious researcher cares about this; the Standard Model has been developed irrespective of all objections by constructive field theorists, a (incompletely understood) theory of quantum gravity has been discovered that has lead to deep and far-reaching insights in black holes, and that has lead to surprises such as the AdS/CFT Correspondence. While one sort of people waste their time agonizing why all of this must be wrong, others just sit down and do the hard work, trying to improve our understanding.

83. **Mentos**
May 20, 2006

“The kind of people you try to argue against here would not accept SYM as well-defined theory to start with. They even do not consider QCD as a well-defined or meaningful theory. It is completely pointless to fight with them about string theory – they are against everything that has happened after their own PhD thesis in the 50’s.”

Which lead one to wonder why Peter (who, otherwise, seems desperate to be taken seriously) is so eager to promote their cause.

84. **Thomas Larsson**
May 20, 2006

T’ Hooft just 2 weeks ago published a very elegant hidden variable theory :
http://www.arxiv.org/quant-ph/0604008

Perhaps you can explain to T’ Hooft that he is a crackpot…

LDM, ‘t Hooft is undoubtedly aware that his position on Planck-scale determinism is very controversial, and that anybody talking about hidden variables without being a Nobel laureate would immediately receive 10 crackpoints for
“9 .10 points for each claim that quantum mechanics is fundamentally misguided (without good evidence). .

I was first quite bemused about ‘t Hooft’s position, but then I realized that his motivation was to combine background independence with locality; this is a serious problem, because there are no local observables in conventional quantum gravity. This motivation makes a lot of sense to me, but I still think that ‘t Hooft is wrong. This is because there is another way to combine locality with diffeomorphism symmetry, which involves observer dependence and diff anomalies.

85. **Chris Oakley**
May 20, 2006

MoveOnOrStayBehind & Mentos,

You people are missing the point, perhaps deliberately. Neither Peter nor the majority of the “silly anti-string club” here are saying that Superstring theory should be abandoned. It is a possible approach. We just think that the effort expended on this quest is disproportionate to the results obtained and it is high time that more effort is devoted to alternatives rather than propping up this failed project. A bit more honesty from the Superstring community would help. If after more than 20 years of effort you cannot calculate cross sections then either (i) you should stop calling what you are doing physics or (ii) you should give it up. I doubt very much if Peter or the rest of us “silly” anti-stringers would have a problem with 10% of the current Superstring community carrying on on the basis of option (i), but to have almost all alternative strategies squeezed out of theoretical physics just because the majority are embarked on this Mission from some 10/11-dimensional God is not acceptable, and none of us are going to shut up about it until the balance is redressed in favour of that which looks more like empirical science.

The whole research process is much more haphazard than you people would like to believe. Whilst I cannot say that I would necessarily bet my life on Schroer’s algebraic field theory or Peter’s geometric quantization delivering the goods (any more than they would bet on my pet projects), I am happy for them to keep working on these and accept the possibility that one or other of them will be right and I wrong. I don’t feel threatened by them and I don’t feel that I have to subscribe to either of their approaches because of peer pressure. This is the way it should be, but then I am not in a position where I need anyone in the academic establishment to like me. For those that do need acceptance, the system at the moment is set up to force them to follow directions they do not necessarily want to go in just because of the unwholesome domination of one particular line of enquiry. This is not good for the subject.

86. **Not a Nobel Laureate**
May 20, 2006

” ‘Could you also find a technical problem with any of the 4000 papers that show that your idea is an undefendable one?’
Science is not a democracy, the laws of nature determined by popular vote. ”

No, it’s not.

Nor does it amount to mere he said/she said.

“Do you have a single rational argument why Maldacena/Witten/Gubser-Klebanov-Polyakov and all of the various people who have checked, rechecked, generalized and extended their calculations are wrong and Bert Schroer is right?”

Sure. Can you point to a single testable prediction about our physical universe to come out of “Maldacena/Witten/Gubser-Klebanov-Polyakov” et al. Otherwise it’s just a lot of mathematical masturbation by some (admittedly clever) people, but that’s all it is.

That the real problem and issue that physicists has with string meta-theory.

Not whether someone’s calcualtions are “right”.

Once again that level of discussion here brings Kissenger’s bon mot to mind.

“Why are academic debates so fierce, nasty and bitter?”
“Because the stakes are so low.”

87. **Not a Nobel Laureate**
May 20, 2006

“The kind of people you try to argue against here would not accept SYM as well-defined theory to start with. They even do not consider QCD as a well-defined or meaningful theory. It is completely pointless to fight with them about string theory – they are against everything that has happened after their own PhD thesis in the 50’s.”

This type of lame argument is know as the “straw man” argument – attributing statements and views/attributes to the other side that they did not make/have to begin with and then arguing against them.

The childness of the debate here, comparing the number and ID of IP addresses, the ad hominem personal attacks, etc. is symptomatic of how this field has degenerated in the absence of experimental data.

Despite the religious type claims by the string theorist that string meta-theory is the only possible way, the space all possible models is probably infinite and without experiments based in physical reality to kill off the incorrect models, the probability of any one approach is being right approaches 1/infinity.

Many of these approaches may lead to interesting math, but without testable predicitions, it’s not physics,
despite what any “authority figure” in the field may claim.

88. **Bert Schroer**
May 20, 2006

Mentos,
there is a deep misunderstanding on your part of the motives behind my critical remarks. I would be the first to uphold the right of Maldacena to write a speculative paper on an interesting subject; speculative freedom is an essential ingredients of theoretical physics.
What worries me is the apparent misunderstanding of thousands of his colleagues who completely ignore that
(a) there exists a general relation between CFT and AdS (a structural rigorous mathematical theorem of the kind you seem to be so afraid of, already in Fronsdal´s early work you find indications), it is a kind of different re-packing a la Christo of the same physical substance (if this helps to raise your awareness)
(b) there is absolutely no reason whatsoever to think that SUSY with beta=0 (the prerequisite for conformal invariance) is distinguished by its conformal invariance from infinitely many yet nameless other 4-dim. CQFTs; the conformal richness is not limited to low dimensions
These two points require to view Maldacena´s conjecture within a wider context since all conformal models possess a AdS re-packing and they are all potentially interesting. What I am saying is not new and can be found in the literature; but particle physics has been distorted by very unfortunate sociological developments and either people are not capable any more to see this or are afraid not to collect enough impact points if they are leaving the path of lemmings.
The most important ability of a theoretical physicist (totally different from a mathematician) is that he learns to live with halftruths in an imperfect world but without ever forgetting that the main aim is to make it more perfect.
Certainly when some mathematical physicist say that QED does not exist, this should not be interpreted naively. What it means is that our most successful theoretical Ansatz is not yet conceptually secured. The old Bohr-Sommerfeld QT was also quite successful, but just imagine what would have happened to physics if people would have been as complacent as they seem to be nowadays those which get into these semantic arguments with respect to those colleagues who point out that we (this includes QFT in its present state) live in a provisorial situation. In contrast to all other branches of physics which have been conceptually secured (e.g. by nontrivial examples), QFT and even more so string theory is still conceptually totally unsecured territory.
It was a blessing that the step from old to modern quantum mechanics took place within auch a short time; imagine the confusion it would have created und the many holy cows (like the above one) it would had led to, if several generation would have stepped on the old ideas and in this way solidified them?

89. **Benni**
May 20, 2006

Maybe Schellekens thinks of this paper here
http://ccdb4fs.kek.jp/cgi-bin/img/allpdf?198612321
Together with luest, written in 1986.
There, Luest who is now in Munich and Schellekens write

“It seems that not much is left from the celebrated uniqueness of String theory”.

The paper is from November 1986.

90. **wolfgang**
May 20, 2006

> We just think that the effort expended on this quest is disproportionate to the results obtained and it is high time that more effort is devoted to alternatives rather than propping up this failed project.

I never understood this argument.
Nobody prevents you, Peter, Lee, etc. to work on alternatives.
The internet even makes it zero cost to publish, promote and discuss such ideas and theories.
Do you suggest some sort of committee to determine who should work on what idea?

91. **Arun**
May 20, 2006

When significant professors allegedly say “string theory is the only game in town”, then, Wolfgang, what happens to the likelihood of a student to do something else? You may address this in either frequentist or Bayesian terms 🙂

92. **Bert Schroer**
May 20, 2006

No Wolfgang, things do not work in your simple-minded and probably honest way. Peter and other critical minds are too old and lack the stamina which you need to persue new innovative ideas. Their (and also my) accumulated insight and critical mind has left them with the necessary distance and enhanced power seeing through smoke screens and selfdilusions. It is a bit like the trainers in football, you probably would not suggest that they return as active players.
The people who (through distributions if impact credits) could have an influence on the present situation are the ones who are administering the present crisis e.g. in the editorial boards of new HEP journals and this is the best guaranty that particle physics will continue the same route for the next decades as it has done in the past two decades. If some novice has the intellectual capabilities and the courage to make a deep investment outside the prescribed line, he will pretty soon lose his material support; I have seen several such cases and I know what I am talking about.

93. **Mentos**
May 20, 2006

NaNL said:

“Sure. Can you point to a single testable prediction about our physical universe to come out of “Maldacena/Witten/Gubser-Klebanov-Polyakov” et al.”

One?

OK. How about the prediction (by Kovtun, Son and Starinets) that the ratio of shear viscosity to entropy density in the quark gluon plasma is 1/4pi (plus computable corrections). No other model, nor any known material substance has so low a ratio. But it’s in good agreement with what’s measured at RHIC.

There’s more (lots more) one could say about the importance of AdS/CFT. But you asked for ONE prediction. So that’s what I’ll give you.

Schroer said:

“These two points require to view Maldacena´s conjecture within a wider context since all conformal models possess a AdS re-packing and they are all potentially interesting.”

You’re joking, right? There’s a huge industry finding supergravity duals to other 4D field theories (both conformal and nonconformal).

But, as always, the dual of a 4D (C)QFT on the boundary is a gravitational theory in the bulk of AdS. The claim that one gets another (nongravitational) QFT in the bulk is just wrong.

“Certainly when some mathematical physicist say that QED does not exist, this should not be interpreted naively. What it means is that our most successful theoretical Ansatz is not yet conceptually secured.”

Not to anyone who has assimilated the lessons of Ken Wilson, Steve Weinberg and others.

It means that QED is an effective field theory, valid at low energies, but which must be replaced by some other, better-behaved effective theory at higher energies. (As, of course, happens in the real world.)

In another thread, you professed to take a Wilsonian attitude to QFT. But every off-hand comment of yours indicates that you really don’t believe the central lessons that Wilson taught us about QFT.

94. **Bert Schroer**
May 20, 2006

Mentos
I do believe the central lesson of Wilsonism but I do not think that he ever claimed to prove the existence of a consistent mathematical theory behind those ideas (existence of QED,…) and computations which come to our mind when we look intensly at a Euclidean action as a definition of a model. The word Wilsonian stands for me also for non-metaphoric and non messianic (i.e. far away from a final theory of everything), a meaning which you do not seem to share).
Concerning the various SUSY models I just counted them summarily as one (if you have seen one, you know them all). But if, as you seem to alledge, every of these expected infinitely many different families (which I had in mind) has also a corresponding gravity AdS (by that rather simple Christo-type of repacking, the only real nontrivial case which deserves the name holography is holography on Nullsurfaces) then I find this totally generic terminology “gravity” quite empty and uninteresting, despite the big names with which you all the time seem to try to create the feeling of awe.

95. **Mentos**
May 20, 2006

“then I find this totally generic terminology “gravity” quite empty and uninteresting,”

No, it’s the heart of the matter.

The most basic statement in the AdS/CFT correspondence is that, to every local operator in the boundary (C)QFT, there corresponds a field in the bulk AdS. Now, one of the hallmarks of QFT is the existence of a local, conserved stress tensor.

Can you guess what field that corresponds to in the bulk AdS theory?

“I do believe the central lesson of Wilsonism.”

Perhaps I should ask, “What lesson is that?”

96. **woit**
May 20, 2006

Wolfgang,

Sure, Lee and I can work on what we want to work on, but science is a collective enterprise, and it is far more difficult to make progress on a problem if you are the only one working on it.

There already are committees established that decide who should work on what idea. They're called hiring committees and I've sat on them. One of the main things hiring committees look at is the subject potential hires are working on: is it a "hot" subject the department wants to be a piece of? Many hiring committees are working with explicit guidance as to what ideas the person they will give a job to should be working on. I could go on about this, but for examples, you should consult Lee Smolin, who can give you numbers about how many academic institutions in the US over the last 20 years have been willing to even consider hiring somebody working on ideas about quantum gravity that are not string theory. I gather his forthcoming book has a lot more about this.

97. **wolfgang**
May 20, 2006

Prof. Schroer, Arun, Peter,

I guess we can agree on the following:
i) quite a substantial amount of effort and resources has been spent already on quantum gravity outside of string theory. It is safe to assume that this will continue. Just check the gr-qc section on the arXiv.
ii) If somebody wants to write a thesis about LQG, lattice gravity, or whatever he/she will not have a problem to find an advisor.
iii) There is certainly a difference in funding for string theory vs. other approaches, which is easily explained by the simple fact that string theory was and still is the most promising approach so far.

But none of this has anything to do with my point, which is that students, postdocs, professors etc. are free to explore whatever they want. I am sure each one of them will try to optimize his/her own risk/reward ratio. If you are a "low-risk person" use the main road (string theory), if you are a "longshot person" try causal sets, algebraic qft, LQG, etc.

98. **Bert Schroer**
May 20, 2006

Mentos,
I am sorry, but if such a simple re-packing (a change of the spacetime encoding of any algebraic substrate which was given in the conformal spacetime organization and which is being equipped with a different AdS one) as the one from an AdS to its asymptotic timelike brane (trivial because it keeps all the symmetries and modulo some simple amendments also the causal structure (which a holography onto a Null-horizon definitely does not maintain!!)) creates inexorably something which you generically call "gravity" then you have ruined the magic which many people still expect behind Maldacena, and I wash my hands free of guilt.
Wilsonism to me means that I do not have to know all the world (to the Planck length and beyond), rather I am able to make a conceptually closed theory in the present situation of QFT (and, if I am allowed to add this, also a mathematically controllable one) which is free of cutoffs and elementary length.

99. **Bert Schroer**
May 20, 2006

To Wolfgang,
on the whole I agree, but let me point out to you in all modesty that somebody (who collaborated with me) who has done the pioneering work on modular operator theory on which the ball of QFT got rolling again (and something you probably will notice in the near future) had no career chance against any second rate string theorists. Since you seem to be a string theorist, you probably only see those in the present light and not those in the dark.

100. **Mike**
May 20, 2006

This long discussion about the landscape further emphasizes a few points,

island Says:

" Lee Smolin said:
'I find it bizzare that people have taken the term, and used it both without proper attribution and without recognition of its connotations-which were exactly to avoid the use of the anthropic argument. '

Didn't you know, Lee?… the landscape is now synonymous with the anthropic principle and has been ever since Lenny's book came out."

Only a few years ago, this was posted:

The Beginning of the End of the Anthropic Principle

"We argue that if string theory as an approach to the fundamental laws of physics is correct, then there is almost no room for anthropic arguments in cosmology. The quark and lepton masses and interaction strengths are determined."

Gordon L. Kane, Malcolm J. Perry, Anna N. Zytkow
arxiv.org/abs/astro-ph/0001197

dan Says:

"Peter, I am sympathetic to your concerns, that string theory suffers from problems, such as extracting predictions, and that too much of particle physics has been engrossed in this seemingly unpromising approach, but I am curious as to what research programs particle physicists and theoretical particle physics are pursuing that go beyond the standard model, but do not involve SUSY or string theory or higher dimensions,"

I'm asking this question too, and some answers have been given,

Chris Oakley Says:
"Schroer's algebraic field theory or Peter's geometric quantization…"

BF theory has been mentioned before too,

And Mentos Says:
"QED is an effective field theory, valid at low energies, but which must be replaced by some other, better-behaved effective theory at higher energies."

An attempt to correct QED has also been made by new work with modified Maxwell equations.

While Pauli was the critic who said “Not even wrong”, he was also a leader in searching for new physics, and made contributions regardless of age.

101. **wolfgang**
May 20, 2006

Dear Prof. Schroer,

> Since you seem to be a string theorist

I am not.
Most of my effort was on lattice gravity and I am currently not an ‘active researcher’ 😎

102. **Lee Smolin**
May 20, 2006

Since Peter asked, let me just introduce some objectivity into the discussion about the consequences of choosing to work on an approach to quantum gravity apart from string theory. In the US now there is a single research group with more than one faculty member working on non-string quantum gravity; at Penn State it has one senior and two junior faculty. Apart from Penn State, and a single person who left Penn State and got a position largely on the basis of his work in another field, the last time there was a new faculty position in the US for someone working on a non-string approach to quantum gravity was 1990. There are at most 4-5 NSF funded postdocs now in the US that a non-string quantum gravity person might apply for. The situation is slightly better in Canada, Mexico, and a few European countries, but the situation is that there is no graduate student or postdoc-even the stars with widely read and admired single authored papers-who has an easy or assured career.

The situation would be vastly improved if there were open competition on the basis of quality, originality and promise for the large number of postdoc and faculty positions controlled by string theorists. But I am unaware of a single instance of a string theory group hiring a postdoc or faculty member in any other approach to quantum gravity, in spite of the fact that this has happened in reverse several times- because the ethic in non-string quantum gravity is to choose on the basis of quality and individual promise, whereas the string theorists seem uninterested in applicants who do not work in the mainstream of string theory.

As far as someone wanting to do a Ph.D. in non-string quantum gravity, there are many and indeed the number of applicants is increasing dramatically because of the visibility of recent important results. But there are very few places in the few groups around the world where this work is done. We literally turn away good applicants weekly who apply to our group. As a result, an increasing number of very promising students are doing PhDs in non-string quantum gravity on their own without the benefit of an advisor in the field.

The only advantage of this is that the few young people who persevere against these odds have visibly much more creativity, intellectual independence and courage than their counterparts in trendy, mainstream fields. So they do better science, and indeed young people are responsible for the bulk of the new results and ideas which have driven the fast rate of progress of recent years. So it is getting increasingly evident that their exclusion from consideration for the best positions cannot be justified on any objective scientific basis.

And yes, my forthcoming book is not an attack on string theory, it is an examination of how this kind of situation can develop, which hurts not just many of the best young researchers but the progress of science itself.

103. **wolfgang**
May 20, 2006

Lee,

I am certainly not up to date and probably misunderstood your comment about the ‘only one research group’ in the US.
Without Google’s help I can name at least three groups in the US,
around Raphael Sorkin at Syracuse, Herbert Hamber at Irvine and John Baez at UC Riverside. I am sure there are more … certainly in Europe.

As for “there is no graduate student or postdoc-even the stars with widely read and admired single authored papers-who has an easy or assured career.”
This is certainly true for all students and postdocs. I doubt that string theory guarantees a career …

104. **Aaron Bergman**
May 20, 2006

“I doubt that string theory guarantees a career …”

Heh.

105. **woit**
May 20, 2006

Wolfgang and Aaron,

You’re not addressing what Lee wrote. He wasn’t discussing generic students or postdocs, but the top ones in the field:

“stars with widely read and admired single authored papers”

If you fit this description in string theory you are guaranteed a career. If you fit this description in non-string quantum gravity Lee is claiming you may have problems getting a job. Argue with him about what he is saying, not straw man arguments.

106. **Mentos**
May 20, 2006

Schroer said:

” [blah blah blah]… creates inexorably something which you generically call “gravity” then you have ruined the magic which many people still expect behind Maldacena, and I wash my hands free of guilt.”

I explained why the AdS dual of a (nongravitational) QFT necessarily involves gravity in the bulk. You can wash your hands, if you wish. Won’t change a thing.

“Wilsonism to me means that … I am able to make a conceptually closed theory in the present situation of QFT … which is free of cutoffs and elementary length.”

To the contrary, in Wilson’s approach, QFTs always come equiped with a cutoff. In his framework, there is no “conceptually closed theory … which is free of cutoffs.”

The point is to, nonethless, extract cutoff-independent answers from an inherently cutoff-dependent formalism.

Your AQFT approach is about as anti-Wilsonian as one can ever be.

107. **Lee Smolin**
May 20, 2006

Dear Wolfgang, I chose my words carefully. Raphael Sorkin at Syracuse, Herbert Hamber at Irvine, John Baez at UC Riverside, and a few others (Steve Carlip, Louis Crane, Ted Jacobson, Jorge Pullin, Bob Wald) are doing important work but they are single faculty members. As good as they are, by current NSF rules they are not always able to support a postdoc, as single faculty members are rarely given postdocs.

It is a bit better in a few European and Latin American countries, as I said, whose systems are structured so that there are a few good positions where the competition is in terms of individual accomplishment and promise without regard to research program or subfield.

Thanks,

Lee

108. **wolfgang**
May 20, 2006

Lee,

I see your point. But I assume that in the long run funding and interest in general will depend on results.
The results of Witten, Maldacena etc. made string theory interesting.
If Reuters et al. can demonstrate the existence of a UV fixed point, Loll et al. can show that CDT reproduces GR etc. this would certainly increase interest and funding.
Ultimately, experiments are the most interesting results. If the LHC and other experiments will not provide evidence for super particles the interest in superstrings and subsequently funding will probably decline.
If GLAST provides evidence for LQG you will probably have an easier life 😎

Unfortunately, overall the interest in theoretical physics and the willingness to fund it is declining (at least in the US), since politicians understand that the 1940s and 1950s will not repeat …

109. **wolfgang**
May 20, 2006

I am sorry: Reuter not Reuters

110. **Juan R.**
May 21, 2006

Wait a moment Wolfgang, are you claiming that string theory is more promising or may be funding before other approaches because technical points?

If yes, let me say that string theorists have proved absolutely nothing in last decades. Nobody have proved finiteness of perturbative string theory (it is claimed that solves all renormalization issues of QFT on gravity but i never saw a proof) and still today nobody has proven that string theory coincides with GR in the large scale low energy regime.

Even asuming backgrounds and large spacetimes by default, even asuming some compactification of extra dimensions, the result is a perturbative expansion over a flat metric. GR is NOT that.

About the LHC and other experiments, i can assure you that string theory hype will remain independently of the experimental results. There is historical evidence for such one attitude in the string comunity. Exactly 40 years of successive experimental failures of "predictions" of string theory. One of most recent were supposed cosmic strings…

Let me remark that problem of super partners is not if they are there (at high energies) but they are NOT here (at current energies) and string theory fails to provide a low energy regime without super partners. That is one of reasons string theory is unable to reproduce the standard model results.

Any new theory of physics may be backward compatible with experimental results known. Before to claim about it will be seen in next HLC, stringers would explain data is already known and explained by GR + SM.

Juan R.

May 21, 2006

To Oakley:
"You people are missing the point, perhaps deliberately.
Neither Peter nor the majority of the silly anti-string club here
are saying that Superstring theory should be abandoned.?

What? I have read innumerable times here that string theory is
"all wrong", "not even wrong", must be "given up", etc.

"… We just think that the effort expended on this quest is
disproportionate to the results obtained and it is high time that
more effort is devoted to alternatives rather than propping up this
failed project."

I would say that the most important, fascinating results in theoretical
particle physics and mathematical physics in the last decades came
right out of string theory. Holography, AdS/CFT, insights in
non-perturbative gauge theories, quantum black holes.., even Hawking

gave up his bet. Could you name any other field with remotely as
many important results?

And what are your alternatives? This sounds like if there would
be any. How would LQG help solving non-perturbative Yang-Mills
theory? How do you describe with that flat space, anyway? It's
an evil strategy of certain people to present things as if there
would be alternatives, such that as their own pet theories …
laymen such as you think that alternatives must be better just
because they contradict the mainstream, isn't it? Try to build
an alternative moon rocket out of wood…that's as silly.
Keep on trying.

"A bit more honesty from the Superstring community would help"

All the respectable collegues I know say what they think. A few
like Kaku grabbing media attention do not stand for the community.
The dishonesty is on your and your friends side, for presenting
such a distorted picture.

" If after more than 20 years of effort you cannot calculate cross
sections then either (i) you should stop calling what you are doing
physics or (ii) you should give it up."

Well I think I can compute cross sections. And thanks for a layman's
tip how I should call my work. What do you think brings you in the
position to make such proposals? Decades worth of hard work on your
own, or just out the arm chair?

"I doubt very much if Peter or the rest of us silly anti-stringers
would have a problem with 10% of the current Superstring community
carrying on on the basis of option (i)"

Well, I do certainly think that investigating the quantum behavior
of black holes and gauge theories is physics, isn't it?
And do you seriously think that LQG and other "alternative" approaches
you may propose would be more physical? Did it ever occur to you
that we first need to understand the physical concepts how things
work, in simplified settings, rather than trying to make direct
contact with reality? Most of the leading figures in the field do
pursue exactly this, because they know how difficult it is to make
contact with reality. It is simply not so that everybody would work
on "realistic" model building and the landscape – actually, among
the leading people it is a minority. And how should one then call
with your permission other research in mathematical physics, like
the one magnetic monopoles, algebraic QFT, integrable systems, which
also do not have a direct experimental confirmation?

"For those that do need acceptance, the system at the moment is set
up to force them to follow directions they do not necessarily want
to go in"

Right now, the pressure everywhere is to go into particle phenomenology.
Do you know what you are talking about?

112. **woit**
May 21, 2006

"What? I have read innumerable times here that string theory is
"all wrong", "not even wrong", must be "given up", etc."

For the innumerable + 1 time: the idea of using strings in 10d (or 11d M-theory, whatever that is) to unify the standard model and gravity has failed miserably, is "all wrong", "not even wrong", must be "given up", etc. More than twenty years of work by much of the theory community thinking about strings has led to interesting insights about strongly coupled gauge theory, about enumerative problems in algebraic geometry, and speculative ideas about quantum gravity. Many of these latter things are worth pursuing, but so far they have given no insight into beyond standard model particle physics. The claim that research in string theory is a promising approach to beyond standard model particle physics is not just made by Michio Kaku, it continues to be made by almost every string theorist who gives talks to a non-specialist audience on the subject. This raises serious issues of intellectual honesty.

I don't doubt that most of the people who make these arguments are making them honestly in the sense that they believe them. I do question whether they are being intellectually honest: are they willing to actually confront the seriousness of the problems string theory faces and draw the conclusions that follow from them, even if this is painful? I don't see many string theorists willing to do this. Instead I see them doing things like anonymously posting here attacks on me and others in which they willfully ignore points I've made a thousand times that they have no answer for, making up straw man arguments they prefer to deal with.

113. **amused**
May 21, 2006

Lee Smolin wrote: "…the ethic in non-string quantum gravity is to choose on the basis of quality and individual promise, whereas the string theorists seem uninterested in applicants who do not work in the mainstream of string theory."

Facinating. Do tell us, Prof. Smolin, what are the concrete criteria you use to evaluate "quality and indvidual promise"? If a young person working independently on, say, formal aspects of gauge theories, including a certain topological gauge theory of relevance for LQG, were to apply to you for a postdoc, what would it take for you to hire him/her? How many single-author publications in Phys.Rev.Lett should this person have in order to satisfy your "quality and individual promise" criteria? (I happen to know that this number has a lower bound of 3.)

From what I have seen, postdoc applications from young people whose topic is neither strings nor LQG generate no more interest from LQG groups than they do from string groups (unless their topic happens to be a pet interest of Smolin, e.g. the so-called foundational approaches to QM etc.) Smolin's appeals, here and elsewhere, for jobs to be awarded on the basis of quality and promise rather than research topic, strike me as little more than an amusingly disingenious attempt to help his own people in the current string-dominated environment.

If people really were serious about promoting quality and promise irregardless of research topic, here is a way to do it: Remove hiring decisions from individual research groups (who will inevitably favour people working on their own topic), and individual physics dept.s (which will inevitably favour people working on fashionable topics, or who have famous thesis advisors etc, which will make the dept. look good), and let the decisions instead be made by large national committees whose members represent the whole spectrum of theoretical physics research. Research groups or individual physics dept.s can then sponsor the applications of people they would like to hire, but with the actual hiring decisions made by the national committee after an open competition. (This is basically the way things work for the EU's Marie Curie fellowships.) Would you be willing to hand over your individual hiring powers to a national committee in the interests of promoting quality/promise over reseach topic, Prof. Smolin?

[Apologies to Peter for continuing this discussion in an off-topic direction.]

114. **Chris Oakley**
May 21, 2006

MoveOnOrStayBehind,

I am not sure I like getting into arguments with people who refuse to identify themselves, but my experiences in the in the world of theoretical physics are described in detail on my web site (link above). I should point out that this "armchair" you refer to exists only in your imagination; I left physics because I had to and have been earning my living since then by doing financial modelling and programming. The job I have now at least gives me more time to think about other things, and when the dust settles, there is at least one significant piece of (original, as far as I know) theoretical physics work that I plan to revisit.

> I would say that the most important, fascinating results in theoretical particle physics and mathematical physics in the last decades came right out of string theory. Holography, AdS/CFT, insights in non-perturbative gauge theories, quantum black holes.., even Hawking gave up his bet.

Obviously your definition of the word "physics" is not the same as mine.

As for alternatives to ST, I have my own ideas. They do admittedly put me in a "minority of one" (as helpfully pointed out by a former HEP colleague), but they are ideas nonetheless and will be pursued when I have the leisure time to do so. And no, there is no quantum gravity component. I am not interested in building models when there is no experimental data.

As regards the Anthropic Landscape, I am sure that you are right in pointing out that most have not signed up for this. But even one is too many.

> Right now, the pressure everywhere is to go into particle phenomenology. Do you know what you are talking about?

Probably not … my information may well be out of date, but if many are voting with their feet then this may well be because they acknowledge that Peter has a point.

115. **Aaron Bergman**
May 21, 2006

It's not so much a matter of voting or "acknowledg[ing] that Peter has a point". Rather, it's that the LHC is turning on. Faced with the prospect of having actual data, people will naturally move from speculative stuff to stuff that's related to the incipient data. Really, Peter's criticisms aren't particularly new or original (see, for example, [Ginsparg and Glashow](#)), and the anthropic stuff remains a source of disagreement in the field.

I am always astounded that people are willing to declare something wrong based on metaphysical constraints. That string theory hasn't developed into a complete theory in 25 years or that it may have a zillion or so vacua doesn't make it wrong. Useless, at worst, but it's entirely possible that that's just how the universe (multiverse?) is.

And for the people disparaging the study of SUSY gauge theories and various other things that aren't the real world, the study of toy models has a long and useful history when the real problem is (presently) intractable.

116. **woit**
May 21, 2006

Aaron,

What's the difference between being "useless" and being wrong? This is what I cannot understand about what is going on today among string theorists. They seem willing to accept the possibility that the theory is useless in terms of predicting anything about physics, but unwilling to draw the obvious conclusion that if this is the case it is wrong.

117. **Who**
May 21, 2006

Mr. M.O.O.S. Behind wrote thusly:
"…And what are your alternatives? This sounds like if there would
be any. How would LQG help solving **non-perturbative Yang-Mills
theory?** How do you describe with that flat space, anyway? **It's
an evil strategy of certain people to present things as if there
would be alternatives,.."**
http://www.math.columbia.edu/~woit/wordpress/?p=392#comment-11000
Mr. Behind sir, in reply to your comment, you seem to use LQG as a convenient blanket term for alternatives. And I concede there is an identifiable LQG community (pursuing various related approaches to QG). My point is that at least one researcher in that community just posted something about the problem you mentioned "non-perturbative Yang-Mills". In case you would like a link, here is one:
http://arxiv.org/find/grp_physics/1/au:+freidel/0/1/0/all/0/1

In the comment you ask several rhetorical questions which make it seem that you are not very familiar with what you are talking about.

Your question **"How would you describe flat space anyway?"** is interesting (if taken non-rhetorically). If you try that link you can see how Freidel, for one, is addressing this question. His research is not unique in this respect but you may wish to do the author-search and check out some abstracts before making further pronouncements on the subject. That would also pick up the two papers on 4D Yang-Mills, one co-written with Robert Leigh and Djordje Minic.

I believe you would also find some papers there concerned with deriving flat space and the Feynmann diagrams of usual QFT from a spinfoam version of QG that comes under the general LQG heading. Perhaps in a simplified setting from which further work can generalize.

Mr. Behind, you ask another question that may be rhetorical here:

****And do you seriously think that LQG and other "alternative" approaches you may propose would be more physical?** Did it ever occur to you that we first need to understand the physical concepts how things work, in simplified settings, rather than trying to make direct contact with reality?…**

With all due respect, I do seriously think so. Yes, is the answer to your question, **they would and will be more physical.** Note that the alternative approaches try to get at fundamental degrees of freedom of spacetime and matter in a direct physical fashion, often in simplified settings (as you mentioned) and going light on extra baggage. And as one who watches the research scene I would say this strategy seems to be paying off quite well lately in terms of results.

Now, in answer to your question—-which was actually addressed to Mr Oakley:

Did it ever occur to you that we first need to understand the physical concepts how things work,..

I would answer that Yes actually it has occurred to me.

Oh, M.O.O.S. in regard to your warning to us:
** **It's an evil strategy of certain people to present things as if there would be alternatives,..[to superstring/M theory]…****
that sounds indeed very diabolical of them. I can only express my surprise at your discovering this.

Civilly yours,

Who

118. **Lee Smolin**
May 21, 2006

Dear Amused,

In fact I do agree that some of your proposals would be helpful, for example to instutute in the US fellowships analagous to the Marie Curie or Royal Society Fellowships. My answers to others of your questions are in my Physics Today essay from June 2005, page 56. As far as consistency, I do not now, nor have I ever made postdoc hiring decisions on my own, at PI such decisions are made by a committee. But it is true that the majority of the people who hold or have held postdoc or visiting positions at PI in non-string quantum gravity work on approaches other than LQG.

Lee

119. **Aaron Bergman**
May 21, 2006

What's the difference between being "useless" and being wrong?

Ontologically, quite a lot. Epistemologically, maybe not so much.

This is what I cannot understand about what is going on today among string theorists. They seem willing to accept the possibility that the theory is useless in terms of predicting anything about physics, but unwilling to draw the obvious conclusion that if this is the case it is wrong.

Because that simply does not follow. Regardless, you seem eager to give up on the string theory project at every turn. Your original polemic doesn't even include the word 'anthropic'. Others still believe that, even with the surfeit of possible vacua, it's not at all clear that we might not be able to treat string theory like QFT wherein experiments determine a particular vacuum and it becomes predictive. I also believe that, given results like AdS/CFT and Strominger and Vafa, string theory surely is a theory of quantum gravity, even if it isn't our particular theory of quantum gravity. As such, we can learn a lot just from studying how string theory solves the usual problems with quantum gravity, and eventually those insights may help us understand the correct theory if and when it comes around.

But, for all this bickering, data is just around the corner, and that is where the jobs are going right now. If anything, much anthropicism is motivated by the specter of the LHC.

120. **woit**
May 21, 2006

"Regardless, you seem eager to give up on the string theory project at every turn. Your original polemic doesn't even include the word 'anthropic'."

I really wish you'd stop it with the ad hominem arguments, they're just obnoxious and don't prove anything.

Yes, for a very long time I've thought that string theory has failed as an idea about unification. The problems of too many compactifications and how to break supersymmetry have been around since the beginning, and by the late 90s it was clear there was very little chance they could be surmounted (non-perturbative versions of the theory had the same problems). That was the situation when I wrote my first public polemical article. Developments since then have provided even more convincing evidence that I was right that these problems can't be surmounted, backing string theorists into the anthropic corner which I never would have believed back then they would try to take a stand in.

121. **Aaron Bergman**
May 21, 2006

I really wish you'd stop it with the ad hominem arguments, they're just obnoxious and don't prove anything.

I hardly think it's unfair to point out that your opinion of string theory predates this current situation in the context of a discussion why there are people who haven't completely abandoned the field.

And, you asked why string theorists haven't given up. I certainly can't answer for everyone, but I tried to explain to you some of the reasons.

122. **Who**
May 21, 2006

what I have to say has something indirectly to do with how one reacts to the whining of young string theorists that one sometimes hears, but mostly I want to give ANOTHER EXAMPLE OF RESEARCH ALTRUISM besides what Smolin mentioned.

someone, I think “amused”, suggested that Smolin was probably just as self-interested as any string theorist and would only take postdocs that work in his own type of QG, and he said not so, and gave an example of Perimeter policy

===quote===
In fact I do agree that some of your proposals would be helpful, for example to instutute in the US fellowships analagous to the Marie Curie or Royal Society Fellowships. My answers to others of your questions are in my Physics Today essay from June 2005, page 56. As far as consistency, I do not now, nor have I ever made postdoc hiring decisions on my own, at PI such decisions are made by a committee. But it is true that **the majority of the people who hold or have held postdoc or visiting positions at PI in non-string quantum gravity** work on approaches **other** than LQG.
===endquote===

My point is that this non-string QG ethos is strikingly exemplified not only at Perimeter but also in the Utrecht QG program. Loll’s group has 3 postdoc positions. The house brand QG is called CDT (a triangulations path-integral). If you are used to EXCLUSIVITY then you may be shocked by this. Actually I was last year when I learned that the 3 positions went to STAR ROOKIES OF THE COMPETITION. The postdocs of Loll’s Utrecht group are people that Dowker in London co-authors Causal Sets papers with, and Freidel at Perimenter coauthors with, and a self-starter who helped standardize canonical LQG by proving an important theorem. These people are selfdirected reseachers with impressive track records—I’m not kidding. And so what is the good of this for Loll’s particular approach to QG? It simply did not make sense to me. She controls a sizable Dutch government grant based on her own CDT work and can do as she pleases, so why does this go to support some of the best rookies of the competition? People with their own research motivation who are not likely to change direction for trivial reasons.

It seems like the ethos in non-string QG has a large element of SUPPORT THE OTHER GUY’S POSTDOC. I have wondered how a field can survive with so much altruism running amok in it?

But there may be advantages. This year Utrecht has been getting visits from e.g. Dowker and Freidel and Ashtekar. It means that more different non-string QG approaches are being worked on there at one time than probably anywhere besides Perimeter. I guess that could pay off in the long run.

============
Anyway the ethos has a strong anti-parochial streak (wherever they have enough resources gathered so they can actually HAVE postdocs). and that is in strong contrast to the string ethos in typical US department where string faculty have control of ALL the QG positions and will not share ANY. At least as far as I know. It might be amusing to get some statistics on this corresponding but contrasting with the Utrecht and Perimeter examples.

the relevance to the situation of a young string theorist would seem to me that he or she is being supported by an exclusive system that will take on no other type of young researcher, no matter how ingenious, no matter how independent, no matter how inventive, with no matter how good a track record. that is to say a totally bigoted system

123. **Arun**
May 21, 2006

I’d say some people want to know the answers, even if it means that most of their productive research years turn out to have been on the wrong path; while some people want to build empires.

124. **amused**
May 22, 2006

Dear Prof. Smolin,

Thanks for taking the time to reply. In fact I had read your Physics Today essay, and have just re-read it, but am still confused about what exactly your position is regarding supporting young researchers, and how it differs from what people or groups in other areas do. More on this below.

“But it is true that the majority of the people who hold or have held postdoc or visiting positions at PI in non-string quantum gravity work on approaches other than LQG.”

And what areas do these people work in then? As far as I can tell, most, if not all, work on topics that can be classified under “background-independent approaches to QG” or “foundational issues in quantum mechanics”. What is the position of you and your colleagues at PI regarding support for young people not working in these areas (e.g. for someone working on formal aspects of gauge theories)? I don’t see any sign that you care about such people. It seems that on the one hand you advocate supporting independent young researchers irregardless of research area, but on the other hand you have chosen certain specific (albeit broad) areas which a person has to be working in to get support from PI.

So it seems that in reality the policy of you and your colleagues is no different from that of a typical string theory group: In both cases the group has an area, or set of areas, that it wants to support, and proceeds to hire people in these areas. Presumably it happens from time to time that a string theorist working on, say, branes and ads/cft, hires a postdoc who works in another subarea of string theory, say perturbative string theory or string field theory. The string theorist would say that he/she is doing this in order to further the career of a talented young researcher, even though the person is working on a different topic. Where is the difference between this and what you do? (besides that fact that the areas you are willing to support are broader than that of a typical string theorist).

[Peter – apologies again for continuing an off-topic discussion; I’ld understand if you wanted it to stop. I guess at some point you’ll write a post on Smolin’s book after it appears, and that might be a more appropriate time to take up this topic.]

May 22, 2006

Lee Smolin wrote:

(…) Latin American countries, as I said, whose systems are structured so that there are a few good positions where the competition is in terms of individual accomplishment and promise without regard to research program or subfield.

No and no.

Best wishes,
Christine

126. **amused**
May 22, 2006

Who,

“If you are used to EXCLUSIVITY then you may be shocked by this. Actually I was last year when I learned that the 3 positions went to STAR ROOKIES OF THE COMPETITION.”

When I first saw this I thought you were going to say the positions went to string theorists… being under the impression that they are (percieved as) the real competition, and that the various background independent approaches to QG are all in the same broad family…

I don't see that this is such a big deal though. As far as I'm aware, the Ambjorn-Loll group is the only one doing this CDT stuff. So, short of hiring their own students, how could they get postdocs who are already working on this? It seems they had no choice but to hire people from other subareas. Presumably Loll is hoping that these people will get interested in CDT and do some work on it (while continuing with their own stuff at the same time). And it would be natural for them to do this, seeing as CDT is one of the more exciting developments in this general area.

127. **Mentos**
May 22, 2006

Is there any actual evidence that "background independent QG" postdoc seekers fare worse, on average, than string theory postdoc seekers?

Obviously, the field is much smaller so, anecdotally, Lee is more likely to personally know good candidates who failed to get jobs. But there are plenty of top-notch string theorists who don't get postdoc jobs either.

Are there any statistics to the effect that a higher percentage of string theory postdoc seekers obtain jobs than "background independent QG" postdoc seekers? Or is this just another "just-so" story?

128. **woit**
May 22, 2006

Mentos,

The best data out there I would guess is at the new Rumor Mill for theoretical particle physics postdoc jobs. I had kind of started believing the complaints I've been hearing recently from string theorists that phenomenologists are getting all the jobs until I just recently took a look at this. By my count, getting postdocs this year there are 31 string theorists, 12 phenomenologists, and 5 hard to characterize (brane-worlds, QCD amplitudes by twistor methods…). Several institutions that hire lots of postdocs still will only hire string theorists (Caltech, KITP, IAS…)

How many "top-notch" string theorists do you know who in recent years have been unable to get a post-doc position? I personally know of no such examples, but maybe it all depends on what you mean when you say "top-notch". Can you give an example of someone from one of the top few groups in the US who has an impressive thesis but no job? Is the problem that there are more than 31 "top-notch" string theorists on the post-doc job market, or that institutions are hiring second-rate string theorists over first-rate ones?

This is a "particle physics" rumor mill, and thus may not have non-string theory QG jobs listed. Such a list may not exist, but since, as Lee points out there are very few places in the US that ever hire in this area, I would suspect there are no more than a handful such jobs.

129. **Aaron Bergman**
May 22, 2006

My count is slightly different from yours (but I might have miscounted). I'm not sure how representative that list is; there might be a bit of a selection effect (there are very few cosmologists on it, for example). I'm pretty far from the postdoc gossip this year, though. My impression is that there is a much higher proportion of phenomenologists among traditionally stringy jobs than in the past, though, but can't offer anything quantitative.

130. **anonymous**
May 22, 2006

Where is this postdoc rumor mill? I only know of one for faculty.

Also, the IAS only hires string theory postdocs? Funny, I bet Ian Low would be surprised to learn he is a string theorist. Other counterexamples to your claim exist. I don't know about KITP, but Caltech and the IAS do not just hire string theorists.

131. **anonymous**
May 22, 2006

Just so you don't think I'm choosing one exception to the rule, recent phenomenology postdocs at IAS include (but are not necessarily limited to): Mishima, Dermisek, Kitano, Agashe, and Kribs.

132. **woit**
May 22, 2006

I was referring to this site (and counting postdocs hired this season)

http://www.freewebs.com/heppostdoc/

According to it, the IAS is hiring five new postdocs, and I think they can all be reasonably characterized as string theorists. I wasn't claiming that the IAS theoretical physics group never hires anyone but string theorists, but now that you mention it, of their 18 current non-permanent members, how many are not string theorists? You mention 3 (Low, Mishima and Demirsek), and maybe there are a couple others, but its undeniable that IAS postdoc jobs overwhelmingly go to string theorists, both in the past as well as this year.

133. **Mentos**
May 22, 2006

"Several institutions that hire lots of postdocs still will only hire string theorists (Caltech, KITP, IAS…)"

That's kinda funny.

Of Caltech's 8 postdocs, 4 are phenomenologist, and 4 are string theorists.

At the IAS, I count 1 formal Yang-Mills person, 3 phenomenologists, 2 (Kleban and Rabadan) who started out as string theorists, but who are now doing phenomenology, and 7 string theorists.

And, of the KITP's 5 high energy postdocs, 4 are string theorists, and one is a phenomenologist.

"The best data out there I would guess is at the new Rumor Mill for theoretical particle physics postdoc jobs. … I had kind of started believing the complaints I've been hearing recently from string theorists that phenomenologists are getting all the jobs until I just recently took a look at this."

I was previously unaware of the Postdoc Jobs Rumor Mill. I'll have to check it out.

But on the Faculty Jobs Rumor Mill, I count 10 phenomenologists, 6 cosmologists and 6 string theorists getting jobs this year.

134. **Lee Smolin**
May 22, 2006

Dear Mentos,

I have no statistics, but it is not uncommon for top level grad students and postdocs-authors of widely read and cited papers-in non-string quantum gravity to get no offers and to have to apply in succeeding years to get a postdoc. This is not new, many who are now seen as the leaders had periods when we came close to being forced out of science. I certainly did.

Dear Amused,

I think that Who gave the best answer in describing the Utrecht group: there is simply a different ethic that values the personal promise of a young researcher over working on the research program of the faculty. This is in fact an old tradition, it came to me through my mentors who were senior faculty in relativity groups. It contrasts with another attitude towards postdocs which is that they are to be chosen to further the research program of the grant holder. My view is that the former leads to faster progress in science than the latter, because it favors young scientists who are more intellectually independent, original and courageous, and these are the kind of people who make the discoveries that drive science forward.

I disagree with your drawing an equivalence between string theory and the whole field of quantum gravity. I think it is a bad idea to organize groups or departments around research programs rather than subject areas, because that gives research programs, which can succeed or fail, more institutional inertia than is good for science. I have nothing against string theory per se, so long as it is seen as one research program among several aiming towards the further unification of physics.

Hence, I would argue that commitment to string theory as a research program is different than commitment to a subject areas such as quantum gravity or post standard model particle physics. I have never myself worked within one research program; I continue to publish a paper on string theory every year or two and the bulk of my work is seen by specialists as not strictly LQG. I think science would progress faster if we built structures that discouraged rather than encouraged scientists to identify themselves with particular research programs rather than areas.

I do personally agree with you that formal aspects of gauge theories are a neglected, under supported area, which is one reason I have been following the recent work in this area with interest.

As for PI, please do not confuse my views with either policy or the experience at PI. I am one voice and vote among many, and the basic mandate and policies-including the idea that postdocs are to be hired by the whole institute as independent researchers-were set up by the founders and director before any of us faculty were hired.

Dear Christine,

Thanks for the correction.

Thanks,

Lee

135. **Who**
May 22, 2006

Amused, both Perimeter and Utrecht ITP have numerous string postdocs, as well as "background independent QG" postdocs.
I wish that major theory sites in US were more inclined to allocate support to the individual mind rather than to the camp—as I have said–and think that this would LEAD to more diversity in the research pursued at these places. QG research diversity is not a goal *per se*, or is only an accessory interest. It is *symptomatic* of ability to appreciate drive and originality in rival lines and a pragmatic philosophy of "let's get the problem solved however the heck we do it (rather than by my pet method or my club of people)".

If you don't see that philosophy operating in the places I mentioned, or don't see the results of the past couple of years as indicative that it works, then maybe my perception is wrong—I may be deceiving myself or failing to communicate here.

Oh BTW Utrecht also has a postdoc who has co-authored with Martin Reuter—-not in Loll's immediate group—I think he does string part of the time. As does Ambjorn, whom you mentioned as a CDT associate—my impression that his research is at least half, maybe more, in string/M.

I think the style exhibited here is "ecumenical" or maybe pragmatic. There is no intrinsic merit to it—you can only judge by the results. If this does not make sense to you please let me know.

136. **anonymous**
May 22, 2006

"According to it, the IAS is hiring five new postdocs, and I think they can all be reasonably characterized as string theorists."

The rumor mill apparently doesn't know about Gil Paz, who is also starting a postdoc at the IAS next year, and is decidedly not a string theorist.

The IAS is largely composed of string theorists, but for an institution so dominated by string theory in terms of faculty, I think it does pretty well with hiring a more diverse group of postdocs.

137. **woit**
May 22, 2006

Mentos,

My mistake for the wording implying that IAS, KITP and Caltech in the past only hired string theorists, something I didn't mean to claim. I was just talking about this year.

I also had only been aware of the permanent faculty hiring data, which does show more phenomenologists and cosmologists than string theorists getting jobs. I was surprised to see how different the postdoc data is. Perhaps this is because postdoc hiring is more concentrated at a few prominent institutions, and these remain dominated by string theory, whereas permanent jobs are spread out more widely, with prominent institutions doing only a small amount of permanent hiring.

138. **Aaron Bergman**
May 22, 2006

I was surprised to see how different the postdoc data is

I'd be careful assuming that page is a representative sample. Anon above already pointed out one person missed at IAS.

139. **Thomas Larsson**
May 22, 2006

FWIW, I believe that Swedish ur-string theorist Lars Brink was the one responsible for me landng a 4-year postdoc, long ago. So there are counterexamples to the claim that string theorists only hire string theorists. I'm not sure that Lars likes me anymore, though.

I thought I recognized Lars in the City Hall last December 10th, but I'm not sure since it was more than a decade since we last met. Perhaps next year.

140. **amused**
May 22, 2006

Who,
Yes, I am aware that PI and Utrecht have string as well as background independent QG postdocs, that many people who work in the latter area have wide-ranging interests and also work on other topics (a positive thing, of course), and that there has been significant progress in some subareas of BIQG in recent years.

"QG research diversity is not a goal per se, or is only an accessory interest. It is symptomatic of ability to appreciate drive and originality in rival lines and a pragmatic philosophy of "let's get the problem solved however the heck we do it (rather than by my pet method or my club of people)"."

Sure. But can you accept that there might be people of this ilk in other areas of theoretical physics (or science in general) besides QG? Or do they all gravitate towards QG research of some sort or other? Assuming they exist, are the ones who choose non-QG topics less deserving of support than the QG'ers?

If Smolin had simply appealed for more recognition and funding for work on BIQG and fundamental aspects of QM he would have had no argument from me. But when he starts going on about how he and his colleagues support independent young researchers of quality and promise, irregardless of their research area, then the people out there who are, or were, young independent researchers, and who aren't, or weren't, having an easy time jobwise, are going to prick their ears up. Questions will come to mind such as "Hey, I wonder what it takes to meet Smolin's `quality and promise' criteria?". Then some of the older ones might get a flash of recollection along the lines of "Er, didn't we send a postdoc application to that Smolin guy early on, when we had a couple of papers in PRL and various others in NPB, PRD etc… (all single-author of course – we're independent, remember)… and he wasn't exactly enthused, was he…. Well, at least that sets a lower bound on his criteria which we can compare against the people he does hire – so let's look them up." And later, "Hmmm, looks like we overlooked something – the `quality' part of Smolin's criteria appears to include a `quality of choice of research area' factor. At which point cynicism sets in, and a snide comment or two get posted on a certain accomodating webblog.

141. **Lee Smolin**
May 23, 2006

It is a bit unpleasant to have one's motives questioned publicly by an anonymous person over past decisions. I would think that good sense would suggest several reasons why every decision of every research group a person has been a member of may not agree with policies they presently advocate, including 1) they were one vote on a committee, 2) restrictions from funding agencies, 3) their present views are the result of reflection on past experience and have evolved 4) there are so many excellent candidates that one research group in one field cannot be expected to have room for all but a small fraction of the candidates they think are deserving of support. This is why I have begun to speak out about these issues; one institute, however well supported and well meaning (and within which I am at most one vote-when I am on the committee) can only hire a fraction of those who are deserving under our criteria. And this is why I agree with the writer that more programs like the Marie Curie and Royal Society Fellowships would help.

142. **woit**
May 23, 2006

I've deleted a comment from "amused" responding to Smolin in order to terminate this particular off-topic discussion. Evidently the two are in e-mail contact and can pursue this privately if they wish.

143. **John Gonsowski**
May 23, 2006

This probably belongs more in the comments on comments thread but I'd like to amend my comment there and say it does seem bad when an anonymous heckler addresses a Lee Smolin or John Baez by first name only. At least amused seems respectful in this sense and going to email is even better.

144. **amused**
May 24, 2006

To avoid an impression of rudeness, can I just point out for the record that I hadn't seen Prof. Smolin's lengthy comment – the one addressed to Mentos, me, and Christine – at the time I posted my subsequent comment above (the one addressed to Who). Perhaps it was somehow delayed by Peter's WordPress update, or maybe I just overlooked it. If I had seen it I would have addressed his points in my subsequent post, and its tone would have been different. But now it's time to drop this, in accordance with Peter's wishes.

Comment on Comments

May 20, 2006
Categories: Uncategorized

Over the last week or so I’ve heard privately from several very different parties with complaints about the comment section here. The general feeling is that it would be more useful and attract more serious contributions if the level of uncivil, disrespectful ad hominem attacks was much lower. One contributing factor mentioned is that anonymity allows people to behave in uncivil behavior that they would not engage in if their names were publicly attached to their words. On the other hand, the worst offender in this is someone who is not anonymous.

I’d be curious to hear thoughtful comments by others about this. My own feeling at the moment is that the criticism is accurate: the uncivil atmosphere here keeps many serious people who would have something interesting to contribute from doing so. The anonymity is probably part of this problem, although given the current unhealthy situation in particle theory, some people have very legitimate reasons for keeping their comments anonymous.

In many ways I think the comment section has been a success, but it could stand a lot of improvement. Unfortunately I don’t know of any really successful models out there to follow. Among the more active blogs by physicists, Cosmic Variance does a good job of keeping a civil discussion going, but it is rarely about physics these days. Jacques Distler’s Musings has high-level content in its postings, but no one has submitted a single comment about physics there in over a month and a half. The comments at Lubos Motl’s Reference Frame are as uneven as the blog’s proprietor.

I already delete quite a few comments on grounds of lack of civility, but tentatively plan on trying to raise that standard by deleting a larger fraction of uncivil comments, especially if they are posted anonymously. It would help if people could keep the following in mind when posting comments:

1. Please consider abandoning anonymity and posting under your real name, unless you have a good reason for not doing so.

2. Please take much greater care to keep comments civil and respectful. Ad hominem argument about the ignorance and lack of intelligence of people you disagree with has no place here.

3. Please ignore silly comments when they appear. Maybe I’ll also think they are silly and just adding to the noise and will get around to deleting them, maybe not. But in any case you’re not adding anything by submitting a comment criticizing the silliness, but instead are adding to the hostility level.

Constructive comments are welcomed. One thing to keep in mind is that I already am spending more time on this than I should, suggestions that involve a lot more work on my part are non-starters.

Comments

1. **wolfgang**
   May 20, 2006

   > Jacques Distler’s Musings has high-level content in its postings, but no one has submitted a single comment about physics in over a month

   I think this is perhaps because the comment feature is broken.
   The last time (fairly recently) I tried to submit comments on Jacques’ blog it resulted in error messages …

2. **knotted string**
   May 20, 2006

   Can you politely email Jacques, to let him know?

3. **Matti Pitkanen**
   May 20, 2006

   It would be nice if old-fashioned Boolean true/false logic would replace the more modern string theorists/crackpots logic in these discussions. Perhaps we could do well without the word “crackpot”? There have been occasionally very interesting attempts to initiate serious discussion about algebraic quantum field theory, Jones inclusions etc, but soon everything degenerates to the usual fighting which makes me sick.

4. **Who**
   May 20, 2006

   I will think about the problem you describe and will try to offer some suggestions which are constructive and not merely in my immediate self-interest.

   One thing is you could try an experiment involving segregation. At the end of certain postings you could say “Qualified comment only. No anonymous comment.”

   Be very brief, just indicate in a short phrase or two that anybody who is NOT academically qualified for that particular discussion will have their comment deleted out of hand at your discretion. IF YOU SPELL IT OUT IN TOO MUCH DETAIL it might sound snobbish or priggish. So dont spell the policy out too explicitly. Just give a short warning at the end of a selected post, and then be fast and ruthless about deleting anybody that you dont know professionally or that doesnt give their name and SAY they are a grad student or faculty somewhere or have some appropriate professional standing like that.

   In this case it is the commentor’s responsibility to make sure that either you already know him or else to say up front “I’m a physics grad student” or “I do this kind of research” whatever. It is up to commentor to give you enough clues up front about professional qualification, or out it goes.

   Or you could restrict comment on some particular thread to WEBSITE BLUE people plus ones you know personally. Like wolfgang who just commented gives his page. His blue signature is a link to his website that says he is a such and such kind of physicist.

   I wouldn’t advise a blanket policy because it could be a straightjacket on you as on well-meaning commentors. Trying it out with a few postings would be an EXPERIMENT. It might fail in the sense that you might not get a good informed civil discussion after all, even in that case.

   Personally I would be sorry to see a sign on one of your threads that says ” identified comment only” because I enjoy being Who (it’s a quirk I guess: I really like internet anonymity) so I couldnt post comment on such threads. But on the other hand it might every now and then make the thread more interesting reading to have only signed qualified comments.

Some of the silly and/or witty comments here are quite funny and also even some invective is entertaining in small doses, but I get tired of it quickly and would be glad to see some threads ruthlessly cleared of it.

I hear what you say about it soaking up time. I certainly wouldnt mind seeing a lot more rapid unexplained arbitrary behavior, if that means saving time.

Good luck attracting some of that hold-out clientele.

5. **woit**
May 20, 2006

Who,

Thanks for the comments and the suggestion. I don't think though that I have any interest in restricting comments based on professional qualifications. There are plenty of examples I've seen here of people I know to have no appropriate professional qualifications making excellent and interesting comments, and people with illustrious qualifications writing in things that are hostile and worthless.

Maybe it's sheer arrogance on my part, but when people write in with some comment that involves the kind of scientific issues I'm writing about here, I can in most cases immediately tell whether they are well-informed concerning what they are talking about, and that's what's relevant, not professional qualifications.

6. **asubedi**
May 20, 2006

I think you should allow the comments to be anonymous and accessible to all. However, if someone keeps posting a lot of junk, you may delete the postings and ban the ip address for a while.

7. **Chris Oakley**
May 20, 2006

Peter,

I think that you can be proud of what you have created here. Obviously with the provocative title, it provokes and will continue to provoke strong reactions, but what is wrong that? The structures one builds in theoretical physics should be stronger than steel, and if they fall down as the result of a little criticism then they were probably not worth building in the first place.

As for the comments policy, I think that you have got it about right. I am sorry if the whole thing is taking up too much of your time, but I for one appreciate the effort.

Just curious: will your publisher be sending Lubos a review copy of your forthcoming book?

8. **woit**
May 20, 2006

asubedi,

That's essentially what I'm already doing.

9. **woit**
May 20, 2006

Chris,

Strong reactions are fine, and if certain structures topple, great. What I'm concerned about is that I am getting the impression that quite a few very good people, string theorists and non-string theorists, read this blog from time to time, but are put off by the tone of much of the comment section, making them less likely to take the whole thing seriously and consider participating. I'm interested in whether that is a more widely shared impression and what can be done about it.

This weekend I'm supposed to be putting together a list to send to the publishers of who to send review copies to. Not sure about Lubos. I do thank him in the acknowledgements, but I know he's not going to read and think about what I write…

10. **A Different Peter**
May 20, 2006

You can be sure Lubos will have something to say about the book, whether he actually gets hold of a copy or not.

About the politeness question, the problem that you have is not just confined to your blog. It is everywhere on the blogosphere. This new form of human communication is showing its limitations because it is difficult to separate out the comments that one would like to read from the huge volume of worthless and hostile posts.

The natural solution seems to involve heavy moderation. This means either the blogger devotes a lot more time to moderation, or he delegates some portion of the moderation task to blog visitors (look at how slashdot does it).

A simple option which would stop short of mass deletions of posts, and would encourage people to write more relevant posts, would be the following. There can be a number of categories, say "High Physics Content, No Humor", "No physics content; personal attacks" and so on. Visitors to the blog with unique IP addresses (or some other criterion that you prefer) could, upon reading a post, click one of a number of buttons beside it, indicating what category they think that post belongs in. Simple majority voting, or some other criterion of your choosing decides what category the post is given based on how many users have chosen each category for it. At the side, bottom, or top of the comment section, a little clickable box allows the user to choose a filter, so the user can choose to see only high physics content posts, or also humorous posts, or all posts, or only personal attacks (if that's what they really want). They can also choose whether they would like to see posts which have not yet been classified by other visitors.

People who are going to post something will know that, if they post mindless personal attacks, they will be categorized as such and then most people will not bother to read them. People write posts because they want attention, so the only way to give them an incentive to write well is to make the attention conditional on their writing something worthwhile.

Of course, implementing this option involves some programming.

11. **fishfry**

May 20, 2006

The comments at Lubos Motl's Reference Frame are as uneven as the blog's proprietor.

Incivility is as incivility does.

12. **Ron Avitzur**
May 20, 2006

One technique you might consider is disemvoweling posts. It gives you an additional level of discrimination short of deletion to indicate offending material in a way that readers can easily skip over or choose to puzzle out with effort.

13. **Dick Thompson**
May 20, 2006

I hope you will continue to have your comments as they are. I can't agree with Who's recommendations to limit it to "qualified" respondants. After all, Peter, some people are not shy about calling you unqualified to comment on string theory! If you restrict your comments they have already won ;).

This is my real name:

Dick Thompson

14. **Arun**
May 20, 2006

One could moderate comments, e.g., by finding a blog collaborator who will impartially weed out uncivil comments,

or one could institute a comment rating system (presumably a lot of work) where readers can rate the comments, and poorly rated comments become invisible,

or one could follow the (difficult) policy of not replying to any such uncivil comment.

Polite but content-poor comments are a much harder proposition to manage, IMO.

15. **Lubos Motl**
May 20, 2006

Dear Peter,

I must be cryptic in this sentence but I don't believe that you believe that my relation to a certain piece of work of yours is in the status that you described, and most likely you know very well what I mean.

Wolfgang: the buggy comment gadget at a certain blog under consideration is deliberately buggy.

Best
Lubos

16. **Eugene Stefanovich**
May 20, 2006

Peter,

your blog is a valuable resource for anyone who loves theoretical physics. Every day I go to arxiv.org, your blog and sci.physics.research (pretty much in this order) to look for some nuggets of information. Please don't change anything, I like your blog the way it is.

Anonymous comments are fine. It is better to let people speak up their mind anonymously rather than make them silent out of fear … whatever they afraid of. Uncivil comments are not a big deal either. For one thing, they give an interesting insight in who is who and how "healthy" the field is.
Second, most of your readers are intelligent enough to filter out the garbage. Third, you can always weed out excesses, as you already do.

Keep up excellent work!
And thank you for not posting about flowers in your garden, your favorite music, and climatology.

Eugene.

17. **woit**
May 20, 2006

fishfry,

Given Lubos's behavior and the way he chooses to characterize me and others who disagree with him, I think referring to him as "uneven" is being exceedingly civil…

18. **woit**
May 20, 2006

Lubos,

Oh, OK, I'll make sure you get a copy….

19. **John Gonsowski**
May 20, 2006

Don't change it too much, Discover Magazine readers might be disappointed if they came here and didn't find a lively forum for bickering scientists. I can't believe any regulars, particularly ones with sci.physics.whatever experience would have any problems here. Physicists new to internet forums in general could have problems most anywhere due to tone and widely varying subjects that don't even always stay on topic. Having lots of participation is more fun and more educational but it can make forums harder to follow if you haven't developed skimming skills to suit your available time. Maybe you could ask these physicists if they'd like to do guest articles (I think Lubos did this at least once) or have you do an article on them and then we could be extra civil at those times.

20. **anonymous**
    May 21, 2006

    Anonymous comments on your blog seem a good form of communication.

    One negative consequence of counting citations is that too many physicists, especially in the US and especially in speculative fields, are more worried of good relations than of discussing physics. I prefer getting a “you are an idiot” from Lubos to the other extremum: a long discussion, where things are said so politely that the content is obscure.

    Sometimes the comments section contains too much “background”: maybe you could install a software that allows readers to rate comments (“Was it worth reading? Y/N”) and to see only comments above a chosen threshold.

21. **Bert Schroer**
    May 21, 2006

    There is a form of communication which keeps it lively and which I have been trying to use: irony and scientific (not personal) polemics.
    It is often answered by dull personal confrontations (strangly enough, I did not make this experience with Lubos, but I have seen that others did) and it depends on one´s emotional constitution how much one wants to take.
    But I think that Peters argument that some interested onlookers may be repulsed by the vulgar manner should be taken serious. To lift the anonymity may lead to timidness. Perhaps the introduction of a disapproving back-reaction of the participants (by clicking a button) may alliviate the situation because the protection by anonymity is probably not 100% (after finding out the machine, there may be some feeling of discomfort which could lead to a more restraint behavior).

22. **Chris Oakley**
    May 21, 2006

    Let me see if I can guess what Lubos will say in his review:

    “People can be categorised as follows: stupid, average, smart, very smart and Superstring Theorists. The latter category comprises the very smartest, and these people are way smarter than even the very smart. In fact, very smart people are just morons compared to even an average Superstring theorist.

    “Most non-superstring theorists have the good sense to acknowledge their inferiority, and although they provide the money for us Gods of the Human Intellect to do amazing things in amazing multi-dimensional worlds (not enough, by the way), they generally do not have the effrontery to question the validity of our researches.

    “Not so Peter Woit. Anyone reading more than ten words of anything he writes would realize that he is an embittered half wit, who, failing to be admitted to the Superstring club 20 years ago, has unfortunately chosen to vent his rage against those who thwarted his career rather that just getting a job in a McDonalds restaurant, as would more suit his talents.

    “To those of us who seriously explore the higher-dimensional, supersymmetric realms, Peter Woit is no more annoying than a fly that buzzes into your kitchen when you are trying to eat lunch. However, since everyone in the world is less clever than us, it is possible that some may be deceived into thinking that there is some substance to his ravings, so let me make it clear here and now that there is nothing in what he says. Peter knows nothing about physics or mathematics, and nothing he says should be taken seriously.”

23. **Nigel B. Cook**
    May 21, 2006

    That was a very silly comment. Now Lubos can borrow your review. He will say you used Josephson’s string theory ESP to read his mind, as described in the arXiv paper by Josephson: http://arxiv.org/abs/physics/0312012

24. **wolfgang**
    May 21, 2006

    Lubos,

    > the buggy comment gadget at a certain blog under consideration is deliberately buggy

    it seems to work again. Thanks in large part to Peter’s post … 😎

25. **woit**
    May 21, 2006

    Chris and Nigel,

    I realize that Lubos is endlessly entertaining, but try and resist the temptation to make fun of him, it’s too easy and we need a higher quality of humor here.

26. **knotted string**
    May 21, 2006

    Wolfgang: thank you for this update. It is heartwarming that string experts are humble enough accept a helping hand with trivial problems in hosting discussions.

    http://golem.ph.utexas.edu/~distler/blog/

    ‘May 20, 2006

    ‘Technical Difficulties

    ‘It’s been brought to my attention that some people have recently been encountering an INTERNAL SERVER ERROR when attempting to comment here (or at the String Coffee Table).

    ‘The cause, alas, is my determination to be overly clever.’

27. **ksh95**
    May 21, 2006

    Requiring “real names” would definitely stop me from posting. The last thing I need is some one Googling me and finding hundreds of ksh95 blog postings.

Secondly, I'm confused as to why you think anonymity and uncivility are related. That's not obvious to me at all, in fact, it seems somewhat odd as I doubt most "uncivilized posters" consider their postings uncivilized.
Thirdly, my personal opinion is that the comments section is no where close to uncivil (I think some potential contributers may be overly sensitive and fragile).
Finally, if it ain't broke…..

28. **Yuri**
May 21, 2006

I like your blog the way it is.

29. **Fred Diether**
May 21, 2006

Peter,

The solution seems like it could be simple to me. You should just post a warning about ad hominem attacks not being allowed in the "Leave a Reply" section and enlist the help of one or two competent volunteers to help you delete them. When I showed this blog to my particle physics tutor, he asked "What is the difference between this blog and Usenet?" So I do think you have a moderation problem. If it is already taking too much of your time then you should try to get help from someone you trust.

I do enjoy reading much of the content of your blog but I don't really enjoy wading through the personal attacks. They really serve no purpose to the discussion of physics.

Fred

May 21, 2006

Hi,

I want to echo Eugene's comments: this is an *excellent* blog with content of exceptional quality, and I am glad that you stick to physics and leave out your personal hobbies, politics, and weekend experiences. If you want to spend more time editing and purging the comments, that's fine, but please do not let it reduce your primary posts.

thanks,
Michael

31. **Bruce Keener**
May 21, 2006

I love this site because it helps me see that we really don't know as much as a typical layman might think. It's been more than thirty years since I got an MSEE with minors in physics, and more than 25 years since I've had to apply ANY of it, so the math of string theory and QFT is beyond me and always will be – I'm too old to try to learn it, and it's pointless at this stage in my life anyway – I am now and will remain a layman. But I care about how our world operates. I'd like to understand it better and I'd hate to see us postpone understanding of it while we whack away with theories are not "not even wrong." I don't really want to go through the rest of my life with wrong beliefs (an impossible desire, probably), and really work to put as much balanced (pro and con) input into my mind as I can find. This site helps me, at least in the area of physics-related beliefs.

I do learn (slowly) from the comments here, and have no real advice on how to do them differently. I guess the only thing I would offer is that it would be nice to see more variety in topics: potshots at the unproductivity of string theory and at the metaphysical nature of "the landscape" are getting to be a bit old. There's plenty of other topics that would seem fruitful for appropriate critique, such as Alexander Mayer's "revamp" of GR; whether dark matter exists or whether it's just a contrivance that helps make big bang models work; various conflciting ideas of how quantum mechanics ties to consciousness (such as Stapp's and Penrose's philosophies, much of which is over my head but interesting); and so on. However, having said that, it is at least nice that there are voices crying out about string theory and the landscape and making us question whether we really are wise regarding the amount of brain power we are dedicating to these topics.

32. **Christine Dantas**
May 22, 2006

If possible, one suggestion would be to split the comments section into two: technical comments and non-technical comments. So the reader would have to choose to which section he/she would like to write his/her comment. Perhaps things would get more organized. Of course, you would still have to go into moderating the comments. This seems to be unavoidable. I also think that the anonymous contribution is an interesting feature, I would not remove it.

Best wishes
Christine

33. **Kyle**
May 22, 2006

I've been reading this site for over a year now, and every so often I post a comment. I've never found the comment section here the least bit intimidating, and compared to most forums I read everyone including Lubos is really quite tame.

I understand not everyone is as comfortable with conflict as I am, but I can't imagine what the problem with the tone of the comments could be. Surely people aren't avoiding commenting because they worry about the reaction. Surely the good responses aren't lost to the reader because of a few uncivil words above them. Removing uncivil comments will reduce the amount of comments, which could be a good thing – but I don't see how it is going to improve any of the other comments. Definitely let people post anonymously – though it might be nice to force them to choose a handle, just so we can tell them apart.

I don't think there is an easy solution to the problem as you see it. I do not believe a rating system will help, as it is so easily abusable. This is your blog. Hack, slash, and delete comments as you see fit. You are the one who takes the time to make the posts, so make sure the blog has the tone you prefer. Make the rules you follow easy to implement, and then do so mercilessly.

I've found the comments section here to be a gold mine, and I link to the blog all the time. Goodluck finding the right solution for you,

Kyle

34. **secret milkshake**
May 22, 2006

An alternative to Christine’s proposal would be to categorise the entire blog into sub-sections (methink ” Technical Topics and Links, Politics and Academia, Book Business, Latest from Landscape, Media & Propaganda, Applied Lumology”) and enforce a more civil discussion tone (by means of bloodcurdling moderation) just in the technical sub-section.

35. **CapitalistImperialistPig**
May 25, 2006

I am not expert on the subjects usually discussed here, but I do find your blog a valuable resource, uncivilities and all. I personally hope you don’t change it much. I prefer to be anonymous and try to be civil, but like the opportunity to occassionally ask questions of experts. Annoying as Mr Incivility can be, I think he often offers something interesting or at least entertaining.

Fantastic Realities

May 20, 2006
Categories: Book Reviews

Frank Wilczek has a new book out, it's called Fantastic Realities: 49 Mind Journeys and a Trip to Stockholm, and is published by World Scientific. It's a great read by one of the best in the business for anyone interested in physics and should be accessible to people with a wide variety of backgrounds. The book consists of a collection of 43 short pieces, most of which have been published elsewhere (often as "Reference Frame" columns in Physics Today), broken into 11 sections, each with a short introduction. The writing is exceptionally well-informed, elegant, lucid, and thought-provoking.

There's also a section of 6 original poems, which I'll not comment on since I'm not a literary critic, as well as a final section of extracts from Wilczek's wife Betsy Devine's blog Funny Ha-Ha or Funny Peculiar?. The blog entries explain exactly what it's like to be a family member of a Nobel prize winner, and contain lots of useful tips for you and your fellow family members should you ever win a Nobel prize and need to know exactly how to prepare for your trip to Stockholm. I hope I won't be damaging sales of the book by noting that they're available on-line.

Wilczek started out his career with a bang, discovering the asymptotic freedom of Yang-Mills theory in joint work with his advisor David Gross. He was thinking of this work in terms of perhaps showing that the SU(2) part of the new electro-weak gauge theory of Weinberg and Salam might not have the same problem that QED had (effective coupling growing at short distances, invalidating perturbation theory), but Gross was thinking more about the strong interactions and the short-distance scaling behavior recently observed at SLAC. If it could be shown that Yang-Mills theories also had effective couplings that grew at short distances like all other known QFTs, that would rule out QFT as a theory of the strong interactions. The discovery of asymptotic freedom made it clear that Yang-Mills theories might provide a successful strong interaction theory, and there was one obvious choice for the right theory: QCD.

Many of Wilczek's pieces deal with QCD in one way or another, from explaining his original work with Gross, to more recent developments concerning high temperature (relevant to heavy-ion collider experiments) and high density versions of the theory. He also explains some of the beautiful data that has accumulated over the past more than thirty years since its discovery that give us impressive evidence for the validity of QCD. Wilczek puts QCD into a more general context, explaining how logarithmic running of coupling constants can explain the small size of the strong interaction scale when compared to the scale of a putative GUT or even the Planck scale. Besides QCD, he provides excellent discussions of the rest of the standard model, the electroweak theory.

In several different pieces about beyond the standard model physics, Wilczek emphasizes two pieces of evidence that we have for some sort of GUT scenario. One is the fact that if you take the 16 dimensional half-spinor representation of SO(10), under the SU(5) subgroup it decomposes as 1 + 5 + 10, giving all the standard model fields of one generation (including a right-handed neutrino), but in a single irreducible representation. The second is the calculation (that he did in 1981 with Dimopoulos and Raby) of the running coupling constants for the supersymmetric SU(5) GUT (see here, although I'm not sure I agree that this falsifies Popper), which show much closer unification of the three couplings at a single energy than in the non-supersymmetric case.

These two facts are definitely the strongest evidence around for the idea of a supersymmetric GUT, an idea which has dominated thinking about beyond the standard model physics for nearly 30 years, but they are far from convincing. Wilczek deals with the other main idea that has dominated the field, string theory, by essentially ignoring it. I only noticed one or two mentions of string theory in passing in the book. He's not taking a position pro or con on the subject, just deciding that other things are more worth writing about.

The longer pieces in the book are among the best, including a piece on the Dirac equation, written for a book on the most beautiful equations, and pieces on fractional charge quantization and quantum field theory in general, which are a bit more technical than the others. Wilczek brings in interesting historical context to most of the things he writes about, often in an original way.

Perhaps my favorite piece is one entitled "What is Quantum Theory?", which deals with one of my obsessions. Wilczek claims that perhaps we still don't properly understand the significance of quantum theory, especially what it has to do with symmetries. He notes that Hermann Weyl, soon after the discovery of quantum mechanics, realized that the Heisenberg commutation relations are the relations of a Lie algebra (called the Heisenberg Lie algebra), and that this exponentiates to a symmetry group (the Heisenberg group to mathematicians, Weyl group to physicists). Wilczek goes on to speculate that:

The next level in understanding may come when an overarching symmetry is found, melding the conventional symmetries and Weyl's symmetry of quantum kinematics (made more specific, and possibly modified) into an organic whole.

Wilczek is still at it; last week he had a new preprint with Brian Patt which I wish I had time to look at more carefully. In this month's Physics Today, he has another Reference Frame article, now about the anthropic principle, and I'll write about that soon and separately.

There's also a podcast of an interview with Wilczek and his wife conducted at a party in Brooklyn held last month to celebrate the release of the book. If you listen closely maybe you can hear me and others chatting in the next room, despite being told to keep it down because of the recording session…

Comments

1. **Thomas Larsson**
   May 21, 2006

   Five years ago, Wilczek wrote in his Future summary:

   "5.5. Produce the New Particles!
   Of course, the ultimate test for low-energy supersymmetry will be to produce some of the predicted new R-odd particles. Even in the focus point scenario, there must be several accessible to the LHC."

   That is what I call a real prediction!

2. **Thomas Larsson**
   May 21, 2006

   Perhaps my favorite piece is one entitled "What is Quantum Theory?", which deals with one of my obsessions. Wilczek claims that perhaps we still don't properly understand the significance of quantum theory, especially what it has to do with symmetries.

   Gauge symmetries are indeed poorly understood on the quantum level, in more that 2D. This has been noted by many people, e.g. in Haag's book (p 325). One can of course check the Noether identities of the classical action, but quantically one would want to realize gauge transformations as well-defined operators acting on the (kinematical) Hilbert space. To me, it is more important to have such a well-defined realization on *some* Hilbert space, rather than demanding that the Hilbert space comes from QFT in the strict sense (which would be impossible, there are no-go theorems). The missing ingredient can be viewed as explicit observer dependence.

3. **Bert Schroer**
May 21, 2006

My experience leads me to strongly support Thomas Larson´s remark about a deeper quantum understanding of what is behind gauge theory being still very precarious and tentative. In fact I may add some very specific partial (yet unpublished) results which underline this point.
The quantum physical origin of the gauge issue is the fact that family of zero mass finite helicity Wigner representations allow for a covariantization in terms of pointlike field strength, but not for pointlike potentials (a restriction which does not exist in the classical setting because there the positivity of Hilbert space is not an issue). In fact even before one argues about the necessity of potentials in formulating interactions, there is the kinematical observation that it is not possible to write the Wigner inner product in terms of an integral over a local density in terms of field strength, one needs potentials even on a kinematical level. In order to maintain the standard perturbative formalism in terms of pointlike potentials, one is forced to extend the Wigner representation by (Gupta-Bleuler, BRST ghosts), leaving the quantum physical Hilbert space. Although it is deeply relaxing to see that the cohomological aspects of BRST allow a physical descend after having done the computations, such a BRST catalyzer (which was not there in the beginning and left no trace after the physical descent), this situation should not serve as a soft pillow.
Indeed there is a completely different autonomous way (which unlike BRST does not take any hint from the classical selection principle via gauge theory): the best possible localization of potentials in the Wigner space is along semiinfinite spacelike "strings", i.e. the potentials lead to stringlike objects which fluctuate in both the starting point x of the (linear) string and its direction described by a spacelike unit vector e. Since these "strings" have vacuum fluctuation in both x and the de Sitter point e (the space of directions), the fluctuations in x become much milder and are "renormalizable" in the sense of power counting independently of the value of the helicity (Mund-Schroer-Yngvason, math-ph/0511042). So the new problem is how to do perturbation involving such "strings" (since there is no Lagrangian for such objects: how to adjust the Epstein-Glaser method to the more complicated causal geometry of strings). This is a bigger project which I am involved in together with Jens Mund and Jakob Yngvason. But since the results for the metric potential of the (linearized Riemann tensor) field strength are already available, I asked Jens Mund to separate his short computation from the bulk of our joint project and post his short computation onto the server (it should be available within the next two weeks). As far as I know there has been no classical gauge suggestion for helicity larger than one.
Although in the present form these remarks are a bit remote from the main theme of Peters Webblog (to present a platform for alternative ideas to string theory), they may not be so in the future (if it turns out that with there new concepts one can really obtain a well-defined perturbation theory relevant for gravity).

4. **Chris W.**
May 22, 2006

After re-reading physics/0403115, I'd say that Wilczek conveniently ignores the context in which Popper's ideas about the importance of falsification arose. He is essentially saying that he and his colleagues will pursue potential solutions to problems in theoretical physics in whatever way seems sensible to them under given circumstances and in light of prior experience. That's fine, but it in no way undercuts the idea that the impossibility of testing an ostensibly empirical theory is of central importance, and that significant empirical confirmation really only amounts to survival of stringent tests.

To the extent that falsifiability is derided as irrelevant to the actual practice of science by some influential particle physicists one can understand how we have arrived at our current predicament. [Sorry if that remark strikes some as needlessly provocative.]

Someone wrote in to inform me that Alain Connes has made available at his web-site the full text of his long 1994 book Noncommutative Geometry. This is a rather amazing book, in many ways more of a research document than a purely expository work. All sorts of interesting things in it, mainly about Connes's ideas linking the "geometry" of non-commutative "spaces" and the theory of operator algebras, much of this via K-theory.

Last week there was a conference on this topic at Vanderbilt. Connes gave talks there focusing on his recent work related to renormalization. Another main topic of the conference was zeta-functions, and recent developments related to Connes's program for understanding more about them (and perhaps proving the Riemann hypothesis) using ideas from operator algebras and non-commutative geometry. The series of lectures by Consani provide a good introduction to modern ideas about zeta functions and motives that underly this program.

The CERN Council Strategy Group has produced two very interesting "Briefing Books" for its study of strategy for the future of particle physics in Europe.

For something kind of hilarious, see a paper from 2000 pointed out by one of the commenters here. It's by Gordon Kane, Malcolm Perry and Anna Zytkow and entitled The Beginning of the End of the Anthropic Principle. The authors tell us that in string theory, "in principle, and eventually in practice, all of the masses are calculable, including the up and down quark masses, and the electron mass. There is not any room for anthropic variation of the masses in a string theory." The opposite conclusion now seems to dominate string theory research, with the paper many people reference as launching the anthropic landscape that of Bousso-Polchinski written a few weeks after Kane et. al. (although Schellekens and no doubt others would claim that they had the idea much earlier).

David Gross recently gave a series of lectures at Princeton entitled "The Search for a Theory of Fundamental Reality" and they are available on-line. When introducing Gross, Curt Callan noted that Princeton University Press hopes that he'll turn his lectures into a book that they would publish. The last lecture concerns the problems and prospects of string theory and is very similar to one commented on here a couple years ago in the first real posting on this weblog. Gross says about string theory "so far, we haven't really calculated anything", and goes on to give three reasons for this:

1. More and more possible compactifications have been found, all of which seem to be equally consistent.

2. Don't understand how to handle broken supersymmetry.

3. The cosmological constant problem.

The reasons he gives for continued optimism about string theory unification despite these problems are that "we still don't know what string theory really is", and there is no consistent picture of cosmology that is understood within the string theory framework.

He explains the anthropic landscape scenario and how it destroys predictivity, then says that some of his colleagues have given up on Einstein's dream of finding a unique theory with no adjustable parameters, but that he himself won't do so until he is forced to, and he isn't forced to yet since we don't know what string theory is. He made his usual speculation about string theory leading to some still unknown new emergent view of space and maybe time, then went on to give three reasons for supporting continued research in the subject despite its failure to make any progress on its main problems:

1. String theory has given new insights into gauge theory and maybe it will help solve QCD.

2. String theory has given new insights into mathematics.

3. String theory has lead to new speculative phenomenological scenarios (braneworlds).

About point 3. he describes the possibility of evidence for such scenarios showing up at the LHC as "very unlikely" and even says that he is willing to take bets with anyone for any amount of money that the LHC will not see such things (perhaps he should have discussed this with the authors of the recent report that used these scenarios to try and sell the ILC…). I've seen this phenomenon before, but it seems to me peculiar to give as a positive argument for string theory that it leads to the study of phenomenological scenarios that you don't believe.

After his talk, a questioner asked him if string theory might turn out to just be unsuccessful (i.e. wrong), to which Gross responded "String theory can't be wrong (or even killed)". He elaborated by saying that it couldn't be wrong because it was related via AdS/CFT to N=4 supersymmetric Yang-Mills, which was in turn was related to the standard model. Somehow he felt this was an argument that string theory couldn't be wrong, only incomplete. He acknowledged that recently he had come to the point of view that string theory was not something that led to unique predictions about the world, but that it is incomplete. In this view, string theory is just a framework, like QFT, and some new ideas need to be added to it to turn it into something that really relates to the real world.

Someone asked him about LQG, and he responded by saying that he doesn't usually comment on LQG in a polite audience, that it wasn't very successful, didn't connect to GR, and was not of any interest to physics.

He ended with some pessimistic comments about the possibility that the scientific community might lose the will to go on at some point in the future as it became more and more difficult to get information about shorter and shorter distance scales, or moments closer and closer to the big bang.

Update: There's an article entitled Hard Landscape by J.R. Minkel in the June 2006 Scientific American. It deals with the Denef-Douglas work showing that finding a vacuum in the landscape with sufficiently small CC is likely to be a computationally intractable NP hard problem.

"The Douglas-Denef paper is surely a problem for drawing conclusions about what the landscape predicts," asserts Thomas Banks of U.C. Santa Cruz.

Update: Besides the well-known Theoretical Particle Physics Jobs Rumor Mill which deals with tenure-track hiring, there's now the Theoretical Particle Physics Postdoc Jobs Rumor Mill, which deals with postdocs. This year I count among the postdoc hires 31 string theorists, 12 phenomenologists and 5 hard to characterize, with several major institutions that hire multiple post-docs still only hiring string theorists. The rumors I've been hearing that only phenomenologists are getting jobs seem to be complete bunk.

Update: heppostdoc points out that the Postdoc Jobs Rumor Mill is very new and the data is incomplete. Probably complete data would show postdoc hires not as heavily weighted towards string theory.

Update: There's a conference going on near Washington this week entitled From Quantum to Cosmos: Fundamental Physics Research in Space. Mark Trodden is blogging from the conference over at Cosmic Variance.

Update: Eric Weinstein, who continues to conduct his research in mathematics and physics from within the financial industry here in New York, will be giving a talk at the Perimeter Institute on Wednesday at 2pm, with the title "Gauge Theory of Economics". Here's his abstract:

The close relationship between geometry and fundamental physics can be seen from surveying the basic equations underlying the known forces of nature. What has made these repeated appearances of gauge fields and curvature tensors particularly striking in recent years is lack of any comparable applications outside of the Standard Model and General Relativity. In this talk we will pose the question of whether Yang-Mills theory is simply a unifying principle with application well beyond its current use by exhibiting unreasonably effective applications of Gauge Theory beyond those familiar in the Natural Sciences. Armed with these examples, we will then revisit the question about what is most truly special about the Standard Model and Relativity.

1. **Tony Smith**
May 22, 2006

Peter said "… Gross responded "String theory can't be wrong (or even killed)".
He elaborated by saying that it couldn't be wrong because it was related via AdS/CFT to N=4 supersymmetric Yang-Mills, which was in turn was related to the standard model …".

If it is possible (and in my opinion it is likely) that LHC might see only a single Higgs plus stuff similar to what has already been seen elsewhere,
and
if intelligent superstring workers like Aaron Bergman feel that such results would rule out superstring-type supersymmetry so conclusively that superstring workers, in that event, would "give up and go home",
then
why does David Gross feel that superstring theory could be saved (as a theory including the Standard Model – not just as a tool for QCD) by being related to SUPERSYMMETRIC N=4 Yang-Mills ?

As Arun said in a comment on another entry on Peter's blog:
"… some people want to know the answers,
even if it means that most of their productive research years turn out to have been on the wrong path;
while
some people want to build empires. …".

David Gross may, in his heart of hearts, realize that N=4 supersymmetric YM is vulnerable to refutation by LHC results, since he does hedge his bets by saying that he might consider anthropicism if "he is forced to".

As Aaron Bergman said in a comment on another entry on Peter's blog:
"… data is just around the corner …
If anything, much anthropicism is motivated by the specter of the LHC. …".

In short, anthropicism is a way to preserve the superstring empires at Kavli, Texas, etc, no matter what experiments might show at LHC or anywhere else.

As Peter has pointed out, the price of empire preservation by anthropicism is such a threat to the standards of scientific inquiry that objection to anthropicism is something (maybe the only thing?) on which Peter, Lubos, and I all find ourselves in complete agreement.

All things considered, in my opinion the continued prosperity of the empires at Kavli, Texas, etc., would be a good thing, so I will point out an alternative to anthropicism that they might pursue:

Have seminars about currently unfashionable non-superstring (and non-LQG) theories, regardless of their level of development, to see if any of them might have useful aspects that could be incorporated into a post-LHC theoretical physics environment.
Several seminars over the next couple of years (pending LHC results) would
at worst waste some time repudiating in detail incorrect presentations (even the process of repudiation can sometimes produce useful ideas),
but
maybe some would not be worst-case,
and they might possibly produce a few useful gems that might help to save some empires.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

2. **heppostdoc**
May 22, 2006

Hi Peter,

Let me caution against drawing too many conclusions from the postdoc rumor mill. It's still very new, and most of the listings there came from one submitter, who was apparently a string theorist (or at least knew mostly about the string theory jobs). Since you posted this, there were two more pheno jobs posted, and there are probably many holes left. If I had to guess, I'd say that this year will simply be imcomplete. Maybe some useful information will come next year.

3. **Aaron Bergman**
May 22, 2006

Aaron Bergman feel that such results would rule out superstring-type supersymmetry so conclusively that superstring workers, in that event, would "give up and go home",

That's not what I meant. What I meant is that if that's the only thing to be seen, that'd be the end of large scale high energy physics experiment. Without new experiment, theory ends up pretty adrift and it's not a pretty picture what happens next.

"… data is just around the corner …
If anything, much anthropicism is motivated by the specter of the LHC. …".

In short, anthropicism is a way to preserve the superstring empires at Kavli, Texas, etc, no matter what experiments might show at LHC or anywhere else.

It's not a matter of preserving "empires"; it's a matter of people want to be able to make connections with data. Anthropicism is a (misguided in my view) attempt to do so.

4. **Tony Smith**

May 22, 2006

Aaron Bergman said: "… What I meant is that if …
[a single Higgs plus stuff similar to what has already been seen]
…[is]… the only thing to be seen [at LHC], that'd be the end of large scale high energy physics experiment. …".

There are a lot of interesting non-supersymmetric possibilities (in such areas as the Higgs – T-quark system, for example) that might be seen at LHC and explored in detail at ILC. Since Peter has told me that he doesn't want me to talk about such things in detail on his blog, I won't, but they are out there (papers in arXiv, etc) for anyone with interest to see.

Therefore, I think that the only people who would have to "give up and go home" in the stated contingency would be unshakeable true believers in conventional supersymmetry.

I also think that it would be a shame for the ILC proposals to bet the farm on true-belief in such supersymmetry, when ILC in conjunction with LHC might be very useful in exploring particle physics even if it turns out that nature does not use conventional supersymmetry.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

5. **Aaron Bergman**
May 22, 2006

You still don't understand. I'm not talking about if SUSY isn't seen at the LHC. There are plenty of other interesting possibilities. I'm talking about a single doublet Higgs and that's it. Nothing else. I'm not sure I'd bet on SUSY these days anyways, given some of the issues that have arisen. I just hope that there is something more interesting to EWSB than just a boring scalar field with a finely tuned potential.

6. **Chris W.**
May 22, 2006

For a brief summary of what appears to be Weinstein's key application of gauge theory to economics, see this page on his website.

I've often wondered why the basic ideas of gauge theory haven't been more widely applied in economics. One way to think about this is the following: How goods and services are valued in terms of an abstract medium of exchange would seem to have a large element of convention. It should be possible (one imagines) to globally shift the values of all goods and services without affecting the underlying economic "reality", implying that these values are not "real". However, shifts of value *as seen and understood by the participants in an economy* are local, not global, must be propagated through the economy, and therefore have substantive economic effects.

This is strongly reminiscent of a change from a global gauge symmetry to a local gauge symmetry of a physical field; the dynamics of the field must come into play to implement the symmetry.

"Someone asked him about LQG, and he responded by saying that he doesn't usually comment on LQG in a polite audience, that it wasn't very successful, didn't connect to GR, and was not of any interest to physics."

while this does seem to be the view of the majority of string theorists, i wonder if the LQG predictions for the resolution of naked singularities

http://www.ioppublishing.com/news/1044

if observed, would change this.

May 22, 2006

That article is very odd. Last I checked, reasonably generic gravitational collapse produced horizons.

Wilczek on the Anthropic Principle

May 21, 2006
Categories: Uncategorized

Frank Wilczek has a new Reference Frame piece in this month's Physics Today. It's about the question of whether the parameters of our fundamental physical theory are uniquely determined by abstract principles, or "environmental". He gives two reasons for suspicion about the idea that these parameters are calculable from a fundamental theory:

1. They have complicated, "messy" values and, despite much effort, no one has come up with a good idea about how to calculate them (an exception is the ratio of coupling constants in a supersymmetric GUT). He writes:

Could a beautiful, logically complete formulation of physical law yield a unique solution that appears so lopsided and arbitrary? Though not impossible, perhaps it strains credulity.

2. Some of the values are fine-tuned to make complex structures and thus life possible:

It is logically possible that parameters determined uniquely by abstract theoretical principles just happen to exhibit all the apparent fine-tunings required to produce, by a lucky coincidence, a universe containing complex condensed structures. But that, I think, really strains credulity.

Personally I don't see the same degree of believability problems that Wilczek sees here. On the first point, it seems quite plausible to me that there are some crucial relevant ideas we have been missing, and that knowing them would allow calculation of standard model parameters, by a calculation whose results would have a complicated structure.

On the second, it's not at all clear to me how to think about this. Sure, the fact that our universe has highly non-generic features means that it is incompatible with generic values of the parameters, but there's no reason to expect the answer to a calculation of these parameters to be generic. I guess the argument is that there would then be two quite different ways of getting at some of these parameters: imposing the condition of existence of life, and a fundamental calculation; and if two different, independent calculations give the same result one expects them to be related. But the question is tricky: by imposing the condition of the existence of life in various forms, one is smuggling in different amounts of experimental observation. Once one does this, one has a reason for why the fundamental calculation has to come out the way it does: because it is has to reproduce experimental observations.

Wilczek avoids any mention of string theory, instead seeing inflationary cosmology and axion physics as legitmating the idea that standard model parameters are fixed by the dynamics of some scalar fields, or something similar. This dynamics may have lots of different solutions so:

We won't be able to calculate unique values of the parameters by solving the equations, for the very good reason that the solutions don't have unique values.

The fundamental issue with any such anthropic or environmental explanation is not that it isn't a consistent idea that could be true, but whether or not it can be tested and thus made a legitimate part of science. It's easy to produce all sorts of consistent models of a multiverse in which standard model parameters are determined by some kind of dynamics, but if one can't ever have experimental access to information about this dynamics other than the resulting observed value of the parameters, why should one believe such a theory? It is in principle possible that the dynamics might come from such a simple, beautiful theory that this could compel belief, but the theories of this kind that I have seen are definitely neither simple nor beautiful. If you want me to believe in a complicated, fairly ugly theory, you need to produce convincing evidence for it, some sort of testable predictions that can be checked. Wilczek does believe that multiverse theories may provide such predictions:

Of course, the very real possibility that we can't calculate everything in fundamental physics and cosmology doesn't mean that we won't be able to calculate anything *beyond what the standard models already achieve. It does mean, I think, that the explanatory power of the the equations of a "theory of everything" could be much less than those words portend. To paraphrase Albert Einstein, our theory of the world must be as calculable as possible, but no more.*

One can't argue with this: if a model make distinctive predictions, and these can be compared to the real world and potentially falsify the model, one can accumulate evidence for the model that could be convincing. Unfortunately I haven't seen any real examples of this so far. The kind of thing I would guess that Wilczek has in mind is his recent calculation with Tegmark and Aguirre that I discussed here. I remain confused about the degree to which their calculation provides any convincing evidence for the model they are discussing.

Unlike many theorists, Wilczek personally seems to be an admirably modest sort of person, and perhaps this has something to do with why the multiverse picture with its inherent thwarting of theorist's ambitions to be able to explain everything has some appeal for him. Over the years during which particle theory has been dominated by string theory, Wilczek has shown little interest in the subject, perhaps partly due to its immodest ambitions. But I see two sorts of dangers in the way his article ignores the string theory anthropic landscape scenario which is what is driving the interest of much of the theory community in these multiverse models. As his advisor David Gross likes to point out, accepting this scenario is a way of giving up on the perhaps immodest goal he believes theorists have traditionally pursued, and one shouldn't give up in this way unless one is really forced to. None of these models is anywhere convincing enough to force this kind of giving up.

The second danger is that what is happening now is worse than just giving up on a problem that is too hard. The string theory landscape anthropic scenario is being used to avoid acknowledging the failure of the string theory unification program, and this refusal to admit failure endangers the whole scientific enterprise in this area.

Update: It has been accurately pointed out to me that Wilczek does mention string theory briefly at one point in the article ("Superstring theory goes much further in the same direction"), and alludes to it at another place (when he talks about a "theory of everything").

Comments

   May 21, 2006

   Regarding Wilczek's point 2: what Schellekens says is that if the equations of some fundamental theory managed to produce all of these numbers, then the notion that the laws of physics seem to be specially designed to produce life would be replaced by the notion that the "laws" of *mathematics* seem to be specially designed to produce life. And that would be far *worse*! I urge everybody to re-read Schellekens' paper to see what he is saying about this.

2. **Kea**
   May 21, 2006

   The classical physicist's expectation, far from being trivial, is wrong. E. Schroedinger, 1945

   This quote is from the famous book *What is life?* based on a series of lectures that Schroedinger gave in Dublin at the end of the war. Geneticists have a high regard for the place of this book in the history of biology. Anyway, there is no reason whatsoever to think that the parameters for life are anything special, except from the anthropological point of view. What *is* terrifying is the thought that the new laws of physics should say something about biology. But Schroedinger recognised that this was *inevitable* over 50 years ago!

3. **Kea**
May 21, 2006

Of course, I say that (the above) as someone that does think these parameters are calculable. What is so wrong with the idea that biology become more quantitative? It already has.

4. **Chris W.**
May 21, 2006

I don't think the degree to which biology is quantitative is the issue. Besides, that any subject can be made quantitative is trivial, unless one asks what the numbers *mean*. What is interesting are quantities and quantitative arguments that have deep *qualitative* implications. Supposing that certain physical constants of the observed universe are "anthropically" determined—that is, by a selection effect—tells us little or nothing we didn't already know (or think we know) about either life or the laws of physics.

Consideration of the anthropic principle won't get anywhere until it divests itself of the connotations of the word "anthropic" (and for that matter, "terrestrial"). The question is this: Does allowance for the existence *and natural evolution* of autonomous, self-reproducing physical systems somewhere in the universe impose any constraints on the laws of physics, or in any sense dictate their form?

5. **Kea**
May 21, 2006

Does allowance for the existence and natural evolution of autonomous, self-reproducing physical systems somewhere in the universe impose any constraints on the laws of physics, or in any sense dictate their form?

Or conversely: do new laws of physics naturally imply the existence of self-reproducing molecules, say via their appearance in a periodic table of structures?

6. **Haelfix**
May 21, 2006

Yea I agree with this idea in general. If you resort to anthropic reasoning (and I like how you mention that it is often understated that it requires somewhat tautological preexisting empirical output since we only have one universe with life in it that we can measure things in) then you face Occams razor.

eg Pick the simplest theory then that has the least amount of arbitrary continously adjustable free parameters (whether in solution space or theory space) and thats probably what you should go with. Unfortunately at this time, thats more or less the standard model + generic nonrenormalizable GR + maybe a few simple and well understood extras, like GUTs.

I mean the whole starting point of ST and most modern particle physics is to get rid of the naturalness problems, giving up on that most important goal, is premature, badly motivated and frankly annoying to the majority of physicists.

7. **D R Lunsford**
May 22, 2006

"We won't be able to calculate unique values of the parameters by solving the equations, for the very good reason that the solutions don't have unique values."

See Dirac's large numbers work. There is no reason to expect them to have determined values, rather, some inherent relation to be found out (I think a conformal one). Example – in Weyl's theory one could in principle connect the value of the background radiation with G.

May 22, 2006

> Personally I don't see the same degree of believability problems that Wilczek sees here. On the first point, it seems quite plausible to me that there are some crucial relevant ideas we have been missing, and that knowing them would allow calculation of standard model parameters, by a calculation whose results would have a complicated structure.

It's "ecobalanced"…

All of the anthropic coincidences are balanced "just-so", in a "goldilocks" manner, between diametrically opposing runaway tendencies. This goes way beyond the standard model to apply to every anthropic coincidence.

"Coincidentally"… ecosystems are also the most effecient means for uniformly disseminating energy, because they spread the process out over numerous "topological hotspots", over an extended period of time. There are other facets to this…

Given the physical necessity for dissipative structuring, this is the most natural, (the only), configuration that our expanding universe could have. The balance is fixed, in other words.

The expansion process can't maximize the entropic effort per the least action principle if the universe is not economically restricted to dissipate energy in the most "energy-efficient" manner possible.

Energy is not conserved if work isn't maximized, so an expanding universe assumes the form that conserves energy and the second law of thermodynamics via an ecobalanced configuration that maximizes energy.

Dirac's Large Numbers Hypothesis is flawed by his choice to fix the electric force rather than gravity. The mechanism for the AP becomes clear when you reverse this physics.

9. **Eric Dennis**
May 22, 2006

Is there a reference for any systematic study of low energy behavior over the Standard Model parameter space? It seems like a very hard problem to determine the volume of this space (in some reasonable measure) that is life-viable. At least with any kind of rigor. There is the issue of what happens in this space right near where we are — and then there is the seemingly much harder issue of totally distinct life-viable regions.

10. **Who**
May 22, 2006

One admires Wilczek for a lot of reasons, including his flair for winging it philosophically (which a person with his originality can safely do). But since he is talking about philosophical issues in physics and cosmology, I would have suggested he draw on what should become a standard handbook reference:

http://arxiv.org/abs/astro-ph/0602280
Issues in the Philosophy of Cosmology
George F. R. Ellis
To appear in the **Handbook in Philosophy of Physics**, Ed J Butterfield and J Earman (Elsevier, 2006).

"After a survey of the present state of cosmological theory and observations, this article discusses a series of major themes underlying the relation of philosophy to cosmology. These are: A: The uniqueness of the universe; B: The large scale of the universe in space and time; C: The unbound energies in the early universe; D: Explaining the universe — the question of origins; E: The universe as the background for existence; F: The explicit philosophical basis; G: The Anthropic question: fine tuning for life; H: The possible existence of multiverses; I: The natures of existence. Each of these themes is explored and related to a series of Theses that set out the major issues confronting cosmology in relation to philosophy."

Science and the philosophy of science being collective cumulative efforts, what's the use of paying GFR Ellis to write a thoughtful 60-page handbook article about the very issues Wilczek addresses if he doesn't use it? I havent yet seen the Physics Today opinion piece, but it sounds as if (characteristically) Wilczek is winging it.

Maybe the signature fresh outlook is something to be celebrate, and one shouldnt care. But when I get hold of a copy I will check to see if he cites Ellis.

11. **woit**
May 22, 2006

Who,

I think Wilczek is someone whose motivations are primarily from very practical and phenomenological considerations, without taking a lot of interest in abstract philosophical or formal points of view. He certainly doesn't refer to Ellis or anything like it. In any case, this was a short column, a semi-popular piece of science writing, not a serious scientific paper.

12. **Who**
May 22, 2006

In that case what matters is that it be entertaining and provocative, which I feel sure it is. I'll be at the library presently and have a look.

13. **Michael**
May 22, 2006

"The second danger is that what is happening now is worse than just giving up on a problem that is too hard."

Sure, that`s the big concern about anthropic reasoning. If it were only giving up on something that appears to be too hard, the problem would be rectified the moment somebody demonstrates that one can do better. But if this perception is allowed to poison the organizing principles of theoretical physics, it can become a real obstacle to future progress.

That`s precisely why we must understand what string theory is, even if the remote possibility is taken seriously that it might not be a theory of nature. Comprehensively understanding the theoretical possibilities of unifying gravity with quantum mechanics is a necessary step in determining the amount of ad hoc input needed before a theory can become predictive.

Anthropic reasoning is based on the statement that a lot of ad hoc input is needed. Not surprising that this idea is taken seriously by some, while our understanding is still limited. The smart money is on the landscape going away eventually…

14. **Who**
May 22, 2006

In reply to Michael's comment
http://www.math.columbia.edu/~woit/wordpress/?p=396#comment-11077
I would agree that
"Comprehensively understanding the theoretical possibilities of unifying **spacetime** with quantum mechanics"
would be a necessary step for a number of reasons, some perhaps more significant than the one Michael mentioned but including his.

I note that the theory of spacetime dynamics that we have to work with is GR, so that would mean understanding what is involved in unifying quantum mechanics with GR or with some variant of GR—a theory of spacetime geometry exhibiting at least the **salient features** of General Relativity in an explicit up-front way.

As a minimum, something in the theory must represent the spacetime metric as a dynamic variable—or an equivalent surrogate of the metric–because that is the geometry. And the quantum state must be a state of that metric, alias the geometry.

what makes me doubtful of Michael's reasoning (suspicious that it is mere apologetics) is that saying

"Comprehensively understanding the theoretical possibilities of unifying GRAVITY with quantum mechanics" allows "gravity" to work as a weasel word—so that we suddenly find ourselves talking about some theory which does NOT present a straightforward quantum model of the geometry of spacetime and does not actually **quantize General Relativity**. May even lack primary features of GR such as the explicit absence of a fixed background metric.

======================
In case anyone wants to inspect Michael's persuasive argument to motivate further string study I will try to paraphrase:

A. Anthropic reasoning is a poison dangerous to theoretical physics.

B. To guard against the harmful effects of this poison we must understand "the amount of ad hoc input needed before a theory can become predictive."

(This would vary quite a bit: he doesnt say what theory or what kind of theory. Some types of QG have different requirements from string and are already falsifiable. I dont fully understand what he means by "input needed" since a theory either does or does not make predictions which would allow it to be ruled out—-it does not make CONDITIONAL predictions which allow it to be CONDITIONALLY ruled out based on some further assumptions. That would regress to testing those further assumptions. But for the sake of argument let this pass. Michael's "**a theory**" probably means a stringy theory if it means anything definite.)

C. Therefore to guard against the harmful effects of this poison we must diligently study string theory. Because only in this way will we be able to discover how much "ad hoc input [is] needed before [it] can become predictive."

15. **steve**
May 23, 2006

I'm somewhat puzzled here. How many free parameters are okay? Is the ultimate goal to have a testable theory in which all numerical values are functions of pi, e, i, etc. with no observational input? In order for that to happen, you'd have to have a theory with no empirical free parameters which explained the known data but made predictions about currently unknown but discoverable phenomena. Good luck with that, but I wouldn't hold my breath.

On the other hand, if some "brute facts" are allowed to remain unexplained in the ultimate theory, how do you know when you've reached the irreducible minimum? My guess is that it will come down to taste, faith, and the resources available to keep looking, since there seems not to be any reliable inductive method for knowing when to quit.

16. **Kea**
May 23, 2006

Steve

The question is about the parameters of the Standard Model and GR. If we can derive these, and there is every reason to believe it is possible, then we have a complete theory of SM+GR. This does not mean that future investigations will not reveal the necessity of more, as yet unknown, parameters of a post SM physics. So, no theory of everything – we are only human – but from our limited perspective the next breakthrough might well have the semblance of something grand.

17. **nostradamus**
May 24, 2006

Newyear 2007: Lenny Susskind conjectures that the consequences of String Theory are not understandable for the homo sapiens sapiens. He calls it the finite-brain conjecture.

January 2007: String Theorists all over the world realize that the f-brain conjecture naturally supports their believe that String Theory is the Theory of Everything, and moreover, it successfully explains the current crisis. The conjecture is strongly criticized for relating two not fully understood subjects, String Theory and the human mind.

Summer 2007: Ed Witten proves that the conjecture can not be proved. String Theorists realize that their quest is over. Either String Theory is not the Theory of Everything, or it is, and then they can never understand it. Gary Horowitz generalizes the statement by attaching bubbles of nothing to the f-brain. Lee Smolin points out that the conjecture fails for independent brains, but is widely ignored by the community.

End 2007: Thousands of String Theorists retire. They have fulfilled the task of finding the Theory of Everything. They have revealed what was possible, and have shown that the full beauty of the theory is to vast to fit into the human brain. They declare the end of theoretical physics, until intelligent designers improve the human f-brain.

January 2008: Those who are left focus on brain-independent theories.

18. **Peter Shor**
May 24, 2006

I think I've said this before on this weblog, but I will say it again. I don't understand why string theorists are working on the landscape and the anthropic principle, which as far as I can tell has virtually no mathematically well-defined content, when they could be working on the perfectly well formed, although probably unverifiable experimentally question, of "exactly what happens to the information inside it when a black hole evaporates." (Some of them undoubtedly are; let me apologize to these string theorists.)

In other words, if you don't want to work on physics (i.e., stuff you can get at by experiments), at least work on mathematics.

19. **Aaron Bergman**
May 24, 2006

(Some of them undoubtedly are; let me apologize to these string theorists.)

I think you'll find that the majority of them are; just look at hep-th on an given day. The landscape people just happen to be louder.

20. **Moshe**
May 24, 2006

Peter Shor, irrespective of one's opinion on the anthropic principle, it is a sociological fact that this idea as an approach to cosmology predates the string landscape and is still practiced mostly by non-string theorists (such as Wilczek), not that I think such sociological issues are that crucial…
\
Also, again irrespective of one's opinions on the physical content of the anthropic principle, the study of the landscape certainly motivated lots of interesting and well-posed mathematical problems (e.g. see the work of Douglas and collaborators).

21. **Chris Oakley**
May 24, 2006

I am not sure about Nostradamus here's predictions. FWIW, here are my own:

2006: "I can't believe that you guys are so impatient," say leading String Theorists. "Here we are, about to discover the answer to the Ultimate Question – the answer to Life, the Universe, Everything and you are demanding that we connect or theories to the real world. *Of course* we will do that. That and more. You just have to be patient."

2026: "I can't believe that you guys are so impatient," say leading String Theorists. "Here we are, about to discover the answer to the Ultimate Question – the answer to Life, the Universe, Everything and you are demanding that we connect or theories to the real world. *Of course* we will do that. That and more. You just have to be patient."

2040: Ed Witten dies and within six months is canonised Saint Edward of New Jersey.

2046: "I can't believe that you guys are so impatient," say leading String Theorists. "Here we are, about to discover the answer to the Ultimate Question – the answer to Life, the Universe, Everything and you are demanding that we connect or theories to the real world. *Of course* we will do that. That and more. You just have to be patient."

2066: "I can't believe that you guys are so impatient," say leading String Theorists. "Here we are, about to discover the answer to the Ultimate Question – the answer to

Life, the Universe, Everything and you are demanding that we connect or theories to the real world. *Of course* we will do that. That and more. You just have to be patient."

Kea said:

"The question is about the parameters of the Standard Model and GR. If we can derive these, and there is every reason to believe it is possible, then we have a complete theory of SM+GR."

Just out of curiosity, what gives you confidence that it is possible to derive unique values for the parameters of the SM+GR?

I'm sure it would be wonderful if that were true. But I have no idea, one way or the other, whether it is true (either in string theory or in some other, as yet unknown, approach).

23. **nostradamus**
May 24, 2006

All physicists are equal. But some are more equal than others. Be kind. Open the exit door for String Theorists, and offer them a helpful hand. They know it's time to go.

24. **Peter Woit**
May 24, 2006

Moshe,

I think justifying landscape work by its application to mathematics is a real stretch. Sure, it has generated some well-posed mathematics problems, but very few interesting ones, especially in comparison with other areas of string theory (e.g. topological strings), which have generated a lot of interesting mathematics. I spend a lot of time talking to many different mathematicians, especially ones interested in physics, and I can think of exactly one who has ever had an interest in anything generated by landscape studies (in a problem that asked about asymptotics of numbers of sections).

Douglas has a review promoting this kind of work

http://www.arxiv.org/abs/math-ph/0508019

Notice that the only references to work by mathematicians is to that of two of them who have collaborated with him on the problem of asymptotics of sections.

25. **B**

Statistics on the Heterotic Landscape:
Gauge Groups and Cosmological Constants of
Four-Dimensional Heterotic Strings
Keith R. Dienes

p 57

"By contrast, the second danger can be called the "Gödel effect" — the danger that no matter how many conditions (or input "priors") one demands for a phenomenologically realistic string model, there will always be another observable for which the set of realistic models will make differing predictions. Therefore, such an observable will remain beyond our statistical ability to predict. (This is reminiscent of the "Gödel incompleteness theorem" which states that in any axiomatic system, there is always another statement which, although true, cannot be deduced purely from the axioms.) Given that the full string landscape is very large, consisting of perhaps 10^500 distinct models or more, the G¨odel effect may represent a very real danger. Thus, since one can never be truly sure of having examined a sufficiently sizable portion of the landscape, it is likewise never absolutely clear whether we can be truly free of such Gödel-type ambiguities when attempting to make string predictions."

27. **Peter Woit**
May 24, 2006

The invocation of Godel incompleteness is pretentious and absurd since there is nothing deep, subtle, or fundamental going on here. Lots of speculative ideas about physics turn out to be useless once you look into them because they can't be used to actually predict anything about the real world. String theory unification is just one more such useless idea, and the only strange thing about it is the sociological phenomenon of serious scientists refusing to abandon a failed project.

28. **anonymous**
May 24, 2006

A continually stalling project is actually a very safe territory to work on. If string theory was in danger of closing shop by producing the 'final theory' tomorrow, it would be hazardous to base a career on string theory.

On any large project, when success arrives the project workers are out of jobs, because far fewer researchers are needed to continue working on the completed product. If and when the much-touted 'final theory' arrives, a vast change in careers goals will be required.

I think that, far from celebrating, most people will be enraged that the fundamental physics will reach completion. Anyone who say climbs a mountain for the first time removes the opportunity for anybody else to do so, and in that sense is very selfish.

29. **steve**
May 24, 2006

Kea: I'm still not getting it. Any unification of GR + SM (assuming that's possible) will still have some number of parameters. Either these will be empirical parameters with no further justification OR they will all be fundamental math constants such as pi. My question is: How do you know when you've reduced the number of empirical parameters down to the bare minimum, i.e. when is further unification pointless? And how do we know that point hasn't already been reached?

30. **Kea**
May 24, 2006

How do you know when you've reduced the number of empirical parameters down to the bare minimum, i.e. when is further unification pointless?

When you have none *within* the theories that were being unified. Of course, you will probably be introducing *new* ones, because that's what usually happens. But there is no need to focus initially on the new ones when just understanding the unification is a big enough problem.

And how do we know that point hasn't already been reached?

Well, that depends what you mean by the word *know*. Most good physicists that I know would bet their life on the fact that we haven't reached that point with the anthropic principle. And the idea that no one has any idea about any alternatives is ludicrous.

31. **LambchopofGod**
May 24, 2006

Peter Shor: as has been pointed out, there is probably more work being done on the fate of information in black holes than on the landscape. However, I am mystified by Aaron B's remarks. Surely if it is indeed true that string theory inevitably leads to a landscape, this is something that we want to know. Conversely, any discovery of a mechanism that selects a point or a region in the landscape would be an enormous advance. The problem is precisely that there are *not enough* people working on these things, and way too many working on essentially trivial technical exercises justified by the feeble hope that they will teach us "what string theory really is".

Peter Shor again: "In other words, if you don't want to work on physics (i.e., stuff you can get at by experiments), at least work on mathematics. "

Sorry, this was tried for a long time and it did not work very well at all. There was a time when physicists would rush out and learn a new mathematical technique [K-theory, even category theory…] at the drop of a hat. It didn't really get us anywhere at all.
The interest among physicists in pure mathematics has collapsed for a good reason. Nowadays people pin their hopes on the field where the data are, viz cosmology. And work on the landscape should be part of that. I'm not saying by the way that all of these developments are good, just that there is a reason for what has happened.

32. **Thomas Larsson**
May 24, 2006

Sorry, this was tried for a long time and it did not work very well at all. There was a time when physicists would rush out and learn a new mathematical technique [K-theory, even category theory…] at the drop of a hat. It didn't really get us anywhere at all.

Lambchop, of course random new math does not help. You have to learn, and perhaps invent, the right kind of new math. K-theory and category theory wouldn't have helped Einstein finding GR or Dirac finding his equation. Tensor calculus, and the representation theory of SU(2), did the trick. And that was new math (at least new to physicists) at the time.

It has been obvious to me for almost two decades which kind of new math is needed to quantize gravity; since spacetime diffeomorphisms play an fundamental role in gravity, we need to understand the diffeomorphism group and its projective representations. This is why I started to search for, and later discovered, how to generalize the Virasoro algebra to several dimensions.

It really baffles me that others don't want to look in this direction. Urs Schreiber even independently made the same observation, but then lost interest when he realized that I agreed with him.

33. **Moshe**
May 24, 2006

Peter, fair enough, I made a mistake by adding the word "interesting" which represents an opinion. Strike it then, it is not essential to my response to Peter Shor's remark.

34. **Aaron Bergman**
May 25, 2006

There's two issues here. The first is whether it means anything to make statistical predictions. I don't believe it does. The second, however, is that, as best I can tell, there's this huge region of parameter space over which we have absolutely no control. And, even in the vacua about which we can say something, it is almost always in the context of effective field theory with a conjectural nonperturbative scaffolding. So, at best we're learning about some subset of vacua with the hope that there isn't some unknown phenomenon that ruins the whole game. Studying these examples might be useful in that they could inspire new phenomenological scenarios, but I don't think there's much hope of applying string theory to the real world if we don't even know what it *is*. My personal opinion is that that's a much more useful question to research (and do "trivial technical exercises") than to create increasingly complicated tinker-toy vacua that still bear very little resemblence to the world as we know it. I think one of the reasons you're seeing a resurgence of interest in things like AdS/CFT is that it's one of the few things in string theory that, if you kick it, it'll actually hurt your foot. And, for what it's worth, those categories you deride give the best description of gauge theories on D-branes at a singularity and, hence, AdS duals of field theories other than N=4 SYM. Even if string theory doesn't turn out to be the theory of everything in our world, given that it does appear to be *a* theory of quantum gravity, we can at least try to learn how it solves the usual problems associated with that.

But that's just me. I've been wrong before (lots), and I don't have a job anyways.

35. **LambchopofGod**
May 25, 2006

You'll get a job — you just need to switch to cosmology. 🙂
Come on, don't you think that something like

http://arxiv.org/abs/hep-th/0510046

[which, by the way, invokes the landscape]
is far more worthwhile than hopeless calculations aimed at finding out what string theory really IS, but which never seem to lead anywhere? True, they didn't really achieve all that much, but at least they did something that goes in the right direction, towards the real world. Historically [yes, I know this sort of argument is often crap, but anyway….] people almost *never* knew what their theory really WAS until much later. Schroedinger didn't know about probability. Einstein thought that SR could not really handle acceleration. Everybody made all kinds of idiotic mistakes, but in the end they found out what their theories really WERE long *after* they made some connection with the real world. Yes, trying to find out what the theory really IS sounds very noble. But Don Quixote felt the same way about attacking those windmills.
And as for categories — forget it! Even if they are the key to the Universe [like quaternions? 🙂] nobody will pay any attention.

> Most good physicists that I know would bet their life on the fact that we haven't reached that point with the anthropic principle. And the idea that no one has any idea about any alternatives is ludicrous.

Ludicrous is the right word.

I think that it is quite possibly relevant that quantum mechanics isn't inherently able to describe dissipative structuring since it depends very much on Hamiltonian mechanics… except by way of the "Master Equation in the special, Lindblad form, which derives that flatness acts as a natural harmonic damper mechanism that keeps the imbalanced universe from evolving inhomogeneously, so this is the most natural configuration… if the universe is finite and closed… given inherent asymmetry in the energy. This will necessarily maximize the time that the expansion process takes, and that's what a flat universe accomplishes via anthropic structuring.

Peter Woit Says: […]
and the only strange thing about it is the sociological phenomenon of serious scientists refusing to abandon a failed project.

I don't find that so strange. I guess they just don't know what else to do. Front research in physics has fallen apart into specialized subclasses, and it takes time and effort to change subject. Even for a postdoc it's become hard to change the field. (Even more so since knowing the relevant people is an non-negligible factor.) If you have worked for some decades on String Theory, you just don't drop the pen and say: Hey, the landscape sucks, lets go make spin foam models instead.

Or, to put it differently, someone should think about what we ought to do with all the String Theorists.

Best, B.

38. **Peter Woit**
May 25, 2006

The attitude of "LambchopofGod" encapsulates well everything that is wrong with what is going on in particle theory these days. The idea that "too much math" is what caused the problematic state of the field has caused a backlash against investigating new ideas about mathematics and fundamental physics and this is both unfortunate and extremely unhealthy for the future of the subject.

The current prejudice seems to be that the problem isn't string theory, but all that nasty math stuff, and by doing more "physical" calculations in string theory, one will manage to get closer to reality. This is nonsense. There are very well-understood reasons by now why string theory can't tell you anything useful about anything collider experiments or cosmology-related experiments are going to see in our lifetimes. Pretending this isn't so is just going to lead to completely useless work and the continued destruction of this field.

I don't happen to believe that trying to think about "what string theory really is" is the best way to learn anything, but it's a lot more promising than wasting ones time trying to connect string theory to cosmology or LHC physics because that sounds good. At least there's a chance of learning something.

39. **Peter Woit**
May 25, 2006

Aaron,

Sorry to hear you're having job problems, the job situation in this field has sucked for a very long time, and in some ways is worse now than ever, especially for anyone who thinks interesting new math and physics go hand in hand. Undoubtedly you've thought about this, but you might have better luck looking in math departments. Good luck!

40. **Bert Schroer**
May 25, 2006

It is sad to see that virtually all the Millenium Nobel laureates in particle physics left their critical mind at the wardrobe to the string club where the new reality is being manufactured.
The following is an illustration for how facts are manufactured in String theory.
Witten's introduction of the Maldacena conjecture:
"Recently it has been proposed by Maldacena that large N-limits of certain conformal field theories in d dimensions can be described in terms of supergravity and string

theory on the product of d-+1 dimensional AdS space with a compact manifold."
(Note the "proposed")
After more than two thousand citations the Witten passage changed to
(Berenstein, Maldacena and Nastase):
"The fact that large N gauge theories have a string descirpition was believed for a long time. These strings live in more than 4 dimensions….".
The conjecture has been manufactured into a correspondence. The answers to why such things happen are sociological and have nothing to with science (only the the sociology of scientists). String theory is a community and then all the researchers in such a social setting are compelled to accept things like that; no one can refuse to recognize it without undermining the veracity of the whole construct.
Yesterday I listened to one of the available online talks of David Gross. I didn't believe that this is the same Gross whom I met (and discussed physics with a long time ago in Aspen) when he claimed that string theory cannot be proven wrong because it is linked via the Maldecena conjecture to the standard model. What I find so incredible is that the audience in a place like Princeton (where Pauli and other critical minds spend many years) receives such statements with applause.
Having experienced such a weird video, the fact that Wilszeck has not a single profound word of critique for this millenium circus was almost expected.

41. **Aaron Bergman**
May 25, 2006

I should say by the way, that if my previous comment came across as bitter, it wasn't meant to be. I made a conscious decision about what I wanted to do, and I wasn't expecting to get a physics position given my choice of research topic and productivity. Unfortunately, the idea of applying for math jobs occurred to me too late in the game.

For lambchop, actually I like that paper precisely because it is in AdS/CFT. As for the rest, I don't really see where these vacuum contraptions have gotten us thus far. It hasn't given us any new insight into the cosmological constant problem, and there's next to nothing being said about neutrino decay or proton decay from dimension five operators. The best prospects I see are for new mechanisms for inflation (which really is a lot ickier than it's made out to be even ignoring the question about the initial conditions) and supersymmetry breaking (assuming supersymmetry even exists at the weak scale given that current experiments either seem to indicate a fine tuned MSSM or something a bit more non-minimal). I'm not denigrating this, by the way; outside of mathematics, string theory has been most successful in inspiring new ideas in field theory and phenomenology. The odds of this leading towards some sort of smoking gun for string theory, however, seem rather long to me. Of course, I've always been a formalist at heart (closet mathematician, it's been accused), so there's a lot of my personal prejudices speaking here.

And on the mathematics front, in the realm of actually trying to construct vacua like our world (as opposed to, say, immediately postulating gadzillions of them), the constructions are all rather mathematical, (0512177 and 0512149 or 0512170 where they try to do SUSY-breaking).

I saw a sign that someone may have been thinking about it. Baez left a trail of crumbs leading to spinfoam when he titled his last two papers
Quantization of strings and branes coupled to BF theory
and
Exotic Statistics for Strings in 4d BF Theory

Now we will see if the ants find the sandwich.
http://arxiv.org/find/grp_physics/1/au:+baez/0/1/0/all/0/1

4D beef means no extra dimensions.
Best to you too.

43. **urs**
May 25, 2006

> I saw a sign

said who?

I have a summary of the first of these two signs here:

.

Notice, though, that not everything that looks like a shoestring is necessarily an F-string.

But, as someone else already pointed out, there might be a relation here to some sort of solitonic strings.

44. **urs**
May 25, 2006

Hm, I am always having problems with hyperlinks in this comment section. Where there is nothing in the above comment it should read

http://golem.ph.utexas.edu/string/archives/000777.html

45. **Chris Oakley**
May 25, 2006

Aaron,

You should come and work in the software business. The money is better than academic research, it is genuinely creative, people are more interested in what you do and if you get something wrong you will normally know about it straight away. Of course, not everyone would consider the last one an advantage, but I do. In theoretical HEP as currently practised if you get things wrong then you can patch them up *ad infinitum*, or – if the worst comes to the worst – just invoke the landscape. This is not very satisfying.

46. **Who**
May 25, 2006

Chris, I dont know about you or Aaron but I respect it a whole lot when children are curious about where babies come from and when physicists are obsessed to find the fundamental degrees of freedom of spacetime and matter. so I find it jarring when somebody says, to one of these obsessed ones, go do software. it sounds dismissive. I looked up Nature in the dictionary and it comes from the word for "birth". Asking what the world is made of is a sacred question (if any question is).
And maybe the whole scientific enterprise has some elements of high comedy (like self-delusion, hubris, the failure of the best, over and over—or maybe I mean tragedy).
Anyway I want to say to whoever might be listening: Don't stop looking for the sandwich!

47. **Chris Oakley**
May 25, 2006

Who,

If this curiosity is leading most of these grown-up kids into exploring ever more complex mathematical neverlands then I would say that they would be better off without it.

Besides, the search for answers to ultimate questions – done my way – resulted in no academic job. Maybe Aaron is finding the same thing.

48. **Alejandro Rivero**
May 25, 2006

No, modern theoretical physicists are not driven (mainly) by curiosity, but by the joy of solving problems.

49. **Eugene Stefanovich**
May 25, 2006

Who Says:
Bee wrote in a constructive simpatico spirit (IMO) as follows:

Or, to put it differently, someone should think about what we ought to do with all the String Theorists.

Well, I am a German social democrat. We don't just fire people. We give them a second education, and a job so they feel useful. It's called solidarity. The resistance to changes can be significantly lowered when there are as little people as possible suffering from it.

Alejandro Rivero Says:
No, modern theoretical physicists are not driven (mainly) by curiosity, but by the joy of solving problems.

Not sure about that. There are certainly those who find joy in doing what they have learned and what they were educated for. But that's got nothing to do with physics in particular. If I talk to people I often find that they were originally driven by curiosity, but they don't dare to follow it cause it's not career-wise. You wouldn't believe how many people have told me, they would rather do this or that than following the main-stream, but they have to think about their job and family and stuff. That's a problem which can only be solved by reevaluating which research is worth funding, and what 'success' means (imo certainly not getting a paper published).

Best, B.

I didn't say that "too much math" is the problem. I said that very mathematical investigations of the basics of string theory have been tried, as a way of pushing the subject forward. It has been tried, even, in my own insignificant way, by me. Eventually I was forced to admit that it didn't work. Believe me, I would love to see some deep theorem in global differential geometry used as the basis of some vacuum selection principle. That would be wonderful. But things like that have been tried and they didn't work. Now it"s time to try other things {like trying to bend ads cft to get it to say something about desitter }

60. **Bert Schroer**
May 26, 2006

The problem in particle physics is never too much mathematics, rather it is giving less physically suitable mathematics too much hegemonic power over physics.
There are of course some lucky historical circumstances, as the discovery of quantum mechanics, where, after the Born-Jordan observation of the role of infinite matrices in Heisenberg's paper, the intrinsic logic led directly to Hilbert spaces and operators (interestingly enough it was first Fritz London and not John von Neumann who saw this first, but he was at the time a little assistant at the TU Stuttgard and his publication got easily overlooked by those who were leading the quantum dialogue); but the best situations for a happy marriage of physics and mathematics are those in which the mathematical and physical concepts developed at the same time and allowed to merge in an early state. The most perfect example (unfortunately little known outside a small circle of experts) is the birth of modular operator algebra theory from a confluence of vast generalization of the unimodular aspect of (the Haar measure) of noncompact group algebras into the heart of operator algebras, together with the physics ideas of Haag (leading to the Haag-Hugenholz-Winnink paper where modular properties are combined with the KMS condition) on how to do thermal quantum theory directly for open systems (see Haag's book). This has recently led to the totally intrinsic (i.e. without the use of field-coordinatizations) concept of modular localization. In my whole professional life I have never seen such a perfect match and all my recent results and presently evolving ideas are around these new and mathematically quite demanding concepts in QFT.
There are also less fortunate marriages. In the middle of the 70s during a year at CERN there were some interesting mathematical properties showing up in low-dimensional QFT. This was the time when Euclidean methods in QFT were on almost everybody's mind. Before I knew anything about Atiyah-Singer index theory, I observed a connection between Fermion zero modes and the winding number of the (generic) abelian gauge field in the Schwinger model (2-dim. massless QED). I had the intense feeling that I was dealing with a tip of an iceberg. But since I had no proof, those speculative claims of my seminar presentation which went beyond the concrete model calculations were rightfully criticized by Roman Jackiw. Only when I finally went down to the Geneva University library I realized that I had a very special case of an impressive mathematical edifice. I went on happily for several years, learning the mathematics of this new trade, but finally I began to have doubts

whether such a (often banalized) use of the Euclidean is really the wave of the future in real time QFT. My doubts strongly increased when I came back to CERN after 10 years and saw all those enthusiastic wide-eyed yougsters using the phrase "topological" (this was after Atiyah-Witten) in almost every second sentence.
In contrast to Peter I am concinces that this of marrying precise mathematics with ever increasingly mataphoric physics was the beginning of the trip into stringlandia.

61. **Peter Woit**
May 26, 2006

Lambchop,

I agree with you that new math is not going to solve problems like finding a specific string theory vacuum. Buth neither is any physical idea, since this is an inherently insolvable problem. What really bothers me is that instead of admitting this, people blame past failure on the mathematical methods being tried. It would be best if people would just move on to more promising problems, but if they're not going to do that, at least trying out new mathematical methods sometimes leads to a useful new technique that can be applied elsewhere. Trying to get at the "physics" of a situation where there is none leads nowhere.

Bert,

My perspective is a bit different. I think there is still a huge amount to learn by pursuing ideas about TQFT and gauge theory, ideas that are completely independent of string theory. The problem with research in this area is that people will only fund it and pay attention to aspects of it that are somehow related to string theory. Studying those has led to some interesting things, but little recently. The non-string theory connections to gauge theory are quite worth exploring, but no one wants to since it's a hard, long-term research project which no one wants to hear about because it's not string theory.

62. **Bert Schroer**
May 26, 2006

Of course there is Peter, in fact I am exploring problems (massless, spin1 and 2), but already the preliminary results creates doubts whether the historical name (which is primarily a classical name) "gauge" is very appropriate.
On the other hand names in particle physics are increasingly hollow words and if you mean the physics behind the word gauge theory (in particular the physical, alias gauge invariant results) then we are on the same wave length. In fact I am probably much more conservative on the side of physics than you are, but I am upholding the right to use any mathematical concepts which are the most appropriate to implement the physical principles (which only change on scale of one century) and concepts and I happen to think that the present formalism of gauge theory does not meet this test (see my remarks I made earlier, giving support to Thomas Larson in Fantastic Realities, probably more radical than what he had in mind).

63. **MoveOnOrStayBehind**
May 26, 2006

B:

"

"

A nuclear physicist by education who now does "phenomenological quantum gravity" teaches string physicists what to do after their project has failed? By all means, they can't wait to hear!

This is getting more absurd every time I read around here.

64. **Alejandro Rivero**
May 26, 2006

Since Newton age (and even Democritus and Archimedes!) this needed "new math" has been a new math related to the understanding of geometry, particularly of differential geometry. The key word here is not "new"; it is "understanding". Advances in physics are related to our understanding of geometry. This close marriage is maintained in the algebraic side via some dualities, for instance the one between commutative algebras and manifolds.

Advances in string let to set up and solve new problems on mathematics, and even create new mathematics, but it is still to be seen how they help to understand any branch of mathematics, nor to say differential geometry.

65. **Bert Schroer**
May 26, 2006

Alejandro,
Nobody is against geometry, but it has to come from the midst of raw local quantum physics rather than offering a geometric/topological mathematical (or classical physics) stick to particle physics to jump over.

66. **Eugene Stefanovich**
May 26, 2006

IMHO playing with math models and hoping to find something interesting about physics is equivalent to "searching the key far from the lamppost". The chances of finding the key are very slim. I would rather get the clues about physics from … well, physics. More precisely, from experiment. Try to build your theories by only using concepts and ingredients that are (at least, in principle) experimentally measurable. Reject quantities that have no observable counterparts in nature. For example, I would not hesitate to throw away gauges. They have no observational meaning by definition.

67. **Kea**
May 26, 2006

Nobody is against geometry, but it has to come from the midst of raw local quantum physics…

Which is precisely why the category theoretic understanding of local geometry is the *only* way forward.

68. **Kea**
May 26, 2006

The AQFT papers that I have glanced at recently all talk about functors from some suitable category of (local) spaces, such as the category of strongly causal manifolds.

Where exactly do you think this is leading?

69. **Bert Schroer**
May 26, 2006

Kea,
your observation is not quite correct. Categorical ways of arguing were actually used by people who you would not exactly count as algebraic QFTists as e.g. Moore and Seiberg in their approach to the structural properties (related to the new braid group statistics) of chiral observable algebras and their superselection structure In a paper "Einstein causality and Artin braids" which was written at the same time and addressed the same problem (by Rehren and myself) we extract this structure from a new manifestation of the old causality principles which was in a AQFT spirit without any use of categorical arguments (afterwords this spirit was strengthened in collaboration with Fredenhagen who had more experience with AQFT methods).
However categorical arguments are sometimes an ultimate recourse (as in the case of the formulation of the local covariance principle in QFT in CST to which you are referring) and should be considered (in my view) as tentative to be replaced by more geometrical arguments. But when I do use the word geometric, I do not mean that kind of geometry coming from classical physics via quantization (Chern-Simon geometry, geometry of euclidean functional integration manifolds etc) but rather those geometric concepts which AQFT manages (e.g. via modular localization) to extract directly from the autonomous local quantum physical principles, and which in all cases up to now amounted to a widening of the scope of causality and spectral stability principles and not to their "revolutionary" liquidation.
There is a big difference between this geometry from AQFT and that e.g. in the Atiyah-Witten (or for that matter string theory) setting.

70. **Kea**
May 26, 2006

But when I do use the word geometric, I do not mean that kind of geometry coming from classical physics via quantization…but rather those geometric concepts which AQFT manages (e.g. via modular localization) to extract directly from the autonomous local quantum physical principles…

71. **Kea**
May 26, 2006

And if I might be permitted to repeat my question: what is the geometric language for these geometric concepts?

72. **Bert Schroer**
May 26, 2006

Kea, let me try to give an answer to your question inasmuch as this is possible in a weblog.
The modular operator theory is capable to extract spacetime localization from the abstract domain properties of the modular objects related to an operator algebra. The abstract (algebraic) relative positions of operator algebras acting in a common Hilbert space leads (via that modular theory) not only to spacetime symmetries but also encodes the full content of QFT (statistics, inner symmetry, scattering theory…). The theory is pretty much in its beginnings and some of the results may seem miraculous (especially to those who thought that Lagrangian quantiation contains alrady the main messages about QFT) but any mysterious appearance is transitory (simply due to unfamiliarity) and its aim is to de-mystify and it is not to be thought of as a theory of everything. From a pure mathematical point of view it is somewhat related to Vaughn Jones theory of inclusions (subfactors), but the involved algebras are of a different type which is inexorably linked with localization (in my papers in http://www.lqp.uni-goettingen.de/papers/06/04/ I have called that kind of algebra "monade"). If you are interested in some partial results of an ongoing research have look at math-ph/0511042 where there are also references to previous work.
Its main message is perhaps that if a more than 70 years old theory allows for such a radical different approach, it is not (despite the string theoretical carricatures of QFT) yet anywhere near to closure.

73. **Kea**
May 26, 2006

Dear Bert

I do not doubt for a moment that what you claim is true. It sounds fantastic and exciting. It does not, however, answer the question. You used the word *algebra* five times in the above statement. Perhaps we could begin with a clarification of one single term: what do you mean by *domain property*?

74. **Bert Schroer**
May 26, 2006

Although the algebras which feature in those constructions are algebras of bounded operators, the Tomita involution S`(see the mentioned literature), which is a kind of master operator capturing collective properties of all operators in the algebra, is unbounded and its domain of definition is (in the field theoretic context) related to the geometric localization of the algebra. The problem is that this deep mathematical theory has not entered any of the standard mathematical physics books (Reed-Simon,…) but it is explained in the cited articles and their references. A nice little introductory mathematical article can be found on Steve Summers homepage. Please do not expect that such a mathematical subtle and conceptually demanding theory allows an instant packaging in an weblog. The only thing I can do here is to say that it exists and already in its present incomplete form it gave profound physical results.

75. **Kea**
May 26, 2006

Would that be the same Steve Summers who cites Baez, Doplicher, Roberts and Redei?

76. **Bert Schroer**
May 26, 2006

Yes it is the same. Among the recent online collection of articles you find a 10 page article with the title: Tomita-Takesaki modular theory
It is probably also available on the math-ph server. Most of the very recent physical results are however not contained. But your question of how and what kind of geometry emerges from the algebraic positioning of operator algebras is briefly explained and you will be referred to more detailed literature.

77. **Kea**
May 26, 2006

A link to the Summers paper

78. **Kea**
May 26, 2006

I'm looking through it, at theorem 5.2 for instance, where he says the modular unitaries generate a representation of the group of isometries of (2D) Minkowski space. I'm a little confused. For some reason I thought the *geometry* of these wedges and things should be written down in the language of sheaf cohomology.

79. **Chris W.**
May 26, 2006

Eugene,

When the atomic constitution of matter was first postulated was it *known* to have observable counterparts in nature?

The point of view you express is close to that attributed to Ernst Mach. Mach never accepted atomism, and had little use for relativity.

Einstein, despite being influenced by Mach, ultimately concluded that it is the theory we are attempting to test that says what might be observed. It provides a framework for motivating the operations that give rise to observations, as well as specifying the expected features of those observations.

I would rather get the clues about physics from … well, physics. More precisely, from experiment.

Physics has never been simply about getting clues from experiment. It has always had a metaphysical component—again, something that Einstein understood well. However, insofar as it is about experiment it is about understanding stable, reproducible observations. Indeed, in a deep sense it is about the possibility of stability itself. I believe this leads inescapably to a profound reflexivity in the foundations of physics, because if one employs invariant laws to account for stability—or reproducible patterns—one is eventually led to inquire into the stability and success of the laws themselves. I would define physics as this seeking after stability, both stimulated and constrained by controlled observation. This effort has been enormously successful. The question is, why should nature—or existence—accommodate such success in seeking after stability and principles of invariance?

The currently popular incarnation of the anthropic principle gives a trivial and ultimately sterile answer to this question: The Multiverse is so vast and diverse that it accommodates anything—environments where stability can be found, and not incidentally, where life and science can exist, and a vastly greater array of environments where such is not the case. The fact that we exist in an environment where stability can be discovered is from this viewpoint a simple matter of selection; if we didn't, we wouldn't be discussing the topic or have a civilization based on the possibility.

In contrast to such sterility, can the reflexivity explained above point the way to an genuine advance in theoretical physics? That is, can physics advance by reflecting on itself, bearing in mind that what calls for explanation is in part the prior success of physics? (Remember that this kind of consideration is what motivates correspondence principles.)

80. **Kea**
May 27, 2006

Bert

Why did you choose the term *monade*?

81. **Bert Schroer**
May 27, 2006

Kea,
this time the answer to your question is well suited for a weblog.
One reason for substituting the full mathematical name: hyperfinite type III_1 Murray-von Neumann factor algebra by something shorter (in a paper where it occurs many times) is that it is very unwieldy. Writing simply HTIII_1FA is ugly. In looking for a word which reveals something about its conceptual aspects the word "monade"is very appropriate for two reasons. A single such mathematical object is unique i.e. up to isomorphism there exists only one, i.e. it is analogous to a point in geometry. The situation changes radically when you place several copies of this unique object (as operator algebras) into a common Hilbert space; with a carefully chosen positioning dictated by "algebraic naturalness" based on modular operator theory (modular inclusions, modular intersections), you create the rich world of QFT in Minkowski spacetime (including spacetime and inner symmetries) where all the differences between QFT models have their origin only in the huge cardinality of possibilities of modular positionings (to generate chiral theories you only need 2 copies, for 4-dim. QFT the minimal number is 6). This is precisely the quantum physics realization of Leibnize's monade theory of how reality originates from the relative positions of "monades", in fact it is a perfect match (but you had to go up to local quantum physics to find it).
The mathematical physicist who discovered some mathematical properties of this positioning (Wiesbrock, you can find some of his papers he wrote in the 90s in math-ph) could not continue his career; he had the bad luck of living at the wrong time (a time when academic priority was given to string theorists). Most mathemaical Field medalists (exeption Vaughn Jones, Alain Connes) do not know this mathematics; it comes to a large part from a string-free zone in particle physics.
When Haag was travelling through Princeton and met Witten, this issue came up in a conversation; but it seems that Witten apparently dismissed it, probably because he and Atiyah were convinced at that time that real particle physics had to come through the massaging of that (nonexisting) functional integral.
Recently I succeed to obtain 3 quite interesting (published) result using modular methods
1) A very clear understanding of the recipes underlying the construction of factorizing models (including the spacetime interpretation of Zamolodchikov-Faddeev algebras).
2) Together with Mund and Yngvason we finally understood the best localization aspects of the infinite spin Wigner representations (besides the massive and the finite helicity massless representations the third big family of potentially physical representations) and the string-localization of potentials associated with massless finite helicity fields and their mild short distance properties (which makes them ideal candidates in the search for renormalizable islands in the infinite parametric space of the renormalization group)
3) A deep quantum understanding (a modular version of holography) of the infinite dimensional mysterious Bondi-Metzner-Sachs group and of the the close connection of the Volume law of heat-bath created entropy with the area law caused by vacuum-fluctuation at the boundaries of causal localization (as already mentioned in http://www.lqp.uni-goettingen.de/papers/06/04/).

There will be a forthcoming paper by Gandalf Lechner from Goettingen (his thesis) where he succeeded to proof the mathematical existence of factorizing models (the solution of the old nontriviality problem in a still limited context). These models, unlike those superrenormalizable in the book of Glimm-Jaffe, are for the first time only strictly renormalizable.
Together with Jens Mund and Jakob Yngvason I am presently working on a renormalized perturbation theory based on those string-localized field (absolutly nothing to do with string theory). A little note on the string-like potential describing the metric tensor will appear in a little separate communication by Mund within the next two weeks. We are under the impression that within this extended perturbative framework gravity will be renormalizable (finite-parametric) or to phrase it more carefully: the massless higher helicity string-localized potentials permit renormalizable interactions.

May 27, 2006

I just realized that I forgot to mention a result obtained in the algebraic modular setting which will probably interest many participants in this weblog beyond Kea
The idea of modular Euclideanization (as opposed to Osterwalder-Schrader Euclideanization of real time QFT) leads to a structural proof of a temperture-duality of thermal correlations (hep-th/0603118 and literature quoted therein) for chiral theories of which the Verlinde duality arises from the zero-point correlation function (the

partition function or character of loop-groups). As its higher dimensional analog the Nelson-Symanzik duality it is a manifestation of the structural richness of the implementation of the causality principle of local quantum physics. In fact it is much richer than the N-S duality, because it generalizes the Victor Kac observation:
representation theory of loop groups –> identities for modular forms
to:
causality principle for chiral theories –> identities for modular forms,
with other words the totally autonomous modular concept arising from the T-T modular theory of operator algebras contains the concept of modularity of so-called modular forms (all those funny Ramanujan-kind of identities have a common structural root: the causal locality principle of QFT!). And mathematical physicists have a fare share of this modular theory because important concepts as the KMS property (which Connes used for classifying the type III factors which brought him the Field medal) are due to physicists. Although physicists work in a more special context, it would not have been propostorous to call it the T-T-H-H-W (adding Haag, Hugenholz and Winnink) to the list of protagonists.
Kea if you are really interested and you would live in Brazil, I would recomment to attend a Sattelite meeting down in Floripa at the end of July:
http://www.mtm.ufsc.br/~exel/oa/
In normal times such insights would be of interest to more mathematicians, but remember that this is coming from a string theory-free zone.

83. **Joan**
May 27, 2006

For those who are having difficulty getting research jobs,
have you considered lecturer positions? These are usually
not too difficult to find, and while the pay is not great,
you typically have summers free for research, and usually
less administrative responsibilities than you would have
in a tenure-track position.

84. **JC**
May 27, 2006

I've noticed lecturer positions seem to be a mixed bag for the most part.

At some places, they seem to be term contracts which have to be renewed every term or year. In some cases I'm aware of, some lecturer contracts were not renewed because of things like departmental politics. Popular "excuses" for not renewing were silly things like too many poor student rewiews and/or complaints, frequently used by the department to get rid of folks they don't like.

In some departments which had an emphasis on research, the lecturers are treated as 2nd class citizens or "bottom feeders". At a community college, the problem seems to be things like students not wanting to be there and goofing around too much. (The sad part about some community colleges, is that a large number of lecturers there were actually folks who did not get tenure at a research university. Some of these folks seemed quite miserable for the most part).

Though on the other side of the coin, most lecturer positions had very little to no bureaucratic and/or management duties outside of teaching. For many of my previous colleagues which have tenure at a university which emphasized research, their number one complaint was all the bureaucratic duties they had to deal with. In that sense, it wasn't much different than working in a Dilbert style corporation.

85. **urs**
May 27, 2006

Bert Schroer, Kea,

lest the impression arises that Tomita-Takesai theory, von Neumann type III factors and the like play no role in string theory, let me point out the work by Stolz and Teichner, who are in the process (for quite a while now) of giving a geometric interpretation of elliptic cohomology

(http://golem.ph.utexas.edu/string/archives/000737.html)

in terms of CFT with target some string bundle

(http://golem.ph.utexas.edu/string/archives/000799.html).

See for instance page 53 of this review

(http://golem.ph.utexas.edu/string/archives/000712.html)

to see all the machinery – that Bert Schroer mentioned – in action.

86. **Bert Schroer**
May 27, 2006

Urs,
that is not what I meant. The von Neumann algebras e.g. in the last part of the first article are just an epiteton ornans (ornamental addition copied from Wassermann's article) to the main text.
The setting of the authors is that of Greame Segal's axiomatics of (topological) Euclidean field theory, which has only a metaphoric relation to a similar real time axiomatics a la Brunetti-Fredenhagen. What I really meant is an Euclidianization of the T-T modular theory in the Nelson-Symanzik duality tradition which in the chiral setting is a modular analog of the Osterwalder-Schrader Euclideanization (i.e. something which comes from our past in autonomous particle physics i.e. which was there before the Atiyah-Witten era). With other words something which is in the tradition of modular theory a la T-T-H-H-W (a terminology which I explained before) enriched with the notions of modular inclusions and modular intersections (which are essential for my use) which were discovered in the 90s by Wiesbrock before he had to leave academia. One glance at that work on modular holography (mentioned before) would show you that we are talking about completely different conceptual setting which just happen to share a few common references.
Please don't fall prey to the trick in string theory to claim huge areas and semantically incorporate it (a phenomenon which was discussed before with Peter). Since you are a member of a mathematics department you have all the right to be interested in elliptic objects, but I think as a particle physicist I have the right to be proud of our rich and almost forgotten traditions and to use them in a new context (and fight any insinuations that this has grown on the soil of string theory)

87. **Bert Schroer**
May 27, 2006

Dear Peter,
just to get away from that long discussion with various participants on this webblog for a change, I would like to make some personal comments.

Since I was a newcomer to your weblog at the time of its third birthday, let me congratulate you for your fulltime work of managing this weblog so successfully. I hope the physics Columbia university physics department realizes what a useful role this string theory critical weblog plays in very precarious times for particle physics (I think even string theorist can see this point).
As you certainly have realized, we have quite different opinions on what could help particle physics in this situation. But there is no hegemonial claim in either of our viewpoints.
When I listened to these three University of Princeton tapes of David Gross I was shocked by his salesmenship of semantically manufactured facts (described before in a contribution where I quoted from original papers of string theory). We always think of George Bush, when we talk about manufactured facts. Well, it happens in our midst and the intellectual creme of Princeton University is applauding. I also was appalled by what he said about LQG although (contrary to you) I have a somewhat critical position with respect to LQG (and I think some of the questions and comments referring to Lee Smolin are justified; also I do not want to see particle physics and in particular gravity end in an Armegeddon between LQG and string theory). Since I could not believe that a place where I spend some time in the 60s had now fallen so low, I searched for other videotaped talks. I listen to the first talk in 3-talk series by Mark Juergensmeyer with the title: “God and War: The Odd Appeal of War” (also a professor from Santa Barbara) and my view about Princeton was instanteneously corrected; the problem I had is really constricted to particle physics and may also occurs at other ivy league places which have a tradition for such talks.
We probably also agree that it is somewhat disappointing that such a integer and generally critical mind with a Nobel stature as Frank Wilszek does not take a more pointed position with respect to these strange sociological hegemonic manifestations. But then Gross was his thesis adviser, and in addition not everybody has that critical independent mind as Pauli (he was not always right, but he always fought for the coherence of physics and not in order to sell his own ideas).
I have a bottle of red wine on my table (this time from Mendoca, Argentinia) and I am in this moment drinking to your successfull continuation of this weblog. May people recognize what a hell of work you have to do in order to permit yourself some satisfaction.

88. **urs**
May 27, 2006

The impression that algebraic quantum field theory is closer to phenomenological physics than to pure math, at least in comparison to other parts of “formal high energy physics” is something that I have not obtained.

Maybe its just me being ignorant (which I am, in a huge number of respects). But the worthwhile applications of AQFT that I have seen have precisely the status of physics-inspired math which Bert Schroer is so critical of.

The understanding of representation theory of loop groups and related CFT technology using AQFT techniques would be one example. Some math that people like Michael Mueger are doing

(as in his second talk here http://golem.ph.utexas.edu/string/archives/000711.html)

would be another.

I am also not sure why Minkowski-spacetime field theory is so much more “physical” or “real”. Sure, in some sense. But CFT applied to statistical mechanics is a Euclidean field theory. Any concept of field theory we have should be able to deal with Euclidean and Lorentzian backgrouds.

But (correct me if I am wrong) Minkowski spacetime and lightcones are build into the very axioms of AQFT. That looks like too strong an axiom to me.

89. **B**
May 27, 2006

MoveOnOrStayBehind Says:
B:

“Or, to put it differently, someone should think about what we ought to do with all the String Theorists. ….”

A nuclear physicist by education who now does “phenomenological quantum gravity” teaches string physicists what to do after their project has failed? By all means, they can’t wait to hear!

It’s not up to me to judge which research fields are promising. I just say, that it’s definitely necessary to objectively evaluate the situation. There are people who have sufficient knowledge and overview to give advise. Listen to them. I wouldn’t even say string theory has ‘failed’. But its over-rated.

I – in person – am certainly not the one to teach string theorists something besides phenomenological quantum gravity – if they are interested, I would love to do so! I can’t avoid noticing that String Theorists speak ‘stringy’ and someone has to make the translation. The quest for the Theory of Everything has quite some similarities to building the [Tower of Babel](#).

This is getting more absurd every time I read around here.

Dear MoveOnOrStayBehing: You got to move on – or stay behind…

Best, B.

90. **Bert Schroer**
May 27, 2006

Urs,
Loop groups are of course a valuable illustration, I mentioned the that the relation of chiral field theories with modular forms was first discovered in the context of loop groups (Victor Kac…).
The point here is that you do not want to invent a special drawer in which you keep loop group or general chiral field theory separated from the rest of QFT. The only interest in chiral quantum field theory is as a theoretical laboratory to learn something about the nonperturbative subtleties for higher dimensional QFT and for this reason you have to use those structures which are in common to QFT in all spacetime dimension (and that is modular localization). All special structures for families of chiral theories like loop groups (sorry, for me they always remained current algebras) have been investigated or can be investigated by mathematicians, hence why should I loose time in getting into competitions with them? What I can contribute is the update or adaptation of some rich ideas from the past (and largely forgotten, just because you were so busy learning loop-groups and elliptic objects that you had no time to learn anything about the important conceptual past cross roads in particle physics, this is not a personal criticism). The Euclideanization of the modular group which underlies the (field-coordinatization independent) concept of causality and localization in the context of the chiral setting (without specializing to loop groups or other rational families) and which is in complete analogy to Nelson-Symanzik and Osterwalder-Schrader is something to the heart of a particle physicist like me.
I am not negating that for special families you can use other special methods coming from mathematics e.g. the vertex operator formalism of Graeme Segal, which has recently been used by Hu in order to derive the Verlinde formula for a special family (which is characterized in terms of vertex concepts which I am not familiar with (i.e. I do not know their precise relation to Wightman fields, to clarify this would be the obligation of the vertex algebra people because Wightman fields are much older).
I think that particle physics has a strong historical component which has been damaged because in the late 70s people (with the increasing arrogance of people entering

math. phys. they never cared to look back whether some of these ideas already existed so that the already existing terminology could be taken over and enriched by new insights instead of cutting off the link to the past by a new terminology).
It is just as with human history, if you forget and surpress it, it will create confusions and conceptual regress.
Urs, your attempt to separate me from my colleagues of AQFT will not succeed, the past is too strong and even my present influence on what is going on in that community is not negligable.

91. **Kea**
May 27, 2006

I have a bottle of red wine on my table (this time from Mendoca, Argentinia)

Oh! I was in Mendoza a few years ago. Lovely place. I would love to come to Brazil, but alas my poverty forbids it. Thank you, Bert, for taking the time to tell us a little about AQFT. Personally, I am 100% on your side, as regards the relevance to particle physics in comparison with Strings. I had a look at your beautiful paper on wedge localisation last night. Actually, Jones said a few words about his ideas on physics at a conference I was at recently, but unfortunately, as an organiser, he was not given the time to speak about any details.

My point is that certain instances of the category theoretic *monad* share many of the deep properties that you attribute to your monade. I do not think that this is a coincidence. Not all people looking at higher category theory are in the String camp.

92. **Kea**
May 27, 2006

Here is a paper by Halvorsen on AQFT, with some category theoretic input.

93. **Kea**
May 27, 2006

Try again: paper

94. **Bert Schroer**
May 27, 2006

Kea,
of course higher category theory is not the domain of string theory. The first who introduced nonabelian cohomology and higher categories into QFT was John Roberts (in the middle of the 70s). He had a strong physical motivation coming from gauge theories. Things did not work out in the way he expected. But fortunately this was at a time when negative results on deep problems investigated with the best available tools were equally important and interesting äs positive results (somehow related to Pauli's "not even wrong") and so the work was published. I have the impression a negative result on string theory will not be tolerated by the community in fear of endangering the veracity of the whole construct. I am surprized that his work was not mentioned in recent string theory blogs. Street, who is the father figure in Australian n-category research always referred to it.
Returning to Urs:
where did I claim that AQFT is anywhere close to phenomenology? I said that it is directly related to the (utterly successful) principles underlying QFT (which are the condensed form of past experiments), more explicitly the principles together with some mathematical concepts to implement them. In a situation where you are stuck (hopefully only temporarily) on the experimental side, you are not condemned to do speculative blue yonder physics, rather there is the third way: press the principles and the concepts real hard and see what you are led to. But this is very difficult and time consuming and I cannot advise a young man under actual social physics department conditions to go into this since it is very risky for making a living (but there were some people who were willing to take the risk and a very few succeeded).
Urs, you mentioned Michael Mueger. Despite his beautiful conceptual work on order/disorder variables (and the fact that he is very talented) he could not get a position in physics. For quite some time he worked under Turaev in Strassbourg and it is natural that he looked at the more categorical aspects as they were investigated at the mathematics department of that university. He finally got a permanent position in Holland (probably in math.). Please don't msiunderstand me, I am in no way against categorical settings and topological field theory. I only think that if this is already being done at mathematics departments it should not also be done in physics departments. Or to put it into a milder formulation, if it is done at a physics department the individual using it should at least be aware that the first topological field theory was that extraction of a tracial (combinatorial) algebra which carried the representation of the statistics operators in the DHR work on superselection sectors (see Haag's book) and which was later discovered in a much more general setting by Vaughn Jones and called by him extremely appropriatly the "Markov trace" (where Markov refers both to the 19 century Russian probabilist and his son who stands for the braid group aspect). Whereas the topological bones can be perfactly placed into such tracial hyperfinite type II algebras as Vaughn uses them, this is not possible for the localizable and transportable meat.
Kea you said that you saw Vaughn Jones recently, is he well? We are all looking forward to see him in Floripa.

95. **Aaron Bergman**
May 27, 2006

You know, if we're judging string theory wanting for having produced little connection with the real world in the last twenty years, how should we judge AQFT having produced not a single example of a realistic QFT since at least the seventies.

96. **Bert Schroer**
May 27, 2006

Judge it by the results I mentioned this morning (at least something, it is not a theory of everything). In addition AQFT shares all the previous successes of QFT (including all the cross sections and vacuum polarization effects) because it is nothing but an vast conceptual extension (often with a more profound interpretation).
I would repent most of the things I said if string theory would only lead to a fraction of those results.
String theory is not an extension of QFT because the prerequisite would be a structural compatibility without which the standard scale-sliding argument is not worth anything. I have explained this in detail before in some older contribution and I am not going to repeat this here again.
You may not agree with me, but you certainly have to admit that at least it does not wipe out knowledge (which string theory has done and is still doing).

97. **Aaron Bergman**
May 27, 2006

AQFT shares all the successed of QFT? What nontrivial theory in four dimensions has been constructed via AQFT?

98. **Kea**
May 27, 2006

Please don't msiunderstand me, I am in no way against categorical settings and topological field theory. I only think that if this is already being done at mathematics departments it should not also be done in physics departments.

Bert, the people working on fractional QHE, for instance, have hardly been doing nothing for the last 20 years.

99. **Kea**
May 27, 2006

There are *engineers* and computer scientists doing TFT mathematics. The question you should be asking is: how can I link this beautiful edifice of AQFT to what they are all doing?

100. **Bert Schroer**
May 27, 2006

I was under the impression that solid state physicists cherish localized states and material properties and they need the localized carriers of those topological quantum numbers and not just their bones to make trustworthy calculations. Are you sure that you are talking about professional condensed matter physicists? Is among the physical results anything which would impress e.g. Phil Anderson?
To Aaron: if standard QFT would be able to construct a 4-dim. QFT it would be immediatly inherited by AQFT according to the logic I explained. I think you mean by "construct" something entirely different. I do not mean being able to write a functional integral, compute some renormalized Feynman diagrams and put some instantons on top, I meant mathematically controllable model constructions as they have been done in any other area of theoretical physics.

101. **Kea**
May 27, 2006

Are you sure that you are talking about professional condensed matter physicists?

Yes, I am quite sure. Of course, no one is claiming to have worked out completely how to compute things properly. **That is the point.**

102. **Aaron Bergman**
May 27, 2006

The point is that AQFT is one attempt to codify the mathematical structures of QFT. There are others (I can think of at least three mathematicians who have set out to define QFT, two of whom have Fields medals). To date, I think it's safe to say that none of them completely capture what we know ought to be true about QFT. So, maybe you've chosen the right way or maybe not. Beats me. But I hardly think it's fair at this point to say that the AQFT formalism *must be* the right answer when there aren't any realistic examples and, furthermore, it seems to ignore (at least judging by your previous conversations with Mentos) much of the modern Wilsonian understanding of the subject.

How about something easier? Does AQFT have anything interesting to say about TQFTs? In two dimensions, at least, the axiomatization in terms of categories has shown a lot of success. In 4D, the twisted N=2 TQFT that gives Donaldson invariants has proven to be extraordinarily fruitful. Can you see the AQFT structures in this context, and do they say anything new or useful about Donaldson and Seiberg-Witten invariants? Recently, a topological twisting of N=4 SYM has proven to describe much of the mathematics in the geometric Langlands programme. Can AQFT say something there? The categorical structure a la Atiyah, Segal *et al* definitely is apparent.

103. **Bert Schroer**
May 27, 2006

The first step would be to have convincing experimental agreement with those quantum numbers. If those are related to e.g. braid group statistics this would be interesting, since statistics is an almost kinematical property (and the only known property by which low dimensional are structurally different from higher dimensional ones!). I find it perfectly conceivable that e.g. a large statistical (or quantum-) dimension could account for a high temperature in high T_c, but I am not an expert.
You did not answer my question about Vaughn Jones.

104. **Kea**
May 27, 2006

You did not answer my question about Vaughn Jones.

Sigh. All right, then. He seemed well, and did a lot of windsurfing, as usual. But I can't say I really know him personally.

105. **Kea**
May 27, 2006

Can you see the AQFT structures in this context, and do they say anything new or useful about Donaldson and Seiberg-Witten invariants?

This is a very good question. AQFT *should* be able to shed light on these invariants, if it has any computational power.

106. **Bert Schroer**
May 27, 2006

"But I hardly think it's fair at this point to say that the AQFT formalism must be the right answer when there aren't any realistic examples and, furthermore, it seems to ignore (at least judging by your previous conversations with Mentos) much of the modern Wilsonian understanding of the subject."
Sorry Aaron, this apodictic manner is not my style of dialog and if I really said that, it was a lapsus linguae. In fact the situation is quite the opposite: exactly because we know that we are on such slippery ground we are trying so hard to control the existence of 4-dimensional QFT (those successes in d=1+1 are only successes in the sence of a theoretical laboratory, but we have already learned some messages and at least there is a new strategy). Our aim is to make QFT like any other area of theoretical physics.
Concerning the Wlson Renormalization group I once asked that question to Fredenhagen after he finished his work with Duetsch on the AQFT-inspired version of the Petermann-Stueckelberg renormalization group. He told me that this can be done and the result will be written up. Fredenhagen has never claimed anything which he was not able to deliver and I attribute the fact that nothing has appeared yet as due to his very demanding job of leading such a big institute in the midst of a German buerocracy and politicial leadership which come with new directives almost every week.
Concerning those impressive results about Donaldson invariants, Seiberg-Witten, the Langlands program etc. I think that the relation to particle physics is of a more metaphorical nature i.e. they use a language which is taken from particle physics but it is not really particle physics. The setting tends to be Euclidean instead of real time (I am not so sure about Langlands) and certainly I do not know how to get a real time into those mathematical structures. I also confess that I have never seen any mathematically controllable real time operator theory with a electric-magnetic duality although I know order-disorder variables in real time QFTs in d=1+1.

107. **Aaron Bergman**
May 27, 2006

The relation of TQFTs to reality is irrelevant here. They certainly appear to be examples of quantum field theories. For example, QFT arguments were used to invent Seiberg-Witten invariants which were previously unknown to mathematicians. It's hard to believe that these things simply are not QFTs given their success. If your formalism has no room for them, then I don't see why I should take is seriously as an axiomatization of QFT especially given that TQFTs are *easier* than the real thing.

Let me ask about anomalies. There are very beautiful ways of understanding gauge anomalies from the path integral point of view. Does AQFT in any way incorporate this geometric understanding of anomalies?

108. **Kea**
May 27, 2006

The setting tends to be Euclidean instead of real time (I am not so sure about Langlands) and certainly I do not know how to get a real time into those mathematical structures.

The question was really: how would AQFT tackle the problem of smooth 4D invariants? In other words, what is a combinatorial description of them? As for 'real time', many elements of SW theory have twistor theoretic descriptions, and these could possibly be of AQFT type. If so, then these invariants are really, really interesting physics – not just mathematics.

109. **Kea**
May 27, 2006

AQFT, Donaldson-SW
Temperature duality, Coupling duality
Holography, Cobordism
Monade, Monad
Braids, Dehn surgery

110. **Kea**
May 27, 2006

…and you might even convert a few thousand Landscapologists to the true path!

111. **Bert Schroer**
May 27, 2006

Anomalies have been treated and identified in the Duetsch-Fredenhagen AQFT setting of perturbation (naturally it is in real time). Euclidean field manifolds and functional integrals are metaphoric instruments, they are very suggestive and after a lot of massaging leads to correct results but they do not exist mathematically apart from superrenormalizable (and not very interesting) models of the Glimm-Jaffe type. In a previous blog I described how I went through all this in the middle of the 70s looking at the Euclidean integration aspects of the Schwinger model, finding by generic functional integration (the Schwinger model is the only case where this can be done generically i.e. without specializing to instanton configurations) learning everything about the Atiyah-Singer index theory in order to generalize that wonderful Schwinger model relation between zero spinor modes and winding number of the gauge field (partially in collaboration with N. Nielsen and also with Swieca) some years before Alvarez-Gaume, Witten etc. I think I have some credentials in that kind of functional geometry. But I left after a couple of years because it was far away from my conception of real time quantum physics and because I think that artistic manipulations which have no mathematical existence even if they are highly successful are not my favorite passtime. Just imagine what would have happened to quantum physics if people would have been complacent about the quite successful Bohr-Sommerfeld old QT. If you like metaphorical arguments which lead to consistent results that is fine for me, but I find it absurd to be asked (30 years after I left this metaphorical use of QFT precisely for the indicated reason) to produce results which I do not consider to be part of particle physics. Neither QFT as an instrument of particle physics nor its AQFT extension can achieve what you are asking for; however some gifted particle physicists can be inspired by its setting and derive wonderful mathematical results. Not even Graeme Segal, who was inspired by QFT to abstract his nice euclidean setting of gluing via cobordism claims that he is doing what particle physicists call QFT. There is a difference between particle physics and "that what physicists are doing" (quotation from Hrzebruch after giving an account of the Atiyah-Witten work).

112. **Kea**
May 27, 2006

All right, then. How would you calculate the Standard Model parameters? Is that physics?

113. **Aaron Bergman**
May 27, 2006

I just want to make sure I understand you. Is it your belief that TQFTs are not examples of QFTs?

As for the rest, quantum mechanics explains and encompasses the old Bohr-Sommerfeld rule (slightly modified). As best I can tell from you, AQFT neither explains nor encompasses the geometric understanding of anomalies.

I'm mostly going through this, BTW, to show to the various readers here that the reason the vast majority of the field does not pay attention to AQFT is not just prejudice and groupthink or whatever. It is because it does not seem to capture any of the things that are generally understood to be fundamental and useful features of QFT.

114. **Kea**
May 27, 2006

And I have a question: why should a physicist accept Connes' vision of what is really **geometry**? He's just a mathematician.

115. **Bert Schroer**
May 27, 2006

Kea,
I have no aswer and I do not think that anybody else has. Sometimes I think that we had to pay a very high prize for that relatively easy group theoretical entry. We are now in a labyrinth, the best (in the sense of phenomenological success) quasiclassical straight jacket imaginable (remember that the gauge principle is a classical selection principle for L-invariant interactions) i. e. I do not think we will get out of the present mess without a very significant additional conceptual investment. One should be modest and admit that not every problem can be solved at any time. Solving such problems in a diretissima is mostly not possible. We should patiently go ahead and pressing more the inner logic of QFT; in no way did we reach yet the inner core of QFT. But I expect that as in previous cases (except string theoru) the revolutionary aspect may be less in a change of principles but more on the conceptual side of their implementation.
A small piece of cherry on the cake which AQFT-inspired arguments can deliver is that if one starts with massive vektormesons in zero order than perturnative consistency requires the introduction of an additional physical degree of freedom whose simplest realization is a scalar field (Higgs but without that vacuum condensate). So something like the Higgs seems to be a perturbative necessity. But this is probably something expected in any case this has no bearing on your question.
I may have created the wrong impression that AQFT is a community thing like string theory or LQG. It is not, rather it is a shared belief of some pragmatic-minded individuals whose only distinction from others is that they insist that the requirements on the searched for theory should be clearly formulable without invoking "classical

crutches” i.e. without quantization and if possible without highlighting particular field coordinatizations (apart from conserved symmetry currents).

116. **Bert Schroer**
May 27, 2006

Yes Aaron, TQFT is associated to quantum field theory but it is not itself QFT. You can extract from localizable QFT an algebra of the topological bones, but TQFT has no autonomous interpretation because all the interpretation of QFT, I repeat all the physical interpretation, goes through causal localization. Even particle momenta are in first place not Fourier transforms but rather encode geometric relations between events (clicks in counters). One forgets these aspects if one computes Feynman integrals in momentum space but in scattering theory and much more so in curved spacetime QFT one is painfully reminded of this elementary facts of life. Physicists manage to invent a Lagrangian description (e.g. Chern Simons) but this does not make them QFT, they remain at best TQFT. You may not see this directly in the action (unless you really make the Osterwalder Schrader test) but the algebraic content of such a theory is radically different from that of a localizable QFT (they are similar to those algebras Vaughn Jones uses in his subfactor theory). A derivation of e.g. the TQFT containing the mapping class group from a full chiral QFT on a circle was given e.g. in the appendix of the pre-electronic paper I wrote with Fredenhagen and Rehren. Since the original chiral theory was localizable, you know the concrete spacetime interpretation of the knots and mapping class group operators only by pointing to those operators in the QFT algebra from where they originated. The only memory about localization they carry is a distinction between right and left (a property of the braid group). I do not know any construction which allows to reconstruct a QFT from a TQFT. The auxiliary Riemann surface pictures one makes are strictly metaphorical, they have absolutely noyjing to do with the physical localization.

117. **Thomas Larsson**
May 28, 2006

I happen to think that the present formalism of gauge theory does not meet this test (see my remarks I made earlier, giving support to Thomas Larson in Fantastic Realities, probably more radical than what he had in mind).

Bert, my key observation about gauge symmetries is quite radical: not all gauge symmetries need to remain gauge after quantization, due to gauge anomalies. There is a strong, ideological resistance against this (“a gauge symmetry is a redundancy of the description”), despite the fact that several well-known examples of consistent anomalous gauge theories exist; the free, subcritical string (D &lt 26) is the canonical example (no-ghost theorem).

In fact, it is impossible to combine a trivial action of local gauge transformations with nonzero charge, provided that you embed the algebra of gauge transformations into its natural completion containing also divergent, superselection-changing transformations. I made this observation, which is both obvious and trivial, in math-ph/0603024.

From this perspective, the key difference between string and YM theory is whether you allow divergent gauge transformations. In string theory, you allow generators which diverge when z -> infinity (L_m with m > 1), but in YM theory you forbid generators which diverge when r -> infinity.

118. **Bert Schroer**
May 28, 2006

Aaron,
you were a great sparring partner yesterday night. From FAQ’s to the standard prejudices you hit the whole scale of arguments and sometimes I had the impression that you played the devil’s advocate (this is what I sometimes do in order to enhance the informative flux). Since I have reservations about proselyting, this is a good way to conduct a dialog and I tell you that I stayed on the PC up to midnight in order not to loose this ideal opportunity.
I hope that I convinced you that the extension of standard QFT (Lagrangian quantization) called “algebraic” is basically the execution of a step towards intrinsicness which in geometry you already excepted a long time ago, namely independence of coordinates (in the case at hand independence of field coordinatization which requires to go beyond Lagrangian quantization) although, as in geometry, it is not forbidden to use coordinates. Due to the inexorably singular nature of sharply localized quantum fields this step is naturally more sophisticated than its differential geometric analog.
I also hope to have convinced you that TQFT, despite this name, is not QFT, because the most important ingredient since the time of Faraday and Maxwell namely localization (the meaning of fields) is missing. The impreciseness of nomenclature, hugely enhanced by string theory, would have tragic confusing consequences if we fall prey to our own bad semantic creations.
I tried to explain that AQFT achieves the separation of topological bones from the localizing flesh by extracting “kinematical” subalgebras with tracial states (they are never localizable or transportable). This is an extremely important technical step in the DHR theory of superselection sectors. The latter is a phantastic achievement: the reconstruction of the full QFT (including statistics, inner symmetries…) only from its observable shadow (another reductionist construction of AQFT). This is one of these inverse constructions of the kind which Marc Kac characterized in a more acoustic context as “how to hear the shape of a drum”. The idea is that we have very good intuitive insight into local observables, but we enter a conceptual high risk zone if we arrogantly claim that we can pull the structure of the full QFT with all its “unobservable” (i.e. its not directly accessible charge- and halfinteger spin- carrying fields) out of our hat or head.
This extraction of topological (“kinematical” in a certain extended sense of the word) bones in the old DHR work (see Haag’s book) has been extended to the low-dimensional realm of braid group statistics in the appendix of the mentioned FRS work, and I already mentioned that in this richer braid-knot-mapping class group context the tracial states coincide with the famous Markov traces of Vaughn Jones subfactor theory. The latter is a bone theory par excellence, although the bones which in the Chern-Simons-like
“backreading” into a Witten kind of Lagrangian jacket (but outside the Osterwalder-Schrader reflection positivity which is related to localization) take on the appearance of topological bones, are more combinatorial bones in Jones’s subfactor setting.
Another bone framework outside of localization is the LQG. I know too little about its algebraic nature to sav what kind of algebras it leads to but there are definitly no monades (see earlier blogs) around.
I saw many instances of extraction QFT —> TQFT but I am not aware of a single case were localizable meat was put onto topological bones. This is why I am a bit sceptical about the relation of LQG to localizable ordinary quantum matter; but on the other hand I have no argument why such a thing cannot work. Maybe Lee Smolin or somebody else from LQG has an idee how to achieve that.
I will vanish from the radar screen for at least one day and I of course hope that my contributions to this weblog do not only create animosities but are also a little bit helpful in a positive sense.

119. **urs**
May 28, 2006

Is it plausible that the right concept of real-time Minkowski-background 4D field theory is disconnected from that of Euclidean and/or topological field theory?

Taking the risk of sounding like a broken record (at least I won’t be the only one), let me say this:

The FRS result on RCFT (->) shows precisely the opposite. The full understanding of rational conformal field theory has only been obtained after realizing how it splits into a topological part and a part knowing about the conformal background structure.

And I think we all agree that RCFTs are of concrete physical relevance. They describe stuff people measure in laboratories.

Furthermore, the FRS theorem solves a problem (namely that of understanding what full 2D RCFT *is*) which cannot even be formulated with present AQFT technology.

That’s only in part due to the fact that AQFT chooses (by way of axioms) to restrict attention to Minkowski background, while we need Euclidean backgrounds here.

But there are more reasons. It is not known to date how to describe field theories with general boundary conditions using AQFT, let alone field theories with defect lines.

(Defect lines are for instance generated by the ‘t Hooft operators that implement the Hecke transformations in twisted SYM, the way Kapustin and Witten explain (->)).

Klaus Fredenhagen has some first ideas on how boundary conditions might be modeled in the AQFT context. There was supposed to be a project concerned with investigating this question in the new String Theory Research Center in Hamburg (->) – but the referees canceled this particular project.

Anyway, my impression is pretty much the same that Aaron expressed:

AQFT is one attempt out of several for extracting (guessing, really) the right mathemtical structures (the right axioms) from the semi-heuristic physical understanding of field theory. Given the results obtained from these axioms, it does not really look like the AQFT axioms make closer contact with observable physics than, in particular, Atiyah-Segal formulations do.

Moreover, as the example of that Stolz/Teichner paper was supposed to illustrate, where necessary the Segal formulation (which asserts that QFT = representation of cobordims categories in Vect) incorporates useful insights obtained from AQFT.

So, for me, the conclusion is this:

Clearly, AQFT has axioms which are a plausible first guess for the axioms that a real QFT should satisfy. But just as clearly, something about these axioms is not yet flexible enough. Something is still missing. Something of course is clearly right about them.

Surely, as long as the AQFT axioms apply not to a single physically non-trivial theory, they are in need of modification.

What is good about axioms is that they allow people to unambiguously work out their consequences. This is happening using AQFT axioms, and a couple of mathematically interesting insights have been obtained.

However, I see no evidence that Segal-like formulations of QFT, with their motivation in topological field theories, are farther removed from the QFT existing in nature than the AQFT formulation. On the contrary, things like the FRS theorem seem to tell me that the opposite is the case.

Suggesting that Atiyah-Segal is “just metaphorics” only because it is not formulated in terminology of AQFT sounds misleading to me.

120. **Aaron Bergman**
May 28, 2006

I’m just posting this to say that Urs pretty much said what I was going to say and to reiterate that any definition of QFT that does not include TQFT (of which many are not obtained by first starting with a non-topological theory) seems severely wanting to me.

That it does not encompass the geometric insights regarding anomalies and seems to allow perverse theories as are obtained in Rehren duality doesn’t help things either.

121. **urs**
May 28, 2006

Kea wrote:

> The AQFT papers that I have glanced at recently all talk about functors from some suitable category of (local) spaces, such as the category of strongly causal manifolds. Where exactly do you think this is leading?

There is an obvious covariance condition in the axioms of AQFT. You assign algebras (of observables) to subsets of spacetime. You want these algebras to behave nicely under diffeomorphisms of spacetime.

As about any covariance condition, this can be rephrased as a natural transformation of some functor.

As far as I can tell, this observation does not give rise to something qualitatively new.

122. **Mentos**
May 28, 2006

Heh.

Let’s not all pile on at once.

[everything urs and aaron said +]… unable to handle quantum field theories with degenerate vacua (see our previous discussion of Seiberg-Witten theory), does not incorporate renormalization-group behavior a la Wilson, apparently has trouble dealing with supersymmetry, …

In short, it is pretty much silent about the past 30 years of developments in quantum field theory. And when it does speak up (eg, Rehrens Duality) , it says something silly.

Were it not for the efforts of this blog owner (hosting various documents for Prof. Schroer, and enthusiastically promoting his arxiv postings), few would ever have heard of AQFT. And for good reason.

123. **Eugene Stefanovich**
May 28, 2006

Bert, Urs, Aaron, Kea,

The (quantum field) theories you are discussing look very distant from ordinary quantum mechanics of particles that served us so well in low-energy physics. Is there an important reason (a no-go theorem, or something) that forbids application of simple rules of QM (the Hilbert space, the Hamiltonian, the wave function, etc) to high-energy phenomena and requires the complete shift of the paradigm from quantum particles to quantum fields? This shift of the paradigm looks especially strange if one takes into account that predictions of QFT are usually limited to small (radiative) corrections to the QM results, e.g., the Lamb shifts.

Surely, when energies are high, we cannot limit ourselves to the Hilbert space with fixed number of particles, because particles can be destroyed and created in accordance with Einstein’s formula E=mc^2. Thus, instead of the fixed-particle-number Hilbert space we need to consider the Fock space where the number of particles can change from zero to infinity. Then creation and annihilation of particles can be described by simply writing the interaction Hamiltonians as polynomials in creation and annihilation operators in the Fock space. However, this doesn’t require introduction of a radically new formalism, such as QFT.

My question is: why, in your opinion, this simple-minded approach doesn’t work? Are there important reasons (besides historical) to consider fields, rather than particles, as fundamental ingredients of nature? Thanks.

124. **Kea**
May 28, 2006

My question is: why, in your opinion, this simple-minded approach doesn't work?

Oh, but it *does* work…if you try to turn what Bert is talking about into higher category theory and raising and lowering operators become associated with the concept of categorification and decategorification…and Minkowski space gets turned into twistor geometry so that it's true topos theoretic nature can be identified.

125. **Kea**
May 28, 2006

Eugene

How can Bert and Urs/Aaron **both** be right? There is only one way. Urs/Aaron need to accept the possibility that 30 years of String theory has missed something important. Then they can look for it in the higher category theory language that they use. On the other hand, Bert needs to think about a very, very small request – the possibility of reformulating AQFT, without losing any of its structure, in a different mathematical language.

126. **Kea**
May 28, 2006

Oh, I forgot to mention…that conference that Vaughn Jones was organising? For some reason we had a lot of speakers talking about TFTs.

127. **Kea**
May 28, 2006

I think we should call vacuums elephants. Don't you, Who? The word vacuum just has too many connotations of dirty housework and dust mites.

128. **Aaron Bergman**
May 28, 2006

Urs/Aaron need to accept the possibility that 30 years of String theory has missed something important.

What does any of this have to do with string theory? This has been a discussion about whether AQFT is the right way to think about field theory.

For Eugene, you can look at why QFT developed in the first place, I suppose, but a straightforward question is how do you propose to do QCD?

129. **Kea**
May 28, 2006

What does any of this have to do with string theory?

All right. Sorry. I was just using the term as a short hand for the conventional physicist's use of SYM etc.

130. **Kea**
May 28, 2006

…but a straightforward question is how do you propose to do QCD?

The SU(3) confinement comes in at the tricategorical level when one is forced to break the Mac Lane pentagon and use premonoidal structures.

131. **Bert Schroer**
May 28, 2006

I just got back so before I go to sleep I will at least try to answer a few of those questions.
Let me start with Eugene because it is the most physical question and I have a eference for such straight physical questions
The transition from QM to QFT is indeed a total paradigmatic shift, to exaggerate a bit in order to get this point across: the only thing they share is the Planck h.
Let me explain this by looking back at history. Whereas the paradigm changing QFT was discovered by Jordan, Dirac had a better accepted entrance into this issue by placing multi-particle quantum mechanis (leading up to Fock space) into the centre of the stage. For the case of the Schroedinger theory, the both points merges rapidly. Together with the discovery of the Dirac equation, Dirac developed hole theory and some of the first textbooks which contained low order calculation (no loops) worked quite nicely (viz Heitler). But later it was seen that the particle-based hole theory is inconsistent: nobody was ever able to do renormalization theory based on it and when you massaged it so that you could do it, you lost the particle base and slipped into QFT. Another observation which indicated that there was a paradigmatic change was that of Furry and Oppenheimer who realized to their great surprize that an interacting field applied to the vacuum does not create a particle state but rather a state which had a nonvanishing component to the one-particle subspace but in addition the (in infinite order you get a "cloud" which involves infinitely many particle-antiparticle pairs) vacuum polarization admixture. The modern way is to demonstrate this paradigmatic change by a rigorous structural (model independent) theorem which says that if in a compact spacetime region you find any operator localized in that region which creates a polarization-free one-particle state, the theory is necessarily interaction-free (in other words you now have an intrinsic quantization-independent way of seeing the presence of an interaction). The first region where this breaks down is the noncompact wedge region, in that case so-called PFGs ((vacuum)-polarization-free-generators) exist even though the theory is not free. This theories which arise in this way are precisely the d=1+1 factorizing model and the Fourier transforms of the PFGs fulfill the Zamolodchikov-Faddeev algebra relations i.e. the positive/negative frequency components are still close to particle creation/annihilation operators. Although these models have scattering without particle creation (and in this sense they are close to what you wanted in your question), they have very complicated vacuum polarization clouds which prevent any quantum mechanical particle picture for compact regions! It is true that the generators of the noncompact wedge region still look like relativistic particles, but even on that level the ground is somewhat slippery since that elastic S-matrix realizes the full "nuclear-democracy principle" saying that there is no genuine particle hegemony between elementary an bound (though there is still a charge hegemony between fundamental and fused charges) every particle is formed from all the other particles inasmuch as charge conservation allows this. So already in this relatively simple class of interacting theories (where you still can save some of the particle concepts on the level of wedge localization) the paradigmatic change is obvious.
This has very grave consequences. For example those arguments in Susskinds and Weinberg's work you often find the terminology relativistic QM instead of QFT. Unfortunately these are not just words, in computing those cosmological vacuum expectation of the energy-momentum tensor these authors fill levels as if it would be quantum mechanics and get their absurdly large cosmological constant values. This is conceptually totally wrong (it contradicts the local covariance principle which according to Kea does not contain any new information) and was profoundly criticized in a paper by Hollands and Wald (with a very nice title, you find it in one of my old contributions to this weblog). Of course saying that does not mean that you can easily do a correct calculation (the cosmological reference state is not well kown and in gravity you rarely deal with invarianr vacuum states). If this is the basis for anthropical ideas, it is an extremely flimsy basis indeed.
In this context it is interesting to mention another point. The modular methods which we developed recently (in the paper with Mund and Yngvason which I already

mentioned several times) permitted us to solve an old problem from the Wigner representation theory namely what are the fields for those massless infinite spin representations. We showed that they are semiinfinite spacelike string-localized. This solves an old problem which generations of particle physicists tried to understand. Weinberg in his book mentions the infinite spin Wigner representation and then dismisses it by saying that " Nature does not make use of them". But the main job of a theoretician is of course to investigates its physical manifestations and decide afterwards whether it should be dismissed. After all the massless matter separates into two families the neutrino- photon… family and the much larger infinite spin (better helicity tower) family. It is true that this quantum matter has very unusual properties (already Wigner noticed a very strange thermal behavior). I think nowadays with the black matter around, one would think twice before dismissing it with those words.
.

132. **Kea**
May 28, 2006

…it contradicts the local covariance principle which according to Kea does not contain any new information

I never said that.

133. **Bert Schroer**
May 28, 2006

Sorry Kea, I saw it somewhere, but it is not in your blogs. I applogize.
It is natural that there are TQFT at Jones's department because type II subfactors are (in some generalised sense) TQFT. But Jones knows very well (through his work with Wassermann) that QFT needs localization. In fact I am sure that he deepy appreciates the recent construction existence proof (and construction) of the minimal series by Kawahigashi Longo Pennig and Rehren . This is quite an achievment and this cannot be done by Frobenius algebras and sewing (you cannot construct QFT which has localization by sewing bones). It seem that some people have forgotten what a proof is.
Kea, remember I said that without localization you cannot talk about QFT and not that TQFT is a second rate enterprize. or anything like this mathematics does not need the blessing of QFT in order to be brilliant. The entire subfactor theory of Vaughn Jones was done in a context without localization and he would not even dream to use the word QFT for those constructions (although he knows perfectly how to to subfactor theory in the localizable type III setting)

134. **Bert Schroer**
May 28, 2006

Urs you said
"Klaus Fredenhagen has some first ideas on how boundary conditions might be modeled in the AQFT context. There was supposed to be a project concerned with investigating this question in the new String Theory Research Center in Hamburg (->) – but the referees canceled this particular project".
Urs I can perfectly understand that you are quite angry at those referees for having jeopardized this collaboration with the group of which you are a member.
Now we are getting closer. I could have told you already before you lost this collaboration which you desired so much, that whenever string theory related particle physicists get to evaluate QFT projects they would wreck that bit of reasonable research which still exists in Germany because their horizon is extremely limited.
I was a student of Harry Lehmann who together with Kurt Symanzik and Wolfhard Zimmermann, through there discovery of how one can even in the presence of that inexorable vacuum polarization (see the answer to Eugene's question) extract pure particles and their scattering matrix (lehmann received the prestigious Heinemann prize), brought a bit of brilliance to postwar German particle physics.
Two years before Harry Lehmann died I had a conversation (on one of my frequent visits to Hamburg) with him which is engraved in my memory. He asked me what is happening in Berlin, why does such an important position at the Humboldt u]University go to a string theoretician, an area whose contribution to physics was smaller than any pre-assigned epsilon. I told him that neither I nor my colleague Robert Schrader had any say in this; nobody ever asked us. He thought this was the beginning of a downpath in German particle physics.
Once I attended a seminar at the HU given by Sidney Coleman. Maybe younger people do not know, but Sid was the critical conscious of particle physics, a worthy successor of Pauli in keeping particle physics lively and healthy. He looked a bit frail and his behavior was changed from what I remembered from earlier encounters. What really shocked me (just because it did not fit his earlier critical image at all) was that he supported string theory. Later Robert Schrader told me that Sid was unable to continue his critical role because he suffered from an early onset of the Alzheimer disease. Only then I understood in retrospect why things had changed so much.
Well, Urs, I am not surprized that things go that way. Though I cannot hep you, I am sure that now, after the more QFT part of your joint venture was thrown out, you will see certain things my way.

135. **Bert Schroer**
May 28, 2006

Aaron, here is one last attempt to get you away from that proximity of Mentos.
The first derivation of the Hawking radiation in a collapsing star was done by Fredenhagen and Haag using the setting of AQFT (it was the problem which Hawking would have liked to solve, but as a result of conceptual complications he had to settle for the stationary case, see the book of Wald on this subject). I could continue this list, and in addition I already told you that everything which QFT can do AQFT can also do because the first one is included in the second. But there is a whole list of results which you can only obtain from AQFT because the inclusion is strict (not an equality). In my earlier blogs I have mentioned some of these results.
What I however cannot do is provide a vaccine against the string virus which like the bird flew virus is absolutly deadly, but it only kills the mind and the head is then filled with strings.

136. **Kea**
May 28, 2006

…remember I said that without localization you cannot talk about QFT…

Er…hello? I have been agreeing with you about that.

137. **Mentos**
May 28, 2006

"I already told you that everything which QFT can do AQFT can also do because the first one is included in the second."

Provided, of course, one uses a suitably narrow definition of "QFT," which excludes theories with degenerate vacua, theories with nontrivial WIlsonian RG behavior, supersymmetric theories, TQFTs, …

In short, throw out every development in "QFT" of the past 30 years, and AQFT has you covered.

Peter Woit, for instance, will be disappointed to learn that his beloved Chern-Simons Theory is not a QFT.

138. **Bert Schroer**
May 29, 2006

Mentos, you seem to honestly think that my role here is to please the owner of this weblog, well at least you are a honst guy.

139. **amanda**
May 29, 2006

"The SU(3) confinement comes in at the tricategorical level when one is forced to break the Mac Lane pentagon and use premonoidal structures."

" Sid was unable to continue his critical role because he suffered from an early onset of the Alzheimer disease."

Guards! Guards! Major crackpot invasion in the Woit sector!

140. **Chris Oakley**
May 29, 2006

Sid was unable to continue his critical role because he suffered from an early onset of the Alzheimer disease.

He could have just been faking it, having got tired of arguing against Superstring theory.

141. **stevem**
May 29, 2006

"The first derivation of the Hawking radiation of a collapsing star was done by Fredenhagen and Haag using the setting of AQFT. It was the problem Hawking would have liked to solve…"
Bert, why is this a better calculation than Hawking's? I assume you mean the paper: "On the derivation of the Hawking radiation associated with the formation of a black hole", Commum. Math. Phys. 127, p273 (1990).
But this comes quite a bit later than Hawking's so they did'nt do it first. I have not seen this but the archive of Comm. Math. Phys. is available free online, I think at "projecteuclid.com", so will look it up out of curiosity.

142. **stevem**
May 29, 2006

Correction, it is "projecteuclid.org" for anyone interested in the archived math journals there.

143. **Bert Schroer**
May 29, 2006

Chris: the calculation in the nonstationary situation is conceptually much more demanding than that in the stationary envirement of the Schwarzschild spacetime and it is not surprizing that this came quite a bit later.
I did in no way intend to build up a case AQFT against Hawking. I only mentioned this in connection with the ineredicable prejudice which affects some participants of this blog. This serious mental incapacity seems to affect mostly blog contributers who permitted there mind to be run by string theory and I certainly did not have you in mind.
When I entered this blog in April I had the illusion that one can change prejudices by rational arguments and facts, but now I realize that there are limitations. It is extremely difficult to argue with people who desperately insist to hang on some unfortunate premature terminology (before the time when the use of big Latin Latters became popular) and insist to take it litterally and defend their physical confusion-creating semantics with claws and teeth (a new breed of string millenium fundamentalists.)

144. **Bert Schroer**
May 29, 2006

Sorry, it was Stevem; but it could have been also Chris.

145. **Bert Schroer**
May 29, 2006

Eugene,
in order to enjoy some distraction, let me return to an old blog in which you surprized me by your familiarity with the Coester-Polyzou relativistic particle theory of "direct particle interaction". I now understand the origin of your recent question about the paradigmatic relation relativistic QM—-QFT. I do not think that there are many people in this weblog who really know about the existence of a relativistic multiparticle theory (without the property of being "second quantize representable") which fulfills all the requirements one can formulate in terms of pure particle concepts (including the very nontrivial cluster factorization). But you probably agree with me that it is not what we consider as "fundamental (I do not mean the hegemonic string theory interpretation of this word)" since it lacks vacuum polarization (although you could think of manufacturing something which approximates this by adding channel couplings between particle states with different particle number). But I think that even you would not try to understand the Lambshift or the cosmological vacuum problem (involving the energy-momentum tensor) in such a framework; you would rather make this big paradigmatic shift into QFT, would't you?
I looked at some of these other approaches you mentioned, but I have the intense impression (I don't have the time ti make the necessary lengthy calculations) that those fail precisely on this cluster issue. With other words I think that any relativistic particle theory has to look like C-P + more complicated channel couplings.

146. **JC**
May 29, 2006

I do appreciate Bert's "unorthodox" perspectives on physics (in comparison to today's "string" orthodoxy). I've been looking at AQFT on and off over the last two decades or so, though I don't have a complete understanding of it.

I bought into the string hype back in the mid 1980's when I was young and impressionable. In recent years, I was also still largely a string supporter until all that anthropic silliness started. (Though I could change my mind again).

147. **Mentos**
May 29, 2006

"I do appreciate Bert's "unorthodox" perspectives on physics (in comparison to today's "string" orthodoxy)."

That's "string," in the same sense Kea used above, shorthand for standard QFT, as understood by 99% of contemporary high energy theorists?

148. **woit**
May 29, 2006

Wow, the level of activity here is quite something. It's a holiday weekend so I've been very busy not working. Even if I was working and near a computer I don't think I'd have time to carefully read everything posted here, much less figure out how to properly moderate it. Discussion has certainly gotten off-topic, but at least it's interesting…

A couple quick comments of my own:

About the idea that I'm the prophet and promoter of AQFT: this is silly. Like many serious ideas out there about how to make progress on QFT, there are things about AQFT I find interesting, others I'm not enthusiastic about. I'm no expert on the subject, but happy to learn more about it from those who are. It's not obviously the best way forward, but then again nobody has an obviously best way forward at this point. It's a research program that has been pursued for many years by a very serious group of people, any such alternative program deserves attention these days.

About Sidney Coleman. His health problems are relatively recent, and undoubtedly keep him from commenting now on the current state of the subject, which is a loss for the field. By the way, at the party for Wilczek held here in New York last month his wife Betsy told me that they often see Coleman and he is in better shape than it seemed at the recent conference in his honor, something I was glad to hear.

I don't know exactly what Coleman's attitude towards string theory was during the 80s and 90s, as far as I know he made no public comment on it, but also chose not to work on string theory problems. All this was long before he ran into health problems.

May 29, 2006

Mentos,

Yes.

Whether AQFT or any other alternative can replace it in the near future, I doubt it. What would impress me would be something which could calculate the n-loop m-point function (n neq m, in general) in a few lines, without having to crank out zillions of feynman diagrams.

150. **Mentos**
May 29, 2006

"What would impress me would be something which could calculate the n-loop m-point function (n neq m, in general) in a few lines, without having to crank out zillions of feynman diagrams."

Then I suppose you are intrigued by the Witten/Svrcek/Cachazo/Spradlin/Volovich/… twistor-inspired reformulation of (super)Yang-Mills perturbation theory.

I think the goals of AQFT (or any other attempt to give a rigorous account of QFT) do not include an efficient reformulation of perturbation theory.

151. **Bert Schroer**
May 29, 2006

JC
since AQFT incorporates QFT (I mean real time, in the Euclidean case you would need the subtle reflection positivity which is hard to verify and certainly does not hold for Chern-Simons actions) i. e. it implements the same principles (maybe in a conceptually more careful way), then against what do you want to compare it, what do you want to see replaced?
AQFT has not been elaborated for going beyond the speed limits of ordinary computations in QFT; it is not the computational speed you gain, it is the conceptual depth which you sometimes succeed to increase.
There is too much mystery around AQFT in this weblog, somehow I have the impression that you only tolerate sophisticated mathematics in string theory and you want to maintain QFT in a mathematical stone age and in case it is not you want to put it into another drawer.
Is it so difficult to understand that in an area which is so treacherous and paradigm-changing (see my remarks to Eugene Stefanovich) as compared to standard QM one must be a bit more careful?
AQFTists just have a higher awareness about these problems: I have never assisted a talk where speakers forget to explain the setting and the aim of a problem; whereas in string theory the comprehensible talks with a good balance between conceptual setting and technical tools and a clearcut separation of facts&fictions which I have assisted can be counted on the fingers of one hand (although here in Brazil there is somebody who succeeds to do just that).

152. **Thomas Larsson**
May 29, 2006

"What would impress me would be something which could calculate the n-loop m-point function (n neq m, in general) in a few lines, without having to crank out zillions of feynman diagrams."
Then I suppose you are intrigued by the Witten/Svrcek/Cachazo/Spradlin/Volovich/… twistor-inspired reformulation of (super)Yang-Mills perturbation theory.

I'm somewhat confused by this example. My impression was that Witten's original twistor string, which would have led to massive simplifications (perhaps only for unphysical SUSY QCD, but anyway), was simply wrong (important lesson: conjectured dualities may be plain wrong). However, it was possible to save the idea by adding an extra interaction vertex. The modified twistor string is probably right, since it is just a canonical transformation of QCD, but now the question is whether this is useful anymore. A canonical transformation may be useful, e.g. if you reach action-angle coordinates, but this does not seem to be the case here. Otherwise, a canonical transformation usually lead to a formulation which is as hard, or harder, from what you started from. TANSTAAFL.

As an example how ignoring an interaction vertex leads to great simplification, consider QED. If you ignore the electron-electron-photon vertex, QED becomes a theory of free electrons and photons. This amounts to a major simplification, but it is also wrong.

153. **Mentos**
May 29, 2006

Maybe you need to look at Cachazo and Svrcek's year-old review

http://arxiv.org/abs/hep-th/0504194

or (to pick one more recent work) Britto et al's paper on the 1-loop, 6-gluon amplitude in nonsupersymmetric QCD

http://arxiv.org/abs/hep-ph/0602178

154. **JC**
May 29, 2006

Bert,

What I meant by “replace”, was whether AQFT or another framework could completely replace the Feynman diagram method in generic graduate level textbooks on quantum field theory. At the present time, I don’t see AQFT or any other framework being the dominant standard presentation in an introductory quantum field theory textbook. Despite the Feynman diagram calculations being really messy and tedious, I don’t see it being pushed aside yet by any other framework.

Years ago I use to think that string theory could one day completely replace the Feynman diagram framework of conventional “textbook” quantum field theory. (In hindsight this probably sounds very silly and naive).

155. **Johan Richter**
May 29, 2006

Has anyone of you heard of casual pertubation theory? On Wikipedia it was described as a finite, mathematical rigorous formulation of QFT. Is it a crackpot theory?

156. **Thomas Larsson**
May 29, 2006

My observation was based mainly on [hep-th/0605121](), where it was stated that a canonical change of field variables converts the Yang-Mills Lagrangian into an MHV-rules Lagrangian. Perhaps this canonical transformation does lead to major simplifications for SUSY theories (or perhaps not), but it remains to be seen whether this has any physical relevance.

There is no question that Witten’s original twistor string from 2003 was wrong, since it gave the wrong results beyond tree level.

157. **JC**
May 29, 2006

Mentos,

I was quite impressed by the work of Cachazo et. al. when they were able to reproduce some results found earlier by Bern, Dixon, Kosower, et. al, with less labor.

Bert,

For a long time I found AQFT somewhat mysterious, largely because I wasn’t familiar with the mathematics involved. (I could imagine this to be the case for some theorists). It could just be laziness on my part, but for many years I more or less looked at advanced mathematics on a “need to know” basis. I didn’t really put much effort into looking at unfamiliar math, if I didn’t think it was directly applicable to string theory or physics in general.

158. **stevem**
May 29, 2006

Bert, thanks. The paper on the Hawking radiation is interesting. Yes, I see now that this is for the nonstationary case, which is the harder problem with the scalar field in the background of the collapsing star. Peter, off topic discussions like this should be encouraged as long as the discussion stays reasonable, interesting and civil with the prospect of learning something new or getting a different point of view.

159. **urs**
May 29, 2006

> Urs I can perfectly understand that you are quite angry

Hm, I didn’d say I am angry, did I? Maybe I am, maybe I am not. We didn’t speak about that. (At least, given the context, there are clearly more likely candidates for anger, aren’t there?)

I would be happy to further discuss facts about QFT, AQFT and the like. In particular, I would be very interested in a factual reply to my last comment .

([http://www.math.columbia.edu/~woit/wordpress/?p=396#comment-11299]())

What I actually said was that it is not known how AQFT can deal with general boundary conditions.

On the other hand, in Atiyah-Segal-like formulations of QFT we do know how to deal with boundary conditions.

And its actually quite central to the understanding of QFT. The RCFT theorem says, among other things, that you can understand full RCFT from just knowing any one of its boundary conditions.

The reason is that the Frobenius algebra A which appears in that theorem (being the internalization of the Frobenius algebra known from topological 2D QFT, but now internalized, in the category-theoretic sense, into the representation category of some chiral vertex algebra) is nothing but the OPE algebra of open string states both whose ends have some given boundary condition.

It’s pretty remarkable that all other boundary conditions are then obtained by looking at the modules for that particular algebra.

Behind this is a nice little piece of general abstract nonsense, due to a theorem by Viktor Ostrik.

This theorem says ([->]()) that in every module category of our representation category of the chiral algebra, an internal algebra is given by the internal Hom of any one of its objects. These objects are nothing but RCFT boundary conditions, and the internal hom is something like the internal scalar product on these, when regarded as a issue in categorified linear algebra ([->]()). It’s interesting how this abstract nonsense translates into concrete CFT physics.

I am eager to learn, so if you like to teach, go ahead. (Maybe insert a paragraph line break here and there so that I can orient myself in the wealth of information given.) You may imagine that I am not a string theorist. Just a person interested in physics.

160. **Bert Schroer**
May 29, 2006

Peter, I tried to recollect the chronology of my encounters with Sidney Coleman and I think you are right, this Berlin meeting must have been before the onset of that tragic incapacitation; in any case there was nothing visible in his talk (which different from his usual topics was on some fundamental problem in QT). I do remember however that he was behaving more supportive of string theory than the amount of politeness required if one is invited by a string theoretician. Memory is often not completely faithful and depends a bit on those aspects which one is thinking about in the present.

Somehow I have a much clearer memory of those times when I met Sidney in Rio at the invitation of Jorge Andre Swieca. One reason may be that he got me into a very funny situation. He was suffering from a very severe form of diabetis and had to keep his bood sugar always around a certain level and to achieve this he ate sometimes small amounts of bananas. Before his seminar talk he asked me if I could arrange 2 bananas for him, so I left the PUC compound and went to a bar on the opposite side of the street and asked for two bananas (the always used to have small amounts for bananas to make a mixed shake called vitamina). I will never forget that strange look, just the kind of look a Gringo who asks for two bananas in a bar in Brasil would receive.
The next day we went to the Tijuca forest because Sidney wanted to see a macumba. He looked interested at the somewhat strange ceremony but did not comment it. The day after we asked him what he thought. He took a deep breath and said: you know the best situation is to have no religion at all, but if the number cannot be zero, it should be infinite. He was of cause referring to the large almost continuous spectrum which is the result of religious syncretism between African, Indian and European ingredients. In fact some years ago there was a delegation of Nigerian academics who studied the preserved rites and African culture in the Bahian diaspora.
There is also a valley in the mountenous region of Espirito Santo were descendents of Pommeranians live. Their ancestors were bondslaves in the feudal system which came to an end when Napoleon went through Europe up to Moscow. These people were free but without land and so the imperial government of Brazil payed their crossing and gave them land. Since the old Pommerania does not any more exist (after worldwar II it became part of Poland) this is the only place in the world were one can study this unique form of old northern German. They invented German names for tropical fruits; for example the "frutta de conde" which you take apart with your hand in order to get to that marvelous tasting pulp which melts in your mouth, they call "Schmalzapfel", an ingeneously fitting term.
Returning to Sidney, I think that Robert Schrader attended an event which was in Sid's honor, so it probably was the same which you mentioned. He told me that he was in a not so good shape. If, as you seem to say, the situation improved somewhat, one would whish that it reaches a point where it becomes interesting and meaningful for his friends to converse with him. He has done a lot to maintain the clarity of content and presentation (including good terminology) to deserve a satisfying evening of life.

161. **JC**
May 29, 2006

Johan Richter,

I haven't quite understood the point of "causal perturbation theory" in the Epstein-Glaser approach. Other than reproducing some results which were already known previously in conventional Feynman diagram calculatons, it seems to be an attempt at dealing with the formal details of the singular nature of fields which often gets "swept under the carpet" in textbook treatments of quantum field theory. (Somebody else can fill in the details).

Bert,

The main reason I first became interested in AQFT was that I always felt that there should be a way of doing quantum field theory without resorting to a classical Lagrangian in an intermediate stage. Ever since string theory has fallen into the anthropic abyss and particle phenomenology has more or less flatlined, I've been trying to understand other approaches like AQFT, LQG, etc … for which I previously looked at on and off for many years without much understanding. Since I don't write research papers anymore these days, I've been spending more time trying to understand AQFT and other older approaches such as in Bogolubov's two books.

162. **Eugene Stefanovich**
May 30, 2006

Bert:

B.S.: "I do not think that there are many people in this weblog who really know about the existence of a relativistic multiparticle theory (without the property of being "second quantize representable") which fulfills all the requirements one can formulate in terms of pure particle concepts (including the very nontrivial cluster factorization). But you probably agree with me that it is not what we consider as "fundamental (I do not mean the hegemonic string theory interpretation of this word)" since it lacks vacuum polarization (although you could think of manufacturing something which approximates this by adding channel couplings between particle states with different particle number). But I think that even you would not try to understand the Lambshift or the cosmological vacuum problem (involving the energy-momentum tensor) in such a framework; you would rather make this big paradigmatic shift into QFT, would't you?"

E.S.: To the contrary. There is no vacuum polarization in the "dressed particle" approach I was referring to. That's the beauty of it. The idea was first suggested in

O. W. Greenberg and S. S. Schweber, "Clothed particle operators in simple models of quantum field theory", Nuovo Cim. 8 (1958), 378.

In my opinion, this is the best paper about QFT written since Tomonaga-Schwinger-Feynman. The idea is to apply to the QFT Hamiltonian a unitary dressing transformation which kills all vacuum polarization terms and transforms them into particle-particle interactions. In this approach, the Lamb shifts and anomalous magnetic moments are not results of the vacuum polarization and virtual particle loops. They are consequences of small corrections to the particle-particle Coulomb potentials that arise from the dressing transformation. The particle-number-changing interactions that couple different channels result from the same transformation. They are not "manufactured". You can find the latests developments in this area and references in nucl-th/0102037 and in chapter 12 of
physics/0504062.

B.S.: "I looked at some of these other approaches you mentioned, but I have the intense impression (I don't have the time ti make the necessary lengthy calculations) that those fail precisely on this cluster issue. With other words I think that any relativistic particle theory has to look like C-P + more complicated channel couplings."

E.S.: I can't agree with you here. It is shown in vol. 1 of Weinberg's "The quantum theory of fields" that if interaction is written as a polynomial in particle creation and annihilation operators with coefficients that are smooth functions of momenta, then the theory is automatically cluster separable. Both Kita's and Shirokov's models belong to this class, so the cluster separability is not a problem for them.

However, Coester-Polyzou interactions are not written in terms of creation and annihilation operators (they are written as functions of relative momenta and positions of particles), so the cluster separability is a big issue there. It is achieved by a rather complicated combinatorial construction of the interaction potentials.
This is why I think that Coester-Polyzou type models do not have a bright future.

Eugene.

Completely OT: I have just received the NEW book from amazon.co.uk.

164. **Peter Woit**
May 30, 2006

Thomas,

Thanks for the news. Last I had heard British publication date was June 16th.
Interesting to know that it is being shipped. I still only have one copy myself…

165. **Bert Schroer**
May 30, 2006

Urs
Our controversy is about the use of conceptual precision in the terminology of particle physics. Let me make a second attempt to overcome it, or at least to give my position sharper contures.
The reason why I think that terminology and semantics in physics are important in times of "everything goes" (somebody mentioned the tower of Babel the other day) is that, wanting or not, they carry some connotation about the physical content and when a novice enters an area by reading electronic articles there is not always a knowledgable person next to him who helps him to steer around the riffs and cliffs of misinterpretation.
Let us keep the discussion within the borders of the previous hot point: TQFT against QFT and without loss of generality we may look at what Atiyah called the Jones-Witten invariant.
Now there are two ways of connecting certain subfamilies of that gigantic edifice which Vaughn Jones called "the theory of subfactors" (no qualm about this beautiful and meaning-loaden terminology) which via his "Markov trace" formalism (a terminology with a beautiful subtle two-fold meaning as I mentioned on an earlier occasion) leads to that tracial (type II) "bone" algebra (without localization) which contains the data of knots, mapping class groups and all that. There are two QFT-inspired ways to get to this.

One way is to adaptate the DHR technique of 1970,71 (contained in Haag's book) of "thinning out" QFT (always localizable in my use of the word) to obtain tracial "bone" states on the group behind particle statistics. In the higher dimensional DHR context this finally leads from the observable net to a (modulo some conventions) unique field algebra net which contains all the charge transfer operators which communicate between the different superselected representations of the observable net. The adaptation to the richer statistics realization which the locality principle permits in low dimensional spacetime (which you find e.g. in FRS, Review of Mathematical Physics, Special Issue (1992) 113) then leads to the same tracial Markov state on the same algebra (which from the QFT point of view is a subalgebra of intertwiners). This is certainly what Jones would have done if at the time he looked at these structures with Wassermann our paper did not already exist.

On the other there is Witten's derivation (from the great magician of actions) which starts with a a functional integral involving a geometrically based Chern-Simon density. Witten extracts with his typical hindsight and artistic skill (imposing certain framing rules) the mapping class group invariants. This is fine and it finds my unrestricted admiration, but the derivation has little to do with QFT, its relation to QFT is metaphoric. Why? There are zillions of functional integrals which you can write as exponential of an action, but most of them do not lead to QFT (even if you succeed to make some sense out of them by a renormalization-massage which destroys the validity of the representation you started with). There is a very subtle filter (coming from the O-S work) called the "reflection positivity" (insuring together with a certain amount of analyticity the localization which is an inexorable property of QFT) which the C-S action does not pass. Ignoring this subtle property has led to what I call a "banalization" of Euclideaniztion (i.e that structure which is behind the "Wick rotation", if you want to learn more about this criticism look at some lectures of Rehren, hep-th/0411086). This statement about the nature of the C-S action is not a moral or even a mathematical judgement. Even without being QFT (but certainly being QFT-instigated), this looses nothing of its mathematical value.
The general problem behind this is the following. In the QFT setting (either a la Wightmann, or a la LSZ, or AQFT) if something appears as an elephant it really is an elephant. This is not the case at all with functional integrals unless you have gone through the whole O-S litanei.
This may be considered to be pedantic. But we are in the midst of a string-millenium clearance sale of particle physics and if we will not be careful about our Faraday-Maxwell heritage handed down by Dirac, Jordan, Pauli…a sellout of all those of our concepts which were important in past conquests will take place (superficially, just because a group of very influential people with significant past achievements, although this could not happen if the Zeitgeist would not allow them to do this). If we don't wake up and pay attention now, we will have to spend a very very long time on physically feable theories (with physical content smaller than any preassigned epsilon) or even on a totally failed project.
Some people may think that I am very courageous to say such things. Actually I am not, I just think that terminology in the exact sciences should be totally related to the content (examples: Tomita-Takesaki, Hilbert-Schmidt, or from physics Einstein-Hilbert or Haag-Ruelle etc). If we, like it is done in politics, have not only to accept our terminology subject to a hegemonic handdown and mining claims, and if even more so we are forced to accept the literal meaning of words (as in TQFT and as in Christian religions before the enlightenment), than I do not want to participate longer in such a lost course as far as particle physics is concerned. I am already doing part-time fishing in the Atlantic and enjoy it, why not do it full-time. It is as simple as that.
If Vaughn Jones would be around at this weblog, he would totally agree with me, we both have a very developed ability to distinguish metaphorical from intrinsic statements and we had it already at the beginning of the 90 when he invited me to Berkeley (I think that this was where this photo of mine in that collection which appeared the other day must have been taken). He would immediately tell you that category theory, Frobenius algebras + cutting and sewing makes very interesting mathematics (although I think he would not use those instruments) and was suggested from physics, but to construct (not just classify) chiral QFTs you have to use other methods. And he would consider that recent construction of the minimal model family by Kawahigashi et. al. (with an addition of a model which was still missing in the old classification) the finishing touch on a program which he started together with Anthony Wassermann.
Urs, in no way I wanted to downgrade the work which is presently done at the Math. department of Hamburg university in your group, this is honestly not my intention; I only ask you to have the same respect for terminology coming from particle physics as I have for that in mathematics. We both cannot change the existing TQFT terminology, but you should not press me to take that the QFT in that word literally. Even if there is a large community who would look down on me for not accepting that and remaining in their eyes a stone age QFTist, I can perfectly live with this since to have somebody like Vaughn Jones on my side is sufficient for me.
By the way I think that the problem which we are discussing here is very much related to that issue of what should go into hep-th and what should be posted in math-ph or mathematics. It is worthwhile to point out that the majority of AQFT papers are posted in math-ph despite the fact that they are significantly closer to QFT than most of the typical papers there (just have a look at the systematic work on renormalization with the separation from algebras and states which led to those marvelous achievements in curved spacetime QFT, culminating in the new local covariance principle, http://unith.desy.de/research/aqft/). This is because the AQFT authors are more conscious and they certainly do not post anything onto hep-th of the kind were the author has interesting math and desperately wants a connection to physics and hopes to find someone who is able to make that connection. Another reason why Distler allows purely mathematical articles (sometimes given the physics flavor by foregoing rigorous proofs because this may be bad for the physical intuition of those partners or groups which they want to address). But for a change I do not here want to criticize Distler (because he works under a hell of sociological pressure) as long as he does not overplay the saying: quod licet ceasar non licet bovi.

166. **Bert Schroer**
May 30, 2006

Eugene
let us return to that interesting topic within a couple of days (se Peter quiser) since I have pressing other obligations.

167. **Kea**
May 30, 2006

He would immediately tell you that category theory, Frobenius algebras [etc.] makes very interesting mathematics…but to construct (not just classify) chiral QFTs you have to use other methods.

I have asked Vaughn to comment. Let us hope that he does.

168. **D R Lunsford**
May 30, 2006

Bert S said:

Alejandro,
Nobody is against geometry, but it has to come from the midst of raw local quantum physics…

This is a fundamental misconception. Everyone makes it, including string theorists. Insofar as I have a counterexample to this statement, it is wrong in fact, as well as simply in spirit.

-drl

169. **Bert Schroer**
May 31, 2006

Lunsford,
I honestly do not understand what you mean by that

Eugene,
just some preliminary remarks which should yet to be taken with a grain of salt. I do not understand your reading of Wally Greenberg's and Sam Schweber's old article (but since I do not have a copy anywhere near me I will be careful and preliminary).
If you really gave a correct account of the central point of the article, I would be still be reluctant. On the one hand mathematical physics in those days was on a lower level (although these authors belonged to the cream). For example those unitary dressings could lead out of the Hilbert space into inequivalent territory. Or perhaps the maintained a cutoff.
What I really do not understand is how could you dump such a complicated dynamical structure as vacuum polarization which depends on the region of localization (see my treatment of holography posted on that Goettingen server) into a modification of interaction (in standard approach (which was the only one known in those days) probably additional contribution to the interaction.
I think even in those days people had a bit more sophisticated vision of the QFT vacuum than that in that abominable mentioned level counting for the vacuum contribution to the cosmological constant; although my old colleagues (I am not significantly younger) certainly were still far removed from the level of understanding in the mentioned Holland-Wald paper.
Let me add that there is another area where such misleading views about the vacuum in locally covariant theories may have unfolded there treacherous ((wrongly simplifying) lure. This is the juxtaposition of a classical calculation based on differential geometry (Bekenstein's area law) with the Hawking thermal QFT setting. I really do not understand why quantum entropy should jump over that classical stick. Quantum localization and the ensuing autonomous thermal manifestation including quantum entropy are inexorably linked. And by the way, the area law for local quantum matter (which through AQFT holography becames associated with the causal horizon of the bulk in which it is localized) is totally universal whereas classically (taking the quantum entropy interpretation of the Bekenstein area law seriously for a moment) it is only valid for very special classical field theories including of course the Einstein-Hilbert theory.
Eugen, I think even among afficionados of string theory you would find little support for your vaccum viewpoint. And by the way, I have my serious doubts that that dubious sounding derivation of clustering from some momentum space analytic properties is due to Weinberg. What I was criticising before was Weinberg's logic: P-invariance + clustering —-> (local) QFT. But this is something else.

170. **Alejandro Rivero**
May 31, 2006

Eugene,

I just glanced at the abstract of your papers during the coffee time, but I think to recall you were against the need of keeping relativistic invariance at quantum level, were you? I ask because most of the argumentations of string theoretists are that their quantisation of the string breaks reparametrisation on the world sheet and relativistic invariance in the target space, and that the only way to avoid it is to fix D=26 (or D=10). But in principle the non critical strings, at any D, should have Lorentz symmetry back in the classical limit. So it is really a problem?

171. **Eugene Stefanovich**
May 31, 2006

Bert:

If you think that vacuum is a "boiling soup" of particles and antiparticles, then you need to explain the null result of the following simple experiment: place a photographic plate (or any other sensor) in an evacuated shielded chamber. Wait for a long time and then develop the plate. I think you agree that there will be no image on the plate. This means that all those virtual particles are not observable. Then what is the point to keep them in your theory?

…Or perhaps they maintained a cutoff.

Greenberg & Schweber paper didn't reach as far as to the loop integrals and renormalization problems. However, their approach can be used to systematically eliminate ultraviolet divergences from both the Hamiltonian and the S-matrix of QED in each order of the perturbation theory without cutoffs

E. V. Stefanovich, Quantum field
theory without infinities, Ann. Phys. (NY)
292 (2001), 139.

I have my serious doubts that that dubious sounding derivation of clustering from some momentum space analytic properties is due to Weinberg.

I am not sure if Weinberg is the original author of this derivation, but I don't have any problem with his proof in section 4.4. Do you?

I am sorry, most of your other comments about entropy, holography, etc. went over my head. I have no knowledge in these areas.

Alejandro:

…but I think to recall you were against the need of keeping relativistic invariance at quantum level, were you?"

Quite opposite. The relativistic invariance is the cornerstone of my approach. In my view, any sensible relativistic quantum theory should be formulated in terms of a unitary representation of the Poincare group in the Hilbert space.

No comments about strings.

172. **Bert Schroer**
May 31, 2006

Dear Eugene,
you do not see the boiling soup on a plate, but whenever nature converts the Gedanken experiment of localizing quantum matter into reality, like in the case of black holes,

you of course see the soup right on the event horizon and the resulting thermal Hawking radiation at large lighlike distances. Nobody can get this radiation back into virtuality, and if your theory can do, this it is not the right theory.
Whereas I believe that for a certain process you may encode the vacuum-polarization into a modification of interaction between particles, the claim that you can uniformely (i.e. for the whole theory and not only for a preselected process) dump vacuum polarization elsewhere and still maintain the underlying principles of the theory (locality, positivity of the energy-momentum spectrum) is to me totally incredible. After all vacuum fluctuation on the causal boundaries of localized quantum matter is a direct consequence of those principles. Vacuum fluctuation was discovered by Heisenberg in connection with the quantum Noether theorem, when he tried to make sense of a "partial" charge, i.e. a charge attached to a finite bulk region. The above mentioned thermal aspect of localization (which is totally absent in your desired quantum mechanical description because Born localization does not cause such a thing) as a hallmark of QFT (not explainable in terms of the uncertainty principle!!) is of a more recent vintage.

173. **Eugene Stefanovich**
May 31, 2006

Bert:

…whenever nature converts the Gedanken experiment of localizing quantum matter into reality, like in the case of black holes, you of course see the soup right on the event horizon and the resulting thermal Hawking radiation at large lighlike distances.

Nobody have seen the Hawking radiation in experiment, so I reserve the right to remain sceptical about this argument.

Whereas I believe that for a certain process you may encode the vacuum-polarization into a modification of interaction between particles, the claim that you can uniformely (i.e. for the whole theory and not only for a preselected process) dump vacuum polarization elsewhere and still maintain the underlying principles of the theory (locality, positivity of the energy-momentum spectrum) is to me totally incredible.

That's right, in the dressed particle approach, the vacuum polarization terms get absorbed into particle-particle interactions. These are direct action-at-a-distance interactions. So, you are right, the property of locality is lost. The question is how fundamental is this property? Even the usual Coulomb-gauge QED Hamiltonian contains a non-local direct interaction term. Nobody complains about it.

From the experimental standpoint, as far as I know, there is no direct evidence that electromagnetic interactions between charged particles are retarded. However, there are quite a few recent experiments (Chiao, Nimtz, Ranfagni,…) that demonstrate superluminal effects in the propagation of evanescent electromagnetic waves.

I am sure, you are going to say that action-at-a-distance contradicts relativity and causality. This is my favorite topic, and I can give you detailed counter-arguments, but I don't want to abuse the hospitality of our host Peter.
You can take a look at

E. V. Stefanovich, "Is Minkowski
space-time compatible with
quantum mechanics?" Found. Phys. 32 (2002), 673.

174. **Bert Schroer**
May 31, 2006

Eugene,
I am saying what you say is all deja vue, but in a very bad sense. I kindly ask you to look up G.C. Hegerferfeldt, Phys. Rev. lett. 72 (1994) 596. It was claimed in this unfortunately published paper (total incompetence of the referee) that a more careful review of the famous Fermi atomic Gedankenexperiment (which Fermi used in order to argue that the velocity of light is not only the classical limiting velocity but this is maintained in QED as well) led to the possibility of a superluminal propagation. The paper had a grave conceptual flaw, (to say it in modern terms relevant to your problem) the author confused QM Born type of localization with localization carried by quantum fields (in field-coordinatization independent terms: modular localization). This was a big international splash, it went through all the international press (including new York Times), I saw it in Der Spiegel. The editor of Nature Maddox (I hope I remember correctly) had a big article under the headline: physicist from Goettingen proves feasability of time machines.
Two of the colleagues of the author had rapidly written a counterarticle:
http://br.arxiv.org/abs/hep-th/9403027
and I wrote a letter to the editor threatening to never review a paper again unless they undue this mess by publishing the correct version as well which they did (Phys.Rev.Lett. 73 (1994) 613).
Now I do not want to dismiss the Born probability interpretation as irrelevant; to the contrary it is absolutely necessary for scattering theory, there you need a localization with probability interpretation (coming with projection operators which the modular localization does not have) and lo and behold it is asymptotically Lorentz invariant (whereas the modular localization is throughout covariant but comes without a particle probability interpretation i.e. has no projectors). A modern account using this terminology you can find in
http://br.arxiv.org/abs/math-ph/0511042
This superluminal conceptual error is the evergreen of all errors, it is ineradicable and reappears almost vearly like Nessy in Scotland.

June 1, 2006

Bert –

A geometry is an invariance group, and has nothing at all to do with quanta directly. Quanta arise when one imposes a concept of measurement, which is outside the geometry. Therefore, it is simply wishful thinking, or a misunderstanding of geometry, to insist that geometry arise from quanta.

Consider that, in a theory in which space, time, and matter have a common origin, their mutual phase relations can lead to quanta.

-drl

176. **Eugene Stefanovich**
June 1, 2006

Bert,

I knew about Hegerfeldt controversy, but had no idea that it reached New York Times and der Spiegel. That's funny.

I am wondering why you oppose so strongly the Newton-Wigner concept of localization? Is it because the NW localization is observer-dependent? Indeed, if oberver at rest O prepares a particle in a localized state, then moving observer O' sees the wave function of the same state as being delocalized over entire space. However, I don't consider it as something totally unreasonable.

By the way, this observer-dependent localization seems to be helpful in solving the Hegerfeldt's paradox. Suppose that observer O prepares a particle localized at point A. Suppose that the wavepacket spreads superluminally so that detector at point B has a (small) chance to register the particle earlier than at t=R(A-B)/c.
Suppose further that observer O' moves with a high speed, so it (sometimes) sees that detector at B clicks earlier than the particle is released at point A. Definitely, this looks peculiar to O', but he has a good explanation: from his point of view the particle was not properly localized by O from the beginning. He thinks that the wave function of the particle was spread over the entire space (including point B) all the time. So, this doesn't look like a irreparable violation of causality. And this is rather far from building time machines. Isn't it?

The response by Buchholz and Yngvason does not look entirely convincing to me. In order to decide unambiguously whether the excitation spreads slower or faster than light one needs to perform a calculation of the time-dependent wavefunction, which is still missing. This leads to my other question which worries me a lot.

From what I can see in textbooks, relativistic QFT is concerned only with calculations of the S-matrix (scattering cross-sections and energies of bound states are ultimately related to the S-matrix elements). However, I wasn't able to find any RQFT calculation of the time evolution in an interacting system from first principles.
I think I understand why such calculations are missing. Please tell me whether I am right or not.

In my opinion, the problem is that in realistic RQFT theories (e.g., in QED) there is no well-defined Hamiltonian. Without a good Hamiltonian one cannot form the time evolution operator and study the time dependence of wave functions and observables. The Hamiltonian of QED is deficient for two reasons. First, it must contain infinite counterterms (if we want to get the S-matrix right). Second (and most importantly), it contains those vacuum polarization terms that transform the vacuum and one-particle states into infinite linear combinations of multiparticle states, which is totally unphysical.

My diagnosis is this: the particles whose creation and annihilation operators are used to write down the QED Hamiltonian are actually fictitious "bare" particles that are never observed. If we want to study the time evolution we should be concerned about "physical" or "dressed" particles that are some linear combinations of bare particle states. This seems to suggest that time evolution calculations (and, by the way, the solution of the Fermi problem) require transition to the "dressed particle" representation where the vacuum polarization effects are not present. Do you agree, or I am totally wrong?

I am not sure what is the role of modular localization in all this. I am still studying your "string localization" paper, but I have more questions than this weblog can handle.

Thank you.
Eugene.

177. **Bert Schroer**
June 1, 2006

to Lunford,
now that I understand your statement, I can say that I disagree with it. The autonomous modular localization theory (see the last reference in my previous blog contribution) does just this: it extracts geometrical and group theoretical data from the abstract domain of definition of certain unbounde operators in the modular setting. A very poignant account can also be found in
http://br.arxiv.org/abs/hep-th/0502014
One small consolation: I also had to go back to school (already many years ago) and to undue my picture of QFT (not so different from yours) and relearn a lot of things, so I encourage you to make a yet additional investment into QFT and new math. This new setting also leads to a completely autonomous picture of local quantum physical reality (i.e. models of QFT) in terms of relative position of a finite number of copies of (Leibniz) monades as I pointed out in my comment to Christine's last contribution. By the way, string theory can never ever lead to such a setting, because it is a physically-instigated powerful production machine for mathematical conjectures (and pseudo-physics from geometrical imaginations about particle physics, i.e. Lundfors's direction) and as such it is very very good.

178. **Kea**
June 1, 2006

In discussion with Urs, Bert Schroer said:

He would immediately tell you that category theory, Frobenius algebras [etc.] makes very interesting mathematics, but to construct (not just classify) chiral QFTs you have to use other methods.

Vaughn Jones has expressed reluctance to participate in a public discussion of this kind. He has, however, informed me that he completely supports Bert's statement above and that he also confirms the pivotal role of Anthony Wassermann in the first construction of concrete chiral models (the local nets associated with loop groups).

179. **Bert Schroer**
June 1, 2006

Eugene,
I am not at all opposing the use of the (only asymptotically covariant) Newton-Wigner (= Born probability density) localization in the context where it is valid, I am opposing only the context in which you have been using it.
Without N-W localization and the associated probabilties and projectors you would not be able to derive scattering theory from the QFT priniciples (Haag's book, and in more details Arakis little book) and hence there would be no particle physics. One should not emphasize so much its negative side (not covariant=observer dependent for finite distances) but concentrate on its asymptotic covariance and observer independence=invariant S-matrix.
It is very very unfortunate that even philosophers of science have fallen into this pifall see D. Malament, In defense of a dogma, why there cannot be a relativistic quantum mechanics of (localizable) particles, in R. K. Clifton (Ed.) perspectives of quantum reality, Dortrecht Kluwer, 1996 . The title of this article is total humbug but its main No-Go theorem is not only correct, it is something of the finest. The author shows that the N-W non covariance syndrome is part of a more general theorem (which bears his name) which establishes the impossibility of projectors with certain properties; it in turn is a special case of the by now well-understood property that any notion of localization that requires the set of states localized in a spacetime region O to be orthogonal to the states localized in the causal complement O' is incompatible with translational covariance and positivity of the energy. Unfortunately no word in Malament that this conclusion is evaded in asymptotia which makes particle physics more than an entertainment on a high intellectual level for philosophers of science. Working with the right concepts of modular localization (which does not lead to localization probabilities but rather to expectations which cannot be resolved in terms of probabilities). Before you ask any question about such things you should study the articles (I cannot be your weblog nanny). If you look into
http://br.arxiv.org/abs/math-ph/0511042 (in print in CMP)
You will realize that the main problem is not computation or mathematics rather these problems are conceptually unusual and very demanding. As often in life, the biggest step is to overcome one owns prejudices. What makes me sometimes angry are those string aficionados who have lost the intellectual modesty one needs for understanding local quantum physics, but I never had the impression that you, Eugene, are part of that group.
By the way, localization is absolutely crucial for the autonomous physical interpretation of the theory, it is very very basic. It is the place where string theory manages to

create the greatest tohu-wabohu under the sun.
Your other questions I will comment on in a separate blog.
Sorry for the delay, there was some work on my server which took more than half the day.

180. **JC**
June 1, 2006

Bert,

I think I'm starting to understand where you are coming from with respect to AQFT. For many years I more or less looked at AQFT as if it was just purely a formal math problem. After reading your posts here for awhile and some of your papers, I'm getting the impression that the conceptual issues behind AQFT are just as important as the math content. (ie. No math for the sake of math).

When I first studied quantum field theory, I largely glossed over a lot of the conceptual issues. In those days I was more interested in grinding out Feynman diagrams.

181. **Bert Schroer**
June 1, 2006

JC
even such a phantastic vizualization of perturbation theory as Feynman's gift to QFT could become oppressive and counterproductive after half of a century if its iconization is driven to a point where it becomes synonimous with the vast an still largely unexplored territorry of local quantum physics.

182. **Eugene Stefanovich**
June 2, 2006

Bert,

thank you very much for your detailed explanations. Now I start to understand that your earlier comment that the only thing common to both QM and QFT is the Planck constant, may be not as big exaggeration as I originally thought. I can't swallow this so easily.
Need to think.

183. **Bert Schroer**
June 2, 2006

Eugene,
I sometimes use a bit provocative formulation, but I never manipulate facts. In the present case the reason is of course that you are not the only one who has (had?) this quantum mechanical view of the vauum; to the contrary you are in the illustrous company of Weinberg (see earlier remarks) and all those illustrous prople who use the classical (differential geometric) Bekenstein law for quantum mechanical degrees of freedom counting in order to extract an energy/entropy formula.
Without having looked at the details, the violation of the local covariance principle (leading to a localization-dependent vacuum polarization) makes such counting arguments very very suspicious to me (and I am not the only one, see http://br.arxiv.org/abs/gr-qc/0405082). This new principle to which Hollands and Wald have prepared the groundwork and which received the final conceptual and mathematical touch from the AQFT university of Hamburg group, cannot be violated without running into absurdities.

184. **JC**
June 2, 2006

Bert,

The only topics resembling "formal" aspects of QFT which were covered when I first took QFT courses, was stuff like Kallen-Lehman representation, LSZ reduction, and the CPT theorem. The rest of the course was largely covering the details of cranking out Feynman diagrams and doing renormalization.

These days some of my former colleagues start a QFT course by teaching the path integral from the very start, and only giving minimal lip service to "old style" canonical quantization. It's as if they're treating the path integral as if it was a "god given" object of some sort.

185. **Eugene Stefanovich**
June 2, 2006

Bert,

let me get it straight… If I understand you correctly, in your view of QFT there is no Born's probability interpretation, there are no projection operators, and the Hermitian operator of position is absent as well. So, it is fair to say that QFT does not respect the basic postulates of quantum mechanics. Is it right?

Does it mean that the very first sentence in Weinberg's vol. 1 is wrong?

First, some good news: quantum field theory is based on the same quantum mechanics that was invented by Schroedinger, Heisenberg, Pauli, Born and others in 1925-26, and has been used ever since in atomic, molecular, nuclear, and condensed matter physics.

Does it mean that QFT is not (as I naively thought) an attempt of unification of quantum mechanics and the principle of relativity? From your remarks and references it appears that QFT makes its own rules which are quite different from the laws of quantum mechanics as we know them. Is this an accurate description of your position?

186. **Bert Schroer**
June 2, 2006

Eugene,
not quite, you do have localization probability even in QFT and you do also have associated projectors, bot they are neither covariant nor local even though the setting in which they occur is covariant and local (but those noncovariant ones are very good for scattering theory). There is however also a covariant and local concept of localization. If you apply the polynomial algebra P(O generated by smeared field (where the smearing functions range over all smooth functions which have their support in a spacetime region O).to the vacuum i.e. P(O)|0> you get a dense linear subspace of the full Hilbert space (e.g. the Fock space). The totally unusual (from a QM viewpoint) fact is that there is very deep physical information in this inclusion of this dense subspace within the full space. With a change of O the position of there dense subspaces change their position. With the help of the definition of the Tomita operator S (look into the paper) you can write this dense space as K+iK where K is the +1 eigenspace of S. K is real because S is anti-linear! The unusual aspect is the reality of K (which of cause in general have no bounded projectors), nowhere in QM you need to highlight real subspaces. In the case of O being the wedge region W, the polar decomposition of this S (see paper) leads to two operators with a known geometric and physical significance (see paper) which is related to to the K-spaces. As Mund has shown (see previous reference) one can also avoid the introduction of K's and work directly with the S(W)'s and their intersection. S is also intrinsically related to the wedge-localized subalgebra A(W). By forming algebraic intersections you can get to

compactly localized subalgebras. There are of course projectors inside these subalgebras, which behave completely covariantly but none of them has an associated probability interpretation i.e. they are completely consistent with Malaments No-Go theorem.
I think with these remarks I have led you .beyond the first hurdle; try to go the rest of the way yourself (and let me know when you get stuck for more than two days).
This theory is very very deep. For the first time it supplies the entrance into QFT "without classical crutches" which Jordan pleaded for in his 1929 Kharkov talk. But everything is very much at the beginning, there is a vast territory to understand and the expected light at the end of the tunnel would be a genuine intrinsic approach in which objects cannot be characterized any more by their Lagrangian names. The first glimpses of this new way of looking at QFT is supplied by chiral and factorizing theories. If you clinge to Lagrangians, forget it.
Sorry, nobody has planned the great abyss between the standard way and this new perspective, but as a theoretical physicist you have to follow the intrinsic logic of things and not any fashions of the day.

187. **Arun**
June 2, 2006

How does the Hollands-Wald paper tie in with Wilsonian renormalization group ideas, if at all? Presumably the "holistic aspects of quantum field theory" do not show up in effective field theories with a finite cut-off?

188. **Bert Schroer**
June 2, 2006

A very tough question, Arun, since the Wilson RG is in momentum space whereas for the formulation of the local covariance the space of localization space is essential. On top of this, there is the problem that the Wilson RG is formulated in the Euclidean setting where the integration over certain over subvariables (the thinning-out process) corresponds to abelian conditional expectations. On the other hand its real time analog has to face to deal with nonabelian conditional expectations.
There is a related very deep unsolved problem which is to study the relation between boundary problems in the Euclidean setting and the superselected charge sectors in real time local observables. From studies of 2-dim. conformal QFT one knows that there is a relation (the Cardy's Euclidean way and the Longo-Rehren real time setting). Once in the middle of the 90ies, I suggested this problem to Schomerus (he had the necessary conceptional and mathematica recourses), but that was at a time when he had to build his career. Of course usually after people have made it, and could afford to really deep problems they are usually already very much attached to those problems which brought them there.
From Urs formulation I have the impression that this has something to do with that turned down research project of the AQFT Hamburg group, but since I lost the connection with that group, I am not sure.

189. **Eugene Stefanovich**
June 2, 2006

Now the difference between our approaches is clear to me. You insist on manifest covariance (= exact, interaction-independent tensor transformations of observables, = Minkowski space-time) and allow bending of the rules of quantum mechanics.
I adhere to strict QM and relativistic invariance (= Poincare group properties) and I am willing to sacrifice the manifest covariance. This is in
http://www.arxiv.org/physics/0504062

190. **Bert Schroer**
June 2, 2006

Not quite, Eugene, not with the N-W localization, in that case I would only insist in asymptotic covariance. If this would not be possible there would be no invariant S-matrix. But in the case of finite distances where I have to use the covariant localization (achieved by modular theory) I am not forced to use any covariant tensor formalism. The only thing I have to pay attention to is that when I have operators which I suspect to be localized in a spacetime region O, the application of the Lorentz transformation should lead to operators which are localized in the L-transformed region. And this is precisely where the Born localization fails: if something is N-W (quantum mechanically) localized in e.g. a sphere at a given time, then its L-transform is noncompactly spread all over the place although this spread is numerically small at large distances. But there is no uniform controll of this!!
But all of these "superluminal" effect are irrelevant in the asymptotic calculation of the S-matrix, they do not leave any on-shell effect. But do not use N-W (QM) for any other purpose than scattering theory.

191. **Eugene Stefanovich**
June 2, 2006

Bert,

The only thing I have to pay attention to is that when I have operators which I suspect to be localized in a spacetime region O, the application of the Lorentz transformation should lead to operators which are localized in the L-transformed region.

That's exactly what I meant by "manifest covariance"

And this is precisely where the Born localization fails: if something is N-W (quantum mechanically) localized in e.g. a sphere at a given time, then its L-transform is noncompactly spread all over the place although this spread is numerically small at large distances.

I see that you are trying to avoid the Hegerfeldt's paradox at all cost. Even at the cost of abandoning the laws of quantum mechanics. As I wrote earlier, I don't consider this "superluminal spreading" to be that dangerous. If you take into account the probabilistic nature of measurement, this curious effect becomes rather harmless, and it doesn't contradict causality. There is no way one can build a time machine or kill his grandfather by using this effect.

192. **Bert Schroer**
June 2, 2006

Eugene
It would be harmless if you would have a uniform control, but you havn't. Your view gose against Fermi's conclusion from his two-atomic Gedankenexperiment. His way of arguing may be mathematically doubtful (people at that time compensated the more feeble mathematics by stronger guts-feelings) but nobody wants to resurrect Hegerfeldt's paper, not even the author himself. The numerical argument is not enough, you need uniformity otherwise you mav be able to think about a sequence of modified Fermi-like Gedankenexperiments where the effect becomes so large that even you would not want to see the resulting acausality in your life (a time-machine sequence). Lack of uniformity does not permit you to use the word "small" inasmuch as one cannot say that a women is a little bit pregnant. And by the way, all the reported experimental verifications of superluminality turned out to be poltergeist effects

193. **Eugene Stefanovich**
June 2, 2006

Bert,

I didn't mean that the effect is harmless because it is small. In my opinion, it would be harmless even if it were big. I agree, it is strange that different observers disagree on whether the electron is localized or not. But I still don't see how one can build a time machine out of this, even assuming that this effect is amplified to the macroscopic scale. If you have a concrete proposal how to build a causality-violating machine using the "superluminal spreading", then I am ready to abandon quantum mechanics and the Newton-Wigner position operator and join the AQFT research.

194. **Bert Schroer**
June 2, 2006

Eugene,
I frankly do not understand why you have this psychosomatic attachment to an anti-Fermi (pro superluminal) formalism against all common sense (it does not only violate experience, but you also forego any chance to understand the quantum version of the Einstein local covariance principle) and you do get nothing in return. I tried to convince you the quantum mechanical particle interpretation is asymptotically valid in QFT, but you insist to use it outside its domain of its validity. I have reached the end of my possibilities; I cannot stop travellers who go into such a strange direction. In any case I hope at least that I convinced you that you do not have to do this, there is nothing in particle physics which forces you

195. **Eugene Stefanovich**
June 3, 2006

Bert,

thank you for trying to convince me. It was great that Peter was distracted by discussions of his NEW book (congratulations, Peter!) and allowed us to have this totally off-topic exchange. I think it is perfectly OK that we travel in different directions. As long as we stay honest to our core beliefs and respectful to each other we have a chance to find the truth somewhere down the road.

Regarding some of your comments.
1. I don't know a single experiment which directly measures the speed of propagation of interparticle interactions (not to be confused with the speed of propagation of light). So, it is too early to tell that action-at-a-distance *violates experience* . Superluminal effects were seen by experimenters in Koln, Florence, Berkeley, and a number of other physical laboratories around the world, not just in poltergeist movies.

2. I agree that my approach is not compatible with general relativity. There are hundreds of theorist who try to *understand the quantum version of the Einstein local covariance principle* . Did they move an inch closer to this understanding in the last few decades? I just don't think that this road leads to quantum gravity.

3. You asked what I get in return for my stubborn adherence to particle-based quantum mechanics and the principle of relativity (= Poincare group). Most importantly, I have a finite Hamiltonian of QED that can be used not only for usual S-matrix calculations, but also for the time evolution and bound state problems. All integrals are convergent, and there is no need for renormalization or cutoffs. This Hamiltonian incorporates all radiative corrections: the Lamb shifts and what have you… The interaction is written explicitly in the 2nd perturbation order. For higher order terms, there is a well-defined algorithm how to get them and rigorous theorems proving that what I am saying is actually true.

196. **Chris Oakley**
June 3, 2006

Just to chime in here: it is not clear to me what "causality" actually means at the quantum level. If we take

∂2Aμ(x)= jμ(x)

in classical electodynamics we may solve to obtain an "advanced" and "retarded" solution. The "retarded" solution expresses the principle of causality in that the amplitude of the four-current may not be known to observers until the time it takes a light ray to reach them has elapsed. This I can understand.
In QFT a field has a positive-energy part, which creates particles, and a negative-energy part which annihilates them.
Thus
ϕ(x)|0>
represents a particle at position **x** and time x0, but then so does the convolution
∫d4x' C(x-x') ϕ(x')|0>
where
C(x) =∫d4p eip.x θ(p0)
which is a non-local smearing that filters out the positive-energy part, so although it seems clear to me that fields need to commute or anticommute for spacelike intervals, if only because of the spin-statistics connection, the connection with causality, or even the definition of causality at the microscopic level remains – to me – unclear.

197. **Bert Schroer**
June 3, 2006

Eugene,
the local covariance principle is a principle in the setting of QFT in curved spacetime (black holes, Hawking radiation etc.) and not in a still illusive QG.
When I said that you are in the illustrous company of Weinberg I meant this in a metaphorical sence and I certainly did not want you to take this literally and feel encouraged by this. His extreme use of a quantum mechanical argument in the calculation of the vacuum polarization contribution to the cosmological constant is a blooper in is otherwise impeccable ouvre. He has never ever used such a picture for the calculation of Lambshift in his book (which really is an evergreen), whereas your quantum mechanical extremism would force you to do a new computation, of which none of us can imagine of how it would look like.
I am sad, but o.k. as long as you never tell anybody that you talked to me, go in God's name.

198. **Bert Schroer**
June 3, 2006

Oh no Chris, not again.

199. **Chris Oakley**
June 3, 2006

Sorry if I'm boring you, Bert, but I've seen spacelike commutativity/anticommutativity called the "causality" statement on more than one occasion. No doubt AQFT folks would never be so sloppy, in which case, good for them … and why does this ignore <sup> and <sub>? Maybe I should try [tex] … [tex]
\int d^4x' C(x-x') \phi(x') \vert 0\rangle
[/tex]

WordPress Upgrade

May 23, 2006
Categories: Uncategorized

Just upgraded to a new version (2.0.2) of WordPress, and as far as I can tell everything is working normally again. If not, let me know. The one change I plan to make here soon is to try out some of the new anti-spam features. The ones in the older version of WordPress were much better at rejecting valid comments than identifying spam, we'll see about the new version…

Comments

1. **Lubos Motl**
   May 23, 2006

   Your blog is still malfunctioning. For example, the title should only say "not wrong" instead of "not even wrong". Good luck with 2.0.3.

2. **Kasper Olsen**
   May 24, 2006

   Good! Your fancy collider-background is up and running again! (Thought we would never see it again 😉

   Cheers, Kasper

3. **MathPhys**
   May 24, 2006

   Peter,

   Is there an easy way that you can change things, so that when we click on links, they open in a new window?

   That would be very convenient, given that you provide us with very good links on a regular basis.

4. **Alejandro Rivero**
   May 24, 2006

   MathPhys, that is in the user side. You press the link with the right button of the mouse and then you gent the "open in a new window" command. If you are in a mac, and then you do not have right button, then you should press the modifier key in the left side of the keyboard and then click the mouse, the result is the same.

5. **MathPhys**
   May 24, 2006

   Alejandro,

   Thank you so much.

6. **The Anti-Lubos**
   May 27, 2006

   Lubos, I usually only think of you as a psychologically unstable, mean-spirited crackpot, but even I laughed at your comment. Nicely done, even though you're insane and evil. 😉 😉 😉 😉 😉

7. **Nigel Cook**
   May 27, 2006

   Lubos writes (in reaction to a post on Cosmic Variance):

   'A theory is the best result of a scientific or rational analysis of the world you can dream about.'

   http://motls.blogspot.com/2006/05/clifford-johnson-and-word-theory.html

   String theory is 'not wrong' because – judging by the number of citations to string theory – it is simply the BEST RESULT there is. It would be nice if string theory made contact with reality, but this isn't really important anymore. As Lubos says, string theory helps you DREAM, and sleep soundly without worrying about reality.

   More stringy hype

   Scientists Predict How to Detect a Fourth Dimension of Space

   Juan R.

   Center for CANONICAL |SCIENCE)

String Theory Makes Prediction – Pig Grows Wings

May 27, 2006
Categories: This Week's Hype

Several people have pointed out to me the latest press release hyping the supposed testability of an extremely speculative theoretical idea, which then gets promoted to a “scientists finally find way to test string theory” story, and spread throughout the popular press.

This week’s hype example comes from Duke University and is entitled [Scientists Predict How to Detect a Fourth Dimension of Space](). It deals with a [recent paper]() by Keeton and Petters, one in an interesting series of papers about using gravitational lensing to test GR. This latest paper deals with possible lensing effects of primordial black holes in braneworld models. The hype isn’t really in the paper itself, but in the press release, where Petters says “If braneworld black holes form even 1 percent of the dark matter in our part of the galaxy — a cautious assumption — there should be several thousand braneworld black holes in our solar system.” Braneworld scenarios can have any energy scale one wants, and the only thing one knows about this is that it can’t be below a TeV or so, because otherwise we’d have some evidence from accelerators for these scenarios, and we don’t have a shred of such evidence. I just don’t see any justification for calling the idea that 1% of dark matter is made up of these black holes a “cautious assumption” about what a braneworld scenario would “predict”, or for claiming that they have a testable “prediction” for what the GLAST satellite will see, in any conventional scientific use of the word “prediction”.

As usual, the hype level increases as the story is reworked into popular science stories elsewhere. For instance, at Ars Technica it is the inspiration for an article called [String theory makes prediction – pig grows wings](). The writer begins by giving a completely incorrect explanation of why string theory has made no experimentally verifiable predictions to date:

because the governing equations which work so well at very small scales (and very high energies) become impossible to solve when applied at lower energy or larger scales. Thus theorists must make approximations, which then have another layer of approximation applied before any measurable numbers fall out. At this point everything falls apart because that second layer of approximation is governed by existing experimental results, *which means that no new predictions are made.*

this repeats the usual misleading claim of string theorists that they have “equations which work so well at very small scales”, and the only problem is that it is hard to extract physics at long distance scales from these equations. I have no idea what this “second layer of approximation” is, best guess is that it is the “approximation” of assuming that string theory gives you the standard model at low energies, an “approximation” that does kind of make it hard to extract predictions that disagree with the standard model.

The writer also refers to another bogus “prediction of string theory” he attributes to Ulf Danielsson, and concludes that “now we have some real testable predictions from a theory of gravity derived (not in the mathematical sense) from string theory.” The parenthetical remark at least gives some indication that something very fishy is going on, and he does end the piece by pointing out that:

A word of caution should be attached at this point. Braneworld gravity is one of a number of string theory derived candidates, so if braneworld fails don’t expect it to take string theory down with it.

This particular piece of hype so far has been uncritically repeated at various places, including [here]() and [here](), from there making it onto endless blogs, such as [here](), [here](), [here](), and [here]().

Update: As usual, picked up by [New Scientist]().

Comments

1. **Who**
   May 27, 2006

   maybe this is simply a question of terminology. A pig with feathers is a turkey, and if it sits up in a tree it’s called a superturkey.

2. **Knotted String**
   May 27, 2006

   The squadrons of flying pigs (turkeys) that string theorists are so good at breeding will hopefully deposit some manure on the Landscape, and allow the growth of new ideas!

   May 28, 2006

   Dear Peter,

   as a particle physicist, do you think John Baez, Lee Smolin, Markapolou’s approach to standard model physics through LQG through “loop braids” is promising?

   http://math.ucr.edu/home/baez/this.week.html

4. **Who**
   May 29, 2006

   Dan, I realize you asked a specific question of Peter (and not of the gallery) but would like to respond.
   I am glad to see you making an effort to promote real discussion—I regret my flippant comment earlier about the pig with feathers because it seems to have precluded seriousness.

   Since Peter’s post is about TESTABILITY, and you mention Smolin’s stuff (which may be very different from Baez’—I am not sure about the connection yet) I will mention a case of **quick falsifiability** that Smolin mentioned on page 18 of his recent hep-th/0605052

   …The discovery that these theories generically predict emergent particle states certainly leaves them vulnerable to quick falsification. While there is preliminary evidence that a large class of theories can reproduce some features of the standard model, there is a lot that these theories have to get right so as not to disagree with observation…

   What he was talking about in that passage is, I think, what you were referring to. So there is a testability angle to it although it is a different pig. (maybe not a pig, either, but a kind of unicorn, or platypus)

5. **woit**

May 29, 2006

Dan,

Sorry, but that work is for now in the category of intriguing things I just don't have time to seriously study, so I can't intelligently comment on it.

6. **Christine Dantas**
May 30, 2006

Concerning the "crisis of predictability" of string theory, Lee Smolin will be giving a talk in Paris, sorry if it is off-topic.

===========
Mercredi 14 juin à 14h30

Lee Smolin (Perimeter Institute, Canada)

"Against Symmetry"

From the Leibniz-Newton debates to the present debates between string theorists and loop quantum gravity theorists two notions of fundamental physics have stood opposed. On the one hand is the Newtonian vision, which is based on a belief in a fixed absolute space and time and which holds symmetry to be fundamental and its breaking to be contingent. Leibniz's conception of space and time is instead of an ever evolving network of relationships in which complexity is fundamental and symmetry is unnatural and accidental. This distinction characterizes the divide between background dependent theories like string theory and relational, background independent theories such as loop quantum gravity.

In this talk I analyze the present status of the two traditions and the plausibility of their contemporary incarnations. I show that the crisis of predictability facing string theory is a direct consequence of a conception of unification that is opposed to the principles that underlie the successful modern unifications such as general relativity and gauge theories. I close by describing a new kind of unification which emerges from background independent theories.

Amphithéâtre A, entrée par le 25 rue de la Montagne Sainte-Geneviève, Paris 5ème

7. **Bert Schroer**
May 30, 2006

Very interesting Christine,
in QFT such "monade presentations" already exist. An early account of how to build up the reality of QFT (up to 4-dim) in this Leibniz monade spirit, including the spacetime symmetries, the net structure (localization) and (by doing the DHR analysis) the entire inner symmetry structure, can be found in H. W. Wiesbrock and R. Kaehler, Modular theory and the reconstruction of 4-dim. QFT, JMP 42, (2001) 74 and previous literature (this was the last paper this incredible original talent W wrote, after he had developed most of the necessary modular inclusion and modular intersection concepts, and shortly before he had to leave academia because in a world of string hegemony there is no place for this kind of people, he did not even bother to post this paper onto the server).
I have used part of such a monade picture for a number of years (it pervades all of my recent articles and let me to a formula for localization entropy in
http://www.lqp.uni-goettingen.de/papers/06/04/
which is consistent with the new local covariance principle in AQFT).
The problem to reconstruct the generic curved space-time structure together with quantum matter on it is much more complex. I have tried to build up the diffeomorphisms of the circle from the relative position of monades (i.e. without using the existence of an energy-momentum tensor, but the results are still very incomplete, viz.
hep-th/0504206 published in AOP) associated to it.
It seems to me that a program as that of Lee Smolin is very ambitious; maybe one should more modestly understand the relation of quantum physics and monade positioning first in QFT in CST.
I should add that this relative positioning picture was also on the minds of Brunetti and Fredenhagen when they formulated the new quantum local covariance principle, and last not least, without it Einstein would not have succeeded in his struggle with the fantasmas against covariance he himself created with his "hole argument."

8. **Christine Dantas**
June 1, 2006

Dear Bert Schroer,

Thank you. I am ignorant on monades and several other issues. I am stubbornly following with great interest your contributions to this blog, but I must say a lot of material here is a little over my head. However, it is admirable to learn that are still people in this world interested in discussing physics seriously. I am tired of so much degradation elsewhere.

Best wishes,
Christine

9. **Christine Dantas**
June 1, 2006

Concerning the question of the multiverse, it is a relief to see a paper on this by serious enough people:

How Many Universes Do There Need To Be?
[http://arXiv.org/abs/astro-ph/0605709]

Christine

10. **Bert Schroer**
June 1, 2006

Dear Christine,
I am sure that my thinking about string theory did not escape your attention.
Unless you are an active participant with the "string feel" (i.e. you are with it), it is difficult to understand this phenomenon because it is not scientific, it is rather a sociological phenomenon which takes place where one least expects it, namely in the center of particle physics.
That irrational things suddenly spread in the midst of rationality is a postmodern phenomenon whose study is the heart piece of the Frankfurt school of philosophy/sociology. Horkheimer, Adorno and Habermas of course were thinking of right arm-raising crowds shouting Sieg Heil in the midst of a culturally and civilisatorically most developed country and about the catastrophic barbaric consequences.
I must confess that in total lack of any scientific explanation, I also think about this strange grip of mass hype and medial manipulation emanating from the first globalized

attempt to get a hegemonial grip on science by manufacturing and not logically deriving scientific facts (fortunately only with a loss of knowledge and not human lifes) in such sociological terms. I really do think about those collective excitations at the time of my birth which I sometimes see in old films and which leave me stunned and bewildered when I look at the new scientific hype. But perhaps it is better to stop with these analogies. otherwise somebody might tomorrow claim that I compared Joseph Polchinski to Adolph Hitler and Aaron Bergman to his stormtrooper, and I may loose my pension in Germany. I have a Brechtian (the identity of the first names is purely coincidental) personality which does not ask for self-sacrifices but only to subterfuge hollow and oppressive systems.
Let me add that I am totally against racism and political correctness, this is part of the reason I prefer to live in Brazil (by the way I think that such a catastrophy as in Nazi Germany could never have happen in Brazil, even the ethnic cleansing of the Paraguaian indigenous population by your Duke de Caxias is quite a distance away from what happened at the time of the 2. worldwar).
I would suggest to those physicists who's future is unsure (and to those string theorist who already foster doubts in their heart) to take in addition some courses in the philosophy/history/sociology of science, because if things within the next couple of years develop the way as with Bush's Iraq war (also based on maniufactured facts), there will be a lot of interest in the public to understand what happened in the midst of physics and why those things which Michio Kaku, Lenny Susskind and Brian Green were writing about (and telling the US congress) (and all the other popular string theory writers which still appear on the scene) and promised them evaporated in hot air and left such a big crater in the midst of science. This phenomenon will need very thoughtful profound analysis (it is the Zeitgeist which allowed these individuals to do something like this), maybe even a kind of new Frankfurt school geared towards science.
Actually I am already corresponding with such a Jekill&Hide character who comes from the midst of string theory and who got extremely exited about my polemic article. Since he has all the insider knowledge and an amazing overview about the immense string literature, he can immediatetly back up his analysis by explicit citations and this is much deeper (and not polemic) to what outsiders as Hedrich or myself (the polemic part) can do.

11. **Chris Oakley**
June 1, 2006

String Theorists have not yet been defeated (not politically, anyway), and it is not they, but their critics like yourself who are fleeing to South America.

So much for the Nazi analogy.

But they definitely have the "Weltmacht oder Tod" mentality.

12. **Bert Schroer**
June 1, 2006

Chris, things were not quite as bad in Europe, at least at the time when I went to Brazil some years ago. However recently they seem to have taken a turn for the worse, at least in Germany. It is through this weblog that I got to know that one of that new breed of string-possessed referees (a person who knows what particle physics is about and still kept his senses would never do anything like this) deciding the scientific merits of a research project (probably to be funded by the DFG) has thrown out the extremely successful AQFT part and kept the string component (whose contribution has been smaller than any preassigned epsilon, without any hope for future improvements). People like Robert Wald and those who have collaborated with him will immediately understand the devastating significance of this act.
Chris, it is not Weltmacht oder Tod, it is hegemony and death, but death for the others.

13. **Trevor Turton**
June 10, 2006

It's fascinating to see such strong divergence amongst physicists on whether string theory is science, maths, or a fashion statement.

"String theory is the new black"

Accelerator News

May 27, 2006
Categories: Uncategorized

News about various colliders of various vintages:

The Tevatron has been shut down for the past two months for maintenance and various improvements. It should start up again this coming week, for latest news on its status, see here.

Seed magazine is starting a series of articles on the LHC. One prediction about the LHC that I feel confident making is that it is going to get a lot of press coverage.

A group called the LHC Theory Initiative has been trying for a while to get the NSF to fund new postdocs and graduate student fellowships for physicists working on LHC phenomenology. So far they have been turned down, with the panel that recommended not to fund this presumably concerned that money going to this purpose would be taken away from the standard NSF group grants that fund particle theory groups at many institutions. The full NSF proposal is available on-line.

Science magazine has an article about Barry Barish, who is leading the Global Design Effort for the ILC.

The same issue of Science has a paper by Steinhardt and Turok promoting their cyclic cosmological model as explaining the small value of the cosmological constant, together with an article by Vilenkin criticizing them and promoting the anthropic point of view.

Update: Experimentalist Michael Schmitt, sometimes commenter here, has an excellent new blog about accelerator-based particle physics at the Tevatron and LHC entitled Collider Blog.

Update: The Tevatron start-up was going smoothly until early yesterday morning when they ran into serious trouble. Here's the report from the FNAL accelerator update page:

At 1:24 AM, Operations reported a raccoon attack on the Linac gallery. It seemed to be a coordinated effort. Fortunately, by 1:53 AM, a joint force of operators and Pbar experts managed to drive the raccoons out of their hastily made fortifications. Then at 4:18 AM, the raccoons made what some thought to be a counter attack on the Division Headquarters, but others believed it to be only a simple reconnaissance incursion. No raccoons were either injured or captured during these encounters. Operator losses were low.

   Barish came to our lab to give a talk about ILC, and I wanted to ask a question, but didn't because didn't want to appear to be an a$$hole:

   "If ILC is not funded (at least if US gov't pulls out), is this the end of the line for huge "super" accelerator projects"?

   Anyone wants to take any guesses?

2. **Mechanism of Standard Model particle masses, exchange forces and General Relativity**
   May 28, 2006

   […] Woit has a blog post which says in part: '… Science has a paper by Steinhardt and Turok promoting their cyclic cosmological model as explaining the small value of the cosmological constant, together with an article by Vilenkin criticizing them and promoting the anthropic point of view.' […]

3. **sunderpeeche**
   May 28, 2006

   I have asked this question (what if US does not fund ILC?), to people who work on ILC. Nobody will give a clear answer. One can argue nobody knows the answer. Certainly the EPP2010 report, full of "US leadership" does not augur well for "International" anything. The rest of the world may build ILC without USA. If super-accelerators (VLHC?) continue to not find anything beyond SM, it will be ever harder to justify new machines.

   As for the prediction that LHC will generate a lot of press coverage, that is par for the course. All large new accelerators do, whether built or not. CERN generated enormous publicity for LEP. The SSC was not lacking for publicity. The construction of NAL (later FNAL) was a major event in its day, so was the SLAC linac.

4. **Michael**
   May 28, 2006

   If the LHC finds nothing beyond the Standard Model (ie, if it finds only a SM-like Higgs boson), then one can forget about future accelerators, including the ILC. The interest of people outside high-energy physics for another big, expensive machine will whither, and many will ask: what about all the great ideas and promises that were made (for example, in the EPP2010 and HEPAP documents) back in 2005, 2006, 2007?

   There are many basic arguments why new phyisc should show up at the TeV scale, and personally I believe thi s makes the LHC a good bet. However, I have seen comments posted to this web site expressing doubt that supersymmetry or other signs of physics BSM will be discovered at the LHC. Since string theorists are deep thinkers, this has worried me a lot. Yesterday at a dinner I asked David Gross about the skepticism of some of the string community about the LHC. His reply was, basically, that the arguments for new physics at the TeV scale are incontrovertible and that people in the string theory community do not have a basis to overturn them. (Nota bene: I am rephrasing quite a bit…)

   What will be the answer? Only the analysis of real data will tell us. If Nature is cruel, then we will not only be disappointed, we will probably lose an entire line of basic inquiry. Who would fund Colombus for a crazy voyage across the ocean? Only those will lots of money and the desire to be the most powerful. Who would have guessed what was to be learned?

5. **woit**
   May 28, 2006

   Michael,

   What "new physics at the TeV scale" was Gross referring to as there being incontrovertible arguments for? As far as I know, the only solid arguments are that you have to see a Higgs or something else. Things like supersymmetry, technicolor, extra dimensions, not only are not necessary, but already in trouble with precision electroweak measurements from current accelerators.

Sunderpeeche,

My prediction was somewhat tongue in cheek, but more precisely, in units where the publicity for SLAC was 1, FNAL was maybe as much as 5-10 SLACS, LEP and the SSC around 50 SLACS, I'll predict that for the LHC the magnitude will be at least 100 SLACS, achieving a new world record.

6. **sunderpeeche**
May 28, 2006

"My prediction was somewhat tongue in cheek" well yes, I figured as much. Columbus was funded because Queen Isabella wanted to compete with Portugal (and note that Cristoforo Colombo was initially turned down, but Queen I changed her mind). If Columbus had sailed across the ocean, found nothing, turned back and said, "I didn't reach China/Japan, but I found out the ocean is bigger than we think it is" well that would probably have been the end of any further voyages. So it is with the LHC. If it finds no physics beyond SM, justifying the next machine will become REALLY hard.

7. **Tony Smith**
May 28, 2006

As to the Columbus analogy:

Short route to India/China/Japan = supersymmetry a la superstrings

America = something already indicated by Viking voyages etc = SM Higgs

Maybe detailed study of SM Higgs (for which ILC/NLC/whateverLC is needed in addition to LHC) would (as did detailed exploration/exploitation of America) lead to results far more ultimately enriching for humanity
than finding a false-hope supersymmetry = a short route to India/China/Japan would have been.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – As to "… David Gross …[said]… that the arguments for new physics at the TeV scale are incontrovertible and that people in the string theory community do not have a basis to overturn them. …",
that statement may be true if restricted to the universe of superstring true believers.
However, for others,
it seems that the only "incontrovertible" arguments are circular, in that they use assumptions (whether or not explicitly stated) that are equivalent to the existence of TeV scale supersymmetry a la superstrings.
If there are any such "incontrovertible" arguments that do not involve such assumptions, I would be very interested in seeing them spelled out, rather than mentioned solely by vague insubstantial reference.

8. **sunderpeeche**
May 28, 2006

This post is not (totally) tongue in cheek, and is only partially a reply to Woit, and is perhaps totally nonsense. The construction and operation of FNAL (late 60's-early 70's) provided a major source of employment for professional black people, at a front-rank scientific institution, and took place at (or close) to the peak of the civil rights movement. We tend to think of accelerator labs as purely civilian projects., e.g. Robert Wilson famously testified to Congress (this is taken from Wikipedia but I have heard it many times before)

—-
In 1967 he took a leave of absence from Cornell to assume directorship of the not-yet-created National Accelerator Laboratory which was to create the largest particle accelerator of its day at Batavia, Illinois. In 1969, Wilson was called to justify the multimillion-dollar machine to the Congressional Joint Committee on Atomic Energy. Bucking the trend of the day, Wilson emphasized it had nothing at all to do with national security, rather:

It has only to do with the respect with which we regard one another, the dignity of men, our love of culture. It has to do with: Are we good painters, good sculptors, great poets? I mean all the things we really venerate in our country and are patriotic about. It has nothing to do directly with defending our country except to make it worth defending.
—–

It was not quite the same with the SLAC linac. At the time of construction of the Linac, the US military was building the North American Early Warning Defense System, a set of radar domes spread out across Alaska and northern Canada, to detect Soviet bombers/missiles. The klystrons to accelerate the electrons in the Linac were precisely what the military needed to power the radar stations. Nobody talks about this out loud. The military got what it wanted (R+D and contruction knowhow) without any protests from the hippies and flower children of San Fran.

One longs for the good old days when one could trip through the physics lab with bellbottoms and LSD. No internet, no cell phones, no blogs…

In short, major accelerator projects are sociological events, not simply physics experiments. But the publicity for the modern machines seems to contain a much greater degree of hype (all hype?). The SSC was "for America to have the biggest accelerator in the world" which was simply foolish.

9. **Michael**
May 28, 2006

We all seem to agree that no new physics at the LHC is a disaster for experimental high-energy physics.

Concerning the promise of new physics at the TeV scale, people make the argument in various ways. Since I am an experimenter I am not the best person to make the agument, but I do know that is does not necessarily involve supersymmetry. I do understand that string theory does not require a low-scale supersymmetry. However, that is not the point. If there is a SM-like Higgs (one that is responsible for electroweak symmetry breaking), then the mass of that particle is not stable against radiative corrections, in the Standard Model. Therefore, something beyond the SM must enter to "control" those corrections. Low-scale SUSY is one popular possibility, but there are others (such as Little Higgs models, and some extra-dimensional phenomenlogical models). If the low-scale MSSM also provides a way to unify the gauge couplings, explain the Higgs mechanism through the large Yukawa coupling of the top quark, and naturally provide a viable dark-matter candidate, then it may be in a better position as a speculation than other competing models. There is no proof that low-scale SUSY is right, but all of the phenomenologists and model-builders I know insist that new physics must enter at the TeV scale. It was interesting to me that David Gross, a famous string theorist, had the same definite opinion.

It is true that some models are ruled out by precision electroweak data, but the MSSM is not. Also, little Higgs models and many extra-dimensional models manage to survive those constraints. It is supposedly a virtue of the MSSM that it does not lead to large deviations in those observables – the fact that data confirm the SM means they also tend to agree with the predictions of the MSSM, making it difficult to constrain the MSSM using precision ewk observables.

The MSSM does have problems in the flavor sector: why aren't there many CP-violating phases, and why aren't there large FCNC's? Why would one have an alignment of flavor-mixing matrices, or minimial flavor violation in general. But then again, we understand almost nothing about flavor, right?

10. **Tony Smith**
May 28, 2006

sunderpeeche said "… major accelerator projects are sociological events, not simply physics experiments …
The construction and operation of FNAL (late 60's-early 70's) provided a major source of employment for professional black people, at a front-rank scientific institution, and took place at (or close) to the peak of the civil rights movement. …".

IIRC, Georgia, which in the 60s had senatorial influence (Russell) at least as powerful as Dirksen of Illinois, made a bid for the NAL site, but lost out to Illinois primarily because the "professional black people" felt uneasy about living in Georgia (this was before 1973 when Maynard Jackson became mayor of Atlanta).

When I try to think what comparably important sociological reason might be advanced for putting ILC in the USA as opposed to Geneva or Asia, I draw a blank.

Further, when I try to think how the USA military would benefit from a USA site (a la SLAC klystrons mentioned by sunderpeeche), I also draw a blank.

If access to research positions and experimental results is substantially non-discriminatory, then, really, why does the USA physics community feel so strongly that the ILC should not be in Geneva (a very hospitable place for a cosmopolitan work community) or Asia (as they say, it is their turn now) ???

Isn't the most important thing that it be built and used to at least examine Higgs etc in detail,
and not where it is located (and who gets the most construction contracts and labor jobs) ???

If it is REALLY about who gets construction contracts and jobs, then isn't it just another pork-barrel project ???

Isn't perception of pork-barrelling one of the factors that killed SSC ???

Tony Smith
http://www.valdostamuseum.org/hamsmith/

11. **Tony Smith**
May 28, 2006

Michael says "… We all seem to agree that no new physics at the LHC is a disaster for experimental high-energy physics. …".

Since nobody can be everybody without me (even if Harvard Professor Motl's characterization of me as a "moronic crackpot" were to be correct), Michael is wrong.

I don't see any problem with a 115-200 MeV Higgs and no other signals not already seen (although maybe missed by most consensus analyses) at Fermilab and elsewhere, because
ILC (or its equivalent) would in that event be needed to provide more detailed observation of how that Higgs is related to such things as (to mention only one possibility) T-quark condensates.

It would NOT be "a disaster for experimental high-energy physics", although it would take such physics down roads not so well travelled now.
However,
it might be seen as "a disaster" from the viewpoint of some physics empires/castles that would, in such an event, be seen to be built on sand.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

12. **Tony Smith**
May 28, 2006

Sorry for a typo – 115-200 MeV Higgs should be 115-200 GeV Higgs in my immediately preceding comment.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

13. **SomeBody**
May 28, 2006

LHC = Last Hope Collider?

14. **sunderpeeche**
May 28, 2006

Since my post on the SLAC klystrons did not get deleted out of hand, let me provoke the Gods that be…. FNAL provided high-skilled job opportunities for blacks/minorities at the cutting edge. (I assume the Apollo moon project did the same, but I do not know.) The Chicago Industrial Research Corridor was set up along I-80 near FNAL in anticipation that the lab would attract high-quality (or high-tech) research firms to the area. (In the event, Fermilab was too specialized to play such a role, firms like AT&T Bell Labs and Exxon etc were more effective in that regard.)

Pork-barrelling does play a significant role. It makes a difference if a lab is within easy reach. It also provides ancillary employment to hotels, restaurants, etc, (although now people complain of "radioactivity"). When the BNL was being chosen, II Rabi wanted it in New Jersey, close to Columbia because he knew the nearest university would dominate the lab. Norman Ramsey led a strong team from Harvard/Cambridge to have the lab near Boston. So Rabi signed on Johns Hopkins just to move the center-of-gravity of the universities closer to Columbia. The eventual site on Long Island was the compromise.

The host country of the ILC will get major (possibly non-scientific) benefits. Certainly the size of expts today is so large that proximity to a home univ is not so significant. But it seems that with the ILC, pork-barreling is getting mixed up with jingoism (ILC will restore "US leadership" in expt HEP).

15. **Michael**
May 28, 2006

Tony, what I meant is that a non-spectacular outcome from the LHC means that getting funding for the ILC will be extremely difficult and probably impossible. I was not commenting on the physics consequences. Sorry for not being clear.

16. **Tony Smith**
May 28, 2006

Michael, thanks for your clarification. You are probably correct that absence of some spectacular hype-type result at LHC probably does mean " that getting [USA] funding for the ILC will be extremely difficult and probably impossible". Sad but true.
Maybe Asians will want to take their turn in the accelerator game, and, since they are well-positioned financially and know how to think long-term, maybe they will build it and let those of us on the periphery peek in from time to time to see some of the knowledge generated at the Center.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

17. **anonymous**
May 29, 2006

for the first time since 30yrs a collider will explore energies much above previous colliders and above the weak scale: it deserves the attention that it receives.

Unlike in the case of Columbus/Colombo/Colon, now theorists are telling since 30yrs: "go and discover America" (i.e. SUSY or extra dimensions or etc). Finding only water would be truly revolutionary.

18. **RahulM**
May 29, 2006

The problem with a 115-200 GeV Higgs in the Standard Model is that it's mass is not stable under UV corrections. This violates a very basic physics principle we have seen at work from Newton till now: that physics is organized by energy scale. So far the structure we have observed is that phenomenon at lower energy scales are relatively unaffected by whatever happens at much higher scales. It is extremely strange that somehow the Higgs boson is completely different from all physics we have observed thus far. I am not propagating string theory or SUSY or extra-D or whatever, but there is a genuine TeV scale issue here.

19. **Tony Smith**
May 29, 2006

RahulM says: "… The problem with a 115-200 GeV Higgs in the Standard Model is that it's mass is not stable under UV corrections. … there is a genuine TeV scale issue here. …".

There is a genuine issue, but it does not necessarily indicate new physics at the TeV scale.

For instance, in hep-ph/0307138, C. D. Froggatt says in part:
"… the selfconsistency of the pure SM up to some physical cut-off scale /\ imposes constraints on the top quark and Higgs boson masses.
The first constraint is the so-called triviality bound …
The second is the vacuum stability bound: bound: the running Higgs coupling constant … should not become negative leading to the instability of the usual SM vacuum. …
These bounds are illustrated in … Figure 3: SM bounds in the (Mt,mH) plane for various values of /\ , the scale at which new physics enters …
we shall be interested in large cut-off scales /\ = 10^15 – 10^19 GeV, corresponding to the grand unified (GUT) or Planck scale. …".

As can be seen by going to the paper and looking at Fig. 3, a Higgs mass somewhere between 115 – 200 GeV (by looking at Fig. 3, probably roughly around 150 GeV) is consistent with a T-quark mass around 175 GeV and the Standard Model with a cut-off (new physics) at the Planck scale,
so
it seems to me that such a Higgs mass does NOT require new physics at the TeV scale, or anywhere else below the Planck scale.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – Here I am assuming that RahulM's reference to instability under UV corrections is reference to what Froggatt calls "the vacuum stability bound". If RahulM is talking about something else, then I am willing to stand corrected.

PPS – I am NOT saying that the ILC would be useless in such a case. For instance, it would be very interesting to try to explore in detail the Higgs – T-quark system in regions near the boundaries in Froggatt's Fig. 3 to look for phenomena possibly involving triviality or vacuum instability, and the ILC in conjunction with LHC would be very useful in such investigation,
which is consistent with Froggatt's discussion of the possibility that "… that there exists another vacuum state degenerate in energy density with the vacuum in which we live. …". He goes on to say "… Thus we predict that our vacuum is barely stable and we just lie on the vacuum stability curve …".
Since such things are already indicated in data from Fermilab etc, they are not "new physics" in the sense of being new supersymmetric partner particles etc, but such things are (to me, at least) very interesting and justify building ILC to study them.

20. **Tommaso Dorigo**
May 29, 2006

I would concur with Michael that no new physics at the LHC is a disaster for experimental particle physics \em in the short run.

But I prefer to look further. I am not too concerned about HEP 10 or 15 years from now – I have tenure – but much more concerned with the progress of science -well ok let's say (physics \oplus astrophysics)- as a whole.

Now, IF the LHC sees nothing at all (say, not even a single Higgs) that is maybe motivation for canceling the ILC, but just as much motivation for a whole class of new theoreticians to come ahead stampeding the old ones, and produce intelligent new theories. Old ideas die with their supporters in science, just as much as new ones must see them old farts die before they flourish.

As for us experimentalists, a sabbatical to outer space to collect gamma rays would be in order, who knows, maybe it would do us good. The frontier, we all know, is out there now, not in the core of CMS and ATLAS.

I am not at all sure it would be a damage to the progress of science – we have been stuck with the same kind of stuff for too long IMO.

Cheers,
T.

21. **Michael**
May 29, 2006

I think the ILC should only be viewed as a follow-up to discoveries made at the LHC. If there is nothing more that a SM-like Higgs boson, then precision studies of its properties, while very interesting, will not be exciting enough to justify a $10-$20 billion machine. All public arguments for the ILC assume that one will also make precision measurements of whatever new physics is revealed by the LHC. If there nothing to be studied besides the Higgs, then we need to rethink our strategy.

If no SM-like Higgs boson is found and no new phyiscs either, then that would be quite interesting, and as far as I know one would be forced to study longitudinal W scattering, which one would certainly not do with an ILC.

I believe that the future of particle physics does lie at the centers of CMS and ATLAS (otherwise I would not be working there), and that even the amazing discoveries of astrophysics will require some particle physics input to be fully comprehended. We will soon see!

22. **Michael**
May 29, 2006

Thank you, Peter, for the very kind advertisement of Collider Blog!

23. **Alejandro Rivero**
May 29, 2006

Perhaps a composite higgs / technicolour is a better opportunity for the ILC, it would give a lot of parameter space to be searched, shouldnt it?

24. **sunderpeeche**
May 29, 2006

Surely that’s the whole point of building the LHC/ILC? To search and discover what’s really out there (composite Higgs/technicolour new particles …).

To boldly go where no hand has set foot?

25. **andy**
May 30, 2006

It seems to me that funding phenomenologists / collider theorists / model builders whose research has some relevance to experiment is a _good_ thing (rather than shoving more $$$ into the bottomless pit of string “theory”.

26. **sunderpeeche**
May 30, 2006

The corresponding argument that “the public” (somewhat vaguely defined here) makes is that it is a good thing to fund research which has an obvious immediate commercial profit. Nobody knows where this (~string theory/all of HEP) will all lead. The real problem is that Nature is cruel — expt HEP has not produced new puzzles (physics beyond SM) for 30 years.

27. **hack**
May 30, 2006

The raccoons are clearly in their last throes.

28. **sunderpeeche**
May 31, 2006

http://www-bdnew.fnal.gov/operations/safety/critters.html

29. **knotted string**
May 31, 2006

Thanks for that last link about stagnating string theory at fermilab:

‘Objects that have remained undisturbed for an extended period of time may become housing for pests.’

30. **SomeBody**
May 31, 2006

With his usual candor, Dorigo wrote:
“I am not too concerned about HEP 10 or 15 years from now – I have tenure”

In other words, never mind whether I’ll be doing anything that’s of any use to anyone, the taxpayers are stuck supporting me anyway.

Welcome to the brave new world of HEP as social welfare.

31. **sunderpeeche**
May 31, 2006

Let’s present the full sentence, shall we?

But I prefer to look further. I am not too concerned about HEP 10 or 15 years from now – I have tenure – but much more concerned with the progress of science -well ok let’s say (physics \oplus astrophysics)- as a whole.

Read the second half before writing anything mean-spirited.

32. **Peter Woit**
May 31, 2006

SomeBody,

Dorigo has a job at a university in Italy, which I guess is now permanent, so, he has tenure like most people with long-term university jobs in Europe. He's not being paid by the US taxpayer, but is being paid (probably not very well..) by the Italian taxpayer to teach and conduct research at a university. His point was that the question of whether the US taxpayer is willing to pay for a new accelerator or otherwise spend large sums on HEP research doesn't affect his paycheck.

Would you prefer that he not have a permanent job at an Italian university, but have his paycheck depend on the health of the US HEP budget? If you want to rant about scientists on the government tit pushing for more money for HEP research to feather their own nests, that's fine, but Dorigo is just pointing out that that's not the category he's in.

33. **SomeBody**
May 31, 2006

What exactly is it about the second half that you think modifies the first half?

34. **SomeBody**
May 31, 2006

Woit, as in the ILC discussion, you seem to find it relevant whether taxpayers are in the US or elsewhere. I don't.

I know very well where Dorigo is, what he's doing and who is paying him to do it. There is nothing in his post supporting your interpretation that "His point was that the question of whether the US taxpayer is willing to pay for a new accelerator". His point is quite simply that no matter what happens to HEP, his own paycheck is secure (a conclusion which I do not share BTW, considering Italy's precarious financial situation).

In aswer to your questions:
"Would you prefer that he not have a permanent job at an Italian university"

That's correct.

"but have his paycheck depend on the health of the US HEP budget?"

Actually, whether he realizes it or not (apparently not) that is already the case. But as far as my personal preferences are concerned, the answer is no. I'd prefer his paycheck to depend on his performance in a productive activity where he's actually earning it.

35. **sunderpeeche**
May 31, 2006

It's hard (if not impossible) to think of the long-term if you have to worry constantly about feeding yourself in the short-term. That guarantee of employment (such as it is) is one of the features of tenure.

As they say in non-idiomatic non-Italian …. Ach du Lieber.

36. **Peter Woit**
May 31, 2006

SomeBody,

So, this has nothing to do with HEP, US or otherwise, but is just an ideological rant about the socialistic practice of tenure that isolates some academics from the healthy discipline of market forces.

Please, this is tedious, off-topic, and has nothing to do with what is being discussed here.

37. **SomeBody**
May 31, 2006

Woit, it has everything to do with HEP! Once upon a time, HEP was a vibrant source of new scientific knowledge which attracted the best and brightest. You need look no further than Dorigo's post to see who's attracted to it now, and why.

38. **Chris Oakley**
May 31, 2006

SomeBody,

I agree with Peter. Tommaso is probably being paid mostly for teaching, and at a rate lower than a schoolteacher. His research interests are probably tolerated by the funding authorities rather than encouraged. The luxury that you no doubt live in as a result of being a self-made billionaire he will have had to forego in exchange for doing what really interests him.

39. **Peter Woit**
May 31, 2006

SomeBody,

The academic tenure system you object to has been around for centuries, it has nothing to do with the current problems of HEP.

I don't know Dorigo personally, but from his blog posts he appears to be a highly competent, serious researcher who works hard at and cares about what he does. He also has a sense of humor, and knows that there's no incompatibility between doing serious work and not taking oneself too seriously.

40. **SomeBody**
May 31, 2006

Oakley: no. Dorigo is an INFN "researcher", not a university employee. He does what you do for a living (writes code) but of course, unlike you he needs tenure to be able to do it, or (as pointed out by sunderpeeche) he would no doubt be unable to "think of the long-term".

41. **sunderpeeche**

May 31, 2006

The LHC will give “something to do” (expt HEP) for approx 10-15 years. What comes next? The ILC is one answer. Modern expt HEP projects take so long now to come to fruition that one must start thinking years in advance. Who can do that? Not someone whose job contract is due to expire in a year or two.

As I learnt many years ago (biology class? it’s been a long time) we have two hands and two feet to count the four important things in life: food, food, s – – and food. It’s hard to think of the big picture if one has to scurry around all the time to find one’s next meal.

42. **Michael Schmitt**
May 31, 2006

Somebody,

I need to speak up for Tommaso. I know him quite well since several years. He is intelligent, creative, hard-working and very serious, facts which I’m sure are known to the INFN. He is not kept employed simply because he writes code, and I have the impression that INFN standards are higher than that. I didn’t like his comment either and posted my own response, but anyone who knows Tommaso know that he likes to make flippant remarks to provoke reactions. It may be annoying, but please lets not denigrate his strengths as a researcher nor use his remark as a sign of the weakness of HEP.

thanks.

43. **Peter Woit**
May 31, 2006

I’ve deleted the rest of this thread about Dorigo. Please refrain from any more obnoxious attacks on him here. He has his own blog, if you want to attack him for what he has to say, go do it there.

44. **Chris Oakley**
May 31, 2006

Superstrings are snake oil, says Sam from the UK.

45. **SomeBody**
May 31, 2006

Speaking of the devil, am I the last person on the planet to find out that Amazon is comarketing these two as “Better Together”?

http://www.amazon.com/gp/product/0618551050/ref=pd_bxgy_text_b/103-3759420-5756605?%5Fencoding=UTF8

46. **RahulM**
May 31, 2006

Hello, what I meant was that suppose there is a very heavy fermion field at some scale far removed from TeV. Say a GUT-ish fermion weighing 10^15 GeV. Then that would produce a huge correction to the Higgs mass, of the order of 10^15 GeV! Therefore the SM is sensitive to physics far beyond it’s own scale, which is counter to everything in physics we have seen thus far. All you need is a heavy fermion or a scalar lurking somewhere between 1 TeV and 10^19 GeV and the SM will “jump” like crazy. That is why we say some new physics is needed at the TeV scale to have a smooth transition between the SM and whatever happens at GUT/Planck/whatever scale when physics gets unified.

47. **Not a Nobel Laureate**
May 31, 2006

Modern day HEP experiments are similar to the construction of the pyramids of ancient Egypt
in that

1. They are now multidecade undertakings; and

2. It’s great fun if you’re the Pharoah, but questionable if you’re the pleb up to your knees in straw, mud and sh*t.

48. **sunderpeeche**
June 1, 2006

Basically, that’s the way it is. It’s good to be the King.

The racoons are not done yet.

At 8:06 PM, raccoons again tested the cross-gallery defenses. One raccoon was caught by a patrol and questioned. She claimed that she was disoriented by the high frequency noises and accidentally stumbled into the gallery. The patrol took her picture, paw print, and then escorted her out of the building.

http://www.fnal.gov/pub/news06/update_archive/update_5-30_5-31.html

Is a picture of the raccoon available?

Not Even Wrong Available in the UK

May 31, 2006
Categories: Not Even Wrong: The Book

Not Even Wrong, the book, is now available from Amazon in the UK. It's being published in the British Commonwealth by Jonathan Cape, so should also at some point be available from them in Canada. Last I'd heard official publication date was June 16th, perhaps that's the date it will be out in stores. Here in the US it will be published by Basic Books, and should appear perhaps late in September. The US version will have a rewritten and somewhat different preface, but the bulk of the two books will be pretty much the same. Next week I'll be going over the proofs of the US version, my last chance to make any final small changes.

So, I encourage all my non-US readers to go out and get copies of the book for themselves and their 20 closest friends, write reviews saying how wonderful it is on Amazon, etc., etc. If you're in the US and absolutely can't wait until September, I think you can order from Amazon UK anyway (at least that's what some of my friends desperate to appease children demanding the latest Harry Potter recall doing). In September, besides my book, Lee Smolin's The Trouble With Physics will also be coming out, so I guess it will be a trend. I haven't yet seen a copy, but from conversations with him gather that Lee reaches many of the same conclusions about string theory that I do, although coming from a somewhat different direction.

Perhaps my faithful readers can help out with some advice on two points: the US version will have a somewhat different subtitle and controversy has broken out as to whether to use the phrase "the search for unity in physical law" or "the search for unity in physical laws". Both seem all right to me, but if anyone has a strong opinion on the "law" vs. "laws" issue, let me know.

I'm about to leave town, headed to Boston for a few days, but early next week I'd like to start thinking about whether it would be possible to add some features to the blog related to the book. The obvious thing to do is to add all sorts of marketing materials to the blog to get people to go out and buy the book, but I'll try and keep that to a tasteful minimum. No pop-ups or weekly contests. On the other hand I think it would be interesting to provide some sort of features here for people who have read or are reading the book, have questions about it, want to discuss or argue about it, etc. Does anyone know of any other blogs out there associated with a book that have tried to do something like this?

Comments

1. **The Anti-Lubos**
   May 31, 2006

   "Law" resonates better with "unity." "Laws" sounds terrible. Feynman didn't write *The Character of Physical Laws*.

2. **Santo D'Agostino**
   May 31, 2006

   Congratulations on the UK publication of your book, Peter!

   "Laws" is better, because the other phrase might be misconstrued as having something to do with a non-existent branch of the legal profession (you know, corporate law, criminal law, international law, and now physical law).

   I don't find anything wrong with "The Character of Physical Laws." Feynman's title has a distinctly British feel to my ears, and since we are speaking about the US version of your book, that is perhaps another argument for going with "laws." As in many arguments of this type, it is probably not worth fretting over, as either alternative will serve well.

   A solution that sidesteps the controversy, and has the merit of greater brevity, is to go with "The search for unity in physics," but of course there may be reasons why this does not suit your purpose.

   Best wishes,
   Santo

3. **Who**
   May 31, 2006

   I have to see the whole title before I can judge:
   suppose versions A and B are

   Not Even Wrong: the Failure of String Theory and the Continuing Search for Unity in Physical Laws

   Not Even Wrong: the Failure of String Theory and the Continuing Search for Unity in Physical Law

   In that case, if that is the choice, then I slightly prefer B, the latter—with the singular.
   One could say the plural is appropriate because one seeks a pattern to bring a bunch of things together—to unify several laws.
   But I still like the sound of the singular better in this context.

   I think the word "continuing" is important because if you say "the Failure of String Theory and the Search for Unity in Physical Law" there is a danger that people could hear the message that the entire search for unity has failed. the message is that one effort failed but we continue the search. It is important to deliver that positive message (of not giving up the search) to balance the negative.

4. **wolfgang**
   May 31, 2006

   I am not a native English speaker, but "Search for Unity in Physical Law" seems to contain a contradiction.
   If there is only one law how can you *search* for unity in it?

   By the way Clifford and Lubos discussed law vs. theory recently, their ideas might help you 😎

5. **Thomas Love**
   May 31, 2006

Since I really don't like the use of the word "law" in physics, might I suggest "Search for Unity in Physics."

"Law" has the implication of a law maker and I would really not like to think of god as a lawyer.

6. **Chris W.**
May 31, 2006

From Amazon's book description for Smolin's *The Trouble With Physics*: "But as Smolin reveals, there"s a deep flaw in the theory: no part of it has been proven, and no one knows how to prove it."

To the attention of book editors, copywriters, and science journalists:
Theories in the empirical sciences, as opposed to mathematics and logic, can be testable and tested, but they are not and cannot be proven. Got that? *PLEASE* do not conflate testability with the possibility of proof! In 2006, one hundred years after the advent of special relativity and the beginnings of quantum theory in the face of the success of classical physics, there is no excuse for such sloppiness.

I really hope that the main thesis of *Not Even Wrong* is not presented with similar carelessness by Jonathan Cape and Basic Books in their marketing materials and dust jacket copy.

7. **David**
May 31, 2006

I would chose "Physical Laws" for the reason already stated — that one cannot unify a single law. The singular does suggest the kind of "one true law" that string theory set out to create but I think it would be more appropriate to say "the search for a unifying (sic?) physical law"

8. **Who**
May 31, 2006

Law can refer to a body of laws—-the singular can serve to cover the plural.

Check out what it says about Smolin's book. Any comment on the title
"the rise of string theory, the fall of a science"
I think the "a" is important. it is not the decline of all Science but of one particular branch: physics theory—which arguably HAS been going thru some hard times that coincided with the proliferation of string theorists. different ways to interpret this.
I think the title is hard-hitting. which it probably needs to be at this juncture

9. **Tony Smith**
May 31, 2006

Peter, you say "… I think it would be interesting to provide some sort of features here for people who have read or are reading the book, have questions about it, want to discuss or argue about it, etc. Does anyone know of any other blogs out there associated with a book that have tried to do something like this? …".

1997 was before the blog era, but it was the year of publication of David Deutsch's book "The Fabric of Reality".
IIRC, in the months leading up to its publication, he was very active in internet discussions (including usenet etc) about topics related to the book, and, according to the web page at http://www.qubit.org/people/david/FabricOfReality/FoR.html#FoRList , there was (and is)
"… The FoR (Fabric of Reality) internet discussion list
(Note that this is not run by me [David Deutsch], but I [David Deutsch] do contribute occasionally.)
To subscribe, send a blank message to Fabric-of-Reality-subscribe@yahoogroups.com …".

He might be able to give a fairly accurate idea of how internet exposure (roughly equivalent to blogs in today's world) affected sales etc of his book.

As an interested customer who bought and enjoyed the book, I think that the internet exposure was useful both in clarifying points made in the book and in sales of the book.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

10. **Sacha**
May 31, 2006

"law" sounds better – as it refers to the body of physical theories, while "laws" sounds as if it refers to the collection of individual physical theories.

11. **Dan**
May 31, 2006

i would imagine lubos will write an extremely negative review of both books.

12. **amanda**
June 1, 2006

i would imagine lubos will write an extremely negative review of both books.

I'm betting: two stars for PW, and one for LS. Because I have this feeling that LS annoys Lubos even more than PW…..

13. **Chris Oakley**
June 1, 2006

I would just prefer "Why clever people sometimes do stupid things" as the subtitle.

14. **Alejandro Rivero**
June 1, 2006

"*but if anyone has a strong opinion on the "law" vs. "laws" issue*"

Clifford has. Last week in his blog wrote about the use of "theory" and "law".

15. **Lubos Motl**
June 1, 2006

Amanda: your predictions – including the quantitative ones – are so incredibly accurate that you could probably do string theory; see PW's amazon.co.uk webpage now. 😉 I have not yet read Smolin's book, and I promised him to read every single page before reviewing it in the public.

16. **Andy**
June 1, 2006

I checked out the amazon.ca site and the UK edition of NEW is now available for about CAD 31 while if I wait until September for the US version it would be less than CAD 20.

17. **Lubos Motl**
June 1, 2006

Dear Andy,

if you wait until September, you will save not only CAD 11 but in fact CAD 31. 😉

Best
Lubos

18. **sunderpeeche**
June 1, 2006

Indeed there is now a 2-star review on the UK website. Reasonably vitriolic, but then again oil of vitriol is considered to be medicine. The 14 GeV, if true, is an error, as is 14 TeV. The LHC design beam energy (for protons) is 7 TeV leading to sqrt(s) = 14 TeV. No mention of Pierre Ramond? That is curious, but maybe corrected in the published version.

19. **Lubos Motl**
June 1, 2006

Sorry, I should have written the center-of-mass energy of the LHC beams.

20. **island**
June 1, 2006

I disagree with the idea that… "it is not the decline of all Science but of one particular branch: physics theory".

Physics ultimately determines everyone's worldview of reality and their place in the universe, so this also affects the way that ohter scientists approach their fields of study as noted in the description of of my weblog and elsewhere there:

Science In Crisis

Good job, Peter, and it's also good that your book is being offered together with Lee's book on amazon U.S.

I see that Lubos didn't waste any time making a crackpot ass out of himself, per the usual:
Peter Woit is the owner of a well-known blog that provides high-energy theoretical physics with the same service as William Dembski's blog offers to evolutionary biology: it is designed to misinterpret and obscure virtually every event in physics and transform it into poison – and to invent his own fantasies to hurt science.

Translation: Lubos' promise to read every word of Lee's book means that he willfully ignores every valid point that Lee Smolin makes before he misinterprets and obscurse his review to fit his own delusional fanatasies.

surpriseNot

21. **knotted string**
June 1, 2006

I haven't seen the book yet but looking at Lumos' review, particularly the comment in the first paragraph:

"… invent his own fantasies to hurt science. This makes Woit's blog highly popular among the crackpots, for example the first reviewer of this book."

I've complained to Amazon about the personal remarks about other reviewers. Lumo should keep his review to scientific facts related to the book. If he is too half witted to do that, I wish Dr Oakley would issue legal proceedings for damages to his reputation based on this sort of attack.

The danger is of course that people who have studied the problems will fear to review the book – or will do so anonymously – to avoid being personally attacked as crackpots. This is not scientific.

22. **ObsessiveMathsFreak**
June 1, 2006

They're not "laws". They're "just theories" 😉

23. **Lubos Motl**
June 1, 2006

Dear knotted string,

I am going to guarantee to have witnesses, leading physicists, ready to confirm that Chris Oakley is a crackpot if someone indeed finds this observation controversial. Nothing against Chris personally, I like him, of course, but denying the he is a crackpot sounds kind of insane to me. Where have we gotten?

All the best
Lubos

24. **Chris Oakley**
June 1, 2006

The stock of Crackpot Inc. has been devalued so much by the exercise of employee options by String Theorists that I am not sure that it is worth me suing. However, if anyone starts an action against me they ought to know that I will represent myself in court having realised (in my last lawsuit) that I don't need to pay anyone to bullshit for me. I am perfectly capable of doing that for myself.

25. **knotted string**
June 1, 2006

Lumo,

Witnesses who hate Dirac and Feynman's outlook? What have people's opinions to do with the fact that there are real, experimentally known problems in quantum field theory and string theory just invents unobservables?

If there were a single piece of scientific evidence for strings, all you have to do is publish that! There isn't a shred of evidence for string theory, and you know it.

26. **D R Lunsford**
June 1, 2006

I'd drop the "law" part altogether. Just say "physics" instead of "physical X".

-drl

27. **Thomas Love**
June 1, 2006

Well, I succumbed to your propaganda and ordered both books at amazon. I look forward to reading them. The deal from amazon comes with no strings attached! Free shipping even!

As Chris said, scientific "laws" cannot be proven, but they can be disproven, if their predictions are contradicted by experiment. That is why string theory is not scientific, it makes no testable predictions.

28. **Ponderer of Things**
June 1, 2006

laws is better.
"physics" works too, as DRL suggested.

29. **Belizean**
June 1, 2006

Congrats, Peter!

"Law" sounds infinitely better to my ears.

30. **Quanta**
June 1, 2006

I'm unconvinced by Smolin's title, "The Trouble With Physics". High energy particle physics and string theory in particular might have stagnated for 30 years, but the rest of us theoretical physicists are doing fine, thanks for asking. Just look at the interesting things being done in quantum information and computation, or in statistical physics, (cond-mat is full of interesting, worthwhile papers).

I know that many particle physicists think science revolves around them, but the rest of us don't care that much. There is no crisis in physics over here.

31. **fishfry**
June 1, 2006

I'm having a hard time parsing the title. What has failed? String theory alone? Or string theory AND the search etc.?

32. **sunderpeeche**
June 1, 2006

Actually this is something I have noticed also, the persistent identification of HEP theory with "physics". But there's much more to physics than HEP (th + exp). Biophysics etc are doing well.

Die physik stekt in der krise? Es gibt die andere physik nicht steckt in der krise.

33. **Bert Schroer**
June 2, 2006

sunderpeeche
particle theory is a fundamenta area of physics which for generations has supplied innovative services to other areas (condensed matter physics, and even biophysics see the contributions of Tony Zee). And string theory is more than a branch of particle physics, it is a state of mind science in an unleashed global capitalism. Just wait, it will get there too.

34. **sunderpeeche**
June 2, 2006

Quantum physics –> nuclear physics –> particle physics has always been an endeavor to understand matter at the most fundamental level. I have always acknowledged that. And it is a challenge worth pursuing. I have said that too (to various people, years ago, before this blog existed).

The other branches of physics have supplied important ideas to particle physics. Spontaneous symmetry breaking arose in statistical mechanics in the context of phase transitions (~work of Phil Anderson), was adapted to HEP. The Wilson-Fisher collaboration shows that stat mech and HEP can give much to each other. HEP may be a worthy effort, but there is also much good physics that is not HEP, and they are not in crisis.

35. **Bert Schroer**
June 2, 2006

Sorry, the idea of spontaneous symmetry-breaking comes from Heisenberg's investigations of the ferromagnet. I agree with you that there was a backflow from condensed matter physics, but quantum Stat. Mech. was never separated from QFT and particle theory. And fortunately you are right up to now, but probably not any more for very much much longer. Remember string theory is also a state of mind, the state of mind of a hegemon. Although within the limit of science innocent people will not loose there life (like in Bush's war in Iraq), young physicists may for a long time (probably life-long) be deprived of that deep satisfaction which results from having contributed something permanent.

36. **sunderpeeche**
June 2, 2006

I knew SSB originated with the ferromagnet, didn't realize it was Heisenberg. Anderson did some work, but I suppose it came later.

37. **Bert Schroer**
June 2, 2006

Many generations of physicists worked on the ferromagnet, even after Heisenberg observed the notion of spontaneous symmetry breaking. He immedeatly saw the relevance for particle physics, but the first realization in the setting of Lagrangian quantization is due to Goldstone.

38. **Thomas Larsson**
June 2, 2006

Spontaneous breaking of gauge symmetry with the Higgs mechanism was invented by Anderson in the context of superconductivity. I think that the idea of spontaneous (non-gauge!) symmetry breaking in ferromagnets predates Heisenberg and even Ising (who didn't find it in 1D and therefore conjectured that it's absent in 3D as well). Surely people (Lenz? Debye?) knew about SSB within mean-field theory.

39. **Bert Schroer**
June 2, 2006

Thomas Larson
You are probably right, I take you on your word. But there should be a little bit caution since to call the Schwinger-Higgs-Anderson breaking a breaking of gauge symmetry is one of these imprecise manners of speaking (because a gauge of the second kind is a redundant description and not a genuine symmetry). I do not have any access to the literature where I am right now, so maybe you could find out whether Anderson really was before Schwinger. The citation to Schwinger you find in
http://br.arxiv.org/abs/hep-th/9906089
I took a considerable amount of pain to find out about the early history of the Ising model because together with Pauli's exclusion principle it characterized pretty much the big splash by which the history of theoretical physics started in Hamburg (here you find the reference to Schwinger a second time, ref. 15):
http://br.arxiv.org/abs/hep-th/0504206

40. **Thomas Larsson**
June 12, 2006

Peter, I know that you are not into this business for the money, but maybe you should laugh all the way to the bank.

Peter Woit:
Amazon.co.uk Sales Rank: 85

Brian Greene:
Amazon.co.uk Sales Rank: 5,869

Lawrence Krauss:
Amazon.co.uk Sales Rank: 24,280

Leonard Susskind:
Amazon.co.uk Sales Rank: 26,994

Lisa Randall:
Amazon.co.uk Sales Rank: 78,730

I don't know what the sales rank is really measuring, but that it is low cannot be a bad thing.

41. **Alejandro Rivero**
June 14, 2006

Is the sales rank accumulative or instantateus?

42. **Alejandro Rivero**
June 14, 2006

You can use

http://www.touchgraph.com/TGAmazonBrowser.html

to build a network of relationchips between books, based on common buy patterns. It works with amazon USA, so perhaps it does not include Woit's book yet.

43. **Who**
June 14, 2006

Alejandro [*Is the sales rank cumulative or instantaneous?*] I think it must be based on some short time window like the past 24 hours because I see that it apparently fluctuates a lot.

today, on Wednesday 14 June,

Peter Woit 211
Leonard Susskind 27,510

but on Monday 12 June, when Thomas tried the same links, it was
Peter Woit 85
Leonard Susskind 26,994

44. **Alejandro Rivero**
June 14, 2006

Ok, so it is a kind of "top ten list", not a total sales list.

I have seen that amazon accepts order for the newer books, as Woit's or Smolin's ones. If someone gets to plot an interesting touchgraph plot, please capture the screen and share with us!

About Smolin's, I am surprised by the cover design: it accidentaly refers to another 1960s theory, the "bootstrap". There was, of course, some early tryes to relate string theory and bootstrap, in a couple articles of Veneziano, but I am not sure of the impact.

45. **Who**
June 14, 2006

Alejandro, I disagree. As I saw it, I don't think the cover has any intentional reference to "bootstrap". I didn't perceive any when i first saw it. The word that is evoked is "string" (as in "shoe-strings tied together") and not "strap".

there is a proverbial image of someone who is either the victim of a mean practical joke, or such a stupid klutz that he has done this to himself—-the person with their shoe-strings tied together.

It is a proverbial image of a person in a stupid fix that they brought on themselves.

Bootstraps are different from shoestrings and the picture doesn't say straps.

I think the cover-image message is two fold

the "trouble with physics" is string-related (symbolized by shoe-strings)

the "trouble with physics" is a stupid self-imposed predicament that could have been avoided by commonsense (keep your feet able to move independently)

46. **Alejandro Rivero**
June 14, 2006

Hmm you are right, I had an incorrect mental picture of a bootstrap lace where it was the same lace we do with the shoestring, and no a separate lace.

First Public Reaction From String Theorist to “Not Even Wrong”

June 2, 2006
Categories: Not Even Wrong: The Book

Last month I made the following prediction:

String theory doesn't make any predictions, but I can make one: Lubos will be among the first reviewers of my book on Amazon, and I'll get two stars.

This prediction was confirmed today, with a certain Harvard faculty member acting exactly the way you would expect. The reason for the two stars is that Lubos is well aware that Amazon usually deletes one star reviews.

His Amazon review is nutty in so many ways it's hard to know where to start. It begins with:

I have read a different edition of the book than one offered here, and I apologize in advance for any inaccuracies in my review that this fact could cause. In fact, if any errors from the list below have been corrected, it was because of my feedback, so I think it is fair to list them anyway.

I have no idea what “different edition” of the book he is referring to, perhaps it is the earlier version that Cambridge considered a couple years ago, which was circulated by them and by me to various people. Whatever it was he was reading, I never received any feedback from him correcting supposed errors. Besides this weird delusion, pretty much everything else he quotes as an error in the book is something he has made up out of whole cloth. He doesn't directly quote a single word of mine or give page numbers, so I can't even figure out where he is getting this nonsense.

I'll just ignore the ranting and ad hominem attacks, trademarks of someone on the losing side of an argument, and address the very few substantive errors he claims I make where I can actually locate the exact place in the book he claims an error is being made:

Woit writes that the energy of the LHC beam will be 14 GeV, instead of 14 TeV

Page 31: “ is a proton-proton collider with a total energy of 14 Tev”

Note that the original is correct, his correction is wrong (the beam energy is 7 TeV).

In his description of the history of supersymmetry, he forgets Pierre Ramond.

Actually I explain carefully in the preface of the book that the history is quite sketchy and many people are left out. One of my main fears after writing this book was realizing how many enemies I would make by not putting their names in. In this case however, Pierre Ramond is in the index and I write:

Page 154: “The first string theory with fermions was constructed by Pierre Ramond late in 1970”

Page 155: “Early string theorists discovered that string theories with fermions involved a version of supersymmetry…”

He misunderstands how SU(2) can be embedded to SO(4)

There's nothing in the book about embeddings of SU(2) in SO(4). Presumably this is a reference to a mistaken statement I made once on this weblog. Yes, dear reader, among the by now probably thousands of pages of material I have written on this blog, I have sometimes said something incorrect. The book is written a lot more carefully than my blog postings.

Even more seriously, he builds his case upon e-mail messages from undetermined sources that supported Woit's viewpoint. Most of these e-mails were obviously written by crackpots.

In the book I'm quite careful to attribute things I quote and there are very few e-mails quoted. There's only one unattributed e-mail that I can think of, it was written by someone visiting the Harvard string theory group at the time of the Bogdanov scandal, who wrote:

“So no one in the string group at Harvard can tell if these papers are real or fraudulent. This morning told that they were frauds, everyone was laughing at how obvious it is. This afternoon, told they are real professors and that this is not a fraud, everyone here says, well, maybe it is real stuff.”

This is unattributed since I don't know who wrote it. Maybe they were a crackpot, one visiting the Harvard string theory group.
The problematic statement that string theory makes no prediction is repeated hundreds of times, and in many particular contexts, such a statement becomes not only boring but also patently false.

I doubt it's actually in the hundreds, but sure, I do repeatedly claim that string theory makes no predictions, and this is not “patently false”, but completely accurate.

he never mentions names like Weinberg, Gell-Mann, Hawking, Randall, Arkani-Hamed

Weinberg, Gell-Mann, and Hawking are each mentioned many times in the book, and I list Lisa Randall's book as the suggested place to learn more about brane-world scenarios. It's true that Arkani-Hamed is not in the book.

I could go on about the rest of the review, but really, what's the point?

I would like to think that Lubos is a huge embarrassment to the string theory community, but the sad thing is that there's little evidence that they're embarrassed.

Comments

1. **Chris Oakley**
   June 2, 2006

   I could forgive him all of these things. I could even forgive him for calling Dirac and Feynman “crackpots”. But the music on his blog … ? I struggled in vain for a way of turning it off, but in the end had to turn the sound off for the whole computer. This is an invasion of my personal space that I resent.

2. **anon**
   June 2, 2006

This may be relevant to why the string theory community relishes Lubos Motl instead of being embarrassed:

'Crimestop means the faculty of stopping short, as though by instinct, at the threshold of any dangerous thought. It includes the power … of being bored or repelled by any train of thought which is capable of leading in a heretical direction.

'Crimestop, in short, means protective stupidity. But stupidity is not enough. On the contrary, orthodoxy in the full sense demands a control over one's own mental processes as complete as that of a contortionist over his body.' – George Orwell, http://www.panarchy.org/orwell/ignorance.1949.html

This is of course the explanation for how brainwashing works.

3. **Bert Schroer**
   June 2, 2006

   The Lord of misuse again. The string community feels so powerful that, like Royal Courts in the past, they can afford themselves a court jester at Harvard.

4. **MathPhys**
   June 2, 2006

   I just read the blurb of Lee Smolin's forthcoming book, on amazon, and he's damning of string theory in words that are at least as strong as Peter uses in his book.

5. **Lubos Motl**
   June 2, 2006

   Dear Peter Woit,

   I will give you the pagenumbers later, when someone gives me this edition. If you were able to turn your brain on for a while, you would easily determine that I have read the book in extreme detail, and it was certainly not years ago.

   It is also not true that amazon.com "usually" erases 1-star reviews. I have written dozens of 1-star reviews and they are still there.

   http://www.amazon.com/gp/cdp/member-reviews/A1ZDPQA6FLY8XM/

   Only corrupt crackpot authors such as Mark McCutcheon make amazon.com erase all inconvenient reviews – not just 1-star reviews – and indeed, you would not surprise me too much if you acted like McCutcheon.

   I insist that if you corrected any of the errors I mentioned, it was because of my feedback, and I have a proof.

   Best wishes
   Lubos

6. **Lobert Smythe**
   June 2, 2006

   Professor Motl, we will all laugh together at Peter's loss of dignity, and we will respect you as a conquering hero and a force to be reckoned with, if you present the proof that you are talking about and it is actually a sufficient proof.

   Please, show us the proof.

7. **sunderpeeche**
   June 2, 2006

   Why not contact Amazon and point out that LM based his review on an earlier manuscript different from the one submitted to Jonathan Cape? In particular that (at least some of) the errors he mentions in his review are in fact not in the book?

8. **sunderpeeche**
   June 2, 2006

   There is some inconsistency in the Amazon web pages

   http://www.amazon.com/gp/product/0224076051/002-2587755-3205615

   http://www.amazon.co.uk/exec/obidos/ASIN/0224076051/202-9664174-0234244

   The review by Sam is only in the first, not the second, link. The "number of people who found the review useful" is different.

9. **Luboš Motl**
   June 2, 2006

   Sentences with the statements that Peter Woit would like to deny:

   14 GeV: in Accelerators: Future prospects

   The energy of a ring scales linearly with its size and the magnetic field, so one could double the energy of the LHC to 28 GeV either by building a ring twice as large or by finding a way to make magnets with twice the field strength.

   Ramond: Peter Woit accepts that I am right. Yes, the only place where his name appear, is a link to his QFT book, and the sentence that he constructed a theory with fermions. But by doing so, he has constructed the first supersymmetric theory in the West. The first supersymmetric theory in the West was written in the context of string theory, with worldsheet SUSY. Peter Woit either does not know this fact, or he hides it in his comments about the history of supersymmetry. It's like describing Christianity without mentioning Jesus Christ.

   SO(4): yes, I know this piece of ignorance of Peter Woit from this blog where he proposed the "off-diagonal" embedding of groups, but it also appears in the book in the section

   PICTURE OF A WAVE AND A PHASE CHANGE

The whole page is kind of wrong, much like the rest of the book. It tries to describe SU(2) rotations as actions on the two-complex- i.e. four-real-dimensional space. However, it pretends that rotations in the 4D space are given by 1D axes, and they are "unvisualizable". They are unvisualizable for Peter Woit because he has no idea about higher-dimensional orthogonal groups. He does not understand that the SU(2) transformations act on the four-real-dimensional space as SO(4) rotations and how they're embedded. I insist that this is the reason of the errors in that section.

Relying on crackpots

Peter is also saying untrue things when he denies that he builds on support from undetermined sources. Chapter "The only game in town…":

"A huge number of congratulatory messages arrived, many with an aspect that surprised me. These messages remarked on my courage and expressed the hope that I would survive what they expected to be a fierce personal attack from superstring theorists. I hadn't known that so many people in the physics community not only were sceptical of superstring theory, but even felt that the subject was perpetuating itself through some sort of intimidation."

The correct wording should have been: "I became a hero among the crackpots, and in fact one of them: Chris Oakley, MathPhys, Tony Smith, Juan R, Peter Woit, Danny Lunsford, and innumerable anonymous ones".

Another lie of Peter is that he mentions Weinberg's opinions about string theory, much like the opinion of others. I can't provide you with any quotes here because they don't exist.

Not having Arkani-Hamed in a book that pretends to be about particle physics beyond the Standard Model and the struggle not to spend all efforts on string theory is unforgivable. 10% of the reasons above – and the dozens of lethal problems with the book that Peter Woit did not mention here – would be enough to identify the book as nothing else than junk.

10. **Luboš Motl**
June 2, 2006

Dear Peter Woit,

you should realize the idea of one of your uncountable crackpot fans, and contact amazon.com and ask them to erase my review. Mark McCutcheon who has rather similar opinions about physics as you have has done it about 200 times. 😉 I think that this idea quite accurately describes who you are and how you imagine that a discussion should look like.

Best
Lubos

11. **Luboš Motl**
June 2, 2006

Dear Sunderpeeche,

I understand that some people simply can't recognize that Peter Woit's writing is a gigantic pile of nonsense, but you could at least try to understand that amazon.com and amazon.co.uk are two different companies with two different websites that don't have to contain the same datas. It's hard, is not it?

Best
Lubos

12. **Lobert Smythe**
June 2, 2006

The proof, Lubos. The proof. If we don't get to see it then we all end up thinking that you had no proof.

13. **robert**
June 2, 2006

This ranting is too sad for words. I've ordered the book nonetheless.

14. **sunderpeeche**
June 2, 2006

Indeed, there was no need to have this post in the first place. But anyway, verify the various statements (e.g. the 14 GeV). Actually it is the momentum which scales with B and R (p \propto eBR). But for ultrarelativistic motion one can say energy.

15. **Luboš Motl**
June 2, 2006

Dear Lobert, I could easily give you a proof by sending you the full file with the book, but I am afraid that the crackpot king here could sue me for copyright violations, so I prefer if you – and all people like you – will think that I have no proof. 😉

16. **Lobert Smythe**
June 2, 2006

So be it.

17. **woit**
June 2, 2006

Sunderpeeche,

The amazon.com and amazon.uk sites are different, but at least for a while the review from "Sam" was on both sites, but recently was deleted from the amazon.uk site. I'm curious if anyone knows why.

18. **woit**
June 2, 2006

Lubos,

Honestly I don't know what version of the book you have been reading. The last version I have in electronic form is from last summer, since then all the proofs have been sent to me to deal with in paper form. The publishers have pdfs of these, but I don't. Over the years I have circulated various versions to people who expressed an interest or whose advice I was seeking. It's quite possible I sent you a copy at some point if you asked. But I would definitely remember if you'd helped by sending me back "corrections", if you have some record of doing that, please remind me of it.

You have now helped with this, you did find one typo. After listing the total energy at the LHC as 14 Tev, on the next page when I discuss the possibility of doubling it, there's a "28 Gev", which is obviously a typo (although perhaps you think that this is evidence that Peter Woit doesn't know how to multiply by two…). Thanks for the help, next week I'm working on the proofs for the US edition and can fix that typo. If you find any others, let me know, preferably before the end of next week.

Your other comments are pretty much complete nonsense. Anyone who wants to can read the sections in the book you describe and decide for themselves whether what you say makes any sense.

The history of supersymmetry I give is not a "history of supersymmetry in the West", it's a history of supersymmetry, which first appeared as space-time supersymmetry in the East, not the West. The statements about Ramond I make are completely accurate.

I didn't say I mentioned Weinberg's views on string theory. He certainly at one point was a strong supporter. What his views are now is an interesting question that I don't know that he has addressed publicly, so don't discuss in the book. I don't want to quote private communications from him, but one should note that quite a while back he voted with his feet and stopped working on string theory.

I'll stick by my decision to not deal with brane-world scenarios in any detail and thus not mention Arkani-Hamed's work explicitly.

19. **Steve Myers**
June 2, 2006

Peter,

past experience taught me not to read reviews. The best criticism comes from someone who knows the subject and you. Most reviews are so far off (when not personal attacks) that they're a waste of time to read.

20. **Andrew**
June 2, 2006

I wouldn't worry too much about Lubos' review. It's as insignificant as his scientific publications. Most people know that the only way to judge a book is to read it, not its reviews.

21. **Lubos Motl**
June 2, 2006

Dear Peter,

your answer makes the situation very clear. If you have not corrected even the "LHC at 28 GeV" error, then you could not have corrected a single one from my list of dozens of lethal errors in your strange book because the others must be very difficult for you to find – and no doubt, there are dozens of additional errors. So I might have read exactly the same version that was just released and my review is probably 100% relevant for the British edition.

You should not be surprised that people have read the book because you have sent your nonsense to dozens of publishers, attempting to make it publish by a science publishing house. Of course, as a science book, N.E.W. is rubbish.

As an environmentalist I am a moderate one but still, it does not make me too happy to imagine how many trees had to die to print this nonsense of yours.

I am sure that you think that these are details. Confusing TeV and GeV, omitting Arkani-Hamed from the whole book, omiting any positive voices such as Weinberg, Gell-Mann, Hawking, misunderstanding what gauge symmetry and background independence is, missing that the verified QED phenomena are calculating perturbatively, and so on, and so on – these are no details. These are things that put your presentation well below a class presentation of an average 2nd year high-energy grad student.

No person who actually thinks about particle physics would leave such an error with the GeV. No person who has learned the Standard Model well would write that the TeV neutrinos are virtually non-interacting and undetectable. And so on, and so on.

Your ideas about the meaning of gauge symmetry are like from the 1950s. It's completely naive. You complete missed that a gauge symmetry is just a property of a classical limit of a theory. There is no unique answer to the question "what is gauge symmetry" at generic points of the couplings (or parameters in the field theory case). There are often many dual descriptions with very different gauge symmetries. N=4 with orthogonal group is S-dual to N=4 USp(2N). Gravity with diffeomorphism local symmetry is equivalent to a gauge theory on the boundary. There are many equivalences like that. Inventing similar symmetries is only a tool to find a classical limit of a quantum theory, not the whole quantum theory.

Best wishes
Lubos

22. **Tommaso Dorigo**
June 2, 2006

That is enough, Lubos.

I did not mean to buy Peter's book, mainly because I have too little time to read these days, being too busy living on the new social welfare, HEP tenure.

But your comments made it too compelling for me to buy it. Darn, I want to be a part of this. I want to find more inaccuracies, and brag about it. Any given book contains several, and if I work hard enough I am sure I will find one myself. Maybe if I find a compelling mistake in the book and I brag loud enough, people will stop saying I am stealing taxpayers' money ?

Anyway thank you! I'm on my way to the bookseller.
Tommaso

23. **Bert Schroer**
June 2, 2006

I find it totally pathetic that those people who imposed on others for decades the story about the fundamental aspects of "the gauge principle" in QFT when QFTists with a bit higher developed conceptual power knew that this is one of those metaphoric description did not want to spend their energies removing holy cows (nothing intrinsic, since there was never any autonomous structural property which could reveal that allegedly gauge invariant observables where coming from a "gauge" theory) now have to ram into our throats (via their jester) that after all this was not so (a kind of April fool's joke of very long duration).
It is to be feared that this hegemonic moloch which, as we heard from Gross in his special Princeton lecture, cannot die, will devour any kind of potentially useful idea and and make it is own in oder to survive. When it finally leaves (because nothing is forewer) it will leave such a big creater in physics that it takes longer than the time between Galilei and Newton to recover again.

24. **hack**
June 2, 2006

Peter, I hope you properly credit Lubos in the aknowledgements for correcting your typo. After all, this is likely to be his most long lasting contribution to physics.

25. **MathPhys**
June 2, 2006

Lubos,

Do you have any work to do? The amount of time you spend on the internet is incredible. Where do you get the time?

26. **nu**
June 2, 2006

Lubos, I don't see how your doubt about neutrinos is connected with the main topic of the book. Anyhow, the absorption length of a neutrino with TeV energy is more than 10^7 kmwe, comparable the thickness of the sun. This means, for example, that LHC will produce many neutrinos, but none will be detected.

27. **anon**
June 2, 2006

MathPhys,

Lubos is a string theorist!

28. **sunderpeeche**
June 2, 2006

Reasonably mild superstrings article in June 2006 Physics Today p54. But he writes Nicholas "Kenmer" instead of Kemmer.

29. **Mentos**
June 2, 2006

"I find it totally pathetic that those people who imposed on others for decades the story about the fundamental aspects of "the gauge principle" in QFT when QFTists with a bit higher developed conceptual power knew that this is one of those metaphoric description did not want to spend their energies removing holy cows (nothing intrinsic, since there was never any autonomous structural property which could reveal that allegedly gauge invariant observables where coming from a "gauge" theory) now have to ram into our throats (via their jester) that after all this was not so (a kind of April fool's joke of very long duration)."

Since AQFT has proven to be of zero help in formulating a manifestly gauge-invariant formulation of Yang-Mills Theory (or, for that matter, providing any kind of formulation of any asymptotically-free 4d gauge theory), I wouldn't be so quick to dismiss as "pathetic" the observation that there exist, in some cases, multiple formulations with (different) local gauge-invariances.

This desire to return to the "good old days" of the late 1960's, when nobody knew much of anything about 4d quantum field theory and so AQFT was no further behind any other approach to QFT, is rather hard to take seriously, even by theorists without the slightest interest in string theory. For you, string theory's just a metaphor for all the bad stuff (AKA progress) that's happened in the past 35 years.

By contrast, Peter would only drag us back to the early 1980s which, I suppose, should be seen as some sort of enlightened progress.

30. **island**
June 2, 2006

Peter, this is just a suggestion, but I think that maybe you should request that Amazon list your book with Lee's book in what Amazon calls the "Perfect Partner", for the impact of the combined force. It appears that possibly Lee did this too, although, that's not a law, it's only my theory… 😉

My Plug for both books.

I'll probably add more and republish, but let me know if you have a problem with any of it and I'll just dump it.

31. **Tony Smith**
June 2, 2006

Lubos, in a comment on this blog entry, referred to:
"… the crackpots … Chris Oakley, MathPhys, Tony Smith, Juan R, Peter Woit, Danny Lunsford …".

Lubos, in another comment on another entry in this blog, said
that he is "… going to guarantee to have witnesses, leading physicists, ready to confirm that Chris Oakley is a crackpot …".

I propose that Lubos, as Harvard Professor, invite me to Harvard to make a 2-hour talk followed by questions about my physics model, then followed by a vote among the audience as to whether or not I appeared to be a crackpot, with the proceedings videorecorded and an electronic copy given to me so that I can place it on the internet.
If Lubos fails to make such an invitation, then it will be clear for all to see that he is too afraid of my ideas to let me talk on his home turf and let his own Harvard audience express their opinions about whether or not I am a crackpot.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

32. **Kiff**

June 2, 2006

Doesn't gauge symmetry leave a residue in the BRS cohomology?

33. **Bert Schroer**
June 2, 2006

Kiff, BRST is like a catalyzer in chemistry, it was not there in the initial formulation of the problem, and it has left no trace whatsoever one you have removed it by cohomological descend. There should be no catalyzers in particle physics, do you agree? So there is a deep unsolved problem there.

34. **Bert Schroer**
June 2, 2006

It was said, Mentos, but genuine physicists publish things and are not salesman as the 3 mentioned characters in a previous blog who have very very perishable merchandice which you are addicted to. Thats why you are also unable to understand what is acrually going on in QFT, you will only complain if one of your salesmen happen to ursurpate some of the new thinhs and hands it to you. Kleine anonyme Kanaille.

35. **Kiff**
June 2, 2006

I'm not sure if I agree with your philosophy that BRS is merely a "catalyst" or that catalysts ought to be avoided at all costs. There might be something real deep behind it. And besides, how else would you propose working with gauge theories without BRS?

36. **woit**
June 2, 2006

Lubos and Tony,
Mentos and Bert,
Others,

I've deleted a whole slew of comments from people promoting their books and attacking each other. Sorry, but since it's my blog and a posting about my book, I insist that all personal attacks be aimed at me or my book, or I'll declare them off-topic and delete them. I'll leave Mentos's last solely because at least it contains an attack on me, but please, take AQFT and LQG warfare elsewhere.

37. **woit**
June 2, 2006

Lubos,

I see, it sounds like you have a copy of the version of the manuscript that Cambridge considered and that Jonathan Cape ultimately bought. If you have found more typos or mistakes, do let me know, much of that version is the same as the published version. But so far, everything you've mentioned except the 28 Gev is neither a typo nor a mistake on my part (although often a mistake on yours…).

38. **Chris Oakley**
June 2, 2006

Hi Lubos,

I am prepared to make the same offer as Tony Smith, but 1 hour plus Q & A's should suffice. I can pay my own expenses.

39. **Bert Schroer**
June 2, 2006

Kiff, your two last phrases have the same content, It is very deep to get the gauge invariant content without BRST. This problem on which Mund Yngvason and I are working is just this and the preliminary answer is do not insist in pointlike vector potentials but use the new concept of string localization, which has the same effect as ghosts as far as improving short distane behavior, but it does not have the disadvantage to extend the physical space by ghosts. Of course the difficulty is to formulate interactions for string-localized fields, this is virgin territorry. The new free string fields are ready, but since Mund is a perfectionist and has a lot of teaching he told me he is unable to post it only after the IMP conference in Rio de Janeiro. But you find a lot of introductory remarks into this problem in
http://br.arxiv.org/abs/math-ph/0511042
Kiff, have a sniff

40. **SomeBody**
June 2, 2006

Here's somebody else who seems to have read a pre-release version of the book (and to have points of disagreement with it):

http://rivelles.blogspot.com/2006/06/livro-de-peter-woit.html

41. **Steve**
June 2, 2006

On http://www.amazon.co.uk the variance of the review ratings is quite high. Oh good! That's exactly the sort of book that I would consider buying. Thank you Prof Motl for your magnificent contibution to NEW's ratings variance, and thus encouraging me to buy the book. Of course, I am sensitive to factors other than ratings variance, such as the eminence of those who supply the outliers in the data, and as such you have made the but/no-buy decision a no-brainer, as they say.

42. **Jonathan Vos Post**
June 2, 2006

"I've deleted a whole slew of comments from people promoting their books and attacking each other."

I don't think I attacked anyone, nor are any of my books for sale, and hence I was not promoting any book, but, rather trying to explain something about the viewpoint of someone who writes refereed Math papers, refereed Physics papers, and science fiction. If you think that I'm abusing your bandwidth, could you at least email me back my comment, and the comment of Bert Schroer to which I responding?

As a professional scientist/author, I am willing to give away some minutes of thought and work through blogging, but I'd rather not lose access to my own writing. Thank you.

— Porfessor Jonathan Vos Post

43. **woit**
June 2, 2006

Jonathan,

No, you were not attacking anyone, but your comment was largely links to your own material, had nothing much to do with the topic of this posting, and was an attempt (successful, unfortunately), to turn discussion to your interests in science fiction. Please don't do this. The number of comments here is about to overwhelm my ability to deal with them in any sensible way. Lots of people would like to turn this into a more general interest blog where they could discuss things that interest them. I neither can nor want to manage such a thing. Please avoid writing comments that are not about the topic of the posting. Digressions will be tolerated only if they are especially interesting and part of the narrow focus of this blog on certain areas of research math and physics.

I'm sorry but there is no way in this software to recover deleted comments. If you want future access to what you write here (or in any blog), write it in some other editor, save, cut and paste here.

44. **SomeBody**
June 2, 2006

Maybe adding a regular discussion forum to the site could take some pressure off the blog's comment section (and the blogger)?

45. **woit**
June 2, 2006

Somebody,

I may look into discussion forum software and think about how I might use it on this blog. Basic problem though is that it would still need to be moderated somehow, otherwise you end up with sci.physics. People have suggested to me that the kind of software that Slashdot uses might be the way to go, allowing readers to in some sense moderate the thing themselves by kind of voting on which comments deserve attention.

46. **Jonathan Vos Post**
June 2, 2006

woit: you're right. I was politely engaging someone else's comment, but it was rude to you, and bent the blog from your intended trajectory. I'll try to confine myself to the topic (the part about "there's no such thing as publicity" was, in my opinion). My mentor Richard Feynman was well-known to be deeply skeptical of String Theory.

47. **Bert Schroer**
June 3, 2006

Very, very good Jonathan, now you comment is anti-arasing-proved. You learned very fast.

48. **Bert Schroer**
June 3, 2006

It is probably too long ago, but for all us admirers of Fevnman's directness and rather reliable gut reactions (in contrast to Pauli), and assuming that your credentials Jonathan are genuine, it would be very interesting to know whether you remember any reasons Feynman gave for his critical position.

49. **anon**
June 3, 2006

Bert, see:

http://www.math.columbia.edu/~woit/wordpress/?p=272#comment-5295

Feynman just before dying said: "… I do feel strongly that this is nonsense! … I think all this superstring stuff is crazy and is in the wrong direction. … I don't like it that they're not calculating anything. … why are the masses of the various particles such as quarks what they are? All these numbers … have no explanations in these string theories – absolutely none! … ".

Strangely, Jonathan is misleading when he said this is well known. Search the internet! Everyone who is a string theorist claims they are as scientific in objectivity as Feynman.

All those people are LIARS or plain IGNORANT.

50. **Jonathan Vos Post**
June 3, 2006

WARNER BOOKS

lso availabe as an eBook

Drawing on extensive conversations the author had with Richard Feynman, this is the story of a young physicist trying to find his place in the world, and of the famous, old, and dying colleague whose wisdom helped him. Between them, they shared talk, food, science, and laughter that led the younger man to a deeper understanding of both his own creative imagination and the nature of humanity itself.

FEYNMAN'S RAINBOW

In the early 1980s, Leonard Mlodinow came to the California Institute of Technology to begin a postdoctoral fellowship. Mlodinow had written a groundbreaking Ph.D. thesis, but he was afraid he was simply not smart enough to be at Caltech. In danger of losing himself watching hours of Rockford Files reruns while waiting for one good idea, Mlodinow took his doubts and insecurities to Caltech's intimidating resident genius and iconoclast, Richard Feynman. So began a pivotal year in a young man's life and a year of awakening.

In this funny, inspiring, and revelatory book, Leonard Mlodinow looks back at the time he shared with Feynman: the ideas they explored, the views of life and physics they exchanged…

My experiences with Feynman discussing Quantum Computing, Nanotechnology, and String Theory have been recounted in some of my refereed papers, whose discussion has decayed here to the ground state.

I may have more to say on Feynman's take on why String Theory is Not Even Wrong at a later date.

51. **Tony Smith**
June 3, 2006

Jonathan Vos Post, Bert Schroer, and anon have commented here about Richard Feynman's view that "… all this superstring stuff is crazy and is in the wrong direction …".

Another physicist well-known to be both brilliant and practical is Sidney Coleman. Although I have not read an advance copy of Peter's book and so cannot quote it, I can quote from Peter's blog entry of March 2005:
"… Sadly, Coleman is in poor health, suffering from Parkinson's disease … his great Erice lectures … were collected in 1985 in the book "Aspects of Symmetry" … The fact that Coleman stopped giving these lectures after 1979 was to me one of the first indications that particle theory was entering a much less promising phase of its history. Coleman never really warmed to the topics of supersymmetry and string theory. …".

An even more telling account of Sidney Coleman's view of superstrings comes from a March 2005 entry in the blog of superstring guru Jacques Distler, which said in part:
"… Sidney was my PhD thesis advisor. Truth be told, his direct influence on my thesis was negligible. Midway through my graduate career, string theory swept through high energy physics. As a sensible young man, I dropped everything I'd been doing and rode the wave. Sidney was not interested in string theory; he wasn't even particularly interested in supersymmetry. …
No one thought more clearly about quantum field theory. And no one has ever lectured or written more lucidly about the subject. If you haven't read his Erice Lectures, you don't know the heights that scientific writing can attain. …".

Among those Erice Lectures were "Classical lumps and their quantum descendants", in which he described the sine-Gordon equation, its doublet breather solutions, and its equivalence to the massive Thirring equation. At the end of those lectures, he wrote:
"… This has been a long series of physics lectures with no reference whatsoever to experiment. This is embarrassing. …".

Sidney Coleman's embarassment at physics stuff with "no reference whatsoever to experiment" reminds me of Richard Feynman's feelings about superstrings.

With respect to "Classical lumps and their quantum descendants", Sidney Coleman went on to ask "… Is there any chance that the lump will be more than a theoretical toy in our field? …", and mentioned a couple of possibilities, one of which was "… that there will appear a theory of strong-intereaction dynamics in which hadrons are thought of as lumps …". My effort at trying to fulfill that possibility is at http://www.valdostamuseum.org/hamsmith/sGmTqqbarPion.pdf

Whether or not Sidney Coleman's lumps become "more than a theoretical toy",

Sidney Coleman's basic instinct that "… physics … with no reference whatsoever to experiment … is embarrassing …"
is consistent with
superstring guru Jacques Distler's statement "Sidney was not interested in string theory; he wasn't even particularly interested in supersymmetry.,
and
is also consistent with Richard Feynman's view of superstrings.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

52. **Bert Schroer**
June 3, 2006

Thanks, Jonathan, this time I saved your information.
My superficial impression is that at the time of Feynman this was within the usual antagonisms and rivalries in those days. We should not forget this was before the days when this area of particle physics turned into the direction of hegemony and when certain physicists turned salesman (i.e. in particular nicking away the jobs which you are supposed to be doing Jonathan). In the present "Weltmacht oder Tod" (using Chris Oklay's Endsieg terminology) or in my less radical "hegemony and death to the others" characterization one is inclined to see such ealier aphorisms of Feynman slightly distorted.

53. **FT reader**
June 3, 2006

A review from the Financial times (subscription required):

Nothing gained in search for 'theory of everything'
By Robert Matthews
Published: June 2 2006 19:45 | Last updated: June 2 2006 19:45

They call their leader The Pope, insist theirs is the only path to enlightenment and attract a steady stream of young acolytes to their cause. A crackpot religious cult? No, something far scarier: a scientific community that has completely lost touch with reality and is robbing us of some of our most brilliant minds.

…….

Those who have show signs of having fallen prey to the “sunk-cost fallacy”, the huge intellectual effort needed to enter the field compelling them to plough on regardless of the prospects of success. It is time they were put out of their misery by being told to either give up or find funding from elsewhere (charities supporting faith-based pursuits have been suggested as one alternative).

Academic institutions find it hard enough to fund fields with records of solid achievement. After 20-odd years, they are surely justified in pulling the plug on one that has disappeared up its Calabi-Yau manifold.

The writer is visiting reader in science at Aston University, Birmingham

54. **FT reader**
June 3, 2006

The link to the FT review:

http://news.ft.com/cms/s/a482e470-f264-11da-b78e-0000779e2340.html

55. **sunderpeeche**
June 3, 2006

A word of caution about all this. When the SSC was cancelled, some people expected that the funding would go to other fields, e.g. condensed matter physics, etc. Instead there was a general cut across the board ~ “if the HEP community can lose 8B funding, other fields can survive a hit too”. Do not think that if funding for string theory is cut, that the money will go to “other” HEP theory. It will simply disappear. Funding is not a zero sum game where the money must go “to someone”.

56. **knotted string**
June 3, 2006

Sunderpeeche,

Consider the speculation and hype a bit like a cancer. If you delay treatment, you can avoid the unpleasant side effects a short while.

However, you are then increasing long-term problem. Far better to straighted out problems before it is too late.

The funding of bigoted, close-minded string theorists may or may not need to be cut to preserve the integrity of physics as a whole.

If they would only cease to be such a dictatorial menace to physics, such drastic treatment would be unnecessary.

57. **Dan**
June 3, 2006

“I find it totally pathetic that those people who imposed on others for decades the story about the fundamental aspects of “the gauge principle” in QFT when QFTists with a bit higher developed conceptual power knew that this is one of those metaphoric description did not want to spend their energies removing holy cows (nothing intrinsic, since there was never any autonomous structural property which could reveal that allegedly gauge invariant observables where coming from a “gauge” theory) now have to ram into our throats (via their jester) that after all this was not so (a kind of April fool’s joke of very long duration).”

Dear Bert,

the gauge principle concisely summarizes the interactions even if it is not quite unique. This clear organizing principle allowed us to nail down the standard model. Later on we learned, in the context of SUSY gauge theories, that there can be serious ambiguities in such a description. Seiberg duality is the standard example of this. If you “knew” this all along, why did you leave it to Seiberg to give a convincing example? I dare to guess that it’s because you weren’t able to do it.

Please tone it down a notch or two. You sound like an angry teenager when you write your rambling complaints.

Best wishes,
Dan

58. **sunderpeeche**
June 3, 2006

Believe what you will about string theory and funding, and about the integrity of physics as a whole. I presume that “physics” once again means the equating of HEP theory to all of physics. The solution lies in expt HEP finding something beyond SM. And only Mother Nature has the answer to that.

59. **MathPhys**
June 3, 2006

Dan,

Can you explain in a couple of sentences how Seiberg duality is an example of the ambiguity of gauge theories?

Thanks in advance.

60. **Dan**
June 3, 2006

Dear MathPhys,

For a factual statement of what Seiberg duality is, see

http://en.wikipedia.org/wiki/Seiberg_duality

The point is that theories with different gauge groups are dual to one another, that is, they provide different descriptions of the same physics. In other words, the gauge symmetry may not be uniquely determined by the underlying physics.

61. **sunderpeeche**
June 3, 2006

I'm not Dan, and this is only one sentence, and I'm being a busybody, but try this http://en.wikipedia.org/wiki/Seiberg_duality

62. **MathPhys**
June 3, 2006

Thanks to both of you. I'm (a bit) familiar with S duality. I'm just not so sure that allowing for dual descriptions is the same thing as an ambiguity.

But thanks again.

63. **Dan**
June 3, 2006

Two theories are dual if, despite different formal content, they describe the same physics. A duality between theories with different gauge groups *is* therefore an ambiguity in the gauge group — you can equivalently choose either theory, and hence either gauge group, to describe the same physics.

64. **MathPhys**
June 3, 2006

Agreed.

65. **Thomas Larsson**
June 3, 2006

Even if there is an ambiguity, the gauge group is pinned down up to a discrete, and small, number of choices. Besides, I think that Seiberg duality only works for SUSY QCD, so for e.g. the SM the gauge group is unique, and in fact fixed by its global part, the charge assignment.

66. **anon**
June 4, 2006

Woit,

I notice that Lubos Motl's Amazon review claims:

"The book contains a lot of very embarassing errors."

So both you and Lubos use spell embarrassing with a single "r". Do you share an entangled mental state? That would be real reason for embarrassment.

Or did you write the nonsense review yourself and bribe Lubos to put it on Amazon to stir up some controversy and boost sales?

If you seriously want to drop a letter r from a particular word, string. "Sting theory" sounds really cool.

67. **Mentos**
June 4, 2006

It should be pointed out, in all fairness, that Seiberg duality is a duality of the infrared (long-distance) physics. At short distances (high energies), the Seiberg-dual gauge theories are clearly distinguishable. This is in contrast to the S-duality of N=4 supersymmetric gauge theories, which is an exact duality at all length scales.

The difference, really, is the difference between asymptotically-free theories and conformal ones.

68. **MathPhys**
June 4, 2006

So you are saying that Seiberg duality is *not* S duality.

69. **Chris Oakley**
June 4, 2006

anon,

Peter is obviously way ahead of all of us. Lubos Motl does not really exist, being a persona that Peter has created in order to boost sales of his book (I wonder … maybe *I* could do something … let me think …)

70. **secret milkshake**
June 4, 2006

Lubos exists. He is an alien bot, constructed to probe human reactions.

71. **Chris Oakley**
June 4, 2006

ZZRRRFKLG (Lubos's controller): Give me one reason, *one reason* why I should not bust you back down to teaching arithmetic to pre-school kids? I sent you to Earth to set back their science fifty years or more, and it looks like they've rumbled you already!

LUBOS (*grovelling*): But master, surely you appreciate the ingeniousness of my feigned opposition to the Anthropic Landscape?

ZZRRRFKLG: It's not enough, Skrrzlgk [NB: his real name]. You did not take account of that asshole Peter Woit! It looks like people are going to take his book seriously! And what if the best mathematical brains on that pathetic planet start doing science again? *Then* where will we be?

SKRRZLGK: It was *your* fault! You would not let me use the Quantum Entanglement Ray on him! I *told* you he was dangerous!

ZZRRRFKLG: Do not question my wisdom, fool! You know nothing. And what's with all this political crap on your web site? Stick to the primary mission or your next assignment will be in the Kindergarten!

72. **anon**
June 4, 2006

Chris,

If you look closely at Lubos Motl's blog you can see he is now saying even Dr Matthews is

"Robert Matthews: science-hater par excellence"

Dr Matthews has done possibly more to support science than any other journalist in the UK.

Motl states: "A senior physicist has sent me a piece of text that he or she called ' tendentious, malicious attack on scientists and through that on science itself'."

Who is a senior physicist to Dr Motl? Someone deluded, that's for sure. People who hate Feynman's objectivity so much as Dr Motl and try to mix gibberish with personal attacks while standing behind the cover of Dr Motl are very respectable IMHO.

Or perhaps nobody warped is hiding behind Dr Motl, and he is attacking British SCIENCE reporters off his own back. I think this is the case. Ed Witten and Lisa Randall would NEVER be so cowardly, they have more integrity than that, and don't behave this way.

73. **Chris Oakley**
June 4, 2006

Well, I suppose that with the prospect of teaching arithmetic to alien infants, he is getting desperate.

74. **Nigel Cook**
June 4, 2006

I have complete great respect for Dr Matthews scientific reporting. He has easily done more for science in the UK than the entire stringy brigade put together. That's a real accomplishment.

So Lumos is being silly or paranoid as usual. Remember the article which Lumo wrote about Quantoken, painting him as a clown?

http://motls.blogspot.com/2006/01/meeting-quantoken.html

75. **sunderpeeche**
June 4, 2006

Methinks another set of posts are going to get deleted.

76. **kristo**
June 4, 2006

I must say, this post is a welcome distraction from my stuying for exams. Besides being again *enlightening* as to the way some high ranking academics interact socially, it has given me quite a laugh.

Unbelievable.

77. **Bert Schroer**
June 4, 2006

Dear Dan,
This is clear ever since Schwinger argued that there is a massive version of QED (he thought of what would be called in modern terminology composite Higgs). Of course he knew that he had no mathematical control over 4-dimensional gauge theories (and nobody has up to this date) and in order to be somewhat convincing he invented the Schwinger model. Somewhat later Lowenstein and Swieca came up with quite an ingenious paper in which they showed by a very balanced conceptual-mathematical presentation that the physical content is nothing else than a two-dimensional massive free scalar field. And lo and behold the situation can be inverted, the free massive scalar field really reproduces asymptotic freedom; it is the only free field which does this (look up my long paper from last year on two-dimensional QFT… in AOP or hep-th where this cute conceptually quite nontrivial point point is explained in detail). There are many more controllable model where this can be rigorously established. If you only understand things in a much less controllable 4-dim. Euclidean settings, good for you, but allow me to say that I have difficulties to follow Euclidean consistency arguments which are so far away from conceptional+mathematical control. But please do not claim that mathematical physicists got to know about the metaphorical meaning of the gauge theory setting through the Seiberg-Witten duality. But as I said, if you need a Seiberg-Witten Nanny do become aware this is o.k. with me but don´t complain that before there were no Nannys around.
By the way, the Schwinger-Higgs mechanism is (differen from the Goldstone spontaneous breaking of continuous symmetries) valid also in low spacetime dimension.

78. **Bert Schroer**
June 4, 2006

Thomas Larson,
there is no contradition between the metaphoric QFT aspect of the word "gauge" and the extreme usefulness of the calculational gauge theoretic scheme which allows us to extract all the rich information from the action for the standard model. But I think it is a commonplace by know to expect that this whole present setting will change in the future and probably not just by additional modification here and there, but rather by a very radical reformulation on the conceptual side. In the meantime we should be very very satisfied of having the present rather powerful recipe.
To enhance my point, I direct your attention to the surprizing (in retrospect) efficiency of the old Bohr-Sommerfeld theory. It is very beneficial that we already can agree on the metaphorical aspects of "gauge" because that gives us the conviction to look for a different description where (as outside of gauge theory) the principle: something which looks like an elephant really is an elephant is re-established.

79. **woit**
June 4, 2006

Sunderpeeche,

Everything surrounding Lubos is so surreal I can't figure out how to separate sense from nonsense here and moderate this. Someone recently wrote to me that the string theory story would make a great comic novel in the vein of David Lodge. I feel like I'm already living in a comic novel….

Dan, Lubos,

Back from a trip and just deleted a bunch of comments, including yours. I really insist that this is my weblog so you have to stick to insulting me and not others.

80. **Dan**
June 4, 2006

Sure, Peter Woit. [Attack on someone else deleted]. You are a pathetic loser.

81. **Lubos Motl**
June 4, 2006

Dear Peter Woit,

I noticed that you have erased the only meaningful comments on this page – especially those of Dan (and mine), including the comments of Dan that Bert Schroer "responds" to.

You're like one gigantic KGB that protects the leading role of aggressive crackpots with IQ around 75 in the society. You're a good reason to vomit. Incidentally, my lawyer is telling me that we should sue you for all the lies that you are writing about me. I am telling her that it does not matter because your comments are only taken semi-seriously by the human junk that dominates your blog, but she insists that we should act. So be ready.

All the best
Lubos

82. **runge_kutta**
June 4, 2006

Actually Lubos is right most of the time. The only problem is his abrasive and arrogant attitude. It's so ironic and puzzling that someone as smart as him could be so arrogant. Usually, people as arrogant as Lubos are really just fools. I guess Lubos is the odd exception to the rule.
His attitude doesn't reflect his intelligence, and reading his rants, you'd never know he was a harvard professor (ok, assistant professor, whatever), you'd think he was some random retard. I think his attitude can be traced back to his childhood. Some lack of validation that he tries to make up for as an adult, who knows ?

83. **woit**
June 4, 2006

Lubos,

If you have any specific complaint that something I wrote about you is a lie, do let me know. Has your lawyer taken a look at your own weblog and what you write in comments here before providing you legal advice?

Dan (formerly Michael),

Please stop anonymously submitting the same insult repetitively here. If you don't stop behavior like this I'm going to complain to your colleagues at UMass and Brandeis about this.

84. **JC**
June 4, 2006

It would be very surreal to see the validity of string theory being fought in the legal court system. It sounds almost just as amusing as somebody suing McDonalds for spilling hot coffee on themself.

85. **Thomas Larsson**
June 4, 2006

Re legal matters, perhaps Dan/Michael should ponder this:

"Annoying someone via the Internet is now a federal crime.

It's no joke. Last Thursday, President Bush signed into law a prohibition on posting annoying Web messages or sending annoying e-mail messages without disclosing your true identity.

In other words, it's OK to flame someone on a mailing list or in a blog as long as you do it under your real name. Thank Congress for small favors, I guess."

86. **JC**
June 4, 2006

Thomas,

A new "law" of that sort has to survive the legal process, particularly on constitutional grounds, if it's to become the law of the land in America. Otherwise it's just something that's written on a piece of paper with very little to no legal meaning.

87. **Mentos**
June 4, 2006

MathPhys asked:

"So you are saying that Seiberg duality is *not* S duality."

S-duality is an exchange of weak- and strong-coupling regimes of two theories.

For a conformally-invariant theory (like N=4 SYM), such a notion makes direct sense because the gauge coupling constant is really a constant.

In an aymptotically-free theory, what you have is a scale-dependent running coupling constant. So, if I said to you, "the Seiberg-dual theories are related by an exchange of weak and strong coupling," you should retort, "The couplings defined at what scale?"

The answer is, "the couplings in the far-infrared."

In the UV, both theories are weakly-coupled, and clearly have different weakly-coupled degrees of freedom.

A better name for Seiberg duality is "universality." Two different gauge theories have the same infrared physics. But, since it is closely related to S-duality (which I'd like to reserve for theories that are dual at all length scales), "duality" is the name that has stuck.

88. **anon**
June 4, 2006

When will it be decided whether Lubos gets tenure at Harvard? I hope he gets it. Let's give credit where credit is due. No man (sorry Peter Woit, but you are not even close) has done so much to sink the reputation of String Theory than Lubos Motl.

89. **island**
June 4, 2006

> In other words, it's OK to flame someone on a mailing list or in a blog as long as you do it under your real name.

You've got to be kidding me, I was just about to comment on Peter's stinky feet.

And somebody needs to warn Uncle Al, ASAP… 😉

90. **sunderpeeche**
June 4, 2006

Delete the entire thread, except perhaps the ones about duality.

91. **island**
June 4, 2006

Peter, I plugged your book and Lee's on SPResearch, but Phillip is sleeping-in…

92. **sunderpeeche**
June 4, 2006

String theory ("cancer") ~ threat to HEP theory ~ threat to all physics ~ threat to civilization itself.

Mon Dieu im Himmel.

Toss the lot.

93. **island**
June 4, 2006

No, there is a clear and critical difference …

…between understanding that every unproven and projected assumption that has ever been "carried" is always up for review at any time given new physics, until a true ToE or at least a "hard" theory of quantum gravity is produced… then maybe…

…and between taking assumptions and projections for granted to the point of the kind of fanaticism that embraces the ensuing world-view that this entails as if it were real!

Nothing need be tossed when the "hype" isn't passed-off as something greater via a rallying of the masses and politics, over new physics.

I think that it's sad though that it may take the collapse of quantum gravity physics to wake people up to the fact that the conservative approach to resolving old unfinished issues isn't the fringe, rather, the cutting-edge which is OUT THERE.

I think that the whole career commital thing is critical to all of this, and not in a good way for science.

94. **Benni**
June 4, 2006

what I think is interesting on Lubos is that his behaviour is similar to what's under psychiatrists called Aspergers Syndrome:
http://www.udel.edu/bkirby/asperger/
Individuals with AS can exhibit a variety of characteristics and the disorder can range from mild to severe. Persons with AS show marked deficiencies in social skills, have difficulties with transitions or changes and prefer sameness. They often have obsessive routines and may be preoccupied with a particular subject of interest.
it's important to remember that the person with AS perceives the world very differently. Therefore, many behaviors that seem odd or unusual are due to those neurological differences and not the result of intentional rudeness or bad behavior, and most certainly not the result of "improper parenting".

By definition, those with AS have a normal IQ and many individuals (although not all), exhibit exceptional skill or talent in a specific area. Because of their high degree of functionality and their naiveté, those with AS are often viewed as eccentric or odd and can easily become victims of teasing and bullying. While language development seems, on the surface, normal, individuals with AS often have deficits in pragmatics and prosody. Vocabularies may be extraordinarily rich and some children sound like "little professors." However, persons with AS can be extremely literal and have difficulty using language in a social context.

Asperger called them "little professors". It is likely that Dirac was for example a classic case.

This here is about a fields medaillist (Richard Borcherds) with Aspergers:
http://leitl.org/docs/a-professor-of-mathematics.pdf

95. **woit**
June 4, 2006

Please, enough about Lubos's eccentric personality. For the record, it seems to me to have nothing to do with Asperger's.

96. **Ponderer of Things**
June 4, 2006

not to focus on Lubos, but does anyone think that string theorists out there (the reasonable kind) see the arrogant, obnoxious and "below the belt" attacks of Lubos as helpful to their cause? Do they even know/care? It seems like as far as blogs and internet is concerned Lubos is some sort of self-appointed strings guru, at least to regular masses. I wonder how many new graduate students reading blogs, including this one, want nothing to do with string theory – not because of Peter Woit's or Lee Smolin's critisism of the strings, but because of folks like Lubos.

97. **Mentos**
June 4, 2006

So you would base your career decisions on the content of Peter Woit and Lubos Motl's blogs?

Wow.

98. **woit**
June 4, 2006

Ponderer,

I doubt that most string theorists see Lubos as helpful to the cause of string theory, quite the opposite. However I continue to find it remarkable that essentially none of them (Aaron Bergman is one exception) are willing to be seen criticizing him and his behavior. I'll avoid speculating here about why this is.

Mentos,

He explicitly said that graduate students like him aren't much influenced by me, but are influenced by seeing the behavior of Lubos (and folks like him, try the next most well-known string theory blogger, Jacques Distler). Would you want to enter a field that appeared to be happy to be represented by people like this? (Going back to previous point, that the rest of the string theory community gives no indication of having a problem with Lubos or Distler).

99. **Anon-e-mus**
June 4, 2006

Lubos' behavior isn't similar to the typical behavior of Aspergers' people at all. No, he is a classical case of Narcissist Personality Disorder. Just look at all the times he points out that his blog is allegedly the "best" according to google, that he has more google hits than some leading politicians and so on and so on. An Aspie wouldn't care much about that kind of outside confirmation, but Lubos really, really seems to need it: typically narcissist behavior. Self-praise disguised as praise by others, extreme dependence on outside confirmation of superiority, just like the need to put others down, ridicule others etc., all typical Lubos behaviors, all typical of narcissism. Lubos is a narcissist, not an autistic (he may have some mildly autistic traits as well, but some of those are actually fairly common among mathematicians/theoretical physicists).

100. **Peter Woit**
June 4, 2006

People looking for another blog where they can watch Lubos promoting string theory and argue with him might want to look at this:

http://blogs.chron.com/sciguy/archives/2006/06/which_of_these_1.html

101. **Sam**
June 4, 2006

"try the next most well-known string theory blogger, Jacques Distler"

Yeah, Distler's blog is a cesspool of ad hominem attacks and lunatic ravings about the enemies of string theory and mathml.

102. **woit**
June 4, 2006

Mentos=Sam (if you're going to hide behind a pseudonym, maybe it should just be one),

I wasn't so much thinking of Distler's blog postings, but what happens if you disagree with him. You don't see that very often these days since, for whatever reason (maybe because the way he handles mathml no one can read his blog on their browser), virtually no one writes comments there. What I had in mind was more what people who deal with him soon notice, see

http://utphysguide.livejournal.com/3047.html

"Jacques Distler is quite possibly the worst physics professor I have ever had. He has the uncanny ability to make even the simplest concepts utterly incomprehensible. He is a true intellectual snob, and he treats most questions with open hostility. Unless you have a PhD in math and already know string theory, you will not learn anything from Distler. String theory is hard, but not as hard as Distler wants it to be."

Not exactly something that would encourage a student to go into his field, no?

103. **Thomas Reasoner**
June 4, 2006

This has been some interesting reading. I just have one question, and I'm sorry if it's a little off-topic: what's the alternative to string theory? I only have a BS in Electrical/Computer Engineering, so I'm just starting out in this great field. I want to go into cosmology and work on a unified field theory, but I don't want to work on string theory. Is there an alternative for someone like me? This is all I want to do with my life, and I'd prefer not to waste my energies on science-fiction, so any advice would be appreciated. Please email me at thomas.reasoner@gmail.com so as not to get too far off-topic from the post.

104. **woit**
June 5, 2006

Thomas,
It's not that people who are working on string theory are ignoring some obviously better alternative out there. No one has any really good ideas about unification at the

moment, making it a tough field to go into. Given the situation, the choice may be to work on something which is pretty surely science fiction, or to try and come up with something new yourself, which is very hard.

105. **JoAnne**
June 5, 2006

Thanks All, for a most entertaining read! Made me laugh out loud. Peter, no choice but to get your book now.

And, Thomas Reasoner, the alternative to string theory is particle theory. We build theories and fit them to data. If actual data excludes them, they get tossed out. We have many exciting puzzles to solve – the mechanism behind electroweak symmetry breaking, the hierarchy problem, what is dark matter, why are neutrinos massive, what is the origin of CP violation, etc. We have data to confront these puzzles, and our theories, and will soon take a giant leap in our understanding with the LHC. Only Lubos will be left to care about string theory then…

106. **Chris Oakley**
June 5, 2006

The Robert Matthews article in full.

RM studied Physics at Oxford and was in the year below me (1978). What with that Oxford man Penrose having facilitated the publication of Peter's book, I doubt that Superstring Theorists will be queueing up to make donations to Oxford University.

107. **PeterG**
June 5, 2006

As a physics grad student, I must admit I'm finding this controversy regarding string theory extremely interesting, but the manner in which it is being played out as being emabarrassing to all in the field. As scientific professionals there is a definite need for expressing opinions and to challenge other's thoughts, conjectures and theories, but in a respectful manner. Debate rather than intimidation and insult is surely the correct approach. Unfortunately I have now seen the latter in the attacks on Smolin by Susskind and now Motl on Woit.

As to the question of whether or not Mr Motl would convince me to look in another area of physics other than string theory – the answer is no and yes. No, as I am willing to ignore the individual to study the theory, but also yes, as I am yet to hear the leaders of the field criticising his personal attacks on those respected scientists that are providing a challenge to these stringy theories. After all, in science no good theory should go unchallenged.

As I am only a grad student and not a professor with numerous published papers, I will be no doubt seen as an 'idiot', a 'crackpot' or not yet worthy of a comment – all I can say is that out there is perhaps another grad student that some day makes the breakthrough that those condemning them have been unable to do. For me I think I'm going to focus on QCD.

I look forward to reading the book.

PS … if the only reason for not reading it is some typos then I best throw away every text book I have ever had!!!

108. **Chris Oakley**
June 5, 2006

Peter G,

1. Thank-you for providing yet another spelling for the word "embarrassing".
2. You should not consider the Harvard Hammer of Heretics as being representative. Even Jacques Distler is capable of (icy) politeness with critics of ST.

Peter W,

I just bought a copy of your book from Blackwell's in Oxford. Like the aforementioned hammer, I therefore have to call you a liar as I seem to remember you saying that it would not be in bookshops until June 16.

109. **Tony Smith**
June 5, 2006

Thomas, you ask " what's the alternative to string theory? ".

Peter replied
" No one has any really good ideas about unification at the moment …"

and

JoAnne said
"… the alternative to string theory is particle theory.
We build theories and fit them to data.
If actual data excludes them, they get tossed out. …".

I have an alternative physics model that fits "actual data" of particle physics.
A version of it can be found in pdf form on the CERN web site as EXT-2003-087 at
http://cdsweb.cern.ch/search.py?sysno=002414216CER
and also on my web site at
http://www.valdostamuseum.org/hamsmith/TQ3mHFII1vNFadd97.pdf

Further details can be found on the parts of my web site at
http://www.valdostamuseum.org/hamsmith/
that deal with physics, and with the physics parts of my 4 MB pdf web book at
http://www.valdostamuseum.org/hamsmith/BANNEDbyCORNELL.pdf

Note that the web book material includes calculations of
the ratio Dark Energy : Dark Matter : Ordinary Matter, related to JoAnne's question "what is dark matter"
and
neutrino masses and mixing angles, related to JoAnne's question "why are neutrinos massive".

I am sending a copy of this message to Peter Woit because I have,
so far, tried to be very observant of his wishes that I do not
discuss my physics model on his blog, and stay strictly on-topic
(which is mostly to attack superstrings without advocating any alternative).

However, I am very upset about Peter's comment
" No one has any really good ideas about unification at the moment …"
because
he does know about my physics model
and
his statement is a direct attack on it,
just as direct as are his attacks on superstring theory.

Of course, Peter is entitled to his opinion about my model,
and he is entitled to attack it on his blog,
but
since he has attacked it,
I am also posting this as comment on his blog in direct reply
to his attacking comment.
In fairness, I expect that this comment should NOT be deleted
UNLESS Peter's statement
" No one has any really good ideas about unification at the moment …"
is also deleted, and not repeated.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

110. **RahulM**
June 5, 2006

PeterG: It is difficult to debate intelligently in the absence of experimental data. Hence the insults. It's quite fun actually.

111. **woit**
June 5, 2006

Chris,

Thanks for the news. I don't know why at one point recently someone at Cape was telling me June 16th would be the release date.

Tony,

I was not in any way attacking your ideas. The ideas about unification that have attracted attention in the particle theory community are the ones I was referring to as not being successful. Lots of people have ideas about unification (I have my own) which haven't attracted such attention. Maybe one of these will turn out to be very important.

Please though, Thomas politely gave his e-mail to encourage people to discuss ideas about this with him privately, not here where it is off topic.

112. **Juan R.**
June 5, 2006

There is an interesting duality between Distler's wisdom on string theory and mathml.

Distler surrounds both in a sphere of dogmatic true, only-way-to-do-things and *ad hominen* attack to no-believers. Distler's arrogance on string theory is only comparable with his arrogance on Internet technology. He claims his blog is the most advanced of planet somewhat as we heard each day that string theory is the most advanced theory!

This point is very important. Distler, as other string physicists (except some as Nanopoulos working in more advanced stringy approaches or particle physicists as Gell-Mann working in generalized QM), states that string theory is the more sophisticated theory of planet when is a pure joke if you compare with other sophisticated approaches. Moreover, the ultra-advanced string theory is unable to duplicate good experimental result provided by SM or GR since decades.

Similar criticism can be done in the technological side of Distler's insane blog. He states, in a very proud way, the ultra-sophisticated technology (a simple trivial p-MathML 2.0 via inefficient plugin) of his blog, still he is unable to encode material can be encode via old HTML.

In the same way that Distler is unable to compute Mercury anomalous perihelion from first principles of string theory (but can be computed from old but effective GR) Distler is unable to encode (ds)^2 using his xml plugin distler/blog/.

Observe the first block-display math on *Designing the 5th Dimension*. Instead encode (ds)^2 he is writting 2s ds!!! A simple old HTML 3.2 code can do it better

Note the parallelism physics-technology!!

Beliefs on Physics:
– String theory is the most sophisticated theory in the world.
– String theory is the only way.
– String theory can solve any problem of physics: SM parameters, CC, unification forces, quantum gravity…
– Other theories (e.g. loops) are stupid and a person who is not string theorist may be not smart enough.
– Attack to any competitor of the theory (e.g. impede arxiv's link to Woit blog).

Beliefs on Technology:
– MathML is the most sophisticated markup in the world.
– MathML is the only way.
– MathML can solve any problem of internet: accessibility, mathematical rendering, automated search, semantic encoding…
– Other markups are stupid and guys do not developing MathML are nor smart enough.
– Attack to any competitor of MathML or of Distler plugin (e.g. hard criticism to client side ASCIIMath approach).

Results on Physics:
– String theory is not sophisticated enough as claimed in many places (including smart guys as Gell-Mann).
– String theory is the only way to disaster.
– After 40 years of string theory, it has not solved any of promises and is unable to offers results can be easily achieved with old theories as SM and GR.
– Other theories are producing interesting results and string theory often copying them (even Witten recognizes that string theory has a tendency to embrace ideas of alternative theories).

Results on Technology:
– MathML is not sophisticated enough as claimed in many sites (e.g. OpenMath authors are highlighting MathML errors).
– MathML is the only way to disaster.
– After 10 years of MathML, it has not solved any of promises and is unable to offers results can be easily achieved with old markups as HTML and ISO12083.
– Other markups are producing interesting results and recently MathML authors triyng to copying them (e.g. R. Miner asking for XML-MAIDEN way to encode scripts for debate in future MathML 3.0 specification).

Peter Woit, physics is not the only victim of those insane guys who do not know that **scientific method** means.

Juan R.

Center for CANONICAL |SCIENCE)

113. **Bert Schroer**
June 5, 2006

In this blog I would like to take the opportunity to dispel some misconceptions. I am not against string theory per se as one area of possible research in particle physics. What worries and annoys me at times are rather its new sociological aspects, the hegemonial role it has allocated to itself, the enormous collateral damage it causes (rapid loss of basic knowledge in favor of doubtful substitutes), the seducing role (raising false expectations) its proponents excert on the young generation (some called it brainwashing) and last not least the total lack of self-reflection and criticism which used to distinguish science from other human activities in the socio-political sphere. But in no way I want to downgrade colleagues and endanger old friendships; when I mention names it is in their role as iconic figures in this dispute. Fortunately science still permits to do this. In the present sociological situation one is well-adviced to follow Hirzebruch's distinction between physics and "what physicists are doing".
It is not (as Chris Oakley said) that I went to South America to get away from the radar screen of string theory. There is also string theory in Brazil and I attend the talks of my string theoretic colleagues and ask question and get answers (in most cases honest and straightforward). It is true that I did have some problems with one particular person
http://rivelles.blogspot.com/2006/03/ideology-sociology-and-psychology-of.html
But this has little to do with the fact that he is a string theorist, but rather with his inability to make use of that amount of visibility which even according to Weinberg's calculation of the cosmological vacuum energy he would be intitled to have, see
http://br.arxiv.org/abs/hep-th/0605054 page3
I meanwhile arrive in Sao Paulo waiting for the dental repair. Two days before I left Arraial do Cabo (the 1503 landing place of Amerigo Vespucci, originally a small fishing village but now the diver's paradise) there was a street festival where I live. The day before some youngsters came to me and asked for small contribution to decorate the street. In the evening there was a lot of fire-cracker-like noise and when I looked outside I saw an almost continuous lightening with sparks raining down onto the parked cars. In the process of fixing all the paper flag decorations the youngsters hit the main electric cable (ouside big cities the electric and communication wiring is hanging completely exposed exactly as in the US). There was a blackout for the rest of the night. The next day I saw the first paintings on the walls. They started with that inexorable iconic figure of a bearded teutonic type in Lederhosen with a filth heat carrying a feather. In one of his hands, how could it be otherwise, he was swinging a jug of beer. It was clear, this was a warm up to the world cup soccer season. They wanted me to identify with this painting and it did not help much to point out that even if you go down to Bavaria, figures like this have become almost as rare as the abominable snowmen. I told them its iconic just like Ze Carioca and Carmen Miranda with the consequence that the next day their wall paintings were enriched by a very large Ze Carrioca (a parrot who talks) and a mulata adaptation of Carmen Miranda. The patriotic feelings of these rather poor people had something contagious and they would have been extremely confused if I would not have taken up a patriotic fan position in favor of the German time. I really feel great because with the German Nationalmannschaft and the Brazilean seleçao in my family (my wife is Brazilean) I can hardly loose. As most Germans of my generation I naturally have a rather detached relation to matters of national pride, which is natural in view of the past Germany's disastrously deep look our into that bottle containing that dangerous brew called nationalism. The football outing of patriotism is the best one, as long as it does not spill into hooliganism.and racism.
In retrospect I am also quite grateful that Germany had a rather wise leadership in difficult times with tremendous political coercion. The thought that German troops man checkpoints in Iraq and mow down families because they do not understand orders in German would turn my stomach around. Lidice, Ouradour and all the massacres committed in Italy are not deleted in the memory of mankind.
Having lived in Berlin and in the US, I find Brazil a very very different place. In the US I met Palestinean refugees who had very bitter feelings about Israel and Israelis, and the Israelis in Berlin who did not hate Palestineans and considered them as inferior were the exception and not the rule. But here in Brazil I have in my family (from my wife's side) Jews, Arab descendents of people from Syria-Lebanon (which was split up by the colonial powers) and people of Portugese extraction living harmoniously together. Most of the Arabs and some of the Jews came at the time of the decay of the Otoman empire. One of my wife's relative with the illustrous name Canetti (a relative of the famous writer and philosopher Elias Canetti) was actually born in some region which is now Bulgaria (he is 96). Talking to him I had to correct some of my misconceptions about the Otoman rulers being very oppressive (I thought about the massacre of the Armenians). Its seems that as the US has profited from the dissolution of the Habsburg empire, Brazil got most of the migrants who were running away from the uncertainties of the dissolving Otoman empire.
I also recently visited a Jewish friend (from the times with the collaboration with Swieca) in Petropolis. He has two rooms filled with art deco and body sculptures which I link with the Nazi era, although I have seen similar sculptures in Italy and even in the US (from the time of the New Deal). But he also had some SS militaria in his collection. I was quite stunned and asked him what makes him collect such things. He gave me a convincing answer by saying: "look, they are all dead and I survived". His parents fled with him from Rhodos shortly before the Nazis deported the whole Jewish population and executed them. The reason I mention this is because 2 days ago when I looked into the news on the internet I noticed that there is a ferrocious dispute about the removal (or at least covering) of some sculptures at the entrance of the Berlin 1936 Olympia stadion (which were commissioned by the Nazis). Fortunately Stephan Kramer, the chairmen of the Jewish council in Germany spoke against such a strange act of exorcizing history which is usually demanded by some members of the older generation..
I of course would like the German team to win, and I would be happy if it is merited and not just luck. But what would make me even more happy is if those youngsters which are descendends of more than 100.000 Jews (mostly from the former SU) would be among the strongest fans for the German national team (in defiance of all those Nazi skin heads and racist hooligans). Because then, and only then, I would know that the postwar era has finally ended and a new chapter has been opened.

114. **Juan R.**
June 5, 2006

Bert Schroer,

We usually distinguish between string theorists and stringers.

String theorists are physicists/mathematicians who are pursuing a research program for unification of physics (which is a loable program either if sucesfull or not). String theorists are honest, recognize the limitations of their program and obvious failures done in the past. They are the first ones interested in experimental verification of the theory (or at least of part of their foundation) and you can talk or discuss with them in a solid debate where just technical points are of interest.

Some of those also recognize that even if string theory is achieved some day it will not become the TOE, since nature is more complex. Those string theorists understand the need for open debate on hot topics just how they understand the need of the research in alternative approaches.

Now turn to stringers (there is one very popular at this thread).

Real impact of stringers in physics or maths is close to zero, none of them have received a Nobel or similar prize. Stringers are of people more dishonest we know, never recognize limitations and have a tendency to rewirte history of the field for hiding the obvious failures done in the past.

Stringers dislike experimental verification by two motives: i) it could break down string theory, ii) experiments are considered a task for second or third class physicists when compared with beautiful of theoretical studies of divine origin. Remember that stringers claim that "*string theory is the language God wrote the world*".

Stringers do not like technical debate and just focuse on *ad hominen* attacks or embarrassment, and prefer to add noise to discussion. Their knowledge of topics beyond particle physics is so weak that still believe on that they are developing a TOE. (Yes i agree some stringers lack understanding of most basic of particle physics).

Finally, I would add that stringers spend lot of time on deviate funding from alternative approaches and spend many time on political strategy with the only aim of self-perpetuate string theory for ever (independently if is working or is a "colossal failure") how all of us know.

Juan R.

Center for CANONICAL |SCIENCE)

115. **B**
June 5, 2006

when I went to college I learned two things:

a) don't mix up professional and personal matters.

It should be possible to discuss physics without retreating to insults that don't get anybody anywhere. Exept maybe Lubos on the blogtopsite no #1.

Since I haven't read the book, and have a very shared opinion about String theory, let me just state that merely from reading the blogs of Mr. Woit and Mr. Motl, to me BOTH apparently have a large knowledge about String-theory as well as about particle physics. If it weren't for blogs triggering fast and unreflected responses that get much more attention than the scientific content, their blogs could be quite an important contribution to the community (meaning phycisists in general).

Students that choose their field of research from comments like the ones above (regarding alien bots or reasons to vomit), are problably students you can happily forget about anyway.

I also learned

b) Keep my big mouth shut.

With which I apparently have failed again.

Best, B.

PS: The whole discussion about **G** or **T** is completely ridiculous. Everybody who knows what a TeV is will know that the LHC operates at 14 TeV com energy. For those who don't know what a TeV is, it doesn't matter anyway. I have certainly published more embarrassing typos, and the world is still turning.

116. **Christine Dantas**
June 5, 2006

We usually distinguish between string theorists and stringers.

Eh. That reminds me of the distinction between trekkers and trekkies, the two kinds of fans of the classical Star Trek series.

Christine

117. **dan**
June 5, 2006

lubos,
what kind of experimental predictions does string theory makel, which, if experimentally falsified, would cause you to see string theory refuted, in response to below

This is unattributed since I don't know who wrote it. Maybe they were a crackpot, one visiting the Harvard string theory group.
The problematic statement that string theory makes no prediction is repeated hundreds of times, and in many particular contexts, such a statement becomes not only boring but also patently false.

I doubt it's actually in the hundreds, but sure, I do repeatedly claim that string theory makes no predictions, and this is not "patently false", but completely accurate.

118. **MathPhys**
June 6, 2006

Motl's behavior has nothing to do with AS. He's just an arrogant, spoilt kid.

119. **Hech Baan**
June 6, 2006

Dear PeterG,

I'm another physics grad student who decided to study string/M-theory. For me the truth is written in mathematics. If I don't see a rigorous, logical, mathematical proof then statements may be beautiful, ugly, interesting, funny, but not true or false. Therefore I'm not going to change my mind based on people's opinion whoever they may be. Show me the proof!!!

Is string/M-theory correct, wrong, or not even wrong? I don't know. But I'm willing to invest my years to find it out myself.

I'm not going to order Peter Woit's book. Peter is so much against string/M-theory that he can't objectively analyse it.

120. **Bert Schroer**
June 6, 2006

Juan R.
I certainly agree with your remarks on string theorists and stringers as a description of the present reality and as a statement which is capable to generate some feeling of solidarity between those who are everyday more convinced that the Susskind et al. millennium project is the road from physics to metaphysics. But they do not explain at all how it came to this situation. There have been always people around who tried to miscarry physics into such directions, but they had no chance in the past. I think it will take a lot of deep critical analysis within the next decades to understand this phenomenon, which did not come suddenly out of the blue sky, but has its roots in the banalization of certain aspects of QFT. It certainly is not only the result of lack of experimental discoveries in particle physics; in fact given the complexity and the increasing dependence of the experiment on theory, a bad theory may also pull down experimental progress. For this reason it may be somewhat optimistic to expect that the LHC will significantly change the scene.
Dear Hech Baan, if you are unable to sense an autonomous physical beauty and continue to think that particle physics should jump over ready made beautiful mathematical sticks/strings, then I would strongly suggest that you change to mathematics before you start to worsen the present situation in particle physics which is already totally dominated by mathematical beauty (I hope that Peter will not araise this comment).

121. **knotted string**
June 6, 2006

"For me the truth is written in mathematics." – Hech Baan (above).

You have just discredited Feynman's silly, stupid and science-hating remark that agreement with experiments determine truth.

Feynman was really a hateful anti-science crackpot! See this:

"It always bothers me that, according to the laws as we understand them today, it takes a computing machine an infinite number of logical operations to figure out what goes on in no matter how tiny a region of space, and no matter how tiny a region of time. How can all that be going on in that tiny space? Why should it take an infinite amount of logic to figure out what one tiny piece of space/time is going to do? So I have often made the hypothesis that ultimately physics will not require a mathematical statement, that in the end the machinery will be revealed, and the laws will turn out to be simple, like the chequer board with all its apparent complexities."

– R. P. Feynman, Character of Physical Law, November 1964 Cornell Lectures, broadcast and published in 1965 by BBC, pp. 57-8.

122. **Hech Baan**
June 6, 2006

Dear Bert,

Thanks for your comment. Let me explain my approach.

As Einstein said in Motiv des Forschens, 1918, p 29-32 "… Practically, theoretical system is uniquely defined by observations, though there is no logical path from observations to the fundamental principles."

Therefore our challenge is to somehow find the fundamental principles. The ugly news is that there is no enough data to verify our assumptions, the bad news is that we have to work really hard to get any meaningful prediction from our frameworks/theories/laws. But the good news is that there is one tested guiding principle – mathematical consistency and beauty. Why not physical beauty? Because I don't have any sense what an autonomous physical beauty at Planck scale is. I will train my senses using my consistent theories and then yes I can use my trained senses of physcal beauty to enhance the theory. And finally,I think nature is a mathematician not a physicist 🙂

Trust us. One day one or many of us (today's grad students) will come up with the solution. We need everyone's support to get it quickly. I can tell that no any blog, article, or book will stop the progress.

June 6, 2006

Hech Baan,

Peter Woit is much more objective analysing string theory in this blog that any stringer (not string theorist) has been in last 40 years in peer-review papers.

Hi Bert Schroer,

I agree with you again on that people is ignorant on who generated current irrational status on fundamental physics. Stringers are simply unable to understand any criticism from rest of scientific community. Often I received personal e-mails from people who began a PhD in string theory, found the field completely irrational and abandoned physics!!! They were forced to abandon physics (instead changing string theory by some other program) because any other chance to study unification or quantum gravity is highly constrained by political and economic power of string theorists. This autoritarism only can generate disaster and, in fact, has generated.

> I think it will take a lot of deep critical analysis within the next decades to understand this phenomenon

From stringers? I doubt, maybe critical analysis will become from historians and probably from a new generation of physicists will advance physics in next decades. In fact, last book (to be published) by Lee Smolin talks about next generation of young physicists working outside of string theory.

Take the case of own J. Distler. I said here that his views on physics and in MathML are very wrong (in fact, there is a parallelism). I cited the element of line for 5D spaces appears in

http://golem.ph.utexas.edu/~distler/blog/archives/000635.html

The physics here is so wrong as the XML markup used for encoding information. I know stringers and they have a tencency to distort the history of physics. Once you find an error in some point you wait that error was recognized and changed (I always have recognized my errors, and I believe that you, Peter Woit, Chris Oakley, and others here are honest). However, would we wait "critical analysis" from stringers as J. Distler?

What would we wait from a guy calling himself bigthinker?

http://golem.ph.utexas.edu/~distler/blog/images/bigthinker.jpg

Take the case of MathML code, I checked code just before posting, however (yesterday?) Distler changed the code (in a cobardy way) and now you can see that first block equation in

http://golem.ph.utexas.edu/%7Edistler/blog/archives/000635.html

contains ds 2.

Distelr changed code probably yesterday but has not noticed in the blog, not recognized the error in public 🙂

This is like stringers work; if tomorrow HLC produces lot of interesting data against some dense ideas proposed by Distler and others during last decade, they will not recognize in public.

Additional comment:

Either Distler is reading this blog or his favourite … comunicated him the content of this blog.

Dear Distler (or …) still the code generated in your “technologicall more advanced blog” is wrong. Using ds as token you obtain roman rendering whereas the differential in next equation (1) continues rendering in italic. Moreover d is not an identifier. I would suggest you to try again!

P.S: Hech Baan The ugly news is not that there is no enough data to verify our assumptions, the very bad news is that string theory is unable to reproduce experimental result known in last centuries.

Any new theory of physics may be compatible with known data and then just then can do predictions about new data (e.g. HLC). One of most dishonest mantras of stringers is the absence of experimental data that can verify main premises as strings, hidden dimensions and all that. First explain available data (postdictions) and next focuses on predictions.

P.S: I would recommend people to dowload copies from both links before Distler changes them again without noticing :-).

Juan R.

124. **Peter Woit**
June 6, 2006

Juan,

I wish you would conduct arguments over MathML with Distler at his blog, and not here. Bad enough the fighting over string theory, but I don\'t want to get involved in a really vicious, ugly controversy like that over MathML…

125. **Bert Schroer**
June 6, 2006

My suggestion (which I have been following for a couple of years) is a third way which seems to be particularily advisable in times of experimental lull combined with a theoretical blue yonder abberation (Feynman) as the one which is the main topic of this blog. This third way is to press the principles of successful, but yet incomplete theories very very hard and to pay particular attention to unusual new viewpoint which maintain these principles. This is what led Einstein from the eather to the relativistic invariance principle and later to renormalized QFT (the experiments only highlighted aspects which were already there and only had to be worked out). This is extremely difficult and can hardly be done by beginners because it requires a profound knowledge and hinsight about the theory. But one only needs a breach for strong young folks to get interested in entering. Even at the risk of sounding arrogant I think that this breach already exists due to some amazing conceptual progress in QFT being related to “modular localization”. But for obvious reasons I do not want to meddle with things in Peters blog (unless Peter allows this and somebody specifically asks for this).

126. **Juan R.**
June 6, 2006

Sorry Peter Woit, I believe that many of your agree with me on that main problem with string theory is not theory itself but the hype around it. That hype confoundd street people, young undergraduate students, science policy makers, and so on.

Therefore my main attempt has been to illustrate that stringers (or “bigthinkers”) can be so arrogant in physics as they are in other fields, that they can rudely attack interesting alternatives to string theory as attack alternatives to others things and that they are doing really bad physics as they are doing in other fields.

I attempted to illustrate here how “intuition” of stringers is so wrong when they decide choosing string theory by beatiful motives as when they choose support other items.

Sam pointed to parallelism above and you next cite

http://utphysguide.livejournal.com/3047.html

I simple attempted to explain to general public as cobardy and “intellectual snob” stringers can be in a way that readers of the blog could directly observe this attitude “online ” (readers could go to Distler blog for see details) whereas it is more complex that they can go to the library to obtain article X published in academic journal Y and understand the stuff, and next to see how stringers change their views without recognizing errors and call everything “string theory” (even if there is not strings as in many brane papers!!!).

I do not know if I was succesfull but I understand your point and I will not write more about MathML here, just about physics and math.

Juan R.

Center for CANONICAL |SCIENCE)

127. **Eugene Stefanovich**
June 6, 2006

Hech Baan:

the reliance on mathematical beauty could be misleading. Physics is very different from mathematics where axioms are postulated and theorems are proved by simple logic. In physics we often don't even know what our axioms are. Nature doesn't care about our sense of beauty or present day mathematical fashions.

Ancient physicists rightly considered a circle to be the most beautiful mathematical figure. No wonder they presumed that cellestial bodies go around in circles. I guess Kepler was very surprised to discover that the orbits of planets are actually ellipses. Probably, initially he was even disgusted by his own discovery.

Even if axioms are explicitly given, physicists are not careful enough to prove their theorems rigorously. For example, the apex of modern day beauty in theoretical physics is the Minkowski space-time. Indeed, what can be simpler than take the Pythagoras theorem
r^2 = x^2 + y^2 + z^2 and add there one more term:
s^2 = x^2 + y^2 + z^2 – c^2t^2 ? However, you don't need to be a rocket (or string) scientist to realize that the Lorentz transformations and the Minkowski space-time unification do not follow from two Einstein's postulates. The second postulate (the invariance of the speed of light) can be rigorously applied only to events associated with light pulses or light rays. However, the Lorentz transformations are assumed to be valid universally for all physical systems, no matter what is their composition and interactions. Is Minkowski space-time beautiful? Sure it is! Could it happen that this beauty is similar to the beauty of Ptolemean circular orbits, and will be substituted later by more realistic "elliptical" views on space and time? Sure it could!

If you want to build physics as a mathematically consistent and logical theory, then you should return way way back to basics and begin from the principle of relativity and the laws of quantum mechanics. Otherwise you are in danger of chosing beautiful but wrong axioms.

128. **Hech Baan**
June 6, 2006

Dear Eugene,

I understand your points. I can assure you that no any sensible physicist will go and build a physical theory based on abstract axioms alone. That's not what mathematical consistency and beauty is. For instance, I'm reasonably happy with GR and QFT, but they are not mathematically consistent theories. And as a matter of fact I don't think physical theories have to be absolutely mathematically consistent per se. My point is that there are at least two main steps in creating theories. That's how I understood Einstein's quote.

1. Mathematical: Pure logical reasoning (Postulate principles and make predictions)
2. Physical: Experiments (Check your predictions)

One has to apply both steps to find/change/discard physical theories. Today in string/M-theory we are stuck at step 1. We all want to move to the step 2 ASAP. It's proved to be very difficult.

129. **Eugene Stefanovich**
June 6, 2006

Hech Baan:

For instance, I'm reasonably happy with GR and QFT, but they are not mathematically consistent theories. And as a matter of fact I don't think physical theories have to be absolutely mathematically consistent per se.

o.k.

That's how I understood Einstein's quote.

1. Mathematical: Pure logical reasoning (Postulate principles and make predictions)

Did you notice a contradiction in your words? If the theory is not *absolutely mathematically consistent* then you cannot claim that you used *pure logical reasoning*. Or, possibly, your system of postulates was not self-consistent to begin with, so the pure logical reasoning wouldn't work with it? Maybe that's why it is so difficult to move to the step 2?

130. **Hech Baan**
June 6, 2006

Dear Eugene,

Yes, there is a contradiction in my words. If you very quick and read my last posting addressed to Bert, which I suspect Peter deleted, you would have a different prospective to my approach.

I didn't deliberately use axiom or postulate; I used principle in step 1. They are physical not mathematical objects. In step 1 one has to translate physical principles into mathematical axioms in order to apply pure logical reasoning. But, doing this one introduces inconsistencies. Kant explained this beautifully in his thought provoking work. That's the reason you get mathematically inconsistent and physically meaningful theories like GR and QFT.

131. **Jonathan Vos Post**
June 7, 2006

"knotted string" is surely being facetious/ironic in saying: "Feynman was really a hateful anti-science crackpot!" and quoting from – R. P. Feynman, Character of Physical Law, November 1964 Cornell Lectures, broadcast and published in 1965 by BBC, pp. 57-8. Some context for his quote: (1) he was conceptualizing the Quantum Computer. He was wrong in details, but right in principle, and is the grandfather of Quantum Computing just as he is the greatgrandfather of Nanotechnology.

I am not objective in my respect for him, my teacher and coauthor, one of the greatest minds and greatest teachers of the 20th century.

(2) As to "… the hypothesis that ultimately physics will not require a mathematical statement, that in the end the machinery will be revealed, and the laws will turn out to be simple, like the chequer board with all its apparent complexities." [BBC spelling of what Feynman would surely render as "checker"] Feynman oscillated between this Wolfram New-Kind-of-Science Occam's razor position, and one which he spoke about with me several times: that the universe may have an infinite number of natural laws, although some only emerge under unusual boundary conditions.

There is a new Feynman movie being short right now. "Challenger" — starring David Straithairn — is about his role on the Challenger Commission. The Producer bought me lunch last week and picked my brains about Feynman and the Space Shuttle (on which I was a software engineer for Rockwell).

132. **Eugene Stefanovich**
June 7, 2006

Hech Baan:

I have a different attitude. I think, if a theory lacks logical consistency, then its foundations should be examined and the theory either should be modified or discarded altogether depending on the results of this investigation. In my view, QFT belongs to the former category, while GR to the latter one.

133. **Hech Baan**
June 7, 2006

Dear Eugene,

Logical consistency isn't binary, true or false, for fundamental physical theories. E.g. GR is logically consistent for some parameters and inconstant for others. The same is true for QFT. You can't discard them because they aren't absolutely consistent. That was one of my points, I don't think there is an absolutely consistent theory of everything all our theories are/will be consistent for some domain and inconsistent for others. Our task is to enhance the theories to extend the domain of validity/consistency.

134. **Eugene Stefanovich**
June 7, 2006

Hech Baan:

The inconsistencies I was talking about are not limited to some local domains. They are rather fundamental:

In QFT : this theory does a good job in calculating scattering (i.e., the S-matrix) which is just a special case of the time evolution. However, it is impossible to obtain the detailed time evolution of wave functions or observables from relativistic renormalized quantum field theory. This theory does not have a well-defined finite Hamiltonian (= the generator of time translations).

In GR : the problem goes back to the unification of space and time in a single 4-dim continuum already in Einstein's special relativity. Such an unification is only possible when boost transformations of space-time coordinates of events are given by universal linear Lorentz formulas independent on the physical nature of these events and independent on the interactions in the physical system where these events occur. It is true that Lorentz formulas can be rigorously derived from two Einstein's postulates for events with light pulses or non-interacting particles. However, the generalization of these formulas to all events with interacting particles is just an unfounded assumption. Moreover, it can be shown that this assumption directly contradicts the Poincare group properties of inertial transformations.

Furthermore, the treatments of space and time in GR and in QFT (or, more generally, in QM) are fundamentally incompatible. In QM the space and time coordinates are not interchangeable as in GR. Position is a quantum observable with a Hermitian operator associated with it (Bert Schroer would certainly disagree here). Time is a numerical parameter in QM. There is no observable "time", and there is no corresponding "time operator".

I am sure that within current formulations of QFT and (especially) GR their unification and the construction of a consistent relativistic quantum theory of gravity is impossible. Several decades of futile attempts by leading theorists just confirm this conclusion. Before thinking about unification we need to clean up our fundamental theories (QFT and special relativity) and make them consistent both internally and with each other.

135. **knotted string**
June 8, 2006

Jonathan Vos Post,

There were two choices: be facetious/ironic about Feynman's demand for models to be based on facts, and hatred of abject speculation

or

Quote some of Feynman's closing remarks in 1965 which predict the current crisis with stringy speculation people taking control:

'There will be a degeneration of ideas, just like the degeneration that great explorers feel is occurring when tourists begin moving in on a territory.'

(Character of Physical Law, BBC, 1965, p. 173.)

However, despite Feynman's hatred of superstring theory at his peak (around the time he discovered the O-ring problem behind the Challenger space shuttle disaster), the stringers will claim that they are the great explorers and everyone with checkable ideas are tourists.

It's like a world where you have 'professors of mountain ascent' who have uncheckable ideas about using extra dimensions to succeed, sneering at anybody down to earth.

One historical precedent is of course British Admirality problem of finding longitude. Newton thought clocks would always be mechanically defective, and looking at stars solved the problem. However, cloud cover and stormy seas (causing black eyes when using an optical instrument on deck) made Newton's idea rubbish.

When Harrison simply developed a clock that was reliable enough to measure longitude, everyone was too biased in favor of using stars, and didn't want to award the prize. This is of course the usual way. Difficult problems can have unexpectedly simple solutions, which causes conflict between experts and 'simpleton'.

136. **Bert Schroer**
June 8, 2006

Eugene,
I do not disagree with what you say about QM, it is your QM straightjacket you want to impose on QFT where our viewpoints differ significantly. Even in QM your radicalism (before with respect to me, now Hech Baan has taken up certain parts of my role) may prevent you to be able to accept useful contributions as
http://xxx.lanl.gov/abs/quant-ph/0207048

137. **Eugene Stefanovich**
June 8, 2006

Bert,

I take your calling me "radical" as a compliment, but not a deserved one. I think my views are very conservative. I maintain that the rules of quantum mechanics must be strictly obeyed in both non-relativistic and relativistic regimes. The only significant difference of the latter regime is that the Hamiltonian may contain interaction terms that change the number of particles. This is the only important distinction between QM and QFT (in my interpretation).

Thank you very much for the reference. This is a good example of how the issue of time should *not* be addressed in QM, in my opinion. Time is not an observable in the usual meaning of this word, and there is no point to associate an operator or a POV measure with time.

When experimenters measure true observables (e.g., position, momentum, spin, etc.) they bring their physical system into contact with the measuring apparatus. The result of measurement depends on the nature of the observed system and on the state of the system. When the measurement is done, the experimenter also looks at the wall clock and writes down the reading of the clock to his log. So, each measurement has a numerical label attached to it – the reading of the clock at the time of measurement. The value of this label is completely independent on the nature of the physical system and its state. This time label is an attribute of the measuring apparatus rather that a property of the observed system. Therefore, time is not an observable in the usual sense.

There are nine other numerical parameters that, together with time, identify the measuring apparatus, or observer, or reference frame. These are three components of position, three orientation angles, and three components of the velocity of the observer. These ten numbers form a parameterization of different inertial observers and of Poincare group transformations between these observers.

138. **Arun**
June 9, 2006

> When experimenters measure true observables (e.g., position, momentum, spin, etc.) they bring their physical system into contact with the measuring apparatus. The result of measurement depends on the nature of the observed system and on the state of the system. When the measurement is done, the experimenter also looks at the wall clock and writes down the reading of the clock to his log. So, each measurement has a numerical label attached to it – the reading of the clock at the time of measurement.

Two comments

1. the measurement of position localizes the measured particle but just as the time of measurement is read off the wall clock, the position is read off a ruler. Sometimes it doesn't seem that asymmetrical between space and time.

2. Space and time seem even more on an even footing in QFT where they merely label the fields.

139. **Eugene Stefanovich**
June 9, 2006

Arun:

1. the measurement of position localizes the measured particle but just as the time of measurement is read off the wall clock, the position is read off a ruler. Sometimes it doesn't seem that asymmetrical between space and time.

There is an asymmetry. The measurement of position fully depends on the state in which the particle is prepared. If you prepare the particle in a different state, the results of position measurements will be different. So, we may confidently say that position is a property of the particle. Position is an observable that should be represented in quantum mechanics by a Hermitian operator in the Hilbert space.

On the other hand, the wall clock does not care which physical system we are observing and what is the state of this system. The reading of the clock will be just the same regardless of the properties of our system. So, time has no relationship to the observed physical system, and introducing the operator of time in the Hilbert space is not justified.

2. Space and time seem even more on an even footing in QFT where they merely label the fields.

You are right that parameters x and t in the quantum field psi(x,t) are merely labels. Do they have any relationship to real observable positions and times? Or they are simply formal numerical parameters? I tend to think that the latter is true. Indeed, when we form the interaction Hamiltonian V(t), we integrate a product of quantum fields psi(x,t)phi(x,t)… over x. When this interaction Hamiltonian is inserted in the Feynman-Dyson formula for the S-matrix, it is further integrated over t from minus to plus infinity.
As a result we have the S-matrix which doesn't care about the detailed time evolution and positions of particles at intermediate times. It simply maps the asymptotic state in the distant past to the asymptotic state in the distant future. The parameters x and t are no longer present, which indicates (at least to me) their formal character.

I think it is unfortunate that quantum field parameters are denoted by the same letters x and t which normally stand for physical position and time. It would create less confusion if we used some neutral labels, like 'a' and 'b'.

Lusztig Birthday Conference

June 4, 2006
Categories: Uncategorized

I was up in Boston for a few days, and managed to attend a few of the talks at the conference in honor of George Lusztig's 60th birthday. Lusztig started out his career in geometry and topology; his thesis was in the area of index theory, working with Michael Atiyah and using the families version of the index theorem. He soon turned his attention to representation theory, which is the field that he has worked in for most of his career, often from a quite algebraic point of view. His papers are dense and can be difficult to read, especially for someone like me who is not so algebraically inclined, but many speakers at the conference remarked on how their work had drawn important inspiration from one or another of these papers.

Among the things he is famous for are his work on quantum groups, on the representation theory of reductive groups over finite fields (called Deligne-Lusztig theory, for an introduction, see here), on a whole new field in Lie theory known as Kazhdan-Lusztig theory (for an introduction, see the article by Deodhar in the proceedings of the 1991 AMS summer institute on algebraic groups), and many other things.

Of the few talks I heard at the conference, two were really exceptional. One of these was by Michael Atiyah, with the title "Quaternions in Geometry, Analysis and Physics". He began by explaining that not only was Lusztig 60, but, if he were alive, the Irish mathematician Hamilton would be 200. There's a famous story about Hamilton's discovery of the quaternions: this took place in a flash of insight on October 16, 1843, after which he supposedly engraved the defining relations of the quaternion algebra into a Dublin bridge. Atiyah described a piece of history I didn't know, showing an extract from a 1846 paper of Hamilton's in which he takes a square root of the Laplacian and essentially writes down the Dirac equation (in Euclidean signature, this was long before special relativity…).

Hamilton was very taken with quaternions as a generalization of complex numbers, and wanted to develop a "quaternionic analysis" that would be a generalization of complex analysis, a project he thought would take him at least ten years. It turns out that you can't simply generalize the beautiful subject of complex analysis and algebraic geometry over the complex numbers to the quaternionic case. Because of non-commutativity, polynomials behave very differently. Atiyah explained that in his view the correct generalization of complex analysis to the quaternionic case was Penrose's twistor theory. Here one considers all possible ways of identifying $\mathbf{R}^4$ with $\mathbf{C}^2$, forming a 3 complex dimensional "twistor space". Complex analysis on this twistor space is what Atiyah claimed should be thought of as the quaternionic analog of complex analysis (on the complex plane).

He reviewed the story of how solutions to various linear equations are related to sheaf cohomology groups on the twistor space, then went on to the non-linear case, where solutions of the anti-self-dual Yang-Mills equations correspond to holomorphic bundles on the twistor space. One can generalize twistor theory to what Atiyah claimed should be thought of as quaternionic analogs of Riemann surfaces: 4d Riemannian manifolds with holonomy in Sp(1)=SU(2), these are self-dual Einstein manifolds, what Penrose would call a "non-linear graviton" (although this is the Riemannian, not pseudo-Riemannian case). The twistor space of these 4d manifolds is a 3d complex manifold, and Atiyah considers complex analysis on this to be the quaternionic analog of complex analysis on a Riemann surface.

The quaternionic analog of higher dimensional complex manifolds are manifolds of dimension 4k, with holonomy Sp(k). Unlike in the complex case, there are few compact examples. Atiyah went on to discuss how examples (mostly non-compact) could be generated as quotients using the quaternionic analog of symplectic reduction. He described several different classes of examples, noting that this construction first appeared in work with physicists studying supersymmetric non-linear sigma models. While I was a post-doc at Stony Brook, Nigel Hitchin was visiting there and working with Martin Rocek and others on this, leading to the 1987 paper in CMP by Hitchin, Karlhede, Lindstrom and Rocek. Atiyah said that he wouldn't try and describe the relation to supersymmetry, since "I don't know much about supersymmetry, and if I tried to explain it, you would understand even less". That Atiyah, after many years of working in this area, still finds supersymmetry to be something he can't quite understand, is an interesting comment, reflecting the way the subject is still very imperfectly integrated into mathematician's traditional ways of thinking about geometry and algebra.

Atiyah also commented that off and on over the years he had pursued the idea that quantum groups (which aren't quite groups), are in some sense the quaternionification of a Lie group (which doesn't quite exist). He said he hadn't been successful with this idea, but still thought there was something to it, and hoped that someone else would take up the challenge of trying to make sense of it.

The second wonderful talk I heard was that of Igor Frenkel, from Yale, with the title "Quantum deformation, geometrization, categorification: What is next?". Unlike Atiyah's talk, which I pretty much completely understood, Frenkel's covered much too quickly a lot of material I had never understood, but putting it into an intriguing perspective close to the unsolved problems that seem to me the most important ones for mathematicians and physicists to be looking at. Frenkel began by saying that for many years he had been trying to solve the problem of how to generalize the constructions of representations of loop groups that are related to 2d CFT to representations of 3d gauge groups that should be related to 4d QFT. Some of his thoughts about this are in the write up of his talk at the 1986 ICM. He described himself as having for a long time given up on this problem, moving on to simpler things that he could do: quantum groups which are deformations of the affine Lie algebra story. He went on to talk about "Geometrization", by which he meant the principle that "all structure constants are Euler characteristics of some variety, all vector spaces are cohomologies", then "Categorification", to him the principle that "all structure constants are dimensions of vector spaces, all vector spaces the Grothendieck groups of an Abelian category". Many of the examples he was using to flesh this out are not well-known to me, I need to do some serious work learning about them before I can say that I clearly understand exactly what he has in mind here.

The last part of his talk, the "What Next?", went by way too fast but sounded fascinating. He claimed to have some new ways of thinking about the problem of what a representation of these higher dimensional analogs of loop groups should me. I hope to learn more from him in the future to get a better idea of what he has in mind here. He and collaborators at Yale have papers forthcoming, which I look forward to reading. When and if I ever better understand this stuff, I may try and write about it again here.

Comments

1. **Lubos Motl**
   June 4, 2006

   Not sure why he thinks that the complex analysis on twistor space generalizes complex analysis to the case of quaternions. What is quaternionic about the twistor space? I don't see any noncommutative algebra here. Is it just about counting dimensions?

   The interpretation of anti-self-dual Yang-Mills solutions in terms of twistor space you described seem to miss all the new developments since the 2003 Witten paper – which is an expansion around the self-dual Yang-Mills to the full Yang-Mills. The research since that paper has at least doubled the amount of interesting insights in this realm.

   Supersymmetry has not yet been seen in the colliders but it is an extremely physical framework, and it is not too surprising that pure mathematicians may find it counterintuitive. Surely mathematicians in the 21st century will need SUSY because string theory will dominate mathematics of the 21st century. That's why mathematicians will have to be learning many things that are currently taught in physics departments only.

   Strictly speaking, manifolds of Sp(k) holonomy don't define quaternionic manifolds. The holonomy of quaternionic Kahler manifolds is Sp(k) times Sp(1) because it can allow a multiplication by quaternions (Sp(1)) – or quaternionic matrices (Sp(k)) – from both sides. And they don't commute with each other. The manifolds of the more special, Sp(k) holonomy are called hyperKahler manifolds, not quaternionic manifolds.

2. **woit**
June 4, 2006

Lubos,

Atiyah's point was that what you get by naively replacing complex variables by quaternionic ones is not the really interesting generalization of complex analysis that you get in the twistor space picture. He was using quaternions to motivate this, but the twistor space of R^4 is something different than just using quaternions to put a multiplication on R^4.

Related to this, the 4k dim manifolds that Atiyah was discussing were the hyperkahler ones, not the quaternionic kahler ones.

3. **Lubos Motl**
June 4, 2006

Dear Peter, I understand that the twistor is something "different" than using the quaternion multiplication table. The word "different" is clear. What is not clear is why you or he uses the "same" word for "different" things. 😉

Your text also made it clear that he was using Sp(k) holonomy manifolds. But I was trying to convince you that you incorrectly called them the quaternionic analogue of Kahler complex manifolds.

The quaternionic analogue of Kahler (U(k) holonomy) manifolds are the quaternionic Kahler manifolds whose holonomy is Sp(k).Sp(1).

The manifolds with Sp(k) holonomy are called hyperKahler manifolds, and they are, in some sense, the quaternionic generalization of (SU(k) holonomy) Ricci-flat Kahler or Calabi-Yau manifolds. Your sentence about the quaternionic generalization is not quite right.

4. **Peter Woit**
June 4, 2006

Lubos,

I know very well what the difference is between a hyperkahler and a quaternionic kahler manifold. So does Atiyah. I was reporting on his talk, and quoting him; he was the one claiming that hyperkahler (not quaternionic kahler) manifolds are the interesting quaternionic analog of kahler manifolds. If you don't like this, please go write to Sir Michael and explain to him why he's wrong.

5. **Lubos Motl**
June 4, 2006

I agree that the hyperKahler manifolds are more interesting than quaternionic Kahler manifolds, but I disagree that they are the generalization of Kahler manifolds to the case of quaternsions. Instead, hyperKahler manifold is the quaternionic generalization of Ricci-flat Kahler manifolds whose holonomy is SU(n), not U(n).

What you wrote is, in fact, completely incorrect. You did not even use the word "Kahler". You wrote that Sp(k) manifolds generalize "complex manifolds". That's nonsense because "complex manifolds" can have virtually any holonomy you want while Sp(k) is highly constrained. What you wanted to say was "Ricci-flat Kahler manifolds", not "complex manifolds".

6. **Lubos Motl**
June 4, 2006

If Sir Atiyah used your sentence literally and meant every word in that sentence to be treated seriously, I will happily explain the error to Sir Atiyah, too. Unlike you, I don't think that certain people above some level of dignity are infallible and uncriticizable.

7. **woit**
June 4, 2006

Lubos,

If you want to explain to Sir Michael your views on why he's wrong to think of hyperkahler manifolds as the quaternionic generalization of Kahler ones and why his analogy is "nonsense", definitely go ahead and e-mail him. I'm sure he'll be fascinated by your insights into this and glad to be set straight.

Then again, before you hit send on that e-mail, you might take a moment to reflect and realize that there are some people in this world who know about a hundred times more than you do about certain subjects, and geometry might be one of them.

8. **Lubos Motl**
June 4, 2006

Dear Peter, I don't have any trustworthy data that would indicate that Sir Atiyah makes incorrect analogies between different structures that would resemble your incorrect sentence.

9. **sunderpeeche**
June 4, 2006

If the talk is available online (proceedings or arXiv) that would settle the issue. Why argue the details of what is essentially second-hand information?

10. **Peter Woit**
June 4, 2006

Sunderpeeche,

The talk is not available online. You're quite right, this is second-hand information, produced by me wasting much of my evening trying to write out the clearest explanation I could of an analogy ("analogy", as in not precisely the same, check your dictionary) described by one of the world's greatest mathematicians in a talk I attended, based on my written notes and what I remember.

Jeez, why waste time trying to explain something interesting here? I should just go back to string theory bashing.

11. **Carl Brannen**
June 4, 2006

Among those who practice David Hestenes' Geometric Algebra, it is said that this is the natural generalization of complex analysis. An introduction is here:

http://faculty.luther.edu/~macdonal/GA&GC.pdf

Carl

12. **MathPhys**
June 4, 2006

Peter,

As far as I'm concerned, you haven't wasted your evening and I want to thank you very much for your efforts to keep us all informed.

We all benefit from your reporting, including the emotionally unstable kid who reads your blog so frequently and so thoroughly that he's typically the first to write a response to it.

13. **John Baez**
June 4, 2006

It's nice to hear that Frenkel continues to explain the importance of categorification. I got excited about this concept around 1994 when I read his paper with Louis Crane on Hopf categories and the canonical bases for quantum groups; you can see my excitement in "week38" of This Week's Finds. It took a while for this idea of Frenkel's – categorifying quantum groups and their resulting tangle invariants – to bear fruit, but his student Khovanov has turned it into a hot topic. Since you're presumably right next door to Khovanov, you could probably get him to explain anything about categorification that interests you! I'm very excited that my student Aaron Lauda is going to Columbia next year to work with Khovanov on this stuff. I hope he looks you up sometime.

I was in Cambridge this weekend too, but too busy to attend any talks. I'll probably be free on Monday night. If any cool people want to talk, email me. I'd like to have dinner in Harvard Square. I haven't had time to go there this visit, and I haven't been there for over 5 years. I hear it's been much gentrified since I was a grad student here back in '82-'86.

14. **D R Lunsford**
June 4, 2006

Atiyah's statement RE quaternion analysis is absolutely fascinating and obviously correct. It's the conformality that makes complex analysis so rich and interesting.

-drl

15. **Tony Smith**
June 5, 2006

Carl Brannen mentions "David Hestenes' Geometric Algebra" as "the natural generalization of complex analysis".
Geometric Algebra is basically Clifford algebra.
The real Clifford algebra Cl(0,1) has dimension 2^1 = 2 and is the Complex numbers.
The real Clifford algebra Cl(0,2) has dimension 2^2 = 4 and is the Quaternions.

Peter mentions with respect to Atiyah's talk "… a "quaternionic analysis" that would be a generalization of complex analysis …".

Since both Complex numbers and Quaternions are Clifford algebras, a natural way to look at "… a "quaternionic analysis" that would be a generalization of complex analysis …" is to look at Clifford analysis.

John Ryan, in math.CV/0303339 , Introductory Clifford Analysis, said:

"… one can extend basic results of one complex variable analysis on holomorphic function theory to four dimensions using quaternions. … This was developed by the Swiss mathematician Rudolph Fueter in the 1930's and 1940's … So it seems reasonable to ask if all that is known in the quaternionic setting extends to the Clifford algebra setting … the answer is yes …
…[the] type of diffeomorphisms acting on subdomains of Rn [that] preserve Clifford holomorphic functions … is a conformal transformation …
… for dimensions 3 and greater the only conformal transformations … are Moebius transformations …".

Lars Ahlfors, in his paper Clifford Numbers and Moebius Transformations in R^n, published on pages 167-175 of the book Clifford Algebras and Their Applications in Mathematical Physics, Proceedings of NATO and SERC Workshop, Canterbury, Kent, 1985, edited by Chisholm and Common, NATO ASI Series (Reidel 1986), said:

"… Moebius transformations in any dimension can be expressed through 2×2 matrices with Clifford numbers as entries. This technique is relatively unknown in spite of having been introduced as early as 1902 … by K. Th. Vahlen …".

Pertti Lounesto, in his book Clifford Algebras and Spinors (Cambridge, 2nd edition, 2001), said (denoting nxn matrices of X by Mat(n,X) and denoting the quaternions by H):

"… Cl(p+1 , q+1) = Mat(2, Cl(p,q)) …
… Cl(1,3) = Mat(2, H) which implies Cl(2,4) = Mat(4, H) …".

Since the bivector Lie algebra of the Clifford algebra Cl(2,4) gives the Lie group Spin(2,4) = SU(2,2) that is the 15-dimensional Conformal group over Minkowski spacetime R(1,3),
the quaternionic structure of that Conformal group is made clear by Cl(2,4) = Mat(4, H).

Roger Penrose, in The Road to Reality (Knopf 2005) said at page 972, using notation O(2,4) for the 15-dimensional Conformal group:

"… The shortest … way to describe a (Minkowski-space) twistor is to say that it is a reduced spinor (or half spinor) for O(2,4). …".

The above outline shows:

1 – a useful quaternionic "generalization of complex analysis", based on Clifford algebra (as indicated by Carl Brannen's comment)

2 – the answer to Lubos Motl's question "What is quaternionic about the twistor space?"

3 – more details about the view (expressed by Atiyah) that "the correct generalization of complex analysis to the quaternionic case was Penrose's twistor theory".

All the above is consistent with D. R. Lunsford's comment that what makes such stuff "so rich and interesting" is "the conformality".

Tony Smith

16. **Jonathan Vos Post**
June 5, 2006

We used quaternions a lot in GNC (Guidance, Navigation & Control) software for spacecraft at JPL, yet I wrote ground test software that used Euler angles and matrices to validate & verify the flight software of Gaileo, to avoid repeating any conceptual errors of the flight software. I got deep into qaternionic analysis then and since. I've published a paper deadling with whether certain physical quantities assumed to be real (such as momentum and acceleration) for elementary particles, might actually be complex, or quaternions, or Cayley algebra…

As to manifolds, what's the deal on the latest episode of this saga: Joe Lau writes on Slashdot to mention a story running on the Xinhua News Agency site, reporting a proof for the Poincare Conjecture in an upcoming edition of the Asian Journal of Mathematics.

http://news.xinhuanet.com/english/2006-06/04/content_4644754.htm

From the article:

"A Columbia professor Richard Hamilton and a Russian mathematician Grigori Perelman have laid foundation on the latest endeavors made by the two Chinese. Prof. Hamilton completed the majority of the program and the geometrization conjecture. Yang, member of the Chinese Academy of Sciences, said in an interview with Xinhua, 'All the American, Russian and Chinese mathematicians have made indispensable contribution to the complete proof.'"

17. **Thomas Larsson**
June 5, 2006

Frenkel began by saying that for many years he had been trying to solve the problem of how to generalize the constructions of representations of loop groups that are related to 2d CFT to representations of 3d gauge groups that should be related to 4d QFT. Some of his thoughts about this are in the write up of his talk at the 1986 ICM.

Another place where this thoughts as of 1993 can be found is hep-th/9303047. Ref 10 of that paper contains the first interesting representations of multi-dimensional current algebras. The same construction applied to multi-dimensional diffeomorphism algebras led Rao and Moody to the first interesting representations of the multi-dimensional Virasoro algebra.

There is also another extension of current algebras in 3D, the Mickelsson-Faddeev extension. However, it was proved by Pickrell that this algebra lacks unitary reps on a separable Hilbert space; for a simple plausibility argument, see math-ph/0501023, where the two types (KM and MF) of current algebra extensions are contrasted in a Fourier basis.

18. **Aaron Bergman**
June 5, 2006

Re: Poincare: I'm guessing they're just claiming to have finished filling in the details of Perelman's program. A fair number of people have been working on that as I understand it.

19. **woit**
June 5, 2006

Re: Poincare

Yes, Cao and Zhu are claiming to have come up with a full proof based on Perelman's outline. It has been vetted by Yau and is supposed to appear in this month's Asian Journal of Mathematics, which is on-line now, minus the pdf file of the article. I was waiting for the article to appear before writing about this, if anyone knows where a copy is available, let me know.

20. **Bert Schroer**
June 6, 2006

Peter quoted
"Atiyah said that he wouldn't try and describe the relation to supersymmetry, since "I don't know much about supersymmetry, and if I tried to explain it, you would understand even less". That Atiyah, after many years of working in this area, still finds supersymmetry to be something he can't quite understand, is an interesting comment, reflecting the way the subject is still very imperfectly integrated into mathematician's traditional ways of thinking about geometry and algebra."
I would like to add that also modular localization (the adaptation of Tomita-Takesaki modular theory to local quantum physics) which is presently the best sniffer dog in the conceptual arsenal of theoretical particle physics (a gift of AQFTists, who were deeply involved in its independent discovery within a more limited context) is also unable to attribute any significance to supersymmetry. If one starts from a given observable local net structure (pure bosonic in the sense of spacelike commutativity), and hence leaves its previously mentioned very radical and yet insuffiently understood monade approach (leading to spacetime symmetries and observable nets from more basic assumptions of the kind favored by Lee Smolin) outside, there is the DHR theory (which may be viewed as part of modular theory) which is capable to uniquely extend the observable algebra to the charge-carrying field algebra from which one can then read off the compact group symmetry (in low dimensional spacetimes the picture is more complicated). As mentioned on a previous occasion it does so in the inverse problem spirit of Marc Kac's "how to hear the shape of a drum". It leads to compact groups, but not to graded groups. Of course it is not forbidden to extend to supersymmetries by hand, even though modular theory which gives spacetime- as well as inner symmetries does not lead to susy in any natural way.
In addition there is the curious observation that putting a supersymmetric QFT into a heat bath, the resulting situation is characterized by a collape and not a spontaneously broken symmetry as it would occur with Lorentz symmetry
http://br.arxiv.org/abs/math-ph/0604044 see in particular ref. [3] and [4]
The situation throws doubt whether the spontaneous breaking mechanism for supersymmetry permits any consistent formulation (i.e. even outside the heat bath setting) at all. Supersymmetry looks like a man-made thing which is despite its unattractive rigid appearance apparently extremely fragil.

21. **Bert Schroer**
June 6, 2006

Today seems to be a really bad day for supersymmetry
http://br.arxiv.org/abs/hep-th/0606029

22. **Chris Oakley**
June 6, 2006

… but a good one for satanists. Maybe Lubos foresaw all of this in a dream, where the String God appeared to him and intoned the words: "Lubos, my good and faithful servant. I can protect you only until the satanists rise again. Then nameless evils will happen, and I will no longer be able to prevent the publication of Woit's book."

23. **David Corfield**
June 6, 2006

I had only a second-hand commentary on Frenkel's conception of categorification by Dror Bar-Natan about half way down this post. From the perspective presented in the first half of the post, which might be phrased "If it moves, salute it; if it doesn't, categorify it", this is somewhat limited.

24. **D R Lunsford**
June 7, 2006

Well 6's are representative of "hybrid strings", that is, those that close on themselves but leave a tell-tale serif flapping in the vacuum. So 666 is really the Mark of the Proton, forseen in the Book of Zweig, and detailed in Gell-Mann's Letters to the Experimentalists.

-drl

25. **Chris Oakley**
June 7, 2006

The Coming of the Experimentalists, as foretold in the Book of Zweig, is feared above all things by those who worship the String God. If I may quote a passage (Book 5, v. 12-15):

> 12. And those who were content to dwell in the realms of the higher dimensions without the aid of illegal substances took counsel among themselves, for they were affrighted by the angry heathens who said unto them, "Name one thing, *one thing*, that thy bunkum doth predict that can be tested in a laboratory?"
>
> 13. So the Stringers girded their loins and went unto Princeton, to take counsel with the one they call the Pope who dwelt there; for he is held in honour above all others, and understands the workings of the mind of the String God better than any.
>
> 14. And for forty days and forty nights The Pope and his senior priests debated and prayed to the ten-dimensional god, and at length The Pope did say unto his followers, "The String God has spoken, and he spake thus. The sun shall shine upon us and all our endeavours; yea, we will continue to be able to pull the wool over the eyes of the retarded bureaucrats at the DOE and NSF. But the God warned me of 666. He did say unto me that after 666 the power of the ignorant: those not smart enough to do String Theory, and those smart enough but too crass to appreciate its beauty will be granted power by the Evil One".
>
> 15. But the people were confounded. For they knew not the meaning of "666".

26. **Alejandro Rivero**
June 7, 2006

666 means read/write for owner, group and others. But no execute permisions. Better 777.

27. **Tony Smith**
June 7, 2006

Chris Oakley said "… But the people were confounded. For they knew not the meaning of "666". …".

In the 6×6 magic square

01 35 34 03 32 06
30 08 28 27 11 07
24 23 15 16 14 19
13 17 21 22 20 18
12 26 09 10 29 25
31 02 04 33 05 36

the columns, rows, diagonals all add to 111 and the total number is 666.
Cornelius Agrippa (1486-1535) identified that 666 magic square with the sun
(see http://www.geocities.com/CapeCanaveral/Lab/3469/examples.html).

Maybe because some religions considered by Christians to be pagan
were sun-god religions, Christians demonized the sun-number 666.

Maybe, in Chris Oakley's Book of Zweig, verse 16. may have said:

16. What the people did not know was that 666 = Sun = Light of Experimental Evidence that is to come from the Temple of Experiment in Geneva, capable of destroying even that most fervently worshipped of Theoretical Gods, SuperSymmetry.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

28. **Chris Oakley**
June 7, 2006

Tony,

What you say is interesting, but is not what I have. My version reads:

> 16. But they sure as hell soon found out, as on the sixth day of the sixth month of the year two thousand and six, the Anti-String himself arose in power. And he was aided by the printers of Albion. And his wordy refutations of the stringy arts caused the higher-dimensional ones to tear out their hair and wail for vengeance.

29. **Thomas Larsson**
June 8, 2006

06/06 is the Swedish national day, which we celebrate, perhaps, because some obscure coup d'etat in 1809 replaced one king by another. 2006 is the first year it is a holiday.

30. **Alejandro Rivero**
June 8, 2006

I am intrigued: Why did you choose Zweig?

31. **Chris Oakley**
June 9, 2006

Alejandro – no idea. It seems to be lost in the mists of time. But to continue:

> 17. And yet the Stringers were not wholly unprepared for the onslaught of the Anti-String; for the one they call the Pope had foreseen the difficulty of keeping the share of the lion of the HEP theory budget when their metaphysical excursions were no more meaningful than the vapid meanderings of the acid-tripping punk philosopher.
> 18. "But surely," the Pope did say unto the people, "surely our wisdom is not merely of Great Beauty. Surely our writings do predict gravity, and manifold are the verifications thereof."
> 19. But the one who is known as Glashow, and who is held in high honour among the wise, did snort when he heard these words.
> 20. "This Pope of the Superstringers seemeth not to understand the meaning of the word 'predict'," Glashow did say unto the gathered multitudes of PBS. "He seemeth not to comprehend that gravity was known about before he and his followers did take the ten-dimensional path. If he desireth honour from the Swedish Sages then he will surely have to do better than rediscovering that which hath been known for many centuries."
> 21. But The Pope, who is wise and subtle, had foreseen many of the stratagems of his enemies, and took counsel with his most senior acolytes.
> 22. "We must be like Valhalla," he did say unto them. "We must gather heroes to dwell among us. Those who are strong and fearless. Brave men are needed to defend the Citadel of the String from the ravages of the uneducated philistines who would do us harm. And we must cast the net wide. No matter if they are of dubious mental stability provided they support out cause."
> 23. And although many brave men gathered round to defend the Citadel, none were as strong or fearless as Lubos of Bohemia, who did prostrate himself before the The Pope and pledge undying support and loyalty.
> 24. "I bring, O Master," Lubos, "a scourge upon your enemies! I promise ye that as long as I live, none will dare question the rightness of our quest, for they will have to get past me, and I will punish them immoderately!"
> And the stringers were well pleased.

Not Even Wrong in the Financial Times

June 5, 2006
Categories: Not Even Wrong: The Book

As a start on the project of reorganizing this weblog a bit to take into account the existence of the book, I've started using the "Categories" feature of WordPress. Postings about the book will be in a special category, all other postings will remain "Uncategorized". If you don't want to read any more about what is going on with the book, just access this weblog via the "Uncategorized" link over on the right panel.

This past weekend there was an [article in the Financial Times](#) by science writer [Robert Matthews](#) about the problems with string theory and the publication of my book. It's not a book review, but more of a commentary, and is far more critical of string theory than I am. To give you an idea, here's the lead paragraph:

They call their leader The Pope, insist theirs is the only path to enlightenment and attract a steady stream of young acolytes to their cause. A crackpot religious cult? No, something far scarier: a scientific community that has completely lost touch with reality and is robbing us of some of our most brilliant minds.

I thought the article was kind of over the top, but then I read Lubos's commentary on it, entitled [Robert Matthews: science-hater par excellence](#), which makes it seem rather moderate. He writes that a "senior physicist who is not a string theorist" sent him the article with the comment "a tendentious, malicious attack on scientists and through that on science itself." I can see why someone unhappy with the article might characterize it as "a tendentious, malicious attack on string theorists", but I don't see any sense in which it is an attack on scientists in general or on science itself. The one thing I really don't like about the article is the headline "Nothing is gained by searching for the 'theory of everything'", and the fact that at a couple points the writer implicitly identifies the search for a 'theory of everything' with doing string theory. I'm very much in favor of people continuing to search for a unified 'theory of everything', just think that string theory is a failed program for reaching this goal, something which needs to be acknowledged.

Doubtless the Financial Times will be getting various outraged letters from senior physicists, string theorists and non-string theorists, but I'd be a lot more willing to sympathize with their outrage at the article if they had ever expressed similar outrage at any of the extreme hyping and overselling of string theory that has gone on in the popular press over the last twenty years. Unfortunately I suspect that the next few years will see a lot of this kind of backlash against work on unified theories or on the use of sophisticated mathematics in fundamental physics. The theoretical physics community has done increasing amounts of damage to its own credibility because of the way string theory has been pursued and marketed, with the recent "anthropic string theory landscape" promotion providing a perhaps deadly blow. I'm afraid the near future will see de-funding not only of string theory, but of any other ambitious attempts to search for new ideas about how to unify fundamental physics.

One major source of continuing damage to string theory comes from the fact that by far its most active advocate on the Internet is Lubos Motl, and the fact that there is no evidence that his senior colleagues are willing to dissociate themselves from his behavior. Many younger string theorists are appalled by how he behaves, but too frightened of retribution to publicly say anything. Consider a recent review of my book posted on Amazon by a young string theorist:

Need cheering up? Get this book after reading the review below by Lubos Motl, then try to find out how he fabricated his "review". I'm a string theorist by the way, which is why I'm hiding behind a pseudonym (I don't want to be called a "science hater" by my seniors). This book makes a surprising effort to explain abstract mathematical concepts.

Very quickly after it (and any other positive reviews) appeared, it had garnered a large number of votes as not "helpful". Someone out there seems to be spending their time watching Amazon for positive reviews of my book, then repeatedly connecting to the site with different identities to vote against any positive reviews and for Lubos's review. Wonder who could be doing that?

Update: [CapitalistImperialistPig](#) asks a question that I've also been wondering about:

*Why exactly was it you gave this to LM? Luboš, of course, is a very clever fellow, but he also believes practically every crackpot notion known to the modern world – or at least the right wing ones. If you want to discredit some writing, sending LM to do the hit is *not* the way to win hearts and minds. Of course Lumo did say she (or he) was not a string theorist so …*

Comments

1. **Kea**
   June 5, 2006

   Peter

   I like the sound of your book. I think I will go and sit in the bookshop and read it.

2. **LambchopofGod**
   June 5, 2006

   I think a letter from PW to the Financial Times would be particularly appropriate and effective. Note that Matthews is more than a little ignorant — from his website I see that he has dreams of resurrecting the Steady State Theory, based on his own elementary misunderstanding of deSitter space. He's clearly a crank.

3. **woit**
   June 5, 2006

   No, Matthews is not at all "clearly a crank". String theorists can try and engage in ad hominem attacks on him the way they do on anyone who challenges their beliefs, but it's an ugly, unethical and unprofessional tactic. It's also one that is getting really ineffective as it becomes clear to more and more people that it's the only argument they have.

   I was thinking about whether I should write something to the FT, but crap like this doesn't encourage me. I guess at least tonight my feeling is that I'll write into the FT that Matthews has gone a bit too far when senior string theorists start writing into other publications to correct their overhyping of string theory.

4. **Censored**
   June 6, 2006

   I wrote something similar to your post in Lubos comments section.
   But it was deleted.

   The consensus with his/her views might be less than what it seems.

5. **Chris Oakley**

June 6, 2006

The Matthews article is IMHO completely fair and reasonable. A TOE is, at the moment, too big a step to take for anyone, String Theorists especially, and he is right to point this out.

Of course, as this is the first article to appear in the popular media that is strongly sceptical of ST, a lot of feathers have been ruffled, but most of what he says are things that String Theorists should have recognised themselves. It should not need an outsider to provide the bigger picture.

As for the reaction to the article, I would pose the question, “With friends like Lubos, does String Theory need any enemies?”

6. **Lubos Motl**
June 6, 2006

Only a very unreasonable person could believe that the distasteful anonymous first-poster is a young string theorist. Much like all other positive reviewers of Peter Woit’s book, he is a crackpot with IQ around 72, about 1/2 what he would need to be a string theorist. Don’t be kidding. It’s completely obvious that all of these people are complete idiots who have never seen the book, who have no idea about physics, and who have no idea what they’re talking about.

7. **Santo D'Agostino**
June 6, 2006

Lubos,

Consider your statement:

“… all of these people are complete idiots who have never seen the book …”

Yet you have posted on Amazon a review of the same book (Not Even Wrong) and you also have not read it!

Readers are buying the book, not a draft manuscript that has subsequently been revised and corrected who-knows-how-many times, as is completely normal in book publishing. Readers deserve a review of the ACTUAL BOOK, not a preliminary manuscript.

Would you find it acceptable for journal referees to reject one of your papers based on reading a preliminary draft, and ignoring the final submitted version?

I advise you to withdraw your review of NEW until you have actually read the book. If you don’t, consider the damage to (what is left of) your scholarly reputation.

All the best wishes,
Santo

8. **Lubos Motl**
June 6, 2006

Dear Agostino,

I have not only read it but read it in detail, and moreover I claim that every person with IQ above 80 must be able to determine this fact from my detailed review.

All the best
Lubos

9. **Santo D'Agostino**
June 6, 2006

Dear Lubos,

In your Amazon review, you state:

“I have read a different edition of the book than one offered here, and I apologize in advance for any inaccuracies in my review that this fact could cause. In fact, if any errors from the list below have been corrected, it was because of my feedback, so I think it is fair to list them anyway.”

Since this is the first published version of the book, you have not in fact read a different “edition,” but rather an unpublished manuscript, correct? I understand that English may not be your first language, and that therefore you may have to look up the definitions of “edition” and “manuscript,” but being a man of very high IQ, you will quickly understand the difference, if you don’t already.

My previous points remain. It is NOT fair to list errors in manuscript if they have been corrected in publication. Readers are not buying the manuscript that you read, they are buying the published book, and therefore deserve a review of the actual published book.

All the best,
Santo

10. **Peter Woit**
June 6, 2006

Santo,

It doesn’t matter which version Lubos is looking at. Besides the one Gev/Tev typo he found, his list of “errors” contains just his own errors, together with nonsense generated by making up a wild misinterpretation of something I wrote.

11. **Santo D'Agostino**
June 6, 2006

Peter,

Yes, good point. You mentioned this in an earlier posting, but I did not attend to it when replying to Lubos.

Your comment amplifies my point that it is inappropriate (indeed unethical) to review preliminary versions of a published work. I continue to call on Lubos to withdraw his Amazon review.

Best wishes,
Santo

12. **island**
June 6, 2006

FYI: Robert Matthews also wrote an article for the May/June issue of NewScientist Magazine… a review of the 20 year span between the first and second edition of a collection of essays by physicists, published as "The New Physics"

> Physics: Are we nearly there yet?
>
> What major insights have physicists stumbled on in the last 20 years? Hardly any…
>
> Now, almost 20 years on, the publication of a second edition of The New Physics provides an opportunity to discover how all those exhilarating advances have panned out. To judge by the accounts assembled by new editor Gordon Fraser, the short answer is: they haven't. Indeed, the impression is one of physicists not so much approaching a beckoning peak as wandering about in a thick fog.
>
> […]
>
> For sheer stagnation, look no further than the chapter on superstring theory, authored by one of its originators, Michael Green. Over the last 20 years, superstring theory has transmogrified into something called M-theory, which is even more mind-boggling than its forebear. But it is still no closer to being a genuine scientific theory…

And they say that Einstein wasted the last years of his life… uh huh

13. **hack**
June 6, 2006

That is really low, comparing physics hype from 20 years ago to reality! That just isn't done in polite society.

14. **LambchopofGod**
June 6, 2006

Matthews clearly is a crank. Three symptoms:
1. Emotional rants against the "establishment".
2. Having Big Ideas — see his stuff about reviving the Steady State theory. He's a genius, a true polymath. Not.
3. Arrogance, manifested as indifference to the fact that he can easily be exposed — he thinks that de Sitter space has a timelike Killing vector, and is willing to display this elementary ignorance for all to see.

It is of course no crime to be ignorant, but ignorant people should not publicly call into question people's competence or professional ethics. If they insist on doing so, they should expect a robust response. In particular they should not whine about ad hominem attacks when they themselves are guilty of that very thing.

15. **Peter Woit**
June 6, 2006

I've really had quite enough over the last few years of string theorists who can't answer any of the objections being made to the theory engaging in ridiculous, unfair, attacks on the competence of people who disagree with them, often in a cowardly fashion using the cover of anonymity. Instead of addressing what Matthews has to say on this topic, you go rooting around in his writings on other topics, looking for something you can take out of context and hold up as evidence of his incompetence. It's disgraceful, cowardly, dishonest and completely pathetic behavior. Don't do it here anymore unless you're willing to stop being anonymous so that we can all go through everything you have written to check it for possible evidence of incompetence.

And a string theory partisan accusing critics of string theory of arrogance? What a joke.

16. **Jayhog**
June 7, 2006

heh, what other crackpot theory does Luboš belive?

17. **anon**
June 7, 2006

Lamb chop of God, your three reasons apply to string theorists, but that doesn't them all cranks does it? Not in the media.

[String theorist name here] is clearly is a crank. Three symptoms:

1. Emotional rants against the Feynman et al.
2. Having Big Ideas — see his stuff about extra dimensions. He's a genius, a true polymath. Not.
3. Arrogance, manifested …

Jayhog, Lubos believes in everything which gets him publicity.

18. **island**
June 7, 2006

I don't think that it's fair to level everything that's wrong with the behavior of string theorists on Lubos, since there are other, more well-known proponents that are "Living Our Multiverse"… next-door to Alice.

There are valid "quasi"-steadystate models.

Remind me not to use exclamation points.

19. **Tony Jackson**
June 7, 2006

I'm a biochemist – so a long, long way from string theory- but not such a long way from previous interactions with Robert Matthews. I have found him infuriatingly dogmatic and not really interested in nuance. To be fair, he sees himself primarily as a journalist these days, and good copy to a tight deadline often has to place things in black and white. That said, and watching from the sidelines, I have a queasy feeling that he has indeed touched a raw nerve.

Seriously, PW, please write to the FT and make your more subtle position clear. Apart from anything else, if you don't, people who won't read your book will assume Mathews is faithfully repeating your exact position.

20. **Juan R.**
June 8, 2006

LambchopofGod,

No forget that standard string theory is a kind of modern "Steady State Theory".

Juan R.

Center for CANONICAL |SCIENCE)

21. **Who**
June 10, 2006

The Sunday Times review of the book is out
It is by John Cornwall, a 20th century historian known for his study of the relations between the 3rd Reich and the Vatican. He seemed to approve of the book's prose style, among other things, which is a good sign.

http://www.timesonline.co.uk/article/0,,2102-2214707,00.html

===sample quote===
…But is string theory true? Peter Woit, a mathematician at Columbia University, has challenged the entire string-theory discipline by proclaiming that its topic is not a genuine theory at all and that many of its exponents do not understand the complex mathematics it employs. String theory, he avers, has become a form of science fiction. Hence his book's title, Not Even Wrong: an epithet created by Wolfgang Pauli, an irascible early 20th-century German physicist. Pauli had three escalating levels of insult for colleagues he deemed to be talking nonsense: "Wrong!", "Completely wrong!" and finally "Not even wrong!". By which he meant that a proposal was so completely outside the scientific ballpark as not to merit the least consideration.

Woit's book, highly readable, accessible and powerfully persuasive, is designed to give a short history of recent particle and theoretical physics. Ultimately he seeks not only to rattle but to dismantle the cage of the string theorists…
===endquote===

the Harvard ranter had a kitten over this one

22. **Chris Oakley**
June 11, 2006

What gives the book its searingly provocative edge, moreover, is the fact that Woit isn't even a tenured professor, but a mere mathematics instructor specialising in computer systems.

(from the Sunday Times article)

I don't quite get this: Peter has done HEP theory up to post-doctoral level, teaches advanced courses and pursues his own research. These are also what tenured staff do, and at the same level – except that they probably know less about computers – so why the "mere"?

23. **knotted string**
June 11, 2006

I think what is happening is this. The first discussions of string theory occur in chapter 9. Before that you have a hundred pages describing the facts, experimentally validated theoretical physics.

This is probably why reactions are delayed. After you read the facts and see what the real problems with the Standard Model are (chapter 8), it is then obvious that mainstream stringy stuff simply isn't dealing with these problems. Then when you start the last section of the book, you are just swamped with stringy problems.

Page 177: supersymmetry can only be checked by using electroweak force strengths to calculate the strong force: it is 10-15 % higher than observation (which has an experimental accuracy of around 3 %). So the only precise check discredits it.

Page 179: supersymmetry suggests a vacuum energy density 10^56 to 10^113 times high.

Page 181: Gerard 't Hooft: '… I would not even be prepared to call string theory a 'theory' … just a hunch. … Imagine that I give you a chair, while explaining that the legs are missing, and that the seat, back and armrest will perhaps be delivered soon; whatever I did give you, can I still call it a chair?'

The abstraction issue is the cause of the Bogdanov brothers affair: it is disgusting that the state of physics is such that peer-reviewed Classical and Quantum Gravity and also Annals of Physics published their papers on the basis of evidently non-scientific reasons and later had to apologise for making an error.

Page 223: 'The main thing the journals are selling is the fact that what they publish has supposedly been carefully vetter by experts. … The referee's report reproduced earlier shows clearly the line of thinking at work: '… Nothing published in this whole area makes complete sense … maybe there's even an intelligible idea in here somewhere. Why not just accept it?"

At this point the reader must take a walk in the fresh air to try to remain sane. Probably Peter will delete this comment for being too long, but I just can't see how this situation can sort itself out ever.

24. **island**
June 11, 2006

> Pauli had three escalating levels of insult for colleagues he deemed to be talking nonsense: "Wrong!", "Completely wrong!" and finally "Not even wrong!".

What the heck? I thought that Pauli used only one single phrase that came from a too-philosophical meeting with David Bohm… ?

25. **Santo D'Agostino**
June 11, 2006

Update on my comments of 6 June, 2006, directed at Lubos Motl: I have posted similar comments to Lubos on his own blog today (in response to his outrage that the Sunday Times would print what he calls John Cornwell's malicious attacks). My comments were deleted and I am now banned from his blog.

Lubos has never responded to my statement that it is unethical to publicly "review" a book that one has admitted not reading. Instead he continues to insist that he did read the book "as a job," but he claims not to be able to reveal the details.

To repeat: In his Amazon review, Lubos admits to reading a different "edition" of the book. However, there is only one edition published so far, so one infers that he read a draft manuscript, not the actual published book.

It is unethical to review a draft manuscript and claim that it is a review of a published work.

I continue to call on Lubos to do the honorable thing and withdraw his Amazon review.

26. **woit**
June 11, 2006

Chris,
It's certainly true that my academic status is not as high as that of a tenured professor, and it's quite reasonable for Cornwell to point that out. He also calls me a "humble maths instructor", which I have no problem with, although, depending on your interpretation of what "humble" is referring to, some might strongly disagree with that.

27. **Chris Oakley**
June 11, 2006

Peter,

Yes but this whole thing is annoying. If they said a "mere janitor" (like *Good Will Hunting*) or "mere lab assistant" then fair enough, but the fact is that you are just as qualified to have research ideas or to talk generally about the subject as any one of your tenured colleagues. I hate the way that the academic system tries to turn itself into a hierarchical priesthood. The reality is that research is a free-for-all where the good ideas stick (or at least, *ought* to stick) regardless of who they originated from.

28. **mark adams**
June 12, 2006

As a layman whose daughter has just finished a physics degree at Imperial, I've been getting a fuzzy glimpse of her ex-boyfriend's work at at Fermilab and Cern. Plenty politics, plenty bs but in a noble cause he thinks. The SHC will establish…..In commodities' trading and oil refining I've nearly always dealt with known and unknown unknowns. Your manner passes my smell test for discrimination.

Way Too Much Stuff

June 5, 2006
Categories: Uncategorized

I ordinarily keep a short list on my desk of things I've seen recently that I'd like to write about here. The last few days this list has gotten way too long, so I'll try and deal with it by putting as many of these topics as I can in this posting.

The June/July issue of the AMS Notices is out, with many things worth reading. The two long articles are one by Ken Ono about Ramanujan and one by Arthur Jaffe telling the story of the founding of the Clay Mathematics Institute and the million dollar prizes associated with seven mathematical problems. There's also a book review of Roger Penrose's The Road to Reality, news about the proposed US FY 2007 budget for mathematical sciences research, and an account of a public talk by Michael Atiyah, who evidently closed by explaining some of his very speculative ideas about how to modify quantum mechanics, then said:

This is for young people. Go away and explore it. If it works, don't forget I suggested it. If it doesn't, don't hold me responsible.

The June issue of Physics Today is also out. In its news pages it reports that Robert Laughlin is out as the president of the Korea Advanced Institute of Science and Technology (KAIST), and will return to Stanford in July "where he plans to teach, research, and write 'anything that brings income.'" The report gives conflicting reasons for why things didn't work out for him at KAIST, but notes that "90% of KAIST professors gave him a vote of no-confidence and nearly all deans and department chairs quit their administrative posts to protest his continuing in the job."

There's an extremely positive review of Leonard Susskind's The Cosmic Landscape by Paul Langacker, which ends:

The Cosmic Landscape *is a fascinating introduction to the new great debate, which will most likely be argued with passion in the years to come and may once again greatly alter our perception of the universe and humanity's place in it.*

Why any particle theorist would want to encourage other physicists outside their field to read this book and give them the idea that it represents something theorists think highly of is very unclear to me.

Finally there's an article by Jim Gates entitled Is string theory phenomenologically viable? Gates aligns himself with the currently popular idea that string theory doesn't give a unique description of physics:

The belief in a unique vacuum is, to me, a Ptolemaic view – akin to that ancient belief in a unique place for Earth. As I wrote in 1989, a Copernican view, in which our universe is only one of an infinity of possibilities, is my preference, but there were very few Copernicans in the 1980s.

He seems to promote the idea that one should not use 10d critical string theory and thus extra dimensions, but instead look for 4d string theories, and that perhaps the problem is the lack of a "completely successful construction of covariant string theory." For more about this point of view, see Warren Siegel's website.

There are quite a few idiosyncratic things about Gates's article, including the fact that he refers to non-abelian gauge degrees of freedom as "Kenmer angles", after Nicholas Kemmer (not Kenmer) who was involved in the discovery of isospin.

Some of his comments about string theory are surprising and I don't know what to make of them. He claims that "some aspects of string theory seem relevant to quantum information theory", and the one supposed observational test of string theory he discusses is one I hadn't heard of before and am skeptical about (observing string-theory-predicted higher curvature terms in Einstein's equations through gravitational wave birefringence). His discussion of supersymmetry seems to assume that observation of superpartners is unlikely, since for reasons he doesn't explain he expects their mass to be from 1 to 30 Tev. Finally, he worries that people will not investigate things like covariant string field theory since we are about to enter an "era that promises an explosion of data". I certainly hope he's right about the forthcoming availability of large amounts of interesting new data.

The Harvard Crimson has an interesting article about Ken Wilson.

John Baez is getting ever closer to having a blog in its modern form, now he has a diary.

Read about the tough summer life of theoretical physicists in Paul Cook's report from Cargese (which reminded me of when I went there as a grad student), and JoAnne Hewett's report from Hawaii (which reminded me of a very pleasant vacation I spent on the Big Island).

Science magazine has an article about progress on increasing luminosity at the Tevatron, hopes for getting enough events there to see the Higgs before the LHC, and the debate that is beginning about whether to run the machine in 2009.

Slides are available from the Fermilab User's Meeting.

There's a news story out from China (and picked up by Slashdot) about the new paper by Huai-Dong Cao and Xi-Ping Zhu soon to appear in the Asian Journal of Mathematics. This paper is more than 300 pages and is supposed to contain a proof of the Poincare conjecture and the full geometrization conjecture, filling in an outline of a proof due to Perelman, who used methods developed by my Columbia colleague Richard Hamilton. Other groups have also been working on this in recent years including my other Columbia colleague John Morgan together with Gang Tian; for another example, see the notes on Perelman's papers recently put on the arXiv by Bruce Kleiner and John Lott. Cao and Zhu have evidently been explaining their proof in a seminar at Harvard run by Yau during the past academic year, and Yau will talk about this at Strings 2006 in Beijing later this month. When the paper appears it will be interesting to see what some of the other experts in the field think of it and whether there's a consensus that the proof of Poincare and geometrization is finally in completely rigorous form.

Update: According to a blog entry from the Guardian, "Perelman seems to be active in string theory."

Comments

1. **sunderpeeche**
   June 5, 2006

   Why shouldn't Langacker give Susskind's book a favorable review? They might be friends (I do not know). The next to last paragraph states

   "Many scientists are strongly opposed to the multiverse-landscape paradigm. Some objections are technical. For example, are there really 10^500 vacua, or does the multiverse really exist? Others are that the ideas are not testable and not really science, or that they might seduce researchers into giving up the traditional goal of finding a unique and elegant explanation for the observed laws of Nature. Sussking makes no attempt to give an impartial overview — after all, he is advocating his own ideas. However, he does offer a reasonable survey of the objections and his own responses to them."

That’s a fairly balanced review statement. Langacker doesn’t try to whitewash the fact that many people disagree with the ideas in the book. It’s a reasonable review.

2. **Levi**
June 6, 2006

I think the review of “The Road to Reality” in the Notices is very well balanced. I would be curious to know what Peter and commenters think.

3. **Cloud**
June 6, 2006

If Cao and Zhu’s proof is right , what percent of contribution does their work occupy to the Poincare Conjecture? They will share the prize provided by the Clay Math Inst? An amateur

4. **Hujun Li**
June 6, 2006

Dear Prof. Woit:
I’m a science reporter of Southern Weekly, a very influential newspaper which circulates around China. Currently the Chinese media are highly praising the paper pubished by Profs. Huaidong Cai and Xiping Zhu. I’m wondering that if I can quote your blog words in my story, and could you say something more:
1. What’s your comment on the work of Cao-Zhu, and other groups like Morgan-Tian, Kleiner-Lott?
2. Some people thought that Prof. Shing-Tung Yau is making a hype:
(http://mathforum.org/kb/message.jspa?messageID=4767368&tstart=0)
(http://mathforum.org/kb/message.jspa?messageID=4768229&tstart=0)
Do you agree with them or not?
3. Cloud said:
“If Cao and Zhu’s proof is right, what percent of contribution does their work occupy to the Poincare Conjecture? Will they share the prize provided by the Clay Math Inst? ”
That’s also what I want to know.
Best regards,
Hujun Li

5. **Peter Woit**
June 6, 2006

Hujun Li,

It should be made clear that I am not an expert in this area of mathematics, and this blog entry is just quoting other widely available sources. I don’t think you should quote it, you should contact people who are experts. Of the people I have talked to about this, as far as I know they haven’t even seen the Cao-Zhu manuscript, and thus have no basis yet for an opinion.

6. **knotted string**
June 6, 2006

Physics Today is uncritical of speculation so its not surprising they publish nonsense. A decade ago (apr 96) they published Witten’s claim “String theory has the remarkable property of predicting gravity.” Still no string prediction a decade on.

7. **hack**
June 6, 2006

I did a little research, and it turns out Witten’s prediction of gravity has indeed been confirmed in experiments by physicists I. Newton and G. Galilei. I don’t know about you, but I think a Nobel is in order.

8. **Yidun**
June 6, 2006

http://www.wanyidun.com/blog_r2u/?p=65

9. **Bert Schroer**
June 6, 2006

Can anybody explain to me what is the physical meaning of a theory with several vacua (Gates) in view of the fact that the application of the cluster factorization means that (without loss of physical generality) one can decompose the theory into a direct sum of components where each component has a unique vacuum? This is a mathematical theorem and probably its derivation can be found in Streater-Wightman (presently not available to me).
Be careful, I am presently not saying that Gates is wrong, there may be a misunderstanding on my part.

10. **anon**
June 6, 2006

Prof. Schroer,

can you please comment on the paper of Grigore&Scharf “Against Supersymmetry” ?
Thank you.

11. **Bert Schroer**
June 6, 2006

Since I presently don't have the time to read the article, and I do not want to comment on just the basis of the abstract, I asked Dan Grigore to address this question on this weblog.

12. **Tony Smith**
June 6, 2006

I did not see the Cao-Zhu paper listed in the math arXiv. Why would it not be there?
I did see three Grisha Perelman Ricci-flow papers at math.DG/0307245, math.DG/0303109, and math.DG/0211159 , so it seems to me that precedent would be to put the paper on the math arXiv.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – I did not see on either the physics arXiv or the math arXiv any paper by Grisha Perelman that looked like a superstring paper, although some, such as Martin Rocek, have spoken about connections between Ricci flow and string theory, and I think that Perelman may have discussed such things. However, to me that does not mean that Perelman is an advocate of string theory, just that he is open to discussion about possible applications of his Ricci flow ideas to ANYTHING, even string theory.
Further, I did not see anything in the Guardian blog but an unsupported assertion.

13. **Peter Woit**
June 6, 2006

The Cao-Zhu work was not put on the arXiv. As far as I know, many of the relevant experts have still not even seen a copy.

Saying Perelman is active in string theory is a complete joke, which is why I quoted it. In his work he uses the kind of flow equation that also appear in renormalization group flows for sigma models, which I guess to string theorists makes him "active in string theory". I wonder where the Guardian writer got that nonsense.

14. **Yidun**
June 6, 2006

Cao and Zhu's full paper has not even shown up in the Journal yet. I guess by far only Shing-tong Yau and some Harvard mathematicians have read it. It seems that Yau is convinced.

15. **Richard**
June 6, 2006

I'm glad someone is attempting to present a complete unified presentation of a proof of the Poincaré conjecture. It would be a shame if this very important conjecture is finally declared proved, but left scattered to the winds in bits and pieces in various papers published in many different places.

16. **MathPhys**
June 6, 2006

I find it very odd that

1. The paper will appear next month in Asian J of Math, but has not appeared on the arXiv,

2. The result was announced in a press conference, rather than at a regular math meeting (or by simply posting the paper on the arXiv), and

3. In the abstract, the authors declare that their work is "a crowning achievement". I thought they should let the readers say that.

17. **Bert Schroer**
June 7, 2006

Since the authors of yesterdays "Against Supersymmetry" (Grigore&Scharf) did not yet react to my email, I feel that I should make some preliminary comments with respect to their obviously consequence-bearing statement. The title should be understood in the sense: the old suspicions about the incompatibility beetween supersymmetry and gauge theory finally passes to a No-Go theorem.
With their opening statement against the use of functional integrals for the calculation of physically relevant (renormalizable) results they run into my open doors; functional integrals are basically for incantation and baptization of QFT, but not for calculating renormalized results (they only have a metaphorical existence for unrenormalized correlation functions and are incorrect for renormalized correlations of strictly renormalizable theories). Functional integrals totally ignore the singular (distributional) nature of quantum fields and the people who worship them are usually those who believe that the ultraviolet problems are the real limitations of QFT, whereas in reality (Epstein-Glaser) the physical problem is to find finite-parametric islands (stable under a finite-parametric renormalization group) in the "universal" QFT which is a formal construct with infinitely many couplings (shared between Petermann-Stueckelberg and Wilson).
Atiyah belonged to the strongest venerators of functional integrals within the mathematical community and it is interesting to notice that he found other mathematical arguments which cast doubts on the depth and utility of supersymmetry (the starting point of participation in this particular blog section).
I still did not find the time to read the article (but I know the authors as very competent, although not exactly representing AQFT as one participant here was claiming), and I still hope that they will enter this blog and explain themselves what they have done.

18. **anon**
June 7, 2006

Prof. Schroer,

thank you for your comment.
So the LHC has a real chance to falsify the causal AQFT approach?

19. **Bert Schroer**
June 7, 2006

Well it is not the causal approach which is under discussion, but only what the authors call the minimally supersymmetric extended standard model. Other extensions are not investigated but of course their paper is an invitation to do this (including to themselves I suppose).

20. **Deane**

June 7, 2006

Perelman is not just a Ricci flow person. When he first appeared on the scene, he established his reputation in Riemannian geometry and its generalizations. He then disappeared for about 7 years (yes, just like Wiles). When he re-emerged, he started sending emails to Ricci flow experts, asking technical questions. To quote one reaction, "uh-oh". He's written three papers on how to use the Ricci flow to prove Thurston's conjecture. The rumors are that he has moved on and is now working on the Navier-Stokes equation.

21. **Florifulgurator**
June 7, 2006

MathPhys, the abstract says "crowning achievement of the Hamilton-Perelman theory of Ricci flow". This is not odd (no self-praise or theory-hype or whatever), it is true.

22. **Yidun**
June 7, 2006

MathPhys:

The full sentence in their abastract is "This proof should be considered as the crowning achievement of the Hamilton-Perelman theory of Ricci flow". I think that "a crowning achievement"should be understood in its context.

23. **DMS**
June 7, 2006

"I find it very odd that

1. The paper will appear next month in Asian J of Math, but has not appeared on the arXiv,

2. The result was announced in a press conference, rather than at a regular math meeting (or by simply posting the paper on the arXiv),"

Something similar happened when Andrew Wiles informed the world about his initial (flawed) proof. Mathematicians don't seem to use arxiv as much, ulinke theoretical physicists, a shame.

If Yau is wrong, it will be embarassing to him, so I don't think he is doing it lightly.

24. **MathPhys**
June 7, 2006

Wiles is far from being a computer/internet oriented man, and his proof was "announced" in a series of talks at the Newton Institute. It's still quite a different story.

No one thinks that the Cao-Zhu work is wrong. Everyone believes Perelman to be right, so it's a safe bet on Yau's part.

25. **MathPhys**
June 7, 2006

Yidun,

"This proof should be considered as the crowning achievement of the Hamilton-Perelman theory of Ricci flow".

Still sounds like something that a referee or a reader, rather than an author should say.

26. **Chris W.**
June 7, 2006

Regarding Laughlin's departure from KAIST, see the apparently well-informed comments on this post at *The Marmot's Hole*.

27. **MathPhys**
June 7, 2006

Chris W,

I read the post at The Marmot's Hole of Laughlin and KAIST. Very interesting. Very funny too. Almost a script of a funny movie on how third world countries (and I think S Korea is one) manage science.

28. **Lubos Motl**
June 8, 2006

One of my readers has predicted that Prof. Bert Schroer would endorse the crackpot paper "Against Supersymmetry" and he or she was completely right. The paper is completely absurd because supersymmetric gauge theories are a subset of ordinary gauge theories with a properly chosen spectrum and adjusted interactions, after all, so an anomaly of this kind would affect all gauge theories, not just supersymmetric ones.

What the authors have probably (it's hard to decode it in their very unusual formalism and terminology) found is that – in ordinary language – one can't work without the FP ghosts at one-loop level. Their "anomaly" is proportional to two copies of the structure constants, which looks like two cubic vertices in a diagram with a FP ghost loop. If they learned a basic class of quantum field theory, this would have been explained in the second semester. If they did their exercise correctly, they can easily cancel the anomaly by adding fermionic scalar fields in the adjoint representation, the ghosts, and their auxiliary superpartners if needed.

Even at the level of social sciences, a statement that there is a universal anomaly killing supersymmetric theories is a proof of crackpotism. 3,000 very smart people have written 20,000 papers that go well beyond naive checks that these two authors have attempted to do correctly but failed. Moreover, these theories follow from string theory, belong to the powerful web of dualities that imposes all required consistency criteria, and they have been recently studied at a much higher level of rigor in string theory as field-theoretical duals of particular gravitational backgrounds of string theory.

Prof. Bert Schroer has no idea about quantum field theory.

29. **Bert Schroer**
June 8, 2006

Lobos,
if anybody ever claims you understand QFT you may give him a thorough spenking. It seems that the stringy alimentation you already received in Prague has damaged your brain beyond repair.

30. **Lubos Motl**
June 8, 2006

Dear Prof. Schroer,

if you can't learn quantum field theory – indeed, you could not have passed my course QFT II in the spring because this was a standard part of the material written in the syllabus – you could at least try to struggle and learn my name.

My name is Luboš.

All the best to you and all the crackpots here
Luboš

31. **MathPhys**
June 8, 2006

Lubos,
I wrote papers on supersymmetry. Does that make me very smart?

Anyway, I must agree with Lubos on this one, and I'm willing to bet good money that there is no problem, and that the paper (which I haven't read) contains a basic mistake.

Maybe it's a mistake along the lines that Lubos anticipated, or maybe something even more banal.

There is no doubt that susy gauge theories are perfectly well behaved, and the more supersymmetric, the better behaved.

Incidentally, there was a little 'scare' along the same lines around 1984 (when Lubos was still in diapers) when 'tHooft and a PhD student (van Damme) claimed that susy gauge theories have an anomaly at 2 loop level, and therefore unrenormalizable. They were wrong. Van Damme made a computational mistake.

32. **Lubos Motl**
June 8, 2006

Dear MathPhys,

does it make one smart? It may depend on the content of the paper. But more generally, the answer is probably Yes. One needs to be above a certain lower threshold of IQ to be able to write at least a slightly meaningful paper about supersymmetry, and all the data I have indicate that your knowledge and intelligence in the context of gauge theory probably exceeds those of Prof. Schroer.

All the best
Lubos

33. **Bert Schroer**
June 8, 2006

I told you that I have not red the paper (I am still on the road) and that I know both authors as very competent and careful colleagues. Since I was asked on this weblog to say something and since my attempts to get the authors directly involved failed up to now, I tried to at least understand what they are claiming. Nothing to get emotional about. This is what a weblog is for, isn´t it. The previous statement about the physical aspects of supersymmetry which I made in connection with a remark attributed to Atiyah I of course stand by, but they fall short of what these two authors are claiming.

34. **MathPhys**
June 8, 2006

Lubos,

These were some of the silliest and most trivial papers I've ever written. It's too easy.

You see, I know supersymmetry well enough to believe that, while perfectly consistent, susy is the most obvious stumbling block in the development of theoretical high energy physics today.

There is something very wrong with the idea of sypersymmetrizing everything until you can compute something, then break the supersymmetry by hand and push everything you don't want all the way up till you can't see them (only to find that you recover the problems that made you supersymmetrize in the first place).

It is just too easy, and too contrived at the same time. And it doesn't work.

35. **Bert Schroer**
June 8, 2006

MathPhys,
it was just this issue of breaking of supersymmetry which I commented on earlier. It is precisely at this point where SUSY outs itself as being eerily different from any other symmetry under the sun.

36. **Lubos Motl**
June 8, 2006

Dear Prof. Schroer,

Sir Atiyah has co-authored at least one famous paper in which four-dimensional supersymmetric non-Abelian gauge theories play an important role:

http://arxiv.org/abs/hep-th/0107177

Well, yes, one can probably guess which of the two authors wrote most of these physics-related sections of that paper. The complexity and the mathematical depth of this Atiyah-Witten paper exceeds the complexity and depth of the paper by Grigore and Scharf by two orders of magnitude or more.

But Sir Atiyah is a mathematician who does not have to understand supersymmetric gauge theories well and he would never be foolish enough to make far-reaching statements about topics that he does not understand, unlike you.

You may find Grigore and Scharf to be "careful" and "competent" colleagues, according to your standards, but according to the usual standards, they are something very different because the one-loop structure of gauge theories – and all possible anomalies and non-anomalies that might occur at one-loop level – is a standard material in every modern textbook of quantum field theory and no careful and competent physicist would ever publish a paper making far-reaching statements about these topics before he understands their standard presentation in the textbook.

This can't really be compared with the two-loop paper by van Damme et al. in 1984 because one-loop level is something much more elementary, and moreover 22 years have ended since the van Damme et al. paper.

But certain people just think that they can make important discoveries while ignoring virtually all insights that have been made in the last 50 years, checked, re-checked, experimentally verified, and summarized in quantum field theory textbooks. And this is the context in which I just find the word "crackpot" appropriate.

All the best
Lubos

37. **MathPhys**
June 8, 2006

Dear Prof Schroer,

Yes, I get your point.
Incidentally, are you permanently based in Rio now? Do you like the working conditions there?

38. **Bert Schroer**
June 8, 2006

It is worthwhile to remember that wayback there were serious problems to find regularizations which maintain gauge invariance and supersymmetry simultaneously. Not knowing whether these problems have been resolved meanwhile, I find it reasonable to take from AQFT the idea of an approach which avoids regulators and cutoffs altogether and to base perturbation theory on ideas which take care of the distributional aspects of fields throughout the calculation (e.g. the Epstein-Glaser approach). What confuses Lubos so much is that the authors prefer this setting in order to stay on the safe side.

39. **MathPhys**
June 8, 2006

Lubos,
For some very odd reason, British knights are called by their first name, rather than surname, after 'Sir'. So, one says 'Sir Michael' and 'Sir Roger', and not 'Sir Atiyah' or 'Sir Penrose'.
On the other hand, following 'Lord', one uses a chosen name, but the origins of that would be too difficult to explain (Martin Rees is Lord Ludlow).
When in doubt, just call him 'Professor Atiyah'. He wouldn't mind.

40. **MathPhys**
June 8, 2006

Prof Schroer,
There is no problem regularizing supersymmetric gauge theories. Olivier Piguet can tell you all about that.

41. **Bert Schroer**
June 8, 2006

Yes I live in Rio where I have an apartment, but I am presently in Sao Paulo. I retired from the FU-Berlin and the working conditions, apart from a 2 by 3 m desk corner in an office I share with another pensionist Prof. Walter Baltensperger (look up his name in physics/ he has some interesting ideas about the origin of the tropical flora and fauna in earlier geological epochs of siberia) I am creating my own working conditions.

42. **Lubos Motl**
June 8, 2006

They obviously don't stay on the safe side if they can "derive" so completely ludicrous "results". Prof. Schroer is profoundly confused which insights in physics are robust and which are not. As far as I can say, the Epstein-Glaser approach is exactly as flawed as everything else that Prof. Schroer has ever attempted to sell. It contradicts the genuine renormalization group behavior of all the operators and interactions.

Epstein & Glaser also have roughly 100 citations per 33 years. Prof. Schroer must believe that there has been some world-wide conspiracy that makes this important (?) paper look 30 times less important than papers that most experts find really important.

Whether or not one uses a regularization that preserves both gauge symmetry and supersymmetry simultaneously is irrelevant. Even in the case of ordinary gauge theory itself, one can use regulators that don't manifestly preserve supersymmetry. It just means that gauge-invariance-violating counterterms can be generated and must be canceled, as additional renormalization conditions (masslessness of the photon in QED, for example). But once they are canceled, the results are equivalent to manifestly gauge-invariance regularizations such as dim. reg.

Analogously, we may use dim. reg. for SUSY gauge theories which preserves the gauge symmetry. Supersymmetry is then also preserved as long as the couplings are renormalized so that the supersymmetric relations between them are preserved at every order, which is easily seen to be possible in the full quantum theory if it is possible in the classical theory. If you just define Feynman diagrams in superspace, things become more or less manifest.

It may be difficult to put SUSY on the lattice – less difficult with the help of deconstruction – but it is straightforward to preserve SUSY by renormalization at the loop level.

43. **Lubos Motl**
June 8, 2006

"that don't manifestly preserve supersymmetry." in the previous comment should have been "that don't manifestly preserve gauge symmetry".

44. **Bert Schroer**
June 8, 2006

Mathphys,
are you sure that Olivier Piguet does not use the regularization-free algebraic approach? (his work with Sorella is often called “algebraic renormalization”.)

45. **Bert Schroer**
June 8, 2006

Lubos, you are in a weblog about particle physics and not in a bookmaker´s shop.

46. **Lubos Motl**
June 8, 2006

“Lubos, you are in a weblog about particle physics and not in a bookmaker´s shop.”

It certainly does not look so. My feeling is just the opposite.

48. **Lubos Motl**
June 8, 2006

particular -> particle

49. **MathPhys**
June 8, 2006

Piguet uses a ‘modern’ version of BHPZ. Yes, they call it ‘regularization free’, but I’m not so sure that that’s a fair name. There is a lot of debate about that that I don’t wish to get involved in. There was also work by I Jack and D R T Jones (disproving van Damme and ‘t Hooft), where they obtain the same results as Piguet et al, but using a version of dimensional regularization that somehow preserves supersymmetry.

The message is that one can subtract the infinities, while retaining susy and gauge invariance. I’m sure these issues were settled more than 20 years ago.

50. **Bert Schroer**
June 8, 2006

MathPhys,
if I read implicitly between the lines of your blog and take an optimistic (or pessimistic, depending on one’s point of view) interpretation, then you are saying that the off-shell BPHZ (Piguet-Sorella) approach applied to the model (which Grigore-Scharf take to make their point) would be free of that anomaly which they find in the on-shell Epstein-Glaser approach. This is of course a possibility, although I maintain that statements from Grigore-Scharf merit high respect (they are assured of that respect not only from me, but also from Raymond Stora), notwithstanding the obvious fact that we are all fallible (except jesters on the string court as Lubos Motl).

51. **Bert Schroer**
June 8, 2006

MathPhys,
Standard literature works in the BRST approach, i.e. one is studying some classical field theory with Grassmann fields and then constructs the generating functional for the Green functions. Everybody supposes that this process will lead to a good theory in some Hilbert space. One could take the Grigore-Scharf paper as an indication that this road is not so easy. So, you guys who are working in this direction should really construct the quantum theory in all details at least up the the second order of perturbation theory
starting from the functional approach. Then we will see if there is a way to circumvent the no-go result of G-S or if susy is in trouble

52. **JPL**
June 8, 2006

MathPhys:

“You see, I know supersymmetry well enough to believe that, while perfectly consistent, susy is the most obvious stumbling block in the development of theoretical high energy physics today.

There is something very wrong with the idea of sypersymmetrizing everything until you can compute something, then break the supersymmetry by hand and push everything you don’t want all the way up till you can’t see them (only to find that you recover the problems that made you supersymmetrize in the first place).

It is just too easy, and too contrived at the same time. And it doesn’t work.”

My feeling is that what you recognize here is, probably, a sharper indictment of SUSY than the whole of Grigore-Scharf’s argument.
You are also not the first person, among those who actually worked in SUSY whom I have heard express those suspicions…

53. **Alejandro Rivero**
June 8, 2006

Most probably susy could emerge not for everything but in part, or as an approximate symmetry. The fact is that something must control the divergence of the scalar particles; and this something should be a kind of cancellation between diagrams. Such cancellation mechanism, when found, should not be far of the one of supersymmetry.

54. **Chris W.**
June 8, 2006

More interesting stuff from Sean Carroll on *CV*, which might deserve its own post here.

55. **Bert Schroer**
June 8, 2006

Alejandro Rivero,
We all agree about the perturbative aim: to cut a breach into the universal infinite dimensional space which incorporates all particles with all coupling strength, e.i. to find selfclosing finite parametrig islands under the action of a finite-parametrig RG (Petermann-Stueckelberg, Wilson, any way you want).
But the standard way you want to cut these breaches is much too narrow: start with pointlike free fields couple them paying attention to the power counting. You will get stuck, precisely at the place where we are now and supersymmetry does not seem to help in this, it just pushes the problems to a higher order nbut seems to be incapable to generate new islands.
Imagine you start with massive vector fields coupled to themselves and to other scalar and spin=1/2 fields. Any coupling you contemplate to write down, I repeat any coupling will carry you to dimension 5 for the interaction (a massive free vectorfield has scaling dimension 2 and not 1) which is way beyond the limit of renormalizability. We all know what we can do in such a situation, we modify the one-vectormeson space by non-Hilbert BRST stuff and get it down to scale dimension one (paying attention to consistency problems which may require the enlargement by additional physical degrees of freedom). Then we descend thanks to the cohomological properties of BRST and finally obtain a physical theory (back to Hilbert space) in which, lo and behold the the vectormeson really has the physical dimension 2. But we don't know the physical reason why we are doing this.
Alejandro, before you are not perturbed by this magic BRST "catalyzer", you will never make any progress and your proposal to look into the neighbourhood of supersymmetry will only be a loss of time.
The secret to maintain dimension 1 even without that catalyzer is to permit the free fields to have a spacelike semiinfinite stringlike extension (already mentioned before on several occasions) and stay all the time in Hilbert space. I am very confident that the next step of how to implement interactions for such stringlike fields will be understood in the near future; the theory is expected to have a pointlike subalgebra (which must be idential to the old gauge invariants, otherwise the attempt must go into the dustbin). Whereas the BRST magic is essentially limited to spin one, there is no such limitation for the idea of working with stringlike localized free fields instead of the usual Lagrangian pointlike fields. Stringlike localized fields fluctuate in x and in e (unit spacelike direction = de Sitter) and having part of the fluctuation strength in e you can improve the short distance properties in x. I predict it will be this Feynmanian spacetime viewpoint (and not those momentum space manipulations) which will lead to those above islands. The closeness of supersymmetry to such a spacetime view is a Fata Morgana.

56. **MathPhys**
June 8, 2006

Lubos,
When you say that one can put susy on a lattice "using deconstruction", what do you mean?

57. **Anonymous**
June 8, 2006

MathPhys: see, e.g., http://arxiv.org/abs/hep-lat/0503039. As far as I am aware no one knows how to do N=1 SUSY on a lattice, but (for instance) N=4 works.

58. **Aaron Bergman**
June 8, 2006

Try hep-lat/0602007.

59. **MathPhys**
June 9, 2006

Thanks.

60. **Alejandro Rivero**
June 9, 2006

Bert, ah, but I do not propose to look in the neighbourhood of supersymmetry. What I say is that we will first to find the mechanism, and later someone will find a mean to reformulate it as an approximate supersymmetry, because there are tools and coincidences -say, climatic preconditions, to follow your last metaphor- enough to be able to do it.
As for the BRST "catalyzer", I had never thought about it in the way you describe; but it seems worthwhile to take a time on this reflexion.

61. **Bert Schroer**
June 9, 2006

Alejandro,
All free pointlike fields with short distance scale dimension larger than 3/2 (equivalent to spin larger than 1/2) generate a barrier against renormalizability because you cannot find interactions with dimension bounded by 4. The first such beyond case is a free vectormeson (taken massive in order not to confront infrared and ultraviolet problems together) which has dimension 2. Historically we are inclined to follow t'Hooft and invoke the classical gauge principle although it forces us to violate important principles of QT (positivity) in intermediate steps which classically is not an issue at all. The modern form of this intermediate violation (the catalyzer) of QT is BRST. Although we should be grateful for this metaphoric trick which permitted us to start with a free vectormeson of dim=2 and obtain an interacting vectormeson of dim=2 plus logarithmic corrections (i.e. to get around that standard 3/2 barrier), we should on the other hand uphold our Heisenberg heritage which requires to find a formulation which avoids any (even intermediary) use of objects which are not observables. The prerequisites of such a step have already been accomplished: use string-localized potentials for those pointlike field strength as explained in previous blogs. The suggestion can already be found in an old paper of Mandelstam, but the new concept of modular localization leads to a conceptual and mathematical backup for its implementation. The logic of t'Hooft
Lagrangian quantization + classical gauge principle –> renormalization consistent with unitarity
was always subterfuged by the observation that there is only one renormalizable selfinteracting vectormeson theory, namely the one we know (whereas in classical field theory you can write down many Lorentz invariant interactions involving a vectorpotential, that's why you need the selective gauge principle), so we really do not need any principle in addition to renormalizability. In addition, if you abandon the Mexican hat setting and start from the very beginning with massive vectormesons, renormalization theory will convey the very interesting message to you that it wants an additional physical degree of freedom (whose simplest realization is a scalar field, the alias Higgs but now with a vanishing vacuum expectation)
http://br.arxiv.org/abs/hep-th/9906089
Actually this idea is implicit in previous work of Scharf. Remember Gunter Scharf from that discussion yesterday? the one which together with his use of the Epstein-Glaser renormalization approach was vilified by a Harvard professor (Lobos with the Lubotomy).
The advantage of use of string-localized free fields is that (after understanding who to use them in the presence of interactions), different from the gauge idea, there is no limitation to spin=1.

62. **Milnor the Giant!**
June 19, 2006

It seems to me that ST Yau is a fame seeker: he exists wherever there is room for him to expand his reputation. Someone told me that in some Chinese news, Yau claimed that 50% of the credit in "resolving" Poincare Conjecture goes to Richard Hamilton, who developed the Ricci Flow WITH *HIS* (Yau's) SUGGESTION; while Perelman's work worths only 20% and his loyal student Cao and loyal friend Zhu's work takes up 30% of the total credit. What a shame!

The Chinese Media is somewhat ignorant about what actually is going on in the mathematical community and totally rely on the words of this what they called "World famous mathematician, Harvard Professor, and Field Medalist Shing Tung Yau". This creates some sensational moments in China right now. And the report is misleading: it makes people think that the two Chinese mathematicians Zhu XiPing and Cao HuaiDong completely resolved the Millenium Million Dollar Problem Poincare Conjecture. S.T. Yau described that Zhu and Cao's made the final step in resolving the Poincare Conjecture.

It seems that the ultimate winner is Yau. Why? Because of his vision in Ricci Flow, playing 50% in the Poincare proof, he suggested and encouraged Richard Hamilton to investigate it. Then his student Cao and his friend Zhu made the final step into the gate of the PROOF 30%. He seems to imply that he is the MAN behind Poincare Conjecture! Truely beautiful! No Wonder! In several of his speeches, he told people that he had two goals: one is to make himself an everlasting mathematical icon; the other is to help China build world-class math institutes like the IAS. The first one is for real, while the second one has but only an reinforcing kind of effect.

The glory of Fermat's Last Theorem introduced some sensational moments. Andrew Wiles and other mathematicians became the heroes. Although they might have competed to prove Fermat's, they were not malicious towards any of the competitors. On the other hand, they appreciate and admire their fellow mathematicians' efforts in triumph over human intellect. Tian Gang and John Morgan as well as many other mathematicians are also examining Perelman's work and have produced some results in the Poincare Conjecture. Rumor has that Yau was one of the Main editors of the Journal, he would not like that Tian receives such a glory; and he realize that his loyal supporters' work can beat Tian and Morgan's –whichever comes out first wins… Everyone would like to have a moment when Andrew Wiles finished the Proof of Fermat's. But for me this seems like a deceptive stealing.

I do admire Perelman. He's such a humble mathematician. Having made such a revolutionary work, he still works as hard as usual, totally doesn't care about fame or prizes. His contribution to Poincare Conjecture is obvious. He's just a modern Grothendieck or if he doesn't like be called that way, he is just Perelman! If one solves a great problem, he knows that he's triumphed over himself and the problem already; he does not need any complimentary prizes or whatsoever. Because he just knows he can do it and has done it. While for those who always dreamt of making himself more famous and influential but are not able to actually accomplish it, they can only be like that MAN behind Poincare Conjecture.

Yau once claimed that one of his students received Veblen under his influence on the committee. But his student's work is actually not belonging to first class mathematics and he regret helping him. Oh, good lord, how powerful he is!

63. **woit**
June 19, 2006

Please, no more attacks on Yau or anyone involved in the Poincare Conjecture proof. There's too much contention on this blog already.

For the record, I don't think it makes any sense to assign numerical values to people's various contributions to this.

64. **Milnor the Giant-wrong!**
June 19, 2006

woit is right at holding back attacks on Yau. "Milnor the Giant" is just wrongly attibuting to Yau something other people said. Actually you can find some English blogs citing one Xinhua news in Chinese, saying a Chinese mathematician Yang Le estimates a roughly total 105% (Hamilton 50%, Perelman 25%, Zhu-Cao 30%). This cannot be taken seriously. I doubt "Milnor the Giant" was informed wrongly on purpose.

In the original Xinhua news this mathematician was cited saying Perelman's work is 70 pages, now Zhu-Cao 300 pages; hinting that they fill the gaps left by Perelman.

http://news.xinhuanet.com/english/2006-06/04/content_4644754.htm

Let wait and see what will happen in ICM Madrid.

65. **comentator**
June 20, 2006

The proof of the Poincare conjecture has eluded quite a few mathematicians for many years. It would be surprising to know that the chinese mathematicians in two years were able to solve the conjecture without the help of Perelman, Hamilton and others. So at most I believe that their contribution amount to a 10% if it is correct, as per filling gaps and important steps, that will have to be studied and checked.

66. **Peter Woit**
June 20, 2006

The purported proof by Cao-Zhu (I haven't talked to anyone who has seen it) is based on the arguments developed by Hamilton and Perelman.

Populating the Landscape

June 9, 2006
Categories: Uncategorized

Study of the string theory landscape seems now to have become the hot research topic that one should be working on in order to be taken seriously as a cutting-edge researcher in particle theory. Last week there was a workshop at Trieste on [String Vacua and the Landscape]() that drew many researchers. Some of the talks from the workshop are available [on-line]().

Following on the heel's of Susskind's [popular book]() promoting the landscape, which has received excellent reviews from particle and string theorists, there's a new one on the same topic coming out later this month from cosmologist Alex Vilenkin, entitled [Many Worlds in One: The Search for other Universes]().

As string theorists in search of something to write papers about pour into the landscape, with its more than 10^{500} possible hot research topics to work on, Sean Carroll [reports]() from a cosmology workshop at the Perimeter Institute that trouble may be ahead for the subject. Sean gives a short summary of the talks at the workshop, in the majority of cases ending with "Made fun of the landscape", or "Made fun of the anthropic principle".

The main argument for the landscape mania has always been that it justifies Weinberg's "prediction" of the size of the cosmological constant. I've written elsewhere about why this is not a legitimate scientific prediction, and is off by at least an order of magnitude anyway. Evidently Steinhardt and Turok are about to put out a paper claiming that the situation is much worse than this, that if you take anthropic reasoning seriously, the natural "prediction" of the landscape is that:

the cosmological constant should be quite large (many times the matter density, although presumably not at the Planck scale), and we should live in a single lonely galaxy in an empty universe dominated by vacuum energy.

It will be interesting to see if landscapeologists will be willing to admit that the only supposed "prediction" of this subject doesn't work at all, and that it is not only pseudo-science, but failed pseudo-science.

Comments

1. **sunderpeeche**
   June 9, 2006

   All of this just goes to demonstrate the truth of the maxim "Physics is an experimental science". There's just no data beyond the SM (from cosmology there's dark matter and dark energy, but one cannot do controlled expts as a function of pressure and temperature etc, or produce particles of dark matter to measure decay cross-sections and branching ratios, for example). Ultimately, there has to be some data beyond SM (but nobody knows when/where this will happen). Until then theoretical speculation will just pile on speculation.

2. **MathPhys**
   June 9, 2006

   Steinhardt and Turok are serious people. This is very interesting news.

3. **island**
   June 9, 2006

   Does this mean that Lenny will be joining "the other side"…?

   > Amanda Gefter:
   > If we do not accept the landscape idea are we stuck with intelligent design?
   >
   > Leonard Susskind:
   > If, for some unforeseen reason, the landscape turns out to be inconsistent – we will be hard pressed to answer the ID critics.

   –

   Steinhardt and Turok finally discovered the runaway effect, or what?

4. **B**
   June 9, 2006

   sunderpeeche Says:

   There's just no data beyond the SM (from cosmology there's dark matter and dark energy […]

   There is dark matter, there is dark energy, there are neutrino masses, there is the horizon-/ homogeneity/ flatness-problem, the matter-antimatter asymmetry, there are a whole collection of astrophysical mysteries (e.g. the 'axis of evil', the GZK-cutoff, and the Pioneer anomaly (the latter two, I should add, I don't believe in)), then there are the well-known mysteries within the SM: the hierarchy-problem, the values of the Yukawa-couplings, EWSB, family symmetries, etc. If you ask me, we have plenty of data beyond standard, even though not from collider physics. It's the theorists side that has to catch up.

   Best, B.

5. **B**

sunderpeeche said "… there's dark matter and dark energy, but one cannot do controlled expts …".

Actually, there is one controlled dark energy experiment now under way, by P A Warburton of University College London. It is EPSRC Grant Reference: EP/D029783/1, "Externally-Shunted High-Gap Josephson Junctions: Design, Fabrication and Noise Measurements", starting 1 February 2006 and ending 31 January 2009 with £ Value: 242,348. Its abstract states in part:
"… A possible source of this dark energy is vacuum fluctuations which arise from the finite zero-point energy of a quantum mechanical oscillator, hf/2 (where f is the oscillator frequency). … A recent publication by Beck and Mackey … suggests the possibility that dark energy may be measured in the laboratory using resistively-shunted Josephson junctions (RS-JJ's). Vacuum fluctuations in the resistive shunt at low temperatures can be measured by non-linear mixing within the Josephson junction. If vacuum fluctuations are responsible for dark energy, the finite value of the dark energy density in the universe (as measured by astronomical observations) sets an upper frequency limit on the spectrum of the quantum fluctuations in this resistive shunt. Beck and Mackey calculated an upper bound on this cut-off frequency of 1.69 THz. … We therefore propose to perform measurements of the quantum noise in RS-JJ's fabricated using superconductors with sufficiently large gap energies that the full noise spectrum up to and beyond 1.69 THz can be measured. … By performing experiments on both the nitrides and the cuprates we will have two independent measurements of the possible cut-off frequency in two very different materials systems. This would give irrefutable confirmation (or indeed refutation) of the vacuum fluctuations hypothesis. …".

I am aware that there exist no-go type theoretical objections to the work of Beck and Mackey, but it is interesting to me that experiments are under way to answer the question experimentally, thus effectively testing the assumpions of the no-go theoretical objections.

Note that Warburton sees his experiment as worthwhile whichever way (confirmation or refutation of Beck and Mackey) it turns out.

8. **Jonathan Vos Post**
June 11, 2006

If the data from Lund Observatory in Sweden by professor Sveneric Johansson and his PhD student Maria Aldenius in collaboration with Dr Michael Murphy, Cambridge, UK means change in fundamental constants, I wonder how one can "explain" changes in fundamental constants in terms of our universe following a particular trajectory through the multiverse/superspace landscape of all possible universe with fixed fundamental constants? What are the constraints on such trajectories? Do either landscaper or stringers answer these foundational questions? Are such explanations consistent with the April 21 this year findings published in Physical Review Letters implying that a dimensionless constant – the ratio between the electron mass and the proton mass – has changed with time?

LHC Predictions at Seed

June 9, 2006
Categories: Uncategorized

The latest issue of Seed magazine (not yet available online, as far as I know), contains responses from various well-known physicists who were asked what they hoped to learn from the LHC. Here's the gist of what they had to say:

Lisa Randall: *The magnificent thing is that we know there should be an answer to the question of the weakness of gravity, and that it should be revealed at the LHC.*

Leon Lederman: *The long-simmering concern over the weakness of Einstein's gravity may well be confronted. However, what is for sure is that the LHC, with its awesome reach, will answer all of our current astro-particle problems…*

Alexander Vilenkin: *If no trace of supersymmetry is found, this would be – necessarily indirect – evidence for the existence of the multiverse.*

Sir Martin Rees: *I'm hoping that it will clarify the nature of the particles that constitute the "dark matter" in the universe.*

Edward Witten: *The LHC wil tell us whether this notion is correct, and if so how it works.*

Max Tegmark: *Our theory of particle physics has 26 pure numbers in it. Why do they have these particular values? How did the universe begin? Did it?*

Leonard Susskind: *I see only two possible outcomes of the LHC project – either there will be low energy supersymmetry or there won't. … the big question is whether the gauge hierarchy fine-tuning is similar to the cosmological constant fine-tuning, or if it has a more conventional supersymmetric explanation.*

Steven Weinberg: *What terrifies theorists is that the LHC may discover nothing beyond the single neutral "Higgs" particle.. We fervently hope for some complicated discoveries.*

John Schwarz: *There are many speculative ideas for possible discoveries at the LHC. These include indications of extra dimensions, black holes, strings, magnetic monopoles, etc. I believe that all of these exist, and I would be thrilled to have experimental confirmation – but I am pessimistic about the prospects for finding them in the LHC's energy range… I could be wrong. That's why it is important that these experiments be carried out.*

Sean Carroll: *The beauty of science is that we don't know what surprises may await us in these domains.*

Gordon Kane: *The LHC could discover the superpartners in a supersymmetric world. In addition to strong theoretical evidence for Higgs physics, there is strong experimental evidence that Higgs particles do exist with a mass implied by supersymmetry… Probably the main thing we have learned in the past two decades is that any understanding of nature at the most fundamental level (beyond a description) will require extending our thinking to embed our world in extra dimensions… An optimist (like me) can make the defendable argument that the LHC could test supersymmetry, establish string theory and move on to the remaining "why" questions.*

My predictions: The LHC won't see supersymmetry and won't tell us anything about dark matter, dark energy or why gravity is weak. Witten has it exactly right, what the LHC will do will be to start to tell us what is causing electroweak symmetry breaking. It's possible that Weinberg's worry will be borne out, and, at LHC energies, we'll just see what appears to be an elementary scalar, which will be depressing. But I think it's equally likely that symmetry breaking is not coming from an elementary scalar, but from something much more interesting, quite possibly something we haven't thought of, and the LHC may start to give us evidence for what this is.

I'll also predict that we are still a few years from finding out what the LHC will tell us. These will be completely wasted years for particle theory if people just give up on looking for new ideas and sit on their hands (or wander pointlessly in the landscape), waiting for the LHC to revive the subject.

Comments

1. **Alejandro Rivero**
   June 9, 2006

   Yes, Witten gets it exactly right. But why do the others fail to answer right?

2. **robert**
   June 9, 2006

   AR

   Papal infallibility would be a cheap shot. Maybe he doesn't have an obvious agenda, other than his work/research ethic?

3. **rrtucci**
   June 9, 2006

   I think that theoretical high energy physicists have speculated enough already. Time to wait for the data to come in. I suggest that, in the meantime, they should work on quantum computing. This would help balance their highly unbalanced Doritos diet. There was a time when theoretical physicists (Landau, Feynman, …) could chew gum and walk at the same time.

4. **Shantanu**
   June 9, 2006

   Can someone explain to me how one can find indications of magnetic
   monopoles at LHC (John Schwarz's comments)?
   Thanks

5. **Anonymous**
   June 9, 2006

   By "why is gravity weak", you should understand "why is the weak force strong," a question that one hopes will be answered by the LHC. That is, is EWSB natural or is it finely-tuned?

6. **Chris Oakley**

June 9, 2006

I agree with EW, PW and AR, and what are those who think otherwise smoking?

7. **Eric Dennis**
June 9, 2006

You gotta love Vilenkin's reasoning: Prob(Landscape | No SUSY at LHC & String Theory) > Prob(Landscape | SUSY at LHC & String Theory), therefore Prob(Landscape | No SUSY at LHC) > Prob(Landscape | SUSY at LHC). Because of course Prob(String Theory) = 1.

8. **Trackback from LM blog**
June 9, 2006

… Gordon Kane's answer is the best one because it maximizes the product of "interesting content" times "good motivation". SUSY is going to be seen, and obnoxious critics of physics will finally be annihilated. Others either give overly speculative and unlikely answers or uninteresting answers …

http://motls.blogspot.com/2006/06/lhc-predictions-gordon-kane-wins.html

9. **Aaron Bergman**
June 9, 2006

ED:

That would be interesting except that Vlienkin isn't a string theorist. As Sean mentioned in his recent post, many cosmologists are landscapists without any need for string theory.

10. **island**
June 9, 2006

> Alexander Vilenkin: If no trace of supersymmetry is found, this would be – necessarily indirect – evidence for the existence of the multiverse.

This must fall from the same sort of logic that derives that evidence that we're not here by accident is evidence that we are.

11. **sunderpeeche**
June 9, 2006

I see that the list of experts does not include Carlo Rubbia (in fact, other than Lederman there are no expt physicists quoted). People forget that Rubbia did in fact discover supersymmetry (UA1 monojets), also the top quark (Mt = 44 GeV, anyone remember?). Put CR in charge of an LHC expt and there would be monopoles + strings + multiverse in a week.

But, really, only 1 expt physicist in the list?

12. **Anonymous**
June 9, 2006

sunderpeeche:

Experimentalists give boring answers, because they have a realistic sense of the machine's limitations. Similarly, the lack of collider phenomenologists except Gordy Kane, who in his zeal tends to exaggerate what can be done.

13. **sunderpeeche**
June 9, 2006

So the choice is: talk nonsense or be boring? (I think Witten and Weinberg gave good answers, although not "exciting" ones.)

14. **B**
June 9, 2006

I favour the scenario:

They find nothing at all. No Higgs. No susy. No monopoles. No nothing.

15. **Lubos Motl**
June 9, 2006

Dear B,

what you write violates the rule of logic that the total probability of alternatives equals 100%. It is not possible to find nothing at 1 TeV, not even Higgs, because it violates unitarity of the WW WW scattering. Without the Higgs, the Standard Model gives you too high a prediction for the cross section of this process that would make the total probability of scattering greater than 100%.

Best
Lubos

16. **Anonymous**
June 9, 2006

Theorists already predicted everything LHC can see.

17. **Eric Dennis**
June 9, 2006

Aaron,

You're right, I just looked him up at the arxiv. I suppose it's possible he thinks Prob(SUSY | Not String Theory) is not small, in which case his reasoning would be more complicated. Hard to tell.

18. **B**
June 9, 2006

Lubos Motl Says:

what you write violates the rule of logic

Dear Lubos,

whether that conclusion is one of logic depends on the validity of the axioms you use to draw the conclusion. I agree with your argument though.

Best, B.

19. **The Anti-Lubos**
June 9, 2006

Lubos said: *It is not possible to find nothing at 1 TeV, not even Higgs*

Care to place a wager on this, Dr. Motl?

20. **Thomas Larsson**
June 9, 2006

Gordon Kane: The LHC could discover the superpartners in a supersymmetric world.

For many years, I was cautiously positive about string theory. It always bugged me that it apparently was in complete disagreement with experiments, but OTOH the math was cool and obviously relevant for statphys, which was the kind of physics I cared most about. An article by Gordon Kane in Physics Today in 1997, entitled "String theory is not only testable, but super-testable", changed all that. It made it clear to me that string theory is not only wrong but evil, because it has the power to transform senior scientists into babbling crackpots, as is manifest already from the title; IIRC the body of the article was far worse.

But in retrospect Kane's article appears as quite sane compared to the landscape stuff.

21. **John Stanton**
June 9, 2006

I read in an online physics book the prediction:
LHC will discover that the Higgs particle is composite,
not elementary, as there cannot be any elementary
spin 0 particles.

22. **Peter Woit**
June 9, 2006

John,

That's definitely one possibility. But composites of what? Bound together how? And will the composite nature only show up at much higher energies than those accessible at the LHC? There has been a lot of work on some models of this kind (e.g. Technicolor).

23. **Aaron Bergman**
June 9, 2006

You statement really is amusing and ironic, Thomas. The thing is, Gordy Kane has never been a string theory partisan. In fact, he's always been a *supersymmetry* partisan which is something different.

As with the above comment Vilenkin, not all that ails the world can be laid at the feet of the horrible string theorists, it seems.

24. **Anonymous**
June 9, 2006

Aaron, Gordy has been talking for a while about how to use LHC data to help pin down the underlying string theory construction.

25. **Anonymous**
June 9, 2006

dear Lubos,

ideally you are right. But in practice LHC is a dirty hadronic machine: it is not clear if LHC allows to test if WW WW scattering exceeds unitarity. What would an experimentalist really see, in that case?

26. **Peter Woit**
June 9, 2006

Aaron,

Kane has written quite a lot promoting string theory. See for instance

http://feynman.physics.lsa.umich.edu/kane/Zing.htm

He explains there his relation to string theory:

"I am often asked what is the connection between string theory and supersymmetry. String theory is like a musical score. Supersymmetry is like the performance. If you can read the score and hear it in your head you don't need the performance, but most of us do. Or, string theory is the recipe, supersymmetry is the cake."

27. **woit**
June 9, 2006

Several people,

Please, stop posting here advertisements for your unorthodox ideas about physics on the grounds that they are "LHC predictions". If you want to discuss the topics covered in this posting fine, if you want to promote yourself and your own ideas that have nothing to do with this posting, do it elsewhere.

28. **Aaron Bergman**
June 9, 2006

I'm not saying that Kane is anti-string theory. He obviously isn't. He's not a string theorist, though; he's a phenomenologist. When I last saw him (a few years ago at TASI), I got the impression that string theory was interesting in as much as it told us something about supersymmetric model building. (Modulo unlikely things like weak scale gravity, of course.) Along those lines, hep-th/0509157 or hep-ph/0403040.

29. **Alejandro Rivero**
June 9, 2006

Giving that the Yukawa coupling of the top is 0.998 or so, a composite model explaining this phenomena is inviting, but I do not know any. A second question about composites is if it can be really claimed that they avoid the hierarchy problem (at least, it will depend on where do you put the compositeness scale).

30. **David**
June 9, 2006

To John Stanton

John, people say that fundamental scalars cannot exist because in a 4 dimensional renormalizable field theory, the coupling constant would flow to zero under the renormalization as the cutoff is taken to infinity. A similar thing will happen in dimensional regularization as the dimension 4 limit is taken.

Hence the only possible 4 dimensional scalar field theory would be a trivial noninteracting or free one if the the cutoff is infinite. If one considers the possibility that the cutoff is finite, the one can have scalars, but these are not considered fundamental as there must be something beyond the cutoff of the scalar field theory. Peter is right that the interesting thing is what, but unfortunately, that cannot be found unless one makes measurements at the scale of the cutoff or beyond.

31. **Thomas Larsson**
June 9, 2006

Aaron, the article is too old to be available on-line, but the content of the February 1997 issue of Physics Today is available here:

"Superstring Theory Is Testable, Even Supertestable
Many believe that superstring theory, because of its extraordinarily tiny length scale and gargantuan energy scale, cannot be tested. That belief is a myth — Gordon Kane"

If you think my comment is so funny, maybe you could tell us how to supertest string theory.

32. **Aaron Bergman**
June 9, 2006

I read the article. It's available if the library has a subscription.

33. **MoveOnOrStayBehind**
June 10, 2006

"Superstring Theory Is Testable, Even Supertestable
Many believe that superstring theory, because of its extraordinarily tiny length scale and gargantuan energy scale, cannot be tested. That belief is a myth — Gordon Kane"

From what has been cited here and in the blog text it seems evident that it is more the string physicists who have a reasonable opinion (because they know what they talk about), rather than the beyond-the-standard-model extra-dimensional phenomenologists, isn't it? It's them who keep the standards high.

BTW, any idea what the people who actually run the experiment and do all the work think about the outcome? I would think these should be asked in the first place. But probably they are all idiots and busy with pulling cables etc.

34. **John Stanton**
June 10, 2006

A question to the experts: are we completely, 100%, sure
that, in the case that the Higgs is composite,
the components and forces keeping the parts
togther must be new? In other words,
are we completely sure that this is not the strong
interaction, for example?

35. **Thomas Larsson**
June 10, 2006

I read the article. It's available if the library has a subscription.

Means what? That just because you have read a particular piece of propaganda, it is ridiculous to call that piece of propaganda by its right name?

Besides, you didn't answer how string theory could be supertested. Or, since scientific theories only can be falsified, maybe I should ask for a doable experiment which would superfalsify string theory.

36. **Alejandro Rivero**
June 10, 2006

David, John: It should be stressed that the "triviality limit" is shown in most plots of new physics, specially the one from Chris Hillman that appears from time to time in the Review of the PDG, sometimes showing both the "triviality" and the "unitarity" bounds, as well as vacuum stability. In fact this plot is the main argument to claim we will find something at LHC energies.

37. **Aaron Bergman**
June 10, 2006

You're missing the point, Thomas. I'm not defending the article. I'm just amused that it was an article by a phenomenologist who focusses on supersymmetry that turned you off on string theory.

38. **Tommaso Dorigo**
June 10, 2006

Hi all… Nice collection of comments I must say!

FWIW, I agree with Witten, Rivero, and (of course!) Peter Woit.

I am in CMS, but I think CMS and Atlas will see very little. They will do precision physics (t), unfortunately following the tradition of LEP (Z) and LEP2 (W). They will only find the Higgs, but only if they are lucky – not because I think there is none there, quite the opposite! Because CDF and D0 have a real chance to see it first!!

Why do I think that LHC won't find any SUSY ? Because I don't buy it. But also because CDF and D0 should have found something weird in their dataset by now!

In Run I, CDF saw a extremely unlikely event with two electrons, two high-Et photons, and significant missing energy (a neutrino, most likely – or two). I must confess that the eeggmet event was on the verge of changing my attitude toward SUSY, but then… With 10 times the statistics, CDF and D0 haven't seen anything weird anymore; extensive searches (with more acceptance to anything weird) for parents of that event have seen nothing! So one is left with the feeling that the eeggmet event was a fluke anyways. In that case, a SM fluke is, by force of Ockham's razor, to be preferred…

39. **Fred Diether**
June 10, 2006

What about the HyperCP events that claim they might be seeing a SUSY sgoldstino?

Does anyone know if anyone is going to try to recreate the experiment?

Fred

40. **Thomas Larsson**
June 11, 2006

Aaron, I'm sorry that I misinterpreted you.

41. **Kasper Olsen**
June 11, 2006

I think the best prediction is that we will learn more about the "notorious" question of the Higgs (or Higgses); none of us know precisely in what way.

In that sense Sean Carroll is right: the beauty of science is that this is unknown terrain.

And a terrain in a vast and unknown Landscape? Who knows? 😉

I find it wrong – and *not even wrong* – trying to do a cost-benefit analysis here, or to say that time will be waisted with the LHC.

Any other ideas? Trying to find answers by debunking string theory, or modern quantum field theory? Or trying to find a "background independent" answer?

42. **Michael Schmitt**
June 11, 2006

Witten is certainly right that we will learn a lot about EWSB at the LHC. The betting odds are that a SM-like Higgs boson will be found, though this won't by iteself provide clear evidence for low-energy supersymmetry. After that, one's tastes in exotic physics determines what one expects/hopes to find. At that level there is no point in making a general statement about weak gravity or extra dimensions or SUSY or string theory (not to mention multiverses) – only the experiments will tell us what is there. Making pronouncements about what the LHC will find is worse than predicting who will win the world cup! If, as Bee predicts, there is no new physics and no Higgs boson (or its surrogate), then we cable tuggers will be very frustrated indeed, but the community will certainly have learned something big: the Standard Model and most models of physics beyond the Standard Model will essentially be ruled out, and all the enthusiasm over the last few decades about the Higgs mechanism will have been misplaced.

I certainly agree that SEED should have polled more experimenters, especially a couple out of the thousands who actually work on LHC experiments. How strange it would be to publish an article on the national economy based on comments from, say, applied mathematicians. Or even stranger, to write an article on the future of theoretical physics after talking to a dozen experimenters. I guess the lesson is that the star power resides in the theoretical community, so it is good for SEED circulation to tap there…

43. **Alejandro Rivero**
June 11, 2006

robert Says: *Papal infallibility would be a cheap shot. Maybe he doesn't have an obvious agenda, other than his work/research ethic?*

Hmm I'd better tell that Witten's agenda, whatever it is, happens to coincide now with the real physicist agenda. In previous occasions Witten agenda seemed to be the use of his influence on mainstream research to promote interesting mathematical topics, as noncommutativity or K-theory, to name a couple ones. In most cases, the result has not been very happy, with a flood of string-oriented papers obscuring the mathematical and physical meaning of the concepts -mostly because they drank only from Witten's papers-.

44. **tsg**
June 13, 2006

If the LHC doesn't find superpartners, isn't that in itself significant, as evidence against supersymmetry? (Or at least as evidence against SUSY at energy scales where it could be an answer to the hierarchy problem?)

Blogs, Blogs, Blogs

June 9, 2006
Categories: Uncategorized

All sorts of news very recently on the science blogging front:

Seed's ScienceBlogs site has been revamped, with 25 new blogs for a total of 43 science bloggers. First it was Cosmic Variance with 5 bloggers, now it is ScienceBlogs with 43. How can a single artisanal blog maker like myself compete with these massive blogging conglomerates? Still not very many physicists over at Seed. Besides Chad Orzel, one of the new ones is astrophysicist Steinn Sigurosson who has been running a blog called The Dynamics of Cats.

One physics blog I ran across recently, one that isn't moving to Seed, is Angry Physics.

Besides Seed, Nature magazine has started up a site called NatureBlogs. They are running blogs on chemistry, genetics, and neuroscience, as well as a more general one on web technology and science. There's also a newsblog for comments on news stories appearing in Nature, as well as a discussion blog related to a radical new concept in peer review that they are trying out: a blog where certain papers submitted to Nature are posted, asking for commentary on the paper, to be considered as part of the peer review process.

Nature also just launched another new project which I'd been hearing about for a while from my brother, called Nature Network Boston. It's intended as a networking site for scientists in the Boston area, and has news, event listings, groups, and, guess what, more blogs. Maybe Lubos can start a string theory fanatic's group there…

Finally, Jacques Distler is helping to provide access to these proliferating blogs with a new aggregation site he calls Planet Musings. As usual, Jacques is careful to make sure that anything he has control over censors links to people who disagree with him…

Comments

1. **anon**
   June 9, 2006

   I think if we keep making so much progress in the blogging front, we will soon arrive at the idea of having separate groups for users with different, special interests. Perhaps we could call them newsgroups or usergroups or some such

2. **Yidun**
   June 9, 2006

   Prof. Woit,

   Couldn't you just join them? 🙂

3. **Dan**
   June 9, 2006

   You are the right person to complain about censorship…

   http://www.math.columbia.edu/~woit/wordpress/?p=401#comment-11688

4. **knotted string**
   June 10, 2006

   The thing about group-blogs is that people can get censored by the group for being off-topic (even if no readers complain), so there is group-think coercion involved, moderating the posts:

   http://cosmicvariance.com/2006/05/29/gone/

5. **John Sidles**
   June 10, 2006

   The startling thing about the blog list is, no engineering blogs. To leading order they do not exist (in English). Why is this?

6. **Alejandro Rivero**
   June 10, 2006

   Of the last parragraph, I'd prefer to underline helping instead *censors*. If we are near the bang point for physics blogs, all these catalogs and links will be useful while people builds their own menuses.

7. **woit**
   June 10, 2006

   Dan/Michael,

   Yes, on my blog I do delete stupid nasty personal attacks on other people by, especially those by cowardly anonymous string theorists who keep changing even their pseudonyms. You're right, that's exactly the same as having the arXiv censor links to my blog.

8. **island**
   June 10, 2006

   Hey!… you forgot mine… Science In Crisis

   The anthropic principle is continually thrust to the surface of the relevant fields of physics and evolutionary science, yet scientists dogmatically ignore the relevant implication for "biocentric preference"… in spite of the fact that it is highly probable that a true anthropic constraint on the forces of the universe will necessarily include the human evolutionary process, which indicates that there exists a mechanism that enables the universe to "leap".

Next time that someone makes fun of, or pretends like they have the first real clue as to what the anthropic prinicple is really about, send my way and I'll deprogram the dogmatic dingbats for ya… 😉

9. **hack**
   June 10, 2006

   Peter Woit, Lubos Motl, Jacques Distler and Lee Smolin. That would be an amusing group blog.

10. **zoologist**
    June 10, 2006

    We have a saying that goes something like "great is the zoo of God" (perhaps there is something like that in English too), so I would seriously like to support the idea in the previous comment and also suggest further members from the "great zoo of God" to make up the Funniest Physics Group Blog Ever:

    Peter Woit, Lubos Motl, Jacques Distler, Lee Smolin, Bert Schroer, Carlo Rovelli

    and that would be the ultimate entertainment around 7-8 PM just before going home from work.

    Dear would-be members please take up contact with each other and consider the potential of this idea. Greater readership, more media-coverage, more fame, more jokes and last but not least: more fun (for us)!

11. **Dan**
    June 10, 2006

    Peter,

    it wasn't a stupid nasty personal attack you deleted. I pointed out to Bert Schroer that he was apparently misunderstanding a physics argument I posted. He replied saying "OK, 1:0 for you". Deleting such things is *very* different from what you claim to be doing.

12. **woit**
    June 10, 2006

    Dan/Michael/Whoever you are,

    The great majority of your comments here contain some sort of stupid insult about the intelligence or ignorance of anyone you disagree with, a tactic that string theorists like you, Lubos and Jacques seem fond of. At least Lubos puts his real name to them. No physics argument by you expressed in the language of reasonably civil conversation was ever deleted. If you have anything reasonably interesting to say, it won't be censored here. If you insist on going on about how stupid and ignorant people are who disagree with you, I'll continue to delete such things, whether or not you're right on whatever substance may be at issue.

13. **Dan**
    June 10, 2006

    Peter,

    is it appropriate by your standards to point out the difference between Seiberg duality and Seiberg-Witten's electric-magnetic duality? That's what I did "in the language of reasonably civil conversation", as evidenced by the fact that Bert Schroer admitted to his mistake without being offended.

    You see, I don't care much about the deletion of some online conversation by itself. But given the number of complaints you have voiced about what you consider unfair censorship of your statements, it is a remarkable example of how careless and agenda driven your own censorship is.

14. **woit**
    June 10, 2006

    Dan/Michael/Whoever you are,

    From what I recall, you were unable to clarify the distinction between the two dualities without doing so in an insulting manner. I have no agenda whatsover about the distinction between Seiberg duality and Seiberg-Witten duality or whether anyone in particular is aware of it or understands it. The "censorship" in this case was not careless and the only agenda driving it was stopping uncivil behavior on my blog.

    Your claims that you were engaging in "reasonably civil conversation" are hard to believe given the one of your comments I left in edited form:

    "Sure, Peter Woit. [Attack on someone else deleted]. You are a pathetic loser. "

    As people can guess, the deleted part was a personal attack on Bert Schroer, of the same kind as ones in your earlier comments that led me to delete them.

    Look, you have a long history here of anonymously posting extremely rude and insulting comments about me and about others. You're well aware of this. It would be a good reason for me to just automatically delete anything that comes in from you. It seems to me that I've gone far out of my way to allow you to express yourself, given your behavior. End of story, I'm not going to waste more of my time dealing with someone who behaves the way you do.

15. **George**
    June 10, 2006

    Hang in there, you are the only one actually putting physics on your page on a consistent basis. Sean used to do so, but has really cut back – too bad – I enjoyed the two of you. But I would hate for all the help in understanding what's happening to disappear completely…

16. **MathPhys**
    June 10, 2006

    Re George's remark,

    This is the one blog with the highest concentration of mathematical physics that I know of.
    When I look at Distler's blog, it seems to be devoted to elaborate discussions of how to type math on the web (What happened, Jacques? We are meant to do science, not to be web programmers).
    Motl's blog has a lot of physics, but also its fair share of political rants.

17. **Anon**
June 11, 2006

The “blog with the highest concentration of mathematical physics” ?

Urs Scheiber’s blog (the String Coffee Table).

Hands down.

18. **Troublemaker**
June 11, 2006

Urs Scheiber’s blog (the String Coffee Table).

Hands down.

This categorization requires a leap of faith that string theory is relevant to physics.

Snicker, snicker.

19. **Anon**
June 11, 2006

Well, since most of the posts on this blog are devoted to string theory (and how it’s not even science), the same criticism applies.

20. **Theo**
June 12, 2006

See, Troublemaker, some of us care only that physics might be relevant to string theory 🙂

Then again, some of us live in math departments, and find it fascinating that folks would complain that something as beautiful as omega-categories might turn out useful for a physics, whether ours or not.

I smiled most at your comment about String Coffee Table’s “categorization”.

Not Even Wrong in the Sunday Times

June 11, 2006
Categories: Not Even Wrong: The Book

Today's edition of the London Sunday Times has a review of Not Even Wrong by John Cornwell in its book review section. Cornwell is a British historian of science, based at Cambridge University.

The review is very positive and pretty much gets things right, so of course I'm quite pleased by it. It does get one thing wrong, or at least expresses it in a misleading way: David Gross is listed as an ally, which is certainly not the case as far as criticism of string theory goes (although we both agree about the string theory anthropic landscape). A more minor quibble would be with his description of the significance to Pauli of the phrase "Not Even Wrong" (it wasn't purely a term of abuse, but also refers to the untestability of a theory). But on the whole I think Cornwell does a very good job of describing the more controversial parts of the book and what its concerns and arguments are about.

Lubos already by last night had posted his trademark ad hominem attack on the reviewer. By now, his ranting response to any one who publicly criticizes string theory or agrees with me on this topic is tediously familiar, involving launching a personal attack on their professional qualifications, then comparing them to dogs, assigning extremely low numerical values to their intelligence, etc., etc.

Cornwell expresses the opinion that

Now that Woit has thrown a wild cat among the theoreticians, we can be sure that the ruffled string-theory advocates will be preparing a rebuttal.

So far the only rebuttal to be seen is that from Lubos, who tells us that most string theorists agree with him, writing that:

Cornwell predicts that string theorists will be preparing a rebuttal to the dean of the crackpots. I am afraid that with exactly one exception, they have much more serious work to do than to talk to cranks. My simple statement that the dean of all crackpots much like John Cornwell could not become graduate students of physics today because they are unable to understand some very elementary questions about science will probably remain the only reaction.

and

Most string theorists much like most high-energy physicists in general are extremely nice people – too nice people – so they won't say that Cornwell is a breathtaking moron in the public. But be sure that they agree with me and many of them are saying these things in between the physicists. In the public, the only question is how to explain that Cornwell is a complete idiot without making anyone upset.

Lubos claims that most of his string theory colleagues believe that I'm a crank and my arguments about the problems with string theory are not worth responding to. This may or may not be true, but even if it is, I find it hard to understand why they allow him to go on in this way, claiming that he represents their viewpoint, given the immense amount of damage he is doing to the public perception of their field. If you believe Lubos, some of his senior colleagues seem to even think it is a good idea to egg him on in what he is doing. He reports that one senior physicist sent him last weekend's Financial Times piece, describing it as

a tendentious, malicious attack on scientists and through that on science itself

and that another "very famous physicist with more than 10,000 citations" told him:

WOW. I can't believe the FT article. Holy Shit, the world has gone completely bananas.

Update: In case anyone is following the comment section over at Lubos's blog about this, note that his policy there is to delete any comments from anyone he disagrees with. I wrote in a comment answering an attack on me from "LambChopofGod" which was swiftly deleted, and others have had similar experiences. Did make me sit back and think for a moment: what am I doing spending my Sunday evening responding to nasty personal attacks from some fanatical kid hiding behind the pseudonym "LambChopofGod"? This is getting very, very weird…

Comments

1. **george**
   June 11, 2006

   Lubos is just a crazed, socially inept, but brilliant scientist. Anyone who reads Lubos's comments can figure this out, and turn on the appropriate mental filter.

   No, unfortunately, it is you Peter who is doing the greatest amount of damage to the public perception of string theory.

2. **knotted string**
   June 11, 2006

   Every single journalist and every single publication that prints the truth about the lack of science in string theory will be called 'science-hater par excellence' or 'crank/crackpot'. Intimidation strategy:

   1. 'Discredit' people by simply calling them names.
   2. Feign anger: claim objective criticism 'hurts science', etc.
   3. Ignore/suppress alternatives, then claim none exist.
   4. Claim without any evidence that critics have low IQs.
   5. Claim 'string theory' theorists can criticise themselves.
   6. Claim without evidence that all critics are ignorant, etc.
   7. Fabricate/exaggerate false/trivial/straw-man technical 'errors' in criticisms and try to use these to dismiss the entire criticism.
   8. Claim without any evidence that their work is science by definition because they have had a 20-year honeymoon in the media, and then claim (again without evidence) that by criticising it you are objecting to science, rather than encouraging science (objectivity).

   In fairness, there are two types of 'science': dogmatic defense of abject speculation, and objective investigation.

3. **David**
   June 11, 2006

   In general, I agree with knotted string with two exceptions.

1. Not all string theorists behave this way. For example, Zwiebach, in Chap.1 (p.8) of his book, says there is no experimental verification of string theory because of the lack of a sharp prediction.If he chooses to spend his time looking for one that's OK with me. It would be nice to hear something from him about some of the wilder claims by some others(e.g. God used string theory to write the universe).
2. Consider knotted strings last sentance. I know he/she wants to be fair but I think the only type of science is objective investigation as best we can do it.

4. **wolfgang**
June 11, 2006

David,

let me complete your quote:
"String theory is still at an early stage of development, and it is not so easy to make predictions with a theory that is not well understood. Still, some interesting possibilities have emerged."

He then goes on to explain what type of experiments could provide support for string theory.

If you have a copy you can read this from p.8 to p.10.

5. **ks**
June 11, 2006

I do think that most of Lubos behaviour is already socially accepted among scientists for quite some time. And he will likely know this. What can originally be attributed to him is the inflationary use of the term "crackpot" to all colleagues / journalists who fundamentally disagree with his views and of course the puberal rudeness of his insults. But qualifying people as "crackpots" or "cranks" or making any other layman diagonsis of mental disorder is not his invention and it is not specific to string theorists and their excommunication rites.

6. **anonymous**
June 11, 2006

Seriously, what's the deal with Mr. Motl? I've never met him, but after repeatedly encountering his seemingly inescapable web-presence, I can't help but imagine him as television's Tucker Carlson, typing away furiously under a pseudonym.

7. **CapitalistImperialistPig**
June 11, 2006

Peter,

Congratulations! Your book is clearly getting a lot of good press and driving the string theorists "bananas."

Why is its publication so much later in the US?

Anonymous,

Professor Motl is quite real, and an assistant professor in the most imprtant university in the US (and world), Harvard.

Whatever else we may think about him, and I do think (and write)about him frequently, he is definitely an original.

8. **woit**
June 11, 2006

CIP,

Thanks!

The reason it\'s being published at different dates in the UK and the US is just that the publishing business is kind of funny, with different publishing houses operating in the two different countries. So you end up having to have two different publishers. My book was originally bought by a UK company (Jonathan Cape), which got interested in it after hearing about the book from Roger Penrose, one of their authors. The deal I made with Cape involved selling them world rights to the book, and they then went looking for a US company to publish here, finally settling on Basic Books. The whole process ends up taking quite a while, and Cape ended up publishing before Basic. This isn\'t particularly unusual, Lisa Randall\'s recent book was also first published in the UK.

9. **anon**
June 11, 2006

very famous physicist with more than 10,000 citations" told him:

"WOW. I can't believe the FT article. Holy Shit, the world has gone completely bananas."

A coward, letting Lubos do the dirty business. It's cowards and dirty politicians like that who decide which physics phds get jobs in the field and which don't.

10. **George P**
June 11, 2006

Being a "brilliant" scientist isn't enough. Hitler had plenty of those. One needs stewardship and some "street smarts" about what to study, why, and when. One needs to guard against pursuing blind alleys or going down a destructive path. Sometimes you gotta use outside feedback to do that.

Lubos' only response to feedback is childish ad hominem attacks. Also disturbing is his devotion to nutty right-wing causes. He repeatedly demonstrates that he tragically lacks this "meta-intelligence" and that his EQ is so low that it cancels out his ability to put his "book smarts" to any good, worthy use. A pretty smart person with stewardship and discipline is more effective than a whiny "boy genius" brat like Lubos.

11. **MathPhys**
June 11, 2006

Lubos is not a genius. He's smart, but so are many other people.

It’s been about 4 years or more since his PhD and, in spite of the fact that he’s always been right in the middle of the US theoretical physics establishment, his achievements are minor, compared to many others at the same stage of their careers.

Sorry, Lubos.

12. **MathPhys**
June 11, 2006

anon,
I think I see what you mean. Someone gets irritated by something anti stringy in a newspaper. He finds it below him to react to it directly, or maybe just doesn’t have the time. He brings it to Motl’s attention, knowing that the pitbull will bite and never let go.

Yes, Lubos, I’m afraid you’re being used.

13. **Arun**
June 11, 2006

If Peter Woit was wrong, it would be very easy to refute him, maybe even in one sentence, e.g., like “the XYZ experiment makes Woit’s arguments irrelevant”.

John Q. Public may not know much science, but would be able to spot the absence of such a simple argument from the string theorists. Furthermore, he will see the message from Harvard – we cannot discuss physics with morons such as you. He will see “Cornwell explains that the colliders are a waste of money” but read “Even the proposed prodigiously expensive class of accelerators known as Superconducting Super Colliders (SSCs), he claims, would have failed to provide the merest clue as to whether the theory had merit.” – which is only about the uselessness of SSC for string theory. In any case, if the Harvard attack gets as much circulation as the Cornwell review, it will leave little room for doubt on the part of the public.

String theorists might have better luck with the argument that Peter Woit is not entirely right. 🙂

14. **David**
June 12, 2006

Peter,
I admire your patience. It is considerably more than I have.
Best,
David

15. **David**
June 12, 2006

Peter,
I learned a lot tonight. The final portions of my discussion with Motl were deleted which leaves the reader, following Motl’s misquotes, with the impression that I said that you said Polchinski’s book had an error. I never said that. I said I thought there was an error and you told me how Polchinski got his result. That’s all you said. Please leave this up so somewhere it’s clearly stated. I hope you saw the end before it was deleted. I have new thoughts about Motl as a scientist.
Best,
David

16. **John Stanton**
June 12, 2006

A friend of mine told me once that internet
and other ad hominem attacks as a reaction
to an idea are a complicated way to say:

“You are possibly right, but your idea goes so
much against my deeply held convictions that I can
only express this by insulting you.”

Keeping this in mind, one can be more relaxed about
the issue. I know people who use this to check their
ideas: if they get counter-arguments, they think
about them; if they get insulted, they know they are
on the right track.

17. **knotted string**
June 12, 2006

David,

If the definition of ‘science’ is to be kept objective, then we should do the same with ‘theory’ and not associate that with strings. The key strength of ‘string theory’ is incompleteness and vagueness. As ‘t Hooft says, ‘string theory’ is like being given a chair minus arms, legs, back etc. It is just an idea, a hunch.

So calling strings a ‘theory’ elevates it to a status it doesn’t really have. And then calling vacuous ‘string theory’ actual ‘science’ to defend it from critics is just absurd.

I either have to keep denying string theory is science, or I have to invent a new type of science – metaphysics – in which to place string. Interesting summary of a relevant subject:

http://en.wikipedia.org/wiki/Groupthink

‘Groupthink is a mode of thought whereby individuals intentionally conform to what they perceive to be the consensus of the group. …

‘The term was coined in 1952 by William H. Whyte in Fortune[1]:

‘”Groupthink … is a rationalized conformity — an open, articulate philosophy which holds that group values are not only expedient but right and good as well.” [2]

‘Irving Janis, who did extensive work on the subject, defined it as:

'"A mode of thinking that people engage in when they are deeply involved in a cohesive in-group, when the members' strivings for unanimity override their motivation to realistically appraise alternative courses of action." [3]

'The word groupthink was intended to be reminiscent of Newspeak words such as "doublethink" and "duckspeak", from George Orwell's Nineteen Eighty-Four.

'Irving Janis originally studied how groupthink affected the Pearl Harbor bombing, the Vietnam War, and the Bay of Pigs Invasion…

'Causes and symptoms of groupthink…

'Illusion of invulnerability
'Unquestioned belief in the inherent morality of the group
'Collective rationalization of group's decisions
'Shared stereotypes of outgroup, particularly opponents
'Self-censorship; members withhold criticisms
'Illusion of unanimity (see false consensus effect)
'Direct pressure on dissenters to conform
'Self-appointed "mindguards" protect the group from negative information

'… symptoms of a decision affected by groupthink:

'Incomplete survey of alternatives
'Incomplete survey of objectives
'Failure to examine risks of preferred choice
'Failure to re-appraise initially rejected alternatives
'Poor information search
'Selective bias in processing information at hand (see also confirmation bias)
'Failure to work out contingency plans

'Social psychologist Clark McCauley's three conditions under which groupthink occurs:

'Directive leadership

'Homogeneity of members' social background and ideology
'Insulation of the group from outside sources of information and analysis …

'One mechanism which management consultants recommend to avoid groupthink is to place responsibility and authority for a decision in the hands of a single person who makes the decision in private and can turn to others for advice. Others advise that a preselected individual take the role of disagreeing with any suggestion presented, thereby making other individuals more likely to present their own ideas and point out flaws in others' and reducing the stigma associated with being the first to take negative stances (see Devil's Advocate).'

18. **island**
June 12, 2006

I've had comments deleted by Peter and I've never questioned his reasoning. Lumo is a completely different story, as he deletes stuff because he doesn't like the message, but not because it isn't relevant and/or valid.

The most frustrating counterargument is the kind that you get when the people that you're talking to simply go silent because they can't refute your physics, but still won't buy it, so their stategy becomes that of sitting back and waiting for a refutation to come along rather than to admit that you have a point.

Fifty hard facts gets you nothing but air.

Dogma at it's finest.

19. **hack**
June 12, 2006

Lubos is not a boy genius, more like an ageing wunderkind. He had some early success, but now he's 32 or 33 and there are many who have achieved more than he has at that age. I've read that it can be very depressing for a former wunderkind to come to the realization that he is no longer the youngest guy in the room so to speak. I can imagine how he might cope with this in bizarre ways, such as cultivating an adolescent internet persona. But acting like a teenager when you're in your 30's doesn't make you young, it makes you pathetic.

20. **anonymous**
June 12, 2006

[…]

I don't think its a good development that what should be a scientific controversy is discussed in public on such a mediocre level. It is sad, it is very sad, that the physicists community is apparently not able to solve the problem on its own. This tells a lot about what is going wrong in physics research.

How many people who read the book, or the article, can judge on the actual issue? What is created is the impression that theoretical physicist don't know what they are doing, or why they are doing what they are doing. Instead they call each other crackpots, morons, or debunkers, and blame each other to be on the wrong track.

[…]
If I were to decide whether tax money goes into theoretical physics on base of that, I'd say: let's wait till they have sorted out their problems before we invest money.

Do we want that?

Best, B.

I don't.

21. **anonymous**
June 12, 2006

sorry, from Lubo's blog

http://motls.blogspot.com/2006/06/dean-of-crackpots-hitlers-pope-and.html

22. **xpinor**
June 12, 2006

Is the reviewer John Cornwell identical with the professor at St. Andrews and author of the three-volume book on group theory?

23. **amused**
June 13, 2006

This will no doubt test the limits of Peter's tolerance but I'ld like to abuse the hospitality of this blog to respond to Lubos' latest post on his blog, "Science vs Democracy". Lubos usually deletes my comments there, and since he seems to spend almost as much time here as on his own blog, responding to him here seems the only option. His post was in response to comments by someone called "B" on his earlier post attacking the Sunday Times review of Peter's book; so, with more than a little good will, the following is arguably not completely off-topic here.

Lubos, you are being disingenious as usual. Obviously in a string-dominated environment you and your colleagues are going to be all in favour of "leaving the selection of the good ideas to the usual free mechanisms in science", just as the bosses of Microsoft wish for a free market free of those annoying anti-monopoly laws that governments try to harrass them with.

The relevant question is whether string theory deserves its current level of dominance in theoretical hep (at least the non-phenomenological side). As far as I can tell, you guys have two main arguments for this: First is the claim that David Gross likes to make, that the situation in string theory now is analogous to the one prior to the formulation of QM in the early 1900's, where people were groping for the right understanding and formulation of the new physics. The implication being that "Hey guys, major new physics is on the verge of being discovered, everyone should be working on this!". Second is the retort "If we're not to do string theory, then what else? Show us a more promising alternative."

Actually I have some sympathy with both of these arguments. But not much. On the one hand it's certainly a big deal to have found a not obviously inconsistent theory of quantum gravity which has a possibility to unify gravity with the other forces. On the other hand, despite 30 years of effort by some of the best brains in physics, the results so far are spectacularly unimpressive: you have nothing more than hints that string theory (or some parts of it) may have something to do with nature. Contrast this with Bohr's result – in his atom model – where he was able to derive the Ryberg constant in terms of other basic constants of nature. This is the kind of result you guys need to come up with before the claim that the string theory situation is analogous to pre-QM can be taken seriously. You are nowhere near to obtaining such a result, and there is no sign that this is going to happen anytime in the forseeable future.

Now let's consider the "show us a better alternative" argument. To that my reply is: When a completely "top-down" approach like string theory gets bogged down, it might be a good idea to permit some work to be done on "bottom-up" approaches. I emphasise *permit*, because at present you do not permit it – young people who choose formal theory topics which are non-string are seriously harming their career prospects. String theorists and higher-dimensional types are mighty proud of themselves when they make applications of brane stuff to low energy QCD, or lattice chiral gauge theories, but woe betide any young fool who is naive enough to work directly on these topics. They are only considered of interest to the extent that string theory can say something about them, and it is only the results that come from string theory that are considered to have value.

An example of a formal theory topic which has seen major progress over the last decade, and where there is much of interest that remains to be done, but which would be career suicide for a young person to work on, is lattice formulation of chiral gauge theories. (I choose this example since it happens to be dear to my heart; no doubt there are other equally good ones.) A nonperturbative formulation of chiral gauge theories would be quite a nice thing, don't you agree Lubos? It is at any rate a prerequisite for being able to properly investigate the nonperturbative phenomenon of spontaneous electroweak gauge symmetry breaking. And who knows, maybe results from this "bottom-up" topic could later inspire new insights in "top-down" string theory. But with things the way they are now we will never know, because, thanks to string dominance, such topics are not a viable option for anyone who hopes for a career in physics.

24. **Peter Woit**
June 13, 2006

amused,

I pretty much agree with you, and it's remarkable that Lubos now feels that the only way he can handle those with a different point of view about string theory is to delete their comments. Perhaps I should set up a "Lubos's deleted comments thread" here.

"B" is Sabine Hossenfelder, her blog is backreaction.blogspot.com, and you might want to try and carry on this discussion over there with her.

25. **amused**
June 13, 2006

Ok, thanks for the info Peter, and for allowing the comment to stay.

"Perhaps I should set up a "Lubos's deleted comments thread" here."

Lol. Yes, please do!

26. **Aaron Bergman**
June 13, 2006

I'm somewhat confused by your comments, amused. I'm pretty sure I'm not imagining all the lattice gauge theorists in the world. Are you saying that the job prospects for a lattice gauge theorist are worse than that for a string theorist. I have no idea if that's true or not, but I'm just trying to see if I'm interpreting you correctly.

27. **Ponderer of Things**
June 13, 2006

Quote from earlier: "Lubos is not a genius. He's smart, but so are many other people. It's been about 4 years or more since his PhD and, in spite of the fact that he's always been right in the middle of the US theoretical physics establishment, his achievements are minor, compared to many others at the same stage of their careers."

I was going to defend Lubos, as I was under the impression that he was publishing a lot lately. But when I went to ISI, there are only 10 published refereed papers for Lubos, only one in the past 3 years and none in the past 2 years. Well, I have to say I am surprised. And only 2 out of 10 papers as first author?

I personally know plenty of grad students with more impressive publication record than that.

Sorry, Lubos, but arxiv is no substitute for refereed publication process…

28. **Aaron Bergman**
June 13, 2006

Just a factual correction: in string theory, authors are in alphabetical order.

29. **amused**
June 13, 2006

Aaron, regarding the job situation for lattice gauge theorists you need to distinguish between people doing "bread and butter" lattice QCD research – i.e. numerical simulations, algorithms, & phenomenological chiral perturbation theory stuff needed to extract physical results from the simulations – and those (few) people doing formal stuff like construction of chiral gauge theories. For the former the job situation is not too bad, at least at postdoc level. It's tough at the faculty level, but that's also the case for many other fields. I'm not sure exactly how it compares to the job situation for string theorists; certainly there seem to be a lot more of them on the jobs rumour pages, but that could to some extent just reflect that there are more stringers than lattice QCD'ers. On the other hand, for people doing formal lattice gauge theory stuff the situation is pretty hopeless. Almost all traditional lattice gauge theory groups focus on the bread and butter stuff and are simply not interested in hiring people who only want to do formal things. The natural home for the formal types would be in a regular formal particle theory group. But "most" of these groups happen to be focusing on string theory, branes etc and are not interested in people from other fields…

30. **Peter Woit**
June 13, 2006

xpinor,

I don't think it is that John Cornwell.

31. **Anon-e-mus**
June 13, 2006

"L*b*s's deleted comments thread" — me, too! I was even permanently banned from commenting on his blog after repeatedly pointing out that he had misread what various people whom he accused of saying various nasty or stupid things actually wrote. Of course anybody able to "read, mark and inwardly digest" English prose can still see that to be the case even without my comments pointing it out…

32. **Ponderer of Things**
June 14, 2006

Thanks for correction on string publication order – now I recall that it is indeed the rule.

Still, no published papers over the past two years – according to arxiv this doesn't even qualify Lubos as an "active researcher".

33. **Peter Woit**
June 14, 2006

Ponderer,

All the evidence so far is that the arXiv official definition of "active researcher" is "not Peter Woit". Attempts to get them to set a well-defined standard based on number of publications foundered when it became clear that the arXiv moderator, Jacques Distler, wouldn't meet the standard (which was just number of papers, not counting whether they were published). As far as I can tell, neither he nor Lubos would meet suggested numerical standards based on published papers.

34. **Lionell Griffith**
June 14, 2006

All this hoha could be avoided if reality were determined by equations. One could simply write the equation and *poof* the feature would exist in reality. All problems could be solved by scribbles on a scrap of paper.

Unfortunately, the equations must conform to reality. Until that conformance is demonstrated, the equations are nothing but bad fantasy and science fiction. More importantly, they are Not Even Wrong.

I suggest most of the string hoha is about getting grants and writing papers. The last thing they want is a real solution to real problems. If that happened, they might have to get a real job and actually earn their keep. We can't have that. Can we? We common folk have to pay the bills so the "superior" types can play forever without having to produce anything having meaning or value.

35. **Aaron Bergman**
June 14, 2006

I suggest most of the string hoha is about getting grants and writing papers. The last thing they want is a real solution to real problems. If that happened, they might have to get a real job and actually earn their keep. We can't have that. Can we? We common folk have to pay the bills so the "superior" types can play forever without having to produce anything having meaning or value.

So, Peter, do you think this is true?

36. **CapitalistImperialistPig**
June 14, 2006

Aaron,

I, at least, think it's implausible that string theorists don't want "real solutions to real problems."

At the same time, you can't neglect Upton Sinclairs principle that "it's amazing how hard it can be for someone to understand something when his salary depends on his not understanding it."

String theorists all have very high IQs and the ability to work very hard, so unless they are otherwise psychologically disabled, they should mostly be able to make a lot more money doing something else.

37. **woit**
June 14, 2006

Aaron,

No I don't think it's true (by the way, I disagree with many if not most of the comments posted here). I was about to delete it, but didn't partly because I was busy, and partly to show what a lot of everyday people's reactions to the string theory mess is likely to be. I've written elsewhere about the unfortunate backlash against any ambitious work on the fundamentals of theoretical physics that is starting and likely to increase due to the way string theory has been oversold.

38. **Aaron Bergman**
June 14, 2006

Thank you for that. I asked because I figured people would ignore me if I said that it wasn't true, but people might listen to you. Whatever one thinks of string theory as a research programme, I hope things don't degenerate too much into arbitrary attacks against string theorists.

39. **Ponderer of Things**
June 14, 2006

Peter, I find it somewhat ironic that arxiv, with it's supposed aim to "free" the scientific community from delays or restrictions of paper-based publications and sometimes lengthy refereeing process, has been recently busy creating rules for rejecting unpopular among certain circles (but scientifically valid) ideas, blocking trackbacks etc.

I am especially surprised since I was able to post and to quickly become an endorser without any endorsing, but then again, my research is not controversial.

I happen to think that arxiv should be totally "free for all" – if crackpot start posting junk, so be it – let people figure out what is what. As if regular publications are free of junk – surely enough if you go down low enough on the foodchain, you can publish just about anything.

As a product of former soviet block system, I also find somewhat ironic that Lubos, who claims to be self-proclaimed anti-commie right-winger, uses very much the same tactics commonly employed by communists (scientifically or politically – be it Lysenko-Michurinism or Sakharov) to limit critisism – such as simply deleting undesirable comments, and responding to reason with demagogery, namecalling and personal attacks. You'd think he lshould have learned a thing or two about character assasination vs. respectful and civil free exchange of ideas.

40. **Who**
September 10, 2006

CapitalistImperialistPig mentioned:

…you can't neglect Upton Sinclairs principle that "it's amazing how hard it can be for someone to understand something when his salary depends on his not understanding it."

String theorists all have very high IQs and the ability to work very hard, so unless they are otherwise psychologically disabled, they should mostly be able to make a lot more money doing something else.

reminds me that part of the payment must be in real or fancied prestige.
the importance of importance was one of the themes in NEW recent thread about Open Access Publication. (the prestige conferred by publication in top journals balances simple dollar and time considerations)

besides pure interest and excitement, besides money rewards, people work for recognition and status. so one thing that open criticism of the string monopoly in the US might eventually do is **change the prestige payoffs** a bit. don't know if this has much or any significance compared with the plain bread and butter issues of postdoc contracts and junior faculty hires—-just a thought

More in the Times

June 12, 2006
Categories: Not Even Wrong: The Book

In Monday's London Times there's a [piece]() by Anjana Ahuja about my new book and the controversy over string theory. Ahuja worries that I might have multiple spleens, so I want to reassure her and others that I only have one, generally of normal size. I suppose that at times when dealing with Lubos, it may get a bit enlarged.

Ahuja gives a reasonably good account of some of the heated debate going on about string theory, but does get one thing wrong about my point of view on this, when she sets me up as someone who argues that "aesthetics is no substitute for experiment" in contrast to Brian Greene's emphasis on "The Elegant Universe". This is an issue where I'm with Brian, unlike, say, Lenny Susskind. I firmly believe that this is an elegant universe and that the pursuit of more mathematically elegant theories is our best hope for moving forward. I just don't happen to think that the kind of string-theory based unification ideas that people have been pursuing are especially mathematically elegant.

Ahuja also remarks on the fact that Brian and I work in the same department but I don't thank him in the acknowledgements. There's no big mystery about that, I just haven't had any really substantive conversations with Brian about the topics of the book, so didn't explicitly thank him there. Brian is a very nice guy who I first met when he was a graduate student. He came to Columbia about ten years ago, hired by the math department with a joint appointment in physics. During the past few years, unfortunately for the math department, Brian's interests have shifted from mathematics more towards physics and he spends most of his time over in the physics department, where he has started up a successful new research institute called ISCAP.

I've often helped him with computer problems, and last time I saw him a week or so ago in the hallway, he congratulated me on the book, which he had just gotten a copy of from the publisher, and said he was looking forward to reading it. I warned him he might not like some parts of it at all, he said that was fine, controversy and debate was good, or something like that. Basically, he and I disagree about a scientific question: can one make a successful unified theory out of string/M-theory? I think there are good reasons to think one can't, he's still optimistic that it might work out.

Brian is far from the only string theorist I know who I have this disagreement with. Some are very good friends that I've debated with extensively about this, others, like Brian, I don't happen to have spent much time discussing the topic with. But disagreements over whether some speculative idea can ever work are not unusual in science, and most scientists have no problem with healthy debate of this kind. I've found it extremely surprising and disturbing that a small number of string theorists have chosen to engage in personal attacks rather than the usual sort of scientific debate.

   > that a small number of string theorists have chosen
   > to engage in personal attacks rather than the usual
   > sort of scientific debate.

   It's one thing to expect to find beauty and truth in your theories about nature, but to expect to find universal politeness in an entire community is asking more than just a bit too much of human nature.

   Carl

   June 12, 2006

   I found this blog from the article in today's Times. As a mere periodontist who just takes an interest in physics, I was assured by a young friend who happens to be a professor (meaning the top level of UK academic post) of physics at a leading UK university that quarks, leptons and force-carrying bosons are about the smallest things for which there is good experimental evidence. I read Brian Greene's "Fabric of the Cosmos" last year in Arizona, and his "Elegant Universe" a few years before. These books follow in the great mould of Banesh Hoffman's "Strange Story of the Quantum" (which I read in the 1960s) in explaining fairly clearly to non-physicists a bit about recent thinking. I'm hoping Peter Woit's book is as much fun when I get it in a few days. I find his blog very interesting, but do not understand why he has been insulted by other people. Why should anyone insult someone else over anything scientific, particularly something for which evidence appears unlikely to be obtainable? There is an old (Chinese?) proverb which says that the first person to hit the other is thereby admitting he has lost the argument. I'm afraid I tend to discount the views of people who stoop to insults.

3. **Michael Schmitt**
   June 12, 2006

   "…the pursuit of more mathematically elegant theories is our best hope for moving forward…"

   Perhaps you meant this in a narrow sense? My opinion is that particle physics suffers from a lack of revealing data – all that we know is in accord with the Standard Model, so we have no hint from HEP in which direction to go, theoretically speaking. Of course there are other signs of new physics beyond the SM, such as dark matter and baryogenesis, but theorists address these problems with models – the problems do not seem big enough to tell us which theoretical directions are right. Some theoretical work seems to me so far removed from experiment as to be practically untestable, in which case there is no valid guide for progress, including mathematical elegance. Would anyone say that QED is mathematically elegant? Yet by some measures it is the most valid theory ever invented…

4. **knotted string**
   June 12, 2006

   I don't like the fact that the review quotes you apparently dismissing all roads: 'Researchers need, he says, "to acknowledge that this particular speculative idea doesn't really work and there aren't any obvious good ideas out there".'

   But you describe loop quantum gravity (pages 189, 255) and describe other speculative ideas towards such as twistors and the ideas of Alain Connes. You argue for using representation theory to understand the diffeomorphism groups of general relativity.

   Another issue I have is whether string theory is really already falsified? In the book you do argue that supersymmetry in string theory is inconsistent with data for force strengths on pages 177 and for the cosmological constant on page 179. So not only is string theory 'not even wrong' regarding the question of making predictions (landscape of solutions, etc.), it's also just plain wrong when considered as an ad hoc a model for existing observations.

5. **Juan R.**
June 12, 2006

Trevor said,

Why should anyone insult someone else over anything scientific, particularly something for which evidence appears unlikely to be obtainable? There is an old (Chinese?) proverb which says that the first person to hit the other is thereby admitting he has lost the argument.

The Chinese proverb holds in this case. When persons have not arguments substitute them by insults. That is the case of several of string theorists here.

String theory has failed. The only technical argument (from string theorists) could change our current perception is showing us how real problems are solved in string theory approach, that predictions will be done at next HLC series of experiments, how string theory is compatible with Standard Model and General Relativity…

The problem with string theorist cannot do nothing of that even after 40 years of unlikely attempts and unending promises.

Juan R.

6. **woit**
June 12, 2006

Michael,

When I argue that the search for mathematical elegance is our best hope for progress, that's in the context of assuming experimentalists can't get us anything new. I certainly hope that is not true, that the LHC or even the Tevatron will soon radically shake things up with unexpected new data. But if that doesn't happen and we still want to work on speculative new ideas about high energy, mathematical elegance is one of the few criteria we have for figuring out which way to go.

And I do think QED is in many ways a mathematically elegant structure, and QCD is even more so.

7. **Thomas Larsson**
June 12, 2006

You argue for using representation theory to understand the diffeomorphism groups of general relativity.

Knotted string,
I certainly cannot speak for Peter, but you just mentioned the reason why I generalized the Virasoro algebra to several dimensions. 🙂

8. **HH**
June 12, 2006

Hehe, it made it to digg.com:

http://digg.com/science/String_Theory_Debunked_

9. **Chris Oakley**
June 12, 2006

> And I do think QED is in many ways a mathematically elegant structure, and QCD is even more so.

You're welcome to both of them.

Incidentally, the article in *The Times* makes much of Peter's spleen and the "online squabbling" that goes on here, but – apart from the Bohemian Brat – does anyone really behave that badly here? I don't think so. In fact, I see the contributors to this blog as continuing an ancient tradition of gentleman scientists that goes back to Lord Rayleigh. "Lively discussion" is the term I would use rather than "squabbling".

10. **hoggy**
June 12, 2006

Digg = ass of the internet news sites.

11. **David Younger**
June 12, 2006

I too read the article today. I cannot read about string theory without thinking about Prolemy's system of wheels and epicycles. For many years after Copernicus described a sun centred system, Ptolemy continued to prove a better predictor of the movements of the stars and planets. But it was wrong, and all the elegance of the maths behind it couldn't alter that.

12. **Benjamin**
June 12, 2006

Hi Peter. My question may seem off-topic, but I think it's relevant to your site, since it involves the whole issue of what makes good science. I do agree with certain unnamed critics of yours that the climatology behind the global warming hysteria is shaky and questionable. Somehow I would expect a skeptic like you to agree, for reasons somewhat similar to how you view string theory. Any comment? I'm not asking you to deny the global warming hype altogether, just to say whether you think it is full of uncertainties, even if a majority of climatologists think otherwise. Even if you haven't studied it in detail, what does your common sense say about using a computer model to predict something as complex and nonlinear as the weather? Not to mention the uncertainties in the input data. You may take the safe path and say that you simply don't know, but I'll be shocked if you say that you have a lot of confidence in the global warming theory!

13. **Peter Woit**
June 12, 2006

Benjamin,

Please, no climatology debates here. I'll delete any more on this topic.

Despite what some people think, I really don't go on here about things I haven't spent a lot of time learning about and thinking about. Life is short, and climate science is not something I've spent any time at all thinking about.

One of my few data points is Lubos, who seems to be almost infallible at falling for heavily ideological nonsense. Based on what he has to say, my prejudice would be that there must be something to global warming. But then again, on rare occasions he gets it right (e.g. the string theory anthropic landscape), so I can't just rely on his opinions.

So, I stick to my position: I don't know and don't have time to find out for myself.

14. **John Gonsowski**
June 12, 2006

Funny, Susskind actually created the most math elegant M-theory (bosonic M-theory) but unfortuneately he didn't do anything with it and instead went down a really inelegant path. Bosonic M-theory has no superpartners but that could end up being a good thing.

15. **Anonymous**
June 12, 2006

Right now, "Not Even Wrong" has an amazon.co.uk sales rank of 71, meaning that there are 70 books out there which are selling better than it at the moment. That sounds pretty good, even if this is just the early buyers all buying at the same time.

16. **Michael Bacon**
June 12, 2006

Peter,

I think getting the book pubished is gong to be a good thing for you — and the ideas you expouse. Your response to Benjamin seems to strike the right balance — bemused tolerance. Exactly the right attitude to take regarding Lubos. He could very well be right regarding any number of matters, but who knows, given the crazy way he responds to things. Anyway, congratulations on the book and the good reviews, and on your abilitiy to raise fundamental questions that deserve serious answers. I enjoy the blog a lot.

17. **woit**
June 12, 2006

Thanks Michael and others,

I've been surprised at how well the book seems to be doing, and extremely pleased by the positive reaction to it. At one point I was advised that it was just too difficult a book for most people, but the publishers ended up allowing me to write exactly the book I wanted, and it is gratifying to see that people are enjoying it, and not getting put off by some of its more technical aspects.

18. **Thomas Reasoner**
June 12, 2006

Benjamin, the various theories of Global Warming are testable and thus falsifiable, whereas String Theory is not. I see no correlation between the two situations whatsoever.

Now to stay on topic: congratulations on the book! I hadn't planned on buying it, but I think I just might in order to support the cause.

Regarding Brian Greene, I have read a couple of his books, and I've even seen his Nova series, and I must say I was not at all impressed with any of it. Maybe the problem was that I wasn't really in the target demographics. The other problem, I think, is that his works seemed to me to be lacking any real insight. There were no great moments of epiphany for me reading his stuff. Ironically, his "Elegant Universe" really turned me off from String Theory, even though it was supposed to turn the reader on to it.

19. **D. Eppstein**
June 12, 2006

David Younger: You don't think Ptolemy's epicycles were an important forerunner of Fourier analysis? That seems a much more important role than their "not even wrong" description of planetary motion. In fact the ability of epicycle type theories to fit any cyclic motion has a lot to do with how useful Fourier analysis is…

20. **top ten?**
June 13, 2006

from comments on Lubos Motl blog:

Lubos, can you please post the 10 top results relevant for physics achieved by string theory? This would be a more reasonable way of clarifying the present controversy. Since I am worried that you will not like this comment and will delete it, I am going to post it also on Peter Woit blog.

21. **JPL**
June 13, 2006

"And I do think QED is in many ways a mathematically elegant structure, and QCD is even more so."

Peter,

Do I take it correctly that you don't hold the same opinion about Electroweak Theory (GSW Model etc…) ?

22. **island**
June 13, 2006

Peter… don't forget us when you're famous…

er…

Peter won't be able to forget us when he's famous… try as he might… heh

23. **Peter Woit**
June 13, 2006

JPL,
Well, QED is part of the electroweak model, and, ignoring the Higgs mechanism, the rest of the GSW model is a gauge theory just like QCD.

I do think the electroweak model is mathematically elegant, but it's a more complicated situation than QCD. There's the Higgs, which is problematic for various reasons, and certainly makes the whole thing more complicated and less elegant. Also, the electroweak model really forces you to think about chiral gauge theories, and these are in many ways mathematically even more interesting, but much less well understood.

24. **Tommaso Dorigo**
June 13, 2006

Hi all,

despite being grateful for Michael S.'s recent flattering comments about my posts, I need to join the debate here, and throw in my two pence – QED is surely elegant and I understand those who say so. QCD is probably also elegant but its elegance is beyond my reach.
What I really find the most elegant of all mathematical structures involved in our current understanding of the subatomic physical world is group theory. In a sense, without the elegance of group theory, much of the charm of QED and QCD would be gone.

Just a dumb experimentalists' HO…

Cheers,
T.

25. **Tommaso Dorigo**
June 13, 2006

… I missed a part in my preamble above: despite… I need to disagree with Michael.
T.

26. **Anonymous**
June 13, 2006

How surprised would everybody be if no Higgs (or any other new particle) is found at the LHC? I understand that there are good reasons to expect to find the Higgs, but weren't there good reasons to have found it at lower energies, too?

27. **MathPhys**
June 13, 2006

Does anyone know of way to put money on outcomes of the LHC? I want to invest money betting that

1. No Higgs scalar will be seen,
2. No susy partners will be seen

I need the money to buy a new bike, and that's a sure bet.

28. **Aaron Bergman**
June 13, 2006

How surprised would everybody be if no Higgs (or any other new particle) is found at the LHC? I understand that there are good reasons to expect to find the Higgs, but weren't there good reasons to have found it at lower energies, too?

Supersymmetry was the good reason to have seen it at lower energues. There is a *really good* reason to see something that generates electroweak symmetry breaking, however: WW scattering needs something to maintain unitarity. If unitarity is violated, that's a big deal.

The worry, however, is that there might be something but it could be almost impossible to distinguish it from the background of the rest of the standard model. I don't know much about such models, but I hear it could be a problem.

29. **Amitabha**
June 14, 2006

> How surprised would everybody be if no Higgs (or any other new particle) is found at the LHC?

I will be a bit disappointed if the Higgs is found.

> There is a really good reason to see something that generates electroweak symmetry breaking, however: WW scattering needs something to maintain unitarity.

A 3-point coupling W-W-something in addition to pure Yang-Mills seems necessary to maintain tree-level unitarity. In the Higgs model that something is the Higgs field which causes the electroweak symmetry breaking. But you can think of other models with a AAB coupling, in which the new field may not be the cause of electrweak symmetry breaking.

30. **top ten?**
June 14, 2006

about my message above: on his blog, Lubos and others answered my question about: which are the main results relevant for physics achieved by string theory? Some of the answers are worth reading, provided that one knows that it is like reading the Pravda in Breznevian era: Lubos suffered another of his insult crises and started deleting my posts, allowing only the comments that agree with his agenda.

I do not repost here my deleted answers, as they are off-topic.

31. **runge_kutta**

June 14, 2006

I particularly love Lubos' comparison of your knowledge of physics to that of 'the average squirrel'. That made my day. My sides still hurt from laughing.

32. **Eugene Stefanovich**
June 14, 2006

MathPhys:

I also want to bet some money on the absence of Higgs and SUSY stuff at the LHC. I think this would be a very refreshing experience for fundamental physics. I hope this will force us to abandon the modern "bag of tricks" approach to QFT. We will go back to dusty relativity and QM textbooks and examine them under microscope searching for inconsistencies. And I bet we'll find a few.

33. **D R Lunsford**
June 14, 2006

MathPhys,

See this: http://arxiv.org/abs/physics/0006049

-drl

34. **knotted string**
June 14, 2006

Lubos now states on his blog: 'I always like to say that the status of string theory and the status of the theory of evolution … are somewhat analogous: I summarize the reasons at the end of this text. … a group of believers felt that this opinion of mine insulted their religious sensibilities. So they virtually marched to Jacques Distler's office and forced him to officially denounce my analogy, much like the believers who demanded the denunciation and execution of the heliocentric heretics 500 years ago. … Jacques Distler has fully obeyed their requests.'

The failure of crackpots like Lubos (and I'm glad to exclude Jacques in this case), is caused by the fact Darwin had a BOOK FULL of evidence for evolution, while crackpots have NO evidence at all.

I can see how Lubos went crackpot: he is comparing the lack of MATHEMATICAL LAWS in Darwin's book with the corresponding lack of mathematical laws in string theory.

But physicist Michael Faraday formulated all his laws in words like Darwin, and Maxwell later translated them into maths. Darwin's laws can be represented mathematically, too, in models like the Lanchester equations for the groups (or species) to struggle to survive in conflict.

You can see why Lubos prefers to compare strings to Darwin than to compare them to Faraday's researches. It would be just absurd.

Strings are crackpot as they have no predictive equations AND no experimental evidence. There is simply nothing at all useful in stringy theory, not even the prediction of a unique vacuum state.

35. **JPL**
June 14, 2006

Woit says:

I do think the electroweak model is mathematically elegant, but it's a more complicated situation than QCD. There's the Higgs, which is problematic for various reasons, and certainly makes the whole thing more complicated and less elegant. Also, the electroweak model really forces you to think about chiral gauge theories, and these are in many ways mathematically even more interesting, but much less well understood.

Agreed. I asked because I truly think that the dichotomy between mathematical aesthetics and empircal success that journalist insist in making is a false one! As it turns out the aspects of the EW Model that are mathematically more elegant (i.e. the Gauge Principle) are the ones that have experimental support (Weak Neutral Currents, Ws,Zs etc…).
More than a few people recognize the Higgs pattern of SSB as something of a phenomenological kluge. Of course the few proposed alternatives did not fare much better, but that does make the Higgs any prettier…

36. **Jonathan Vos Post**
June 15, 2006

Will you keep us posted on Hawking's forthcoming Superstring lecture in Beijing?

Humans close to finding answers to origin of universe: Hawking Thu Jun 15, 8:47 AM ET
http://news.yahoo.com/s/afp/20060615/wl_uk_afp/sciencehongkongbritainphysics_060615124715

Acclaimed physicist Stephen Hawking has said that humanity is finally getting close to understanding the origin of the universe.

Speaking at a lecture in Hong Kong, Hawking said that despite some theoretical advances in the past years, there are still mysteries as to how the universe began.

"Despite having had some great successes, not everything is solved." …

During his Hong Kong visit he also revealed he is writing a children's book with his daughter about theoretical physics.

Hawking is the author of international best seller "A Brief History of Time", which attempted to explain a range of subjects in cosmology, including the Big Bang, black holes, light cones and superstring theory.

He is on a six-day visit to Hong Kong and will meet Chief Executive Donald Tsang Friday before heading to Beijing Saturday where he will give a lecture on string theory.

June 15, 2006

In recent decades it seems that certain kinds of mathematical structure, and a mathematician's notion of beauty, have been widely regarded as at best essentially synonymous with beauty in a physical theory, and at worst a very good surrogate for it. I think we are now witnessing the pitfalls of that facile notion.

There was a time when "beauty" in a physical theory or idea was understood as having a meaning beyond formal or mathematical elegance; indeed, it was recognizable prior to the formal elaboration of an idea. In my opinion this is abundantly clear in Einstein's early work, and was integral to his particular form of physical intuition. This sense, if not altogether lost, has been largely displaced in the thinking of the last two generations of theoretical physicists.

Various and Sundry

June 14, 2006
Categories: Uncategorized

As usual recently, so much going on that I don't have time to write much about a lot of it, but here are some quick links and comments.

The SUSY 06 conference is taking place this week, hosted by UC Irvine, with talks at the Marriott Hotel in Newport Beach. Here's the program, which now has links to slides for some of the talks in the parallel sessions, although not at the moment for those in the plenary sessions. This evening there will be a plenary session on Naturalness, with talks by experimentalist Burton Richter, theorists Frank Wilczek, Leonard Susskind and Andrei Linde. This line-up is very heavily weighted toward the anthropic point of view, I wonder why the organizers couldn't find anyone from the other side. Various bloggers are at the conference reporting, including Clifford Johnson and Sabine Hossenfelder. B. Yen, who normally covers off-road motor-racing, has decided to cover something even more exciting, academics at a SUSY conference, and is providing stills, video, and podcasts via iTunes from the conference site.

Strings 2006, this year's edition of the big yearly string theory conference held each summer begins next week in Beijing. The conference web-site itself still doesn't yet have even a schedule of talks or titles of talks, but Jonathan Shock will be at least one person blogging from there, and he has begun with a long posting of advice about Beijing for people traveling there for the conference.

The big political news of a few days ago was the blogger convention in Las Vegas, with potential 2008 presidential candidates showing up to try and impress the most influential people in the country at the moment, bloggers. Sean Carroll reports from the science-blogging caucus there that Wesley Clark made his pitch by coming out strongly in favor of Leonard Susskind and the anthropic string theory landscape. I know, this sounds like a weird joke, but it's not.

In other political news closer to home here, today's New York Times has a story about some of Einstein's off-prints being auctioned by Christie's, for the benefit of New York's progressive Working Families Party.

Dave Bacon has a posting about a new arXiv front-end from the IOP called Eprintweb.

The Tevatron is back in business colliding particles, having overcome the attack of the killer raccoons. There's a report from Gordon Watts who explains the importance of plastic ducks for his experiment's data acquisition system.

John Baez's latest This Week's Finds is out, this time it's mostly a very enlightening discussion of the relation of music theory and group theory. His web site also contains some wonderful notes by Michael Shulman from a minicourse John gave on n-categories and cohomology theory. John's web-site increases it resemblance to a modern blog with an RSS feed set up by Serkan Cabi.

The math blogosphere seems to my mind somewhat weirdly dominated by those with an interest in category theory. Besides John and Urs Schreiber, there's David Corfield, Robin Houston, and the only math blog at ScienceBlogs, that of Mark Chu-Carroll.

Urs has interesting reports from the ESI Research Conference on Homological Mirror Symmetry going on this week and next.

Last week was the annual Johns Hopkins workshop on particle physics, this year held at the Galileo Galilei Institute in Florence. Many of the talks are on-line.

Le Monde has an article about Dubna.

There's definitely an increasingly widespread backlash against string theory going on in the wider culture. A Columbia colleague last night sent me an extract from a book his daughter was reading. It's called 100 Bullshit Jobs … and how to get them by Stanley Bing, and one of the "Bullshit Jobs" listed is that of "Quantum Physicist String Theorist". Skills required for the job are listed as

Bullshit at such a high level of discourse, with such a profound understanding of arcane mathematical concepts, that everybody thinks they are stupider than you.

The listing describes

… string theorists, who have now broken up into two warring camps, each fighting for control of PBS. One school says that there are many, many universes, possibly an infinite number. The other school is more conservative and counts just a couple of cosmic alternatives, and has the benefit of being represented by a total babe.

I also heard recently from the people who put out Axes and Alleys, the official magazine of the Royal Tractor Repair and Maintenance Society of Outer Mongolia. Their latest issue has a graphic on page 27 inspired by their impression of superstring theory.

Finally, as near as I can tell Lubos has finally gone completely bonkers. In his last few ranting postings, people who disagree with him no longer have the intelligence of dogs, but are compared to squirrels (or, in my case, microbes). His latest posting is about why the scientific status of string theory and of evolution theory are the same (although he thinks "evolution is more dogmatic while string theory is more open-minded work in progress"), and I'm sure the people at the Discovery Institute will enjoy it greatly. He goes on about the fact that at one point, under great duress, Jacques Distler did admit in the comment section of a blog that he disagreed with Lubos on this point. Lubos compares this to Judas's betrayal of Jesus:

This almost sounds like a story from the New Testament except that in the past, there would be 1 Judas in such a story. Today we have 387 Judases with various confused and triply corrupt self-interests and relations to the bad players in the game of life.

Instead of dissociating themselves from Lubos's increasingly nutty postings about string theory, some string theorists such as Moshe Roszali and Joe Polchinski instead have decided this is a good time to encourage him and start participating in the comment section of his blog. Polchinski contributed to a top ten list of greatest achievements of string theory produced by Lubos two more: the "fact" that the unknown theory is somehow known to have no parameters, and the existence of the landscape and thus the anthropic solution of the CC problem.

The fact that Polchinski seems to think Lubos's blog is a good place for him to spend his time is kind of funny given that he has publicly attacked me for saying unpleasant things about people (I did once describe a paper of his in an uncalled-for way), as well as privately telling people he won't read my blog because of the nasty personal things I say about people. For some reason he seems to have no problem with Lubos, to the point of being willing to encourage him as he gets more and more delusional. This is really sad.

Update: Some of the plenary talks at SUSY 06 are now on-line. The schedule of talks with titles for Strings 2006 is now on-line.

Comments

1. **hack**
   June 14, 2006

   I heard on the public radio program "From the Top", a young musician and aspiring physicist describe string theory as "kind of the joke of the physics world".

2. **sequoia**
   June 14, 2006

   I guess Polchinski and Roszali don't take Lubos' bad behavior as seriously as you or others do. He might be very incendiary on the web but he's actually a nice, charming person in reality, has a lot of good friends and is liked and respected by many. He's of course not as brash in person as he is online so that explains a lot. He has two alternate personas and his web persona is something of an alter ego to his more well-behaved persona offline.
   Plus, in this day and age when there's a lot of backlash against string theory and its advocates, Lubos is the one person ranting and raving the loudest, and because of this, he enjoys quite a lot of support from the silent majority of string theorists. And just as most democrats are reluctant to criticize michael moore, string theorists are hesitant to speak out against lubos. He's their mouthpiece. He's their self-appointed warrior, the one who passionately defends this field they've devoted their lives to. He says everything they wish they could say but can't because they're scared of the backlash, or they just can't take the heat.

3. **John Baez**
   June 14, 2006

   Peter writes:

   John's web-site increases it resemblance to a modern blog with an RSS feed set up by Serkan Cabi.

   Now I just need to get a quarrelling crowd of readers who reply to everything I write by venting their own pet peeves. 🙂

4. **Chris Oakley**
   June 14, 2006

   Sequoia,

   You should read the articles in *The Times, The Sunday Times and The Financial Times* in the UK about Peter's book. Executive summary: Peter has a point. The dominance of String Theory is in no way commensurate with its scientific achievements.
   It may well be that LM is perfectly nice on a one-to-one basis, but he has no judgement. Comparing Darwinian theory with String theory is just stupid. And this man was a boy genius? Well, so was Stephen Wolfram and if he wants to tell me, in 1,200 pages, that all the problems of science can be solved by Cellular Automata then, even though he may be brighter than I am, I have to then say that I know at least one thing that he does not. At least, unlike LM, he provides me with usable software. If just being clever was what it is all about then I – like the vast majority of others – probably cannot compete. But being clever is *not* what physics is about. It is about *building consistent models of the physical world*. This is a particular kind of craftsmanship that has nothing to do with whether people like you or not (cf. Wolfgang Pauli), or whether you are a good person (cf. Werner Heisenberg), and it is not perfectly correlated to your academic record (cf. Albert Einstein). What actually matters is what matters to the craftsman, namely the *quality of the end product*. This is where judgement comes in. String Theorists do not behave like scientists. They behave more like children blowing bubbles, watching and comparing notes on the pretty rainbow flecks that their mathematical games produce. They hope that it might at some stage connect with reality, but this does not seem to be a priority. However, when criticisms are made – of the kind that they should have made of themselves – they start to squeal like children threatened with the removal of their toys. I ask you, why *should* we continue to write them a blank cheque?

5. **hack**
   June 14, 2006

   " He says everything they wish they could say but can't because they're scared of the backlash, or they just can't take the heat."

   If that is the case then they are an incredible bunch of cowards.

6. **Eugene Stefanovich**
   June 14, 2006

   Chris:

   I don't think that string theorists are more guilty than anybody else. Simply string theory occupied such a prominent place in science during last 30 years and developed a huge publicity machine. That's why it is an easy target. I think that the problem with modern physics is much deeper. In part it can be attributed to (rather miraculous) successes of the last 50+ years, when such ill-defined concepts as renormalization, gauge invariance, spontaneous symmetry breaking, asymptotic freedom, etc. actually produced real physical results. It became commonly accepted that we can continue on the same path: invent a trick or two that will eventually bring us a "theory of everything". It seems to me that we reached the limit of such trick-based approaches.

   In my opinion, instead of rushing to TOE, we should carefully reexamine our foundations – the relativity and quantum mechanics. However, as was pointed out a few times on this blog, these lines of research are not considered fashionable or sexy in academia. Indeed, how one can move forward by looking backward? Nevertheless, that's exactly what we need to do. Though this change of attitude would require a major disaster, like the null LHC result.

7. **knotted string**
   June 14, 2006

   Lubos is now linking mention of your name on his blog to a somewhat warped version of this blog: http://sites.gizoogle.com/showpage.php?url=http://www.math.columbia.edu/%7Ewoit/wordpress/

   Warping is what you can expect from a string theorist.

8. **JC**
   June 14, 2006

   I've always wondered whether somebody's aggressive behavior online and/or in person, is a compensation of some sort for shortcomings in other parts of their personal lives. (ie. The Napoleon Syndrome or some kind of inferiority complex http://en.wikipedia.org/wiki/Napoleon_complex)

9. **Aaron Bergman**
   June 14, 2006

   They hope that it might at some stage connect with reality, but this does not seem to be a priority.

This is belied by the focus of many groups on string theory model building. Many people are out there looking for confirmatory possibilities.

In fact, although I doubt you'll like it, for a lot of people this anthropic thing is an attempt to connect to the real world. You may disagree with the philosophy, but that is a separate issue from the motivation.

Most string theorists aren't bad people. Really.

10. **a**
June 14, 2006

Peter, your website is becoming all-Lubos, all the time. You're talking about him several times in every article.

If you were both third graders, I'd suspect you two have a crush on each other.

11. **Walt**
June 14, 2006

Peter: Category theory always seems disproportionately well-represented on the web to me. What's even odder is that it's not just a fascination with categories, but with n-categories. I think part of it is that John Baez has always been such an effective advocate of his n-categorical point of view that he's both attracted people to the subject and inspired them to follow his example and post about it on-line.

None of us at arsmath are big category theory fans, so we'll just have to single-handedly restore the balance. 🙂

12. **hogghy**
June 14, 2006

who's the total babe?

13. **Who**
June 15, 2006

The other school is more conservative and counts just a couple of cosmic alternatives, and has the benefit of being represented by a total babe.

who's the total babe?

Lisa Randall and Eva Silverstein are both lovely young women—accomplished speakers and brilliant to boot. I'd guess that the author of "100 Bullshit Jobs" was referring to Lisa Randall. But the reference is inaccurate—she does braneworld models, rather than string/M theory proper. Babe or not, I don't understand how she could be said to "represent" any group or school of string theorists.

14. **AR**
June 15, 2006

Peter: Burt Richter is as outspoken a critic of the anthropic principle as you could possibly ask for. At the session, he essentially described the anthropic principle as theology. And he got audience applause for it, too.

hogghy: The babe is probably Lisa Randall.

15. **reader**
June 15, 2006

"Moshe Roszali and Joe Polchinski instead have decided this is a good time to encourage him and start participating in the comment section of his blog."
"This is really sad."

NO, this is appropriate. Most of the string theorists don't even mention your name because you have firmly established yourself as a maniac.

16. **David Corfield**
June 15, 2006

Walt: *What's even odder is that it's not just a fascination with categories, but with n-categories.*

Well, once you've see that ladder heading all the way up to the heavens, it seems somewhat unambitious to stop on the first rung.

17. **better ideas?**
June 15, 2006

the serious question about Lubos is: is he following a strategy and we are unable of seeing his goal, or we are having fun of a person with personality problems?

Sorry, a.

18. **Ponderer of Things**
June 15, 2006

Lubos as Michael Moore? More fitting is Ann Coulter, or Bill O'Reilly. Some of it may be calculated to get attention, a big part of it is narcissism. intolerance towards people who have audacity to form a different opinion and simply lack of tact/manners.

Saying that he is perfectly nice person except for his internet persona is like saying that your neighbour is a nice guy, except for occasional killing sprees.

I really do wonder what other faculty members at Harvard think of him – I will ask around. Since a lot of his psychotic rantings are now part of permenent record on the web, anyone with access to google can find them, even years later. I only imagine that while most faculty members don't give a flying fart about string controversy, they don't want to be sharing commitee duties with someone who doesn't handle opposing opinion well and is likely to fly off the handle, spewing personal attacks and put-downs every time he gets a little "upset".

Some people really ought to pospone getting a blog until they are fully tenured – at least. Most of us learn to control our emotions, instead of going off and letting everyone know how we REALLY feel.

Blogs seem to be opening up a channel to peek beyond that "filter" in some people. And what we can all see is often not very pretty.

Note to self – think twice about getting my own blog.

19. **anonymous**
June 15, 2006

Maybe Polchinski's and Roszali's support has more to do with Motl's political opinions than his persona as a strong theory spokesperson. I recall Motl invective against those who called Summer's statement of "anti-semitism in intent if not in effect" as ridiculous. Perhaps this endeared Motl to them. Sort of like how Motl would perhaps appear as an ally to those against saving our environment. Though its hard to imagine even those people sinking as low as these two…

20. **Jeremy**
June 15, 2006

I missed a math babe? Where?

Anyway, after finding the reviews online and finding this place, I had no idea that it would be so controversial to say, y'know, prove it.

Since I'm in the U.S. I haven't been able to read the book yet, I couldn't actually compare it to whoever this Lubos person is. All of that writing seems needlessly caustic (unless there's some caustic language in the book I don't know about).

21. **amused**
June 15, 2006

I don't think much can or should be read into the appearance of Moshe and Polchinski on Lubos' blog; the discussion there just happened to turn to something that interested them. Polchinski also posted his comment on Christine's blog, and Moshe seems like a reasonable enough guy who just wants to have pure physics discussions without all the sociological stuff etc (which is easy enough for him since he doesn't have to deal with the consequences of it). I'm sure Moshe would also join in here if there was a pure physics discussion on a topic that interested him; he has done so regularly in the past at any rate.

As for Lubos and his 387 Judases, that's quite bizarre indeed! Presumably Distler is supposed to be one of them, but then who are the other 386?

22. **Peter Woit**
June 15, 2006

AR,

Thanks for the report. Any insight into why the organizers couldn't find a theorist skeptical of the anthropic stuff and had to bring in an experimentalist to do the job?

23. **Peter Woit**
June 15, 2006

amused,

Unclear who the other 386 Judases betraying Lubos/Jesus are. In his comment section, he does thank Clifford Johnson for refusing to publicly renounce the evolution/string theory analogy, so Clifford isn't one of them.

Note that Roszali and Polchinski's comments were purely about their own suggested additions to Lubos's list of the great achievements of string theory. In context I wouldn't describe this as pure physics discussion without the sociological stuff.

anonymous,

I strongly doubt that Roszali or Polchinski's support of Lubos has anything to do with his political views.

better ideas?,

"the serious question about Lubos is: is he following a strategy and we are unable of seeing his goal, or we are having fun of a person with personality problems?"

He's following a strategy, one which is obvious: paint anyone who criticizes string theory as a crackpot who should not be paid attention to. Sympathy with this strategy is probably why string theorists almost universally refuse to criticize him. His problem is that he does have personality problems, which makes his efforts self-defeating.

24. **amused**
June 15, 2006

"Note that Roszali and Polchinski's comments were purely about their own suggested additions to Lubos's list of the great achievements of string theory. In context I wouldn't describe this as pure physics discussion without the sociological stuff."

Neither would I, but from their perspective it probably was.

25. **Aaron Bergman**
June 15, 2006

Do I get to be a Judas, too? The idea that string theory is remotely as well supported as evolution is inane.

(extra letters may be added to said description as per the reader's discretion)

26. **island**
June 15, 2006

> Thanks for the report. Any insight into why the organizers couldn't find a theorist skeptical of the anthropic stuff and had to bring in an experimentalist to do the job?

Maybe they've been reading my blog or website and have finally realized that you have to actually put forth a meaningful argument against the physics and facts, since willful ignorance and comparisons to theology don't mean squat to science.

27. **amused**

June 15, 2006

Btw, on the topic of Lubos, he has let slip in a comment over on Sabine H.'s blog that he will soon be leaving academia to start a new religious cult. Or more precisely, to bring an existing one to the masses. Apparently it is going to be called the Church of M.

(Ok he only explicity mentioned the leaving academia part, the rest is from reading between the lines.)

28. **Yidun**
June 15, 2006

Dear Prof. Woit,

Thanks for your useful info!

Best, Y

29. **Who**
June 15, 2006

this was the 4:57 PM comment on a certain thread of Bee's in case anyone wants to find it.
http://backreaction.blogspot.com/2006/06/science-and-democracy.html#c115024305475393420

"Lumo said…
I am not so much concerned about the future of any funding because I am leaving Academia soon and I never cared about money much anyway.

Moreover, I am also a leading expert in loop quantum gravity so that switching funding to LQG would not affect me even if this question were relevant. 😉

What I am primarily concerned about are aggressive crackpots who have no idea what they're talking about and who attempt to distort science as such and force scientists to share their idiotic beliefs, just like the religious bigots in the 16th century wanted to stop scientists from doing their work, and sometimes they did so rather efficiently.

Sorry to say but the list of these bigotic individuals also includes Christine who just told us that she believes that string theory is not a "theory". What is it? Apple juice? Have you lost your mind?

Sorry to say but I have just seen far too much about her so that I must conclude that Christine is clearly just a plain stupid person. Every sufficiently well trained parrot can say these simple sentences that XY theory could be plain wrong, and all these things…"

Bee's original post was here
http://backreaction.blogspot.com/2006/06/science-and-democracy.html
and was dated Monday 12 June in the evening.
Comment seems to have begun at around 7AM the next morning, if I interpret correctly, and to have continued throughout the day. The greater part of what appears in the first 30 comments was by Dr. Motl.
The comment in question is #22, by my count.

I hope everyone realizes how privileged we are to have the pleasure of witnessing these e-vents, or perhaps a better word would be e-ruptions.

30. **Peter Woit**
June 15, 2006

Before anyone gets too excited about the prospects for Lubos leaving physics to found his own new religion, I'll just point out that quite a while ago he was already mentioning to me the possibility that he might leave physics. Several years later, he's still here. I don't see any more reason to take seriously what he says about this than anything else he writes.

31. **amused**
June 15, 2006

"Do I get to be a Judas, too? The idea that string theory is remotely as well supported as evolution is inane."

Hi Aaron, I guess that's a decision for Lubos, but it might help your chances if you refer to Lubos by name in your denunciation. Like Jacques did 😉

Btw according to my computer your comment just appeared now, or at least subsequent to the others above. I'm pretty sure the same thing happened before with a comment from Smolin during our previous encounter. So there might be some bug in the blog software. I noticed the same thing happened with a comment on Lubos' blog today, in fact Lubos also noticed and remarked on it.

32. **woit**
June 15, 2006

amused,

The spam filtering software I'm using (Akismet) is highly mysterious in its ways and every so often for reasons I can't fathom decides to identify a valid comment as spam. When this happens the comment is held in a queue, not released until I get around to checking what's in the queue. So sometimes you'll see comments mysteriously appearing here many hours after they were submitted.

33. **Thomas Larsson**
June 16, 2006

Before anyone gets too excited about the prospects for Lubos leaving physics to found his own new religion, I'll just point out that quite a while ago he was already mentioning to me the possibility that he might leave physics. Several years later, he's still here.

But there are good reasons to expect that he has problems finding attractive positions. It would surprise me greatly if Harvard would offer Lubos tenure – a school that fired Paul Ginsparg would hardly offer tenure to somebody with Lubos publication record, or lack thereof. Normally other schools would be happy to pick up whatever Harvard threw away, but perhaps not in this case; everybody knows that offering Lubos a position is asking for trouble, which most departments are reluctant to do.

I suspect that when Lubos described himself as leashed last year, he had been given warnings that his blogging activities jeopardized his chances to get tenure. As he now evidently has given up hope, he feels completely unleashed.

34. **Ponderer of Things**
June 16, 2006

I am sure if denied tenure, Lubos will feel that it is because of his “controversial” right-wing political views or his stand on global warming or women in science.

Lack of interesting or even incrementally productive scientific results, his lack of manners, or his blog behavior will not enter as a possibility.

Leaving aside his “internet persona” he would have a solid chance at landing a faculty position in second-tier school, if his tenure gets denied. But behaving like a jerk and pissing people off left and right is not exactly a good way to make friends. I suspect by the time he is on the market again, the number of people who “heard” of Lubos’, let’s say “excentricity”, to put it mildly, will reach critical mass, when most departments will have a couple of faculty who know him (and not from a good side). Once again, this has nothing to do with political views, blogging or string theory – just basic civilty and manners. Surely he is a character, and will be famous, but notoriously famous. Simply put, he is a liability for the department. A timing bomb waiting to go off in a meeting, or in a class or in a seminar. Could you imagine if he called students the things he calls people who disagree with him?

I come to conclusion that while a lot of people are smart in a bookish way, a lot of success in science comes down to how well they can coexist with others. A high ratio of egotistic nerds with lack of communication skills often makes it more difficult to form scientific collaborations.

35. **Alejandro Rivero**
June 16, 2006

I have difficulties to grasp the concept of anyone “leaving physics”. I tend to believe that if one is in, it is in forever. I can understant “leaving publication” or even “missing focus”. But for instance, if it happens that some result depends seriously on the work of a person that has “leaved physics”, I tend to believe that one can phone this person, explain the situation, and get it back.

36. **D R Lunsford**
June 17, 2006

It’s completely amazing that by a fortunate circumstance, (3/2)^12 just slightly larger than 2^7 (that is, 12 fifths are very nearly 7 octaves). The next “close call” (at least as close as the 12-7 case) is (3/2)^53 ~ 2^31. Someone actually built an organ with scales containing 53 notes (in effect, 31 white keys and 22 black keys). A major scale has 32 notes and the stave has 17 lines and 16 spaces. There are 53 separate tonalities and a bewildering variety of minor and diminished scales.

If the first “good number” had been much less or more than 12, Western music as we know it would have been much, much different.

-drl

The Scientific Curmudgeon

June 15, 2006
Categories: Uncategorized

John Horgan has an excellent new blog that he has recently started up, called The Scientific Curmudgeon. Horgan may be best known for his provocative 1996 book *The End of Science*, which was one of the first books for the general public that expressed skepticism about string theory (another was David Lindley's 1993 *The End of Physics*). His portrayal of Witten in the book was a bit of an unfair hit job, but he got the story of what was going on in particle theory about right, unlike just about every other science writer working at the time. In recent years his attention has turned to issues of neurobiology and cognitive science, as well as the relation between science, religion and mysticism. He now teaches at Stevens Institute of Technology in Hoboken, and runs its Center for Science Writings.

Horgan describes himself as a "hopeful skeptic", writing:

I still see science as our best hope for understanding ourselves and the universe, and for creating, if not a sci-fi utopia, then at least a much better world. Scientists can provide us with cleaner, cheaper sources of energy; better treatments for cancer, AIDS and other diseases; more detailed accounts of how brains make minds. That's why, in spite of writing a book called The End of Science, I've remained in the science-journalism racket, why I work at a science-oriented school, why I encourage young people to become scientists. But I also encourage greater recognition of science's limitations and fallibility. It is precisely because science is so consequential that we must treat its pronouncements skeptically, carefully distinguishing the genuine from the spurious.

One of his recent postings discusses the issue of the Templeton Foundation, yesterday's is a charming story about his daughter, linked with a tale of his adventures among the cosmologists back in 1990.

Comments

1. **Jonathan Vos Post**
   June 15, 2006

   Is "hopeful skeptic" a reasonable position on String Theory, as opposed to, say, "hopeless skeptic"? I like Horgan's science writing, and blog, but am not clear why he is hopeful.

2. **island**

Christine

9. **Eugene Stefanovich**
June 15, 2006

While reading Horgan's writings I had a thought about why public should be sceptical (if not suspicious) about theoretical sciences, especially when the experimental part is stagnant. It seems to me that scientific process has a huge amount of inertia built into it. There is a very low threshold for canonizing theories and a very low tolerance for alternatives. I don't think this changed much during last 2000+ years.

We all laugh at medieval astronomers who couldn't accept the heliocentric system. Aren't we laughing at ourselves? According to present day standards the Ptolemy's theory was a very respectable scientific achievement, worth defending against such "crackpots" as Copernicus and Galilei. It had a beautiful math behind it. There was a lot of experimental support. It was written in all textbooks. It was supported by smartest people (Aristotle) during millenia (not just 30 years). What else could you ask for to canonize a theory? How is it different from modern canonical HEP theories (I am talking not just about superstrings)? When will we ever learn?

10. **woit**
June 15, 2006

runge_kutta and Christine,

Yes I have briefly met Lubos in person, and it was a perfectly pleasant encounter. It's also a little-known fact that I once wrote a recommendation for a fellowship for him. But back then he was just an over-zealous fanatic (my recommendation said something like: "I don't think you should support string theory, but since you're going to do it anyway, you might as well fund a smart true-believer"), he hadn't yet been driven over the edge into nuttiness by the failure of string theory.

11. **Sailorstar**

12. **John E. Gray**
June 17, 2006

Woit, I have been reading the back and forth between you and Motl for the past couple of months. I have found it quite interesting to deconstruct what is at the heart of you arguments. I have concluded that the heart of the problem is Horgan claims science is versus Motl's viewpoint. That is what divides the two of you is a total disagreement about what constitutes fundamental science. While I am not qualified to discuss string theory, I have thought a fair amount about what constitutes good and bad science. Below are some comments about the scientific method that are at variance of what was found in "The End of Science". I have somewhat a contrarian viewpoint, so have included somewhat extensive comments from a paper I am revising. If you think these comments add some clarity to you monologue, please post them, if not don't feel you have insulted me. I wish you both well in you monologue about science, I have found this foodfight too distracting and need to return to other matters:
Scientific theories have three important characteristics: compression, usefulness, and generality. Without compression, there is no advantage to developing a theory, tabular results or taxonomies would be sufficient. Taxonomic sciences such as biology and paleontology are still scientific, A technical discipline that has large amounts of data but little interpretation contains little information since there is no surprise associated with new data. information gain cannot be measured by acquiring new data.
Usefulness has two components: engineering application and predictability. Without the ability to apply a theory to accomplish calculations, the theory becomes a tautology without an exterior world to which it applies. It becomes mathematics. Predictability is a component of usefulness, since predictions lead to the ability to design rather than just build. Most theories advanced provide compression and usefulness. We also require theories to have generality. Falsifiability plays a key role in probing the generality of theories (Popper 1959). The importance of falsifiability is the role it plays in the understanding and development of proper science has been often misinterpreted by commentators rather than practitioners of the scientific method. Falsifiability should be properly understood as the complement to generality. While it is often claimed that a theory can be disproved by a single negative observation, this is not the correct interpretation. A negative observation is simply defines limitations on the generality of a theory. In other words, falsifiability does not negate theories, but rather it limits the boundaries within which theories are applicable. Since usefulness is an important criteria, there is always a boundary associated with the theory in terms of applicability. There is, of course, a point where repeatedly falsifications cause one to reject a theory (Jaynes 1968).
A single positive observation is much less compelling test than a negative one, since almost any single prediction can be verified by appropriate selection of evidence. There is an intimate connection between observation and sampling in the sense of Shannon's formulation of communication theory that is needed for all sciences. A principle of ontology is advanced by espousing a specific type of deconstruction of uncertainty (Sardis 1995) and the nature of uncertainty is always an important component for understanding ones discipline. In general, the more information gain we receive from data, the more biased (in the colloquial sense) we should become because informative priors converge in a parametric sense to the correct result (Jaynes 2003). Thus, a theory of sampling needs to be extended when we go beyond the reduction to numbers and instead accomplish a reduction to symbols. Most sciences would benefit from a deeper exploration between sampling and confirmation that a symbolic theory of sampling relative to their particular subject would accomplish.
There are several aspects of confirmation that should be clarified relative to the symbolic. If when measurement reduces to a number, the process is symbolic in the sense that is not usually considered from both an experimental and computation viewpoint. All computation and measurement is interval based. One does not measure a point, one measures an interval number associated with the interval of experimental uncertainty. The same thing occurs when one is engaging in computation as was pointed out first by Young (Young 1932). Thus confirmation is less related to theory since the instruments used for confirmation and computation within the theory are not formulated within the theory. Another issue is the compression. The ontology associated with algorithmic information theory (Chaitin 1987) suggests that a theory that doesn't have redundancy built into is not a good theory. But redundancy is not so easily discussed beyond the realm of the rational numbers. What redundancy means when one discusses abstract symbols is less clear. Issues such as interference and correlation are always possible between symbols.
Theory plays a different role than experiment; it writes sentences that in some cases explore well beyond the restrictions of instrumentality. Theory, while driven by the words and grammar of experiment, is always trying to introduce new forms, establish metaphors, and use words in less experimentally important context, so theory is more concerned with trying to ferret out meaning (mostly by detailed working out of specific examples or models). It does this by concerning itself with constant refinement of the explanations for what is known, establishing metaphors that connect previously unrelated subjects, improved tool making (both new mathematical concepts that aid theory and instruments that change what it is possible to measure), and making predictions. Theory, while keeping in mind Feynman's dictum, allows one to define and explore semantics of the subject while being ground in the syntax imposed by experiment. Mathematics provides the theoretician with an entirely syntactic language to explore and maintain rigor. But as has been noted before syntax is not science, metaphors are how we establish the "truth" and metaphors are inherently transformational or substitutions by their nature. Thus, syntax may tell us whether a transformation is correct but semantics is necessary to decide if the transformation results in something meaningful.
Truth is primarily established through experiment. But truth also has a logic associated with it. Philosophers have tended to ignore such concepts as metaphors and tool

making in their critique of science, and giving short shrift to the concept of refinements based on new methods for accomplish measurement that revolutionize the ability to observe (Dyson 1999). All measurements are metaphors of a sort, though many treat measurement as a tablet from Moses. Measurement is canonized by theoreticians in their writings, yet those who have dealt with data are much more circumspect about it. At some point, axioms relative to what and how we measure will be ferreted out by mathematicians. Once this has been accomplished, then we will have to face some logical limitations. Already we know that there are problems in physics that are undecidable in the sense of Godel (Wolfram 1985). But the question is whether there are more fundamental limitations than that. If the axioms which encompass the experimental methodology are sufficiently rich to encompass arithmetic, then there are experimentally undecidable issues in physics and in science. This is troubling–"Is science decidable?" in an experimental sense is far more troubling than a specific theoretical result that is undecidable. Equally unsettling is question of complexity that was first raised by Godel in the theoretical sense (Godel 1936). He noted that there were problems that had proofs that were intrinsically long, so long in fact that some theorems could never be established within a given set of axioms. He further noted that by adapting additional axioms that proof's length might be shorted considerably. What if conformation by experiment has similar difficulties? What good is a theory that can never be confirmed by instruments because the number of measurements that would lead to its acceptance is longer than human civilization's life span? Could this not be the case when and if we ever find a theory that has the possibility of being a "unified theory of physics"? I wonder if this message from the Landscape, if it becomes more real. If we adopt speedup axioms, then what are the consequences for our epistemology? The symbolic, from a experimental viewpoint, is fraught with potentially unpleasant consequences from a logical and complexity perspective.
If the symbolic viewpoint was more universal, then most of what constitutes science and its boundaries would have to be reexamined. This is why the ongoing monologue between Woit and Motl is so rich in terms of its implications about what is and isn't science. I find that science is its infancy in terms of understanding what constitutes science because of the issues of information gain, conformation, sampling, as well as the theoretical aspects of metaphor. Drawing on Feynman's "It is surprising that people do not believe that there is imagination in science. It is a very interesting kind of imagination, unlike that of the artist. The great difficulty is in trying to imagine something that you have never seen, that is consistent in every detail with what has already been seen, and that is different from what has been thought of; furthermore, it must be definite and not a vague proposition. That is indeed difficult." Imagination in science is like writting a sonnet, but richer and more difficult.
The rich possibilities of at what point an intellectual discipline that can be confirmed or falsified by data suggests that concepts and boundaries of science have to be rethought. Sampling and confirmation based on data or the lack thereof need to be completely rethought from the symbolic perspective. The algorithmic perspective needs to be incorporated as well, but not necessarily the way Chaitin has suggested. In many ways, we are closer to a beginning of science and determination of "The scientific method" rather than "A scientific method" as currently exists. Understanding why science is successful from a ontological and metaphysical perspective, remains to be accomplished. If I had any doubts about us being at the beginning of understanding of what science is, they have been erased by the strange and amusing postings I have seen here. Best wishes to you all and thanks for all the fishes.

June 17, 2006

I like John Horgan thinks that widely accepted assumptions, like inflationary theory, are crap, and he has good reason to say that if you simply do all of the demanded science, rather than science that's strictly limited to the belief that it requires a naked singularity to produce a big bang.

Projecting backwards to the point where it requires inflation to account for the horizon problem should be a clue that there is a mechanism that enables a universe with volume to have a big bang. Especially since the problems of causality and structure that are associated with the horizon and flatness problems don't exist when a universe that has volume has a big bang.

I continually notice that people keep calling for accepted assumptions to be, once again, reassessed, but eveyone has their own ideas on which assumptions are open to review, because, for example, the flawed theory does do some things quite well. What they apparently fail to recognize is that the solution to fixing a fundamental flaw is in the foundation below, but not in some more grand theory that exists beyond the the flaw.

I think it was Urs who fairly recently commented in the research group to someone that, "this isn't 1917″…

Yes, it is.

14. **Eugene Stefanovich**
June 17, 2006

island,

"this isn't 1917″… Yes, it is.

Great point! I think this is precisely where the boundary between science and theology lies. As soon as we declare a certain physicist or certain theory beyond criticism, we stop doing science and switch to theology.

I like this quote from Oppenheimer (which for an untrained ear may sound as a definition of crackpotism):

There must be no barriers for freedom of inquiry. There is no place for dogma in science. The scientist is free, and must be free to ask any question, to doubt any asssertion, to seek for any evidence, to correct any errors.

As for me, I don't mind to discover that we are still in 1905.

15. **Chris Oakley**
June 17, 2006

> There must be no barriers for freedom of inquiry. There is no place for dogma in science. The scientist is free, and must be free to ask any question, to doubt any assertion, to seek for any evidence, to correct any errors.

And in his case, free to vaporize, fry and otherwise irradiate a lot of people.

16. **Jonathan Vos Post**
June 18, 2006

Good thread.

There is irony in John E. Gray writing:
"Drawing on Feynman's "It is surprising that people do not believe that there is imagination in science. It is a very interesting kind of imagination, unlike that of the artist. The great difficulty is in trying to imagine something that you have never seen, that is consistent in every detail with what has already been seen, and that is different from what has been thought of; furthermore, it must be definite and not a vague proposition. That is indeed difficult." Imagination in science is like writting a sonnet, but richer and more difficult."

That's because Feynman did in fact coauthor a sonnet with me, which was published by AAAS, republished, and set to music. My Physics professor wife and I, for that matter, had a poem in the magazine Science. Hence mainstream science journal referees and editors have openly shown ability to recognize scientific imagination in the methodology of poetry. For that matter, NASA commissioned me to write a poem as the frontispiece of a conference proceedings. Gray is exactly right about imagination in this context. The issue in this blog becomes something like: “Do String Theorists have too much imagination, in inventing pretty math that defines 10^500 universes in a multiverse; or do they have too little imagination in not being able to follow Feynman’s dictum ‘ it must be definite and not a vague proposition?'”

Or is the problem that String Theory is not Science, but rather Science Fiction or Poetry or Theatre, but does not meet Woit’s criterias for GOOD Science Fiction or Poetry or Theatre? Are we waiting for a happy ending, a lovely final rhymed couplet, a final act that wraps up all the subplots? Or are we Waiting for Godot?

Censored Comments From the Reference Frame

June 15, 2006
Categories: Uncategorized

Since many people have been posting off-topic comments here that were censored over at Lubos Motl's Reference Frame, I'm creating a separate posting so that there will be an appropriate place for these. Also, if you want to try and carry on a discussion with Lubos on the topics of these comments, here is the place to try (although I don't quite know why you're bothering…).

Comments

1. **runge_kutta**
   June 15, 2006

   Peter I've always wondered why you never post on Lubos' blog, though he posts on yours. Are you banned ? If so, don't worry, I was banned too, for making an offhand comment about Bert Schroer. I no longer remember the discussion we were having, except that it had something to do with Bert Schroer, so I guess I can't continue it here.

2. **Anon-e-mus**
   June 15, 2006

   Lubos, I may not always (more precisely only very rarely) agree with you on many topics, but I believe you are certainly much, much more intelligent than that. Peter is clearly not referring to **all** deleted comments, but only to those bona fide comments that were deleted because of your "zero-tolerance with those who disagree with me"-policy. Even if you appear to think poorly of his intelligence, you cannot possibly believe that he is interested in archiving porn/pills/casinoes spam deleted from your blog.

   (Recently, I was told by someone who knows you personally that you are in fact a normal/nice person in real life, so maybe you should try and get you online persona back in line; he/it seems to suffer from too many forms of personality disorder to even begin to enumerate; if that is not your real self, and I have no reason to doubt the word of your colleague, why would you want to project that kind of appearance? A polite manner usually gets you a lot further.)

3. **MathPhys**
   June 15, 2006

   Motl,
   You're a sick kid. Get help.

4. **Alejandro Rivero**
   June 15, 2006

   Hmm I guess the title should be "supposedly deleted comments…"

5. **woit**
   June 15, 2006

   I've deleted some of the spam comments Lubos posted here (and my spam filter caught others). I suppose I could set up a separate place for comments deleted from this posting….

   runge_kutta,

   The last couple of times I wrote a comment on Lubos's blog he immediately deleted them. One was responding critically to something he said about me, the second was responding to something that one of his commenters ("LambChopofGod") was saying about me. Not something I'm likely to waste my time doing again.

6. **Kasper Olsen**
   June 15, 2006

   If you

   "don't quite know why you're bothering…"

   then why do YOU bother to make this post?

7. **amused**
   June 15, 2006

   Here's the most recent of mine, deleted from the comment thread of his "Dean of crackpots" post.
   ————
   LM: "The reason why the situations of string theory and evolution are analogous is that both of them are more or less inevitable given the known data, known approximate laws of Nature, and known and derivable logical constraints."

   Oh dear, Lubos, looks like we're going to have to call on Jacques Distler to denounce you again.

   (You remember the previous time over at cosmicvariance, right?)
   —————

   By remarkable coincidence, a couple of days later Lubos writes his "Darwiniana: evolution and string theory" post, referring to the denunciation episode and elaborating on his string theory/evolution analogy…

8. **woit**
   June 15, 2006

   Kasper,

Not much of a bother, only took a few minutes to make the posting. The reason I did it was to deal with all the Lubos-deleted comments that people were posting here. If I left them in the postings where they were, they interfered with the discussion about the topic of the posting. But I didn't want to delete them, to be in the position of censoring those already censored by Lubos. This is the best solution I could come up with, if you have a better one, let me know. The best one would be if he would not delete reasonable comments from people who disagree with him.

9. **Ponderer of Things**
June 15, 2006

Lubos, since you have been offered asst. prof. in spring of 2004, you haven't published a single scientific paper. Is there something in the works, or does editing your blog comments take away all of your research time?

26 months, or roughly 800 days. Are you going to go for 1,000 days? More?

Any brilliant stringy ideas lately? Are you not afraid of some youngsters soon calling you what you call others – intellectual rodents/microbes, crackpots, washed up, etc.?

That would be… ironic?

10. **Dan**
June 15, 2006

http://arxiv.org/abs/hep-th/0606100

http://arxiv.org/abs/hep-th/0601001

Don't worry: one day, besides pondering, you'll be learn how to use search engines…

11. **MathPhys**
June 15, 2006

My comment to Motl posted above ("You're a sick kid"), was specifically a reaction to a post by him (since then deleted by Woit) that contains pornographic references which I thought that was way, way out of line.

Motl, I have no idea what goes in your mind, but please tone it down a bit, because you push people too far, and it's no longer funny.

12. **MathPhys**
June 15, 2006

Dan,

Co-authoring two speculative papers, within the span of 3 years, is by far not a whole lot, particularly for a young theoretical physicist at this stage of his career, working in a field that's supposedly "active".

13. **top ten**
June 16, 2006

my attempt of discussung the main achivements of string theory relevant for physics in http://motls.blogspot.com/2006/06/science-vs-democracy.html was interrupted by insults (Harvard can be proud of the "squirrel"). My deleted answer was, after some re-editing

—
dear Lubos, you misunderstand me: I am not telling that "AdS/CFT" was not invented by string theorists. I am telling that string theorists made a few true achievements, but only on issues that physicists do not consider much relevant, and failed on the issues that would have given real progress in physics.

This is why usually string theorists don't talk to experimentalists, and why their talks often annoy phenomenologists and cosmologists. Realizing this fact is a medicine that cures many young string theorists, grown in a community where everybody agrees that counting the entropy of black-hole-like-SUSY-states was an enormous achievement.

I comment on "AdS/CFT" that is the most interesting result: the interesting part of "AdS/CFT" is the "/". Indeed people who classified CFT or supergravities in AdS often notice that their works did not attract much attention until the "/" was recognized. Indeed my squirrel committee planned our universe such that we do not live in AdS nor in CFT, so that "AdS/CFT" beautifully connects two theories of which we do not care much (this is another check that they are dual). Attempts of applying "AdS/CFT" to QCD did not improve what we already knew from other less celebrated approximations"
—

Later, Lubos defended his arguments applying the technique known as "useful idiots": comments that agree with his line are allowed and the rest is deleted. A normal person understands that applying this technique without having control of all media is not intelligent, and the situation of string theory is not so bad that a constructive discussion has to be stopped at any price. This is I why I fear that Lubos does not think "string theorists will reward me for this dirty job" but he really thinks what he says: "I am Jesus defending civilization from crackpots". This would be sad.

14. **top ten**
June 16, 2006

to defend Lubos, let me add that it is true that in past years he co-authored only one paper, but it is a good one: conjecturing that quantum gravity implies "gravity is weaker than electromagnetism" is closer to physics than deriving from string theory that "gravity exists". However these good results also show how this line of research is far (and possibly hopelessly far) from getting something relevant for physics.

I see no point in lowering quality standards such that the rediscovery of hot water can be considered as a major achievement. No hype will convince physicists, laymen and crackpots that it deserves a Nobel prize.

15. **RM**
June 16, 2006

deleted post was simply: "Mr. Motl, what are the predictions of string theory that you say will shortly be confirmed by experiment?". (I guess there aren't any).

16. **Christine Dantas**
June 16, 2006

To anyone interested, you can discuss Lubos Motl's top ten results over at my blog:

http://christinedantas.blogspot.com/2006/06/top-10-string-theory-results.html

No posts will be deleted there, except those with personal attacks.

Best wishes,
Christine

17. **Chris Oakley**
June 16, 2006

The quoted text below, by LM, appeared in his blog. If I answer it there, the comment will probably be deleted, so let me try here. It concerns my Amazon review of "Not Even Wrong".

> 5 stars. Hi, my name is Dr. Chris Oakley, it is my fourth review and I am the 110,000th best reviewer. As my name indicates, I have a physics PhD and as the degree proves, I will be in Sabine's committee that will democratically vote about the future of physics. Twenty years ago, I wrote three or four preprints. Unfortunately, no other physicist has yet appeared who would think that they make any sense – but that's probably because of the string mafia.

Actually, I only blame the String Mafia indirectly for this. The issues raised are not really considered to be problems by anyone other than AQFT people. Some of the latter did make sense of my work, but seemed not to be willing to accept any of the conclusions. One of the papers was in fact published in a respectable journal (Physica Scripta).
One minor quibble: at Oxford a Ph.D. is called a D.Phil.

> I am especially proud about the paper that renormalization is not needed. My excellent solution is to insert random factors into the loop Feynman diagrams, such as the delta functions and step functions: I call the added step functions "positivity of energy". I have figured out that for some smart extra factors, this can miraculously make the integrals convergent! I don't care that the unitarity is sacrificed because unitarity is just a stringy propaganda. And I hope that the experiments will be changed to fit my predictions. My theory is clearly more important than AdS/CFT, and I will vote to replace AdS/CFT scholars by scholars who study my theory.

Lubos links to the first paper in the series, entitled "On the possibility of quantum field theory without renormalization". The title is, as he suggests, optimistic. Local field equations seem always to lead to infinities, whichever way one does QFT. But there is no tampering with the graphs (I think he is confusing my methods with the Epstein-Glaser approach). The graphs I show in the paper are indeed always finite as they are just phase space integrals, but there are ones which have pathological divergences and, yes, the "removal" of infinites here is handwaving. I think now that one just has to start with non-local field equations. As for experimental tests, I was considering [tex]\Phi^4[/tex] theory in this paper! A later paper, on quantum electrodynamics, reproduces the results from tree Feynman graphs, so he had better have the discussion about experimental verification with someone else.

As for unitarity of the S-matrix, there is no S-matrix here as I am trying to be consistent with Haag's theorem. You should read the whole story on my web site some time, Lubos, if you can spare the time from your busy schedule.

> I have not read the book – in fact, I am writing this review half a year before the book is published. But I think it has something to do with the Star Trek by Isaac Asimov, and I prefer Asimov over the string theorists. Advocates of all physics theories would only admit that the author is right, in his book that I have not read, if they were wired up to a Polygraph. Also, I recommend you Second Creation.

Mostly correct except that I have a January 2005 copy of the manuscript which Peter gave to me when I visited that month. I also have a copy of the finished product. There are updates, but as far as I can see, no substantial differences.

18. **Chris Oakley**
June 16, 2006

Oh, and I should add: in January of last year we were sitting on the tarmac at JFK for two hours as the flight was delayed. With Peter's book to read, the hours just flew by. It is a great read.

19. **Ponderer of Things**
June 16, 2006

Dan,
I thought someone will mention this.

arxiv is a depository of unrefereed, unpublished drafts that may or may not see become an actual publication.

It is no substitute for peer-review, a fact some stringy fellas need to be constantly reminded of.

Any crackpot, to use Lubos' language, could make a dozen of arxiv posts within a couple of days.

According to ISI Web of Knowledge, Lubos has 10 publication, with h-index of 7. Over the past three years he had one paper – from APR 2004. He had zero papers in 2005. He had zero papers in 2006, so far. Look it up if you don't believe me.

I wonder how many assistant physics professors ANYWHERE have this sort of publication record.

20. **Patrick**
June 16, 2006

I'm not sure whether I should post this here, it's got nothing to do with Lubos Motl, but it is a question about string theory. I've just downloaded a copy of

"The String Theory Landscape: a Tale of Two Hydras"
Joseph P. Conlon, Contemporary Physics, vol 47 2006

I have a background in condensed matter physics, but am pretty ignorant of the standard model, QFT (except the RG stuff that we studied in Stat. Mech.) and string theory. I was wondering if anyone here has read it and if it is reasonable summary of the issue.

Thanks.

21. **Ponderer of Things**

June 16, 2006

More data points – let's look at other young string theorists.
Sergei Gukov (currently a professor at CalTech), who has received his PhD in 2001, the same year as Lubos, has published 21 papers since then. Marcus Spradlin (now a faculty at Brown), and another 2001 PhD recepient, has published 22 papers. Nima Arkani-Hamed had over 40 new publications in the 5 years following his PhD (1998-2002).

Lubos has published 5 since his PhD.

These are all *published* papers, not hypothetical pre-prints.

I am sure people will point out it's unfair just to look at the toal number of publications, that he had a single brilliant paper that is better than anything those other folks has produced, but that's open to interpretation.

By any standard, Lubos has not been as productive as some of his colleagues. Experimentalists can often find their work to be disrupted by having to setup a new lab at a new university, but even then most of them manage to keep producing results.

22. **Peter Woit**
June 16, 2006

Patrick,
The paper you quote is a reasonable summary of the current anthropic string theory ideology, written by a graduate student string theorist. I may comment more on it in the next posting.

23. **garbage**
June 16, 2006

Peter,

I kinda agree with Lubos this time, why moving his trash can to your blog?

24. **woit**
June 16, 2006

garbage,

This isn't the trash can that Lubos is describing, it was intended as a place for people to post intelligent comments that he has censored. He has chosen to run his weblog by deleting any comments from people who disagree with him, trying to give the impression that what he has to say has unchallenged support. People censored in this way have chosen to bring their comments over to my blog and post them. What should I do about this, delete them as off-topic, or set up a separate topic to accomodate them? Do you have a better idea. If so, let me know it.

25. **Eugene Stefanovich**
June 16, 2006

Hi Chris,

I am appalled by Lubos' suggestion that you didn't earn your D.Phil. He has no right to say that.

Looking at his writings, it is clear to me that he has a very distorted picture of what science is all about. It seems that he is longing for some orderly structure in physics where a few high priests (Witten, Hawking, Maldacena, who else?) will decide which direction is promising and which is not; the rest of us, like obedient ants, will bring our small pieces to solve the big puzzle; and crackpots and heretics will be confined to torture chambers.

OK, I am exaggerating, but not much.

I think your work on renormalization is an interesting attempt to solve a long-standing problem whose importance was recognized by Feynman, Dirac, and Landau among others, and whose relevance to physics is unquestionable. I happen to disagree about your particular approach to the solution, but I have no doubt that what you are doing is physics at its best.

26. **Chris Oakley**
June 16, 2006

With reference to the comments on Lubos's post about Amazon reviews for "Not even wrong":

1. I think that Brian Greene and I had the same thesis advisor (Graham Ross)
2. My thesis did not contain anything significant about renormalization, for or against. It was almost entirely about free field theories.
3. Lubos seems to have no clue about what I actually said in any of my anti-renormalization papers (see earlier posts on this thread).
4. But if he ever takes the trouble to find out – if he's smart enough (case not proven as yet) – he may be interested to know that Brian Greene had the same idea, as did Stueckelberg (1934) and Kallen (1950).

27. **Chris Oakley**
June 16, 2006

Hi Eugene,

As with most things, there is little point in taking Lubos seriously. My thesis was not about anything especially controversial but my external examiner, Lochlainn O'Raifeartaigh (of Supersymmetry no-go theorems fame) did acknowledge that the work – in his words – "tied up a few loose ends nicely". If anyone is going to call me a crackpot then it should be for my later (anti-renormalization) work, and that alone.

28. **ad**
June 16, 2006

It may be possible that Lubos spends some time in reacting to string theory critics and to some others which he might have invested in research entirely (although only he can say best about it). But THIS IS NOT WASTE OF TIME. One can easily see that the scientific community can be served in several ways, not just by doing active research. Astrophysicist S. Chandrasekhar once remarked about one famous physicist who had to neglect his research to play active role in setting up a scientific institute (which later became famous and still is) that his dedication to science is not less than any other active researcher. In the same way I find Lubos's reaction to critics a service to string theory community. Not every string theorist would be able to play the same role as he does. His comments are often deep, illuminating and very sharp as opposed to many people (Lubos's targets) who merely reveal their ignorances.

29. **da**
June 16, 2006

setting up a scientific institute is not the same thing as insulting people on blogs

30. **MathPhys**
June 16, 2006

While it's clear that Motl knows quite a bit about strings, his comments on physics in general, and physics that's older than strings in particular, are often myopic and blinkered.

31. **Peter Woit**
June 16, 2006

ad,

"I find Lubos's reaction to critics a service to string theory community"

Perhaps the string theory community enjoys reading the way Lubos writes about his critics, but they're making a big mistake if they consider this a service to them. He's doing a fantastic job of convincing the rest of the physics community that there is something very wrong with string theory and with the way it is pursued.

32. **anonymous**
June 16, 2006

This is where I lose you, Peter. If indeed he is screwing up the reputation of string theorists, why don't people publicly oppose him? Or at least clearly distance their stance/opinions from him?

It seems to be that you are implying more than just Lubos' commissar-like behaviour. You are implying something about the broader string theory community. But, where is the evidence of that?

33. **Peter Woit**
June 16, 2006

anonymous,

Some string theorists would never read his blog, think he's a fool, want nothing to do with him, and so see no reason to mention him one way or another. Others seem to think it's a good idea to participate in his blog and encourage him.

All I can say is that an astounding number of people, particle theorists and not, have told me that reading Lubos's blog convinced them that there was something seriously wrong with string theory and string theorists.

34. **Who**
June 16, 2006

This is where I lose you, Peter. If indeed he is screwing up the reputation of string theorists, why don't people publicly oppose him? Or at least clearly distance their stance/opinions from him?

It seems to be that you are implying more than just Lubos' commissar-like behaviour. You are implying something about the broader string theory community. But, where is the evidence of that?

Interesting question. forgive me for intruding, since it was asked of Peter and he will doubtless respond.

We don't know as of present that the string community is NOT reacting so as to distance itself from Lubos Motl, though perhaps not fast enough for its own good.

Be that as it may, there is the historical question why the string community (well organized and having its own interests at heart) DID not distance itself or take steps to control EARLIER as in 2004 and 2005 when the mean and misleading statements were flying.

I think I can bend your question slightly so that it asks **why did they not then** realize that Motl's public ranting would be harmful to the longterm interests of the string community and more generally of physics theory? What does this say about them, and perhaps about US academic communities more generally? Is there something amiss? And what (besides this) is the evidence for it?

One possible answer is that it was not expected (in 2004-2005) that non-string quantum gravity would proceed as rapidly as it has. Although understaffed and underfunded, especially in the US, it has made notable, even enviable, advances towards goals which string theorists might themselves aspire to.

If that had not happened, the community might have been able to laugh off Motl's antics, since they would have done no general harm besides the chagrin of those outsiders whose inconsequential work he belittled. In other words he didn't HAVE to turn out to be such a liability. But now when there is some serious challenge from the competition, it looks bad to have a half-informed madman for advocate.

Just my take on it. will be interested to hear our host's response.

35. **Aaron Bergman**
June 16, 2006

There is no "string community" to take some sort of uniform action. What I do know is that most people just want to completely stay of all this online stuff and stick to research.

36. **garbage**
June 16, 2006

"…What should I do about this, delete them as off-topic, or set up a separate topic to accomodate them?"

I guess if they dont fit anywhere in your posts this also become kind of your ‘trash can’ as well doesnt it?

That doesnt mean that nothing intelligent could come out of garbage 😉
Indeed, the lore says that once upon a time an indian mathematician by the name Ramanujan first discovered mathematics in an old book he found in the trash. I, in the other hand, wouldnt recommend the latter as the best source of education 😉

37. **Ponderer of Things**
June 16, 2006

Other string theorists might

a) not know/care about blogs (especially older faculty)

b) find Lubos’ behavior reprehensible but decide not to interfere publically for the same reason why one should never wrestle with pigs – you will get dirty and the pigs might enjoy it

c) disapprove of his behavior and tell him of their disapproval personally (to which he reacts as if he is being “leashed”)

d) disapprove of his behavior but also assume that Lubos is a big boy who can speak for himself and if he makes a fool out of himself it is not damaging reputation of his scientific community

e) approve of his behavior and see Lubos as a brave warrior (knight in shining armor) taking on heretics and doubting thomases where everyone else is too chicken to say anything

I think it used to be a), quickly shifting to b), with people who tried c) are now reverting to safer option b). Of course in Lubos’ Wonderland Multiverse the correct answer is e) and only e). Anyone who thinks otherwise is a squirel, a microbe or a crackpot.

38. **MathPhys**
June 16, 2006

Ponderer,
I think it’s option (d). It’s too messy to start quizzing your colleagues about their personal business, and Motl’s blog is his personal business. I don’t see Vafa wanting to get into that.

39. **MathPhys**
June 17, 2006

I think we have psychoanalyzed Motl long and hard enough. Time to move on.

40. **anonymous**
June 17, 2006

String theorists wait hoping that LHC will discover something that is or can be named “stringy”. Like supersymmetry, or extra dimensions, possibly with branes, or an anthropic nothing,… We will see.

41. **Aaron Bergman**
June 17, 2006

My comment (which seemed to take quite a while to show up again) should read “completely stay off all this online stuff”.

42. **anonymous**
June 17, 2006

“There is no “string community” to take some sort of uniform action. What I do know is that most people just want to completely stay of all this online stuff and stick to research.”

Standard nonsense from Aaron, as usual. If that were the case, the converse would be true as well, i.e., any bad press for string theory would not bother them, since they just want to “stick to research”. Polchinski, Distler, Srednicki all write in to reprimand Peter for inaccuracies etc. when the chance arises. The last one’s responses are especially comical, I recommend the readers to browse through Peter’s earlier posts’s comments.

We also have (Peter’s word) evidence that people PRIVATELY write to Peter saying how much they appreciate his work, but hesitate publicly themselves. ,

Its pretty easy (and cheap) when funding is flowing, and the press is glowing, to say “it doesnt matter, I’m just interested in research”. But then jump in if string theory gets bad press.

43. **Aaron Bergman**
June 17, 2006

I urge you to consider the word ‘most’ in my comment.

44. **JC**
June 17, 2006

Why not create a new “category” of posts, where all the stuff Lubos censors ends up? This is probably bound to show up many times in the future, with folks posting their deleted posts here.

45. **Peter Woit**
June 17, 2006

JC,

The WordPress category feature applies to posts, not comments. For now, having one post devoted to all things Lubos I think is more than enough. In the past I’ve had to shutdown the comment sections of postings after a few weeks in order to control spam, but the new version of WordPress has an anti-Spam feature that may be good enough to do the trick itself (although it still misfunctions sometimes for reasons I don’t understand, sorry Aaron…).

46. **Benjamin**
June 17, 2006

Sometimes I wish I knew if this apparent bad feeling is for real, or whether ambitious and spirited physicists are just jousting with each other for fun.

47. **alexis**
June 18, 2006

If you read this:
http://motls.blogspot.com/2006/06/top-ten-results-in-loop-quantum.html
.. and the (currently) 'quick' comments, you'll see what a bunch of sexist mouthbreathers these buttheads are.

48. **Peter Woit**
June 18, 2006

In case people are wondering what alexis is referring to, in his latest posting, in the middle of supposedly explaining what is wrong with a list of achievements of LQG, Lubos includes a photo from the website of Louise Riofrio. The photo shows her with an impressive lizard. Lubos puts this up with links to her web-site and a not very good paper she wrote, trying to humiliate her as an idiot (although she's an attractive woman, so he writes that she "may have other virtues of course"). His intent is to show that people with Ph.Ds in physics can not know what they are talking about (besides Riofrio, I'm clearly another physics Ph.D. he has in mind). Problem is, Riofrio doesn't have a Ph.D., she is (or was) a student at San Francisco State University which doesn't have a Ph.D. program in physics (they do have a master's degree program). In his comment section he and his commenters speculate on which is Riofrio, the woman in the picture or the lizard, with Lubos explaining that he had thought of using a picture of her with a monkey, to better make the point.

The guy is just completely grotesque and subhuman, it's amazing that anyone takes him seriously.

49. **Ponderer of Things**
June 18, 2006

Have you no manners, Mr. Motl? Seriously, did your parents forget to teach you about not making despicable "jokes" at others' expense?

I hope you realize that making sexist comments (and then commenting on how "hillarious" similarly sexist comments of others are) puts your position on the whole Summers affair in quite a bit of context…

50. **not deleted by Lubos**
June 19, 2006

in order to be allowed to post comments on the Reference Frame, just write in a polite politically-correct way. For example, my hoax below even got a kind honest answer (in the post about Hawking and the John Paul II):

Dear Professor Motl, I recently read the enlightening books by Hawking, Greene and Randall. Do you think that the hidden reason behind these attacks against you string theorists is that String Theory is getting too close to understanding the origin of the Universe, revealing our role in the immanent?

51. **Chris Oakley**
June 19, 2006

Lubos,

I think that your red neck credentials are now sufficiently well established for you to apply to appear on Jerry Springer. Application form below.
— —

Last name: Motl

First name: (Tick appropriate box)
(_) Billy-Bob
(_) Billy-Joe
(_) Billy-Ray
(_) Billy-Sue
(_) Billy-Mae
(_) Billy-Jack

What does everyone call you?
(_) Booger
(_) Bubba
(_) Junior
(_) Sissy
(_) Other___________________

Age: ____ (if unsure, guess) _____ Not sure

Shoe Size: ____ Left ____ Right

Occupation: (Check appropriate box)
(_) Farmer
(_) Mechanic
(_) Hair Dresser
(_) Unemployed
(_) Dirty Politician
(_) Preacher

Spouse's Name: _________________________

2nd Spouse's Name: ______________________

3rd Spouse's Name: ______________________

Lover's Name: ___________________________

Relationship with spouse: (Check appropriate box)
(_) Sister
(_) Brother
(_) Aunt
(_) Uncle
(_) Cousin
(_) Mother
(_) Father
(_) Son
(_) Daughter
(_) Pet

Number of children living in household: _____

Number of children living in shed: ______

Number that are yours: ______

Mother's Name: _______________________(If not sure, leave blank)

Father's Name: _______________________(If not sure, leave blank)

Education: 1 2 3 4 (Circle highest grade completed)

Total number of vehicles you own: ___

Number of vehicles that still crank: ___

Number of vehicles in front yard: ___

Number of vehicles in back yard: ___

Number of vehicles on cement blocks: ___

Firearms you own and where you keep them:
____ truck
____ bedroom
____ bathroom
____ kitchen
____ shed

Model and year of your pickup: 196_

Do you have a gun rack?
If no, please explain:

Newspapers/magazines you subscribe to:
(_) The National Enquirer
(_) The Globe
(_) TV Guide
(_) Soap Opera Digest
(_) Rifle and Shotgun

Number of times you've seen a UFO:_____

Number of times in the last 5 years you've seen Elvis:_____

Number of times you've seen Elvis in a UFO:_____

How often do you bathe:
(_) Weekly
(_) Monthly
(_) Not Applicable

Color of eyes: Right_____ left_____

Color of hair:
(_) Blond
(_) Black
(_) Red
(_) Brown
(_) White
(_) Clairol

Color of teeth:
(_) Yellow
(_) Brownish-Yellow
(_) Brown
(_) Black
(_) N/A

Brand of chewing tobacco you prefer:

(_) Red-Man

How far is your home from a paved road?
(_) 1 mile
(_) 2 miles
(_) Just a whoop-and-a-holler!
(_) road?

52. **wendell**
June 19, 2006

Peter Woit, you shouldn't call Lubos names like 'subhuman'. That just brings you down to his level. We all know he isn't subhuman and making unrealistic, extreme and exaggerated insults like that should be left for Lubos.
I agree that what he did to Riofrio was in bad taste.

53. **Peter Woit**
June 19, 2006

wendell,

I'm trying to ignore Lubos today and I suggest everyone else do the same. You're quite right that one shouldn't descend to his level. On the other hand, I think "subhuman" is a more accurate characterization of his recent behavior than "in bad taste".

54. **the true YAWN**
June 20, 2006

after answering to a few hoax like this one, Lubos deleted his whole post:
—
Lubos, maybe the problem with "Carroll joins Woit" is that feminists are not more intelligent than females.
—
It is not funny, but maybe it is educative

55. **Chuckles**
June 21, 2006

Mea Culpa: Since the comments were off on the last link about the book / Carroll, I took the liberty of posting the cache link in an off topic thread (LHC News). Guess I didnt scan long enough to find this section. Skeptical about the \"carrying on a discussion with Lubos\" part though. Is he tenured? I dont think he was tenured at the time of the Summers affair.

56. **YBM**
June 24, 2006

A funny side effect of this story, is that Lubos Motl who have (somewhat) supported once the Bogdanov tricksters (by the only reason that Peter Woit reacted to the dishonest way he was quoted in their book) is now quoted (in support of the authors) at almost every pages of the June 06 reprint of Igor & Grichka Bogdanov "Avant le Big Bang", a cranky book where it is explained how wrong string theory is, and how it could be replaced by a non-existent theory, based on wrong statements, which suggest a mystic and mathematical origin of the Universe.

57. **YBM**
June 24, 2006

Incidentaly, I just got my first censored comment on Motl's blog :

" You are involved by being quoted in the new version of their book, period. You are now involved with real cranks, what is quite funny given how you try to qualify as 'cranks' anyone, like Woit, expresses different views as yours.

I wonder where you've got that I could "deduce anything about string theory from this"… given I've never write anything like this.

You seem more and more unable to read honestly any paper, just like you did by linking Carroll to Woit.

Who's insane ? "

Given that I was responding to a post from him qualifying me of "insane", I can now deduce to what kind of guy I was dealing with…

58. **YBM**
June 24, 2006

hum, looks like Motl's blog is not running so well, posts are popping in and out at every reload…

59. **woit**
June 24, 2006

YBM,

Lubos clearly has been driven completely over the edge recently, maybe the appearance of my and Lee Smolin's books and various articles in the press about the problems of string theory have something to do with this. He's never had much interest in facts or logic, but recently he has become completely delusional. I hope his colleagues are trying to get him help, but if you believe what he has to say, they seem to just be encouraging him in his madness.

60. **YBM**
June 24, 2006

It is indeed quite strange he did wrote this "The book is also full of inconsistencies. In one chapter, he argues that the alternatives to string theory in the field of quantum gravity should be supported. In the following chapter, he argues that they should be suppressed – the work of the Bogdanoff brothers is one of his examples.", so he is now comparing Quantum Gravity side by side with Bogdanov's work, even if he did wrote elsewhere how poor their work is. He seem being unable to grasp that you could consider the Bogdanov brother as crank (what they are) on the ground of their behaviour and poor work even if they happen to attack string theory.

The (not so) funny consequence is that now Motl will be known in France as the only (apparent) academic support of a cranky book which explain how string theory is a complete failure !

61. **Peter Woit**
June 24, 2006

YBM,

That is kind of funny. I think the only reason Lubos is supporting the Bogdanovs is that I described them as cranks. Maybe I'll try to come up with ideas of who else I think is a crank that I would like Lubos to support, then write something attacking them.

62. **YBM**
June 24, 2006

It's more and more obvious every day that it is the reason of his support.

BTW, yet another censored post of mine (after he reinserted my previous one) :

" No surprise you've find my name linked almost exclusively to this
affair on Google, given that the Bogdanovs and their fans (none of them being able to deal with the scientific issues I've raised) managed to turn the debate into personal attacks from the first (of four) article I wrote on this subject.
I hope you'll never have to deal with fans totally uninterested by science when writing about any scientific issue. If you could read french, you'd notice that the defaming accusation you've found out came from a fan and that she was unable to provide a single sample.

I usually don't put my name on front when posting or publishing on the net, you are confusing Google with life.

For instance, typing your name on Google will make appear almost exclusively rants against Peter Woit (such as your comment on amazon.com), I wouldn't think nevertheless that you spend your life turning around Peter Woit.

On one hand you are qualifying Peter Woit as a crank when he is attacking string theory, on an other hand you are now known in France as the only apparent academic support of the Bogdanovs in France, as stated in a book who qualify string theory as a complete failure.

Perhaps it will make you think about the proverb "the enemies of my enemy are my friends", and the way it doesn't match well.

P.S. Your posting system doesn't work well, first some posts disappeared, then appeared twice. "

This will be my last censored post there. I won't post anymore on such a dishonest blog.

63. **YBM**
June 24, 2006

Given how you've been misquoted in the first print of their book, you could be amused to see how Igor & Grichka Bogdanov translated this sentence from Lubos :

"[…] the Bogdanoff brothers are proposing something that has, speculatively, the potential to be an alternative story about quantum gravity."

Here is what he supposed to have written, as quoted in a footnote of the new print of "Avant le Big Bang" :

"the Bogdanoff brothers are proposing something that has, speculatively, the potential to be an alternative to quantum theory".

suprisingly enough (not !), the link the brothers provide in the footnote to Lubos' blog is incorrect.

64. **Chris Oakley**
June 24, 2006

Don't the Bogdanovs have a popular science TV show in France? Maybe if things don't work out in academia – or even if they do – Lubos could appear on their show. He could even have a regular "Crank of the Week" slot, where he denounces a new person each week, obviously being careful to steer clear of the brothers themselves in this regard. In time, I am sure that being a Bogdanov/Motl Crank of the Week will be considered the highest academic honour short of a Nobel Prize.

65. **Billy Bob**
June 24, 2006

> I think the only reason Lubos is supporting the Bogdanovs is that I described them as cranks. Maybe I'll try to come up with ideas of who else I think is a crank that I would like Lubos to support, then write something attacking them.

This is a wonderful idea. I vote for John T. Nordberg (who looks like Lubos!) with Archimedes Plutonium coming in a close second, and deserving extra marks for style.

66. **Peter Woit**
June 24, 2006

YBM,

I haven't seen a copy of either the first edition of "Avant le Big Bang", or the new paperback. Someone (was it you?) sent me copies of the pages of the first edition that misquoted me. Do you know if the misquotes attributed to me have been removed in the paperback? Also, do you know what happened with the brother's lawsuit against someone who had written an unflattering magazine article about them?

67. **Chris Oakley**
June 24, 2006

Here's another one for you to attack, Peter: the Flat Earth Society

68. **YBM**
June 24, 2006

They are now quoting you correctly, at least on the quote I checked (they are no more pretending you would have write "absolutely sure" when you wrote "certainly possible"). BTW, I'm not the one who send you copies of these pages (it could be Fabien Besnard).

I will ask about this lawsuit and will keep you informed.

69. **runge_kutta**
June 25, 2006

I've just been reading John T. Nordberg's website. Wow, this guy is a crackpot extraordinaire. Does anyone know what university he's affiliated with (if at all he's affiliated with any) ?

70. **woit**
June 25, 2006

Please, don't start discussing more crackpots here, there's a very large number of them, and what they really want is attention.

Back on-topic, Lubos seems to have just deleted a link to a report on the public talks at Strings 2006, once someone pointed out to him that the report said the talks were boring and most of the audience went to sleep (except for Hawking's talk). Anyone have a record of that deleted link?

71. **YBM**
June 25, 2006

Well, I'm now banned from Motl's blog entry comments page (at least, I won't see anymore my post *modified* as the previous one was).

What's interesting anyway, is how he reacted to Bogdanov's creative quotes :

" Dear YBM, thanks: that's not a terribly accurate translation , but as I indicated many times, I am not gonna sue them.

Very speculatively, they might also have an alternative to quantum theory or anything else. "

Basically he don't care being notorious as a support to crackpots he clearly recognizes as such.

Here what is I could have answered to this post comming after one of mine he had the dishonesty to edit, just after having deleted the one I responded to his rant.

"To sue is a typical bogdanovian activity, as well avoiding scientific issues.

You could now realize what kind of people you've been dealing with (even if without consent).

Did they ask you for any kind of authorization ? Do you know that there is an excerpt from you (at least this one correctly translated) on the cover of their book ?

Forget Woit (who has real arguments), you are now the only proeminent apparent support of the most insane anti-ST ever published in France ! Félicitations !"

72. **Peter Woit**
July 5, 2006

Lubos,

Who told you that I "made amazon.co.uk erase all reviews" except the 5 star ones? Your review was complete nonsense, but the only action I took about this was that when I first read it a month ago I clicked on the "report this as inappropriate" link at the bottom. That's it, I have done absolutely nothing else.

As far as I know, no one else has written a negative review of the book on Amazon, and your crazy one caused several people to write very positive reviews answering it.

I have no idea why Amazon UK recently deleted yours. Maybe lots of people hit the "report as inappropriate" link, maybe someone there read it and recognized it for what it is.

73. **X**
July 6, 2006

dear Lubos,

I agree that your review on Amazon of the book by Peter Woit was deleted by some conspiracy, but you are wrong in writing that it is a crackpot-capitalistic conspiracy. There is a more plausible interpretation.
A recent string-theory paper (hep-ph/0607029) revealed the existence of intelligent civilizations with extended life expectancy in the 10th superstring dimension. Clearly, these aliens do not want to be discovered by us and are trying to prevent further progress in String Theory by deleting your review.

The bastards might even try to delete my comment from The Reference Frame.

74. **Motley**
July 10, 2006

Soon to be deleted:

I came to this blog as a young physicist seeking information in cutting edge physics research, and through sheer luck on my first visit I found it.
Now all I find here is the unreasoned rants and 'reactionary' insults of a man who cannot see past his faith in a theory that has much to live up to.
I have no doubt that this comment will be deleted, but hope that perhaps you will come to grasp just how damaging your behaviour is, to the image of string theorists and of physicists in general.

75. **Mahndisa**
July 31, 2006

07 31 06

Hello Peter:
I recently found your site. I was quite naive to all of the insult tossing that goes on in the physics world. I visit Christine Dantas's blog for some LQG links, then Lubos's blog for some deconstruction. It appears as though I must regularly visit your site for further deconstruction. The diversity in opinions is what I love about science. And in the end, only time will tell who was right eh? 🙂 Please have a nice day:)

76. **M**
September 8, 2006

dear Rae Ann,
Lubos forgot to ban me, so if you like I could re-post my deleted comment that solved the mistery about what M of M-theory really means.

However, censorship made the comments section of the "Reference Frame" somewhat uninteresting, so I prefer to refer you to page 196 of "Not Even Wrong".

77. **Eric Dennis**
September 25, 2006

Lubos, As usual there is much naive garbage and unearned arrogance in what you say, but I will have to be selective.

First, you don't understand Bell inequalities. The fact that a QFT Lagrangian (or Hamiltonian) is local, and hence that space-like commutators vanish, does not imply that the whole theory is local. If you look at spin operators measured on the two sides of a Bell experiment, you will notice that they commute as well. The whole point of Bell's analysis is that despite this commutation, entangled states still exhibit behavior that's profoundly non-local. The standard attempt to cover this up with references to information transfer and no-signalling is itself diversionary philosophical tripe.

Second, whether or not positions make a complete set of observables in (Relativistic)QFT is beside the point. The point is that position-space is inherently special in RQFT, and so criticizing a particular interpretation for recognizing this special status is hypocritical. (Note, I did not say the act of recognizing this special status and demanding a local Lagrangian is hypocritical, as per your straw man.)

Interestingly it is only in the kinds of interpretations of QM/QFT that you prefer that one requires a special philosophical superstructure for measurement theory. In fact the point of the very interpretations you criticize is to formulate QM in such a way that does away with the superstructure — in which measurment processes are normal dynamical processes just like any others, not requiring ad hoc postulates, or collapses, or Born rules.

On any of these subjects, I would consider receiving something other than an F from you a blemish on my credentials. And your girlish preambles about not countenancing any counter-arguments are transparent.

78. **anonymous**
March 11, 2007

censored from http://motls.blogspot.com/2007/03/panel-michael-duff-and-lee-smolin.html

dear Lubos, you (and Duff?) seem to think that the big problem of string theory is that Smolin might have 2 or 3 faces. The big problem is that string theory has 10^500 faces. Instead of arguing about Smolin, please present ideas about how to do physics despite the landscape; this is what will make the difference between success and failure

79. **a.n. onymous**
March 15, 2007

Just a reminder to everyone nerdy: Discover magazine's deadline for submissions of a 2-minute U-tube explanation of string theory is 16 March, so submit today.

Details: http://www.discover.com/twominutesorless/

"The winning video will be selected by Columbia University physicist Brian Greene, best-selling author of The Elegant Universe and The Fabric of the Cosmos, and broadcast via a prominent spot on the homepage of Discover.com … The video should present an accurate, basic understanding of string theory that will stick in the brains of relatively intelligent non-scientists."

Therefore, make sure you include a full proof of how gravity and the standard model are uniquely derived from 10/11 dimensional M-theory, proving how the 10 dimensional superstring universe is a brane on the surface of the 11 dimensional supergravity bulk. I don't know they require you to explain how the 10^500 solutions of string theory correspond to the multiverse.

The main thing to get across is that a 1-dimensional string, when moved, gains a time dimension so it has 2-dimensions (a worldsheet). Then you add another 8 dimensions to satisfy conformal symmetry if there is 1:1 boson:fermion supersymmetry, or 24 dimensions without supersymmetry (i.e., for boson string theory). This explains the reasoning behind 10 dimensional superstring and 26 dimensional bosonic string.

Next, because general relativity is only 3+1 dimensional, you need to roll up of 6 dimensions in superstring, which is done by the Calabi-Yau manifold which compactifies those unseen dimensions. The great benefit here is that the Calabi-Yau manifold can have all many kind of sizes and shapes for its dimensions, so the resulting little vibrating strings which constitute fundamental particles can have 10^500 sets of states or standard models, corresponding to 10^500 parallel universes. The anthropic principle will tell us that the particular universe we inhabit in this landscape of solutions is the one necessary for our existence. It's a very beautiful theory.

80. **ana nonymous**
March 15, 2007

Why do you tell "10^500 sets"? Use "discrete infrared ambiguities".

Why "anthropic principle"? "Structural principle" is more elegant.

So, replace the last sentences with:

Thanks to a rich set of discrete infrared ambiguities, string theory naturally implements the structural principle, providing the only known solution to a fundamental problem at the basis of our life: the smallness of the Cosmological Constant.

and Lubos will not have to censor it. For example I improved my previous post into:

dear Lubos, I understand how much you value intellectual honesty and freedom of speech, but is it worth for you (and Duff) spending so much of your valuable time fighting with crackpots?

and this one was not censored. It's just a matter of good taste.

81. **Censored from Jacques Distler's Musings**
March 16, 2007

I know this is a little off topic, but here's a comment seeking refuge after Jacques Distler deleted it from a Musings post where he suggested that the landscape just isn't a special problem in string theory (because it is possible to create messy landscapes with fictitious, non-empirical assumptions from the framework of the Standard Model and general relativity):

http://golem.ph.utexas.edu/~distler/blog/archives/001200.html

Re: The Standard Model Landscape

Thanks for the link to http://arxiv.org/abs/hep-th/0703067 which mathematically is straightforward for a change. The physical basis, however, is abstruse.

Any idea that particle physics (the standard model) and general relativity have a landscape of solutions is a reversal of the idea that such a theory is defined as representing experimental data.

The only way you can have a landscape for the Standard Model and general relativity is to change this definition, so as to include unobserved, unreal solutions. I.e. you can claim that the basic field equations have lots of solutions if the parameters can vary to unphysical (non observed) values. Thus, general relativity would predict a closed universe if the CC was small and the density was very high. By changing the parameters in the Standard Model, you can also get a landscape of unphysical solutions to particle physics.

But in the case of general relativity and the Standard Model, this landscape literally is not a real problem. This isn't just because measurements and experiments determine the necessary values which go straight into the theory, but it is also because the physical theories are really based on empirical data: the Standard Model and general relativity are derived from empirical data, e.g. symmetries in particle properties, spacetime, gravitation, energy conservation for a gravitational field, etc.

Comparing the unphysical landscape from empirically developed theory to that from string theory (where the spin-2 gravitons, extra-dimensions, and 10^16 GeV unification are not observations), misses Woit's point that in one case the landscape is neither physically real nor a problem, while in the other case the landscape is a real problem.

Nobody has proved that any landscape really exists in nature. The assumption that there might be other universes with different values of standard model parameters is just speculation. If it turns out that those parameters are interdependent and so can't vary in the way assumed for landscape analysis (even if the multiverse is accepted), then this would eliminate or reduce the landscape size.

The objective of physics for some people like Feynman was to find the reasons for why general relativity and the standard model have the form they do. If this quest is successful without string theory, and all the constants and parameters are predicted to have unique values from a theory that doesn't allow other values, then there will be no landscape whatsoever.

82. **Arun**
March 16, 2007

Censored from Jacques Distler's Musings Says – your eminently sensible posting was censored? It is to the point, pertinent, polite — I'm really amazed! Thanks for letting us know that things have become so bad.

83. **TCO**
March 19, 2007

I'm banned from the Reference Frame. I only wanted to disaggregate an issue (do issue analysis) in a discussion of global warming. Lubos managed to muddle two effects (becoming like Venus and posited temp increase for CO2 doubling) as well as two sources of information (ice cores and Venus temp/CO2 levels). He also does not understand how to bound a problem and when he is doing it and when he is not doing it. I really don't get the impression of an honest, curious scientist.

84. **amused**
March 20, 2007

"I really don't get the impression of an honest, curious scientist."

No kidding 😉 Sometimes it works to tell Lubos to do the opposite of what you want him to do. E.g.:
"Go ahead and block me Lubos, there are plenty of other internet cafes in the city where i live"
or
"Lubos, please hurry up and delete this comment. I want an excuse to repost it over at Peter Woits blog where it will be seen by lots more people."
Both of these worked for me in the past.

85. **M**
March 21, 2007

hi, amused. Here is an example of what happens with your strategy. I posted:

dear Lubos, do you agree that your slogan "String theory is the language in which God wrote the Universe" must be updated into "String theory is the language in which God wrote the Multiverse"?

If you answer no, you are defending something that does not exist: there is only one string theory, and it has a landscape of 10^500 solutions.

If you answer yes, you are ready to start arguing with Woit.

If you censor, this question will be moved to the "censored by Lubos" section of Not Even Wrong.

This was not censored, and got a thoughtful answer:

…you are a mentally retarded imbecile…

But my later reply was censored:

dear Lord Motl, if it'so easy for you, why don't you show us the solution to the 10^500 problem, and I will be pleased to hear your insults at your Nobel prize conference?

86. **amused**
March 21, 2007

Hi M,
Thoughtful replies of that nature are all you will ever get from Lubos with that type of question. For what it's worth, here are a few recommendations for interacting with him. Serious discussion is not possible, so think of it as a sport – motlbaiting. There are two possible goals. The first is to wind him up so much that he has to write a whole new blog post full of abuse to recover from it. Your comment will of course be deleted, but nevermind, you can just repost it here. Physics points should be avoided for this; snide remarks containing unfavorable comparison of his publication record to those of various "crackpots" are much better. The alternative goal is to try to slip in as much string-bashing as you can while taking a joking around approach, and avoid getting deleted or blocked. It's for this that the suggestions in my last comment apply.

87. **gunpowder&noodles**
March 21, 2007

"snide remarks containing unfavorable comparison of his publication record to those of various "crackpots" are much better"

LM actually posted Smolin's publication record as a way of proving that he, Smolin, is a failure. Smolin's record, in reality, is extremely good, far better than I would have expected actually; and of course it is literally an order of magnitude better than LM's. The fact that he can't see that most readers would think this is a strong hint that he is really cracking up.

88. **TCO**
March 21, 2007

I'm really getting dissapointed with the honesty and smartness level of conservatives lately. Am I the only smart, honest one?

89. **TCO**
March 24, 2007

You know, I lack the math or physics ability to understand the arguments, pro/con with string theory. I do find your manner to be much more pleasant than Mr. Motl. What's ironic is that he defends the "skeptics" of global warming, but he disdains those in his own field. A real scientist should be curious of all. Skeptical of all. And able to formulate the key questions to resolve what is trustworthy.

I've also never been able to really have a conversation that got into thoughtful issue analysis with him. Maybe part of it is my hesitancy, out of respect for superior math ability. And my tendancy to play game to cover that. But I think a part is Motl, not really being intellectually curious. Not being an issue analyzer. A disaggregator of causes and effects.

90. **Kea**
April 12, 2007

13 April 07: I just invited Lubos to join our discussion on his 2002 Tripled Pauli Statistics idea, which appears in our version of M theory. I'm not sure whether he will look upon the invitation kindly or not.

91. **amused**
September 6, 2007

Rudely deleted by Lubos from the thread of "Nobel Prize winners vs crackpots":

Hi Lubos,
Considering that you are very far from being a leader in string research, why on earth did PI want to give you a job? Is it because of your charming personality?;)

Btw, congrads to the string theorists on having recruited a new cheerleader among the science journalists. It's fortunate for you guys that Chalmers doesn't have a background in particle theory research, so that he is able to swallow the string hype whole without getting indigestion!

92. **amused**
September 16, 2007

Lubos is full of fun and games these days, and rather than just deleting comments he's taken to "improving" them… For example, in the thread of this post, where Lubos lists himself along with Witten, Maldecena, 't Hooft and Einstein as reknowned physicists, I added a little comment
"Gene, you forgot to mention Lubos' awe-inspiring publication record 😉 "

(In response to a comment by one of LM's groupies chastising those who dare to doubt his guru's towering intellect, since LM had `read Dirac's book when he was only in high school' (Wow, who needs PRL publications with that kind of achievement under their belt!)) Well, Lubos decided to "improve" that comment into something quite different… In fact my own views are more along the lines of this, which I like to think might have responsible for the amusing rant ("omnipresent intellectual trash…") at the end of this post 🙂
And Lubos was so inconsiderate as to block me, which means I'll have to walk an extra block to the next internet cafe next time ;-(
Btw Lubos, here's something else I've been meaning to ask you: Is the SLAC faculty member who wrote this post also a crackpot?

More Landscape, and Peer Review

June 16, 2006
Categories: Uncategorized

The anthropic string theory landscape seems to be having ever greater success in taking over fundamental physics and turning it into pseudo-science. It's being promoted by no less than 2008 presidential candidate Wesley Clark, the following is from a transcript of his remarks to science bloggers at a blogger convention in Las Vegas:

Read Leonard Suskind's new book, called "The Cosmic-" It's called "The Cosmic Landscape And Intelligent Design" if you want to see something that's overpowering. Suskind is the inventor of cosmic string theory, and what he does is he takes cosmic- he takes the idea of the universe. He says the universe is- see, what's happening in intelligent design is people are saying, 'Ah well, you see, the, the, the wavelength of, of, of the electron and Planck's Constant and all these numbers are so odd. They don't- they're not even numbers, you know. They, they, they don't balance each other. It's sort of 1.- It's like the figure of pi, 3.14159… Why would it be such an odd number? Why, why wouldn't god make the universe, you know, symmetrical?'

(laughter)

Then they said, 'well, because, you know, it's like there's only one on 10 to the 50th chance that the universe could have worked out in a way that mankind could survive. Therefore, you know, this must have been an intelligent designer who created this universe especially for us.' What Suskind does is he turns it on its head. He says, "You know, if you look at string theory and the 9+1 dimensions" or 10+1 dimensions, and I'm not sure how he knows that time only has one dimension, but he does. (inaudible) would say I'm very arrogant for questions questioning this.

(laughter)

But what Suskind does is he turns it upside down. He says, "Look there are- there is an infinite number of universes." He calls it a multiverse, and he says that however the motive forces, and nobody understands why quarks pop in and out of existence. Nobody understands it, but apparently they do. And apparently there are many, many universes, and we're here in this one. And maybe there are others in which Planck's Constant has a different number, in which the speed of light is not 186,200 miles per second. Who knows? We don't know.

Commenter Patrick wrote into point out a review article on this from graduate student Joseph Conlon, published in the latest issue of Contemporary Physics (not available on the arXiv or anywhere else for free as far as I can tell). It's entitled, "The string theory landscape: a tale of two hydras", with the first hydra the non-renormalizability of gravity (supposedly slain by string theory), the second the proliferation of vacuum states. Conlon seems to think that the fact that string theory can't ever be used to predict anything is not a serious problem:

We started with a dream of a unique string theory compactification reproducing the structure of the Standard Model. This is a dream apparently shattered by the existence of the landscape. Granting the landscape and its existence, does this mean string theory is inherently unpredictive at low energies? If this is true, this is sad but no disaster. Quantum field theory, of itself, is also unpredictive.

I've written elsewhere about why this analogy with QFT doesn't hold, but on the face of it there's obviously something wrong, since we use QFT all the time to make detailed, testable predictions about the real world, something that string theory, according to Conlon, will never be able to do.

Talks from the plenary section on "naturalness" at SUSY 06 are online. The usual advertising job from Susskind and Linde, the one that seems to have impressed Wesley Clark. Wilczek gives a more substantive talk, and seems to have some interesting new speculative ideas about models near the end.

On another topic, I've been wondering what the current state of peer-review of hep-th papers is. Personally I think it has been several years since I've looked at any of the main journals that publish papers in this area, and I suspect this is true of many people these days. The Bogdanov affair several years ago showed that refereeing in this area had become pretty much a joke, with the brothers having no trouble finding five journals willing to accept utter nonsense.

Looking at the arXiv and SPIRES listings, which seem to contain publication information after submitted papers have been accepted, many papers (e.g. Susskind's single-authored papers on the landscape), don't seem to ever have been peer-reviewed and published. I'm curious what people think of this. How many hep-th authors have stopped submitting their papers for refereeing? Is the data on the arXiv and SPIRES an accurate reflection of this? Does the fact that an author's preprints don't have publication data for the last few years mean they weren't submitted for refereeing, or could this be due to time lag in refereeing/publication, or incompleteness of the data?

Update: Courtesy of Google, there's now an on-line talk by Washington Taylor promoting the Landscape to people working for the company. He gives the number of vacua as at least 10^{1000}. The number of well-known physicists out there promoting this nonsense to the general public is amazing (via Lubos).

Comments

1. **Warren**
   June 16, 2006

   I haven't submitted my single-authored papers (or books) to publishers in 10 years. But most of my papers are with others, and I haven't forced them to do the same. I don't have much faith in the refereeing system. Besides, by the time they publish something, it's history. And then there's the problem of errata.

2. **hack**
   June 16, 2006

   Susskind has no peers, therefore it is impossible for him to be peer reviewed.

3. **Kasper Olsen**
   June 16, 2006

   There is actually quite a few famous papers which have never been published, for example

   hep-th/9805114,
   hep-th/9907189,
   hep-th/0006071

   and

   hep-th/9701025

😉

Kasper

4. **sunderpeeche**
June 16, 2006

a) Bloggers have conferences?
b) Why would Wesley Clark even read the book? Did Susskind give him a copy?
c) The whole attitude to the landscape is wrong. First, you need an acronym. “Anthropic string theory landscape” is a non-starter. Landscape (of) anthropic string theory = LAST ~ Lubos Adores String Theory. Now we’re getting somewhere. Next print some t-shirts and make some money off of ST, instead of railing against it.

5. **Christine Dantas**
June 16, 2006

In the astrophysics community, it is somewhat rare to see a paper in the astro-ph that has not been at least submitted to a refereed journal. Of course the refereeing system is faulty sometimes and needs some reformulation. (For instance, it would be interesting that the authors’ names be omitted for review in order to reduce some prejudice on the part of some referees and to allow them to unbiasedly focus on the paper contents. There are other problems as well, I could talk about a few examples, but I do not think Peter Woit intended to open a whole thread on this.)

I do find it strange that the majority of papers in the hep-th (is it correct, the majority?), including those considered important contributions, are not submitted for refereeing. Being myself used to post on the arXiv only after having my papers accepted to a good refereed journal, maybe this is just my personal impressions. In any case, I have learned this good practice from my supervisor since I was an undergraduate student, and I am quite satisfied with it.

The arXiv is a great idea, but I do not think it is a substitute for the refereeing system (despite its flaws), specially if your work is supposed to represent a significant contribution to the field. It must somehow be appropriately reviewed.

6. **Brett**
June 16, 2006

I think that peer review works pretty well, at least for the better journals. In high-energy theory, this means Physical Review Letters, Physical Review D, Physics Letters B, Nuclear Physics B, and some others. It is very difficult to get something that is pure rubbish published in those journals. By “rubbish,” I mean a paper that is flawed in a fundamental way–a paper will problems in its conceptual or mathematical underpinnings. (How interesting physically some of the results published in these journals are is a separate question.) The fact that almost all the high-energy theory papers submitted to these journals appear in advance on the arXiv is good for the peer review process, since referees can (surreptitiously–or perhaps not) get input from their colleagues about papers they are reviewing.

Most people I have interacted with in the high-energy physics community certainly do pay attention to whether and how papers are published. Publication in the journals I listed above means something; however, publication in many lesser journals does not. It is understood that peer review is significantly imperfect, and even extremely poor papers can be slipped into minor journals if the authors are diligent. I think many serious physicsts would never even submit a paper to one of these publications; if they can’t get papers published in top-tier journals, they just leave those papers on the arXiv and don’t bother trying to get them published somewhere else. Of course, there are journals that occupy a sort of middle ground and are somewhat respected. The Journal of Mathematical Physics is still considered to have fairly high standards for correctness, but the papers published there are usually expected to be less interesting than those published in more prominent journals.

Peer review for the better journals can be uneven in quality. Good papers get held up by difficult referees, while somewhat weaker (still correct, just less interesting) papers may slip by with little comment. However, while there is some noise, there is also a clear correlation between the quality of a paper and how likely it is to be rejected. When I have gotten negative referee reports, I have always (with one exception) understood the referee’s point. Obviously, I disagree with the referees, but these rejections are not being made for stupid reasons; the reviewers have put time and effort into evaluating my papers. I have also appreciated the many comments and suggestions for minor improvement that I have received in more positive reports–again, clear indications that the referees are almost always paying attention.

Speaking as a referee, however, I know it can be difficult to reject a paper that has some interesting ideas, but which also contains some serious mistakes. I have never allowed a paper like that to be published, but one cannot help but feel empathy for authors who may have put months of work into something (and come up with several innovating ideas), only to be undone by a small but crucial mistake they made early on.

7. **knotted**
June 16, 2006

I agree authors names shouldn’t be passed on to reviewers, but neither should the laboratory name unless it is an experimentally based paper. Peer review is only meaningful is the reviewer has to review the content. Usually it is the exact opposite, with journals requesting names of peers to sent the paper to review to. This is asking for bias. It makes it easy for mainstream and virtually impossible for outsiders. arxiv could easily be reviewed by blog trackbacks, if someone would be objective about it…

8. **The Great Inquisitor**
June 16, 2006

The social dynamics of the string community is that of a sectarian totalitarian system, hiding from the rules of scientific objectivity, due to the absence of both experimental provability and disprovability.

The string theory community is a personality cult with Witten its high priest. Once Witten retires, chances are high everything will pop like a soap bubble (or like the high tech stock market crash not long ago), leaving the reputation and credibility of theoretical physics in pieces for decades to come.

Witten creates credibility among the mathematicians, by his ingenious works in geometry and topology that have nothing to do with string “physics”. On the other hand, he has surrounded himself with an army of loyal, brainwashed followers who dress like him, who talk like him, who write preprints in same style format like him. The string community is like a mass of half-baked Witten clones, with some members more prone to hysteria than others. One has to study mass cults in order to understand the personality defects that motivate people to join such movements (presumably, weak self-respect, paired with a will to power, plays a role).

One should read the episode “The Grand Inquisitor” in Dostoevsky’s “Brothers Karamasov”: The devil tempts Jesus in the desert, and explains to him that humankind will follow anyone who provides them with bread and miracles; therefore, an overwhelming demonstration of the power to support people with food, and with miracles, would convince humankind to forfeit its free will, and to follow that person wherever he/she pleases to go. But Jesus refutes this methodology; he wants people to follow him out of free will and belief. Witten makes a different choice than Jesus in Dostoevsky’s piece. He provides his followers with jobs and miracles, and they literally follow him to the end of the world of theoretical physics.

Fortunately for humankind (or at least for future generations of theoretical physicists), there is no successor to Witten. Therefore, there is reason for the joyful hope that the string hysteria will evaporate in a couple of decades.

On the other hand, one has to admit that string theory has produced amazingly interesting mathematical insights. If things go well, some mature parts of string theory will be absorbed into a branch of topology or number theory, which is ok and worthwhile. I just hope that string theory will disappear from the physics landscape, not because I particularly resent it, but because I'm scared by the populist, totalitarian, sectarian social dynamics of the strings community.

And if some string theorists insist on the eternal lifespan of their favorite theory, I would like to remind them of the fate of communism, and of that of other totalitarian systems, which were defended as vigorously by their proponents some decades ago.

9. **Eugene Stefanovich**
June 16, 2006

Brett,

I agree that the review process is useful when you can talk to the referee, argue, and get feedback. Now, how would you argue with the Editor of one of the fine journals you mentioned when in response to my submission he writes this?

In general, [journal] does not publish purely formal developments of old and well-established theories or alternatives to old and well-established theories if the new alternatives do not make different predictions that can be experimentally verified; if the new alternatives do make different predictions, it must be shown that the predictions are consistent with the present experimental situation. Applied to your manuscript, this policy would require that you provide an explicit, detailed, and quantitative prediction of your theory that differs from the predictions of standard quantum electrodynamics. Since you have not done so, I am afraid that we cannot accept your manuscript for publication in [journal].

After I explained the relevance of my work to current and future experiments, I got

I am afraid that, even after considering the points that you make, I still conclude that your manuscript is not suitable for publication in [journal].

End of story. How can I argue with that?

Eventually, this paper was published as

E. V. Stefanovich, "Quantum field
theory without infinities", Ann. Phys. (NY)
292 (2001), 139

(there is also a copy on the web if you are interested) So, you can judge for yourself whether it has anything new to say about QED and its agreement with experiment.

10. **Peter Woit**
June 16, 2006

Eugene and others,

I'd rather not start a discussion here of refereeing itself, it's a huge and complicated subject. What I'm trying to understand is how widespread is the phenomenon of people giving up on the journals and refereeing system, just ignoring them. I see more and more of what looks like evidence of this happening, and Warren provides another data point. Given the fact that virtually no one looks at most journals anymore, this may be an increasing trend.

11. **Peter Shor**
June 16, 2006

One comment: I don't think absense of any journal reference on the arXiv means anything about publication … it means the author was too lazy to update the arXiv. You can often find journal versions of quant-ph articles by googling, even when there is no pointer on the arXiv. It would be interesting looking at a sample of hep-th articles from several years ago, and see how many are still unpublished.

12. **Peter Woit**
June 16, 2006

Peter,
I was looking more at SPIRES, which I believe they update automatically with journal information as the journals come out. This isn't up to the author. But if anyone knows differently, I'd be curious to hear about it.

One set of examples of papers that don't appear to have been submitted to journals are Susskind's, e.g.

hep-th/0302219 (the original anthropic landscape one with 257 citations)
hep-th/0407266
gr-qc/0503097
gr-qc/0504039
hep-th/0101029
hep-th/0011164

Another example would be Jacques Distler, who doesn't seem to have any published papers since one he wrote back in 2001.

If anyone knows of how to find out if and where these papers were published, let me know.

13. **Bert Schroer**
June 16, 2006

The Great Inquisitor
A perfect analysis of the sociology underlying string theory! It is very unfortunate that in order to write something like this one has to use a pseudonym (at least before retirement), whereas the Lord of misuse (comissioned by the hegemonic string court to prolong the lifetime of string theory beyond the lifetime of their protagonists) can spread his vitriolic brew to confuse young physicists and frighten more knowlegeable and mature members of the community.

14. **Joe Conlon**
June 16, 2006

Ha! I was wondering Peter when you would run across that. I have some vague vision of long Woitian tentacles spreading across the web in search of anything landscape, and I'm sure they don't miss much.

Let me elaborate a bit on what I meant. Almost by definition, it is very hard to find exclusively stringy predictions at low-energy that cannot be reproduced by effective field theory. If you are willing to go to Planckian energies, then we can run with exponentially soft scattering amplitudes and towers of excited stringy states, but there are no Planck-scale accelerators and this is somewhat of a toy game.

However, all effective field theories are not equal. There is clearly lots of structure in the Standard Model that is bursting for an explanation. One example: the QCD theta angle. Your underlying theory has a big role to play in the models you use to try and explain and understand the Standard Model. There are better and worse ideas on what are the underlying principles – e.g. base 10 numerology is mostly held to be an unpromising idea. In this sense I regard string theory as the best organising principle for thinking about models or effective field theories explaining the structure of the SM.

So, at low energies, I see `string theory' as conceptually analogous to `gauge symmetry', `spontaneous symmetry breaking', `quantum field theory', etc. It is an organising set of ideas and assumptions that is not *in itself* predictive but sets the framework to build predictive models. Clearly `models inspired by string theory' do not compare experimentally with `models inspired by gauge symmetry', but that's why the one is research and the other taught in undergraduate courses. String theory does differ in that it has wonderful UV properties and is intrinsically predictive in that regime, but I'm not holding my breath for the Trans-Galatic Super-Duper Quasar Collider.

If you can argue technically that you can get any effective field theory out of string theory this may not apply – but this is certainly false for the IIB flux vacua that provoke all the chatter about 10^500 and so on, as these have rather similar properties.

I also note that on a personal level I am far more interested in the correctness of My Models than in whether My Models are a unique low-energy prediction of string theory.
I see some of these landscape discussions as more sociological than anything. Maybe in 1985 people thought string theory was about to explain everything in two weeks. I don't know, I wasn't around then. I don't think people enter the field now with that illusion. The theory is still vastly more capable of talking to the particle physics-GR-cosmology triangle than anything else. It's not a binary distinction between a theory that predicts everything and a theory that is entirely useless.

Best wishes
Joe

15. **Brett**
June 16, 2006

I realize that this is off topic, but I was asked a direct question, and I want to respond.

Eugene-

I too have had a paper initially rejected because it did not state any specfic predictions that the referees deemed sufficiently important. My response was to add futher numerical calculations detailing the non-standard model behavior. You comments seem to imply that you did not make any changes to the manuscript after receiving the rejection, but merely tried to convince the referee of your paper's importance. However, I think the referee initially had a quite valid point, as I did not see any new predictions in your paper, and so I am not surprised that he did not change his mind.

16. **Eugene Stefanovich**
June 16, 2006

Peter,

I think there are rational explanations of why people may prefer arXiv publication to refereed journals. I suspect that Susskind does not care anymore about his publication record, so why bother to submit papers to journals? Others may have less impact papers that simply add finer details to the points made in their previous journal articles. So, they decide not to go for the full-blown paper. I have a couple of those in the arXiv. Yet others (mostly those who are out of the mainstream) may give up after referee's or editor's rejection.

Brett,

if I may, just a few points. First, the person who wrote this was not a referee, but the journal editor. You can have a discussion with the referee, but if the editor rejects your manuscript, you are done.

Second, if you read the paper more carefully you'll see that it opens up a whole new *class* of experimental predictions which go beyond the S-matrix and allow one to calculate the time evolution of interacting systems. It is another matter that such a time evolution is beyond the resolution of modern experiments. However, one doesn't need a "Trans-galactic Supercollider" to see it.

Third, I am wondering how many string theory papers satisfy the stringent criterion of providing an *explicit, detailed, and quantitative prediction* ?

17. **catherineD**
June 16, 2006

Aw, come on.

Clark planned to become a physicist back in high school, but now he's just a really smart guy who picked up a book to read for pleasure on topic he enjoys. Don't expect him to be up on what's going on.

The current guy in the White House can barely read. Here's a guy you could talk to and is open to learning more.

Appreciate it.

18. **woit**
June 16, 2006

catherineD,

Wasn't really complaining about Clark, just marveling at how far into the culture this whole landscape thing has gotten.

Joe,

Thanks a lot for writing, it's too late tonight, but I look forward to reading carefully what you have to say tomorrow.

19. **arnold**
June 16, 2006

I went through some talks of the SUSY conference.

The funniest one is Linde's slide that says about the anthropic principle:

"IT IS SCIENCE"

Every child knows that science is about making predictions and be tested by experiments….but these old physicists, that have no more ideas, want to convince us that science fiction is science.

Probably every other scientist outside theoretical physics (people who that are used to experimental verification!) would think these people are just crazy.

20. **arnold**
June 16, 2006

…and it is sad to see how throetical physics (that was once upon a time the mother of sciences) is leaving the objective scientific method to go into the world of the opinion, where some famous powerful person decides what is good and what is bad….and not experiments.

21. **MathPhys**
June 16, 2006

I just watched W Taylor's lecture on google. It's scary how intelligent people can give talks like that.

22. **anonymous**
June 17, 2006

dear Joe,

recently people liked to speculate about brane-worlds with large extra dimensions because this allows quantum gravity at the TeV scale: LHC would be your Trans-Galatic Super-Duper Quasar Collider. This scenario was motivated by string theory, and gave to string theorists an opportunity to show what they can really do. The resulting literature shows that all concrete work was done by phenomenologists who tried to apply Einstein general relativity by avoiding or parameterizing (and sometimes ignoring) UV divergences.

Even in the quantum gravity regime, string theory failed to give results. Some examples:
Q: What is the mass of the string states in units of the quantum gravity scale?
A: it depends on the dilaton vev.
Q: What is the tension of our brane?
A: It depends on how supersymmetries are broken.

23. **anonymous2**
June 17, 2006

Refereed journals are still relevant in fields that produce results relevant for different fields.

For example, hep-ph and astro-ph contain some papers that experimentalists consider relevant. But experimentalists often are not expert enough for judging themselves if such papers are correct, and therefore often adopt the following rule: only papers published on good refereed journals are ok.

24. **Eugene Stefanovich**
June 17, 2006

Peter,

thank you for the link to Washington Taylor's video. Believe it or not, I've never heard this full story from the mouth of real string practitioner. My opinion about the whole enterprise is this: childish logic + superiority complex + arrogance + fanatism. We have entered dark era, indeed.

25. **Joe Conlon**
June 17, 2006

Dear anonymous,

Of course I'd be very happy if TeV-scale Large Extra Dimensions were seen at the LHC. But there are lots of hints that the cutoff scale should be larger (axions, cosmic rays, proton decay, neutrino masses, GUTs…) and I for one would be surprised if they were found. Long odds, big payoff. I also don't think `string theorist' is an identikit. Some who work on string theory are algebraic geometers at heart, others only care about BSM phenomenology, and most are some way inbetween. It's a big community. If `string theorist' is only used to refer to the former, then of course such people never go near BSM exotica.

I'm not quite sure I understand your Q and As. Stringy states have masses given by the inverse string length, which is determined by the volume and dilaton. We don't know the string scale, but it's always less than the Planck scale. With the second, there are universal formulae for brane tensions which are in e.g. Polchinski. I also don't see how brane tension is an (easily) measurable quantity.

Best wishes
Joe

26. **island**
June 17, 2006

Wasn't really complaining about Clark…

I'm am… complaining about anybody that is that quick to stereotypically follow suit with the all-to-familiar mindset of a **pack** of anti-fanatics who choose to willfully ignore the strongest implications of empirical evidence by instead automatically reaching for the most extreme anticentrist cop-out on first principles in the history of science in order to counter-respond to fundamentalist abuses of the evidence.

Panel of extremists:
science panel w/gen. wesley clark, chris mooney, ***pz meyers*** *and darksyde*

Michael Moore has a better shot at 10^500:1

~

And thank you, Peter, for being clear:
The anthropic string theory landscape…

27. **The Great Inquisitor**
June 17, 2006

I haven't read Susskind's book, but the inclusion of "intelligent design" in its title demonstrates the cheap moral standards and ethical bancruptcy in his community. Although the content of the book may prove otherwise, his choice of a title shows that he intends to get customers from another sectarian group of extremists, namely the right-wing Christian right.

The present US government is the first in recent times not only to have understood the size and the power of the Christian right, but to also cast aside ethical concerns, and to use it to its advantage. This is clever, but of course also degrading and ethically reproachable. Maybe the strings people only see it as clever propaganda, and are planning to learn from it.

What distinguishes a typical member of the strings community from a traditional physicist or mathematician is surely not intelligence; there are some extremely smart ones among them. It is their failure to feel an obligation as a scientist to a scientifically verifiable truth. The problem is a lack of scientific ethics. They trust the visionary abilities of people like Witten more than scientific objectivity and scientific method. This is an extremely dangerous, and short-sighted road. Witten does possess self-restraint and good taste in mathematics, but most of his followers don't. They inadequately use mathematical language, which they only understand marginally, to try to impress all sorts of people, including Wesley Clark. The question is who they believe to do a service for, string theory, theoretical physics, or science ?

I am not concerned that after the Witten era, the strings movement will navigate itself into oblivion, due to the bad taste and lack of self-restraint of its members. However, their present propaganda is scientifically unethical, irresponsible, and dangerous.

28. **island**
June 17, 2006

Although the content of the book may prove otherwise, his choice of a title shows that he intends to get customers from another sectarian group of extremists, namely the right-wing Christian right.

Capitalizing on the popularity of the politics while blackmailing the string community.

> Amanda Gefter:
> If we do not accept the landscape idea are we stuck with intelligent design?
>
> Leonard Susskind:
> I doubt that physicists will see it that way. If, for some unforeseen reason, the landscape turns out to be inconsistent – maybe for mathematical reasons, or because it disagrees with observation – I am pretty sure that physicists will go on searching for natural explanations of the world. But I have to say that if that happens, as things stand now we will be in a very awkward position. Without any explanation of nature's fine-tunings we will be hard pressed to answer the ID critics.

29. **The Great Inquisitor**
June 17, 2006

Island,

What Susskind says here is that the only alternative to ID is strings and landscape. This is complete BS. The truth is that ID is based on an argument that is inacceptable to scientific methodology; it is not scientifically verifiable.

ID argues as follows: We have this creationist theory that explains the universe for those people who believe in it. Since it is not accessible to scientific disproof, it must be true.

String theory argues in a very similar way.

So it's in a sense true; string theory and ID are both belief systems, one mathematical, the other not, which are neither provable nor disprovable by scientific experiment. So their claim for truth is similarly vacuous.

But it should be emphasized that Susskind is extremely irresponsible in not putting it this way, but to claim that strings + landscape is defending physics against ID. This is not true. Strings is not traditional physics based on scientific methodology.

30. **anonymous**
June 17, 2006

dear Joe,

I fully agree with you that lots of hints disfavour TeV-scale quantum gravity is unplausible. Indeed, what keeps this possibility alive is the fact that we do not have a predictive theory of quantum gravity, so that we can make optimistic speculations.

Concerning my Q&A, the main issues that phenomenologists would like to know are: supposing that "quantum gravity" is what cut-offs quantum corrections to the Higgs mass, how much is the D-dimensional Planck scale? And the first string excitation? And the tension of our brane? 1 TeV? 5 TeV? 200 GeV? String theory does not give any useful answer.

Collisions of particles excite brane fluctuations giving missing energy signals that are detectably large if SM particles live on a brane with tension smaller than about a TeV. Formulae for brane tensions on Polchinski book apply when many supersymmetries are unbroken, not in our universe.

31. **hogy**
June 17, 2006

The actual name of the book is "The Cosmic Landscape: String Theory and the Illusion of Intelligent Design".

32. **hogy**
June 17, 2006

and Wesley Clark is just trying hard to make himself look cool to geeky voters.

33. **Peter Woit**
June 17, 2006

Joe,

The problem with your philosophy of string theory = generator of models is that it generates far too many of them, and the ones that look at all like the real world are ridiculously ugly and impossible to do precise calculations with. The theoretical framework of these models gives an infinite number of publishable research projects for people to work on, but zero reason to believe that this will ever lead anywhere, and no way of ever showing it is wrong. There is no criterion in this game for when to stop, give up and admit it doesn't work. Your only hope is for a miracle to happen and something orders of magnitude more successful (in agreeing with the SM, being computationally tractable, and constrained enough to allow predictions) to all of a sudden appear. Hoping for a miracle is not a valid scientific research program.

34. **Joe Conlon**
June 17, 2006

Hi Peter,

The judgement of whether research programs are promising or not is subjective. Both reasonable and unreasonable people disagree. On the issue of whether string-based models are promising things to work on, I happen to think you are dead wrong. Of course, it's your prerogative to disagree 🙂

Best wishes
Joe

35. **wolfgang**
June 17, 2006

>Hoping for a miracle is not a valid scientific research program.

What scientific research program would you propose?

36. **Arun**
June 17, 2006

"What scientific research program would you propose? "

– Presumably any where the following is false:
"There is no criterion in this game for when to stop, give up and admit it doesn't work. "

37. **wolfgang**
June 17, 2006

> Presumably any where the following is false:

Which is?
This is a serious question. If Peter or you suggest to give up on string theory, then it is a legitimate question to ask what better alternative you have.
What theory are you or Peter working on which will help us determine the value of the cosmological constant?

38. **Arun**
June 17, 2006

Wolfgang, you are posing a false question. One need not be working on some lesser nonsense in order to call the bluff of greater nonsense. We may simply have to say that there are no viable ideas today for the theoretical determination of the cosmological constant. It is better to face that truth than to have false hopes about some program. Activity for the sake of activity (what will we do otherwise) is pointless.

39. **Peter Woit**
June 17, 2006

Joe,
Reasonable people can disagree about prospects for these models, but I've been watching people work on them for almost 22 years, and they are further away now from being able to use them to predict anything than at any previous time. The derivative has the wrong sign.

Wolfgang,
Unlike many of my dear commenters I don't want to use this forum to endlessly promote my own favorite ideas. I did write a long paper about some of these, and hope to get some other things written down in the future. If you look at the non-string theory things I write about on this blog you can get an idea of what I find interesting. Obviously I don't know how to compute the CC, if I had to guess I'd guess that the answer to that problem will come after you solve some other problems. Just thinking about the CC is probably not going to get you anywhere.

But I think the whole field would be a lot healthier is people tried to come up with their own new ideas, whether about the CC or anything else. If one is not willing to try and do this, this isn't a good career choice and one should stop trying to be a particle theorist and find something else to do where one can make a contribution. Putting one's efforts into an idea which obviously can't work is just a waste of one's time and talents, there is no justification for doing it.

40. **wolfgang**
June 17, 2006

> We may simply have to say that there are no viable ideas today for the theoretical determination of the cosmological constant.

OK, but if you or Peter do not want to be active it does not follow that everybody else has to give up as well.
Many decide that string theory is a good starting point for such activity, because it contains quantum gravity already (which is certainly a necessary ingredient). Others may decide that it is
better to think about causal sets, simplicial lattices, LQG or whatever.

But why should they stop doing whatever they are doing just because you or Peter feel that it is taking too long already?
(By the way, it is not 20 years. People have been working on quantum gravity for more than 70 years.)

41. **wolfgang**
June 17, 2006

Peter,

I am sorry, our comments crossed.
I am looking forward to read your paper.

42. **Arun**
June 17, 2006

Wolfgang,

The question of whether string theory can produce a physical prediction or not is utterly independent of what my opinion is, and needs to be answered prior to "why should anyone stop doing what they're doing"?

Let us consider a patent absurdity to drive the point home.
If someone is proposing to compute Einstein gravity perturbatively to three loops, it is a legitimate question to ask why, what for, what do you hope to learn by it?

The question on the table is – at what point does any approach reach that level of absurdity?

43. **Bert Schroer**
June 17, 2006

Great Inquisitor,
I am quite impressed by your forthright description of the present crisis. But whereas you describe the symptoms you say little about the deeper causes. Obviously things are not that simple that some leading figures on the top decided to conspire to push a particular metaphysical fashion at the expense of more reasonable ideas.
One idea I have been thinking about is that as a result of an increasing sophistication of mathematical methods and a rapid grows of knowledge the time an individual particle theorist needs to pursue an idea and arrive at a breakthrough is perhaps longer than say at the beginning of last century. Even very intelligent and ambitious people may come into a situation where they have spend a sizable part of their lifetime with a problem without experiencing the satisfaction and joy of a significant accomplishment. Couldn't there be a strong temptation to force a situation in which such an experience is still possible within one's lifetime? In that case one would do everything which keeps this idea in the headlines against all ethics which the pursuit of science requires. Hegemonic control and arrogance as well as squandering, wholesale clearance of the conceptual treasures and their substitution of depth by banalizations seem to be the poisonous gift of string theorists to particle physics. Isn't this the equivalent of Enron and World com which we are witnessing? The fact that it is not an isolated phenomenon but a general hallmark of the Zeitgeist of unleashed globalized capitalism shows that this not something which is likely to stop if Witten gets disappointed with string theory or Susskind disavows anthropic arguments.
Wolfgang
any theory of something is a reasonable alternative of a TOE. I have never seen as many interesting and deep problems in my over 40 year professional life as there are now. I even think that I am working on a very interesting one. Nobody is forcing you to do work on the lattice which you obviously consider not as a worthwhile alternative to string theory.

44. **The Great Inquisitor**
June 18, 2006

Dear Bert,

Thank you for your kind response. I think that you describe the temptations facing a researcher in contemporary theoretical physics very well. My take on understanding the roots of the crisis is as follows:

The time of the CREATION of grand physical theories is over, at least for a long time, after the revolutionary discoveries in the 20th century (qft, general relativity). Many young theoretical physicists enter the field in the belief that a theoretical physicist's obligation is to discover new theories. They, and also many of the older theorists, have not learned to accept that in order to be successful, one's success strategy must adapt to the situation in which one lives. Schroedinger, Einstein, Heisenberg, etc. are success stories of the past, and cannot serve as valid role models for a contemporary theoretical physicist's career any longer. A string theorist's dream is to relive this era once more.

Now is the time for the ANALYSIS of the grand physical theories discovered in the past century. None of these fields, be it quantum mechanics, quantum field theory, general relativity, solid state physics, etc, are mathematically satisfactorily understood. In fact, they are incredibly poorly understood from a mathematical viewpoint. Isn't it baffling that after 100 years of quantum mechanics, no one has the slightest idea how to explain the simplest chemical processes mathematically rigorously from first principles ? While the theoretical physicists are missing the boat to appreciate and learn the exciting new mathematical methods available today to reach a better comprehension of the existing theories, several areas of mathematics that analyze problems in theoretical physics are nowadays booming.

Many theoretical physicists base their life on the hope to discover the holy grail of it all, the link between qft and general relativity. This is certainly a noble goal, but is it a reasonable one to build one's career on ? It's at least as unreasonable for a theoretical physicist to judge his/her success on his/her progress on this problem as it would be for a mathematician in the case of the Riemann hypothesis. Common sense, good taste, maturity, and modesty would forbid such a foolish and naive career strategy. This would certainly be the common viewpoint, were it not for the emergence of the miraculous genius of Witten, which has ever since tempted intelligent researchers to abandon all good judgement, and to give in to the hope and illusion of a quick answer to a big question.

The desire for a theory of quantum gravity finds some cheap gratification in string theory; it is the link to the observed world which is a problem. I have to remark here that in all this discussion of quantum gravity, one believes that gravitational waves need to exists in quantized form, and that they are not an emergent, effective phenomenon in some macroscopic limit. The dogma of gravity wave = graviton field has, as far as I know, not been really criticized. Perhaps the de Broglie principle is being taken too literally, and ad absurdum ???

While the theoretical physicists are either in despair of the absence of the last grand theory, or lost in a grand illusion, neighboring research areas are taking over, and solving extremely interesting and important problems stemming from theoretical physics. For previous generations, the natural evolution of physical theories was that they were first discovered by physicists, and when they became more mature, the mathematicians took over to manifest their true structure in all profundity. Perhaps, nowadays, theoretical physicists should take a step back, reject the sensation of a cheap miracle, and do the hard work to better understand the inner structure of the existing theories which are still as amazing as ever.

45. **rof**
June 18, 2006

Great Inquisitor,

You may be right about what is necessary for progress, but it is not likely to happen. The least well understood part of fundamental physics is the foundations of quantum mechanics, and studying this is bad for your career. In fact, anybody who even mentions it is a crackpot.

The problem is that attempts to get a clear understanding of quantum mechanics compels one to consider philosophical questions, and physicists do not handle this situation well. They consider philosophy a waste of time, a pursuit for lesser minds, so they are overly dismissive of their opponents' philosophical positions. It's philosophy, metaphysics, a waste of time, not even worth taking the time to understand. So they have a communication barrier, and end up calling each other crackpots, so the field of the foundations of quantum mechanics is in some disarray.

46. **Eugene Stefanovich**
June 18, 2006

rof:

The least well understood part of fundamental physics is the foundations of quantum mechanics, and studying this is bad for your career. In fact, anybody who even mentions it is a crackpot.

And, I believe, anybody who mentions Einstein's relativity is a triple crackpot… So, here we go. The most fundamental problem of theoretical physics is the incompatibility of SR and QM, and we are not even allowed to think about SR and QM. When are we going to wake up?

47. **Bert Schroer**
June 18, 2006

G I,
these thoughts you expressed so clearly have been on my mind for more than a decade. But I am not quite as pessimistic as you seem to be with respect to the chance of experiencing the pleasure of great new discoveries and insights. I think that the way particle theoreticians have been trying to force this during the last decades is futile and counterproductive. Instead of being extremely caring about physical principles underlying our most successful particle physics theory and to be more imaginative about extending the range of their implementation, they do just the opposite. They are ultraconservative on the side of the implementing formalism and "revolutionary" about speculations which squander established principles and concepts in an uncontrolled way. How else could you understand the slavish adherence to a metaphoric quantization approach culminating in the formalism of functional integration which is known to be artistic and metaphoric i.e. lacks any intrinsicness? To discover something in an artistic way is quite normal and human, see the Bohr Sommerfeld old style QM. Fortunately in that case the better implementation of the evolving principles was discovered so rapidly that there was no time for a fossilation of formalism. A very good illustration of the point I am trying to get across is the discovery of the renormalization theory during the 1940ies. The principles underlying QFT were already in place, but a totally inadequate implementing formalism prevented people from extracting the correct physical results and this led to quite wild speculations which cast doubts on the principles which were already clearly formulated by the protagonists of QFT. It was only after a radical change in the implementing formalism which upheld the principles, that real progress was made.
Roughly speaking string theory is what you get if you maintain a functional setting at all costs and instead massage the principles and concepts so that they seem to describe reality within an obsolete formalism. If you have such an efficient formalism as that of Feynman, it is understandable and even reasonable to explore it beyond its range of validity, but you should never allow it to play the role of a holy cow.
To keep the revolutionary ideas away from the the principles on the side of innovative and extended implementations is difficult, in fact very very difficult. One needs a lot of time, patience, knowledge, modesty and hindsight. There are a few people who have chosen this path, most of the ones I know work in algebraic QFT (Local Quantum Physics) and I have been trying to be one of them. It is not a carrier-supportive path and if my carrier would not have been completed before I took this decision, I may not have done it.
My worry is not so much if the span of my left lifetime is sufficient to experience the joy of a genuine discovery, rather I am worried if the knowledge which is necessary to achieve that and to understand its conceptual implication will not be wiped out by the increasing addition to get hegemonic control over particle physics and the arrogant idea of making nature like a dog jump over a string. In the media you hear a lot about string theory and considerably less about LQG (which likes to position itself as the adversary in the final Armageddon over the hearts and minds of particle physics). There will be a forthcoming book by Lee Smolin but I would bet that there will be no mentioning of the ideas on that topic coming from AQFT. In fact up to now that liberal atmosphere at the Perimeter seems to have been tested by only one AQFTist and even that one (Hans Halvorson) is more involved in the study of philosophical aspects of AQFT than in the main topic at the perimeter.
The pictures emerging in AQFT about physical reality (e.g. the characterization of the full content of QFT in terms of the relative position of a finite number of copies of the "monade", which I mentioned on some occasion) are quite startling precisely because they emerge from a totally conservative setting. But the ability to recognize, evaluate and to execute (i.e. its material basis at universities) these subtle new concepts has been significantly diminished by that banalization coming with that metaphoric way of thinking supported by string theory.
Since you mentioned the role of Witten in this process, I would like to direct your attention to the interesting fact that there was a different Witten before he was directed away from the physical beauty (see e.g. his analysis of the Kosterlitz-Thouless phase transitions in terms of infrared quasiparticle clouds) towards mathematical beauty by Atiyah. Nothing against mathematical beauty, but one should pay attention to its originating from physical beauty. Even now his role in the Maldecena "revolution" his role was relatively restraint (I think this is a residue of the early Witten) in the way a conjecture was manufactured into a fact and (after thousands of papers, I supported the various stages of this manufacturing process in an ealier blog by citations from some of these papers) became the pivotal argument why the fate of string theory is (according to Gross) inexorably linked to that of the Standard Model. Since this is a watershed (something akin but reverse to the phlogiston-oxygen change of the theory of combustion) which visibly separated the new metaphoric approach from the good old science, it may be interesting to return to this crucial event and analyze it more carefully (and without any polemics).

48. **wolfgang**
June 18, 2006

Dear Prof. Schroer,

> I have never seen as many interesting and deep problems in my
> over 40 year professional life as there are now.
I agree, physics is as interesting as ever if not more than ever.

> Nobody is forcing you to do work on the lattice which you
> obviously consider not as a worthwhile alternative to string
> theory.
You must have misunderstood my comment.
Recently there is some progress by people who try to put supersymmetry and superstrings on the lattice (look at papers by Kawai, Catterall an others) and I find this very interesting.
And there is still a chance that lattice gravity without
supersymmetry could work. I mentioned one example on my blog
here.

49. **Bert Schroer**
June 18, 2006

Wolfgang,

in that case there was a misunderstanding on my part. So we both agree that the world of particle physics is full of interesting and important problems (even below the challenges coming from gravity) which is a far cry from the "no other game in town" hype of stringers.

50. **The Great Inquisitor**
June 18, 2006

Bert,

Thank you for your clear comments and arguments.

I do agree that for a particle theorist working on approaches to QG other than string theory, everything is fine as long as he/she is self-motivated, has a job, and doesn't mind that he/she is getting a lot less attention than string theorists (but this is true for a lot of fields in science, right ?).

Maybe there will be the next jump forward very soon in one of these alternative fields, who knows. I think that young theorists should not enter the field out of a desire to see the next revolution in their lifetime (essentially, this is already true for at least one entire generation).

I agree that the strings approach is conceptually too conservative, despite its mathematical sophistication, while other approaches are in need of more mathematical sophistication. I also agree that it would be worthwhile to push alternative theories of QG, but the proponents of those alternative approaches should pull their act together, and do something really impressive for their PR.

What the strings community has understood is that propaganda and group organization helps tremendously to get "credibility" and, more importantly, financial funding. They are a very strong political lobby in the physics community. Any proponents of a physical theory other than strings should keep in mind that in order to promote and protect themselves, they should work on building political significance, too. This is the 21st century, times have changed.

One of the questions that have bugged me for a long time is how one of the strongest movements in theoretical physics in the past could have lost so much of its influence. Why have the constructive field theorists not built a lobby as strong as that, or why did they give up their position in physics ? At the end of the 70s, they were as strong as any movement in physics ever, and despite the fact that the Wightman program might have been to rigid and narrow to begin with, there would have been myriads of alleys to build along in order to further manifest the importance of the field. However, today, this area has almost entirely vanished.

I blame it on poor political skills, and the naivety of many of its members that the importance of the field would support itself. Some constructivists have learned the language of neighboring fields, and have remained very successful. Although we are complaining about the populist practises of the strings community, we have to acknowledge that their methods are working. They are getting recognition in the public, money, etc. More purist minded physicists shy away from such practises for ethical reasons, but in the 21st century, it might very well be that every branch of science needs a lobby.

Finally, I'd like to say that many young theorists are drawn towards strings, not because of its physical beauty, but because of its mathematical sophistication. Here I'd like to comment that it is much more worthwhile in such a case to directly go into pure mathematics which is so much more beautiful than string theory can ever be.

51. **island**
June 18, 2006

Inquisiter wrote:

Actually, Lenny is wrongly admitting that the anthropic principle constitutes evidence for intelligent design if we don't accept the landscape:

Lenny also said:
'The "appearance" of design is undeniable…'

…'So if you don't accept my theory'… … … is blackmail.

It's true that this is crap, but that's only because cosmological evidence that we're not here by accident does not constitute proof for ID without direct proof, since the default position in this case is that this is part of a natural goal directed process that includes intrinsic finality.

ID theories that don't include a deity are potentially falsifiable… but IDists don't want to play that distantly plausible hand because the really do believe that godidit, regardless of what they may claim in public.

At least Lenny has guts enough to recognize that the anthropic principle constitutes evidence that we're not here by accident without a multiverse of potential to lose its significance in.. even if he is doing so strictly for selfish reasons. It is very bad for science that this is only a conditional admission which most refuse to even recognize does indeed exist.

52. **JC**
June 18, 2006

Arun,

For something like calculating Einstein gravity perturbatively to 3 loops, the only reasons I can think of offhand would be things like:

– the person is incredibly naive
– they're a glutton for punishment
– they have nothing else better to do with their time
– they've been under a rock for the last 40 years, and still think Einstein gravity is the "language of God"
– they've been under a rock for the last 30 years, and have never heard of supergravity or string theory

53. **Joe Conlon**
June 18, 2006

Dear anonymous,

I think the precision of the answer has to be proportionate to the precision of the question. I don't know exactly which scenario you're referring to, but the expression `our brane' sounds like ADD or Randall-Sundrum style scenarios. Direct stringy brane constructions of the Standard Model – e.g. by the Madrid group -need 3 or 4 stacks of different branes to get all the gauge group factors. If the original model is to some extent ill-defined and not fully embedded in string theory, it is not fair to hold string theory to account for failing to predict out all the O(1) factors.

This isn't a criticism of these kinds of models: they're interesting and fun. But I think the distinction between 0.5 and 1TeV here can be accounted for in the uncertainty of the model's definition.

Brane tensions are universal and are not affected by supersymmetry breaking. How they are perceived may depend on the local metric and so be red-shifted by e.g. warping.

Best wishes
Joe

54. **Arun**
June 18, 2006

JC,

The point was that one does not have to have a more promising alternative to point out that a particular line of inquiry is not fruitful.

55. **anonymous**
June 18, 2006

dear Joe, yes I refer to ADD. As far as I understand, the tension of a stack of n branes is n times bigger than the tension of a single brane only if supersymmetry is unbroken. Otherwise there is a non zero force between the branes, and the tension is affected by the resulting "binding energy".

56. **D R Lunsford**
June 19, 2006

Well, I know of at least ONE peer-reviewed and published paper, which exists also at CERN, that was removed from arxiv (my own). Any other examples?

-drl

57. **nc**
June 19, 2006

Another example: my paper on CERN, ext-2004-007, published in Electronics World, vol. 109, pp. 47–52 (2003), was removed from arxiv in a matter of seconds in 2002. (I don't mind about getting on arxiv – after all it is American-funded and I live in Europe, but CERN now prevents external papers from being updated except via automatic arxiv feed. I can't update it, because it now only accepts external papers automatically from arxiv. I can log in at the CERN server database, but that's all.)

58. **Peter Erwin**
June 20, 2006

I got curious about what were the different (stated) journal-submission rates for different areas of the arXiv, so here's a crude overview, mostly based on the May 2006 postings for each group.

The percentage is the fraction of postings during May (or, for some areas with low traffic, Jan through May) which have *no* mention of a journal (submitted to or accepted at) or of a conference where the work was presented at.

astro-ph: 15% (considering only the first 200 posts of May)
cond-mat: 72% (ditto)
gr-qc: 62%
hep-ex: 17%
hep-lat: 50%
hep-ph: 73%
hep-th: 84%
math-ph: 80%
nucl-ex: 27%
nucl-th: 63%
physics: 61%
quant-ph: 79%

Caveats: this is all based on what posters wrote in the "Comments" field, or on the "Journal-Ref" field if it exists. As Peter Shor pointed out, at least some people may not bother filling in journal info in the Comments field, or updating the Journal-Ref field, even if the paper *is* submitted or accepted at a journal.

Nonetheless, it's interesting to see the difference between the more experimental/observational areas (astro-ph, hep-ex, nucl-ex) and the theory areas like hep-th and quant-ph.

59. **Chris Oakley**
June 20, 2006

Peter E,

I suppose that this shows that HEP theorists are a bunch of hippies who don't care much for respectability. Or getting the number of spacetime dimensions right.

60. **Bert Schroer**
June 23, 2006

G I,
I could not react to your last weblog since I was offline for almost one week. After perfect agreement with your analysis and conclusions about the present situation in particle theory, there was one point of disagreement (which by the way also indicates to me that our agreements are not the result of belonging to the same area of mathematical physics as I, since most in that small community with profound knowledge about QFT would also disagree on that point) which I find worthwhile to return to:

"I blame it on poor political skills, and the naivety of many of its members that the importance of the field would support itself. Some constructivists have learned the language of neighboring fields, and have remained very successful. Although we are complaining about the populist practises of the strings community, we have to acknowledge that their methods are working. They are getting recognition in the public, money, etc. More purist minded physicists shy away from such practises for ethical reasons, but in the 21st century, it might very well be that every branch of science needs a lobby."
I claim that any area in theoretical particle physics which uses the similar methods of lobbying and hype as the stringers and succumb to the temptation of hegemony of a certain doctrin in a still volatile area of particle theory will inevitably eventually also suffer from the same sociological diseases as string theory. In fact I predict that if the loop gravity (LQG) people allow themselves to be drawn into the use of these public relation methods and attempts of hegemonic control (as it seems the case at the present conference in Peking), they will before short or long have seized to be part of the solution and become part of the same problem. Looking forward to a kind of Amargeddon with string theory, they will only end up deepening the metaphoric confusion in particle theory.
Exact sciences have the very distinguishing aspect of objectivity which sets them apart from any other human activity; this unfortunately creates some friction with the subjective activity of lobbying and appearing in front of an elected political committee to sell half-baked speculative ideas. Of course when large and expensive pieces of hardware and years of constructive planning are involved, as in experimental high energy physics, there is no other way. But if on the other hand one is facing a volatile theoretical situations as the one in post-standard model particle theory this, method is not compatible with securing a healthy future of particle physics, although it may be securing the material comfort and cementing the intellectual hegemony of a group.
In this context I also vehemently disagree with a point which was made recently by Sean Carrol:
"…people like string theory for intellectual reasons not for socio-psychological-political ones. It's not a vast string theory conspirancy, funded by shadowy billionaires who funnel money through Princeton and Santa Barbara to brainwhash naïve onlookers into believing the hype. It's trained experts who think that this is the best way to go….."
It is impossible to reconcile such a statement with what string theorists are actually doing. Take as an example the affair around the Maldacena conjecture as exemplified by the following citations from original papers:.
Witten's introduction of the Maldacena conjecture reads as follows:
"Recently it has been proposed by Maldacena that large N-limits of certain conformal field theories in d dimensions can be described in terms of supergravity and string theory on the product of d-+1 dimensional AdS space with a compact manifold."
(Note the "proposed")
After more than two thousand citations the Witten passage changed to
(citation from Berenstein, Maldacena and Nastase):
"The fact that large N gauge theories have a string desrcipition was believed for a long time. These strings live in more than 4 dimensions….".
The process of "fact-manufacturing" culminates in the last of the 3 online Princeton talks by David Gross (http://www.princeton.edu/WebMedia/lectures/) in which he answers a question coming from the audience (can string theory be proven wrong?) stating that string theory cannot be proven wrong because it is inoxably linked via Maldecena's discovery to the Standard Model.
What I find so incredible is that the audience in a place like Princeton (where Pauli and other critical minds spend many years) receives such statements with applause. No Sean Carrol (please check the citations if you do not believe me, I can provide you with the exact citations including the page number), these kind of mortal blows to an exact science whose hallmark used to be objectivity is not done as part of a conspirancy. David Gross is not the boss of a mafia scheme to derail particle physics. It is this selfdilusion which we are all prone to succumb to if we hear from all directions (as the result of the lobbying) how fundamental and important our ideas are (especially after their importance is so obvious from the material support they obtain and the hegemony they exert). But what is the difference for physics that there is no underlying willful misleading intention? And why did Sean ever think that smebody could believe that the influence of globalized capitalism consists in some billionaires exerting influence over the content of particle physics by giving money to universities in Princeton/Santa Barbara? The influence of globalized capitalism on the moral fabric of objective sciences goes via Enron and Worldcom and via Bush's manufacturing of facts in order to be able to start a war: it is the manufacturing of facts which very ironically bind together the string theory in the US, in Teheran or (beginning right now) in China.
I have many other documentable arguments for advancing my viewpoint, but if people like Sean Carrol want to see or define them as harmless for particle theory, then my means are exhausted. But then I do not understand at all what it is is he wants to dicuss in his weblog. Unsucessful attempts to get hegemonic control over particle physics always were tried (see the bootstrap S-matrix approach of Chew-Stapp and others) before, but they never reached that level of introctination and control as now.
One does not get the full impression about the destruction of knowledge unless one really gets into contact with young people who went through that mindless string PhD mill, where one learns how to write impressive looking thesis with almost no knowledge of particle physics at all. My estimate is that a sizable fraction of young people who did this became meanwhile frustrated Jeckill&Hyde characters, the new proletariat created by their exploiting string theorist peers. The rest of the stringers fall like locust into other areas in order to devour everything and convert a banalized copy of what they can digest into string theory. For the last couple of years they have been trying to do this with integrable QFTs.
In good times for theoretical physics, for example the times of Nernst, Planck, Einstein, Born, Heisenberg,…in Germany, there was no lobbying at all. Rather the excellent scientific quality at universities, research institutes and academies was achieved by the relentless work (largely outside the public domain) by state secretaries for science and culture of city and state governments, people with an impressive academic background and first hand knowledge who could officiate with a remarkable autonomy without depending on the result of political elections.
Sometimes, when that did not work in due time, as it happened at the new (1919) founded University of Hamburg which remained for almost two years without a chair in theoretical physics, scientist applied a harmless trick. In this particular case the mathematicians Hecke and Artin inbited Albert Einstein for a public talk on a weekend (with Einstein perhaps not knowing what was the real purpose behind this) and some month later the chair for theoretical physics became a reality (with Wilhelm Lenz having Pauli as his assistant and Ising as his OPhD student).
Although in the US such a system probably never existed, the second worldwar and the subsequent cold war created a situation where lobbying for survival in theoretical particle physics was not necessary and where the increase in once's personal power and influence did not lead to the choking of other interesting points of views. The appearance of a metaphorical approach which gains a hegemonic control is a recent sociological deformation. The idea that a hegemonic control about the material and intellectual resources can be compensated by one individual who not only has to manage to reconquer the lost knowledge, but also (like a particle physics messias) comes up with an innovative idea which will direct particle physics out of the present crisis is utterly naïve.

June 23, 2006

Bert,

Thank you for your reply. I very well understand how much you reject the idea of focused political organization among physicists to reinforce the impact of their research field. As we all know, this carries the danger of abuse, and anything that can be abused will be abused in due time (as string theory proves).

I did not mean to imply that the same sort of irresponsible, aggressive propaganda should be used. However, string theory has pushed many areas of theoretical physics to the edge of extinction. My question is: Should one react or not ? Should one just accept the way things are, and wait until the bubble busts when Witten steps down (until which yet another generation of non-string theorists will leave the field), or should one try to get organized in an ethically responsible way. String theory is a relatively harmless illustration of the situation where a suppressed minority is forced to ask if, how, and when resistance is a moral obligation.

I brought up the constructive field theorists because their area is probably one of those that suffered the most from the brain- and job drain induced by string theory.

When I talk about lobbying, what I meant was (perhaps using an inappropriate choice of language) thatevery research field has a responsibility to organize itself in a way that the proliferation of its tradition is ensured. Every older generation of a research field carries a responsibility towards its younger generation of getting sufficiently organized (politically and otherwise) to ensure a good chance of survival. My question was how it happened for the example of constructive field theory that the situation has deteriorated so much, after a very excellent time in the 70's.

Of course, I couldn't agree more with you that in fundamental science, lobbying practices should not have their place. However, I ask how one should react if a neighboring field becomes totalitarian, and begins to spread and metastasize like a cancer ?

Did anyone read any of the articles in the "New Republic" and the "Nation" authored by Witten before he became a physicist ? As everyone knows, he studied political science, and was an aide for the McGovern presidential race. What is for sure is that he knows what he is doing.

62. **Peter Woit**
June 23, 2006

I have read the Witten article in the New Republic and the Nation. One is about visiting a commune in Taos, the other is about the New Left's political strategy. Both were written when he was a teenager, and don't show any signs of interest in Machiavellian political tactics. They're both extremely earnest in a late sixties sort of way; Witten seemed to be a very young man trying to make sense for himself of what was going on at a period of dramatic change in the US.

I think it's a big mistake to lay all of the problems with how string theory has and is being pursued at Witten's door. He's responsible for a lot of what happened, but to a large extent he was just doing what every scientist should: work hard on the ideas you find most promising, and try and get others enthusiastic about them. The fact that he is so talented and has accomplished so much gave him a huge amount of influence, not any particular political skills on his part.

At the moment the problem with string theory seems to me to not be Witten, but to be those much less talented than him who have devoted most or all of their career to string theory, can't conceive of working on anything else, and are willing to fight to the death anyone who tries to get people to give up on string theory and work on other topics. Witten himself for the last year has not been doing string theory, but something quite different. If he continues to develop interesting ideas about gauge theory and mathematics, they may ultimately really lead somewhere important. At the moment I don't see him going around giving talks about how wonderful string theory is, or engaging in anthropic pseudo-science, or any number of the other problematic things much of the string theory community is doing. He's one of the few hopes for the subject, one of the few people capable of coming up with the kind of new idea the field needs to start making progress again. There are plenty of people around now whose behavior regarding this is highly problematic, I just don't think Witten right now is one of them.

63. **The Great Inquisitor**
June 23, 2006

Dear Peter,

In principle, I do agree with you; as is said in one of the superhero comics, "With great power comes great responsibility".

My question is what Witten has done to contain the damage his field is doing, of which he is undeniably too smart to be unaware of ?

64. **woit**
June 23, 2006

The GI,

I do agree with you that Witten can be validly criticized for not having taken any responsibility for doing something about what has happened to the field. In particular I think it would be very helpful if he were to take some action on the issue of the anthropic landscape, perhaps pointing out that people who believe string theory is compatible with anything should give up on the theory and do something else, not start selling pseudo-science.

65. **The Great Inquisitor**
June 23, 2006

Peter,

Yes. As the saying goes (approximately), "There are two lessons of history: History repeats itself, and humankind never learns from history."

Isn't it ironic that the physics community, which has traditionally prided itself so much of supreme scientific objectivity is having this problem nowadays ?

Perhaps, it would be worthwhile to analyze what precisely it is that this lesson is teaching, and what one should learn from it.

66. **Bert Schroer**
June 24, 2006

Peter,
This time I have to agree 100% with G I even though he seems to come from a different area and may have slightly different reasons for his conclusions. It is really not the good intentions, the richness of imagination and mathematical talent of a person which is under discussion here. According to those criteria Witten is way beyond Heisenberg, Dirac, Pauli, name anybody from the pioneering days of QM. Without any question Ed Witten has been the most inspiring figure for a whole generation of young mathematically inclined theoretical physicists and even if this great attraction to people of the same age already showed up in his fighting for political liberal courses, it is of no direct relevance where his magic attractive personality showed up for the first time. A big difference to the previously mentioned physicists is that none became the guru of a group. Especially Pauli was respected and feared at the same time. But at no talk of Pauli (or any other one of the pioneers) everybody before the talk started was whispering in the corridors "What will Pauli (Witten) tell us ?" (concluding remarks by Ooguri at http://strings04.lpthe.jussieu.fr/.)
It is this kind of idolation which brings in a new element into rational science namely some sportish expectations which long for immediate fulfillment if possible coupled with some entertainment value.
Peter, will you tell me that people nowadays are condemned to be gurus whether they want or not? If you want to tell me that even Pauli under such circumstances may have lost his critical objective abilities, you run into open doors with me, but of course the historical Pauli did not (you may say that he lived in a different Zeitgeist and I would add maybe one which was more conducive to particle theory).

Take as a total contrast to the life work of Rudolf Haag. He felt already in the early 60s, when particle physics was still under the spell of the (most conservative) renormalization revolution that this will not be enough to really understand the inner working of the principles underlying QFT and that an additional step away from classical metaphorics towards a more autonomous understanding (similar to the liberation of geometry from coordinatizations) had to be undertaken before one can trust that the renormalizable/nonrenormalizable dichotomy has anything to do with the true conceptual frontiers carved out by the underlying principles. I learned in due time to appreciate that Haag's contribution was one of the best investments into the future of particle physics. This was not always so, because after a short collaboration with Haag at the beginning of the 60s (In the after sputnik time I had a research associate position in Champaign-Urbana without yet having a PhD) I left that area because progress was too slow for my taste at that time. I entered the critical phenomena (Callen-Symanzik setting) and later I found a generic relation between winding gauge configurations and zero spinor modes in the Schwinger model which sucked me more and more into the mathematically quite sophisticated Atiyah-Singer theory. I wholly embraced the subsequent reign of Euclidean topology and differential geometry i.e. the Witten-Atiyah Atiyah Zeitgeist. But when at a stay at CERN in the 80s I saw all these wide-eyed youngsters who dropped the word "topological"in almost every sentence I woke up again and the increasing trend of metaphorical arguments in particle physics finally brought me back to the algebraic approach which meanwhile had acquired an impressive amount of conceptual maturity. I am mentioning this here because very often in this weblog one reads complaints about the lack of alternatives to string theory (or LQG if one focuses on gravity only). If I would never have met my teachers Haag and Lehmann, I probably would also be among those apologists of string theory.

There is no particle physics setting these days which leads to results which are so markedly different from those coming from string theory or other mainstream ideas concerning issues of vacuum polarization (cosmological constant, black hole entropy) as those coming from LQP (local quantum physics). On the hep-th Tuesday listing you can convince yourself by looking at two updates which in this form I submitted to Class. Quant. Grav.
Coming back to the issue raised by G I's last blog contribution I would completely agree that somebody who has created a community has a critical responsibility. To say that an important leading figure abstained from stringy physics (like Berlusconi abstained from sex before the election) is not enough.

67. **Peter Woit**
June 24, 2006

Bert and TGI,

I agree with you that Witten has a lot of responsibility for the current situation. But it's also true that one could make a very long list of Nobel prize winners and other people with positions of great responsibility in particle theory who have chosen not to say anything about the problems caused by the way string theory research has been pursued. I've always found it kind of ridiculous that I should be the one prominently making the case that this is a problem, when there are many, many people who are much more than me in a position where they should be taking some responsibility for this.

68. **The Great Inquisitor**
June 25, 2006

Peter,

I believe that a problem with Nobel prize winners speaking up is that in the last few decades, very few theoretical physicists with a strong mathematical background have won it. Those who did usually obtained it late in life, and might not consider themselves competent to judge over string theory. Some particle physics nobelists did speak up, like Richter or Glashow, but it is easy for string theorists to dismiss them as mathematically uninformed.

Only when someone is very familiar with the mathematics of some aspects of string theory, it is possible to tell with certainty that something dishonest is going on. Mathematically less educated observers might either give string theory the benefit of doubt, or not feel threatened at all because their jobs are not at stake. So those people naturally in the position to speak up are mathematical physicists who work with the standards of rigor of pure mathematics.

If one looks for people in this area in a position to openly attack string theory, one ends up with a very small list. It is not without reason that these people are fought by the strings community; they are the only ones who can see that the emperor has no clothes, and who are therefore dangerous for them. Those people have observed what happened to colleagues in their circle who dared to openly express their thoughts (take Jaffe-Quinn for an example), and have decided that a silent status quo is better for their survival than an open conflict. And there is little reason to doubt their conclusion as long as Witten and a few other strings people are indeed producing supremely important results for *mathematics* (not for physics; I dare to claim that among large amounts of magnificent results for mathematics, string theory has not produced one single true result for physics).

I would like to make the following tentative conclusion what the issue with string theory really is about.

The best present argument in favor of tolerating string theory (and the fact that a lot of half-wits are among the practitioners) is to consider it as a testing ground for new mathematical ideas. This would justify the inclusion of ridiculous physical ideas (of the type presently made tasty for the uninformed public) into the discussion because they might in the end have interesting mathematical structure. String theory becomes ethical at the moment where it declares officially that, despite its beginnings, there is nowadays no link to particle physics anymore; only some of its methods are remnants of particle physics.

The true value of string theory is that of a mathematical experimental playground where methods of theoretical physics and geometry/topology are freely combined, to produce insights into topology, number theory, etc. This alone does justify its existence, but string theorists are extremely afraid of admitting that their field is not physics because they will lose a lot of funding and job positions in this process. However, I am sure that even then, there will always be excellent jobs for the best of them (but less jobs for the weaker ones; a statement which is true and natural for the rest of the physics and mathematics world). They would then still carry the job label "string theorist", but would work in a "department of experimental mathematics" that needs to be newly founded.

They would have the same working relation with number theorists and topologists as experimental physicists have with theorists; they generate interesting observations, but have to leave it to the community of higher mathematical rigor to produce theorems (actually, this is already the real situation nowadays). Those areas in mathematics will never give up their support of string theory because they are profiting from an extremely fruitful symbiosis (see the responses to Jaffe-Quinn from eminent topologists and geometers). They are experiencing a similar explosion of theoretical advancement as Heisenberg, Schroedinger, Pauli, Einstein, Dirac, Gell-Mann, Feynman, etc did during the physics revolution of the last century, thanks to the amazing observations of their experimental contemporaries.

The real problem with string theory is that as long as they do not officially give up their claim of a link to physics, they are stealing a lot of jobs from true physicists; in fact, they have such an overflow of positions that they end up filling them with people of very objectionable quality. To be able to further afford this unethical luxury, especially the weaker string theorists invest large amounts of efforts to try to convince the uniformed average taxpayer that what they are doing is in fact physics (they are not capable of higher mathematics, so they focus on phenomenology, but phenomenology necessitates a link between strings and physics).

So the Gretchen-Frage here is: Is it physics or not ? This is what the whole fight is about, because it determines the distribution of resources.

Therefore, I believe the right strategy the physics community should use is to reach an agreement with the mathematics community to newly create interdisciplinary departments of experimental mathematics, which accommodate string theory. This would solve the conflict for everyone. In fact, the string theorists then won't have to worry about the painful lack of physics anymore, and can be totally free in their model building. And even though they haven't proven themselves worthy as a subfield of theoretical physics so far, they have massive credentials as a field of experimental mathematics. While they are doing physics a disservice, they are doing certain areas in mathematics a monumental service; they should move in with their mates.

69. **Bert Schroer**
June 26, 2006

G I,
Your proposal to convert string theorists into experimental mathematicians and to create a group of experimental mathematics within a mathemaics department would indeed be a first step to get particle theory back on track, but unfortunately it is not realizable. There are too many string theorists whose professional knowledge of mathematics is completely insufficient; no mathematics department would want them. The few excellent individuals who have a profound knowledge of modern mathematics at their fingertips would of course be highly welcome (and I am certain that their impatience if it comes to prove theorems would be no obstacle especially if the word "experimental" is added), apart from the fact that mathematicians will loose their illusion about the magic power of physics by learning that all their golden castles which have been inspired by string theory were in fact constructed on the ruins of particle physics.
Actually there are already such groups in mathematics with the effect that they are entering joint research projects together with the stringers outside, and given the pro-string opinion in many decision-making comitees and with referees of research projects, this renders the situation of genuine mathematical particle physics even more precarious.
The situation in this weblog develops into a very interesting direction; unfortunately I can only occasionally contribute. But since the problems you raised will be with us for a long time (even if string theory will be recognized by leading theoreticians as a failed theory, there will be the long-time problem of damage repair) this may not be a

bad thing.
Among the topics which I very much would like to publically discuss with you in future weblogs are
1) Did the metaphoric kind of thinking which is the hallmark of string theory start already before, and if yes, where and when did it start? This is a problem on which I expect considerable differences in opinion with Peter, but on the other hand I am convinced that his prime motive is to stop the damage of string theory and not to plead e.g. for the resurrection of gauge theory a la Atiyah-Witten or to continue with the standard model within the limitations of the present Lagrangian framework.
2) How widespread is the system of “colonial exploitation” by more senior string theorists who distribute serialized little pieces of computations to their young innocent and unsuspecting PhD students without providing an overall view of particle physics, and how many cases are there where students who insisted to apply their greater conceptual and mathematical knowledge were actually removed resp. their support was cut so that they did not disturb the smooth computational grinding of the others? I know personally about two cases.
3) How big is really the damage with which have to cope even after the failure of string theory will be eventually recognized by a majority (many positions taken by individuals who know particle physics only via metaphoric glasses and social constructs and whose social success has deprived them of any intellectual modesty which is a prerequisite for a re-orientation).
4) How can one prevent the metaphoric mode of arguing entering other problems of particle physics (string-like arguments without string theory)
5) How can one stop the erosion of already acquired good solid knowledge of particle physics, and in particular how can one prevent that those few young researchers (who had the courage to resist the work on merchandize with a fast spoilage date) from having non career chances as compared to any candidate who hides successfully behind big Latin Letters?
Such discussions need time and should not be rushed through. T G I, I propose to you that you scan occasionally this weblog for contributions from me or other more serious contributers to this subject, as I will do the same. As long there is no special place for such exchanges of opinions about more long range aspects concerning the crisis of particle physics, this place could serve this purpose.

70. **The Great Inquisitor**
June 26, 2006

Bert,

Thank you for your kind reply. I would very much like to continue this discussion in this forum.

As to your question concening the damage string theory causes to physics when it goes down the drain:

I think that it is fair to say that the weakest element in string theory is string phenomenology, where a bridge is sought between string theory and physics. This is the area that will ultimately bring everything down. People will get impatient with the loud, naive, irresponsible, and low-quality physical predictions made by the mathematically weakest string theorists. When they fall, they will endanger both the existence of string theory, and the reputation of theoretical physics (which they have already damaged enough). String theorists will then have to make up their mind if they want to fall together with them, or disassociate from them, and consequently, from physics. In the long term, a future in an experimental mathematics department of the mathematically most able string theorists might be their only strategy of survival.

String phenomenology has a very poor scientific track record and life prognosis; it’s the sickest part of the area. When string phenomenology goes down, traditional physicists must recognize the opportunity of the moment, and wake up from their decades-long silence. That would be the moment to toss aside their self-restraint out of intimidation, and openly disassociate from string theory. If they remain lethargic, they might go down together with them, because the public eye is not capable of distinguishing string phenomenology from serious theoretical physics.

What happens afterwards ? We should perhaps learn from the fate of the former communist countries. There will be chaos for some time, small fragments of groups will attack one another, despite of their equal insignificance, and eliminate one another. Then, when the dust settles, the seeds that have survived the storm will grow fast in fertile grounds. More often than not, new golden eras have grown on the ruins of their preceding culture after those have completely disintegrated. Cultures, economies, research fields, obey the same lifecycles as organisms. They are born, grow to maturity, florish, then become either decadent or old and tired, and disappear (maybe Oswald Spengler’s “Der Untergang des Abendlandes” might be inspirational for this discussion).

We have to ask whether string theory emerged from theoretical physics completely coincidentally, or whether theoretical physics was already in a state of demise and decadence, and string theory was the logical fate that was waiting for it.

The danger and blessing of theoretical physics and mathematics is that they provide spiritual food for atheists and agnostics. It has been reported that Jane Goodall, who had been studying chimpanzee cultures for decades in Africa once observed a group of apes discovering a waterfall for the first time in their lives. The reaction of these primates was a self-forgotten dance, a celebration of exhilaration and awe, it was a spiritual experience for them. The insight derived from there was that higher primates have an instinct for spirituality, it is not a rational decision that compels people towards their spirituality. People need a sense of awe and wonder in this world. Organized religions serve that purpose for the masses. However, for the most mathematical and logical minded persons, only mathematics and theoretical physics are elaborate enough to calm their need for spirituality.

When string theory emerged, it gave theoretical physicsists who were in the 80’s starving for that sense of awe and wonder after a decade of no real new fundamental insights in their field. Many theoretical physicists were at that time unaware of geometry and topology, and when they were first brought into contact with those mature mathematical areas, for instance through the work of Witten, they lost themselves in the intoxicating beauty of it.

As I stated in my first contribution to this weblog: As Dostoevsky describes in his piece “The Grand Inquisitor” in the “Brothers Karamasov”, there are very few human needs besides that for food which absolutely cannot go unsatisfied. The need for spiritual wonder is one of them. The pursuit for satisfaction of this need has brought humankind art, science, and all the nearly divine accomplishments that our race can claim its own; on the other hand, the satisfaction of the same need has also led to the deepest morass of tyranny, fanaticism, genocide, and totalitarian hell humankind has experienced.

71. **The Great Inquisitor**
June 26, 2006

Just as a remark, here is a link to excerpts of Oswald Spengler’s work (here translated as “The decline of the West”). Bearing in mind that it was first published in 1918, it is baffling how well some parts match what we are watching every day.

http://www.duke.edu/~aparks/Spengler.html

And if for some readers here, it might turn out of interest, here is the segment of Dostoevsky’s “Brothers Karamasov” I was alluding to

http://perso.orange.fr/chabrieres/texts/grand_inquisitor.html

72. **Bert Schroer**
June 26, 2006

G I,
by the way I have mentioned the impact of Oswald Spengler’s work in particular on the development of QM in my polemic article http://br.arxiv.org/abs/physics/0603112
I think you find a quite realistic description of the actual postmodern Zeitgeist in the work of Theodor Adorno:

http://en.wikipedia.org/wiki/Theodor_Adorno
He is the one who had to understand how rationality can breed in its midst the most extreme form of irrationality. In his case the motivation was to understand Auschwitz, that is really the hardest problem; all other genocides and ethnic cleansing are not that hard.
There are many elements in his thoughts which can be applied to science as well.

73. **Alejandro Rivero**
June 26, 2006

Hmm a friend tried to read Adorno to me while sailing between Valencia and Salerno, and even in this quiet situation I was unable to grasp it 🙁 On the contrary I find easy to follow, for instance, things as touchy as the view about Time of Agustin Garcia-Calvo, so perhaps it is really -literally- a language problem and one needs to read Adorno in German.

74. **Aaron Bergman**
June 26, 2006

in fact, [string theorists] have such an overflow of positions

Hah.

75. **Bert Schroer**
June 26, 2006

Alejandro Rivero,
you are right and this is the reason why Adorno is less known in the English speaking philosophical and sociological world. The German language has this extraordinary possibility to synthesize new words by juxtaposing already existing ones. This makes reading difficult but at the same time one is able to highlight nuances and concepts which transcends existing ones. For example this conceptual flexibility was very helpful for Einstein in presenting the special theory of relativity with that masterful clarity. The issues treated by Adorno are extremely subtle and complex.

76. **Eugene Stefanovich**
June 26, 2006

Bert Schroer:

1) Did the metaphoric kind of thinking which is the hallmark of string theory start already before, and if yes, where and when did it start?

The Great Inquisitor:

We have to ask whether string theory emerged from theoretical physics completely coincidentally, or whether theoretical physics was already in a state of demise and decadence, and string theory was the logical fate that was waiting for it.

These are exactly the questions which I would like to see asked and answered. Shall we learn something important from the rise and fall of string theory (besides the trivial fact that some individuals sometimes make unscrupulous claims)?
Shall we reconsider the entire culture of theoretical physics? What is the role of experimental verification and mathematical proof in a physical theory?

If we forego this chance now, we are destined to repeat the same mistakes with some other “theory of everything”.

77. **The Great Inquisitor**
June 26, 2006

Bert,

Thank you for the weblinks. I have read your article with interest, and if time permits, will try to become more informed about Adorno’s work.

Eugene,

I think these are really key questions, and what you are asking is also central to it all.

Maybe we should not forget the roots of the tradition of Western Science. Science has been the vehicle that pulled western civilization out of the hell of mindless superstition enforced by the Church some centuries ago. Objective experimental verifiablility and mathematical provability, identified as the most appropriate and solid cornerstones of science, have made it possible to leave behind the terrors of that time. Today’s technology-centered western civilization owes its stature to those inquisitive and irrepressible minds back then who defended scientific methodology against Christian oppression.

Theoretical physics has been one of the absolute crowning achievements of this long struggle. But look at what string theory is making of it.

A small remark: My first contact with this forum was only a couple of weeks ago, and I have also not been more familiar with the competing one by Motl. I know that Peter does not want any more comments on this, but if he allows, just one observation: I read that he has been an Assistant Professor at Harvard since 2004. Did anyone observe that since then, he has only produced an extremely meager scientific output (a few short, multiauthored papers), way below the average for his field ? Being in prediction mode today, my prognosis is that he will be history very soon; he is burned out, has become psychotic due to the pressure to perform mathematically beyond his capacities, and is wasting very large amounts of time on his blog, on which he has become addicted.

Richter Talk at SUSY06

June 17, 2006
Categories: Uncategorized

Burton Richter's talk at the panel on "Naturalness" at SUSY06 is now on-line. Richter blasted his three theoretical colleagues on the panel (two of whom are his colleagues at Stanford) in forceful terms as no longer doing science:

… I think some of what passes for the most advanced theory these days is not really science.

I see no problem if part of the theory community goes off into a kind of metaphysical wonderland, but I worry that they may be leading too many of the young theorists along into the same wonderland. Simply put, it looks to me as if much of what passes as the most advanced theory these days is more theological speculation that it is the development of practical knowledge.

… the distinction between theory as theological speculation and as the development of practical knowledge. Theological speculation is the development of models with no testable consequences.

The price of this invention is 124 new constants which I always thought to be to high a price to pay.

Naturalness may be a reasonable starting point to solve a problem, but it doesn't work all the time and one should not force excessive complications in its name.

*The Anthropic Principle is an **observation**, not an **explanation**…. I have a very hard time accepting the fact that some of our distinguished theorists do not understand the difference between observation and explanation, but it seems to be so.*

… what we have is a large number of very good people trying to make something more than philosophy out of string theory. Some, perhaps most, of the the attempts do not contribute even if they are formally correct.

It is not that the landscape model is necessarily wrong, but rather if a huge number of universes with different properties are possible and are also probable, the landscape can make no real contribution other than a philosophic one. That is Meta-physics, not physics.

After all, the Hebrews after the escape from Egypt wandered in the desert for 40 years before finding the Promised Land. It is only a bit more than 30 since the solidification of the Standard Model.

Update: Clifford Johnson was there, and has a report on the session. He describes Richter's talk as "It was basically a loud fart in a quiet cathedral, during evensong. Excellent."

Comments

1. **Christine Dantas**
   June 17, 2006

   Sorry if I quote too much, but here it goes:

   > "(…) But in this quantum-gravity research area, since there was no experimental guidance, it was inevitable for theorists to be tempted into trying to identify the correct theoretical framework relying exclusively on some criteria of conceptual compellingness. Of course, tempting as it may seem, this strategy would not be acceptable for a scientific endeavor. Even the most compelling and conceptually satisfying theory could not be adopted without experimental confirmation."
   >
   > "(…) And often in the media the different approaches are compared on the basis of the "support" they have in the community: one says "the most popular approach to the quantum gravity problem" rather than "the approach that has had better success reproducing experimental results". So, it would seem, the Quantum Gravity problem is to be solved by an election, by a beauty contest, by a leap of faith."
   >
   > "(…) Quantum gravity phenomenology requires of course a combination of theory and experiments. (…) One here is guided by the expectation that quantum-gravity research should proceed just in the old-fashioned way of scientific work: through small incremental steps starting from what we know and combining mathematical-physics studies with experimental studies to reach deeper and deeper layers of understanding of the problem at hand (in this case the short-distance structure of spacetime and the laws that govern it)."

   Amelino-Camelia
   Introduction to Quantum Gravity Phenomenology

   Thanks,
   Christine

2. **John Stanton**
   June 17, 2006

   There is a good argument against the Anthropic "principle":
   Apes or pigs could equally state that the universe is made for them.
   One could equally speak about the Simian or the Porcine principle.

   I read this somehwere on the internet. Always liked it.

3. **Not a Nobel Laureate**
   June 17, 2006

   And I'm relieved to see a great physicist like Richter pointing out in forceful terms that what the pseudo-theorists are doing today is theological meta-physics not physics.

   Although "pata-physics" may be a more appropriate description of their activities.

4. **Tony Smith**
   June 18, 2006

Back in January 2000 (version 2 of hep-ex/0001012) Burton Richter said:
"… To the experimenters I would say that supersymmetry is a pure "social construct"
with no supporting evidence despite many years of effort. It is okay to continue looking
for supersymmetry as long as it doesn't seriously interfere with real work (top, Higgs, neutrinos, etc.). …".

It seems to me to good advice today, particularly to those lobbying for building the ILC.

Back then, 6 years ago, Richter was more or less agnostic about string theory, saying "… String/brane theory … represents an attempt to bring together gravity and quantum mechanics, a problem worth serious effort. … these are early days … String/brane theory may even give the necessary constraints that supersymmetry needs to reduce the number of constants to a believable level. It is still too early to say, but it may be much more than metaphysics. …".

Sadly (for string theorists) but realistically (for the rest of us), the results (or lack thereof) during the past 6 years lead Richter to say (as quoted by Peter) as of now:
"… what we have is a large number of very good people trying to make something more than philosophy out of string theory. Some, perhaps most, of … the attempts do not contribute even if they are formally correct. … it looks to me as if much of what passes as the most advanced theory these days is more theological speculation that it is the development of practical knowledge. … Theological speculation is the development of models with no testable consequences. …".

A problem with contemporary high-energy theoretical physics is that the mainstream, dominated by superstring theory plus a bit of Loop Quantum Gravity, is unwilling to make any significant effort to understand and evaluate alternative approaches leading to the deveolpment of models that do have testable consequences.

Tony Smith

5. **Sailorstar**
June 18, 2006

As a young theorist, it benefits me if as many potential competitors spend their lives on string theory as possible. Meanwhile, I will follow theories that produce testable results. Go ahead, make my day.

6. **MathPhys**
June 18, 2006

Peter,
Could you please link to Motl's blog where he says that B Richter is an average squirrel and all that? It must be there somewhere but I can't find it.

7. **string advocate**
June 18, 2006

dear Peter,

the fact that string theory happens to be "vacuous" enough to be a candidate theory for an anthropic interpretation of the smallness of the cosmological constant and of other old anthropic coincidences is not something that string theorists wanted. Rather, string theory was over-sold as the uniquely predictive theory of The Elegant Universe, and various string theorists, including Lubos, are still trying to defend this old propaganda. Discovering theories better than theorists is not unusual: Einstein tried to prevent the expansion of the universe and Dirac tried to make the positron 2000 times more massive than the electron, etc.

Probably we will never be able of testing the landscape, but it is the most plausible scenario (or, if you prefer, theology) we have today. String theorists willing to explore this direction hopefully understand that doing meta-physics with hype is much more dangerous than doing physics with hype.

8. **Chris Oakley**
June 18, 2006

> Peter,
> Could you please link to Motl's blog where he says that B Richter is an average squirrel and all that? It must be there somewhere but I can't find it.

Squirrels are very smart. They can do complicated multi-factor dynamical calculations using local approximations to Newtonian gravity with air resistance taken into account far better than any String Theorist. They also have a strategy for coping with tough times that does not involve wishful thinking or deception.

9. **MathPhys**
June 18, 2006

Very clever, Chris 🙂

10. **nontrad**
June 18, 2006

Peter,

Thanks for bringing this to attention!

It is a welcome relief to hear someone of Richter's stature make such sober comments. If only there were more of the same from similar High Energy figures.

Alas, the combination of a lack of data, lack of funding for extracting that data, power in the wrong hands, the glory of the Einstein effect (successful theories such as SR / GR crafted by an individual in isolation) and the addictive nature of pursuing beauty for beauty sake (unchecked by reality's unforgivingly counter intuitive nature QM / SR / GR / Chaos)… is too powerful a temptress. So, instead, until the day when there is finally some data, we will continue to hear of the wild pie in the sky speculations in HEP.

I suppose the consolation for the interim are voices such as yours, Richters or Laughlin's. We can only hope that these voices grow in number and finally impact the check writers.

11. **Doug**
June 18, 2006

If what passes for advanced theory today is not really science, but theological speculation, then, given the huge amount of government money spent on supporting it, the ACLU should be expected to step in soon on grounds that such expenditures are a violation of the doctrine of separation of church and state.

If they don't, and the high priests of string theory get more and more state sanction, the likes of string theory priests such as LM may eventually be able to enforce their views by purging heretics through a program of inquisition, funded by the "holy see [it our way or no way].

12. **knotted**
June 18, 2006

'If they don't, and the high priests of string theory get more and more state sanction, the likes of string theory priests such as LM may eventually be able to enforce their views by purging heretics through a program of inquisition, funded by …'

Doug, you need the past tense throughout that sentence.

The mainstream has been using state money to fund LM for the inquisition for ages, also the purging of heresy off arxiv has been done by Jacques Distler. The mainstream has the power and uses it to censor out all criticism and to label all alternatives crackpot. It is all over. Physics was conquered by complete lies (deceiving hype) funded by the taxpayer and the media. If I lied that I had extra dimensional-based unification and quantum gravity, without actually having a shred of evidence, I'd be ashamed of myself.

13. **Walt**
June 18, 2006

Sailorstar: Funny.

Knotted: Note that HEP is not all, or even most, of physics.

14. **Chris W.**
June 18, 2006

String Advocate says: *Probably we will never be able of testing the landscape, but it is the most plausible scenario (or, if you prefer, theology) we have today.*

It is only as plausible as string (and M-) theory. Insofar as string theory deserves to be judged by its consequences, including those that undermine its very testability, it's high time to start regarding string theory *as it stands* as implausible—not because of its lack of experimental confirmation, but because of the emptiness of *any* putative experimental confirmation in the context of the Landscape and its anthropic interpretation.

The question that ought to be asked now is why the original physical idea—a shift from a dynamics of point particles interacting in spacetime to a dynamics of one-dimensional objects with certain properties in spacetime—should have produced any interesting results at all, even if only in the nature of a rough correspondence. What does this mean? If quantum field theory and spacetime itself have a substructure, as GR + QM lead us to suppose, what sort of substructure might lead to string dynamics as a sort of residual trace? M-theory is supposed to be the answer to that question, but it is much more obscure than string theory itself. When deep physical questions are at issue we ought to be willing to step back from the formalism and ask simple, penetrating questions. Most string theorists, and for that matter, particle physicists, seem to have little interest in this kind of thinking. (Gerard 't Hooft is a notable exception.)

——————————
PS: Putting the Landscape on a par with the positron and the Hubble expansion is laughable.

15. **anonymous**
June 19, 2006

dear Chris W

I disagree with you. Anthropic arguments have not been invented by string theorists. Anthropic arguments survived for many years at the borders of science because they offer plausible interpretations of various observations: why there are many nuclei, why the cosmological constant is small, and now why string theory never gave predictions. For the first time all this makes a coherent scenario.

The only little difference with respect to Einstein and Dirac is that we miss experimental confirmations and ideas on how to get them. If you want to see something laughable, the probability distributions in the talk by Linde are a better candidate.

16. **ObsessiveMathsFreak**
June 19, 2006

Anthropic arguments are essentially an isomorphism to more basic "God of The Gaps" arguments. They run thusly:

> We cannot (currently) explain $phenomenon, therefore $deity is responsible for $phenomenon.

As far as I can see, anthropic arguments explain nothing, and do little except say "This is as it is because it is." Universal constants are "fined-tuned", but this in itself is evidence of nothing, except that the constants are as they are.

For all we know, any number of supposedly "sterile" combinations could have produced a universe with life. Just not as we know it. It's safe to say that universes are chaotic systems and that small perturbations in the initial conditions can have big effects on the final solution.

17. **Not a Nobel Laureate**
June 19, 2006

Life imitating Humour.

String theory and the Antropomorphic "Prinicple" can be summed up by that famour cartoon.

http://www.drabruzzi.com/images/Then%20a%20Miracle%20Occurs.jpg

18. **Tommaso Dorigo**
June 20, 2006

I think Burton Richter either knows Galileo Galilei's sentence (written in golden letters on the stairs of my Physics Department, which bears his name),

"Io stimo piu' il trovar un vero, benche' di cosa liggiera, che il disputare lungamente delle massime questioni, senza conseguir verita' nissuna",

("I have higher regard of finding a truth, although on something silly, than to discuss endlessly about the most important questions, without achieving any truth") or would easily subscribe to it.

Any reference to the meeting in Beijing is voluntary…

Cheers,
T.

Strings 2006

June 18, 2006
Categories: Strings 2XXX

Strings 2006 is about to get underway in Beijing, at a hotel next to Tiananmen Square, with public talks by David Gross, Andy Strominger and Stephen Hawking. Jonathan Shock reports that an agreement was formally signed today creating the KITPC, a Chinese version of the KITP, to be funded by philanthropist Fred Kavli and sited in Beijing.

The conference will attract about 400 physicists from around the world, as well as international press from many major European and American publications. There will be a press conference held Wednesday afternoon. Monday afternoon Witten will be giving the first scientific talk of the conference, on “Gauge Theory and Geometric Langlands Program”. He has given talks at almost all the Strings conferences since the first in 1995, but this will be the first one at which he won’t be talking about string theory. He will be followed by Cumrun Vafa, who will talk about his Swampland studies. On Tuesday evening, the schedule says “Prof. Yau present his new research result”, which presumably will be about the proof of the Poincare conjecture.

Monday evening will feature a panel discussion, which could get exciting. Last year’s panel discussion in Toronto featured Jacques Distler walking out in a huff, pointed questions from the floor about whether research in string theory was still defensible, and a clash between the panel, which was rather in favor of the anthropic landscape, and the rest of the conference attendees, who were very much against. Perhaps the Strings 2006 organizers, unlike the SUSY06 ones, will be able to find a prominent theorist who is not in favor of the anthropic landscape to put on the panel. An obvious candidate who will be there is David Gross, who at Strings 2003 gave a rousing Churchillian speech urging string theorists to not give up on science, and around that time suggested that his colleague Joe Polchinski had contracted a disease and should consider giving up his professorship (Polchinski in return accused Gross and Witten of being members of a cult). Gross hasn’t been publicly heard from on this topic recently, perhaps he has moderated his opinions and/or gone over to the other side.

Update: This posting has been edited, and many comments related to despicable behavior of a certain Harvard faculty member have been removed. I’m looking forward to hearing reports of what is going on at Strings 2006 from anyone attending.

Update: It turns out that Kavli is founding two new institutes in China, one for theoretical physics, one for astronomy and astrophysics. There’s more about this here. The Chinese press has also started to report on the conference, as usual media attention focuses on Stephen Hawking and the origin of the universe.

Update: Victor Rivelles is blogging from the conference, where he reports that 3000 people gathered in the Great Hall normally used for communist party meetings to hear promotional talks about strings. He also reports that the panel discussion was uneventful, with no mention of the landscape:

In the evening we had the panel discussion with 13 people. Strominger was chairing it. No real debate. Too mild. Some interesting questions but none of them provocative enough. No discussion on the landscape either. Toronto was much better…

Update: There’s an article in Tuesday’s New York Times about Hawking and the Beijing conference by Dennis Overbye. According to Overbye there are 800 physicists there and 6000 people turned out to hear Hawking. Anyone know if this is right?

Update: There’s a detailed report on the first day of the conference from Jonathan Shock.

Update: Victor Rivelles reports on day 2 of the conference. He describes Yau as taking credit for proving the Poincare Conjecture, which, if true, would be seriously misleading. ChinaDaily describes the number of physicists at the conference as 600. I’m guessing that 400 is the number of participants from outside China, 6-800 the total number. If so, this would be the largest string theory conference ever held.

Update: Day 3 report from Victor Rivelles, who seems to be have the mistaken impression that there are two Brian Greenes…

Update: Day 4 report from Victor Rivelles, who clears up the two Brian Greenes confusion. Brian couldn’t make it to Beijing, so his talk was given by Koenraad Schalm. Also a report from Jonathan Shock.

Update: More reports from Jonathan Shock (aided by Paul Cook), and Victor Rivelles. The publicly announced plan until now has been to have Strings 2007 in Madrid, Strings 2008 at CERN, and Strings 2009 in Rome. Rivelles reports a rumor that the CERN conference will be delayed until 2009, Rome then in 2010. Summer 2009 is when LHC results may start to appear, so he comments:

… if supersymmetry is found in 2008 then we all will be together to celebrate it and if it is not found we will be together for a collective suicidal.

Update: There’s a wrap-up of the conference from Jonathan Shock, including a description of Dijkgraaf’s summary talk. I have no idea if it is accurate, but it makes Dijkgraaf sound highly unrealistic

…LHC, astroparticle physics and the next generation of microwave observers may give us real signs of string theory in the coming years…

…a golden age of physics?

inaccurate

…Douglas et al’s recent work showing the finiteness of the number of vacuum solutions

and just tasteless

the possibility of success for loop quantum gravity, though this tactic ended with an own goal, and rapturous applause.

So far no sign that the organizers of the conference of the conference will be putting up any materials from it on the web, so that people who weren’t there can see for themselves what the speakers had to say.

It also seems that Dijkgraaf commented favorably on the very reasonable censorship policies of the Chinese government:

One particularly important point was that being behind the great firewall, people could read Peter Woit’s blog but not Lubos Motl’s!

Comments

1. **Ryan**
   June 18, 2006

Not to nitpick, but it’s spelled “Tiananmen.” I had to look it up, but I knew there was another “n” in there.

2. **woit**
June 18, 2006

Thanks Ryan, fixed.

3. **Peter Motl**
June 18, 2006

Last time i checked, there’s no canonical way for spelling chinese words in english.

4. **Troublemaker**
June 18, 2006

Then you’ve never heard of any of the standard transliteration schemes for writing Chinese in the Latin alphabet.

5. **MathPhys**
June 19, 2006

Is the Strings 2006 web site difficult to navigate and find information in, or do I imagine things?

6. **Peter Woit**
June 19, 2006

MathPhys,

The Strings 2006 web-site is difficult to navigate. The “What’s New” section doesn’t appear to have been updated since two months ago. I’m hoping that various bloggers will help fill the information gap…

7. **hongbaozhang**
June 19, 2006

When String06 starts in Beijing, Loop driver Carlo Rovelli comes to Center of Gravitation in China—Beijing Normal University. He will give series lectures on construction of scattering amptitude in loop quantum gravity. Today he gave the first one, which is so physical and clear. I enjoy it.

8. **Who**
June 19, 2006

This is wonderful!

I think someone with a name similar to yours was at the Loops ’05 conference where Rovelli gave a talk about constructing graviton in LQG. Maybe you heard this talk. (I could not come to the meeting and did not.)

It amazes me that Rovelli is talking at Beijing Normal about LQG scattering amplitudes now at the same time as Strings ’06. This was a creative move by the planners, or by somebody at Beijing Normal. It was a good new idea to do this, in my humble opinion.

9. **Babe in the Universe**
June 19, 2006

This is a very exciting time to be in science. Some branches of theory look increasingly like medieval epicycles (you all have opinions on which ones) but there is opportunity for huge advances in science. Hopefully this conference will result in much useful conflict!
My Chinese travels described this week found a fascinating and vibrant society. Since the Chinese are so interested in energy, perhaps a theorist will sell them something they really want. That may result in all sorts of funding. Any ideas?

10. **hack**
June 19, 2006

I had heard than Strominger went through a Maoist phase in his youth. Preaching strings in the People’s Hall seems quite appropriate.

11. **Who**
June 19, 2006

Hongbao Zhang,
sorry I made a mistake. I see you are author of a number of articles in Phys. Rev. D, some of them about Loop Quantum Gravity and related proposals. But it was someone else, a Dr. Hua Zhang, who was at the Loops ’05 conference last October in Potsdam.

12. **Rufus T. Firefly**
June 19, 2006

Haha, new message for the link from here to Motl’s blog:

“Error
You have attempted to visit a serious physics-oriented page from a major crackpots’ discussion forum called “Not Even Wrong”. That generated an error message. In 15 seconds, you will be redirected to the main page of “The Reference Frame”.

This policy is designed to reduce the amount of garbage and spam that the crackpots attempt to post on “The Reference Frame”, especially the targetted garbage ordered and provoked by the owner of “Not Even Wrong”. If you’re not a crackpot, we appologize for inconvenience.”

13. **Peter Woit**
June 19, 2006

Please, I’m trying to stick to John Baez’s excellent advice that the effort needed to ignore Lubos is amply repaid. No more about his idiocies here, if you must, use the recent posting related to him.

14. **Yidun**
June 19, 2006

Dear Who,

Hongbao Zhang is not Hua Zhang. Hongbao focuses on cosmology and gravity. He does have couple of papers, coauthored by Prof. Ling Yi, who is a former student Prof. Smolin's at Penn State. Hua Zhang is another graduate student, working on canonical QG with Prof. Yongge Ma, who gave a talk in Loops'05 last year.

Best, Y.

15. **MathPhys**
June 19, 2006

In case anyone is still unable to find the conference program, you do as follows

1. Click on "Agenda and arrangements" somewhere in the middle on left panel.
2. Ignore the table titled "Program and Reports" that occupies almost the entire page. That's no longer being updated. It just sits there.
3. Look for a link on top that says "(PDF file)" (it's to the left of an unlinked picture).
4. Click that to get a pdf file titled "schedule5.pdf".

16. **hongbaozhang**
June 20, 2006

To Who,
Who is who?:)

17. **Hans de Vries**
June 20, 2006

Weed smokin' 2006 in Beijng….

18. **Hans de Vries**
June 20, 2006

Weed smokin' 2006 in Beijing

OK, the saved screen-shot then:

http://chip-architect.com/physics/WeedSmoking.jpg

Regards, Hans

19. **mathjunkie**
June 20, 2006

I like the name Peter Motl!

20. **Pindare**
June 20, 2006

Peter, you said Witten won't be speaking about string theory for the first time at a Strings conference. I've noticed he'll be giving a set of lectures at Berkeley next november, and probably this will also be about Langlangs stuff, not strings (there's no program yet).

http://math.berkeley.edu/index.php?module=announce&ANN_user_op=view&ANN_id=63

Question is: has Witten decided to do some maths until the LHC data arrives just as a side project, or has he in fact started doing this to be able to quickly jump off the bandwagon in case nothing much comes out of LHC?

21. **Peter Woit**
June 20, 2006

Pindare,

Thanks for the link to the announcement of Witten's lectures.

I doubt that his decision about what to work on has anything to do with the question of what will come out of the LHC. If he had a good idea about LHC energy scale phenomenology, he'd probably be working on that. His decision to work on a more mathematical topic related to gauge theory presumably just reflects the fact that this is where he sees how to make some progress, and he doesn't see how to make any progress on string theory at the present time.

22. **D.J.**
June 20, 2006

"In 1988, Hawking published his great book, A Brief History of Time: From the Big Bang to Black Holes, which is still considered by the scientific community to be a milestone."
(http://english.people.com.cn/200606/19/eng20060619_275174.html)

What can I say?…

23. **Peter Woit**
June 20, 2006

D.J.,

Well, it was a milestone, convincing many publishers and scientists that there was a mass-market for popular books about science…

24. **Victor Rivelles**
June 20, 2006

Dear Peter,

I can't asnwer your comment in my blog because blogspot is blocked in China. Please see the update in my post for an asnwer to your comment.

All the best,

Victor

25. **Stalyn**
June 21, 2006

From http://www2.math.northwestern.edu/langlands/index_moreinfo.htm

"It has long been suspected that the Langlands correspondence is somehow related to various dualities observed in quantum field theory and string theory."

You can also find notes for a lecture with the same title given by Witten dated August 2005.

http://insti.physics.sunysb.edu/itp/conf/simonswork3/talks/Witten.pdf

26. **Aaron Bergman**
June 21, 2006

From the math side of things, I give you The Ben-Zvi Repository of All Things Langlands. Recently updated and now including valuable and little known television references.

27. **csrster**
June 21, 2006

Maybe some people have trouble spelling "millstone"?

🙂

28. **Steven H. Cullinane**
June 21, 2006

Xinhua has a story from June 20 on Yau showing a video in Beijing of a talk by Hamilton on the Poincare conjecture. This Xinhua story is rather Sinocentric, but it is balanced nicely by a document from China's Morningside Center of Mathematics that gives a more complete record of Hamilton's talk.

29. **Jean-Paul**
June 21, 2006

This incredible success of strings in China reminds me of fading stars like Michael Jackson trimphant tour of Germany few years ago or Prince's full-stadium concerts in Switzerland in the early 90's. Hopefully, the new KITP will help Chinese to focus on the cutting edge of science intead of wasting time on failed ideas or b.s.ing on multiverses.

30. **Nick**
June 21, 2006

I just posted a rather scathing reply at http://greenr.com to Hawking's remark from the seminar where he said he was "very worried about global warming," and that he was afraid that Earth "might end up like Venus, at 250 degrees centigrade and raining sulfuric acid."

He has become so detached from scientific reality it is ludicrous. Why is he still respected?

I of course included a link to Not Even Wrong, as well as Junk Science's global warming debunking, as well as Crichton's "Aliens Cause Global Warming" lecture.

I'm glad to have found this blog, and appreciate all of your efforts to bring sanity back to science.

31. **Peter Woit**
June 21, 2006

Nick and others,

Please stop attempts to involve me and this blog in the climate change debate, which seems to me to be almost entirely carried on by people who don't know what they are talking about. I want no part of it, and it has nothing to do with the concerns of this blog, which deals with particle physics and mathematics.

32. **MathPhys**
June 22, 2006

I'm disappointed that the String 2006 talks are not posted online, videos, transparencies and all. It's not hard work, and it's a great service for the entire community.

33. **MathPhys**
June 24, 2006

The Cao-Zhu paper is not online (everybody else's papers on the subject are, including Perelman's), and the Strings 2006 talks are also not online in any shape or form (in contrast with tradition in these conferences).

If someone here knows S T Yau, could you please bring this to his attention? I'm sure he'd do something about it.

34. **Amy Zeck**
June 30, 2006

I saw these math T-Shirts and had to share them with everyone:

The String Theory Backlash

June 19, 2006
Categories: Not Even Wrong: The Book

Over at Cosmic Variance Sean Carroll has a posting about The String Theory Backlash. Probably best if anyone who wants to discuss it do so over there, so I'll turn off comments here.

Update: More about this here.

Update: The posting in the last link (which was an impressive anti-Sean Carroll rant) is now gone, presumably because many of the author's colleagues finally realized something had to be done, and wrote in to his blog telling him that he "must be on crack", and had "completely jumped the shark".

No Comments

LHC News

June 20, 2006
Categories: Uncategorized

JoAnne Hewett at Cosmic Variance reports that the latest LHC commissioning plan will not involve collisions at 14 TeV until 2008, with earliest physics run in April 2008. First collisions will be in November 2007, but at Tevatron energies. Until recently the plan had been to try for first collisions at full energy next summer, and some had hoped that a bit of new physics data could be acquired in 2007, but it looks like that is not to be. For a summary talk on the situation, see here.

Comments

1. **Babe in the Universe**
   June 20, 2006

   Hello Peter:
   Your blog has long been a source of enjoyment for many people. Thank you for the support in the recent mini-controversy. You can see that I have gone far beyond those student papers. The slings and arrows haven't hurt at all. Bring it on!

2. **sunderpeeche**
   June 20, 2006

   Very rarely do accelerators achieve their top energy on the first pass (although w/ upgrades in *later years*, many have exceeded their original design energy). Especially with something as complicated as LHC, it will be a major feat just to demonstrate collisions and maintain a stable beam. Will all of the detectors be ready?

3. **JoAnne**
   June 20, 2006

   sunderpeeche: Both of the high p_T detectors (ATLAS and CMS) will be working good enough by Fall 07 to measure the interactions from the first collisions. Both, however, will be missing quite a few pieces (i.e., ATLAS will not have full muon coverage). It will take a long time to calibrate the detectors once the data starts pouring in.

   I have no knowledge of the status of LHCB and ALICE, but imagine they are in the same boat.

4. **Chuckles**
   June 20, 2006

   The Motls piece against Carroll is available via Google Cache. Very Impressive, I must say. So the argument is that the far left Carroll is basically the countertype of the far right Dembski – which makes Motl what exactly? A reactionary physicist pontificating about brains and sex, subjects in which he is eminently qualified, unlike Carroll and Woit pontificating about…ah, never mind.

   Cache 'em young:

   Copy then paste the above link to your browser's address bar. If you click directly you will get a Motl intercept (worth a look though for a laugh).

6. **JoAnne**
   June 21, 2006

   Could someone please tell me how the comment thread to this post – with a subject matter of the LHC and hard science with real experimental data – degenerated into an irrelevant thread about Lubos Motl, Peter's book, and loop quantum gravity???

7. **Peter Woit**
   June 21, 2006

   Joanne,

   1. People love to post off-topic things here trying to turn the discussion away from the topic of the posting to whatever they would rather hear about.

   2. Unfortunately, there seem to be a lot fewer people out there who want to have an informed discussion about particle physics than would like to discuss Lubos or LQG.

   3. Last night I deleted some of the Lubos discussion and tried to see if WordPress had some way of moving the comment with the link to another posting but it doesn't seem to have a way of doing this. Considered deleting this, decided not to since some people might find it amusing or enlightening, even if off-topic. Went to sleep, thus unable to moderate continuing off-topic comments…

   Someday I should write up a FAQ with answers to recurring questions like "What about LQG?", no time now. Please, if you must discuss Lubos, use the recent thread devoted to him, and try and avoid posting comments unless you have something interesting to say about the topic of the posting. What many people continually do here is analogous to joining a discussion that has gotten going among a group of people and starting to go on about a different subject. It's rude.

   Back to the topic of the LHC. Anyone want to guess how long it will be from April 2008 until the experiments have enough data to say something interesting, understand their backgrounds, and are ready to go public with results of the data analysis? How long did it take in the case of the Tevatron?

8. **sunderpeeche**
   June 21, 2006

   Others may have better info on the Tevatron, but FWIW it started operations in 1983

   http://www.fnal.gov/pub/news/history_tevatron.html

It was initially a fixed-target machine (now it runs sometiimes as a collider and sometimes fixed-target). Antiproton beams were first circulated at Fermilab in 1985.

http://history.fnal.gov/brochure.html#IV

Don't know about fixed-target expts, but the first collider detector was CDF which started taking data in 1985 (D0 came later). One of the earliest significant physics publications from CDF was a precise measurement of the Z mass (1989), the result was competitive with LEP at the time.

http://prola.aps.org/abstract/PRL/v63/i7/p720_1

9. **Seth**
June 21, 2006

As a member of one of the experiments, something I would note is that this may be less of a delay in good physics results than it looks like. Even if the accelerator had started at 14 TeV CM energy, all the data from 2007 would likely have been used for detector commissioning. And many of those commissioning tasks can be done almost as well with 450 GeV beams.

10. **anonymous**
June 21, 2006

dear Seth,

can you explain to a theorist the reason behind this decision?
At "Cosmic Variance" it is said that it is safer to start with less energy stored in the machine, but why reducing the energy rather than the intensity of the beams, at the price of using magnetic fields much below their planned values?

11. **Seth**
June 21, 2006

I'm a few pay grades below management, but what it looks like Cosmic Variance says is that the much of the machine simply won't be ready to run at all full energy in time, or at least not fully checked out. (There are more ways to break an accelerator than simply storing too much total energy into it, I'm sure.) So they prefer to run at low energy rather than not running at all.

From the standpoint of the detector folks, this has positives and negatives; one positive I discussed in my last comment, but a major negative is we won't have as much time to get our detectors fully installed as if they delayed until 2008. The detector installation on the two major experiments is running on an extremely tight schedule still, even though there is some delay in when the experiments will be closed in the new LHC schedule.

12. **sunderpeeche**
June 21, 2006

To reach top energy the magnets must run at full magnetic field, regardless of how many particles are stored in the beam. This is especially risky/difficult when dealing with superconducting magnets.

13. **Fred Diether**
June 21, 2006

Peter,

The HyperCP collaboration had one of the biggest data set captured from experiments and it took them about 5-6 years to find the 214 MeV X particle. And they are still analyzing data. I would expect that LHC will have even bigger data sets than HyperCP. So it could be quite a few years before new physics is found if at all. Hopefully not though. 😉 They are definitely going to need a lot of data crunching capability.

Fred

14. **Tommaso Dorigo**
June 21, 2006

Hi all,

not only will CMS and Atlas be short of a few components, but – to me, more to the point – they will have to work a lot before they make sense of their triggers.

The delays in CDF physics somebody mentioned above were due to precisely this problem: triggering in a hadronic environment is a nightmare in its own right.

I am in CMS, but I do not care if the 2007 run is taken at 2 TeV, 2 GeV or 2 PeV. The data will not be useful for significant physics measurements. Rather, it will allow us to start making sense of our trigger primitives. Calibrations ? Calibrations come later. As was mentioned, W and Z boson physics measured by CDF was an early successful measurement, where that experiment beat the 630 GeV competition. But still, quite some time after the first shot.

Now flame me if you must, but I predict that no physics measurement will be published by CMS and Atlas before summer 2009. That includes the total inelastic cross section 🙂

Cheers,
T.

15. **sunderpeeche**
June 22, 2006

nothing in over 24h? it's curious how posts about expt hep generate so few responses, but something on theory generates volumes of the most appaling trash

16. **Peter Woit**
June 22, 2006

sunderpeeche,

Probably just too few experimentalists willing to spend their time slumming here among the theorists.

My tactic on the last posting of turning off comments and telling people to discuss on Cosmic Variance inflicted some of the usual suspects on them, forcing Sean Carroll (instead of me) to spend his time deleting people's off-topic comments. Maybe I should do that more often (sorry Sean…)

17. **JoAnne**
June 23, 2006

Peter: your prose is brilliant.

Sunderpeeche: it is disappointing, isn't it (the lack of interest in blog posts on experimental/phenomenological issues). I try not to let it get me down or stop me from posting, but sometimes….

Tommaso: I agree that caution is needed, given some of the particularly wild forecasts of discovering SUSY at the LHC in the first 3 minutes! However, there will be physics papers in 2008, I think. Even if they are only about Z/W or top production. I am betting the accelerator & detectors will work well enough to get at least these measurements out. Plus, if there really are blackholes at a TeV, or if there is a heavy gauge boson (or Randall-Sundrum type graviton Kaluza-Klein resonances) at 2-3 TeV, then we will know very quickly. Probably during the 2008 physics run. However, missing energy signatures or the Higgs to gamma gamma channel will most likely take a few YEARS, in my opinion. As you know, those signatures require exact calibration and knowledge of the detector and Standard Model background. So, the wait for new physics depends on what nature has in store for us!

18. **Marty Tysanner**
June 23, 2006

JoAnne,

Am wondering what your perspective is of the impact on grad students who are hoping to base a thesis on LHC data. Do you think the LHC schedule change will cause many experimentalists to delay graduation due to a need to wait additional time for data? Do you foresee many experimentalists switching to a different experiment as an alternative, or is that even a realistic option for those who have already committed themselves to the LHC?

19. **Chris Oakley**
June 23, 2006

> nothing in over 24h? it's curious how posts about expt hep generate so few responses, but something on theory generates volumes of the most appaling trash

Sunderpeeche seems to be forgetting that most of the readers here are theorists, former theorists or wannabe theorists. The lack of posts should just be interpreted as a quiet confidence that the experimentalists are doing a good job, and that lacking any specific expertise on the matter, many of us do not see the benefit of making comments.

But here is one anyway: IMHO text books with the emphasis on experiment – I'm thinking of Perkins' "Introduction to High Energy Physics" specifically here – do a better job at theory than most theory text books. They almost completely ignore QFT, doing all calculations with elementary quantum mechanics. Those who think that reproducing QM is not a requirement for a properly-formulated QFT should take note.

20. **Walt**
June 23, 2006

Jo Anne: The biggest mistake anyone can make about blogging is thinking that there is any relationship between interest and comments. People don't comment when they're interested; they comment when they're irritated. Lubos: irritating. LHC: not irritating. Guess what's going to draw the comments.

21. **JoAnne**
June 23, 2006

Walt – how true!

Marty – The effect on grad students working on the LHC will be small. Everybody expects new accelerators and detectors to be delayed and we are all delighted that this delay with the LHC is so *short.* It's only a couple of months!!! It could have been years….(of course we don't know how the actual start of operations will go). If the commissioning phase goes well, the students will get plenty of data for their theses during the 2008 run. Even just observing Standard Model processses such as gauge boson or top-quark production at energies of 14 TeV makes a great thesis! And, thanks for being concerned about the younsters.

This Week's Hype

June 22, 2006
Categories: Uncategorized

The Economist has an article this week entitled To catch a gravitational wave. It's about the proposed LISA satellite experiment designed to measure gravitational waves, with a much greater sensitivity than LIGO. According to the article, what would you guess is one of the main goals of the LISA experiment? Exactly, like most other ambitious experiments, it will solve the problem of how to test string theory:

could allow scientists to examine the validity of string theory, which says that there are more than four dimensions to space-time and that the extra dimensions are hidden. String theory has come under fire because its predictions have so far proved untestable. The normal version has it that these dimensions are curled up in strings that are smaller than the known elementary particles. However, in some versions strings form very long "superstrings" that stretch across the universe. These superstrings form loops and vibrate, radiating gravitational waves; they can also crack like whips, sending bursts of gravitational waves towards Earth. "Seeing direct evidence of strings would be as important as discovering that the world is made of atoms," claims Craig Hogan, an astronomer at the University of Washington, who is a member of the international science team for LISA.

The writer appears to be a bit confused about what a superstring is, guessing that it is a really big string (a cosmic string). This is presumably all based on the idea promoted by Joe Polchinski that it is in principle possible to come up with superstring theory models with cosmic scale superstrings, whose effects would be visible through gravitational lensing and gravitational waves. As far as I can tell, this is just another case of the phenomenon that one can get pretty much anything one wants out of string theory, and there's no reason at all to expect cosmic strings with just the right properties to have been invisible so far, but visible through gravitational wave effects measurable by LIGO or LISA.

Two years ago there was a press release about this from UCSB quoting Polchinski as saying

the gravitational signatures from cosmic strings are remarkable because they are potentially visible even from the early stages of LIGO! That means 'potentially visible' over the next year or two.

LIGO hasn't seen anything, so time was up for this nearly two weeks ago but I haven't noticed any UCSB press releases reporting that things haven't worked out.

There was some excitement a year or so ago when a group claimed that an astronomical object might be a single galaxy lensed by a cosmic string. Turned out to just be a pair of nearby galaxies.

LISA is tentatively scheduled for launch nearly ten years from now, so it will be a while before this particular "test of string theory" brings in any results. This past week the 6th Annual International LISA Symposium was held in Maryland.

Comments

1. **sunderpeeche**
   June 22, 2006

   Just like expt HEP (or even before HEP), it takes years for astronomy to build a new telescope/detector. I don't blame the science writers for writing about strings (cosmic or super). It does not matter. What matters is that LISA actually gets built and launched. When the results come out, they will be analyzed on their own merits, whatever may have been said initially about any prospective discoveries.

2. **Peter Woit**
   June 22, 2006

   sunderpeeche,

   Scientists shouldn't spout nonsense to non-scientists in order to justify funding their experiments. Besides being dishonest, its threatens their credibility. If the cosmic string hype had been used as the main justification for funding LIGO, before coming up with the money for LISA, funding agencies might very well start asking about what happened to the cosmic strings ("you mean we gave you X milliion dollars for LIGO to test string theory, now you've spent it and learned nothing about string theory, but are asking for more for LISA to test string theory???")

3. **sunderpeeche**
   June 22, 2006

   A friend of mine (i.e. not I) worked at Daresbury Lab in the UK, and they gave a tour to journalists, about the van de Graaf and the synchrotron. Next day there appeared an article about the "world's tallest synchrotron". Scientists say what they hope to find, and the string theory people will hope for strings.

4. **Kea**
   June 22, 2006

   From Padmanabhan's new paper :

   There is more to gravity than gravitons.

5. **Peter Woit**
   June 22, 2006

   Kea,

   Please, don't get a discussion going here of alternatives to GR. It more or less immediately becomes too depressing for me to try and moderate.

6. **Kea**
   June 22, 2006

   Sorry.

7. **Matt B.**
   June 22, 2006

   The last part of your blog post is missing, you know, the subjective part. What would your ideal press release for LISA look like?

8. **Thomas Love**
June 22, 2006

Peter said: “Scientists shouldn’t spout nonsense to non-scientists in order to justify funding their experiments. Besides being dishonest, its threatens their credibility. ”

But they do and even nonscientists have seen through it.

“Are researchers over-hyping their results, and prematurely, in order to impress the grant-giving bodies? And are they using ‘jargon’ to keep hold of their special status as a secular priesthood and excommunicate the rest of us?”—from “Mad, Bad and Dangerous?; the Scientist and the Cinema” by Christopher Frayling

Grant-giving bodies are impressed when scientists seem to agree on one theory. So funding thrives on conformity. The search for truth thrives on diversity.

9. **woit**
June 22, 2006

Matt,

Most of the article about LISA was fine, I just think the scientists involved shouldn’t be telling the press that the thing will “test string theory”, because it’s just not true.

10. **Tony Jackson**
June 23, 2006

BBC Radio 4 has a programme called “Start the Week” in which guests from the humanities, politics and science discuss issues great and small. Over a year ago, Michio Kaku was a guest and talked about his then new book “Parallel Worlds”. You can hear this programme at:

http://www.bbc.co.uk/radio4/factual/starttheweek_20050131.shtml

Kaku waxed all theological about the cosmological implications of string theory (I think), and added gems like: “we physicists are the only scientists who can use the word God and not blush”. About 13 minutes into the recording, one of the guests brought up the awkward problem of experimental verification, at which point Kaku emphatically mentioned that the LISA satellite would provide the necessary data. I’d be interested to hear what people from this blog think of such comments.

11. **csrster**
June 23, 2006

I think they should invite Peter onto Start The Week.

12. **Troublemaker**
June 23, 2006

People from this blog, and from most of the theory community, know that whatever Kaku says is a steaming pile of baboon crap.

13. **anti-Troublemaker**
June 23, 2006

Dear Troublemaker,

Kaku is entertaining. If you critics are right, and things are less complex than the extradimensional landscape and cosmic strings, then physics will be boring.

Better change your scientific attitude. This is a difficult process, so go gently. Start off training yourself to be a pseud by believing one lie each morning before breakfast.

Gradually build up your stamina until you can force yourself to believe six hoaxes a day:

Alice laughed: “There’s no use trying,” she said; “one can’t believe impossible things.”

“I daresay you haven’t had much practice,” said the Queen. “When I was younger, I always did it for half an hour a day. Why, sometimes I’ve believed as many as six impossible things before breakfast.”

– Alice in Wonderland.

Reading that book inspires string theorists (according to testimony in the book “Warped Passages”).

14. **Christine Dantas**
June 23, 2006

Kaku emphatically mentioned that the LISA satellite would provide the necessary data.

For those interested, I am keeping a post on papers related to the predictions of quantum gravity about the gravitational wave phenomenon. More papers will be added opportunely.

Best wishes,
Christine

15. **D R Lunsford**
June 23, 2006

sunderpeeche,

You are mistaken – just building and running instruments is a worthless endeavor if their only purpose is to reinforce preconceived notions (witness WMAP 3).

-drl

16. **sunderpeeche**
June 23, 2006

Indeed yes, if the real purpose of building an instrument (accelerator, telescope, …) is just to have some machine in the lab, to keep the staff employed, then that is worthless. There has to be some scientific goal, and typically those goals are formulated in terms of the theoretical prejudices of the day. Today it's strings. Don't know about WMAP 3 ~ they tried to probe the CMB in more detail, and presumably new instruments will keep doing so. Will LHC be worthless if it finds a SM Higgs and nothing else?

The nuclear power and fusion industry does offer an example of overhyped promises, though. Today the knee-jerk reaction is to be suspicious of any new nuclear power plants. It may become so with particle accelerators. (It has already become so?)

17. **tsg**
June 23, 2006

sunderpeeche wrote: "Will LHC be worthless if it finds a SM Higgs and nothing else?"

I posted this comment in response to "LHC predictions at Seed", but a little too late to get a reply. But now that the topic has come up again.... Wouldn't it be significant if LHC *doesn't* find superpartners, as evidence *against* super-symmetry at low enough energies to solve the hierarchy problem (which I thought was one of the main arguments for believing in supersymmetry in the first place)?

That doesn't seem analogous to LISA looking for cosmic strings, though, since I don't think anyone is really expecting to see any. If a negative result doesn't make anybody question the theory (who wasn't questioning it already), then it can't be called much of a "test".

18. **Peter Shor**
June 23, 2006

I don't think this has been mentioned in this blog before (apologies if it has), and it's related to LIGO. The gravitational waves resulting from two black holes colliding can now be calculated! I have heard that in the last year, several groups, including one at NASA, have figured out how to overcome the numerical instabilities and simulate black hole collisions. You can google and find some news reports and a really neat video from NASA. I can't really find anything about what this means for LIGO and LISA, though.

19. **Peter Woit**
June 23, 2006

Peter,

From what I've seen the magnitude of these waves is such that for them to be detectable by LIGO, the black holes would have to be relatively nearby, so much so that no one really expects to LIGO to see such a signal while it is running. Don't know about LISA…

20. **Krotos**
June 23, 2006

D R Lunsford: "You are mistaken – just building and running instruments is a worthless endeavor if their only purpose is to reinforce preconceived notions (witness WMAP 3)."

I think calling WMAP worthless is a bit strong (disclosure: I was a co-author on a few WMAP-related papers). It's given significantly improved bounds on various cosmogical parameters and on things like neutrino masses.

However, I do see and agree with your broader point. I remember the NASA press release calling WMAP results "stunning" and "one of the most important scientific results of recent years." I'm sorry, and I intend no disrespect to the WMAP team, but that's hype. It was a fabulously well-done experiment, and it did give rise to some mysteries such as the low quadrupole moment, but it essentially confirmed the broad details of what was already suspected. It certainly wasn't comparable to, say, Rutherford's experimental discovery of the atomic nucleus in the sense of being a revolutionary, paradigm-shifting result.

I was in early-Universe cosmology for several years, and one of the reasons I switched fields was that I was starting to see the same factors that have distorted particle physics — primarily, too much theory and not enough data (and secondarily, increasing amounts of starry-eyed hype that give a misleading impression of how certain or complete the science really is) — appear in cosmology. It's not nearly as severe, of course, and in most respects it's still a very healthy field. But how are we going to, say, get more than a very rough idea of the inflaton potential, let alone make controlled measurements of an inflaton or a dark matter particle in a lab? I have a nagging feeling that CMB and gravity wave measurements, though important and significant, just won't be enough to give the kind of experimental verification to these theories which is utimately needed in science, and I'm not sure the technology that would allow it will be here any time soon.

(My apologies to Dr. Woit if this is getting too off-topic.)

21. **Moshe**
June 23, 2006

Peter(s): Frans Pretorius from Caltech (formerly UBC) gave a very nice colloquium at PI, available here , worth checking out.

22. **Moshe**
June 23, 2006

Not quite… in any event it is on page 2, and the title is "Simulation of Binary Black Hole Mergers".

23. **Nick**
June 24, 2006

P. Woit Said:
…for them to be detectable by LIGO, the black holes would have to be relatively nearby, so much so that no one really expects to LIGO to see such a signal while it is running. Don't know about LISA…

If anyone wants a figure for how nearby, I could shed some light, I was a undergrad researcher at LIGO Hanford during a previous summer. LIGO often measures the detector sensitivity by the range at which it would detect a "typical" neutron star binary inspiral. The LIGO Hanford 4K interferometer currently runs at about 13Mpc. The Virgo cluster is about 15 Mpc away, which is a good place to expect a good number of inspirals.

Of course, Advanced LIGO (the upgrade which will start in the next few years ~07 or 08) will see 10 times farther, and LISA won't be up until at least 2015, so my money is on LIGO.

24. **FT reader**
June 24, 2006

"From what I've seen the magnitude of these waves is such that for them to be detectable by LIGO, the black holes would have to be relatively nearby, so much so that no one really expects to LIGO to see such a signal while it is running. Don't know about LISA…"

LISA is guaranteed to see gravitational waves, at least from white dwarf binary systems in our galaxy. So many in fact, that they cannot be resolved and will form one of the important sources of "noise" (see e.g. gr-qc/0204090).

25. **Juan R.**
June 27, 2006

sunderpeeche said,

Scientists say what they hope to find, and the string theory people will hope for strings.

No, there is an etical code for scientists is sistematically violated by string theorists. These sistematic unethical news are not common in the rest of normal science.

It is so unethical to claim that string theory is falsable as claim that string theory predicted gravity, when is even unable to reproduce GR results from *first* principles.

Juan R.

Center for CANONICAL |SCIENCE)

NEW in the WSJ

June 23, 2006
Categories: Not Even Wrong: The Book

Today's Wall Street Journal has an article by Sharon Begley entitled Has String Theory Tied Up Better Ideas In Field of Physics? (sorry, subscription required for on-line version). The summary of the article goes

After two decades in which string theory has been the doyenne of best-seller lists and the dominant paradigm in particle physics, some critics say it may be tying up better ideas.

and in some sense it covers for the public in simplified form the discussion going on over at Cosmic Variance at the moment. It quotes Lee Smolin and me as critics, with Mike Peskin as the only defender of string theory. Peskin acknowledges the compactification problem, and then makes only a strikingly weak argument for string theory: that it can claim some success because it explains the number of generations. This "explanation" in terms of the topology of the Calabi-Yau is no explanation at all, since you can get any value for this number you want. I don't see how changing the parametrization of your ignorance from that of a single natural number to that of the topology of a Calabi-Yau is any improvement.

I assume that any moment now Lubos will be producing a rant comparing Sharon Begley to one sort of animal or another.

There's also a long review of Not Even Wrong from John Walker over at his blog called Fourmilog. He does a good job of laying out the controversial argument of the book, and we seem to be mostly in agreement, although I don't share his conviction that government funding is a major source of the problem.

Update: I just heard that official publication date in the US is September 8, although books should be for sale a bit earlier than this. Lubos has a posting about the WSJ article, less of a rant than some of his recent ones. He has restored his anti- Sean Carroll screed, which was a classic that many people were sorry to see suppressed.

Update: A commenter points out that the WSJ article is available on-line here. There's also a mention at Slashdot. The extensive discussion there is heavily anti-string theory which is an interesting sign of the times, but also convinces me that the idea of moderating this kind of discussion by having participants vote on which comments are worthwhile just doesn't work at all.

Update: There's commentary on this from science writer David Appell here, who pretty much gets the situation right.

Comments

1. **QWERTY**
   June 23, 2006

   DEAR PETTER,

   ARE YOU ABLE TO RELEASE SALES FIGURES FOR YOUR BOOK? THIS WOULD SHOW YOUR CRITICS THAT THEY ARE THE IDIOTS FOR DOUBTING.

   SUPERSYMMETRY IS A COMPLETELY SILLY IDEA IN PHYSICS, THERE IS NO EVIDENCES AND IT IS WORSE THAN THE EPICICLES. BUT IT IS A SHAME THAT IT IS SO USEFUL IN MATHEMATICS. WITTEN AND KAPUSTING HAVE BEEN USING IT IN THEIR GEOMETRIC LANGLANDS PAPER WHEN THEY TALK ABOUT THE MODULI SPACE OF THE N=4 SUPER YANG-MILLS EQUATIONS OVER RIEMANN SURFACES.

2. **woit**
   June 23, 2006

   QWERTY,

   STOP USING ALL CAPS!

   I don't know sales figures for my book, and from what I hear publishers tend to be cagey about these numbers with authors (since they determine the size of the check they have to write). I've also heard that they way the book business works, bookstores can return unsold books. So, you don't know how many books you've sold until you see how many unsold ones come back, which can take quite a while.

   And, whether the book sells well or not has nothing to do with whether I or my critics are right. Whether a book has a good argument or not in it doesn't necessarily correlate with how it sells (some would argue that the these things are inversely correlated…).

   Supersymmetry is very useful in math, and this is not a shame, but a very interesting phenomenon, the reasons for which I think we still don't completely understand. When we do, we'll have learned something very important.

3. **Doug Natelson**
   June 23, 2006

   FYI, Lubos has re-edited his post re: Sean Carroll; at least, the section quoted my blog has been changed. The basic point remains unaltered, though.

4. **woit**
   June 23, 2006

   Off topic bickering about background independence deleted. Please don't do this unless you have something completely new to say on the subject and it actually has something to do with the posting.

5. **Garrett**
   June 23, 2006

   Hey Peter, congratulations, you just got slashdotted:

   http://science.slashdot.org/article.pl?sid=06/06/23/2226257

   Perhaps fortunately, they didn't link directly to NEW, or your machine might have melted…

6. **nukular**

June 24, 2006

As a PhD (pure qft) physicist, I was a little curious about this book after a blurb on slashdot. It seems reaonable then that I would browse my way to the Amazon webiste, only to read Lubos' "criticism" and find myself scratching my head. I have to admit this is the first time that I have decended into this pit but his comparision of string theory to the modern theory is WAY over the top. While not an expert at either string theory or evolution I know enough about both to make an educated statement or two, but the fact is that the evidence for the modern theory of evolution is overwhelming! Comparing the any of the actors in this drama Demski is quite inflamatory and completly inappropriate. I expect better…

7. **ks**
June 24, 2006

It's not really funny to notice that besides the notorious Lubos all kinds of freelancing witch-hunters and exorcists are around to crack "crackpots" in science and accuse them for having "weird", "silly" and "abnormal" ideas. In the 70s and 80s philosophers like Paul Feyerabend accused science to be like the catholic church i.e. repressive, dogmatic and hierarchical. Now one might get the opposite impression that the research frontier becomes ever more splitted into antagonistic sects following one or the other set of speculative ideas and a bunch of millenaristic preachers whith or rather without charisma. Paul Feyerabends "anarchism" was likely mentioned to be some multicultural tolerance. Now it turns out to be the exact opposite: a late medieval hystery and persecution of alteration. Unfortunately there is no "age of reason and progress" at the dawn because this is our own imaginary scene, where we are still living in.

Sharon Begley's WSJ article is available online as a reprint in a Florida paper
http://www.nwfdailynews.com/articleArchive/jun2006/notevenwrong.php
I haven't compared this with the original in the WSJ

9. **John A**
June 24, 2006

I've made my comment to Lubos thus:

> If you're deliberately trying to make Peter Woit look even more sane and string theory ever more implausible by making hysterical ststements such as these, then you're going the right way about it.

I cannot claim advanced knowledge of physics, but I do know some philosophy of science. If string theory cannot make testable predictions then it is not a scientific theory, regardless of the intelligence of its proponents, how beautiful its math, how wonderful its consistency. What has bothered me for a good while is that quantum gravity appears no more achievable a unification than it did 20 years ago.

I heard the same criticism levelled at Steve McIntyre on ClimateAudit.org regarding his finding that large numbers of the better known reconstructions of past climate are statistically meaningless and based upon unphysical assumptions (a finding recently upheld by a specialist panel convened to look at these issues). The retorts back have been (in no order of particular precedence): to compare Steve (and myself) to creationists, Holocaust deniers, to suggest that if they don't agree with a "scientific consensus" they must be deranged or paid to shill for a shadowy right-wing fossil-fuel funded conspiracy, and so on, that we must be crackpots, that we must be jealous, that we must believe in fairies or ghosts.

Now, that isn't to say that Steve McIntyre is vindicated because he is villified – but simply that the reaction to Peter Woit's book and views are strikingly similar.

Oh and the repeated refrain of "if you're so smart why don't you do a proper reconstruction using tree rings" as if it was all a slip between measurements and calculations.

Please, I don't wish to align Peter Woit's beliefs about one subject with my own about another as if they were equivalent or even that Peter Woit agrees with me(and I'm sure people reading this will have strong views one way or another), but surely the point is that showing that a widely used method is invalid and a derivation mistaken is every bit a part of the scientific method as discovering a new particle or an explanation for a new experimental result. Steve McIntyre has written that in a sense, what he has done is entirely negative, in showing that popular methods for climate reconstruction are invalid, without offering an alternative method.

I find the invective between what Lubos has written about Peter and what has been written about Steve and myself on occasion to be spookily familiar.

For those of you who have read the books or the weblog of James Randi know that he receives the greatest diatribes from the most intelligent people who have convinced themselves of notions which are ridiculous (like the idea of Uri Geller bending spoons with his mind). I'm glad to say that in his 70s Randi still delights in demonstrating that the most intelligent people on the planet can be fooled by trickery and easily deceive themselves.

I've no doubt that Lubos Motl and Edward Witten are highly intelligent people, but what should always be remembered is that that very intelligence can lead to foolishness, as James Randi is fond of relating.

I will buy the Peter's book (and "The Elegant Universe" as well) so as to get a rounded perspective on this controversy.

I will add that no scientist I've ever met, nor corresponded with, nor read about has been orthodox in everything. All of them had had foibles, weird ideas and made fantastic leaps of illogic on occasion. It appears to go with the territory.

10. **John A**
June 24, 2006

Oh and Lubos has deleted my comment above, and remarked that:

> … I would really appreciate if he stopped nuking my blog articles about theoretical physics – which he does not understand a single bit – with nonsensical and emotionally charged reactions.

It would appear that I have inadvertently joined a select club.

11. **Isaac**
June 24, 2006

I have to correct your misunderstanding of how Slashdot moderation works. Officially, you can't both moderate a discussion and participate in it, though undoubtedly some people get around this with multiple login. And the whole body of users doesn't moderate: moderators are chosen randomly from a pool of "normal" users.

Which is not to say that the Slashdot moderation system works all that well. But it's rather more than just people voting on who's most worth hearing.

12. **Joseph**
June 24, 2006

that explains why “Some people really get tied in a knot about stuff like this.” is the most popular comment on this story.

13. **J.F. Moore**
June 24, 2006

“…the idea of moderating this kind of discussion by having participants vote on which comments are worthwhile just doesn’t work at all.

If the signal-to-noise ratio is low enough, using any filter becomes pointless.

14. **Benjamin**
June 25, 2006

I have a basic question about scientific methodology. One of the main criticisms of string theory is that it has not not produced a prediction which can be falsified by experiment. But suppose it does, and that prediction is falsified. That is not necessarily the end of the theory (or any other theory). To be fair, the protagonists should have a chance to correct any flaws in their theory, perhaps in light of the new experimental discoveries. That may take time, perhaps quite a bit of time. It seems to me there is never a definite cutoff point for any theory, though as time passes the theory will slowly fade away, unless it mends its ways or a better one comes along. This may seem basic but I thought it was worth mentioning.

15. **Thomas Larsson**
June 25, 2006

Benjamin, something like that has happened already. During the quarter century which I have been seriously interested in particle physics, at lot of people have promised that the experimental discovery of SUSY is just around the corner. It hasn’t happened. Many experiments have tested various natural signals for SUSY – sparticle detection, light Higgs, proton decay, WIMP detection, permanent electric dipole moment, muon g-2, B_s oscillation, and probably several others that I don’t know about. The problem is that all these experiment have produced null results. Also, my impression is that people think that the Tevatron should have seen something weird by now, had SUSY been there in the first place. So you might say that SUSY is almost disproven already.

As Witten stated repeatedly for 20 years, string theory predicts SUSY. Thus string theory is already having serious trouble with experiments. But when a lot of people have invested entire careers in a program, experimental failure is simply not going to be accepted. It took a long time for H A Lorentz and other aether theorists to accept the Michelson-Morley experiment, Geoff Chew and Fritjof Capra still seem to believe in the analytic bootstrap, and string theorists employed the ultimate excuse for denying experimental facts: the anthropic principle.

16. **woit**
June 25, 2006

In many cases, a theory that makes a wrong prediction can be fixed by making it more complicated. Falsification is not so simple; it often works by forcing the people who believe in a theory to make it more and more complicated, with true believers never giving up, but most people losing interest in the theory because it has become a useless mess.

This is completely off-topic, since string theory does not make a single prediction, so it hasn’t yet even reached this state. One could argue though that it already has reached the end-point of this process: just to get it to agree with what we already know about the world, its proponents have been forced to turn it into a useless mess (aka the anthropic string theory landscape).

17. **Ponderer of Things**
June 25, 2006

I find it rather remarkable that Lubos retracts a post, and reposts it after a few days of thinking about it.

It shows that he has limits (maybe he is not completely “out there”).

I also feel that the tide has been turning in Peter’s favor lately (the past year or so, compared to pre-2005 situation). I think blogosphere has more to do with it, rather than lack of results from string theory.
The style of argument that we get from Lubos vs. the style of argument from Peter Woit and Lee Smolin may be another reason. People in general and physicists in particular have developed BS detector – so even without getting into details about Calabi-Yau manifolds and multiverses, one can usually tell who is bluffing and who is arguing honestly. It’s like Bill O’Reilly vs. George Clooney, I can tune in half-way into the argument, but the argumentative “bully” style vs. the reasoned and polite voice of conviction tells me everything I need to know.

18. **R. Avry Wilson**
June 26, 2006

Dear Peter,

I wasn’t sure exactly where to post this comment on your blog, so thought to put it here – if that’s ok.
—–

Thank you for writing this book. Mere moments after I first came into contact with string theory I recognized its innate failures and ‘endless’ possibilities. Vast, complex, and untestable mathematics is (to me – I don’t wish to offend anyone with the following analogy) as much a waste of intelligence as solving the trillionth prime number, i.e. what exactly is the point of carrying out work that in the end doesn’t really do anything to move us along? My primary concern is why it took so long for someone (anyone) to take a stand against the theory(-ies); to me, it screamed ‘obvious’ to the extreme of pedantic physics. I’d expected string theory would have been dinosaur-bound by 1980.

From where I stand, the problem has always been simple: limit components to 3 dimensions in all of physics. I remain boggled by any theory that uses multiple dimensions; using unreality will not define reality – ever.

Kind Regards,

R. Avry Wilson

19. **ObsessiveMathsFreak**
June 26, 2006

One comment in the Slashdot discussion really leaps out of the page.

> Extra dimensions are the epicycles of Modern Physics

It's a very bold statement, and in many ways, has a lot of validity. The physics community owes it to itself to respond to this statement. In what way are extra dimensions fundamentally different from the old theory of epicycles?

20. **Riofrio**
June 26, 2006

    Of course they are epicycles, as are dark energy and inflatons. Does anyone remember the Emperor's New Clothes?

21. **Chris Oakley**
June 26, 2006

    > In what way are extra dimensions fundamentally different from the old theory of epicycles?

    Well, here's one way: you can calculate things that agree with experiment using epicycles.

22. **Aaron Bergman**
June 26, 2006

    Well, besides the fact that they have absolutely no similarities to speak of, you mean?

23. **Chris Oakley**
June 26, 2006

    Not only that, I've done it. The Tibetan and (old) Hindu calendar are based on circular lunar and solar orbits with a a single epicycle superimposed. This is used to calculate their calendar, and yes, it is not especially accurate, but it is OK.

24. **sunderpeeche**
June 26, 2006

    String theory may go the way of phlogiston and the aether. Both concepts became more and more elaborate (phlogiston had to have negative weight), until something better simply displaced it. But in both cases, there had to be (and there was) expt data (which the theories could only explain by adding more twists to the formalism, until they became untenable). Ultimately, one needs expt (HEP) data, nothing else will displace ST (or LQG or anything else).

25. **JPL**
June 26, 2006

    I am afraid the analogy between epicycles and extra dimensions is misleading, since epicycles at least had some predictive power (you could compute observed orbits from them with some effort) and that is surely part of the reason that they lasted 1500 years or so. Extra dimensions, on the other hand, don't seem to predict much that has been observed!

Yarn Theory

June 25, 2006
Categories: Uncategorized

A couple people wrote in this morning to tell me about today's Doonesbury, which features slacker Zipper Harris (who has a blog) trying to impress a woman he last saw in sophomore year of college. He's still undecided about his major, but tells her:

I'm thinking physics. Yarn theory.

Talks at Strings 2006 Now Available

June 26, 2006
Categories: Uncategorized

Slides from the talks at Strings 2006 are now available. I've spent a little while looking through them today, and am sorry I don't have time to say much about them. Lots of more or less the same thing as in earlier years, and many talks devoted to complicated arguments designed to, as Eva Silverstein writes, populate, probe or constrain the Landscape. Nothing remotely like a plausible idea about how to ever get a prediction of anything out of this, but also virtually no anthropic arguments. I assume this was due to the iron fist of organizer David Gross.

I was pleasantly surprised to see that there were quite a few mathematically very interesting talks. Besides many talks of the sort that have been common in recent years dealing with the topological string, there were several that had nothing to do with string theory, but involved interesting mathematics related to QFT, and many of these had to do with work Witten is involved with, so they may get some attention. These were:

1. Witten's own talk on Gauge Theory And The Geometric Langlands Program.

2. Kapustin' talk on the same topic, entitled Topological reduction of supersymmetric gauge theories and S-duality.

3. Gukov's talk on Surface Operators in Gauge Theory and Categorification, where he mentions that some of what he discusses is based on on-going joint work with Witten.

4. Nikita Nekrasov's talk on Beyond Morse Theory.

So, as far as physics goes, the organizers are not allowing any talks on alternatives to string theory (the only mention of LQG seems to have been Dijkgraaf's making fun of it), but they are willing to allow mathematical talks on QFT that are not related to string theory, especially since this is the field that Witten seems to be doing a lot of work in.

Comments

1. **Thomas Love**
   June 26, 2006

   Peter wrote: "organizers are not allowing any talks on alternatives to string theory". My first thought was "typical Chinese censorship", but then I remembered the string motto: "There are no alternatives".

2. **Aaron Bergman**
   June 26, 2006

   Nobody called this a conference on "quantum gravity". It's a conference on string theory (and perhaps more generally, those things people who call themselves string theory choose to work on). I'm don't see why there should some sort of moral obligation to have talks on alternatives. If the "Loops" people want to have talks about whatever, they're certainly welcome to, but that's not the point of this particular conference.

3. **sunderpeeche**
   June 26, 2006

   It makes sense that if the conference is "Strings 2006" then the organizers would not allow talks on, e.g. condensed matter physics or biophysics, etc, so "no talks on alternatives to string theory" doesn't surprise or bother me. What would be relevant is, one day, if some testable prediction is made (~on extra dimensions), and a talk is presented offering a null result (~prediction is falsified) — if such a talk were disallowed then that would be serious.

4. **woit**
   June 26, 2006

   sunderpeeche,

   There's never been or ever will be any danger that a testable prediction will be made at a Strings 2006 conference.

   Aaron,

   The organizers can do whatever they want, but given the sad state of affairs of string theory in recent years, I'd think it would be advisable for them to deal with alternatives in some other way than by making fun of them. I'm quite glad to see that they're having talks on alternatives in mathematical physics, that's great.

5. **Jason**
   June 27, 2006

   Thomas Love,

   Hey, this is a academic conference about string theory! Please, do not intend to relate everything to the "Chinese censorship". Situation in China is not that bad.

   Anyway, I found those talks on mathematical physics very interesting. I think this is great.

6. **ObsessiveMathsFreak**
   June 27, 2006

   > Hey, this is a academic conference about string theory! Please, do not intend to relate everything to the "Chinese censorship". Situation in China is not that bad.

   I don't know. The party line seems to have everyone all strung up. And no doubt Chairman Gross' firm stance on religious debate had more than a few dissidents taken away in knots.

7. **sunderpeeche**
   June 27, 2006

   Consider a conference on "alternative energy resources". Suppose someone came up with an idea to process crude oil more efficiently, to get double the quantity of gasolene per unit of crude oil, effectively doubling the world's gasolene reserves. Would such a talk be accepted at the conference? I would guess not. But there would be other places to present such work. So it is that there are other conferences to present significant non-string theory research. What about the Lattice 200x conferences? I doubt they would accept papers on subjects having nothing to do with lattice QCD ~ e.g. string theory. Why should they?

8. **Eli Rabett**
June 27, 2006

I've been to many topical conferences where there were one or two invited talks on related fields, the point being to keep people up to speed on what is going on around them, especially new developments, and to relieve the monotony of the landscape.

9. **Peter Woit**
June 27, 2006

sunderpeeche,

Taking a look at the proceedings of a randomly chosen Lattice 200x (Lattice 2000), I note that one of the plenary talks is "Recent Developments in Superstring Theory" (see http://arxiv.org/abs/hep-lat/011073) by Ashoke Sen. From what I recall it has not been uncommon for the Lattice XXXX conferences to have summary talks about developments in string theory, although perhaps less so the last few years as most theoretical physicists have lost interest in the subject.

10. **sunderpeeche**
June 27, 2006

Good. It would be good if the String xxxx confs also had summary talks about developments in other fields. Strings 2005 had a talk on developments in Cosmic Strings (Polchinski), which is not quite the same as ST. Depends on the organizers.

11. **Who**
June 27, 2006

I've been to many topical conferences where there were one or two invited talks on related fields, the point being to keep people up to speed on what is going on around them, especially new developments, and to relieve the monotony of the landscape.

By way of illustration, Loops '05 scheduled two invited string talks in plenary session and a third talk in parallel session. The first two were by Dijkgraaf ("Quantum geometry and topological strings") and by Thiesen ("Gravity from String Theory"). The third, by Dorothea Bahns, was more narrowly focused ("The Invariant Charges of the Nambu-Goto String").

12. **Matthew**
June 27, 2006

From what I recall it has not been uncommon for the Lattice XXXX conferences to have summary talks about developments in string theory

Well, the ones I was at had "Lattice" SUSY/string talks, but nothing specific to string theory that was non-lattice related. It's common practice to have one or two experimentalists give plenary talks, and one talk on high energy theory, such as Zoltan Ligeti's talk on CKM physics at lattice 2005.

although perhaps less so the last few years as most theoretical physicists have lost interest in the subject.

It's more that lattice people tend to have slightly lower energy things in mind (like hadronic decay constants). There is a fair fraction of the community that does SUSY/Strings/"formal" QFT type though. See Neuberger's talk at lattice 2005, for example.

13. **sunderpeeche**
June 27, 2006

I just saw this. Has it been mentioned elsewhere? Apologies if so. (Smiting dragons?) "Wrong" "completely wrong" "not even wrong" … I had not heard of the first two, only the last.

http://www.movementarian.com/2006/06/12/peter-woit-smites-dragons-during-the-day-and-superstrings-at-night/

14. **Kea**
June 28, 2006

I finally had a look at these talks. I thought Gukov's was a nice introduction to the link between String theory and recent work on Khovanov homology in the paper by Pfeiffer and Lauda.

Responses To WSJ Article

June 27, 2006
Categories: Not Even Wrong: The Book

The lack of any serious (Lubos doesn't count) response to my book from string theorists since its appearance in the UK a month or so ago has begun to surprise me a bit. I was also suprised at how weak the defense of string theory was that the Wall Street Journal's Sharon Begley put in her recent article. It seems that she did talk to some string theorists, but couldn't get much usable from them (one supposedly told her that the best argument for string theory was the anthropic landscape). Peskin's argument that string theory's biggest success is its "explanation" of the number of generations was evidently the best he could come up with, although it's obviously very weak.

I've heard that the WSJ has gotten some correspondence about this, with Jacques Distler writing in to complain about the article. In one letter from him (also signed by his two collaborators), he claims that Smolin is wrong to say that string theory is not falsifiable, since Distler has a recent paper called Falsifiying String Theory Through WW Scattering .

This paper was discussed extensively here. You can make up your own mind about it, but it's undeniable that the calculations in the paper don't involve string theory at all (Distler's two co-authors are not string theorists). Pretty amazing trick to show that a theory is falsifiable without actually using the theory at all.

There are two obvious problems with the claim in the title of the paper, the first is that when one says a theory is falsifiable, one is talking about the characteristic predictions of the theory, and that's not what the paper is about. The second is that "string theory" is an ill-defined term, and many versions of "string theory" don't satisfy the assumptions of the paper (one of the co-authors admits this in the comment section). To fudge his way around this, in the letter to the WSJ, Distler refers to "the canonical definition of string theory" as opposed to "string theory", although he provides no reference to what this is. Putting "canonical definition" and "string theory" into Google doesn't turn up anything relevant.

It will be interesting to see if a referee can be found who will go along with allowing the "falsifiying string theory" claim. Most physicists, string theorist and not, that I've talked to about this think it's way out of bounds. It seems to me pretty amazing that Distler would choose to take this case to the Wall Street Journal.

We'll also see if the WSJ publishes the letter, if not I've asked one of the co-authors if they'll let me publish it here.

I could certainly do a better job of defending string theory than the people Begley talked to. The strongest argument string theorists have is clearly the one that they have "the most promising approach to quantum gravity". The problem with this is that there are plenty of people who disagree, especially those who do LQG. This is the reason that Distler has been on an anti-LQG campaign throughout the blogosphere recently. His latest posting is about this, with comment section featuring the always incoherent Lubos Motl, and the trademark Distlerian sarcastic sneering at people he disagrees with, e.g. the following comment on a paper by Thomas Thiemann:

I suppose that it is only Thomas's natural modesty that prevented him from submitting this paper for the Clay prize.

In the first comment, someone quotes from my book something I have to say about the issue being discussed in this posting. For the record, I'm no expert on LQG, and can't judge exactly how close they are to having a fully satisfactory quantum gravity theory, but my impression is that what they are doing is a more promising approach to quantum gravity than string theory, and the fact that they are convincing more people about this is what is getting Distler and others very worked up. I also don't think either LQG or string theory has made any headway on the problems of the standard model, although several orders of magnitude more effort have gone into the string theory approach.

Since Distler has a whole posting and ongoing discussion in his comment section about this and I'm no expert, if you want to discuss LQG, its problems and prospects, or comparisons to string theory, please do it there, not here.

Comments

1. **woit**
   June 27, 2006

   As expected, the first comment here was another sortie in the string theory/LQG warfare. I've deleted it, and will delete any others. The commenter did make the useful suggestion that an alternate location for people to discuss this is:

   http://christinedantas.blogspot.com/2006/06/top-10-results-in-lqg-and-spin-foams.html

2. **Aaron Bergman**
   June 27, 2006

   No, the comment was about mostly about you. I only mentioned the link and the frustrating fact that nobody has responded and referred them there.

3. **Peter Woit**
   June 27, 2006

   OK Aaron,

   I don't want anyone to feel that what I'm doing is deleting criticism of me, so here's the relevant part of your deleted comment:

   "I'm beginning to think that string theorists can't win. When we ignore LQG, we're being insular and closed-minded. When we criticize LQG, it's because "they are convincing more people" and that's making us "very worked up.""

   It was deleted purely because since it wasn't explicitly aimed at me, I was sure others would take up the cudgels and respond and the battle woud soon be raging here.

   If this criticism is aimed purely at me, I'll just note that my comments about this have not been that string theorists "ignore LQG", it's that their response to it is nearly uniform hostility. Robert Dijkgraaf, normally a sensible sort, spent part of his summary talk at Strings 2006 making fun of it. David Gross at his recent public talk called it something he didn't normally discuss in polite company.

   Whether this hostility is reasonable or not depends on what you think of the achievements of LQG versus the achievements of string theory. Personally I don't think it's reasonable, but that discussion belongs elsewhere, not here right now.

4. **Garbage**
   June 27, 2006

Hey Peter,

The Distler et al. paper would in principle (in the absence of a light higgs) falsify any theory whose S matrix obeys Lorentz invariance, unitarity and analyticity for all scales. Given that (at least in its perturbative version) string theory was constructed to produce an S matrix obeying such requirements, a violation of the given bounds will imply that whatever it's been called string theory so far can not be a valid UV completion of the standard model. To me, the fact that the paper does not explicitely reffers to what string theory is, or any GUT in particular, is more of a virtue than a weakness, and it is a very elegant way to overcome the decoupling problem (Distler quote as Georgi's). There is a remaining question, namely, at which scale the new physics will enter and whether or not it will be Planck supressed. We are yet to await until LHC answers that question…
Regarding LQG, or other attemps such as discrete QG, it is possible that they might emerge as possible candidates since Lorentz, as well as unitarity violations (without so far drastic consequences) have been found in such scenarios.

5. **Johan**
June 27, 2006

Not that this proves much of anything, but of all the scientists I've talked to, no one's made an impression on me like Thomas Thiemann. He's so smart that it's depressing.

6. **Carl**
June 27, 2006

On the subject of "sarcastic sneering", it seems to me that this is a lot more common now than it once was, and the only explanation for this is that it is more effective now. That is, that people are more afraid now of being ridiculed as a fool.

I am reminded of the Kaczynski's manifesto, where he said that the population was being excessively socialized, and that this was removing their ability to achieve satisfaction. (He found satisfaction by living off the woods and mailing bombs.)

In the logical world of physics and mathematics, sarcasm is an appeal to social pressure that has little obvious place. I've almost just written that it is too bad that there is not more Unabomber types in Physics.

Carl

7. **Arun**
June 27, 2006

Peter,

While not disputing at all the way you characterize the tone of the discussion at Distler's blog, it is true that there is a serious point there. I'll only say that it seems to me that one must read the papers for oneself, there is no other reliable way of knowing the state of LQG.

8. **Peter Woit**
June 27, 2006

Garbage,

The paper is never going to falsify anything. Even the authors admit that their result is only relevant if something that they think is extremely unlikely happens: no light Higgs and you see a violation of their bounds. This is not going to happen, even they don't think so. The result is of purely theoretical, not practical interest.

The claim of "we can falsify string theory" is there for a political reason, to allow one of its authors to attack people like Smolin (e.g. by writing letters to the Wall Street Journal), and any one else who dares point out that string theory is a vacuous idea since it predicts nothing and can't be falsified.

You can't get something for nothing. You can't "falsify string theory" by writing a paper that has nothing to do with string theory. If the authors can show that their results apply to all the classes of models that people doing string phenomenology are currently using to try and make contact with experiment, that would be interesting. They need to actually discuss such classes of real, viable string models and write a paper that says something about string theory before they can claim to be able to falsify the idea.

If their bounds actually were by some miracle violated, what you would see happen is that most string theorists would argue that this meant that QFT was no longer viable and one had to do string theory.

9. **Anon**
June 27, 2006

Is there any class of string models (however unrealistic) that their dispersion relation bounds would not apply to?

If you know of one, you should write a paper about it. As far as I understand, these relations are generic to all (perturbative?) string theory backgrounds.

10. **Peter Woit**
June 27, 2006

Anon,

Most supposedly realistic string theory models that I know about involve introducing branes, which are inherently non-perturbative objects. I just don't see that their arguments apply to these models. If they have an argument that they do, they should make it.

In any case, it's ridiculous to go around saying that you can "falsify string theory" when your argument only applies to perturbative string theory, and the standard ideology of the subject is that understanding non-perturbative string theory is what is going to save the subject from its well-known problems with making contact with reality.

Recall that Gross and many others continually tell us "we don't really know what string theory is", and that understanding what it is will involve getting rid of our conventional ideas about space (and maybe time). Once we do that, what happens to the author's Lorentz invariance and analyticity assumptions?

11. **Anon**
June 27, 2006

Every string background (with some number of flat dimensions) that I know of has an S-matrix which satisfies the usual analyticity assumptions.

If you're arguing that some future developments in nonperturbative string theory will produce backgrounds which violate this property, it's hard to say with any certainty that you're wrong. But there's zero evidence that you're right.

On the other hand, if you are arguing that there's a known string background that violates this property, then you should just say what it is, and end the argument right there.

12. **Aaron Bergman**
June 27, 2006

Robert Dijkgraaf, normally a sensible sort, spent part of his summary talk at Strings 2006 making fun of it.

I wasn't in Beijing, but Dijkgraaf often gives humorous talks. I'd guess that the 'hostility' you're referring to was simply a joke.

I find it depressing that you seem to ignore all the scientific criticisms and just focus on this 'hostility'. Frankly, I'd wish you'd focus a lot less on personality issues and more on science. So, Lubos is an idiot, and you don't like Jacques. That has absolutely no bearing on whether string theory is 'not even wrong' or not. Take this, for example:

The claim of "we can falsify string theory" is there for a political reason, to allow one of its authors to attack people like Smolin (e.g. by writing letters to the Wall Street Journal), and any one else who dares point out that string theory is a vacuous idea since it predicts nothing and can't be falsified.

This is baseless speculation. You have no idea whether it's true or not. So, why say it? I doubt it helps you convince other people.

13. **woit**
June 28, 2006

Anon,

My point is that you don't know what the underlying non-perturbative theory is that determines the background. In the full string theory these "backgrounds" are supposed to have some sort of dynamics. You're working in an approximation where you ignore that and fix the background. In this approximation, if you make certain assumptions, like 4 flat dimensions, maybe you will get the properties at issue. But I just don't see any argument that they are still there outside this approximation.

Again, every talk I've seen David Gross give in recent years he goes on about how really understanding what non-perturbative string theory is will require giving up our standard idea of what space and time is at short distances At short distances, Lorentz invariance is more or less precisely our standard idea of what space and time is. If Gross is right, where's the argument that the analyticity and Lorentz invariance properties at issue will survive in a full theory without conventional short distance notions of space and time?

String theorists assume for no good reason that some unknown dynamics is spontaneously breaking the 10d Lorentz invariance of the perturbative superstring down to 4d Lorentz invariance, no? What's the argument that this unknown mechanism that ruins things in 10d leaves them alone in 4d?

14. **Anon**
June 28, 2006

"You're working in an approximation where you ignore that and fix the background."

In asymptotically-flat spacetimes, different backgrounds are superselection sectors.

"Again, every talk I've seen David Gross give in recent years he goes on about how really understanding what non-perturbative string theory is will require giving up our standard idea of what space and time is at short distances…"

In other words, you don't have an example of a string background whose S-matrix violates these analyticity assumptions, and you are wildly speculating that some future developments in nonperturbative string theory might produce one which does.

That's a pretty thin basis on which to go on the attack.

15. **woit**
June 28, 2006

Aaron,

Yes, Dijkgraaf's comment was a joke, one about how incompetent the LQGers are. Supposedly the audience erupted in laughter at this.

I take one look at Jacques's comment section on his posting, see him up to his normal sneering, other major participants Lubos and Lubos-wannabee Michael, and have a very hard time believing that these are people trying to have a serious scientific discussion. I've had the experience with all three of them of trying to have a serious scientific discussion about string theory, and finding it a waste of time since they weren't interested, but were only interested in attacking me as a crackpot/incompetent/whatever.
Sorry, that's a commentary on personalities and their hostile behavior, but that's what I see.

As for the "string theory is falsifiable" issue, again, I'm calling it as I see it. The WSJ article contained the perfectly accurate statement by Lee that "string theory cannot be disproved". Distler chose to write to them to complain about this, invoking a bogus argument about "canonically defined string theory" that is besides the point, and he should know it.

16. **woit**
June 28, 2006

Anon,

You're ignoring what I write and bringing in irrelevancies.

"In asymptotically-flat spacetimes, different backgrounds are superselection sectors"

Is it known that realistic backgrounds are all different superselection sectors of non-perturbative string theory? I know plenty of string theorists who don't want that to be true and are operating under the assumption that it isn't (e.g. Gross).

The rest of your comment just completely ignores my answers to your question. I don't see the point of retyping it again.

17. **Anon**
June 28, 2006

I think you completely misunderstand Gross's position, and am pretty certain he would disagree with you on the S-matrix in nonperturbative string theory.

If you want to cite him as an authority in your argument with Distler & co., you'll have to do better (like maybe solicit a statement from him, supporting your position).

18. **Aaron Bergman**
June 28, 2006

Sorry, that's a commentary on personalities and their hostile behavior, but that's what I see

If you don't like the tone there, how about the criticism by people like Nicolai, Peeters & Zamaklar, Helling & Policastro, and others? It's hardly fair of you to ignore it. Regardless, the personality of the person doing the criticism has absolutely no bearing on the legitimacy of the critique.

19. **DC**
June 28, 2006

Question:

Is each of the 10^500 worlds of the anthropic principle a (theoretical) closed system? If so, I would say that the requirement for the existence of 10^500-1 universes completely immune to observation is a particularly troubling weakness of string theory.

(6 yr old Physics *AB* here, so please don't get too technical…)

20. **sunderpeeche**
June 28, 2006

One obvious question is why did 2 coauthors agree to put their names on a paper with a title "Falsifying String Theory …" if the paper has nothing to do with ST?

21. **Cecil Kirksey**
June 28, 2006

Peter:

I have enjoyed reading your blog. I discovered it by googling for "critique of string theory". I will certainly buy your book when it comes out. I think I understand your arguments against string/M theory. But to help clarify your position can you please respond to the following.

There seems to me to be three possibilities:
1. String/M theory is wrong. Our universe is not described by this theory.
2a.String/M theory is correct but our universe is not unique and that there is no vacuum selection principle. There are multiple universes and ours is just one manifestation of this theory.
2b. String/M theory is correct. Our universe is unique but we humans will forever lack the mental capacity to discover the vacuum selection principle.
2c. String/M theory is correct. Our universe is unique and we humans have the mental capacity to discover the vacuum selection principle but as of yet have not done so.
3. In the development of string/M theory a logic error or incorrect assumption was made and if corrected a valid theory will be discovered.

If 2 is correct then by definition the theory CANNOT be falsified. And the theory can make very general predications and be adjusted to agree with any observation. This seems to me to be your primary issue.

I am most interested in the third possibility. If you believe that string/M theory is "not even wrong" is it due to option 1 or 3? It seems to me that it maybe possible for some smart iconoclastic theorist to revisit the formulation of string/M theory and revise some of the assumptions used to develop the theory. Thus possibilly avoiding the vacuum selection problem. Reducing from "real" 10 or 11 spacetime dimensions to 4 forces one to invent or discover a vacuum selection principle. But suppose we are misled in to believing that compactification is even required?

Suppose that the universe really has a fourth spatial dimension of the same "size" as the other three that we experience. How would this fourth dimension make itself known to us? Either through our senses or instruments that we make to observe some measurement. But the measurement to be made is based on some theoretical prediction. Most arguments that reject more than three spatial dimensions assume that GR is valid in more than four spacetime dimensions. Suppose it is not valid then what? How would string/M theory look if compactification was not invoked? Just some thoughts.

Thanks for a great blog. I look forward to reading your book.

22. **woit**
June 28, 2006

sunderpeeche,

The two coauthors are not string theorists.

Aaron,

I don't know how many hundred times I have to say something like this. I'm a particle theorist, not a quantum gravity theorist. As a result, I've not spent time paying close attention to exactly what the state of the LQG program is and don't intend to. Many other smart people are and I think that's great, but life is short and one has to decide what to spend one's time on. People with these interests should respectfully debate the technical problems involved, learn new things and try and make progress, or give up and do something else if the problems are insuperable. If I wanted to work in this area, I would encourage this discussion here and take part in it. I don't at the moment, but want to think about and discuss other things. I have every intention of ignoring the detailed criticisms of LQG, just as I ignore the details of what people working in LQG have accomplished, and I think this is perfectly fair. If string theory's only claim was that it was a theory of quantum gravity, I'd be ignoring that too, and so would most of the rest of the physics community.

Anon,

You continue to just ignore the points I make and questions I ask and raise irrelevancies. I was not invoking Gross as an authority for anything I had to say, just as the most well known example of someone who believes that string theory is someday actually going to explain the properties of the standard model. If string theorists have completely given up on this, they should say so, and let Mike Peskin know he should stop telling the media the reason to believe in string theory is that it is going to explain the number of generations.

23. **woit**
June 28, 2006

Cecil,

My belief is simply 1. As an idea about unification, string theory is just wrong, and fundamentally so. It can't be fixed by just changing one piece of it.

The physical effects of extra dimension depend on exactly how you introduce them. The study of these possibilities is what thousands of physicists have been working on for more than 20 years. None of the infinite variety of effects predicted by any of these possibilities have ever been observed, and even most string theorists don't expect to be able to observe them in the forseeable future.

24. **sunderpeeche**
June 28, 2006

As a non-string theorist, I would not put my name on a ST paper. I would not put my name on any paper where I was not satisfied or could not validate the contents (I might compromise on the wording etc with coauthors, but not on the substance of the paper). Why would 2 non-string theorists agree to put their names on a paper if they could not establish the veracity of its contents?

25. **woit**
June 28, 2006

sunderpeeche,

You'll have to ask them. I assume that they found assurances from their co-author and other string theorists they talked to sufficient. It's not exactly unusual though in science for some co-authors of a paper to not be experts on all aspects of the paper, and to rely on the expertise of others.

26. **Tony Smith**
June 28, 2006

Peter, you say
"… The lack of any serious (Lubos … and the trademark Distlerian sarcastic sneering … doesn't count) response to my book from string theorists since its appearance in the UK a month or so ago has begun to surprise me a bit. ….".

Such silence sounds to me similar to the 1950s when Oppenheimer, the then-current Pope of Princeton who advocated the Copenhagen interpretation of QM, said about Bohm, who was working on an alternative interpretation:

"… if we cannot disprove Bohm, then we must agree to ignore him. …".

The source of the quote was Max Dresden (in my opinion impeccably honest) and The Bohm biography Infinite Potential, by F. David Peat (Addison-Wesley 1997),page 133. Here are some relevant excerpts from that book:
"… Max Dresden … read Bohm's papers … errors were difficult to detect … von Neumann's "proof" … did not rule out the sort of theory that Bohm had proposed. … Oppenheimer [said]…
"We consider it juvenile deviationism … we don't waste our time …" [by] actually read[ing] the paper …
Dresden … present[ed] Bohm's work in a seminar to the Princeton Institute …
The reception he received came as considerable shock to Dresden. Reactions to the theory were based less on scientific grounds than on accusations that Bohm was a fellow traveler, a Trotskyite, and a traitor. It was suggested that Dresden himself was stupid to take Bohm's ideas seriously. … all in all the overall reaction was that the scientific community should "pay no attention to Bohm's work" … Abraham Pais also used the term "juvenile deviationism". Another physicist said that Bohm was "a public nuisance" …".

It seems that the silent treatment plus ad hominem attacks has been a tradition of the USA physics community for at least 50 years. Plu ca change …

June 28, 2006

sunderpeeche said:

> As a non-string theorist, I would not put my name on a ST paper. I would not put my name on any paper where I was not satisfied or could not validate the contents…

My name is on papers I have yet to read fully. Many times (if I know the other authors personally and trust them) I have written my section and, based on a few meetings, have assumed the other authors would do a good job.

I am not in anyway endorsing my own actions, but I am making the point that not all scientists take as much care as you.

28. **D R Lunsford**
June 28, 2006

OK, a quick glance at this paper, where is the string theory? You might as well replace the words "string theory" by "homuncular biology", "phlogiston dynamics", or "epicyclic astrometry".

Suppose that the universe really has a fourth spatial dimension of the same "size" as the other three that we experience. How would this fourth dimension make itself known to us?

You couldn't tie your shoes.

-drl

29. **justin**
June 28, 2006

"I've not spent time paying close attention to exactly what the state of the LQG program is and don't intend to." — PW

This is a little frusterating for those of us who would like to engage you in a discussion in the relative merits of string theory as a research program.

1) You say that you would like to see hep-th research substantially diversify.

2) Many of us point out that there is really no viable alternative to string theory as a theory of quantum gravity. If planck scale physics is your interest, string theory is the only game in town.

3) You object, saying that LQG is a neglected but nevertheless thriving alternative to string theory as a research program in QG.

4) We disagree, and try to explain why in scientific and technical terms

5) You shut down the discussion, explaining that you don't care about QG anyway and you have no interest in becoming educated on the issue.

Unfortunately, QG is the primary achievement of string theory. If you don't care about QG, its no wonder that string theory is not of interest to you—for physics at the TeV scale, everyone will agree that the explanatory power of string theory is weak at best. Fine, but if you don't care about QG, you have no right to criticize people who do.

But I suspect that you do care about QG. Every hep theorist wants to know physics at the ultimate cutoff. In this case, if you want to be critical of string theory, you should have something to say about its obvious alternatives. Especially, you should be open to the possibility that the alternatives might not be any better, or even far worse (as is the case for LQG, in my opinion).

30. **sunderpeeche**
June 28, 2006

A very nice letter from Michael Peskin to the EPP2010 committee. In the end, one must just see what the LHC produces (and build the ILC!). It's the only way to know just how wrong life, the universe and everything is.

June 28, 2006

"If Gross is right, where's the argument that the analyticity and Lorentz invariance properties at issue will survive in a full theory without conventional short distance notions of space and time?"

Sure the scenario might no be that realistic, nevertheless, it opens a new windows worthwile exploring. But that is not the point here, the point is that, if the bounds are actually violated in the absence of a light Higgs (physically possible though unlikely) ST will have to start taking these ideas you point out a bit more seriously….LQG at al. have explored them enough to start to be a serious candidate if such case were to happen in nature.
I dont understand why is it so hard to admit that this sort of dispersion relations are sensitive to the UV in such a way that assumptions on the UV completion of the SM can be tested, included ST or whatever GUT you want.

33. **Thomas Love**
June 28, 2006

Peter wrote:

"I'm a particle theorist, not a quantum gravity theorist. "

Einstein's basic idea was that the particles (he only spoke of the electron and proton) should arise naturally from the geometry of space-time. What is quantum gravity but a study of the excitations of space-time? Thus I would argue that 'particle theory' and 'quantum gravity' are synonyms.

34. **fh**
June 28, 2006

Aaron Bergmann, the critique is unreasonable because some of these issues at least have been pointed out to Distler and he keeps making the same wrong or irrelevant points over and over again.

Most of the criticism can be reduced to "it's unfamiliar".
Other of the criticisms voiced (re: QCD) have actually been answered by Thiemann on the String Coffee Table more then a year ago. The attack on the mathematical quality and accuracy of the work of people on the level of Thiemann and Freidel discredits Distler further. It's hard not to read this as malice.

35. **Cecil Kirksey**
June 28, 2006

Peter:

Thanks for the reply. But if you believe #1 in my list of possibilities, and since the theory has not been falsified what do you SPECIFICALLY believe that the theory assumes is not compatible with our universe. Is it the idea of strings per se or some addition assumptions that are invoked to eliminate some apparent mathematical problems.

36. **woit**
June 28, 2006

Justin,

I don't agree at all with your comments about the relative value of string theory and LQG as theories of quantum gravity, but that's just not a point I want to spend my time arguing. Other people can do that much better than me. I'm not shutting down this discussion, I'm pointing people to the most appropriate places to carry it on, which are at the blogs of people working on LQG or actively interested in discussing it. Some string theorists refuse to believe me, but I honestly take great care to not go on about things I don't understand. I just don't have the time now to develop the kind of expertise required for me to feel comfortable engaging in the kind of arguments over LQG that people want to have.

The problem with string theory as a theory of particle physics is not that its explanatory power at the TeV scale is "weak at best". Its explanatory power as regards particle physics is zero at any scale, up to and including the GUT scale and beyond. If string theorists will finally admit this, and stop continually promoting their subject as a unified theory that is going to explain the standard model, you're going to hear a lot less from me about this. What I am upset about and trying to do something about is the disastrous effect string theory has had on the subject that matters most to me, particle theory. If you want to argue this point, I'm happy to do it here. If you want to argue about LQG, you should be doing it with an LQG expert.

37. **woit**
June 28, 2006

Cecil,

I specifically believe that the idea that the universe is 10 or 11 dimensional, with the properties of particles dependent on how you get rid of the other 6 or 7 dimensions, is fundamentally wrong and can't ever work.

38. **sunderpeeche**
June 28, 2006

Reply to ksh95 — in a large expt HEP collaboration, indeed one cannot demand editorial control over the whole paper. But (I presume) you could in principle validate the contents of the whole thing if you tried. Surely the two coauthors on Distler's paper could verify if the contents of the paper actually had any ST? Or if the title was appropriate?

39. **woit**
June 28, 2006

Thomas,
Unfortunately, Einstein was wrong about this. Particles are excitations of quantum fields. If someone has an idea of how to get these quantum fields out of the geometry of space-time, I'm all ears, but I haven't seen a really promising one yet.

40. **Anon**
June 28, 2006

FH,

Maybe you should leave a comment over there, pointing out his errors and misunderstandings. If he's wrong or off the mark, it should be easy to point out where he's gone astray.

41. **Alejandro Rivero**
June 28, 2006

The subtext of Justin's comment it is very clear: a theory of particle physics is not ultimate, so particle physics is not a worthy pursuit, only gravity is.

42. **woit**
June 28, 2006

Garbage,

What I'm denying is that "string theory" is well enough understood in the UV for this kind of argument to falsify it. That's all. The argument is "If string theory satisfies A, B, C then bounds". If bounds are violated, this doesn't falsify string theory.

43. **woit**
June 28, 2006

I should perhaps explain my point of view about quantum gravity a bit more.

Sure, I'm interested in it, and try and follow what people are doing. But, unless somebody figures out a way to measure QG effects experimentally, it's a problematic research area. I've written about this elsewhere. I believe that we're not going to really understand QG until we understand in a unified way the dynamics of space-time geometry and the dynamics of the Standard model geometry. If and when we do that, we'll have a QG which is linked into a structure which is testable. String theory purports to do this, but it has failed. Pretty much all the LQG stuff I have seen doesn't even try and do this, except for some recent stuff, which to me looks highly preliminary, but if it starts looking more convincing, I'd definitely be spending time paying attention to it.

44. **Aaron Bergman**
June 28, 2006

Aaron Bergmann, the critique is unreasonable because some of these issues at least have been pointed out to Distler and he keeps making the same wrong or irrelevant points over and over again.

What does Jacques have to do with any of this? As best I've been able to discern, the questions I asked over on Christine's blog have not ever been responded to, except that Lee did say that he has wondered about the Immirizi parameter issue, too. A lot of physicists read this blogs if you haven't noticed, and I can tell you that the silence in response to these issues plays into the bad reputation that LQG has with some people I've talked to.

Out of deference to Peter, I won't say any more here, but if you claim the questions have been answered, can you please post some links over on Christine's blog, and I can respond there?

45. **Thomas Love**
June 28, 2006

Peter, "It's a difference of opinion which makes horse races".

I replied privately with details.

46. **Aaron Bergman**
June 28, 2006

I did a little more googling, and I'm being a bit unfair to Lee. He did respond that, *contra* Carlip, he believed there was a unique quantization of quantum gravity in 2+1 dimensions (I believe Freidel implied the same) and encouraged me to do further research on the comparison of Carlip and LOST.

47. **Cecil Kirksey**
June 28, 2006

To D R Lunsford:

You responded to my completely reasonable question:

"Suppose that the universe really has a fourth spatial dimension of the same "size" as the other three that we experience. How would this fourth dimension make itself known to us?"

with:

"You couldn't tie your shoes."

I suppose that is to be interpreted as a rejection of a large fourth spatial dimension. But maybe you can tell me: How do you know? How would this fourth dimension reveal itself? In some braneworld models the higher dimensions are hidden apparently except through gravity. But I was even questioning this. How do we know that GR is valid in more than four spacetime dimensions?

48. **Garbage**
June 28, 2006

"The argument is "If string theory satisfies A, B, C then bounds". If bounds are violated, this doesn't falsify string theory."

??????

If string theory satisfies A,B,C and the bounds which follow from such assumptions are violated, the only logical conclusion is that A,B,C can not be part of the UV completion of the SM, and all the version of ST with A,B,C should be ruled out [There are thecnical issues as to whether higher order operators might spoil the bounds if the cutoff is somehow lower than naively expected]
If, as you point out, that means we should give up in Lorentz invariance, that is a huge step and the efforts to produce such type of constraints extremely important an worthwhile pursuing. Can you imagine to turn on the LHC and be able to probe Lorentz invariance!!
Again, it is unlikely there is a light higgs as it is that the bounds will be violated, it is also unclear whether there is Planck supression, this is also related to extra dimension and the actual scale of gravity. That doesnt mean, as a matter of principle, that all the forms of ST known so far to obey Lorentz invariance (analyticity and unitarity) will be potentially falsified!

Note: I'd say that unitarity might as well break down at scales where our notion of spacetime doesnt make any sense. I have no intuition for analyticity though… 🙂

49. **Chris Oakley**
June 28, 2006

Peter,

I found your book in the two main Cambridge (UK) bookshops (Heffers & Borders) today. FWIW, the Borders one had a handwritten staff recommendation (the only one in the science section). One thing though – I don't think that the picture of you on the inside back cover is very suitable. You look too much like a student who has just committed a prank.

So for the US edition I propose the following: a picture of you holding a sword aloft with a suitably stern expression and hair and doctoral robes billowing out behind. Borrow a wind machine from the labs if necessary to achieve the latter effect.

50. **Tony Smith**
June 28, 2006

Sunderpeeche said "… A very nice letter from Michael Peskin to the EPP2010 committee. In the end, one must just see what the LHC produces (and build the ILC!). …".

Although I very strongly agree with Peskin's overall recommendation that the LHC should be supported and the ILC built (particularly with respect to getting a fuller understanding of the Higgs mechanism), Peskin made a statement that I consider to be significantly historically inaccurate:
"… Super-symmetry was first discovered as a theoretical concept in superstring theory. …".

IIRC, supersymmetry became of high interest to particle physics theorists with respect to supergravity theories, in which super-Lie algebras were used to evade the Coleman-Mandula theorem that obstructed unification of gravity with the Standard Model.

This is not just a minor historical nit-pick, in light of the tendency of partisans in the superstring/LQG war to act as though the only games in town for Quantum Gravity are superstrings and LQG,
despite the fact that
supergravity theories united Gravity and Particle Physics by using the MacDowell-Mansouri mechanism with respect to a Sp(2) = Spin(2,3) Lie algebra (as part of the relevant Lie superalgebra) to produce a gravity Lagrangian that looks a lot like Einstein-Hilbert.

Therefore, it seems to me that modification or generalization of supergravity should be at least an equal participant in the Quantum Gravity wars now dominated by superstring and LQG partisans.

In fact, since some M-theorists see N=8 supergravity as a possible limiting case of M-theory, it may be that supergravity could be advocated as part of the string theory agenda, but to do that right, they would have to show explicit equivalence between the direct superstring gravity formulation and the limiting case supergravity MacDowell-Mansouri gravity (i.e., to explicitly show in detail the superstring – M-theory – supergravity relationship). AFAIK, that has not yet been done.

My primary point in writing historical comments such as this and a few other recent ones on this blog and JoAnne's entries about LHC data at Cosmic Variance is that those who ignore history may be condemning themselves to repeat its mistakes.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – It seems to me that DRL's statement that if we live in 4 large spatial dimensions we could not tie our shoes is clear, but another commentator seemed to have difficulty with it, so here is another (more or less equivalent) formulation:
If we lived in 4 large spatial dimensions there would be no way to distinguish left-handedness from right-handedness, thus invalidating a lot of particle physics experimental results (there was an old Outer Limits TV show about that point).

51. **justin**
June 29, 2006

Dear Peter,

I respect your desire not to engage in discussion outside of your knowledge base… however, I encourage you to form some opinion on the alternatives to ST, since I think this is very relevant to the discussion. If there were 15 alternative approaches to QG which were even half as promising as string theory, the state of our field would be very different.

"The problem with string theory as a theory of particle physics is not that its explanatory power at the TeV scale is "weak at best". Its explanatory power as regards particle physics is zero at any scale, up to and including the GUT scale and beyond." –PW

I think this is unfair. We don't know physics beyond the TeV scale, so we have no idea whether string theory could provide a useful explanation for it. String theory at least provides some pictures for what this physics could be.

52. **anonymous**
June 29, 2006

Hi Aaron,
The lost theorem only talks about the uniqueness of the kinematical (prior to solving the Hamiltonian constraint) Hilbert space. Different choices of Hamiltonian constraint operator can lead to inequivalent physical Hilbert spaces. (ofcourse how to define inner product on kernel of Hamiltonian constraint in the absence of observables is a even more vexing issue.) Also as the lost theorem is based on a number of requirements (unitary-anamoly free implementation of spatial diffeomorphism being one of those), violation of any one of those could lead to an inequivalent Hilbert space (even prior to solving the constraint).
I apologise if this answer isnt pertinent.
Also on a side note, as a graduate student in lqg i find it astonishing that many people seem to think that string theorists who have studied lqg and are skeptical about it (jaques and aaron and urs for example) are trying to undermine the field. All they do is ask genuine technical questions, & there's absolutely no malice involved in any of it. It seems to me that there is always a bit of overselling of results going on in this field (& maybe in high energy physics in general), pointing it out, or questioning it doesnot amount to any offense at all.

53. **D R Lunsford**
June 29, 2006

Justin,

Sorry to butt in, but you said

I think this is unfair. We don't know physics beyond the TeV scale, so we have no idea whether string theory could provide a useful explanation for it. String theory at least provides some pictures for what this physics could be.

But that's just what it doesn't do – things which provide accurate "pictures" (however you want to interpret that) also provide accurate physical calculations according to a precisely defined model – this is the ultimate credo of physics. Correct me if I'm wrong.

-drl

54. **Alejandro Rivero**
June 29, 2006

If there were 15 alternative approaches to QG which were even half as promising as string theory, the state of our field would be very different.(justin)

Any comment about why string theory papers are uploaded to hep-th instead of gr-qc, then?

55. **Chris Oakley**
June 29, 2006

Lubos seems to have removed his review of NEW from the amazon.co.uk web site.
Or maybe it did not meet Amazon standards, and they removed it themselves.

56. **Tony Smith**
June 29, 2006

Chris Oakley said "… Lubos seems to have removed his review of NEW from the amazon.co.uk web site.
Or maybe it did not meet Amazon standards, and they removed it themselves. …".

However, as of the time I am writing this comment, Lubos's review is still among the 9 reviews on the USA amazon.com web page for the UK version of Peter's book.
The USA web page seems to have listed the UK version for book resellers who have UK versions for resale in the USA. In the past, there have been a number of such books for sale on that page, but now the page says
"… THIS TITLE IS CURRENTLY NOT AVAILABLE. If you would like to purchase this title, we recommend that you occasionally check this page to see if it has become available. …"
so I guess the USA resellers are as of now sold out of the UK version.
Maybe they will restock and it can again be bought through the USA amazon.com.

Here are the 5 current customer reviewers of the UK book on the UK web site amazon.co.uk
LEJ Brouwer
J. B. Cook (UK)
Reader (Australia)
Sam "Sam" (UK)
Dr. C. G. Oakley (Dunstable, Bedfordshire United Kingdom)

Here are the 9 current customer reviewers of the UK book on the USA web site amazon.com
LEJ Brouwer
truth eker (Canada)
Knotted String
Humble Priest "String Theorist" (USA)
M. Wang "mrnexus" (CT United States)
J. B. Cook (UK)
Lubos Motl (Cambridge, MA United States)
Sam "Sam" (UK)
Dr. C. G. Oakley (Dunstable, Bedfordshire United Kingdom)

It is interesting to read all those customer reviews.
Here is an excerpt from the 5-star review by Humble Priest "String Theorist" (USA):
"… I'm a string theorist by the way, which is why I'm hiding behind a pseudonym (I don't want to be called a "science hater" by my seniors). …".

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – I think that amazon must not allow customer reviews of books not yet available, as there are no customer reviews on the USA amazon.com web page for the not-yet-released USA version of Peter's book. However, there is a Beta-version customer discussion feature (as of now it has only one participant, me).

57. **You**
June 29, 2006

Lubos has posted Barton Zwiebach's response on his blog.
http://motls.blogspot.com/2006/06/barton-zwiebach-letter-to-editor.html

58. **I**
June 29, 2006

In regards to Zwiebach's response, this pretty much sums things up:

"All that is needed to rule out string theory is showing that no solution describes our universe."

That should be easy.

(BTW, Isn't that what led to the anthropic landscape in the first place?)

59. **Tommaso Dorigo**
June 29, 2006

Hi all,

in Lubos' site, today Zwiebach is quoted as saying:

"[string theory] has explained, for example, why black holes have entropy and temperature."

Can I get some insight on this ? What is Zwiebach referring to, and what is true about it ? Sorry for my ignorance…

Cheers,
T.

60. **Tony Smith**
June 29, 2006

As "You" noted, Barton Zweibach's letter to the Wall Street Journal editor is posted on Lubos Motl's blog. In it, Zweibach says:
"… string theory … computations give unequivocal answers.
… All that is needed to confirm string theory is finding one solution that describes our universe. All that is needed to rule out string theory is showing that no solution describes our universe. An answer must exist. …".
That is true.
What Zweibach does NOT say is that after two decades of work by many well-funded superstring theorists, none of them have found ANY "string theory … computation" that "describes our universe" in the sense that it gives the force strengths and particle masses of the Standard Model.
Perhaps two decades of failure to find such a solution is an indication that such a solution does in fact not exist, thus providing Zweibach's "answer":
conventional string theory, as a unification of gravity and the Standard Model, is probably wrong.

Zweibach also says:
"… a healthy equilibrium exists where string theory and other good ideas are explored and compete for attention …".
However,
a competing model that allows computation whose answers (unlike those of superstring calculation) are explicitly known and consistent with experimental measurements of such parameters of the Standard Model,
is
ignored by theoretical physics institutions and and its developer (me) is blacklisted by the Cornell arXiv for physics papers and is subjected to ad hominem attacks by Harvard Professor Lubos Motl as a "… moronic … crackpot …".

Tony Smith
http://www.valdostamuseum.org/hamsmith/

PS – My competing model can be formulated in terms of a NON-supersymmetric string theory in which strings correspond to world-lines of particles, but Lubos Motl attacked it as not being "string theory" because it did not have conventional supersymmetry.
Maybe when the LHC collider data that is to begin to be taken around 2008 will show whether or not such supersymmetry is consistent with experiment. Peter, in his blog entry "Strings 2006", quoted Jonathan Schock as saying, about the coming LHC experiments:
"… … if supersymmetry is found … then we all will be together [at a Strings 2009 meeting] to celebrate it and if it is not found we will be together for a collective suicidal. …".

61. **Benjamin**
June 29, 2006

Tony, You say ‘That is true’ to Barton Zwiebach’s claim that “All that is needed to confirm string theory is finding one solution that describes our universe.” But is that so? If I understand Peter Woit, a theory with 10^500 possible universes is a ‘theory of anything’, unless you can specify the mechanism that singles out one of these vacuum states. If it is just something like ‘spontaneous symmetry breaking’, which sounds like pure chance to me, then it seems to me you haven’t really explained anything. Of course, as an ignorant layman, I may not have my facts straight. 🙂

62. **sunderpeeche**
June 29, 2006

Tommaso this may be helpful

http://en.wikipedia.org/wiki/Black_hole_entropy

63. **PPCook**
June 29, 2006

Dear Tommaso,
I think Zweibach is referring to the emergence of the Hawking-Bekenstein entropy law from a string theory picture of a black hole. While we have very little evidence of black holes themselves, general relativity leads to a theoretical framework where there is a duality between black hole properties on one side and macroscopic thermodynamic properties, such as entropy, temperature, free energy, on the other. There is no parallel for microscopic properties from GR alone.

Using string theory to model a black hole, and imagining the microstates of a black hole to be string excitations, Strominger and Vafa, were able to find the entropy of a 5-dimensional Reissner-Nordstrom black hole from the microscopic states. The entropy calculations have been extended to a large range of black holes with success. That string theory can model the microstates of a black hole means it fulfils a necessary criterion for any theory of quantum gravity. In this sense sometimes this is (mis)referred to as an experimental test of string theory.

It is a very actove area of string theory reserach at the moment, and the string picture has lead to corrections to the Bekenstein-Hawking area/temperature law and even to the idea that the black hole has no precise event horizon when viewed from close-up – the event horizon becomes pictured as a statistical distribution, like temperature, that only makes sense when viewed from far away (in the same way that if you were riding a molecule in a gas, the temperature of the gas as a whole would be a strange concept for you, but if you were macroscopic experimenter then temperature is a very clear concept). The theoretical picture is making progress, all we need now is a black hole to experiment with…

This is, arguably, the greatest result of string theory to date. Zweibach’s wonderful purple book, Chapter 16, has an excellent introductory review.

Best wishes,
Paul

64. **Chris Oakley**
June 29, 2006

From Zwiebach’s article:

> [String theory] has explained, for example, why black holes have entropy and temperature.

Right … so ST has explained the existence of unobserved physical properties about a possibly non-existent class of objects.

That’s good enough for me. I’ll now go and remove all the negative things I have said about ST from my web site.

65. **fh**
June 29, 2006

The “it has many sollutions” paradigm is already a change to what, for example Lubos Motl was arguing a while ago, that is, that it’s essentially unique.

As such it is of course not a theory of anything. Newtons formula F = ma is of course completely unspecified until you define F in terms of x, yet few would argue that it’s therefore vaccuous.

String theory is unique in getting a relationship between the effective QFT picture and Gravity. There is no other theory that can do this at the moment (some loopy results might be getting there, but it’s not here yet). At the same time it’s hard to see how to answer the hard conceptional questions from the String theory PoV precisely because it is so tightly tied to the effective field theory picture.

JDs critizism of LQG is that it does not relate to the effective field theory picture, well yes, that’s the point. It’s not a local field theory.

66. **sunderpeeche**
June 29, 2006

Why claim that black holes do not exist? Hawking (+ Penrose?) proved long ago that GR must have singularities. I believe there is expt observation of black holes, see this from HST

http://hubblesite.org/newscenter/newsdesk/archive/releases/1994/23/

67. **Tony Smith**
June 29, 2006

As Benjamin said, I said “… ‘That is true’ to Barton Zwiebach’s claim that “All that is needed to confirm string theory is finding one solution that describes our universe.” …”,
and
Benjamin asks “… But is that so?
… unless you can specify the mechanism that singles out one of these … 10^500 possible … vacuum states …[other than]… pure chance …
then it seems to me you haven’t really explained anything. …”.

Benjamin, I think you do have your facts straight.
When I said “That is true” I was assuming that Barton Zweibach’s “… finding one solution that describes our universe …” would be based on his finding some sort of

reasonable uniqueness criterion, not based on something like a pure chance random search.

So, I stand corrected. I should have said:

Zweibach says:
"… string theory … computations give unequivocal answers.
… All that is needed to confirm string theory is finding one solution that describes our universe.
All that is needed to rule out string theory is showing that no solution describes our universe.
An answer must exist. …".

Zweibach's first alternative should be divided into two possibilities, giving a total three:

1 – finding one solution that describes our universe, and finding that it has unique characteristics (other than just happening to correspond to the properties of our universe) that single it out from all other (about 10^500) possibilities, would confirm superstring theory;

2 – finding one solution that describes our universe, but finding that it has no uniquely distinguishing characteristics from all other (about 10^500) possibilities, would show that superstring theory is Not Even Wrong;

3 – finding that no solution describes our universe would show that superstring theory avoids being Not Even Wrong by in fact being Wrong.

Among those three alternatives, I think that "An answer must exist".

Thanks, Benjamin, for pointing that out.

My personal guess as to which alternative is true is still that superstring theory is Wrong (my third alternative), because failure to find a solution (in ANY way, random or not) by two decades of work by many hundreds of very (techically) smart, well-funded people indicates to me that such a solution is unlikely to exist, thus providing the "answer":
conventional string theory, as a unification of gravity and the Standard Model, is probably wrong.
My conviction as to my guess is supported by the attitude of people like Jonathan Schock, who (according to Peter's quote) said that at Strings 2009, "…if supersymmetry is … not found [by LHC] we will be together for a collective suicidal. …".

Tony Smith

June 29, 2006

I just wrote a new posting about the Zwiebach letter. Please continue discussion of it there.

69. **Kris Krogh**
June 29, 2006

Sunderpeeche,

You're twisting Chris Oakley's words. He's not claiming black holes don't exist. Just saying it hasn't been proven they do. That's true.

The NASA page you point to describes a dark, supermassive object in the M47 galaxy. There are GR alternatives that predict such things (see http://www.arxiv.org/abs/astro-ph/0606489) without black hole singularities.

There's also a dark, supermassive object, Sgr A*, in this galaxy. But a close look shows it or something nearby radiates at long wavelengths.

70. **Kris Krogh**
June 29, 2006

Sorry for the typo. That should read M87, not M47.

71. **Kris Krogh**
June 29, 2006

Peter,

Sorry again. Missed your last comment.

72. **Shantanu**
June 29, 2006

Peter and others,
since we are discussing quantum gravity., I urge all of you to read this nice
preprint which appeared just yesterday gr-qc/0606120 (which talks about possible
experimental tests). I am surprised no one has discussed it in the blogosphere/

73. **D R Lunsford**
June 29, 2006

Cecil,

http://www.people.fas.harvard.edu/~math21a/exhibits/unknotting/index.html

And, what Tony said.

-drl

Zwiebach Letter to the WSJ

June 29, 2006
Categories: Not Even Wrong: The Book

Over at his web-site, Lubos has posted a [letter to the Wall Street Journal]() from Barton Zwiebach. The letter seriously misrepresents the current state of string theory in several ways:

string theory is an extraordinarily precise and rigorous framework where facts can be proven beyond doubt and computations give unequivocal answers.

All that is needed to confirm string theory is finding one solution that describes our universe. All that is needed to rule out string theory is showing that no solution describes our universe. An answer must exist.

Zwiebach gives the impression that there are rigorously well-defined, "extraordinarily precise" equations that characterize string theory, and all that is needed now is to solve the technical problem of finding the solutions to these equations and seeing if one of them agrees with what we observe. This is simply not true. Since we don't know what non-perturbative string theory is or what its equations are, all equations used by string theorists to generate solutions are not "extraordinarily precise", but are explicitly approximations, often very crude ones, whose reliability is unknown. If you look at the debate over the landscape, you will find that not only do most string theorists not believe that the solutions involved are "facts can be proven beyond doubt", many of them believe these are not real solutions to the full unknown theory at all.

Even if one does believe in the rigorous nature of the landscape solutions, Zwiebach's claim that all one has to do is examine them to see if they agree with nature is again highly misleading. If there are 10^{1000} or more of these solutions, all evidence is that identifying which of them have desired properties (e.g. the correct CC) is an inherently computationally intractable problem. Even if one could do this, the class of solutions that agree with all known values of the parameters characterizing the standard model seems likely to be so large that no new testable predictions would be possible.

Zwiebach also claims:

String theory has explained, for example, why black holes have entropy and temperature.

This is what Hawking did back in 1974 with a semi-classical calculation. Any theory of quantum gravity should reproduce this. What string theory adds to Hawking's calculation is a long story, but if we manage to observe a black hole any time soon and it behaves as Hawking predicted, he's the one who is going to get a Nobel prize for explaining "why black holes have entropy and temperature", not string theorists.

I had been wondering what the response from string theorists would be to the public dissemination of arguments from Smolin and me about string theory. The response seen here from Distler et. al. and Zwiebach is not at all what I expected. Most serious string theorists I talk to take the reasonable attitude that string theory is still so poorly understood that it cannot be confronted with experiment, even in principle. Many publicly say that we still don't know what "string theory" is. Zwiebach seems to believe that there now exist "extraordinarily precise" equations, with solutions that will give "unequivocal answers". Whether this is true is a well-defined question. All he has to do is explain what these equations are, and let's see if the string theory community will really stand by this definition and let string theory be judged accordingly.

Finally, perhaps the most surprising aspect of Zwiebach's letter is the form in which he has chosen to distribute it. I and many people have been wondering what Lubos Motl's colleagues in Cambridge think of the way he is defending their subject. Now at least one of them has made clear that he is fine with this and willing to encourage it.

Update: The [usual response]() from Lubos Motl/Bill O'Reilly: an endless rant about how stupid people who disagree with him are, completely ignoring the scientific questions at issue.

Comments

1. **sunderpeeche**
   June 29, 2006

   Write a rebuttal letter to WSJ.

2. **Peter Woit**
   June 29, 2006

   sunderpeeche,

   First let's see which if any of the letters the WSJ decides to publish. They may very well not find them credible or worth publishing. If they do, then maybe a rebuttal would be in order.

3. **Chinmaya Sheth**
   June 29, 2006

   I am no string theorist (I haven't even completely digested the possibility of extra dimensions yet) but this is my opinion:
   Zwiebach is a serious string theorist: in his book he explicitly states that string theory is not yet completely understood and that it makes no sharp prediction. In the letter itself Zwiebach doesn't say there are precise equations defining string theory, only that it is a precise framework; again hinting that it is not completely developed.

4. **Robert**
   June 29, 2006

   I would say Hawking demonstrated *that* black holes have a temperature and radiate. To say *why* you have to give a microscopic description.

   QED is also only known perturbatively (lattice QED is no good) so do people know what it means?

   The rest has been said over and over again, so I am not going to repeat it.

5. **Peter Woit**
   June 29, 2006

   Chinmaya,

I suppose that perhpas one can parse Zwiebach's letter in some way that makes what he says technically true. But claiming to the public that you have an "extraordinarily precise and rigorous framework" and can do "computations that give unequivocal answers" is seriously misleading if the situation is that the framework is insufficiently developed to produce equations that could be used to reliably answer any questions about physics.

6. **Peter Woit**
June 29, 2006

Robert,

What Hawking showed was that there is a reason black holes have entropy and temperature, completely independent of the microscopic description. This explains these two facts, you don't need to know the microscopic definition. Actually, he didn't show "that" they have a temperature and radiate, for that we'll have to find one and look at it…

The comments you make about QED are completely irrelevant. In QED the physical vacuum state is the perturbative one, so you can do most physics without worrying about non-perturbative effects. In string theory, the perturbative ground state is the wrong one, all the "backgrounds" people are working with are supposed to come from some putative non-perturbative effect. You can't ignore non-perturbative effects, and this is why you can't predict anything.

7. **sunderpeeche**
June 29, 2006

Say the above in the rebuttal letter if WSJ publishes the Zwiebach letter.

8. **D R Lunsford**
June 29, 2006

Robert – this completely misses Peter's point. QED has definite equations that come about in a perfectly well-defined physical way, that can be evaluated with a certain amount of – apparently physically plausible – wishful mathematical thinking. Some people (Chris Oakley) apparently have taken it farther even than this. Yes, we know what QED means, in all its details, once the renormalization program is accepted as a tentative approach to *actual calculation*.

The point about black holes – which you also missed – is that what is being described by Hawking does *not* require a detailed microscopic theory, any more than evaluating the efficiency of a refrigerator requires quantum statistical mechanics. So the kudos for keeping your beer cold go to Carnot and Gibbs, not Ehrenfest and Landau.

-drl

9. **Quanta**
June 29, 2006

Why does Hawking get so much more credit than Bekenstein? Perhaps I'm missing some historical perspective, but Bekenstein laid out a beautifully simple argument as to why black holes have entropy and that the entropy must be proportional to the surface area. I thought Hawking's contribution was to reconcile the apparent contradiction that black hole radiant by invoking quantum mechanics?

10. **anonymous**
June 29, 2006

if string theory has 10^500 vacua and the SM has 20 parameters, to check string theory in the way suggested by Zwiebach we simply need to predict and measure the first 25 digits of each one of them. It sounds like a joke.

11. **joe minahan**
June 29, 2006

Peter said:

—They may very well not find them credible or worth publishing.

Why would they not find him credible? He is a professor of physics at a leading institution and has a long publication record. He has also written a famous string theory textbook, based on an undergraduate course he developed and taught at MIT that received the top university teaching prize.

But then again, he doesn't have a blog…

12. **Thomas Larsson**
June 29, 2006

Does string theory really say anything about the kind of black holes which, perhaps, have been observed? I thought that Strominger-Vafa was about extremal black holes, whereas real black holes are very non-extremal.

13. **Bob McNees**
June 29, 2006

Hawking did not show that a BH has an entropy. He showed that a quantized field in a BH background experiences particle production at a specific temperature related to the surface gravity of the black hole. From there, he expanded on Bekenstein's claim of a generalized second law by suggesting that there are quantities (the surface gravity and area) that seem to play the role of a temperature and an entropy. So he showed that there is a quantity that is analogous to an entropy. He was very clear in making this distinction in his 1974 paper.

Why doesn't this demonstrate the existence of a "real entropy"? An entropy counts the number of microstates consistent with a course grained description of a system. Unless you can count the microstates, you haven't demonstrated the existence of an entropy. So when Peter states "Hawking showed was that there is a reason black holes have entropy and temperature, completely independent of the microscopic description", that is wrong.

Even if you aren't interested in quantum gravity, this should be clear. As Peter said, Hawking's calculation used semi-classical gravity, where the matter is quantum mechanical but gravity is classical. So it should come as no surprise that a framework in which gravity is treated classically can not explain "why" a feature of the gravitational field has an entropy associated with it.

Peter points out that any theory of quantum gravity should reproduce this, and he's correct. String theory, as a quantum theory of gravity, offers several examples of black holes where the microscopic degrees of freedom *can* be counted. The result is one-quarter of the area, as predicted by Bekenstein and Hawking. In that sense, String theory explains why these black holes have an entropy, as Zwiebach claimed in his letter.

14. **woit**
June 29, 2006

Joe,
You've changed my words. What I wrote was about the credibility of his arguments, and was based on scientific arguments that I made in detail in the posting. Instead of addressing my points and discussing the scientific questions at issue, you put words in my mouth and make this about who has more impressive scientific credentials.

Lubos Motl is a string theorist with many publications and is a faculty member at Harvard. Do you think that the Wall Street Journal should publish one of his rants if he were to choose to send it to them?

The attempt to change the topic from the science at issue to who has the best credentials is one of the tactics I was expecting here. It's not going to work.

15. **sunderpeeche**
June 29, 2006

Eh? If and when the WSJ receives Zwiebach's letter they will check who he is and his credentials (professor at MIT etc), and will almost certainly publish it. If LM writes a letter to WSJ they will check on him too. If his letter is a rant they will justifiably toss it. But Zwiebach's letter is not a rant.

16. **woit**
June 29, 2006

Bob,

I think this is all a matter of language, we don't disagree on the science. Hawking showed that semiclassical arguments imply that black holes carry properties with the characteristics of entropy and temperature, and that any underlying quantum gravity theory has to have states that realize these properties. To me that counts as an "explanation". Understanding the quantum states is of course a more complete explanation.

Thomas is also correct that string theory has yet to provide this kind of microscopic explanation for physical black holes, so in this case the only explanation is Hawking's. If one wants to demand a true, complete fundamental explanation of the entropy and temperature here, one should also note that the string theory brane arguments, in the absence of a full non-perturbative theory, show just that the brane framework passes a consistency check, and a final explanation of all this still does not exist.

Anyway, I note that all of this defense of Zwiebach's points is about the black hole issue, which is actually irrelevant to the question here, whether string theory is unpredictive, i.e. not even wrong. Is anyone willing to defend the claim that what is currently known about string theory gives "an extraordinarily precise and rigorous framework where facts can be proven beyond doubt and computations give unequivocal answers"? The only other string theorist I've ever heard go on like that is Lubos.

17. **woit**
June 29, 2006

sunderpeeche,

My comment was just that it should be the content of the letter that is the main deciding factor, not who wrote it. If the WSJ consults other experts and they say that Zwiebach is just wrong, should they publish it?

I honestly don't know what they will do or how they will make a decision. Editors of a business publication are not in a very good position to figure out what is going on in the case of a contentious scientific argument in a notoriously difficult and obscure field. Good luck to them in dealing with it.

18. **Bob McNees**
June 29, 2006

Joe quoted you. You said:

"First let's see which if any of the letters the WSJ decides to publish. They may very well not find them credible or worth publishing. If they do, then maybe a rebuttal would be in order."

So Joe did not change your words (though he did quote a single sentence from a three sentence paragraph). He just asked why they would have a reason to doubt Zwiebach's credibility, and followed up with a list of reasons why they might consider him a reasonable source.

I don't think he attempted "to change the topic from the science at issue to who has the best credentials", even if that is "one of the tactics [you were] expecting here". You suggested the WSJ might "very well" decide that the letter wasn't credible, and Joe pointed out that that probably won't be the case.

You may have meant other letters, or you may have meant that you feel like the WSJ editors won't buy Zwiebach's arguments, but there doesn't seem to be anything unreasonable about Joe's interpretation of, and response to, your exact words.

19. **Bob McNees**
June 29, 2006

I was writing my last comment when you posted your reply to sunderpeeche, which sounds much more reasonable to me than your first reply to Joe.

20. **woit**
June 29, 2006

Bob,

My English was quite clear. "them" refers to the letters and their contents, not to people who wrote them. Joe changed "find them credible" to "find him credible", which is something quite different.

21. **sunderpeeche**
June 29, 2006

The WSJ is fundamentally a profit-making business. Unless the letters received are obviously polemics, or slander/libel, the WSJ has no reason not to publish them. What it would like best is a free-for-all flood of letters and watch the fur fly. It might even (gasp!) boost readership for a few days.

22. **joe minahan**
June 29, 2006

Peter said:

You've changed my words. What I wrote was about the credibility of his arguments, and was based on scientific arguments that I made in detail in the posting. Instead of addressing my points and discussing the scientific questions at issue, you put words in my mouth and make this about who has more impressive scientific credentials.

I did not change your words, I quoted your line. In any case, I was only responding to whether the WSJ would publish his letter. I simply pointed out that the WSJ will likely take into account Barton's professional credentials when they make their decision whether to publish or not. Why wouldn't they? I doubt that they are going to closely examine the finer points of Strominger-Vafa. By mentioning his credentials it was not meant as a comparison to anyone elses.

Okay, I also made a snarky comment about having a blog. So what.

23. **woit**
June 29, 2006

Joe,

To repeat myself:

"find them credible", with "them" clearly referring to letters, is not the same as what you wrote: "find him credible"

24. **RHIC?**
June 29, 2006

dear Peter, you have not quoted this part of Zwiebach letter: "theories of strong nuclear forces are equivalent to theories of gravity. Over the last two months, several new papers use string theory to describe the motion of quarks in the plasma created by the Relativistic Heavy Ion Collider at Brookhaven!"

Indeed strings have been tried as an approximation to QCD. Maybe somebody knows how good the string approximation is and what they are trying to compute?

25. **anonymous**
June 29, 2006

Peter,

LOL. You made a straightforward point that they might not find his letters credible in content, and you have to clarify it again and again and again and … with ppl continuously misconstruing it. Actually it makes perfect sense, since argument by authority is one of the strongest ones they have…

If this is the annoyance with one trivial paragraph you wrote, good luck in dealing with less idiotic critiques! I don't envy you your position…

26. **woit**
June 29, 2006

RHIC,

What's discussed in the WSJ article and is at issue here is whether string theory is "Not Even Wrong" as a unified theory of particle physics and quantum gravity. Whether you can use it to solve QCD is a very different issue, there it certainly has promise. The calculation Zwiebach mentions is part of that story, a really different topic. If string theorists were just saying that they were working on a way to solve QCD, there would be no controversy here.

27. **Anonymous**
June 29, 2006

If string theorists were just saying that they were working on a way to solve QCD, there would be no controversy here.

You hear that, everyone? A well-defined route to ending this blog in finite time! Sounds promising….

28. **Arun**
June 29, 2006

Well, some physicists are joining the ranks of snake-oil purveyors and used-car salesmen. Perhaps this is typical of our times, when the truth without embroidery is not interesting to almost anyone.

29. **John A**
June 29, 2006

I wonder how much science is settled in the Letters page of the Wall Street Journal? Not much.

I would suggest that Peter make a reply to Zweibach with quotations from his book. It's a win-win situation.

30. **sunderpeeche**
June 29, 2006

One might ask why did the WSJ print an article on string theory at all?

31. **knotted**
June 29, 2006

There's finally a short but sweet review of "Not Even Wrong" tucked away on page 56 of the 1 July issue of New Scientist:

"String Weary

"Not Even Wrong … Reviewed by Amanda Gefter

"This is like two books in one. The first is a technical overview of the mathematical structure of the standard model of particle physics. The second is a highly readable look at the sociology of string theory. In the end, Woit ties the two together in one fell swoop by suggesting that physicists should search for answers in the unexplored symmetries of the standard model, rather than in strings. Woit is taking a shot at the string theory clique, but this book is more than that – it is a call to arms for physicists to pursue multiple paths in search of truth, not funding."

Seeing that the powers that control Wikipedia aren't happy with a lot of links to reviews of N.E.W. on the Woit article, perhaps Peter can sometime get around to actually putting a list of links to newspaper an magazine reviews on this blog somewhere (say somewhere low down on the right hand side of the main page). Or perhaps Peter can put up a page listing the contents of the book somewhere as he wrote long ago that he would?

I've seen N.E.W. on sale ONLY in large city bookshops, so far, in the U.K. So don't get the idea it is widely available offline over here. Do you know how many copies they've printed? Since it's hardback the usual figure in the U.K. for a well established London publisher is 5,000. That isn't going to compete with the established string theory books.

In the small/major towns, the popular science shelves of bookshops are still creaking under a load of stringy speculation, with not a single copy of N.E.W. yet in sight. OK, so the Sunday Times marketing dept have have sold some after their review, and people can order it in from any bookshop, but don't get complacent. Maybe you should take a look at the tacky publicity techniques string theorists use for their popular books? (Like tacky internet sites full of promotion gimmicks; when wrestling with pigs people must be prepared to get dirty, or lose.)

32. **Borun D. Chowdhury**
June 29, 2006

Hawking and Bekenstein showed that the entropy has to be proportional to area. They did not show what the microstates are. Moreover Hawking's argument of thermal radiation leads to information paradox and this is where string theory (if correct) will contribute. One should be well informed on what string theorists working on black holes are trying to do before comparing their work with Hawkings.

33. **knotted**
June 29, 2006

Hi Boron,

I notice you say at the top of your home page: "I am a graduate student in Physics at the Ohio State University. I am currently trying to understand **Supersting** [sic] Theory."

34. **Torbjörn Larsson**
June 29, 2006

"If there are 10^1000 or more of these solutions, all evidence is that identifying which of them have desired properties (e.g. the correct CC) is an inherently computationally intractable problem."

Eh? Wasn't a result that it was a NP-complete problem, so if the number of solutions are finite it is computationally tractable? And isn't there a recent paper that shows the finiteness?

OTOH, if you mean practically tractable…

35. **Peter Woit**
June 29, 2006

Borun,

Just who is it who you think doesn't know what string theorists working on black holes are trying to do? It seems to be a pathology common in the string theory community to believe that non-string theorists don't know well-known things about string theory, a pathology especially common among string theory graduate students. Just because you just learned something doesn't mean that people who have been around this business for 30 years don't know it.

36. **Peter Woit**
June 29, 2006

Torbjorn,

Everyone seems to believe that the recent paper by Acharya and Douglas "shows" finiteness, when, if you look at it, you'll see that they are just making conjectures. It's amazing how much of this goes on in string theory, with conjectures magically being quoted by everyone as solid results.

And no, even with the kind of finiteness that Acharya and Douglas conjecture, the words "computationally tractable" definitely don't apply in this case.

37. **Robert McNees**
June 29, 2006

Peter said:

"Borun,

Just who is it who you think doesn't know what string theorists working on black holes are trying to do? Just because you just learned something doesn't mean that people who have been around this business for 30 years don't know it. "

This is an unnecessary comment. Where do you get off jumping down his throat for not being properly deferential to you? You've stated, on this blog, that you aren't interested in spending your time on quantum gravity. He is, so give him a break. He made a fair comment. There are explanations of Hawking's contribution on this page that are wrong. Whether or not it was a mis-statement, or a question of language, is beside the point. Furthermore, he brought up the information paradox. That is relevant to the discussion.

For someone who was so worried about making this discussion about "who has more impressive scientific credentials", that was a very telling comment.

38. **LDM**
June 29, 2006

"This is what Hawking did back in 1974 with a semi-classical calculation."

Hmmm…The Hawking paper I have says "Received April 12, 1975."

If you read the paper, you find Hawking and before him Beckenstein only make the argument that S + A/4 is a reasonable definition of Entropy – by using an analogy with classical thermodynamics and an earlier 1973 result for the FIRST law of thermodynamics for black holes — and not because a density of states calculation was done… You will also discover that particle emission by black holes (the MAIN result of the paper) is REQUIRED to prevent violation of the Generalized Second Law (entropy does not decrease). Beckenstein made his analogy without this result…and so Beckenstein was technically wrong, and Hawking justly deserves the credit.

However, it is a HUGE improvement to get the result from a first principles density of states calculation. Hawking's result applies to ALL (charge, uncharged, rotating, whatever) black holes…string theory has made a few calculations that agree with Hawking….the only question is do you believe they are valid calculations. If so…then Zwiebach is partly correct…The problem I have is these string theory papers are sometimes so weakly refereed and authored…I am not sure I believe these calculations.

39. **Peter Woit**
June 29, 2006

Bob,

This has nothing to do with "being properly deferential" to me, and has nothing to do with my comments about not wanting to spend more time thinking about quantum gravity. Anyone who has ever read any of the hundreds of overhyped promotional pieces about string theory knows that string theorists have calculations counting microstates of black holes and what an important contribution to physics they believe this to be.

Sorry, but I'm just sick and tired of being insulted as ignorant by completely clueless, arrogant string theorists, young and old, who think that this is an appropriate way to behave in response to scientific criticism of string theory. I'm not going to put up with it, and will jump down their throats when they do it, no matter who they are (except for Lubos, who is playing a wonderful role as public poster-boy of this particular pathology, and so deserves to be encouraged).

40. **Peter Woit**
June 29, 2006

LDM,

My source, I'm not proud to say, was Wikipedia, which says 1974. The SPIRES entry for the paper however also says 1974. Perhaps it was circulated earlier as a preprint before the final version was submitted to CMP.

41. **sunderpeeche**
June 29, 2006

If one is going to critique string theory and call it "not even wrong" (or anything else ~ the oil industry?) then one has to take what comes. It goes with the territory.

42. **Peter Woit**
June 29, 2006

sunderpeeche,

Sure, I refer to string theory as "not even wrong", but that is a criticism of a scientific theory and not a personal attack on anyone.

I'm quite used to being insulted as an ignorant crackpot by string theorists who don't have a scientific argument. It does go with the territory and I'm sure there will be a lot more of it to come. But one wonderful aspect of this glorious new blog software is that when they choose to do it here, I can immediately give them a piece of my mind.

43. **Eugene Stefanovich**
June 29, 2006

Peter:

Sorry, but I'm just sick and tired of being insulted as ignorant by completely clueless, arrogant string theorists, young and old, who think that this is an appropriate way to behave in response to scientific criticism of string theory. I'm not going to put up with it, and will jump down their throats when they do it, no matter who they are…

Chill out! You have good scientific points, and most people reading your blog (even your opponents) recognize that. They can also see for themselves who is clueless and who is arrogant. When you "jump down somebody's throat" it doesn't help your cause. There is no need to be offensive. Stick to your scientific arguments, and you'll be o.k.

44. **Peter Woit**
June 29, 2006

Eugene,

Excellent advice. The ability of the glorious new blog software to let me immediately give someone a piece of my mind may not be such a good thing…

45. **Robert McNees**
June 29, 2006

"This has nothing to do with "being properly deferential" to me"

Sure it does. You said "Just because you just learned something doesn't mean that people who have been around this business for 30 years don't know it.", which means that he should know better than to try and tell you something about Hawking's caclulation. And you said it on the same page where you accused Joe of trying to turn this into a discussion about who has more impressive scientific credentials.

In fairness, I would also be annoyed if I felt like a grad student were lecturing me about something I understand. But has he ever commented on your blog? Does he have a history of being uppity with you? How do you justify your claim that he thinks you are "ignorant"? For all you know he was trying to contribute to the discussion. But you're upset about the way you perceive people as treating you, so you jumped on an easy target.

Feel free to kill this, because it's headed off-topic.

46. **joe minahan**
June 29, 2006

Peter said:

"find them credible", with "them" clearly referring to letters, is not the same as what you wrote: "find him credible"

Peter,

My mistake was not putting in the full quote, so here it is:

-First let's see which if any of the letters the WSJ decides to publish. They may very well not find them credible or worth publishing. If they do, then maybe a rebuttal would be in order.

The clear implication from this quote is that the WSJ might not find Zwiebach's letter credible or worth publishing. Maybe that was not your intent, but a reasonable person could certainly take this as its meaning. I only pointed out that the WSJ would have good reason to treat Zwiebach as an expert on this issue, based on his scientific credentials.

It's your blog so I am sure you will get the last word on this.

47. **Malo Juevo**
June 29, 2006

Ridiculously overbroad claims are nothing new for Barton.

When I was in graduate school, I remember looking at some of the stuff he was working on (with Minahan, I seem to recall). It was actually fascinating stuff, and although his interest in the subject matter was related to string theory, no knowledge of or regard for strings was required to appreciate these particular explorations of quantum theory. It was stuff that I would describe as having an "extraordinarily precise and rigorous framework," in fact. It was just utterly divorced from real-world physics.

He was doing very good work on this stuff, but at the same time, he made claims about this material that were ludicrous! He was discussing the material at one fairly informal seminar, and at one point, he displayed some extremely interesting solutions to the theory. Then he claimed that he had shown that all the solutions had this form. Scribbling on a borrowed piece of paper at the back of the room, I had falsified this claim by the end of his talk, by finding a very special exact solution. I showed him the solution, and he acknowledged it was correct. (Barton is a very nice guy, and I respect him for that, at least.) A little more work showed where his reasoning had gone wrong. It looks like he had been trying to do something like inferring the properties of a function from working, term by term, with an assymptotic series–not a very reliable method.

But it's exactly the kind of technique that would "allow" one to infer facts about nonperturbative string theory from what is known right now.

48. **David**
June 29, 2006

Peter,

I might be remembering wrong, but the initial Hawking result was first published in a very criptic short letter to nature in 1974. It was criptic because it didn't have much details for one to assess the validity of the result. This letter was before the CMP article.

One should be aware that if one performs Hawking's calculation in Schwarszchild coordinates, one does not obtain radiation and entropy. On the other hand, this might not be kosher as it leads to all sorts of divergences as one approches the horizon. I forget who performed this calculation, but it was before Hawking in the early 70's in a PRD article. I am not claiming Hawking to be incorrect. I am just pointing out that there are many inconviniences and inconsistencies with semiclassical gravity that are ignored and have never been fully resolved.

49. **Garbage**
June 29, 2006

The only reference I have seen in the letter to ST as a theory of anything, and not just stringy versions of known physics (yarn theory? 🙂), is the Black hole entropy/temperature thing, though so far the "explaination" for the real ones is yet to come to your hometown theaters [It is absurd to say that ST explains BH entropy, as absurd as the claim it predicts gravity.], and the following sentence:

"All that is needed to confirm string theory is finding one solution that describes our universe. All that is needed to rule out string theory is showing that no solution describes our universe. An answer must exist."

Such postdictive power would look better in a history book than any science literature. I would rather predict which one is ours and why. In fact, is the theory ever going to tell us which universe we live on or that comes as an external bit of information?
It is true in the other hand that to rule out ST it is enough to show that no solution describes our universe. That's exactly what the Distler et al. paper attempts. If our universe violate "the bounds" steming from assumptions A,B,C (unitarity, analyticity and Lorentz invariance), any ST version having A,B,C as properties must be discarded. So far I havent seen any string theorist claiming Lorentz invariance isnt a fundamental ingridient of the theory [Besides Peter's comments on vague ideas of David Gross]. If I remember correctly at the end of the string05 conference Lee Smolin pointed out that tests of Lorentz invariance would falsify ST, to what Ed Witten was reluctant to comment on. If LHC turns on, we dont have a light Higgs and the bounds are violated, we better start taking Gross' ideas a bit more seriously, or perhaps also taking a closer look to LQG et al. 😉
I personally find such possiblity fascinating, though logically possible and physically unlikely…

50. **Peter Woit**
June 29, 2006

Joe,

You're quite right, what I said was that the WSJ might not find Zwiebach's letter credible. Anyone who has listened to many famous string theorists publicly saying that we still don't know what string theory is might find his claims in the second paragraph of the letter to be not credible. The distinction you seem to be not able to get is that the credibility of an argument and the credibility of a person are two quite different things. I was only referring to the credibility of the arguments in the letter and I objected very much to your turning that into a comment on his credibility as a person.

The most credible person in the world will sometimes make an argument which is not credible. This doesn't make them not the most credible person in the world, for that they have to keep making such arguments.

For the record, I think the WSJ should publish Zwiebach's letter, even though I think part of it is scientifically inaccurate. The scientific issues are not ones they are capable of adjudicating, and having a response from a well-known string theorist to the article is quite appropriate. If they don't publish it, it would be most likely because it is only one of several letters from that side they receive, and they do have space limitations.

I was thinking of taking "Malo Juevo" to task for not sticking to science, but on rereading his comment, it is a relevant story. The fact that you can't infer properties of a function from properties of terms of its asymptotic series is precisely the problem at issue here.

Bob,

Yeah, this is definitely off-topic and not a useful discussion. I'll admit that some days I do have a short fuse on this particular topic, and, as Eugene pointed out to me, would do better to ignore some people rather than respond to them.

51. **Roy**
June 29, 2006

"What Hawking showed was that there is a reason black holes have entropy and temperature, completely independent of the microscopic description. This explains these two facts, you don't need to know the microscopic definition."
I must admit don't know the technical details of string theoretic calculation of microstates, but isn't that the entire point of thermodynamics and stat. mech? For example, most of undergraduate thermal physics can be done without stat. mech by somehow guessing or physically arguing for a equation of state or the some potential function, but the stat. mech approach is superior because it actually derives everything from first principles. Of course stat. mech is not certainly limited only to providing proofs for thermodynamic equations– it has infinitely many more interesting applications and ideas and I do not know whether the string theoretic approach has similar advantages and I think Borun is claiming(and perhaps quite correctly) that string theory provides a better framework for the understanding of the black hole entropy calculation(Borun, please correct me if I am wrong here)
If string theory has managed to derive a semi-classical result that is widely believed to be true– and managed to calculate the microstates correctly– isn't that a strong point for the credibility of string theory?
May be you had further objections to Borun's claim, or in general this string theory result, based on technical points that I do not understand and in that case it will be nice if you would explain why you think that string approach is not satisfactory in this case.

Again, I am not trying to be confrontational or arrogant here– I would genuinely like to know your objections .

52. **Arun**
June 30, 2006

Is it true that the extremal string blackhole has the right Bekenstein entropy, but has no energy to radiate because it is a minimal energy state of the string? i.e., where the exact calculation is possible, we have the entropy but not the Hawking radiation? Are non-radiating black holes a prediction of string theory?

53. **scott**
June 30, 2006

Peter,

I doubt that joe doesn't understand that "the credibility of an argument and the credibility of a person are two quite different things" However he thinks, and with good reason, that WSJ not being a qualified expert, will likely simply look at his credentials instead of spending an employees time contacting other experts to see if they think the argument itself is credible. Apparrently regard the WSJ in a much higher regard then Joe. I think Joe's appraisal of how the WSJ would determine credibility to be more realistic.

However there is another possibility that they will simply not publish it because they don't think the issue is worth the space regardless of credibility. Or as you point out because they publish some other string theorist's responce.

54. **scott**
June 30, 2006

Apparrently regard the WSJ in a much higher regard then Joe. I think Joe's appraisal of how the WSJ would determine credibility to be more realistic.

um this should say something like:

Apparrently **you** regard the WSJ in a much higher regard then Joe. I think Joe's appraisal of how the WSJ would determine credibility to be **the** more realistic **one**.

there is some other sentences with bad grammer but they are(I think) still understandable.

55. **scott**
June 30, 2006

and of course even in my correction the grammar is still f'ed up.

56. **Arun**
June 30, 2006

One may also ask how the ordinary matter from which any black hole in our universe is assembled turns into the highly wound-up string + brane state in the string blackholes.

If this is not known, then the result really is that the exotic string matter that makes up a string blackhole has the correct number of microscopic states to produce the Bekenstein entropy. I agree it is an impressive result, in that we cannot yet count the microscopic states in any other framework. There are some scenarios in string theory that gravitationally are blackholes and where microscopic states can be counted; but presumably there are many scenarios (e.g., with everyday matter) where microscopic states cannot be counted, and one has to demonstrate this doesn't matter, the count of microscopic states remains the same.

Presumably molecules interacting like billiard balls, or with van der Waals forces or with any of a large set of force laws produce the right thermodynamics, and thus thermodynamics sets only a weak constraint on how molecules may interact.

57. **woit**
June 30, 2006

Roy,
Yes, it certainly is a point in favor of string theory if it can provide a microscopic definition. I was not arguing with that, all I was doing was pointing out that you don't need the microscopic definition to know what the entropy and temperature of a black hole will be, Hawking already told us that long ago. It's also true that string theory arguments do not provide such a microscopic definition for physical black holes, which Zwiebach neglects to mention.

58. **D R Lunsford**
June 30, 2006

RE Motl's latest rant –

Motl is doing classic Jungian shadow projection, just like O'Reilly does. Obviously he is insecure in his own understanding, and this is why he does not argue facts, only opinions – he doesn't have facts to argue with, nor the grounding in history to draw correct inferences. (Compare O'Reilly's claim that Germans were massacred by American GIs at Malmedy.) Effective shadow projectors often rise to prominence – only to have their crippling flaw publically exposed. This is some kind of healing process in the projector's divided psyche.

-drl

59. **Torbjörn Larsson**
July 3, 2006

"Everyone seems to believe that the recent paper by Acharya and Douglas "shows" finiteness, when, if you look at it, you'll see that they are just making conjectures."

I took it they were pretty solid results, and that they confined the number of string vacua. Thank's for supplying the missing reference!

"And no, even with the kind of finiteness that Acharya and Douglas conjecture, the words "computationally tractable" definitely don't apply in this case."

I found http://www.citebase.org/cgi-bin/citations?id=oai:arXiv.org:hep-th/0602072 by Denef and Douglas that argued that "such problems are typically NP hard". That is different yes, they are computationally intractable.

Some Links

June 29, 2006
Categories: Uncategorized

The Cao-Zhu paper at the Asian Journal of Mathematics that is supposed to have a complete proof of the Poincare and geometrization conjectures is still not available, but the introduction to the paper has been posted there.

If you're not getting enough string theory bashing today, head over to John Horgan's Scientific Curmudgeon blog, where he has a posting entitled Pulling the Plug on Strings. It contains a wide selection of string-puns (or whatever you call such things), and he has decided to refer to string theory advocates as "yarn-heads" and braniacs. For his trouble, his comment section is under assault by the usual suspects. There's also this site, containing a graphic mentioned here before which I refuse to admit to finding funny. The proprietors have an interesting way of dealing with the comment section.

Sabine Hossenfelder has an excellent posting on Science and Democracy.

This past week I've spent some time at the 26th International Colloquium on Group Theoretical Methods in Physics, being held here in New York at the CUNY Graduate Center. It was ably organized by Sultan Catto, who somehow convinced me to give a short talk on the blog and the book, one where I think I disappointed people by keeping string-bashing to a minimum. I enjoyed seeing people at the conference, and there were some good talks, including one by Greg Moore on his recent work with Dan Freed and Graeme Segal (see here and here).

Urs Schreiber has been putting his notes on-line about elliptic cohomology. Lots of interesting material, but his comment that he expects the landscape of superstring theories to be equal to the spectrum of elliptic cohomology sounds frightening. Maybe he means a different landscape…

I was quite sorry to hear of the recent death of Irving Kaplansky. Kaplansky was an algebraist, and director of MSRI when I was there in 1988-89. At the time I wasn't much interested in algebra, so didn't talk to him about math, but he was responsible for making MSRI a really wonderful place to work.

Update: The slides from Yau's talk at Strings 2006 are now available here.

Comments

1. **Chris Oakley**
   June 30, 2006

   I think that Peter was right not to use this jacket in the end: "Superstrings" should be in the plural, and having basic mistakes like this only gives ammunition to critics.

2. **Kea**
   June 30, 2006

   Re Urs:…*but his comment that he expects the landscape of superstring theories to be equal to the spectrum of elliptic cohomology sounds frightening*.

   Maybe he just means that rederiving the landscape rigorously will put a solid nail in the Landscape as a *physical* idea.

3. **Kea**
   June 30, 2006

   I meant coffin thereof, of course.

4. **urs**
   June 30, 2006

   > […] sounds frightening

   The fun of making things precise: you suddenly actually know what you are talking about. 😉

   The space of 1d SQFT is homotopy equivalent to the K-theory spectrum. That's a theorem.

   It is a conjecture (well motivated, though) that, similarly, the space of 2dSCFTs is homotopy equivalent to the spectrum of elliptic cohomology.

   (Of course you need to make precise what these QFT spaces are. You do this by looking at certain transport functor spaces.)

   Actually, that's an old idea. Segal has proposed 20 years ago in the last section of his paper on elliptic cohomology, that CFTs should be elliptic cocylces, roughly.

   The statement has been refined and sharpened, and brought a little closer to being provable, in the last ten years by Stephan Stolz and Peter Teichner.

   I gave the talk in our seminar in front of a mixed audience of mathematicians and string theorists. So I simply went ahead and mapped some math terms to the corresponding string terms.

   Under that dictionary, "space of SCFTs" becomes "landscape".

   All up to some details.

5. **urs**
   June 30, 2006

   Ah, and maybe this is a good opportunity to mention that it was in particular Aaron Bergman who originally made me aware of these topics and of the relevant literature. Thanks a lot!

6. **ObsessiveMathsFreak**
   June 30, 2006

   From the John Horgan article:

> Along with such quasi-scientific notions as Gaia, complexity theory, psychoanalysis and the anthropic principle, strings seize the public's imagination not because they explain the world but because they mystify it.

That's a very damning statement, for any scientific theory. Science has always been rolling back the fog of ignorence and mysticism. For any science to reintroduce it is a cardinal sin.

7. **Kea**
June 30, 2006

Urs

Please correct me if I'm wrong, but AFAIK SCFT would only describe one sector of the Landscape…and the evidence for the Landscape that some people take to be most compelling does *not* belong to that sector.

8. **Bee**
June 30, 2006

Hi Peter,

thanks for the link to my post.

I am still at reading your book, and I just found that you formulated some of my concerns about the specialisation much clearer than I could ever had (pp 205):

"This huge degree of complexity at the heart of current research […] means that a huge investment in time and effort is required to master the subject well enough to begin such research. […] Since the whole subject is so complicated and difficult, theorists trying to evaluate what is going on often rely to an unusal extend not in their own understanding of the subject, but also on what others say about it." (possible typos are entirely mine)

Best regards,

B.

9. **urs**
June 30, 2006

> Please correct me if I'm wrong, but AFAIK SCFT would only describe one sector of the Landscape…and the evidence for the Landscape that some people take to be most compelling does not belong to that sector.

Ok, of course I am talking about the space of all SCFTs (but including all information about the possible D-branes for a given SCFT, and also, in particular, all possible worldsheet phenomena like worldsheet instantons). That's what the conjecture would apply to.

So maybe I should say "perturbative landscape" instead of "landscape".

10. **Nicholas**
June 30, 2006

"Moreover, even if most physicists no longer take the theory seriously, stringy memes will continue to infect the culture at large. New Age authors in particular have embraced string theory. The appeal is obvious. Along with such quasi-scientific notions as Gaia, complexity theory, psychoanalysis and the anthropic principle, strings entwine the public's imagination not because they explain the world but because they mystify it."

As a researcher in granular systems I certainly must take some offense with this notion of complexity being first of all lumped in this group and additionally with the very statement that it is somehow mystifying nature.

I am not here to discuss the merits of chaos however, but rather to state that it is not an argument to suggest that someone's misappreciation of science reflects upon the subject itself.

I have often encountered individuals with significant misunderstandings pertaining to heisenburgs uncertainty principle, special relativity or a variety of other physics. That in no way diminishes the validity of these as proper scientific theories, and it should not ultimately reflect on string theory, regardless of that theories actual scientific validity.

NM

11. **Peter Woit**
June 30, 2006

Nicholas,

About string theory, I think Horgan is right, it isn't explaining how to unify physics, it is mystifying the issue. About complexity theory I have no opinion. Horgan is trying to be provocative. If you're provoked, you should take it up with him.

12. **nontrad**
June 30, 2006

At the risk of an 'off topic' comment, I take it Nicholas M. hasn't read Horgan's 'End of Science'.

For NM and others who haven't read it, my proverbial internet 2 cents is …. read that book!!! Seriously, Horgan's book is interesting / entertaining for numerous reasons; including aspects of science journalism, philosophy of science, string theory, cosmology, "chaoplexity", evolution, neuroscience / AI etc (such as narcissitic personality disorder / hubris kicked up copious notches).

Since several of those topics (ST, cosmology, phil of science, sci journos) are repeatedly addressed at 'Not Even Wrong', readers here might well appreciate the book (even if they don't agree with the general thesis).

Horgan's pretty insightful in general, he doesn't pull his punches, and at times he's damn funny!

13. **John Baez**

June 30, 2006

Back in 2003, I wrote week197 of This Week's Finds to explain some stuff Stephan Stolz told me about elliptic cohomology. Elliptic cohomology studies a space by mapping it into some spaces called "tmf(n)", for "topological modular forms". These spaces are currently understood only in an indirect way. Some people conjecture that tmf(n) is roughly the space of supersymmetric conformal field theories of central charge -n. There's a lot of evidence that *something* like this is true.

The space of such theories is not the same as the "landscape" studied by string theorists today… but, it's still an intimidating structure. If the conjecture is true, this structure has a lot more order to it than one might at first guess!

14. **J.F. Moore**
June 30, 2006

I can also recommend 'End of Science' as a well written series of fleshed-out interviews on the general topic of whether fundamental discoveries in science are behind us (and touching on strings as one example). I enjoyed discussing the subject before and after that book was published, and was dismayed when colleagues would crudely dismiss the arguments Horgan put forth based on his 'lack of credibility' rather than putting forth an actual counterargument. John Maddox' rebuttal book was pretty weak and only led me to think more highly of Horgan.

I'll have to read it again, but I suspect it's held up just fine in the last decade.

15. **MathPhys**
July 1, 2006

Urs,

I still find your statment above confusing.

If you include "all information about the possible D-branes for a given SCFT, and also, in particular, all possible worldsheet phenomena like worldsheet instantons", then you should say "landscape" rather than "perturbative landscape".

Can you make the statement of the conjecture really precise, please?

Also the way that you type your notes on the web site using html makes them less than fully readable. Why not use Latex and post a pdf file. It's a pity when so much work is less than fully readable.

16. **Michael**
July 1, 2006

MathPhys,

D-branes appear as boundaries of the worldsheet CFT. Worldsheet instantons are essentially worldsheets wrapped an (small) non-trivial two-cycles in spacetime; despite being non-perturbative they are well under control in a worldsheet description. Thus including these effects is possible in a string-loop expansion, which is what Urs meant by "perturbative". At generic points in moduli space the string-loop expansion is not useful, something people like Peter Woit love to complain about.

17. **MathPhys**
July 1, 2006

Thanks, Michael.

18. **urs**
July 2, 2006

> Also the way that you type your notes on the web site using html makes them less than fully readable.

Which browser are you using?

I have tried not to use any symbols that are displayed only after the user installs extra fonts.

I am currently sitting in some random internet cafe, and the formulas in that entry are fully readable and displayed nicely using

– either plain Mozilla Firefox

– or MS Internet Explorer with the free MathPlayer plugin plugin installed (takes 2 seconds)

But you are of course, right, I could have produced a pdf instead.

19. **urs**
July 2, 2006

> Can you make the statement of the conjecture really precise, please?

Not *really* precise, but more precise than I did before.

I guess it should go like this:

Conjecture: *The space of all 2-functors from superconformal 2-paths to graded 2-Hilbert spaces carries a topological structure and is homotopy equivalent to the tmf spectrum*.

This is not *really* precise, yet, for a couple of reasons.

1) Nobody has yet a good idea of how precisely the 2-category of superconformal 2-paths looks like. Its 2-morphisms are superconformal disks with two marked points on their boundary. Horizontal composition seems to be troublesome. But Hilbert Uniformization might help here.

2) When I talk about 2-Hilbert spaces I am indicating that this is the true structure which is secretly behind the vonNeumann algebra bimodule bicategory that Stolz/Teichner use. In fact, I am pretty sure that what they discuss is the special case of a 2-vector bundle associated to a String-2-bundle, using a representation of the string 2-group on 2-Hilbert spaces.

20. **MathPhys**
July 2, 2006

Urs,
I can read your formulas (I'm using IE 6.0), but the layout is awkward (lines are too long, etc) and things are sort of all over the place. I would like to be able to download what you are write in a clean way and read it, annotate it, etc.

A pdf file of a latex document will give you a lot more versatility. You can also build on it in the future, if you want to, and turn what you write into papers.

Re science, I'm trying to understand what you're saying, and not let your overuse of "decategorification" put me totally off the subject.

21. **urs**
July 3, 2006

> can read your formulas (I'm using IE 6.0), but the layout is awkward

Hm, for some reason this happens on some configurations. Not on the ones I am looking at at the moment, though. I guess that in general Firefox is the better option.

> I'm trying to understand what you're saying, and not let your overuse of "decategorification" put me totally off the subject.

I guess you mean categorification instead of decategorification. And its meant precisely to help you to understand what is going on. *Whithout it*, there is hardly a chance. It is a tool that organizes apperently intricate ideas in a conceptual way.

So that's why I emphasize, in that entry (in the second but last part) the situation for the toy example of 1-dimensional supersymmetric field theory and K-theory.

If you understand this example, and you know how categorification picks every item of this example and increases its dimension by one, you understand the main idea of the conjecture that I stated.

Actually, the main idea becomes pretty obvious then. All that remains are some technicalities. That's what categorification does for you: it provides you with all the big picture and the general ideas. All that remains to be done then is figuring out the technicalities.

I'd be happy to try to answer more detailed questions. But maybe we should do that over on the SCT, lest we run into off-topic territory here.

22. **urs**
July 3, 2006

John Baez wrote:

> Back in 2003, I wrote week197 of This Week's Finds to explain some stuff Stephan Stolz told me about elliptic cohomology.

BTW, I do list TWF197 together with other relevant literature available online at the beginning of the first entry of the series.

> The space of such theories is not the same as the "landscape" studied by string theorists today…

But that's mainly because the landscape studied by string theorists today is a small subspace of the full landscape, namely that subspace whose points satisfy a number of phenomenological prejudices and technical restrictions, like being large volume CY compactifications with fluxes.

Maybe I am wrong, but it seems to me that asking the question "Which of 10^500 large volume CY flux compactifications is chosen, and why?" is only a small subquestion of the full question, and motivated mainly by constraining the full question by available and/or expected phenomenological input.

23. **MathPhys**

Many Worlds In One

July 2, 2006
Categories: Uncategorized

Alex Vilenkin has a new popular book out about cosmology, entitled Many Worlds In One. It's mainly about the extremely speculative end of cosmology, and much of it is devoted to explaining the author's ideas on eternal inflation, creating the universe by tunneling out of nothing, and the anthropic landscape, together with stories about how he came to these ideas. It contains various amusing anecdotes, especially about Alan Guth. Sean Carroll is credited with the following story:

One of the leading superstring theorists, Joseph Polchinski, once said that he would quit physics if a nonzero cosmological constant were discovered. Polchinski realized that the only explanation for a small cosmological constant would be the anthropic one, and he just could not stand the thought.

He also describes the reaction to his anthropic arguments back during the years when these were not all the rage like they are now:

After one of my seminars, a prominent Princeton cosmologist rose from his seat and said, "Anyone who wants to work on the anthropic principle – should." The tone of his remark left little doubt that he believed all such people would be wasting their time.

Vilenkin's book covers much the same ground as Susskind's, although from the point of view of a cosmologist, not a particle physicist. A huge amount is made of the supposed anthropic "prediction" of the value of the cosmological constant (any news of the rumor from Sean Carroll of new work by prominent Princeton cosmologist Paul Steinhardt showing this is bunk?). Unlike Susskind, Vilenkin at least doesn't seem to be on a campaign to attack the "Popperazi" and convert everyone to anthropics, but he demonstrates a similar lack of concern for the fact that the ideas he is discussing don't lead to much if anything in the way of a testable experimental prediction.

Here's his scientifc program for 21st century physics, which he hopes will be spent working on the anthropic landscape:

First, we will need to map the landscape. What kinds of vacua are there, and how many of each kind? We cannot realistically hope to obtain a detailed characterization of all 10^{500} *vacua, so some kind of statistical description will be necessary. We will also need to estimate the probabilities for bubbles of one vacuum to form amidst another vacuum. The we will have all the ingredients to develop a model of an eternally inflating universe with bubbles inside bubbles inside bubbles… Once we have this model, the principle of mediocrity can be used to determine the probablility for us to live in one vacuum or other.*

Unfortunately for this research program, it has yet to even begin to get off the ground, and there are very good arguments that it can never succeed. There are an infinite number of possible vacua, and trying to make this finite so one can do statistics requires putting in cutoffs, with results then strongly depending on the cutoff. The large numbers of these vacua make any attempts to identify ones that agree with the real world computationally completely intractable. Even if one could do this, all evidence is that one would end up with broad statistical distributions for many of the parameters of the standard model, providing no useful prediction of what new experiments will see, or any insight into why these parameters have the values that they do.

Comments

1. **MathPhys**
   July 2, 2006

   Look on the bright side, Peter. They have solved all our problems. In the immortal words of Alyosha Zamolodchikov when asked what he thinks of strings as the final theory of everything

   "That's good. Now we can all relax and go and have a drink".

2. **Tommaso Dorigo**
   July 2, 2006

   Hi,

   as a plot-inclined person, I would be soooo happy to see a graphical description of just one of the 19 parameters of the standard model as a function of any one of the possible needed cut-offs that allowed a mediocrity principle to work out… That would be a start.

   …Naah. It would only mean starting to get plot-bombed by 10^500 possible graphical descriptions…

   Cheers,
   T.

3. **Who**
   July 2, 2006

   A huge amount is made of the supposed anthropic "prediction" of the value of the cosmological constant (any news of the rumor from Sean Carroll of new work by prominent Princeton cosmologist Paul Steinhardt showing this is bunk?).

   maybe this is merely background to still newer work?

   http://arxiv.org/abs/astro-ph/0605173
   Why the cosmological constant is small and positive
   Paul J. Steinhardt, Neil Turok
   15 pages, 1 figure
   "… we show that a cyclic model of the universe can naturally incorporate a dynamical mechanism that automatically relaxes the value of the cosmological constant, … nearly every volume of space spends an overwhelming majority of the time at the stage when the cosmological constant is small and positive, as observed today."
   ==================

   As for straightforward debunking, Abraham Loeb has presented an observational test to show that the CC is not of anthropic origin:

   http://arxiv.org/abs/astro-ph/0604242
   An Observational Test for the Anthropic Origin of the Cosmological Constant
   Abraham Loeb (Harvard)
   JCAP 0605 (2006) 009

"…Here we propose a simple empirical test for this anthropic argument within the boundaries of the observable Universe. We make use of the fact that dwarf galaxies formed in our Universe at redshifts as high as z~10 when the mean matter density was larger by a factor of ~10^3 than today. Existing technology enables to check whether planets form in nearby dwarf galaxies and globular clusters by searching for microlensing or transit events of background stars. The oldest of these nearby systems may have formed at z~10. If planets are as common per stellar mass in these descendents as they are in the Milky Way galaxy, then the anthropic argument would be weakened considerably since planets could have formed in our Universe even if the cosmological constant was three orders of magnitude larger than observed. For a flat probability distribution, this would imply that the probability for us to reside in a region where the cosmological constant obtains its observed value is lower than \~10^{-3}. A precise version of the anthropic argument could then be ruled-out at a confidence level of ~99.9%, which constitutes a satisfactory measure of a good experimental test."

Loeb disposes of any *a priori* argument that the CC is anthropically determined, since it is plausible that habitable zone planets will be detected in the descendents of dwarf galaxies (this is what he proposes searching for) which would rule out an anthropic CC, as he explains. One has every reason to expect to find evidence of planet formation in dwarf galaxies just as one finds it in our own galaxy.

I don't know if Steinhardt has any current work debunking anthropic CC but it does not seem that he NEEDS debunk it. Loeb has taken care of that. And Steinhardt has proposed a mechanism by which, in his cyclic scheme, the CC value could be explained.

4. **steve**
July 2, 2006

The original Weinberg mechanism never really worked. The anthropically-favored value of the CC depends on the prior distribution of magnitude of density fluctuations. We were not the only ones to notice this…

Anthropic Distribution for Cosmological Constant and Primordial Density Perturbations

Authors: Michael L. Graesser, Stephen D.H. Hsu, Alejandro Jenkins, Mark B. Wise

Journal-ref: Phys.Lett. B600 (2004)

Abstract: The anthropic principle has been proposed as an explanation for the observed value of the cosmological constant. Here we revisit this proposal by allowing for variation between universes in the amplitude of the scale-invariant primordial cosmological density perturbations. We derive a priori probability distributions for this amplitude from toy inflationary models in which the parameter of the inflaton potential is smoothly distributed over possible universes. We find that for such probability distributions, the likelihood that we live in a typical, anthropically-allowed universe is generally quite small.

and Georgians too.

8. **Martin Kochanski**
July 3, 2006

To the extent that anthropic arguments are intended to answer "why" questions about constants (such as the cosmological constant) that have a continuous range of possible values, they are surely flawed because they can never yield a single answer.

You can have anthropic arguments for the number of dimensions of space – where the possible values are integers – but surely any anthropic argument applied to a continuous-valued constant will still yield an uncountable infinity of allowable values?

9. **Stalin**
July 3, 2006

actually the situation is worse: different regions of the landscape will give different broad distributions; heretic versions of the antrhopic religion will proliferate, unless we obey Slatin's order 227: Ни шагу назад.

10. **annoying lurker**
July 3, 2006

Peter, since the attacks are against the anthropic principle, perhaps you should comment on what you think about Hoyle's use of that principle to successfully predict the fusion of 3 alpha particles into carbon in stars. Hoyle realised that for the observed amounts of C-12, there must be a resonance at 7.65 MeV in C-12. Experiments confirmed it.

Hoyle thought he didn't win the Nobel Prize because he criticised the fact that the Nobel Prize for the discovery of pulsars was awarded to the PhD adviser (Hewitt) of the person who actually made the observation (Bell). However, perhaps it was because of the anthropic principle. Hoyle wasn't predicting anything in the usual sense, just showing that one set of observations (measured carbon 12 abundances in stars, people, etc.) are consistent with a particular nuclear reaction rate.

I think the cancer of corruption in physics is that in default of real understanding, obfuscation is preferred. String theory and its landscape are the ultimate obfuscation with which to sink any questions anyone asks about physics.

When exactly was it that crackpotism won? Bohr at Solvay in 1927, Aspect "falsifying" causality in 1982, or M-theory in 1995?

Do you ever just feel like giving up and embracing the extra dimensional multiverse? It is so much easier to be a crackpot, peter!

11. **sunderpeeche**
July 3, 2006

Hoyle showed that other mechanisms would not work. For our universe to exist (people etc) there had to be a resonance in C-12, and he calculated its energy (correctly). Observations confirmed his claim. That's more than just saying the existence of people is consistent with a particular reaction rate.

? crackpotism Bohr Solvay 1927 ?

12. **annoying lurker**
July 3, 2006

"Hoyle showed that other mechanisms would not work."

Similarly, I can "predict" the width and smoothness of a road from knowing the widths and suspension systems of cars!

Other "mechanisms" (like flying cars through the sky) can be shown simply not to work. Hence, for cars to exist, the roads must possess very constrained, predictable features. Where's my Nobel?

BTW, Bohr wasn't actually awarded a Nobel for disproving causality (despite his long philosophical arguments with Einstein in 1927).

13. **Peter Woit**
July 3, 2006

All,

Unless you really have something new to say, please resist the temptation to start rehashing various aspects of the anthropic principle every time the landscape gets mentioned here. At this point, all this is doing is adding to the noise level.

14. **CapitalistImperialistPig**
July 3, 2006

17. **kristo**
July 4, 2006

Alexander Vilenkin has an article Philosophical Implications of Inflationary Cosmology published in the March issue of The British Journal for the Philosophy of Science.

18. **woit**
July 4, 2006

CIP,

You should look at Douglas's papers for the details. One part of the story is that he wants to put a bound on the volume of the compactification manifold, arguing that if it is too big, we would see its effects already (i.e., we'd be aware that we live in more than 4 space time dimensions by various experimental results).

This kind of bound (together with others), allows him to argue that possibly the number of vacua given by various flux compactification constructions is finite (because the size of the manifold grows as you add fluxes). One problem with putting in a cutoff though, is that, even if you make the number of vacua finite, the distribution of them may be peaked near the cutoff (lots more ways to put in fluxes at the maximal number of them).

If you look at his sequence of papers on counting vacua, you'll see that he started off hoping that statistical distributions of vacua would allow a landscape prediction of whether the supersymmetry breaking scale was low or high, depending on which was statistically favored. He seems to have given up on this, partially because of this problem. People who talk about statistical calcuations of these vacua possibly providing predictions are just ignoring the fact that this idea has been tried, and now is dead for a good reason.

19. **Who**
July 4, 2006

z3,
could you provide a date for the article in the NYT?
I am not a regular Times reader. Any help with finding it? Author name?

NY Times, "Physics Awaits New Options as Standard Model Idles" describes the lack of progress in theoretical HEP in the past 30 years and portraits the sense of frustration in this field. String theory received a passing mention that's sort of dismissive.

20. **woit**
July 4, 2006

The NYT article is an essay by Dennis Overbye (who was in Beijing for Strings 2006), and it is at

http://www.nytimes.com/2006/07/04/science/04phys.html

Unlike many articles in the press full of hype about extra dimensions, etc., Overbye gets the mood in physics right, and emphasizes the lack of any experimental data that could help us figure out how to get beyond the standard model.

21. **Visitor**
July 4, 2006

Secretmilkshake, the answer to your question "Is ST getting like SA? Anybody shot in the back?" is "Motl will certainly be willing to act as an Obstacle Detachment."

22. **andy**

32. **Bee**
July 5, 2006

[From the present to the past]

Cambridge physicist Stephen Hawking and his CERN colleague Thomas Hertog have proposed a radical new approach to understanding the universe[…]

The new theory aims to get round a fundamental problem of string theory — the most popular candidate for a "theory of everything" — which is that it allows the existence of a multitude of different types of universes as well as our own. Each possible universe in this "landscape" has its own fundamental constants and even different numbers of space-time dimensions. Moreover, string theory does not favour any particular universe over another, which is not a good state of affairs as we clearly live in a universe with a particular set of physical properties.

The Statistics of Supersymmetric D-brane Models
http://arxiv.org/abs/hep-th/0411173

http://arxiv.org/abs/hep-th/0510170
One in a Billion: MSSM-like D-Brane Statistics

Abstract
Continuing our recent work hep-th/0411173, we study the statistics of four-dimensional, supersymmetric intersecting D-brane models in a toroidal orientifold background. We have performed a vast computer survey of solutions to the stringy consistency conditions and present their statistical implications with special emphasis on the frequency of Standard Model features. Among the topics we discuss are the implications of the K-theory constraints, statistical correlations among physical quantities and an investigation of the various statistical suppression factors arising once certain Standard Model features are required.

We estimate the frequency of an MSSM like gauge group with three generations to be one in a billion.

34. **Peter Woit**
July 16, 2006

Benni,
What is dead is the idea of extracting any physical predictions out of such calculations. There are no predictions in the papers you mention.

35. **Benni**
July 16, 2006

This papers are the reason why Douglas has given up counting vacua. He referes in his talk at Solvay directly to Luests work.
The Idea of counting vacuas is not death, it was solved.
However one could say the chance of 1 over a Billion to find the standard model is a prediction! At least the only prediction statistical arguments can make, since their only sense is to answer the question "How possible is it to find the standart model"

This is answeared by Luest.

But then we have the case that at the end, one has a certain possibility in string theory to describe our world. Since no one can find the solution explicitely (because of Douglas Complexity paper)
I think it is indeed fair to say the whole subject is at its end.

(as Luest has said to me in person: If the LhC doesn't find supersymmetry, then we need some good advise)

36. **Benni**
July 16, 2006

to be more concrete, you wrote Peter:
Once we have this model, the principle of mediocrity can be used to determine the probablility for us to live in one vacuum or other.

Unfortunately for this research program, it has yet to even begin to get off the ground, and there are very good arguments that it can never succeed.

The point why I send you these papers was, that I think this program has succseeded in the papers from Luest! The answer is one over a billion!

Must be something in the air, lots of weird things going on recently:

My book has been officially non-endorsed by the people at Axes & Alleys.

I finally realized why Lubos was carrying on about how if any errors in my book had been corrected it was because of him. Evidently one of the university presses I sent it to decided he was an appropriate reviewer for the book, and sent it to him to referee. I assume the review was as loony as the one he put on Amazon, but I never saw it, and have no idea whether it convinced the publisher to turn down my book. I do wonder which if any string theorist suggested Lubos to the publisher as an appropriate referee. The "free marketplace of ideas", indeed…

Lubos has put up a paranoid rant about how someone just told him that I "made amazon.co.uk erase all reviews" of the book except for the 5-star ones. This is complete nonsense. When his review appeared there and I first saw it over a month ago, I did hit the "report as inappropriate" link at the bottom of the review, but that's all I ever did about this, and I never saw any other negative reviews except his. Actually, I think his review was responsible for several people posting positive reviews in response to it (thanks folks!). I have no idea why Amazon UK recently deleted his review. Perhaps lots of people hit the "report as inappropriate" link, perhaps someone there just read it and recognized it for what it is. I wrote a comment on Lubos's blog explaining this, but it was immediately deleted (and has now been added to the Censored Comments From the Reference Frame section of this blog). It's pretty hilarious how exercised he is about censorship.

Over at the arXiv in hep-ph, a few days ago there was a paper from Tom Banks entitled Remodeling the Pentagon After the Events of 2/23/06. Somehow, Banks seems to be comparing the appearance of the paper of Intriligator, Seiberg and Shih about metastable SUSY breaking to the events of 9/11, and the following "neo-conservative revolution" in the US. Banks had a SUSY model containing a "Pentagon" (a "new strongly interacting SU(5) super-QCD with 5 flavors of pentaquark"), which he now enhances with metastable SUSY breaking to get what he describes as "a lean and mean, stripped down version of the Pentagon, suitable for rapid deployment to solve all of the problems of the supersymmetric standard model" (a footnote warns about the Pentagon's propensity for hyperbole).

A commenter here pointed to another paper on hep-ph, from last night, entitled Neighboring Valley in the String Landscape. Pretty much pure science fiction, although it did make me realize that just about any Landscape paper could be improved by doing what this author did, including an impressive color graphic of the earth de-materializing.

Over at hep-th, there's a new paper last night, entitled Generalized Flux Vacua. Using a new construction, the authors find an infinite number of solutions that are supposed to be consistent backgrounds for string theory. This pulls the plug on the arguments from a couple weeks ago by Acharya and Douglas that the Landscape should be finite (after imposing varous cutoffs). The authors also claim that this drains some of the swampland promoted recently by Ooguri and Vafa. They do note that, although string theory is a completely precise and rigorous framework, it's impossible to tell whether the backgrounds they describe really are consistent vacua for string theory (because of, among other things, possible non-perturbative effects):

This somewhat surprising result seems to contradict recent predictions regarding properties of the string landscape, though as we will discuss there are some reasons why the solutions we find may not correspond to stable nonperturbative vacua in a complete string theory framework.

Comments

1. **John A**
   July 5, 2006

   For Lubos to keep referring to you as "the lecturer in Discipline" rather than by your name, is just desperately sad.

   I cannot judge the finer points of your argument about string theory, but judging by the extraordinary behavior of Lubos, I'd have to say he's completely lost it.

   String theory is a metaphysical theory. It has no laboratory.

2. **Peter Woit**
   July 5, 2006

   John,

   I don't know, at least he's getting my official title right. Seems like an improvement over the usual "crackpot", "scientific microbe", "one gigantic KGB", "Goebbels", "inquisition", etc…

3. **Kea**
   July 5, 2006

   "Pentagon" (a "new strongly interacting SU(5) super-QCD with 5 flavors of pentaquark")

   OK, I won't say it…..

4. **Who**
   July 5, 2006

   Freidel's paper is out
   there has been some discussion of the anticipated results already by Urs and by fh, at the Distler blog.

   http://arxiv.org/abs/gr-qc/0607014
   Particles as Wilson lines of gravitational field
   L. Freidel, J. Kowalski–Glikman, A. Starodubtsev
   19 pages

   "Since the work of Mac-Dowell-Mansouri it is well known that gravity can be written as a gauge theory for the de Sitter group. In this paper we consider the coupling of this theory to the simplest gauge invariant observables that is, Wilson lines. The dynamics of these Wilson lines is shown to reproduce exactly the dynamics of relativistic particles coupled to gravity, the gauge charges carried by Wilson lines being the mass and spin of the particles. Insertion of Wilson lines breaks in a controlled manner the diffeomorphism symmetry of the theory and the gauge degree of freedom are transmuted to particles degree of freedom."

5. **woit**
July 5, 2006

Who,

Somehow I don't think you believe the Freidel et. al. paper fits under the current topic of "Various Weirdness"… You really need a blog devoted to LQG, maybe you can get Distler to host an "LQG Coffee Table". Now, that would be weird…

6. **Who**
July 5, 2006

you are being conversational about my sin of offtopicness, instead of delivering cuffs of disapproval. you must be in an exceptionally good humor. I am glad

7. **Shantanu**
July 5, 2006

Peter , what exactly does "officially being non-endorsed mean"? also who or
what is the "Axes & Alleys" ?

8. **woit**
July 5, 2006

Shantanu,

Can't say that I know the answers to your questions, your guess is a good as mine. As near as I can tell, the mysterious forces behind this publication and blog are string theory skeptics, and thus fans of Not Even Wrong. The official non-endorsement has something to do with my refusal to admit that I found their string-related graphic funny.

Like string theorists, they seem to have a very original relation to the question of "reality". Unlike string theorists, they seem to be aware of this…

9. **Chris W.**
July 5, 2006

Who,

Compare gr-qc/0607014 with [hep-th/0403137](hep-th/0403137). There seems to be a conceptual connection here.

(Peter: I beg your indulgence; could you leave this comment in place for a day or two?)

10. **Mike**
July 5, 2006

Is the business in that paper about remodeling the Pentagon after the "events" of a certain date — admittedly not 9/11 — perhaps in bad taste, rather than a sign of cleverness? If I knew someone who had died there, I might find it so.

11. **woit**
July 5, 2006

OK, that will teach me to be a nice guy. Next off-topic LQG commenter will be shot.

12. **woit**
July 5, 2006

Mike,

I'm not sure about poor taste, but it's definitely weird. Promoting the latest advance in SUSY breaking as being like 9/11? A very, very, weird field, this one, if you ask me.

13. **D R Lunsford**
July 5, 2006

I don't want to be shot, so I won't explain my plan for rebuilding the World Trade Center as a hyperdiamond Feynman lattice. Wait, that's on topic! Go ahead! Make my day!

-drl

14. **Jeremy**
July 5, 2006

D R:

I fully-endorse your plan! Of coursed, at this point in time I would endorse I giant rubber duck there.

While I understand the fully-human reaction Lubos shows to a complex questioning of an idea so closely identified with the core of his life, I still think the denigration involved is out of place. That aside, I have enjoyed reading him when he's not cranky (so every four days or so).

Dr. Woit, have you read or seen the new publication on the 10th Dimension? I find its explanation of the 5th, which is one essentially of choice, to be quite amusing.

15. **andy**
July 6, 2006

Peter: Get over Lubos. Ignore him. He craves recognition and notoriety. Sure, he probably legally libelled you in his post, but "whaddaya gonna do aboudid?"

Lubos is a nutbar, and he's the "best" proof that string theory is dead. Celebrate it!

16. **andy**

July 6, 2006

ps: and how many papers has LM written recently?

17. **Aaron Bergman**
July 6, 2006

    Re: Banks

    Lighten up, dude. You could argue that the joke is in poor taste, but it's certainly not "promoting the latest advance in SUSY breaking as being like 9/11".

18. **woit**
July 6, 2006

    Aaron,

    Re: comparing 9/11 to 3/23

    Lighten up, I don't especially think it's in poor taste. I think it's nutty. Watching gonzo surrealism take over the subject of particle theory is kind of fascinating to watch.

19. **John Gonsowski**
July 6, 2006

    Well being a surreal Gonso all my life, I might as well add something… rebuilding the World Trade Towers as a hyperdiamond Feynman lattice could allow it to be protected by the variable physicality of the conformal degrees of freedom but you would have to make sure it doesn't drift off into a pure 8 dimensional non-supersymmetric universe. Woit, that's on topic! Go ahead! Make my day!

20. **John A**
July 6, 2006

    Security backup of comment:

    > I'd like to know why the name of this blog morphed from "Lubos Motl's Reference Frame" to "The Reference Frame".
    >
    > Surely the first implied that this was your point of view on things, while the latter seems to imply that everyone should see view the world in exactly the same way as you do.

21. **Carl**
July 6, 2006

    Now that you mention it, "The Reference Frame" seems to suggest an aether.

    Carl

22. **Mike**
July 6, 2006

    Let me make it clear: I think the 9/11 – 3/23 pairing is weird. That doesn't mean it isn't in poor taste as well. Especially to people — aka citizens and taxpayers — who know nothing about physics, but understand 9/11 very well.

    I remember the colleague whose reaction to 9/11 was that it was horrible, but it sure was great theater. That has always struck me as weird, and as in very poor taste, especially given the fact that he was a citizen of another country (albeit one which lost many in the WTC).

    It's all probably a minor point. Maybe not even wrong, but I doubt it. On with physics!

23. **Aaron Bergman**
July 6, 2006

    Banks has done this sort of thing for yaers.

24. **anonymous**
July 6, 2006

    astro-ph/0412647 of 29/12 was inspired by the tsunami of 26/12, an event worse than 9/11.

25. **John Gonsowski**
July 6, 2006

    Personally I am too into 9-11 to stay depressingly serious about it 100% of the time but it is important for sensitivity and seriousness of issue reasons not to go overboard. One day and one day only during my four years at Carnegie Mellon we trashed our floor of the dorm (nothing permanent), the clean-up crew just seemed to smile knowingly.

26. **Peter Woit**
July 6, 2006

    Aaron,

    At least in the case you mention Banks's analogy of the state of string theory with Dante's Inferno makes good sense…

27. **Aaron Bergman**
July 6, 2006

    I'm sure you don't want the unsolicited advice, but you really need to look at things without the lens of your crusade against string theory occasionally and not take everything quite so seriously, Peter.

Or, put another way, not everything needs to be interpreted as part of the growing malaise that will soon overwhelm string theory and exile us all to the the world of financial derivatives.

28. **Peter Woit**
July 6, 2006

Aaron,

Good advice, but I can assure you that at least in the case of this posting, this is all about not taking things seriously. There's an extremely entertaining surrealism to so much going on in this business these days.

29. **Mike**
July 8, 2006

Not a string theorist myself, so I have no personal stake, but if string theory crashes, there are other possibilities besides financial derivatives (and anyway, that too will soon be saturated anyway). There are many interesting things going on in science, more likely to lead to something worthwhile than the (N + 1)th string theorist, to which physicists, theoretical physicists, can contribute. Things involving cooperative phenomena in a whole bunch of fields, inside and outside of physical science. I say at least have a look at other "options" if you are a young person thinking of bailing from the string world!

String Theory for Undergraduates

July 5, 2006
Categories: Uncategorized

I hadn't realized how many of the physics departments at the top universities in the US have instituted undergraduate string theory courses. The only one I was aware of was MIT's 8.251, [String Theory for Undergraduates], taught by Barton Zwiebach, who developed a textbook for the course, A First Course in String Theory.

Maybe now that there's a textbook, that is what has caused other institutions to follow suit. Caltech has Physics 134, String Theory, and Carnegie-Mellon has Physics 33-652, An Introduction to String Theory. Stanford goes its competitors one better by having two undergraduate courses in string theory: Physics 153A, Introduction to String Theory I, and Physics 153B, Introduction to String Theory II. This last course even promises to explain to students how string theory is connected to particle physics.

Comments

1. **D R Lunsford**
   July 5, 2006

   Needless to say, this is absurd. Is physics trying to commit suicide? In fact there is no longer any need or use for American scientists and engineers, only Home Depot clerks and the matching consumers, so I guess they figure – why not?

   It's as if law schools were to begin teaching from Deuteronomy. Let's bring back Aristotle and Pliny!

   -drl

2. **Kea**
   July 5, 2006

   Gulp! In my country we don't even have any String theorists.

3. **LDM**
   July 5, 2006

   It is probably not too unreasonable to state that many critics of the theory have not studied string theory even at the level of Zwiebach — and even Feynman said (read the letters book for the exact quote) he did not believe in it, but he admitted he did not know enough about it to say why…

   As long as the undergrads have the necessary background, I think this is an EXCELLENT decision — to offer undergrads courses, so they can judge the merits (or lack thereof) of string theory themselves.

   They will also then be in a position to judge when its supporters have let their enthusiasm overpower their scientific better judgment (As an example, Zwiebach's recent letter comes to mind — it was, unfortunately, egregiously biased and overstated — however, one can only really make these judgments if one has studied string theory sufficiently to realize Zwiebach was exaggerating its results) — OR when the beauty of its ideas and its partial results, despite the current lack of experiments, justify a continued optimism that that the theory has substance and is worth continued investigation.

4. **z**
   July 6, 2006

   After a cursory look at Zwiebach's course page, it seems to me some mathematics only at the sophomore or junior level is required – PDEs, linearity, multivariate calculus. What exactly do they hope to accomplish with such courses other than to inculcate a new generation of graudate students and benefactors? Connections explored in these courses to experimental tests is superficial at best, in my opinion.

   I'm not saying these courses are worthless — there's a lot of neat mathematical tools an undergraduate could learn to apply in them. However, an undergraduate education in physics should be firmly based in reality. Speculative theories such String Theory and even LQG should be in the domain of graduate school or applied mathematics, not undergraduate physics.

5. **biophysicist**
   July 6, 2006

   I took the class myself a couple years ago back when we were still given the typed manuscript for free (there now I've definitely given away my identity for a couple readers of the weblog for sure) and even though obviously I chose a different branch of physics for my graduate work I have to say that the course was simply outstanding and Barton Zwiebach is one of the finest teachers I've ever had. Yeah string theory as science has definitely seen better days, but the class itself is a great way to learn a lot of the tools used in modern physics. The way Barton teaches it also makes it a neat way to see how different theoretical underpinnings can come together – the calculation of the Beckenstein-Hawking entropy result for example played a big role in my personal decision to pursue statistical mechanics as a graduate student (now of course, as a statistical mechanician, I can laugh at all you particle guys whose work is simply an input into our theories 😉).

   Also I'd like to point out that while the class started with probably 60 people (including 30 or so undergrads) the year I took it, we only ended with 6 undergrads by the end I think and about 20 graduate students. So before anyone gets too worried about Barton's corruption of us youth I think it's worth thinking about the positive aspects of the class – I of course cannot speak to the other institutions' courses, but I learned a lot of useful tricks in 8.251 that I use to this day.

6. **Richard**
   July 6, 2006

   String theory for undergraduates is excellent for students who want to think about classical mechanics and E&M in a more abstract way in preparation for graduate school. Additionally, these courses can serve as "capstone" courses for physics majors who aren't planning on going to graduate school. Most students who are interested in theory will take either GR or QFT instead. Perhaps a course that would serve both groups of students better would be an introduction to conformal field theory with applications to condensed matter for undergraduates, but no one has written a book for that subject comparable to Zwiebach's.

7. **Doug**
   July 6, 2006

   I would like to take the course, if nothing else just so I can get the answer to one question:

Why does David Gross and others say that they don't know what string theory is? What does this statement actually mean?

8. **Jimbo**
July 6, 2006

After 10 yrs of college physics teaching in Calif., Colo., Florida and Oregon, I can guarrantee that 99.9% of the undergrads, at 95% of US universities, contemplating signing up for an intro string course out of Zwiebach's book, will drop the course in less than 2 weeks !
In the 5% I am excluding, are of course Caltech, Harvard, Stanford, Princeton, Cornell, UC, CU, UWash, etc.
However, even at prestigous schools, where undergrads have excellent preparation, faculty are overcommitted to teaching std. req'd courses, and will probably be reluctant anyway, in the dubious light of anything stringy these days.
Mike Duff was very harsh on the mathematical unfitness of physics American students, and I can personally vouch for the veracity of his comments on this sad state of affairs.

9. **misslemon**
July 6, 2006

Re: LDM's arguement:
"I think this is an EXCELLENT decision — to offer undergrads courses, so they can judge the merits (or lack thereof) of string theory themselves.
They will also then be in a position to judge when its supporters have let their enthusiasm overpower their scientific better judgment "

Would you say, then, that it's also an excellent idea to teach "creation science" to biology students? Not to say that string theory is in the same class, but this IS the arguement often used for allowing creationism into the biology curriculum.

10. **MathPhys**
July 6, 2006

The first half (or so) of Zwiebach's book is good because he assumes so little, so he has to explain lots of basic physics before hand, so you can think of this, indeed, as a motivated introduction to general physics.

I'm not so sure I like the latter parts of the book, where he introduces those aspects of string theory that he's interested in. That makes the book less than suitable as a standard textbook.

11. **D R Lunsford**
July 6, 2006

Richard said

String theory for undergraduates is excellent for students who want to think about classical mechanics and E&M in a more abstract way in preparation for graduate school.

I can't see this as being in any sense true. In fact, having wrestled with both things at length, I declare it categorically false.

All the hotshots I ever knew had glaring holes in their understanding. I assume hotshots everywhere are similar. One has to work at rounding out one's understanding, and it ain't comin' from string theory. There is a magisterial tone in your misunderstanding that illustrates the actual source of the current unpleasantness.

-drl

12. **Alejandro Rivero**
July 6, 2006

A problem with Zwiebach's book is that it is very easy to follow in the first part but it is at the end expected to be taught by an expert of the field, because when it goes into complications it just promises that in the real research papers all the questions are rightly answered. SO you are forced into Ponchiski's are GSW and it is not undergraduate anymore.

Still, it is interesting for an undergraduate to think about the quantisation of extended objects.

13. **X**
July 6, 2006

maybe it is interesting for undergraduates that already understood quantization of point particles?

I think that an undergraduate needs to get some idea about what string theory did/will accomplish, to decide if it is worth to study it. While learning some details of string quantization (at the expenses of not learning other physics) is not a good idea.

14. **Warren**
July 6, 2006

Stanford is on the quarter system, so it's really more like 1 1/3 courses.

15. **LEJ Brouwer**
July 6, 2006

I would love to see a textbook on modern string field theory in the Batalin-Vilkovisky formalism of which Zwiebach was a pioneer. The beautiful thing about Zwiebach's work, and I think this is shows through in all his research papers, is his emphasis on clarity and rigour, despite the inherent complexity of the subject matter.

16. **Doug**
July 6, 2006

But, again, how can a university course, based on a textbook, teach something that nobody can identify? What is it that I'm missing here? What do string theorists, like David Gross, mean, when they say that they don't know what string theory is?

Please, can someone take a moment and explain this to me? Books, pro and con, are flying off the presses about something no one understands, but everyone feels so strongly about.

I can understand the idea of strings vs. point particles. I can understand the difference between the 26D bosonic string theory and the 10D superstring theory with its five dualities and how the 11D M-theory unifies these. I can even understand how compactified dimensions make it possible to have n-dimensional equations of motion in a 3+1 manifold, but what do they mean when they say they don't know what string theory is? This I don't understand.

17. **Kasper Olsen**
July 6, 2006

Dear Peter,
did you read the book? It is – in my opinion – actually quite good; all of it might not be important for eventually going beyond the standard model, but don't you think it is important to learn about the most promising ways of going beyond the SM? If somebody wanted to give a course on LQG or twistor theory, don't you think it would be OK?

– regards, Kasper

18. **Jason**
July 6, 2006

Relax, people.

19. **Peter Woit**
July 6, 2006

Doug,
It's very simple. What is known about string theory is how to construct a (divergent) series, one that is supposed to be a perturbation expansion of some still unknown exact theory, and thus an asymptotic series in the string coupling for the true result. There are lots of partial, conjectural ideas about what properties this non-perturbative true theory will have, and some conjectured constructions in special backgrounds that don't look like physics. But no one has a good idea about what this exact, underlying theory is. There has always been a lot of speculation about how it will be something completely new and different, involving new ideas about space and time.

Kasper,

No, I don't think it would be OK for a physics department to set up an undergraduate course in LQG or twistor theory. This kind of highly speculative stuff involving advanced mathematics belongs in upper-level graduate courses, not undergraduate courses where the students still have yet to learn many of the most basic things about physics and the most basic mathematical techniques needed. I know of no other example ever where multiple US physics departments have instituted undergraduate courses in a subject for which there is no experimental evidence.

Yes, I own a copy of the book and have read some of it, although it covers material I've read about many times in other string theory books and expository papers over the last 20 years. It's a good exposition of the subject from a true believer, but it's completely inappropriate for undergraduates. There are many, many more useful things for them to study than the details of how to quantize the string in light-cone gauge.

I completely disagree with you that string theory is a promising way of going beyond the SM. It has completely failed at this, something you won't learn by reading all the hype in Zwiebach's book. Even if it were a promising way of going beyond the SM, undergraduate students don't even yet have the background to understand the SM, and they need to do that first. It is becoming a huge problem in particle theory that students are being trained in the details of string theory before they have really mastered the details of the SM.

20. **D R Lunsford**
July 6, 2006

Peter,

The time would be better spent on, among other things, an intensive course in "Intuitive Relativity". I found that very few undergrads understood relativity at all well. I think a history course with readings of original papers would be good (e.g. the "Dreimaennerarbeit", Pauli's review articles, Einstein's big papers etc.)

-drl

21. **LEJ Brouwer**
July 6, 2006

I agree that string theory is not a useful topic to study at the undergraduate level. However I think the study of Clifford algebras and their applications to physics (see e.g. the book "Geometric Algebra for Physicists") could prove to be a useful broad framework for those intending to carry out future research in theoretical physics.

22. **Doug**
July 6, 2006

Thanks Peter. Does the book explain that, or is it assumed that an undergrad physics student would ordinarily realize it?

23. **James**
July 6, 2006

Peter,

It might be a shocker for you but several European universities offer undergraduate string theory courses and have been doing so for at least 15 years (that is what I am aware of). Examples: Amsterdam, Groningen, Utrecht, Brussels, Budapest, Prague, Moscow and I'm sure there are plenty more.

Mind the fact that there are loads of old professors for whom the phrase "string theory" means something from the 70's and that is what they teach. It would be very difficult for you to convince them that this material is some new age hype when they were studying it 30 years ago.

Of course there are European universities where the more modern approaches are taught to undergraduates under the banner "string theory", e.g. Amsterdam and I suspect this area is where you actually target your criticism.

My observation is only to enlighten anyone who thinks that "string theory" is a large monolithic blob which can be commented on and criticised in one go.

Hope this helps,
James

24. **James**
July 6, 2006

Peter,

You write "What is known about string theory is how to construct a (divergent) series, one that is supposed to be a perturbation expansion of some still unknown exact theory, and thus an asymptotic series in the string coupling for the true result." and perhaps you allow me to notice a certain negative tone in this sentence.

However, I guess you agree that nothing is known about the Standard Model non-perturbatively (except for QCD but that is also not rigorous) and all what is known is a perturbative expansion but that doesn't cause us any headache. So this particular criticism of string theory is not really honest as you could say the same for the Standard Model as well. Put it this way: a rigorous non-perturbative definition is *not* a requirement for a good physics theory.

I can already hear you saying that the Standard Model has been confirmed experimentally and string theory has not, which is completely true but in your above mentioned criticism you brought up the lack of a non-perturbative definition and haven't talked about experiments. In other words just because one valid criticism exists does not mean that *any* criticism is valid.

Hope this helps you understand why string theorists and other high energy physicists do not respond to your book in a serious way and why string theorists and other high energy physicists do not take you seriously over all. If they are looking for criticism of string theory (plenty exists surely, lack of experimental evidence being one) they go to the experts who are also plenty. Even plenty of string theorists exist who are critical in a reasonable way, unlike you I am sorry to say.

Again, it is my intention to help you understand the reason for your considerable isolation in high energy circles especially since you yourself asked the question in one of your postings why there is no serious string theory reaction to your book.

All the best,
James

25. **Chris Oakley**
July 6, 2006

Hi Anonymous James,

I don't think that your observations are very relevant. Many of us have come to the conclusion that the String community is not capable of reforming itself and therefore the change has to come from outside. This is where writing books for the general scientific audience comes in. Peter is surely in the vanguard here, but if he had not taken it upon himself to draw the world's attention to the extent to which fundamental physics research has poisoned itself, someone else would.

26. **anonymous**
July 6, 2006

Dear James, the main problem is not the lack of experimental evidence, but the lack of any experimental signal. I hope you agree that, if strings have nothing to tell to experimentalists, the lack of a rigorous non perturbative definition is solved as: who cares?

27. **Peter Woit**
July 6, 2006

James,

The problem with string theory is not that it doesn't have a rigorous non-peturbative formulation, the problem is that it has no non-perturbative formulation at all (other than on unphysical backgrounds). This is especially problematic because the vacuum state people want to use in string theory can't be the perturbative one. This is why you can't predict anything in string theory. You don't have a non-perturbative theory that can tell you what the possible vacuum states are and allow reliable calculations in these states.

This is completely different than the standard model, which has a well-defined non-perturbative lattice formulation. This definition is completely rigorous, the only thing non-rigorous is that you can't prove that it actually has all the properties you expect. You can do approximate calculations, either perturbative or semi-classical ones where appropriate, or fully non-perturbative ones using Monte-Carlo methods. All the results of these approximate calculations are consistent with the non-perturbative theory having the properties one expects.

For the electroweak part of the SM, the vacuum state is the perturbative one, you can do perturbative calculations, and these have been confirmed experimentally to very high accuracy. For the strong interactions, the low energy behavior is non-perturbative, you can calculate it using Monte-Carlos methods, and, within the accuracy of the calculations you get agreement with experiment. At high energies because of asymptotic freedom, you can use perturbative methods also in QCD, and get good agreement with experiment there too.

The situation of the SM is just completely different than that of string theory, and the fact that you don't know this seems to indicate that you don't know much about this subject at all. I don't know who you are, since you choose to hide behind anonymity, but you give every appearance of being an undergraduate who has no idea what is going on here.

As for my "isolation in high energy circles", I can assure you that that is not the case. I regularly talk to high energy physicists of many different stripes, and find that the only ones who significantly disagree with me are the more fanatical among the string theorists. From my conversations with many physicists in recent years, my impression is that the great majority of the physics community now has a low opinion of string theory (often lower than mine). Even the majority of string theorists that I talk to think the state of the field is highly problematic. Several of the people who regularly comment here, but choose to remain behind pseudonyms because of fear of retribution from fanatics, are known to me and are theorists who work on string theory.

I wasn't asking about why no one agreed with me, most theorists do. What I'm curious about is why those string theory true believers who disagree with me refuse to publicly answer any of the criticisms I make of the theory. So far, the only one willing to do so is Lubos, and he is crazy. The only others heard from are people like you, who don't seem to know what they are talking about and can't answer any of my criticisms, but yet insist on attacking my competence to make them in a cowardly fashion using pseudonyms. This kind of defense of string theory is not going to work. It is becoming widely realized in the physics community that string theorists are not able to answer the scientific criticisms being made, and the way they are choosing to respond to their critics is rapidly stripping them of any credibility.

28. **Peter Woit**
July 6, 2006

Doug,

I haven't looked at everything in the book carefully, but it certainly was my impression that the book did not explain exactly what the problem is with having no non-pertubative formulation. I have no idea whether Zwiebach explains this to his students, but his recent letter to the WSJ not only didn't mention this problem, but tried to imply that it doesn't exist or is not serious.

29. **Clifford V Johnson**
July 6, 2006

Hi Peter,

I hope you're well.

A few things:

(1) I can think of numerous times when well-known non-crazy string theorists have answered your criticisms, on this blog and on others. The problem is that you choose to forget the answers and keep repeating yourself. So people have gotten terribly bored with the whole thing I suspect. It's nothing personal, at least not on my part, just really really boring, I'm afraid. How about searching your own blog's archives for some of the answers? And those of CV? There's really been no significantly new discussion points since last August or so, so all this stuff is hard to distinguish from a PR exercise to sell a book. Not that there's anything wrong with PR exercises per se, and I am of course not accusing you of engaging in one, just making an observation.

(2) The only time you seem to come over and join in a discussion (or whatever) over on CV about strings is when you've something negative to say. Why not come and join in the other discussions (there and elsewhere) where we are all publicly visibly learning new things about ongoing research in the field as we go along? Not doing so while continue to make the same old answered points again and again -your current practice- might lead the uninformed observer that maybe you have a fixed idea about what you want to believe and will only discuss results consistent with that. See my last two sentences of (1).

(3) You speak with certainty that string theory has failed as a theory of Nature. Actually, you don't know if that is true, and nobody knows that. It is your hunch that it is so, and it is my hunch that it is not so, and we are entitled to our hunches. It is a subject of ongoing research. That is as much as anyone can say. To say more is hype. I thought you did not like hype. See my last two sentences of (1).

(4) You say that the majority of string theorist that you talk to think that the state of the field is highly problematic. I cannot dispute that you got that impression, but I do question the validity of the sample that you have ahda access to. I and several of the people I work with or meet regularly in the field (from many of the most active groups around the world) don't seem to have that strong an opinion. But that's consistent with the fact that none (or few) of these people have actually met you at any conferences or meetings. (Unless they are meeting with you in secret?) So there seems to be little or no intersection between the set you are meeting with and the set that I and my colleagues and collaborators are meeting with. Interesting, don't you think? You're a smart guy and ordinarily would not make such an empty point unless….. oh…see the last two sentences of (1).

(5) The real reason I came on to comment (since I've said much of the above before) is to ask whether you really think that (as a faculty member of a respectable university, but we'll let that pass) it is consistent to publicly beat up on an undergraduate (if that is what James actually is), and call him or her ignorant about string theory and other issues *in the very comment thread of the post you wrote saying that undergraduates should not be taught string theory*? Also, he/she made some interesting historical and factual points that you chose to ignore. How come? This all seems a little odd to me.

Summary: With all due respect, please change or update the refrain of the song. It's got rather boring. Stop being so transparently selective about what you choose to mention about the string theory program. Try harder to apply the same standards of rules of engagement in discussion that you apply to others. (I know this latter is hard…. I fail sometimes too).

Anyway, the repetitive refrain and the selective memory about what has been addressed…. these the main problems. It is just boring. Nobody wants to play anymore, and standing on the mound beating your chest yelling "why will nobody fight me?" is looking a bit silly. I'd stop that if I were you. (Although it is good for book sales and press attention. The press and the public love the old tired "underdog vs the establishment" story.)

Ok, I'll go now. I hope to have a pleasant, reasonable, and *new* discussion wth you sometime soon.

Cheers,

-cvj

30. **Eugene Stefanovich**
July 6, 2006

cvj:

I don't see anything wrong in what Peter is doing. We had enough "PR exercises" of different kind – "The elegant universe", and Kaku, and all that. We all heard how M-arvelous and M-ysterious the string theory is. Now it is time to hear a second opinion. I find it refreshing and healthy that a person like Peter spends time and effort to debunk stringy hype attempts.

If Peter is right, then the question of scientific validity of the string theory may never be resolved by scientific methods. It looks like it is impossible to prove this theory wrong, and there are no visible signs of experimental evidence in favor of strings. Nobody wants to forbid stringy research. The question is how much of taxpayers' money should go there? String theorists enjoyed enormous amount of public trust for a couple of decades. The question is whether we should continue to trust them, or better start investing in something else?

Peter, I also don't like when you attack your commenters (even anonymous ones) on a personal level. This doesn't make your position stronger.

31. **woit**
July 6, 2006

Hi Clifford,

Thanks for stopping by. Sorry I don't have much time time to respond. Actually I'm leaving early tomorrow morning for a very short vacation in LA. From CV, I gather you're not there, but enjoying the south of France.

I do pay close attention to the responses I have gotten here and elsewhere from string theorists to my criticisms of the theory. They're a mixed lot, ranging from offensive personal attacks by Lubos and followers at one extreme, to much more sensible comments from you and others. I'd characterize your response to my criticisms of string theory as roughly "it's still too early to evaluate, we're working on it, look at the progress we've made in AdS/CFT for instance". This is fair enough, it's a point of view I can understand and respect, although I don't fully agree with it (22 years is a very long time, the amount of progress is exaggerated, etc….).

The main problem with your point of view seems to me to be that you're pursuing one set of goals (e.g. for instance better understanding AdS/CFT, topological strings, 2d strings), which are reasonable, but selling the subject to the outside world as a much more ambitious program, without acknowledging that it has failed. Your work on non-critical string theories may or may not someday lead to something interesting, but what is being promoted to the public is the idea of unification via a critical 10 d string (or 11d M-theory). This has created a whole industry of people investigating an infinitely complicated variety of "backgrounds" for such a string, and ultimately led to the landscape fiasco. This has been a disaster, and it needs to be acknowledged before it leads to more damage to the field than it has already caused.

When I say that the majority of string theorists I talk to find the state of the field problematic, the main thing they often have in mind is the landscape, which often completely appalls them. Besides this, most also feel that there has been a depressing lack of exciting new ideas in the subject, across the board. I can't believe you don't also find many if not most of your colleagues disturbed by the landscape. As for the number of exciting new ideas question, this can be quantified by looking at what papers are being cited in new ones coming out, and I can back up what I say with some very solid data.

In terms of people I talk to or exchange e-mail with, my sample size is small, but it's non-trivial. When I go to conferences, it is often (but not always) to mathematics or mathematical physics ones, since that's where my research interests lie, but I have been to and even given talks at conferences or workshops where there were quite a few string theorists. On the whole I found when talking to them that they shared many of my concerns about the subject. Unfortunately, some string theorists have very much isolated themselves from the rest of the physics community. Sorry to have to tell you this, but many of your physics colleagues tell me they think the field of string theory has become a bit of a closed religious cult. Skeptics aren't welcome there and have little motivation to try and participate. The last physics conference I was at was last week, here in New York, the one about group theoretical methods in physics. I talked to more than a few physicists then, and I can assure you that the level of hostility to string theory and how it is currently being pursued surprised even me.

About "James". I have no idea who he is or whether he's an undergraduate, quite possibly he isn't. If he is one, he has no business writing ignorantly in here to attack someone who knows far more than he does. My conduct towards him was significantly better mannered than his towards me.

As for CV, I do post comments there when I think I have something worthwhile to say. Often they're not about string theory at all. When they are associated with one of the postings about the string theory controversy, they're often respectfully disagreeing with a much more positive take on string theory due to one CVer or another. Sorry if you find my objections to string theory "boring". I find the endless continuing overhyping of the subject equally "boring", but feel that someone should do something about it. I'd be very happy if it wasn't me.

As for your endlessly repeated attempts to pin this all on my trying to sell books, just come off it. This has nothing to do with that. I've been making these criticisms privately for 20 years, publicly for more than five years, long before there was any book. This is a complicated business and the book is my best attempt to lay out what I've learned in a long career, and explain a point of view about where the subject of particle theory is now that I strongly believe in and hope people will pay attention to. Sure, I definitely think people should read the book, I'm arrogant enough to think that I have something important and valuable to say. But if it's a complete failure as far as the publisher is concerned and doesn't make a dime, but a sizable fraction of the particle physics community reads it and thinks about what I have to say and whether my point of view makes any sense, I'll consider the project to have been a huge success.

Hope you're enjoying Marseilles and meeting some mathematicians, they do some very worthwhile things…

Peter

32. **Jimbo**
July 6, 2006

I spoke recently with an Indian string theorist (Tata Instit.), and he basically wrote off Peter & Bert Schroer as "disgruntled whiners, without any significant research in years". My retort was, might we add Veltman, Glashow, Richter, & Gates to that list as well, and who knows how many other field theorists that might emerge from the closet to signal their opposition to the dominant paradigm in HEP ?
Pro or Con, we are all college educated people, and how do they settle arguments: Forensic Debate. Lets gather together 5 prominent stringers, and 5 prominent anti-stringers, and have a live debate, with theorists from neutral camps for judges. The media would devour it !
In addition, why not CLOSE the N.E.W. blog Peter, now that your book is out, the Discover article is months old, and get on with your life & research ? It must be very taxing doing this 24/7, and lets face it, the word IS out, and I don't think the stringers will get carte blanche much longer, when in just a few years, the LHC tallies up evidence.
Who knows if you close, Lubos might just as well too.

33. **Peter Woit**
July 6, 2006

Jimbo,

The one criticism I get for how I've been spending my life the last couple years that I do agree with is that I'd be better off spending more time on my own research ideas. I'm hoping to spend less time on the blog and more on research, and perhaps changing the emphasis of the blog so that it's more about research level topics I'm thinking about. Urs Schreiber's blog is an interesting example of this kind of thing. Unfortunately this may not be so easy the next few months. Clifford thinks I'm spending my time trying to get people interested in my book, but it's not quite like that. There's a lot of interest in it already, and it is taking a signficant amount of time now to respond to people who contact me about it for one reason or another. The response has been very gratifyingly positive, but dealing with it does take time away from other things. Current plan: try and find as much time this summer as I can to work on research, write off September as hopeless since the book is coming out and a new semester will be starting, then hope by later in the fall things quiet down, my job is done, everyone agrees with the NEW critique of string theory, so that part of the blog can fade into irrelevance.

34. **Anonymous**
July 6, 2006

Pro or Con, we are all college educated people, and how do they settle arguments: Forensic Debate.

Really? To me that phrase conjures images of unreasonable people talking as fast as possible, emphasizing the same points repeatedly, and not listening to the people they're talking to. Oh, wait, that sounds familiar….

35. **Jonathan Vos Post**
July 6, 2006

Why not compile the course descriptions and see what is being taught by whom, perhaps with what textbooks?

From Caltech's catalog:

Ph 134. String Theory. 9 units (3-0-6); third term. Prerequisites: Ph 125 ab, Ph 106 ab. A basic course in string theory designed to be accessible to a broad audience. The main topics include the motion of relativistic point particles and strings, actions, world-sheet symmetries and currents, light-cone quantization, and the spectra of relativistic open and closed strings. The course will conclude with an exploration of D-branes, T-duality, or string thermodynamics, depending on student interest. Instructor: Schulz.

36. **JC**

July 6, 2006

I wonder if Lubos will write his own string theory book for freshman undergraduate students. 😉

37. **Michael**
July 6, 2006

"changing the emphasis of the blog so that it's more about research level topics I'm thinking about"

YES!! Tell me all about your interesting new ideas, especially the off-diagonal ones. 😆

38. **Peter Woit**
July 6, 2006

Always charming to hear your witty remarks Michael/Dan/whoever you are. Now go back and play with your big brother Lubos…

39. **Hmm**
July 7, 2006

Perhaps, before making grandiose statements about the past and future directions of theoretical physics, and especially before "correcting" people with authority, it would be useful for you to understand, say, some elementary quantum field theory?

Lets take your response to James about the difference between non-perturbative effects in the Standard Model vs. string theory. You contradicted James and said that the Standard Model has a perfectly rigorously defined lattice formulation. Even ignoring gravity, this is nonsense. Hypercharge is not asymptotically free and hits a Landau pole at a scale \Lambda–so there is no "perfectly well-defined" lattice formulation. The Standard Model by itself simply isn't "well-defined"–there are effects of order \sim E^2/\Lambda^2 \sim e^{-1/g^2} that *can't even in principle* be calculated, as they depend on the details of what would UV complete the theory above \Lambda. This is trivial field theory (pardon the pun) which you don't seem to understand. Of course string theory doesn't have this sort of problem, but there isn't any point discussing this till you understand the simpler field theory case first.

So James was right on the money, both in his physics point and more broadly. Much as you like to think that experts aren't paying any attention to you because you're an outsider declaring uncomfortable truths, and much as the journalists covering your book eat up this story, the real reason you're ignored is very different. String theorists have many harsh critics, and are fully aware of all the criticisms themselves. Many of the well-known critics have spectacular records of research accomplishment, which means that they not only understand the basics of the field, they also have a sense of the ebb and flow of ideas and the creative process of discovery. String theorists respect these people and listen to them. Of course you don't have a real record of research accomplishment (and it is funny to blame your blog for this–what were you doing before that?). But your gaffes with non-diagonal SU(2), your above lack of understanding of landau poles and countless other instances also reveal that you don't even solidly understand the basics. We are all familiar with the annoying undergrad who thinks he knows it all, knows all the fancy words and catchphrases, but can't do any calculations and doesn't really understand physics. I'm afraid that all external indications are that you are like that undergrad writ large–except you don't have the excuse of youthful naivete and the undergrads aren't going around making pompous pronouncements about the sad state of particle theory. Most beginning grad students could give better, harsher, more incisive criticisms of string theory than you can–but of course with a solid command of the fundamentals and a close-up view of the research frontier, they are also in a better position to understand why it is still so compelling.

I am glad to hear that you are finally going to devote yourself to research. Best of luck–it is a far more worthwhile endevor than your blogging, and much more difficult and challenging. I daresay you have a lot of catching up to do. If you don't mind the advice, the field has come a long way since you were last active–you might want to sit in on a refresher QFT course at columbia before you dive back in.

40. **Clifford V Johnson**
July 7, 2006

Peter,

Thanks very much for choosing to give a level headed reply. On some things we can just agree to disagree, on others, there is a right and there is a wrong. With that I will refer you to my point (3) above.

> (3) You speak with certainty that string theory has failed as a theory of Nature. Actually, you don't know if that is true, and nobody knows that. It is your hunch that it is so, and it is my hunch that it is not so, and we are entitled to our hunches. It is a subject of ongoing research. That is as much as anyone can say.

The other point that I regularly make to you is that you should not characterize all work in string theory as what is being done by a relaive few people. Anyone who reads your blog would assume that there are hundreds and hundreds of people all working on the landscape. That is an mischarcterization of the state of research of the field. I think that the program of invesigation there is interesting, actually, and it is important for some people to explore some of that program. But it is not my cup of tea. But that's fine, its enough to know that we've got some good people working on it, and I can focus on other stuff. That's not atypical. There are hundreds of people focusing on other stuff, chipping away at the problems and learning a lot about what we're doing. You hardly ever acknowledge their existence when you talk about the program of research in string theory, and characterize it in sometimes amusingly apocalyptic terms. Case in point: You mention my work on non-critical strings, which you can of course learn about from blog posts I've written and a quick search on SPIRES. So in about 5 minutes you can learn about the existence of this. But then you characterise it as essentially nothing to do with the program of connecting strings to Nature. How do you know that? A closer look (which you have not done, it seems) will reveal that this work is focused very much on trying to understand *in a controlled environment* several of the key ingredients and stringy phenomena that are used in constucting the landscape vacua! Our best models of various non-perturbative phenomena in string theory are to be found in such models….. It is as though you are saying that studying the Ising model will teach us nothing about phase transitions in the laboratory. Another case, and this one is typical: I recently did a post on CV about a new result in understanding tachyon condensation in the critical bosonic open string. You evidently read the post, and made no comment, as have and will others. As usual, this post will probably be largely ignored in this way as compared to the other type of post about string theory which is all about people just coming and and yellling "it's all crap" or “the program has failed”, and others yelling “no it’s not” or “no it has not” back and forth. So as a result, once again the whole thing is skewed. People -including some impressionable young people in the field- get the impression that its all about the landscape, when in fact that result may be one of the single most significant and beautiful results to be presented in the field for several months. Rather than contributing to a discussion about what it might mean for the program of string theory, or even asking some questions to find out more about how it might affect -one way or another- your view of the program of research, you instead choose to ignore the existence of this kind of work in the field, or at least you don’t inform people that it is going on very much. In fact, there’s much more work of this kind going on than just a ton of people sitting chatting about the Landscape.

I could go on with this, but I won’t. I just want to say that it is very important to stop this distortion of what is going on the field. This sort of explains this impression you have obtained from people about the “state of the field”. If “the field” is characterised entirely in terms of the landscape discussion, then of course if you meet several people who don’t like it (and may themselves be deluded into thinking that is all that is going on in string theory because they’ve been decieved into think ing that way by a variety of sources) then you’re going to come away thinking that there’s a whole bunch of disgruntled string theorists.

I’d like to say in closing that there is a wealth of exciting work going on in the subject. We are not all currently working in lock step on the shock wave of some new explosion or revolution of ideas, and that’s simply ok. It is a healthy time indeed to have a large number of different problems be worked on. It is naive of you and those few apparently immature string theorists to whom you seem to have been talking to measure current progress by how far we are from the last time we all were writing papers on the same thing. Sure, revolutions are nice. I love them just like the next string theorist, but I don’t sit around waiting for them to happen and get drepressed that there’s no progress. No, instead I carry on chipping away gathering results that -along with those several others who are doing the same that you again and again don’t mention in your characterisation of the program of research- may well contribute to the next great leap forward, or at the very least, the steady march forward.

This is just how research is done, and how it always has been done in any field of science. It is not done by public talks and TV shows and books and counter-books and yelling matches on blogs. That sort of public “yes it is-no it isn’t” stuff is just a soap opera that feeds the press, deludes the public, and serves as meagre nourishment for the timid and impressionable individuals in the research game who need to be told what to think. (Reaching out to the media is important in general, and sure it is nice to try to temper the extraordinary claims of the stringevangelists from time to time, but the tail should not wag the dog.)

I love a soap opera like the next guy, but that’s all it is. I hope that the members of the press and publishing industry who are reading this also take note of what I said. You’re focusing on -and feeding- a soap opera that is a huge distortion of what is actually going on with research in the field. If you, members of the press and publishing industry, truly believe that your mission is more than about selling newspapers and copies of books (but I do understand that you have to pay the bills), and if you still remember that you may have come into journalism and publishing to actually inform people about what is going on in science, then please stop always focusing on the soap opera aspects. Take a broader look at what is going on. Don’t frame all discussions of string theory research in terms of pro- and anti- landscape.

That’s not all that there is.

-cvj

41. **woit**
July 7, 2006

Hmmm,

Ahh, yet another string theory partisan who wants to lecture me about my incompetence from behind the cover of a pseudonym. It’s amazing how many of you there are up in Boston.

Believe it or not, I’ve actually heard about the problem of the lack of asymptotic freedom of the U(1) part of the standard model. It’s discussed on page 98 of my book. There was a limit to the amount of detail I was willing to go into in my response to “James”. I was oversimplifying for the sake of concision, this point has nothing to do with the issue at hand. For the U(1) theory perturbation theory is not valid at high energies, but that is irrelevant to the argument I was making.

Sorry, but your Lubosian tactic of dealing with my criticisms of string theory by insulting me and trying to paint me as an incompetent by sleazy methods isn’t going to work. You just make my point even stronger that there is a real sickness in how string theory is being pursued. The problem is not just Lubos, but quite a few other people it seems who are as pathetic characters as him.

42. **Eugene Stefanovich**
July 7, 2006

cvj,

did you voice the same passionate opinion against publicity vs. science after “The Elegant Universe” was released? Peter is just restoring the balance. That’s all.

43. **Hmm**
July 7, 2006

Sorry–given how wildly silly your SU(2) ideas are, its hard to know what you do and don’t understand; and there was no need for “concision” in your response to James. There is no “rigorous” formulation of the standard model on the lattice, and no reason to bring it up.

And indeed, it does have to do with the point you are trying to make. The non-pertubative phenomena invoked in modulus stabilization–e.g.gaugino condensation–are in fact non-perturbative properties of the low-energy effective theory, and at least as in control as the computation of the eta’ potential in QCD. That *you* don’t understand would make me think you’re one of those annoying undergrads I mentioned who doesn’t understand the issues involved, if I didn’t know better.

And shame on you for being so condescending to James, telling him *he* doesn’t understand the physics, when what he said (minimally about physics) was precisely correct, while your “concise” statements were trivially wrong.

But enough of this–I agree with cvj that its really really really boring. And like Michael, I look forward to seeing the fruits of your research labors. Even better than blogging about it, why not write a paper, filled with concrete predictions stemming from your studies of the the glory of Dirac operators?

44. **Hmm**
July 7, 2006

Actually, come to think of it, since you always complain that people call you incompetent when you’re not, here’s an opportunity to shut them all up. Its about exactly the subject we are discussing–non-perturbative effects in string theory. Lets make it easier, and ask about non-perturbative phenomena in SUSY gauge theories (thats at least QFT which you should know all about right?). If you profess to have some understanding of the issues involved, surely you can tell us what gaugino condensation is, and how (and in what sense) we know it exactly. I think understanding this is simply a prerequisite to even talking about modulus stabilization, and since you go on and on about how we can’t use non-perturbative phenomena in a theory we only understand perturbatively, you should minimally know about something as basic as gaugino condensation. If you do, you would have no trouble whatsoever writiing a little physics post explaining it to your readers in a nice way, right? It would even be a welcome prelude to a more physics-centered blog. While you’re at it, you can explain how we know the exact beta function in N=1 SUSY theories–this is merely perturbation theory, and surely nothing compared to the glory of Dirac operators. For an extra special post, tell us all about N=1 Seiberg duality. All very beautiful field theory, that I'm sure a QFT master like yourself would have no trouble explaining to the masses. I for one would be disappointed not to be enlightened by your post on the subject.

45. **woit**
July 7, 2006

Clifford,

It's late and I have to get up early to get on a plane, so I don't have the time to write the response to your comment that it deserves, and may not have any such time for several days, but let's see what I can do in a few minutes before bed.

First of all, I'm trying to have an intelligent, respectful conversation with you, but I'm starting off in a really foul mood, after having to deal with the "Michael"s and "Hmm"s that infect the world of string theoryand hide behind pseudonyms. An incredible degree of arrogance and conviction that anyone who criticizes string theory is an incompetent infects the field you work in. Lubos is an amazing example of this, but he is far from the only one. It's completely disgraceful that many people in your field behave in this unprofessional way, and I've seen extremely little evidence that anyone has much of a problem with it. Given what I have to put up with from people like this trying to bully me into silence, you may find me less than sympathetic to some of your criticisms, for instance that I was not nice enough to "James", whoever he was.

I've been kind of surprised over the last year to see to what degree there is an increasingly widespread negative view of string theory. Among journalists I talk to, there is a backlash against much of the hype they have been fed about the subject over the years. Among non-string theorist physicists, there is a revulsion at the kind of viciousness and arrogance demonstrated by Michael, Hmm, Lubos, and others. Over the next few months and years, if you want to know why you'll be seeing anti-string theory hostility, this is a large part of it. You may not be personally responsible for hype and ignorant arrogant behavior, but your field has far too much of it.

I do understand what you're trying to do by better understanding non-perturbative string theory in toy models. I try and follow this kind of work, although I obviously don't have the time to become an expert and fully understand all of it. From everything I've seen, it seems to me you may ultimately learn many interesting things, and may have real success at understanding QCD, but I just don't see any evidence at all other than wishful thinking that any of this can solve the deadly problems that afflict the idea of trying to get unification using strings in 10 dimensions. When I say that string theory has failed, it is that failure I'm talking about. This is an issue that can be intelligently discussed: I don't see a plausible way that you're going to get around the well-known problems, if you do I'm interested to hear about it. You need to have a better answer to this question than just "we don't understand the theory, when we do maybe the problem will go away" If you don't it looks like your research program is based on wishful thinking.

I'm well aware that not all string theorists work on the landscape, but I don't think your attitude towards it holds water. If it really exists, string theory as a unified theory is just dead. You're welcome to the view that it doesn't really exist and you're trying to better understand the theory to show why. Susskind and others will tell you you're in denial. Personally I agree that it remains an open question until you truly understand non-perturbative string theory. I just don't see much in the way of progress towards this in recent years, or much reason to believe that in my lifetime anyone is going to be able to answer the question.

While I think refusing to admit that the landscape is there and trying to get rid of it is a reasonable scientific position, what is remarkable about the landscape issue is that a large number of prominent scientists accept it, and yet refuse to admit the obvious fact that it kills the idea of string theory unification. This behavior is just irrational, and bizarre, and the fact that it is going on at such a high level is seen by many people as a scandal and as evidence that there is something seriously wrong with the way string theory is being pursued. There seems to be no way to get the people involved to ever admit that things are not working. This is an amazing story to watch, and you'll find journalists are not going to resist the appeal of telling it.

There's more to say, but no time now, perhaps another…

46. **woit**
July 7, 2006

Hmm,

Even if it wasn't late at night, I'd have no interest in submitting to your little tests about my knowledge of supersymmetric gauge theory. I've written a long book about the things at issue here and hundreds of pages here on the blog. People are welcome to judge for themselves whether I know what I am talking about based on those. And I'm definitely not going to waste any more time discussing anything with you unless you tell us who you are. Doing what you are doing from behind the cover of anonymyity is incredibly unprofessional behavior.

47. **Hmm**
July 7, 2006

You keep complaining about "arrogant" behavior. I think it is amazingly arrogant to pontificate on the sad state of particle theory when you haven't actively participated in it for over 15 years. People are working hard, with little guidance from experiment, and poring years of their lives into studying these questions. On the other hand you left the field, have done little or no research (the hard work in this business!), and yet wax away on how lousy everything is. You complain about Lubosian tactics, yet bully those who bring up valid physics points–James isn't the only case–there are many instances where you pull rank on someone by saying they're "probably an undergraduate who doesn't know what is going on". You say that scientific giants like Weinberg, Wilczek and yes even Susskind have sold out the field–when they probably know a thing or two about science. This is all breathtakingly, stunningly arrogant. And I don't say this because you're a critic of stirng theory. I know and hugely respect many people who are very critical of string theory. If I want a critique of string theory, I'll take it from 't Hooft or Wilczek or Glashow, not you.

You also always, *always* back down from serious, technical physics discussions. You always refer to authority. The trouble with loop quantum gravity? "Don't know, haven't studied in detail". What about modulus stabilization? Same thing. How about gauge coupling unification in SUSY? Ditto. These are all questions that any working theorist should have an informed opinion about. You have to understand, Peter, that being a dilletante with a passing word-level knowledge of the field is fine for a silly blog, but is completely worthless for physics. Without *some* demonstrated expertise in areas that actually matter, you don't have any credibility with anyone other than your adoring blog fans and the equally uneducated science press. But in the long run it isn't their opinions, or mine or yours that matters–its the physics that matters, and your approach to it–not being an expert at anything, while loudly complaining about other research programs without doing anything yourself–doesn't further the cause at all. The cause it does push is the attainment of your 15 minutes of fame. Enjoy.

48. **Chris Oakley**
July 7, 2006

> Enjoy

I certainly will, even if Peter does not. Everyone focusing on the next, biggest, trendiest thing has been the bane of HEP. One would think that HEP theorists have given up individual thought altogether. Hmm mentions the word dilettante (spelled like this, by the way), but that is exactly what most theorists now are: a far cry from the hard-bitten sceptics like Pauli who would accept nothing unless they could derive it for themselves. But without the likes of Pauli we would have nothing of value at all. I wonder what *he* would have thought of this un-physically-motivated mass migration to ten dimensions?

49. **anonymous**

July 7, 2006

to Hmm: I try to answer to your points about "physics":

1) The Landau pole at 10^40 GeV is irrelevant, because we do experiments at 100 GeV, with less than 80 digits of precision. Probably the Landau pole is cured by quantum gravity at 10^20 GeV, but again quantum gravity seems irrelevant for the same reason.

2) I am surprised of hearing that "there are effects of order \sim E^2/\Lambda^2 \sim e^{-1/g^2} that *can't even in principle* be calculated". What are these effects? Do you mean that works on baryogenesis/leptogenesis, where e^{-1/g^2} effects are computed and crucial are crap? If instead you again confused physics with mathematics and your point 2) is something as irrelevant as 1), please don't loose time in answering.

To Woit: please don't explain us gaugino condensation in hidden sectors.

To Clifford: I think that this debate remains interesting for two reasons. First, it is an unusual phase in the history of (high-energy) physics. Second, it is unusual that inner problems get publicly discussed. These two dangerous things are slowly moving; after a few years we will see where they are going.

50. **Alejandro Rivero**
July 7, 2006

Believe it or not, I've actually heard about the problem of the lack of asymptotic freedom of the U(1) part of the standard model. It's discussed on page 98 of my book.

Funny, we mentioned this issue past yesterday at physicsforums, see post 15 at
http://www.physicsforums.com/showthread.php?t=124893#15

51. **woit**
July 7, 2006

Hmm,

If you're willing to put your name to the slander, lies and viciousness that you're engaged in, I might bother to respond. But you're unwilling to do that, presumably because you realize how deeply disgraceful and unprofessional your behavior is. It's really pathetic.

52. **D R Lunsford**
July 7, 2006

Peter,

[attack on Jacques Distler and conjecture that he is Hmm deleted].

-drl

53. **MathPhys**
July 7, 2006

Hmm, Clifford,

What's really boring is the continuing PR job of selling strings as "the theory of everything". It's been 22 years now. Can you tone it down a bit?

The mathematics has been great, but that's not physics. The extra dimensions, the compactification, the extended supersymmetries and the landscape are all suchsilly, naive ideas. We listened to these stories for almost 3 decades now (supergravity in higher dimensions is around since the late 70's), and it's not working.

Please stop selling this science fiction to the public and to unsuspecting students as deep physics, because it's not, and it has failed.

By the way, I'm not in any way anti-strings. I would have loved to see the string program flourish as it contains everything I've learnt. But it's not working. Something is wrong. So can we all be a bit more modest, please?

54. **woit**
July 7, 2006

drl,

Leave the crude personal insults to string theory partisans. I see no evidence that Hmm = Distler.

55. **Hmm**
July 7, 2006

Anonymous:

(1) Well duh, of course the Landau pole is at an irrelevantly high energy. As James was also saying, these effects are practically irrelevant; its a question of principle. Indeed quantum gravity effects should swamp these as this is where the real UV completion is.

(2) But in the absence of gravity, the theory does break down at a high-energy scale \Lambda. This means that there are uncertainties in predictions, of order powers of (E/\Lambda), which can't be resolved without specifying the UV completion. And very basic issues can depend sensitively on the UV. Here is an example. One might imagine that just before the theory hits a Landau pole, it gets embedded in a bigger non-Abelian gauge theory; so that e.g. U(1)_Y gets embedded in an SU(N) which is asymptotically free. There is dynamics that Higgses the SU(N) down down to some subgroups. It could be (indeed it typically happens that) this dynamics has many symmetry breaking patterns, only one of which is SU(N) -> U(1)_Y. Some of the other patterns of breaking could correspond to vacua of lower energy. This means that our vacuum would be unstable to decay, with a rate that would be proportional to e^{-1/g^2_{UV}}. Or it could be that our vacuum is the lowest energy one, and this decay doesn't happen. The basic question–is our vacuum stable–is a UV sensitive one, and the answer clearly has to do with the details of the UV completion, and can't be predicted simply knowing the low-energy theory. And again this happens simply because the low-energy theory is not complete. There is no "rigorously defined" Standard Model where everything can be calculated.
Of course in asymptotically free theories, non-perturbative effects are often dominated by IR physics e^{-1/g^2_{IR}} (like the eta' potential in QCD) and are calculable. This is indeed an important point: the non-perturbative effects used in string theory modulus stabilization are these calculable ones which dominate.

Oh, and quantum gravity kicks in at 10^18 GeV or earlier, not 10^20. As with Peter, my advice to you is to lean some basic QFT.

MathPhys: For the record, I can't stand the string theory "hype" peddled by Kaku, and am no fan of the elegant universe either; but none of the real leaders of the field do this. Why didn't they spend time fighting the positive hype? For the same reason they ignore Peteres negative hype now. It is unimportant trivia; instead they are focused on their research. Likewise, to you and Peter I say again: instead of whining about sociology, write papers on whatever alternatives you want, no one is stopping you.

And no,it isn't the same old story from the 70's. The strucutre is much deeper than anyone anticpated; with the idea of emergent space and holography making a stunning appearance first in Matrix theory and then in most convincingly with AdS/CFT. Gone is the statement that everything is a little loop of string; the best definition of the theory is back in terms of a QFT. But of course all these remarkable facts were discovered by string theorists. For the simple reason that when you follow non-trivial ideas, good things are bound to happen; when you sit around and whine from the sidelines, nothing will come of it.

DRL: You guys all have a persecution complex, its quite remarkable. No I'm not Distler…

Peter–you keep attacking my tactics but don't address any of the substansive physics or other points I'm making. Its easier to do this rather than to address concrete points isn't it? Just as it easier to blog away than to produce meaningful research. I too won't interact with you again. Instead I await with bated breath your forthcoming research paper with concrete predictions for physics.

56. **ks**
July 7, 2006

> I can think of numerous times when well-known non-crazy string theorists have answered your criticisms, on this blog and on others. The problem is that you choose to forget the answers and keep repeating yourself. So people have gotten terribly bored with the whole thing I suspect.

"Voltaire, you had your 15 minutes of religion-criticism fame and now let us pray to god that he will forgive you"

You shouldn't be too worried about the blog of a single fighter. But when your church goes down, you might ask yourself less about the lack of cleverness but that of reason. People can clearly see the presence of the one but the absence of the other.

57. **anonymous**
July 7, 2006

I know that it is 10^18 or less, but unless it is much less, who cares?

Vacuum decay is a good example of UV sensitive observable: I brought you a bottle of good wine to celebrate, in the eventuality that the earth will be eaten by a bubble of true vacuum.

PS: my persecution complex tells that Hmm might be the author of fig. 4 of hep-ph/0607029

58. **Umm**
July 7, 2006

"… write papers on whatever alternatives you want, no one is stopping you." – Hmm

No, there is widespread censorship everywhere in theoretical high energy physics, inspired by a mainstream intent to pursuing abject speculation and sneering at critics without studying or responding to alternatives based on observed facts.

Alternatives have a long struggle any road. They have to make checkable predictions and get those predictions checked, which requires a lot of work on money. But first they have to be published and then debated. With the field dominated by string theory at all levels from undergraduate up, alternatives are starved to death.

59. **MathPhys**
July 7, 2006

Hmm,

I actually agree with you that holography, emergent space, matrix models and AdS/CFT are all stunning ideas. It's too bad that relatively few people work on these deeper aspects of string theory.

I also agree with you that some of us have allowed the sociology of string theory to get us. I think that people like Motl, on the web, and Kaku on the popular books/lectures front, have done string theory enormous damage.

Maybeb we should all cool it.

60. **anon.**
July 7, 2006

"It's too bad that relatively few people work on these deeper aspects of string theory."

Funny, I thought *almost everyone* is working on this sort of thing. From Spires:

"Relatively few" compared to what?

61. **woit**
July 7, 2006

Hmm,
If you were making any substantive physics points I'd consider answering them. You don't have any answers to the substantive criticisms of string theory made here and in my book, and thus choose to deal with them by attacking my competence and right to make these scientific criticisms. This tactic is all too transparent. It's not going to work, and is just going to convince more people that there is a serious problem with string theory, and the way it is being pursued.

62. **anon.**
July 7, 2006

But Hmm *did* make a substantive physics point: moduli can be stabilized by gaugino condensation in the low energy effective theory, an effect that is calculable and well-understood. You don't need a complete nonperturbative framework for string theory for this to work, you just need to know some things about the low energy effective theory based on perturbative string vacua. You might *hope* that nonperturbative physics somehow makes most of the landscape vacua decay very quickly, but there doesn't seem to be any good reason to believe that. So, if we stick to physics, you keep saying that we need a nonperturbative formulation of the theory before we can address these questions. But you haven't suggested how this nonperturbative formulation can make all these vacua go away. So, let's have a physics discussion: where can the current analysis suggesting the theory supports all these vacua go wrong? If it does or does not go wrong, what does this mean for physics?

63. **woit**
July 7, 2006

anon,

Good, a substantive physics point.

I find it funny to be simultaneously carrying on an argument with Clifford and with "Hmm" here. Clifford's point of view is that we don't understand string theory well enough to have to accept these flux compactifications as true vacuum states of the full non-perturbative string theory. From what I've seen of these constructions, fully fixing the moduli requires more than just gaugino condensation. But I'll defer this question to Clifford, who is much more of an expert at this.

I'm pretty sure I've said this before, but again: I don't know whether the full string theory has these vacuum states or not. Maybe yes, maybe no, most likely it's still an ill-posed question until we have a real non-perturbative string theory. But it doesn't matter, the point is that there are two alternatives here, both leaving string theory in a highly problematic, failed state as an idea about unification:

1. The landscape exists, and string theory can't predict anything, it's a useless theory.

2. The landscape doesn't exist, for some unknown reason involving non-perturbative string theory. Then, despite what Zwiebach and others say, string theory is currently an empty idea and can't predict anything, because we don't even know what equations to solve.

The bottom line is the same in either case: you can't predict anything about particle physics in this framework, it explains nothing about the subject.

I'll leave it to Clifford and Hmm to sort out whether it's 1. or 2. I'm not claiming to know the answer, half of the experts say one thing, half the other. Doesn't really matter which it is though.

64. **woit**
July 7, 2006

Another thought,

Hmm seems to be a colleague of Lubos's, at least he's in the Boston area. If he can't get an answer out of Clifford, he can take the issue up with Lubos, who, from what I recall, also doesn't accept the existence of the landscape as true vacuum states of the full theory. If these people do sort this out and come to an agreement about what the answer is, I hope they'll let us know.

65. **D R Lunsford**
July 7, 2006

Sorry. I have to calm down about all this.

I'm just reading "End of Faith" by Sam Harris. You could replace "Islam" by "string theory" and "Christianity" by "LQG" and "Judaism" by say "geometrodynamics" and the book would still make a lot of sense. These discussions about string theory seem as unreal to me as the calculus of virgin allotment in the eternal beyond. It makes one crazy.

-drl

66. **Aaron Bergman**
July 7, 2006

Or, as has been mentioned to you multiple times, it's possible that the situation will end up like field theory wherein one can measure enough parameters to obtain predictivity with the others.

67. **Peter Orland**
July 7, 2006

Hi Peter,

I can't concentrate at my desk in Copenhagen, which is nearly as hot and
humid as New York at the moment and lacks air-conditioning.

It is reasonable that some people express their opinions
anonomously. People looking for jobs in physics may not want to
be too controversial. Why would anyone DEFENDING
string theory would wish to so anonymously; what is the risk? Answer:
because vicious vituperative attacks don't make anyone look good.

Other people seem to be questioning your qualifications. I'll defend

yours (maybe now they'll come after me – since I am not a regular
contributor/blog reader, I probably won't find out). You're a former physics guy who
did some good stuff in lattice gauge theory, and now
pursues math I know next to nothing about. I don't see any grounds
for these anonymous attacks.

Regards From the Not Especially Frozen North,
Peter

68. **anonymous**
July 7, 2006

dear Aaron,

what do you mean? All the physics we observed so far is described by a QFT with about 25 parameters. Are you hoping to predict the top mass or something like that?

69. **anon.**
July 7, 2006

Clifford's point of view is that we don't understand string theory well enough to have to accept these flux compactifications as true vacuum states of the full non-perturbative string theory.

As you are aware, these don't *have* to be "true" vacuum states. They just have to be very long-lived metastable vacuum states (which, as recent field theory studies have shown, seem to be much more common when searching for broken SUSY than are true SUSY-breaking vacua).

So it seems to me that to doubt the landscape, one needs *either*:

a) A rapid mechanism for these metastable vacua to decay.
b) An argument that somehow they were never there to begin with.
c) A cosmology that is guaranteed not to populate them.

(Is there some other possibility I've missed?) All of these seem to me to be somewhat implausible, but references to suggest otherwise would be appreciated.

Anyway, if the landscape really exists, you say "string theory can't predict anything, it's a useless theory." But that's not at all clear. As Aaron says, "string theory" might become the same sort of general framework that "field theory" is now. It might not predict every constant, but it might clarify some relationships between them which are not apparent in field theory. It might mean, say, that string theory can't predict the cosmological constant, but can explain the SUSY breaking scale and associated spectrum in terms of it. This, as I understand it, is the sort of thing Tom Banks proposes. If it were true, wouldn't it be fantastic? Surely ideas like that are deserving of further research, for their potential to connect LHC-scale particle physics with observations in cosmology? And if the idea is true, then the LHC could also falsify the framework. So, maybe we should try to understand if it's true? If not, we might learn other interesting things along the way.

It's clear that there are a lot of unknowns, but you seem to take this as a reason to give up on the theory, whereas to me it seems possible that this theory *does* describe the real world, in which case it looks like much more work is needed to figure out what can and can't be predicted. Giving up now just because not *everything* is predicted seems rather silly.

70. **anonymous**
July 7, 2006

…because *nothing* is predicted.

71. **John Gonsowski**
July 7, 2006

Wasn't the original idea of string theory that it was supposed to end up exactly field theory as in the E6 GUT? Then all the good stuff about the Standard Model becomes part of string theory? The stuff Peter is and has been interested in is the stuff you need in a good GUT. Even Lubos once mentioned in the context of supersymmetric GUTs that not enough people work on it. I don't like supersymmetry but often it seems good non-supersymmetric stuff comes from people mostly interested in the supersymmetric part. I know Lubos at least used to like the traditional E6 GUT too. Lattice related ideas may also be more useful for string theory than people realize, need more people working there too.

72. **Clifford V Johnson**
July 7, 2006

Peter, Others…..

As I said in my first comment on this thread, we've had most (if not all) of this discussion before… the answers and comments have just been conveniently forgotten. I can't do this again, as it is just. so. *boring*. Let's spend even a tiny amount of time looking at what we said already. Several of the things asked here (of me and others) have already been gone over in this thread for example:

http://cosmicvariance.com/2005/08/14/the-landscape-for-real-this-time/

August 14th 2005, people. August 14th. We're going in circles. Sigh. (There are other threads like this…. use the search engine or the pingbacks that I was careful to put in, and you'll find them.)

I think I'm done here.

Best,

-cvj

73. **anonymous**
July 7, 2006

Clifford, this time it's you that isn't adding anything constructive. All you're doing is declaring how much better than the rest of us you are, how we repeat ourselves and don't listen to your profound replies.

Basically, you're just producing the same argument that Lubos does – "Everybody who disagrees with me should shut up because I've explained with tremendous clarity why they're wrong, and the people who don't shut up are idiots." You should either stop this pretentious posing (yes, saying things like "Sigh" and "really really boring, I'm afraid" is pretentious posing – you are trying to convey a style, an attitude that you think others will perceive as cool) or stop declaring yourself to be so much more reasonable than Lubos.

74. **woit**
July 7, 2006

Aaron,

Comparing the situation of the landscape to that of the standard model is just absurd. Clearly I haven't been writing enough postings here explaining exactly what the problems with the landscape are.

Clifford,

Well, you certainly made me regret staying up last night to try and write a serious response to you. I guess we now have the official response from string theorists to my criticisms:

1. Peter Woit is an incompetent who knows no more than an undergraduate about this subject.

2. Criticisms of string theory are just boring, so we won't respond to them.

You know, this is really pathetic.

75. **woit**
July 7, 2006

anon.,

I've posted here many times about what the problems with the landscape are and why it seems very clear to me that it leads to an inherently unpredictive theory. If someone has a plausible idea about how to make even a single vague prediction using it, I haven't seen this. Banks certainly does not have a real prediction.

76. **Aaron Bergman**
July 7, 2006

Comparing the situation of the landscape to that of the standard model is just absurd.

Proof by assertion? You have no idea whether or not it's possible to get generic predictions out of the landscape of vacua and neither do I. There's no particular reason, for example, to assume that the landscape will uniformly fill the space of standard model-like theories or, say, weak susy breaking lagrangians. Your gleeful pessimism on the subject is hardly an argument.

You know, this is really pathetic.

I will have something to say at some point, depending on how things go with my current research. I regret to say (truly) that it won't be terribly positive. Perhaps you wouldn't expect any different (you seem to be finding ill in a lot these days), but I was hoping otherwise.

77. **Kea**
July 7, 2006

You know, the blue-ringed octopus is very poisonous to the Landscape…especially when it sheds it rings.

78. **Kea**
July 7, 2006

Here's a nice picture.

79. **nigel cook**
July 8, 2006

"You have no idea whether or not it's possible to get generic predictions out of the landscape of vacua and neither do I." – Aaron Bergman

Exactly! It isn't science. So why are people working on it?

"I can't do this again, as it is just. so. boring." – Clifford Johnson

Yes, but that's string theory! No physical predictions, nothing.

80. **fh**
July 8, 2006

Just saw this, well, there have been undergrad String Theory courses at my home university for a while (also conformal field theory and other more mathematical physics minded courses), but then, in Germany undergrad goes a bit higher then in other places.

81. **Eugene Stefanovich**
July 8, 2006

nigel cook:

Exactly! It isn't science. So why are people working on it?

I disagree. String theory is a branch of mathematics which uses physical terminology and desperately wants to make a connection to the physical world, but wasn't able to do that yet. String believers are honestly trying to calculate a number that can be compared to measurements. We shouldn't discourage them from doing that. We should just keep in mind that their loud promise of 20-or-so years ago to revolutionize physics hasn't materialized, and draw conclusions.

82. **D R Lunsford**

July 8, 2006

Eugene said

String believers are honestly trying to calculate a number that can be compared to measurements.

In the past many people honestly tried to deduce the parallel postulate, square the circle, and solve the fifth order polynomial equation with radicals. The point is, the structure of string theory seems incapable of producing any numbers comparable to anything. No one can answer Peter's challenge. If anyone could, he'd probably shut down this blog on the spot. Given its extremely shaky physical motivation and structure, combined with its impotence, the only "honest" thing to do is move on.

83. **Eugene Stefanovich**
July 8, 2006

D.R. Lunsford:

In the past many people honestly tried to deduce the parallel postulate, square the circle, and solve the fifth order polynomial equation with radicals.

If somebody wants to prove the parallel postulate, let him do that. May be he'll figure out a non-Euclidean geometry eventually. If somebody wants to do strings, no problem. The only real question is how much tax dollars (euros, pounds, rubles,…) shoud be invested in these attempts?

84. **D R Lunsford**
July 8, 2006

Eugene,

This is the main point – one has to use something else other than hope, reason, and persistence to get ahead. You have to recognize when you are going in the wrong direction. To use our example, Saccheri had everything at his hands to deduce non-Euclidean geometry. He even wrote a book, "Euclides ab Omni Naevo Vindicatus" (Euclid Freed of all Flaws), that came a hair's breadth from a revolutionary idea – but, because he had a fixed notion in his head about what constituted progress, he missed his chance and became a footnote in the history of mathematics. Even Felix Klein, with his vast intuition, missed relativity when it was right in his hands. What is most needed is sound judgment and a prepared intuition, and the willingness to go in a new direction when the old one becomes a dead end. The judgment of string theorists is manifestly unsound. They are willing to be completely tangled up in absurdity. Hope and bluster is not enough.

-drl

85. **Eugene Stefanovich**
July 8, 2006

D.R. Lunsford:

I am all for *the willingness to go in a new direction*. I am tired of people telling the same old story about how we have two wonderful theories – the Standard Model and general relativity – and the only thing left is to make them work together. If these theories do not want to work together, then either one or both of them are wrong. Let's face it. Nevermind that they were tested in experiments/observations. Epicycles were tested in observations too.

Sorry, Peter. I probably went too far off-topic.

86. **D R Lunsford**
July 9, 2006

Eugene,

Obviously the SM and GR in their own worlds is *the wrong direction*. So we agree.

-drl

87. **stefan**
July 9, 2006

I've read some posts on strings and related material across various blog-sites around the Net; it seems that most physics-related researchers are tossing various views on the (assumed) correctness or incorrectness of the string-theory programme. I still wonder if this whole enterprise is pre-mature; after all, the "giants" of the field still contend that string/M-theory is still not fully understood. Then, shouldn't the community focus more on understanding more rigorously the subject-matter? Wouldn't it be a great service if we had more discussion(s) and debate on the mathematical aspects of our current Yang-Mills gauge theories… after all, this issue has genuine value since it is a requisite (and appropriate) problem of discussion. (One only needs to look through the Millenium Problems site at Clay Institute).

How would everyone at this forum react to this suggestion. Your feedback would be most welcome.

Stefan

88. **Peter Woit**
July 11, 2006

Hi Stefan,

I agree with you completely. There is still a huge amount we don't understand about the gauge theories that are relevant to the standard model, and these problems deserve a lot more attention than they're getting. At the moment, only one is getting attention, that is understanding strongly coupled QCD, and in this case only one possible approach to that problem is getting attention, that of string theory. I've been keeping a list of what seem to me important aspects of gauge theories that are not understood, hope to turn this into a paper or a series of blog entries at some point.

89. **Who**
July 11, 2006

Undergrad string courses = top of the market behavior.
When it is time to sell off, professional investors will instinctively see lots of reasons for the small private investor to buy.

As string research becomes less exciting, it gets attractive for former researchers to teach undergrad string, perhaps even (eventually) in the liberal arts colleges, but first of all in top universities. Stanford curriculum can serve to lead other venues. The pros will **instinctively** want to be as convincing as possible that their overstocked specialty should be taught to undergraduates—come up with lots of reasons: maybe even liberal arts-type reasons. Enriching the mathematical education etc. Because it will give the surplus research crew something to do they can consider useful.

The undergraduates pay as usual, like the private investor, for the mistakes of their betters.

90. **Stefan**
July 12, 2006

Hi Peter,

Thanks for the reply. I guess I'm not the only one with some reservations on how this whole string / M-theory enterprise is taking some of our brightest minds towards. I should however state that I'm nowhere near the position of a researcher (an undergrad, actually) to provide a detailed technical critique on strings / M-theory; but one doesn't have to be Newton to understand that what is currently taking place is more speculative than science – at least as it is understood in the traditional sense of the term.

I fear that with so much hype and hoolabaloo surrounding the "mother of all physics theories" some of the most creative and thoughtful minds of our generation are getting swept away by this whole issue/affair. I don't mind string theory as a programme of study, the problem is how it is hogging up much of the landscape of theoretical physics with it suffocating stranglehold on research – much to the limitation (and disadvantage) of other well-motivated programmes. (I would rather term this SPECULATIVE programme as "string hypothesis" (!!) – it stays true to the terminology of science.)

Anyhow, thanks for this forum… a whole lot of fun to read! 🙂
By the way, do you know of any site / focus group specifically addressed to the mathematical aspects of gauge theories? If not, do you want to start a forum? I would love to become a member.

Bye.

Stefan

91. **James**
July 12, 2006

Peter, although I am a 12 years old elementary school kid, I can't notice you not responding anything to this earlier post which I will replicate below. My question is whether you think that all the European universities mentioned below are run by some crazy professors who don't know how to put together an undergraduate curriculum? Or how else would you characterize these aforementioned professors who are responsible for the string theory undergrad courses at these fine universities?

It might be a shocker for you but several European universities offer undergraduate string theory courses and have been doing so for at least 15 years (that is what I am aware of). Examples: Amsterdam, Groningen, Utrecht, Brussels, Berlin, Budapest, Prague, Moscow and I'm sure there are plenty more.

Mind the fact that there are loads of old professors for whom the phrase "string theory" means something from the 70's and that is what they teach. It would be very difficult for you to convince them that this material is some new age hype when they were studying it 30 years ago.

Of course there are European universities where the more modern approaches are taught to undergraduates under the banner "string theory", e.g. Amsterdam and I suspect this area is where you actually target your criticism.

My observation is only to enlighten anyone who thinks that "string theory" is a large monolithic blob which can be commented on and criticised in one go.

Hope this helps,
James

92. **woit**
July 12, 2006

James,

Sorry, but responding to people who anonymously insult me just isn't high on my priority list of things to do when I'm very busy. I was away for a few days and wasted much of the little free time I had responding to string theorists accusing me both of being incompetent and of being nasty for beating up on someone like yourself who clearly only had at best an undergraduate's knowledge of the issues here.

As for your comment, first of all it wasn't a question; you're claiming some facts are true, and I'm both dubious about some of them and don't think they're relevant at all to the implicit question in my posting of whether string theory is something appropriate to teach to undergraduates in the US.

Some comments of my own:

1. European undergraduates are more advanced and more specialized than U.S. undergraduates, often more comparable to a master's degree program here.

2. I just find it very hard to believe you that people are teaching courses on 1970's style string theory at all these institutions. I strongly suspect you're thinking of S-matrix theory sorts of things, which are not really string theory. But I don't know, I may be wrong. It would be interesting if you had any links to syllabi of these courses so one could judge.

93. **JC**
July 12, 2006

Peter, James,

Years ago I remember several older professors mentioning that at some places, they did have the equivalent of a graduate course on topics in analytic S-Matrix back in the 1960's. This was in the days when that analytic S-Matrix bootstrap stuff was at its peak popularity. The most they ever mentioned about dual resonance models (ie. "string theory") such as the Veneziano model, was a lecture or two typically at the end of the course. (That is, after the Veneziano model was first published in 1968). Before the Veneziano model was published, courses on analytic S-Matrix theory mainly covered the sort of topics in Geoff Chew's 1961 book on the subject.

Just like any other graduate course, there were some highly motivated undergraduate students enrolled. None of these particular older profs could recall there ever being an undergraduate course on analytic S-Matrix theory and/or dual resonance models, in those days. They all said that the attitude in those days was that if a motivated undergraduate student really wanted to know some "advanced topics", they can just take the graduate courses, attend seminars, and/or read the original papers on it.

Offering a string theory course aimed towards undergraduate students appears to be a first these days. Albeit, this may not be totally unprecendented. Over the years I've heard of folks teaching undergraduate courses on particle physics which involve calculating Feynman diagrams. In these courses, they just "quote" the Feynman rules and a prescription to work out tree-level Feynman diagram calculations (all without proof). They just assumed that interested students will eventually take courses on quantum field theory. Years ago when I first took an undergradaute course on particle physics, the professor didn't even bother calculating any Feynman diagrams.

94. **shame**
July 12, 2006

Peter–

There you go bsing again! You say to poor James "…someone like yourself who clearly only had at best an undergraduate's knowledge of the issues here". You're really quick to pull the authority card aren't you? As was clearly explained above, James's understanding of the issues was correct and yours was just wrong. If he is only an undergraduate, all the more power to him. Quit bullying people who understand physics better than you do. If anything, as an amateur you should be grateful that experts take time to explain things to you, especially when you tend to be so hostile and rude.

Oh, and we're all still waiting for your electrifying ideas for new directions in theoretical physics. Preferably–a paper with some specific predictions that can be falsified. When can we expect it?

95. **woit**
July 12, 2006

shame,

Now, what's your excuse for hiding behind anonymity to attack me? I think your behavior is deeply shameful, you know it, and that's why you're doing it this way.

I wasn't at all bullying James, I think I was actually being extremely polite in dealing with someone who came here to engage in nasty attacks on me from behind the cover of anonymity. The line you quote was a reference to Clifford's attack on me as bullying a poor undergraduate. Clifford seemed to believe James is an undergraduate, but I have no idea what he is since he's hiding his identity, and (like you), attacking my credentials by refusing to tell us what his are.

And no, I'm not an amateur, but a professional with a Ph. D. in this subject. Are you? You certainly are behaving in an extremely unprofessional way here.

96. **woit**
July 12, 2006

shame,

Looking at my logs, you seem to be at the KITP in Santa Barbara, and to have found your way to my blog via Lubos's site (since your connection here came via his charming translation of my site into "jive"). You seem very concerned about my bullying behavior, just wondering if you have written in to Lubos's blog to criticize him in a similar way, or if you think the way he behaves is fine.

97. **James**
July 12, 2006

For those of you coming late:

Peter wrote "What is known about string theory is how to construct a (divergent) series, one that is supposed to be a perturbation expansion of some still unknown exact theory, and thus an asymptotic series in the string coupling for the true result."

To which I responded that the mere fact that there is no non-perturbative definition of string theory does not constitute a serious criticism. Clearly, the Standard Model has no non-perturbative definition (except for QCD but that is also non-rigorous) and it is a perfectly fine physics theory.

I also emphasized that the lack of prediction and consequently the lack of experimental verification *is* a serious criticism of string theory. This valid criticism however does not mean that *any* criticism is valid.

That was our short chat about physics. Now here is what Peter calls "insulting":

I wrote "Hope this helps you understand why string theorists and other high energy physicists do not respond to your book in a serious way and […] do not take you seriously over all. […] Even plenty of string theorists exist who are critical in a reasonable way, unlike you I am sorry to say. [….] Again, it is my intention to help you understand the reason for your considerable isolation in high energy circles especially since you yourself asked the question in one of your postings why there is no serious string theory reaction to your book."

Since Peter himself was wondering why string theorists are not responding to his book I truely believe that I am doing him a favour for giving a possible explanation. He is entitled to think that this explanation is wrong, but it can hardly be insulting. Now the fact that I do not consider him an expert in string theory can also hardly be considered an insult, since Peter himself declared this a number of times. My statement that he is not taken seriously in high energy physics circles is I believe factual. The basis for this statement is that I believe the following (somewhat vague) ingredients are necessary for being taken seriously:

(1) Well-known high energy physics results in research papers
(2) Presence as an invited lecturer at respected high energy physics conferences
(3) Persuing a serious research program in high energy physics

Peter, if you disagree that the above ingredients are necessary for the label "taken seriously by the high energy physics community" then what ingredients *are* the necessary ones? Or do you think that the above mentioned ingredients are applicable to you?

It goes without saying that Peter is a high energy physicist with a PhD. It also goes without saying that he is entitled to express his views on any subject he chooses let it be high energy physics or string theory in particular and in any shape or form he chooses let it be a weblog. However I believe I am again doing a favour to you Peter by point out that this alone is *not* enough to be taken seriously by the high energy physics community and it is foolish to demand attention when you do not deserve it. It will only serve to increase your frustration.

Please consider these comments as help expressed by a friend in the good faith that you will one day realize that the path you have taken is completely disconnected from the path of a high energy physics researcher. I truly hope that once you realize this you will go back to research and publish your results that will be serve as well as be appreciated by the community. Once that happens I am sure you will realize that the years you spent diverged from this path were completely lost years.

Your friend,
James

98. **woit**
July 12, 2006

James,

You're just repeating your same incorrect argument that the status of string theory and the standard model are similar. It's nonsense and I explained why, an explanation that you chose to completely ignore.

If you want to discuss scientific issues, I'm willing to do so, although it would help if you would actually respond to what I write. I'm not about to waste my time dealing with ad hominem attacks, especially not from someone unwilling to put his name to them.

As for my research results, they're sketched in http://arxiv.org/abs/hep-th/0206135 and I hope in the future to write up more recent things I've been working on. I certainly think it would be better if I did a better job of writing things up, but I don't regret at all having spent much of my career working on ideas that are quite different than those pursued by most of the high energy physics community.

99. **James**
July 13, 2006

Peter,

You say you are acting in a professional way. That is analogous to a prime minister acting professionally at the housewarming party of his nephew since the set of activities performed as the professional duty of a prime minister and the set of activities performed at a housewarming party do not intersect. Similarly, the set of professional activity performed by a physics researcher and the set of activity performed while posting to a weblog do not intersect.

If we were in a religious context I would close by saying that I am praying for your soul but since we are not I merely repeat again that I hope one day you will again utilize your professional skills to the benefit of the high energy physics community in a form that is demanded by the profession of a researcher.

Your friend,
James

100. **woit**
July 13, 2006

Thanks for the advice James, but I do think that what I am doing here and with the book that I wrote was to utilize my professional skills to the benefit of the high energy physics community.

And both projects are parts of my professional life.

101. **Stefan**
July 13, 2006

To Everyone:

This weblog seems filled with posts from individuals already committed to one view or the other on the (supposed) correctness or incorrectness of string theory. If we were discussing religion – say on the issue of how many angels can dance on the tip of a needle – "scientists" would readily dismiss us for being dogmatic-minded zealots. The ultimate anyone (at least those who do not claim to know the inner workings of nature beyond that which is currently known via experimentation) can say is… "Let us see. Maybe it will turn out ultimately be the correct formulation of fundamental physics, maybe not; but it doesn't hurt to explore…" I think every string "hypothesist" would ultimately agree to that point. Otherwise, we lose that ultimate sense of objective understanding which has guided the scientific enterprise so fruitfully since its inception.

To Peter:

When is your book coming out?
Also, (as asked in the previous post), do you know of any site / focus group on mathematical aspects of gauge theories? If not, do you want to start a group? I'm hoping this may prove valuable for the general HEP and Math-Phys communities. (At least it should to a cross-section, including string-"hypothesists" themselves.)

Best wishes.
Stefan

102. **Stefan**
July 13, 2006

Hi Peter (again),

Just finished reading 'String Theory: An Evaluation'; I encourage open-minded individuals to have a look through it; for string-enthusiasts: there probably isn't much to change your minds.

Some quotes (please read the article first, because these quotes can readily be misinterpreted):

"From a mathematician's point of view, the idea that M-theory will replace the Standard Model with something aesthetically more impressive is rather suspicious."

[Stefan]: Do you elaborate greatly on this point in your book? What motivated you to remark as you did?

"To the extent that the conceptual structure of string theory is understood, the Dirac operator and gauge fields are not fundamental, but are artifacts of the low energy limit. The Standard Model is dramatically more "elegant" and "beautiful" than string theory in that its crucial concepts are among the deepest and most powerful in modern mathematics. String theorists are
asking mathematicians to believe in the existence of some wonderful new mathematics completely unknown to them involving concepts deeper than that of a connection or a Dirac operator. This may be the case, and one must take this argument seriously when it is made by a Fields medalist, but without experimental evidence or a serious proposal for what M-theory is,
the argument is unconvincing."

[Stefan]: Good remark. Where can we find useful info on Dirac operators? What about Steven Weinberg's opinion? Does he feel similarly to you?

"Even granting that string theory is an idea that

deserves to be pursued, how can theorists be encouraged to try and find more promising alternatives? Here are some modest proposals, aimed at encouraging researchers to strike out in new directions:
1. Until such time as a testable prediction (or even a consistent compelling definition) emerges from string theory, theorists should publicly acknowledge the problems theoretical particle physics is facing, and should cease and desist from activities designed to sell string theory to impressionable youths, popular science reporters and funding agencies.
2. Senior theorists doing string theory should seriously reevaluate their research programs, consider working on less popular ideas and encourage their graduate students and post-docs to do the same.
3. Instead of trying to hire post-docs and junior faculty working on
the latest string theory fad, theory groups should try and identify young researchers who are working on original ideas and hire them to long enough term positions that they have a chance of making some progress.
4. Funding agencies should stop supporting theorists who propose to continue working on the same ideas as everyone. They should also question whether it is a good idea to fund a large number of conferences and workshops on the latest string theory fad. Research funds should be targeted at providing incentives for people to try something new and ambitious, even if it may take many years of work with a sizable risk of ending up with nothing.
Particle theorists should be exploring a wide range of alternatives to string theory, and looking for inspiration wherever it can potentially be found. The common centrality of gauge fields and the Dirac operator in the Standard Model and in mathematics is perhaps a clue that any fundamental physical model should directly incorporate them. Another powerful and unifying idea shared by physics and mathematics is that of a group representation.
Some of the most beautiful mathematics to emerge from string theory involves the study of (projective) representations of the group of conformal transformations and of one-dimensional gauge groups ("loop groups"). This work is essentially identical with the study of two dimensional quantum field theory. The analogous questions in four dimensions are terra incognita, and
one of many potentially promising areas particle theorists could look to for inspiration.

[Stefan]: Why not post all the most important reference works on the above topics? This will no doubt attract more individuals looking for further ideas to work on.

During the 1960's and early 1970's, quantum field theory appeared to be doomed and string theory played a leading role as a theory of the strong interactions. Could it be that just as string theory was wrong then, it is wrong now, and in much the same way: perhaps the correct quantum theory of gravity is some form of asymptotically free gauge theory? [Stefan: Important proposition] As long as the
best young minds of the field are encouraged to ignore quantum field theory and pursue the so far fruitless search for M-theory, we may never know."

[Stefan]: Agreement all-round.

Seems like we have great many things we can agree upon. 🙂

Stefan

103. **MoveOnOrStayBehind**
July 13, 2006

>The basis for this statement is that I believe the following (somewhat vague) ingredients are necessary for being taken seriously:

(1) Well-known high energy physics results in research papers
(2) Presence as an invited lecturer at respected high energy physics conferences
(3) Persuing a serious research program in high energy physics

Well, you forgot the most important point above all: namely saying something which is reasonable and makes sense. This and nothing else counts. The statements given here and elsewhere constitute a gross misrepresentation of a well-motivated and very successful major research effort, and thus it is no surprise that they are not taken seriously by any expert, rather the only people who react are laymen who can be easily fooled by such statements. To impress experts and be taken seriously by them, takes somewhat more than what emanates from here; laymen of course cannot distinguish this from real science, and easily become victims of this private crusade.

104. **woit**
July 13, 2006

Stefan,

Sorry, but I don't know of any specific group of the kind you ask about, and I'm afraid I'm already overwhelmed by moderating this blog, not interested in starting up another forum that would be even harder to moderate.

I'll try to answer some of your questions about the material in the book, don't have time right now to really do them justice:

1. The passage you go on to quote is an elaboration of the remark about M-theory. Not sure what I can say that would be helpful and not just repeating it.

2. There are many, many sources of different kinds about the Dirac operator, from every advanced quantum mechanics books to a huge mathematical literature. The Dirac operator is crucial to understanding the index theorem, and there's lots of places to read about that. One thing to do is to get ahold of Atiyah's collected works and try reading every expository paper by him on the subject.

3. Weinberg has not been publicly critical of string theory, although after working for a while on it, he long ago voted with his feet and left the field to do cosmology. His perspective is quite different than mine, traditionally he has been quite hostile to the use of geometry in theoretical physics.

4. In my 2002 paper on the arXiv there are references of this kind. Unfortunately when I say little is known about these problems, I'm quite serious, there isn't much useful literature. One good place to read about a lot of this is Jouko Mickelsson's book "Current algebras and Groups".

105. **woit**
July 13, 2006

MoveOn,

Maybe you can explain to me why almost all string partisans (except Lubos) who attack me as incompetent hide behind anonymity?

You're quite right that the relevant criterion is saying something which is reasonable and makes sense, which is exactly what I'm doing. The criticisms I am making here are definitely taken seriously by many experts, some string theorists some not. Recall that Lee Smolin has written a book making much the same points I do. If you actually think something I write is incorrect, feel free to say so and we can discuss this. Just joining other string theory partisans in anonymous attacks without any scientific argument gives strong indication that you can't actually do this.

106. **Peter Woit**

July 13, 2006

Stefan,

Publication date in the US is Sept. 8, copies should be available starting August 29.

107. **David**
July 13, 2006

Stefan,
Some recent mathematical results that I found interesting on Dirac operators can be found at the following people's websites:
Gerald Teschl-Math U of Vienna, Susanne Teschl- Technikum Vienna, and Fritz Gesztesy- Math U of Missouri.
Best,
David

108. **Stefan**
July 14, 2006

Thanks to both of you – Peter and David – for your generous feedback. As for the focus group – don't worry Peter, I will search for it myself.

Regards,
Stefan

109. **Stefan**
July 16, 2006

Judging from how the field of high-energy physics is currently chugging along one gets that peculiarly unnerving feeling that HEP is nearing its (pragmatic) end. Even with all the fanfare being given to strings and other approaches there does not seem to remain much scope for futher experimental verifications in the near future. As I see it this may imply one of several predicaments:

(a) HEP research will remain murky and unsubstantiated – for as long as we can delve out great theoretico-mathematical edifices lacking any accessible means of empirical verification; but since many of us like speculative studies this shouldn't cause us much unnecessary discomfort;

(b) Many researchers (as hinted above) will begin to explore and branch out into new territories – territories once considered taboo within mainstream academia… like consciouness studies (a la Penrose), philosophical speculations (of all types, shapes and flavours), and so on;

(c) some amazing body of discovery will jostle us out of our doldrums – this will most likely come from high-energy astrophysics (or some hitherto unsuspected corner of physics); a flurry of activity will ensue… until quietude once again engulfs the frontier…

What is my point you ask? Not much, except to point out that that once-glorious field prided and envied the world over as the "crown jewel" of fundamental science is nearing its painful and aged death…

…so let it be… so let it be…

I wonder what former hep scientists do for a living once they leave the field?

110. **D R Lunsford**
July 16, 2006

Stefan, don't you think it is a little arrogant to claim that physics is dying? Would you have said that in 1895?

The fault, dear Stefan, is not in our Hodge stars, but in ourselves.

-drl

111. **Walt**
July 16, 2006

Stefan pretty clearly said HEP, not physics as a whole.

112. **David**
July 16, 2006

Stefan,
Try molecular physics. It's fun and there are even experiments. Some of us teach in strange departments but they let us research what we want (often anyway).
Best,
David

113. **Stefan**
July 17, 2006

I was thinking more in the line of non-linear science – which promises to open up a territory still as-yet unexplored; and which may provide us with very important insights into the "physical" world – the world that we – as physicists – claim to want a more complete and thorough understanding of. I think perhaps the most crucial and outstanding results in the coming years (with attendant Nobel prizes) will evolve from this branch (my hunch anyway; Stephen Hawking was among the first – to my knowledge – to air such a view publicly).

[If anyone is further interested Ilya Prigogine's fantastic work 'Order out of Chaos' may prove a valuable read.]

The current approaches (in HEP-research) all seem exciting – regardless of their ultimate relevance (or lack thereof) to physics as a field; I just don't think in the long-run younger scientists will want to wager their careers on an area (say string theory, LQG, or other theory topics with little prospects of experimental verification – atleast in the near- to middle- term) which remains so far removed from experimental verifiability… but then we are all entitled to our own views…

If strings (and perhaps altogether current HEP research) proves less and less appealing with time, some (randomly suggested) propositions include:

(a) studying mathematical physics – there are very many traditional problems which to-date remain unsolved, e.g. finding rigorous mathematical framework for QFT, modern approaches to classical mechanics, N-body problem, and other well-known problems;

(b) condensed-matter physics – generally a good field to study nowadays I hear;

(c) nonlinear science – not a bad place to devote oneself if you aspire to do some ground-breaking research;

(d) whatever scientific problems one finds interesting and/or worthy of study… as long as it remains in the purview of "experimental science" (vs. "philosophical science"); this, in its truest spirit, has been what has kept the field so rich with activity since its initial founding, and why the term "science" is held in such high regards the world over…

Some random thoughts from my part… hope we can make a meaningful debate out of this…

Stefan

114. **Eugene Stefanovich**
July 17, 2006

Stefan:

I like point (a) of your program. Besides, with our emphasis on "high energy" in HEP, we seem to be missing a very important part of physics, both experimentally and theoretically. There are virtually no studies of time-dependent processes. In HEP experiments, such studies are almost impossible, because everything happens very fast. On the theoretical side, QFT can tell nothing about them, because renormalized QFT lacks a well-defined finite Hamiltonian.

The property accessible to modern experiments and theory is the S-matrix, but there is a lot of physics beyond S-matrix, and we know almost nothing about this kind of physics. To learn more, it is not necessary to go to higher and higher energies. There are quite a few fundamental things that can be learned from low-energy processes with much improved resolution (especially, time resolution) of instruments.

For example, I am very interested to know whether interaction potentials between charged particles are retarded (i.e., Lienard-Wiechert potentials). So far, nobody has measured the retardation directly.

115. **Stefan**
July 18, 2006

Peter,

I reference to our recent dialogue on gauge theories: I just saw the movie of Atiyah on People's Archive: Atiyah seems to have worked on Dirac Operators during his middle-years. I'm wondering if you can give me a list of important contributions Atiyah (and collaborators, e.g. Drinfeld, Hitchin, Manin, etc.) made on this topic, and also on gauge fields / theories in general (only the most significant ones).

I gather you will have teaching / research responsibilities, so please take your time. I'm thinking this should be useful reading; I want to start a website devoted to this area.

Just wondering why no-one has done so already.

Your friend,
Stefan

116. **Stefan**
July 18, 2006

Quick Links

July 6, 2006
Categories: Uncategorized

Taking off tomorrow for a long weekend, internet access may be spotty. Here are some things that may be of interest:

HEPAP is meeting today and tomorrow, the presentations given at the meeting are available here. JoAnne Hewett is there and has a posting on Cosmic Variance.
The Seed article with various physicist's views about what to expect at the LHC that was discussed here earlier is now available online.

There's an article about Jim Simons in Newsday (via Angry Physics).

Maybe a cosmologist can comment on the significance of this, but over at CosmoCoffee there's a discussion of a new paper reanalyzing the latest WMAP data and coming up with a scalar spectral index n_s= .969 +/- .016. This is now 2.0 sigma away from 1, instead of the 2.7 sigma of the earlier analysis. This deviation from 1 was widely sold as evidence for inflation (since the simplest inflationary models give values slightly less than one), the fact that it is now only a 2 sigma effect seems to make this case a bit weaker.

The Institut Henri Poincare in Paris will be having a three-month-long program on Groupoids and Stacks in Physics and Geometry. The web-siter there contains a good associated overview of the subject.

Bruno Kahn has an excellent expository article on motives.

Over at the Edge web-site Lawrence Krauss has a piece called The Energy of Empty Space That Isn't Zero. It's partly about the cosmological constant, and discusses a workshop on Confronting Gravity that he organized back in March, which brought many prominent theorists together at a Caribbean resort to discuss physics, travel in a submarine, and hang out at the "private island retreat" of the funder of the event, science philanthropist Jeffrey Epstein.

Krauss has many provocative things to say about the current state of theoretical physics, including perhaps the most concise and vivid description I've read in a while:

It's been very frustrating for particle physicists, and some people might say it's led to sensory deprivation, which has resulted in hallucination otherwise known as string theory.

He also has a somewhat longer skeptical take on extra dimensions, together with an attempt at positive spin:

Many of the papers in particle physics over the last five to seven years have been involved with the idea of extra dimensions of one sort or another. And while it's a fascinating idea, but I have to say, it's looking to me like it's not yet leading anywhere. The experimental evidence against it is combining with what I see as a theoretical diffusion — a breaking off into lots of parts. That's happened with string theory. I can see it happening with extra-dimensional arguments. We're seeing that the developments from this idea which has captured the imaginations of many physicists, hasn't been compelling.

Right now it's clear that what we really need is some good new ideas. Fundamental physics is really at kind of a crossroads. The observations have just told us that the universe is crazy, but hasn't told us what direction the universe is crazy in. The theories have been incredibly complex and elaborate, but haven't yet made any compelling inroads. That can either be viewed as depressing or exciting. For young physicists it's exciting in the sense that it means that the field is ripe for something new.

   July 6, 2006

   For young physicists it's exciting in the sense that it means that the field is ripe for something new.

   This should be exciting not just for young physicists, but for everyone. When David Gross talks about not understanding what is space-time and Roger Penrose wants to change quantum mechanics, that's a sign of something big coming.

2. **Peter Woit**
   July 6, 2006

   Eugene,

   I'd like to be that optimistic, but I seem to remember both Gross talking about getting rid of space-time and Penrose wanting to change QM at least 15 years ago. Krauss is right that the time is ripe for people to give up on things that haven't worked and try something new. Will they do it though?

3. **rof**
   July 7, 2006

   Right now it's clear that what we really need is some good new ideas.

   The anthropic principle, extra dimensions and parallel worlds. These are the new ideas you will hear about, again and again and again. They are the exciting new ideas that each generation of daydreaming physicists echo again and again. They aren't even new ideas.

   And anyway, if somebody announced what the correct new idea was today, they'd be dismissed as a crackpot. A good old fashioned no-nonsense attitude has thoroughly infused the physics community. As a result, they are dismissive. If there is a lesson to be learned from string theory, it should be that it takes careful investigation to distinguish between nonsense and complex but correct ideas. But that lesson will not be learned. People display dismissiveness because the immature are impressed by dismissiveness and consider it worthy of imitation.

   Each individual physicist will insist that he is perfectly reasonable. All you have to do to convince him that your new idea is worthwhile is immediately produce a full theory of quantum gravity and have it endorsed by some celebrity physicist (even though that celebrity physicist will make the same demand of you before listening to your idea). Otherwise you're a crackpot.

   Physicists need to face the facts: As a community, they're too immature to be able to provide an environment where new ideas can be communicated without ridicule. Too much narcissism and arrogance. Children.

4. **Eugene Stefanovich**

July 7, 2006

Peter,

I was not suggesting that new big ideas will come from Gross or Penrose. Most likely, not from them, in my opinion. I was just hinting that the current state of disarray, when frustrated people are willing to give up the most secret things, is a prelude to some radical change. I just smell it in the air. You are right that in order to move forward we should not be afraid of new crazy ideas. The question is: how "crazy" is good enough?

5. **Anon**
July 7, 2006

The reduction of the significance that the spectral slope of the primordial perturbations is less than one does not have a strong effect on the possibility of inflation. The spectral slope may be used to distinguish between various potentials for the inflaton. But the current experimental constraints are not that discriminating. There are a couple of s that were favored pre-wmap but now give a bad fit to the data. The PLANCK satellite will dramatically improve this situation. So will better polarization measurements by ground and balloon based experiments. Ultimately, a polarization satellite will probably be needed to really be conclusive.

6. **Krotos**
July 8, 2006

For young physicists it's exciting in the sense that it means that the field is ripe for something new.

My take on this as a youngish physicist is that I'd like to believe it, but the fundamental problem that has led particle physics (and, increasingly, cosmology) to the current situation is the inability to satisfactorily test these theories experimentally. And I don't see that changing any time soon. Even the LHC will be orders of magnitude below the energies necessary to really probe the physics behind, say, dark energy or inflation. The best we'll be able to do with forseeable technology is pretty much what we're doing now, i.e., indirect observations and inferences from astrophysical measurements. That's good and valuable, but generally it doesn't provide the precision necessary to do more than favor one large class of models over another large class.

Yes, one can certainly hold out hope that some 21st century Einstein will come up with a rigorous, revolutionary new theory that unifies gravity and quantum mechanics and explicitly predicts the value of the cosmological constant, etc. But historically, that kind of thing has not tended to occur in the absence of data.

7. **Who**
July 8, 2006

Krotos, I beg to differ
**… not tended to occur in the absence of data…. **
which suggests there is a lack of observational data.

On the contrary, one might say that theorists now have TOO MUCH data. More data than they know how to assimilate. If you are a theorist today, you have dark energy (70 percent of universe) and dark matter (another big part). You will soon have results on very high energy gamma photons and cosmic rays from projects such as GLAST (2007) and AUGER (current).
Dark matter you can see very clearly in galaxy rotation and lensing. Dark energy or its equivalent is seen clearly in accelerating expansion and in the microwave background. These look like major puzzles of just the sort that a theorist could wish for. Imagine if you could make a model of spacetime and matter that would fit all this hugely unexpected data!

And I mean fit even APPROXIMATELY, to first order. You seem to be asking for higher precision measurements to distinguish between closely similar models, when, as far as I am aware, we don't even have the **beginnings** of a model to explain the measurements we already have.

8. **Krotos**
July 8, 2006

You seem to be asking for higher precision measurements to distinguish between closely similar models, when, as far as I am aware, we don't even have the beginnings of a model to explain the measurements we already have.

Certainly there's a lot of "data" in the sense that dark matter and other non-SM phenomena have been indirectly observed and have had approximate limits put on their density fractions by WMAP and other experiments, and of course any unified theory would have to predict these. But my point is that it would, IMO, be extremely hard to construct an underlying particle physics model from which you could "derive," say, inflation, without knowing, even approximately, what the inflaton mass/potential/etc. even *is*. And the same goes for dark matter and dark energy. What forseeable astrophysical observations will be able to determine their properties even remotely to the extent that a controlled experiment in a laboratory could? That's what I meant by saying that there isn't enough data, and what data there is isn't precise enough.

I agree with you that we don't have even the beginnings of a model that simultaneously predicts these things — I just don't see how we're going to get even to *that* with cosmological measurements alone, let alone to something with the precision of the Standard Model.

9. **Eugene Stefanovich**
July 8, 2006

Krotos:

I disagree. How can a theorist be not excited about the current mess in theoretical physics? Even in the absence of new experimental data, there are so many delicious paradoxes within our theories that are just screaming at us begging for resolution. Take for example two completely different ways the time is treated in quantum mechanics and in relativity, and the whole issue about the incompatibility of QM and GR, or the problem of UV divergences. These are deep problems and they require some bold thinking. I wouldn't complain that theorists have nothing to do until LHC begins to deliver data.

10. **Krotos**
July 8, 2006

Eugene, certainly I agree that these are fascinating problems and deserve a lot more investigation and thinking about fundamental concepts like time and space. But as I said in my response to Who, I just don't see how we'll be able to get beyond the theoretical speculation stage (even with LHC data) on them. Theoretical physics in indeed arguably in even a bigger mess now than it was in 1900. But the difference, IMO, is that in 1900 the technology either existed or was on the horizon to experimentally investigate the problems physics was then facing. The data informed and enriched the theory. For the most part, that's not the case now.

11. **Eugene Stefanovich**
July 8, 2006

Krotos:

Yes, in 1900-1920 when there was an ocean of new controversial experimental data, it was much easier to develop theory. Now we don't have this luxury, and we should draw inspiration form internal theoretical inconsistencies rather than from comparison with experiment. This is much more challenging, no doubt about that. However, I think this is just as exciting now as it was then.

I think we will start to make progress only after we admit that there is something wrong in our textbooks (about special and general relativity, QM, and/or QFT), even though these theories passed numerous experimental tests. I don't think we have this courage. I see that from discussions on Peter's blog: it is next to impossible to convince people to admit mistakes even it the research program that passed zero experimental tests. I am talking about string theory, of course.

12. **Sebastian Thaler**
July 9, 2006

Peter,

Lubos is now calling you a jellyfish on his blog.

13. **nigel cook**
July 9, 2006

Sebastian,

As soon as stringers are defeated scientifically (which is as soon as they make any type of claim to be scientists), they have to either retreat quietly, or else start calling people names which they hope will be taken as insults.

These insults tend to backfire. Anyone can throw that sort of thing around. All it shows is a lack of ability to either succeed with a scientific discussion, or to admit he has no answer, like a responsible adult. His trick in the review of Not Even Wrong, comparing string theory to evolution is extremely misleading.

14. **D R Lunsford**
July 10, 2006

Speaking of quick links,

This article in Time repeats the fantasy that Mileva Maric was key to the development of relativity, specifically that she "helped [Einstein] with the math of his 1905 paper". This claim is absurd – the math is Maxwell's equations and simple algebra, and was common knowledge. In fact Maric failed to gain a teacher's certificate in 1900 because of low math scores, and left ETH in 1901.

How did this revisionist falsehood work its way into the public mind? I see this as passive hostility to Einstein himself (despite the usual fawning), and somehow connected with the current devolvement of science into superstition and mysticism.

See also here:

-drl

15. **nonblogger**
July 11, 2006

Another quick link then: next september there will be a conference in Cambridge (UK) on the "fundamental structure of space and time" gathering mathematicians and physicists (Connes, 't Hooft, Schwarz, Penrose, Douglas, Hawking, Freidel, etc.)
http://www.newton.cam.ac.uk/programmes/NCG/ncgw02.html

The aim seems to be to put people from all sorts of backgrounds (strings, LQG, non-commutative geometry,etc.) in the same room. I hope some videos of the talks and panel sessions will be made! (Too bad that the main sponsor seems to be the John Templeton Foundation…)

16. **Alejandro Rivero**
July 11, 2006

Hey, I will attend to the meeting pointed by nonblogger. And I should solve the problem of accommodation for at least a couple months, not only the meeting. Any idea, please mail me (al.rivero # gmail.com)

17. **Chris W.**
July 11, 2006

Regarding the above-mentioned conference, note the participants and theme of the planned panel discussion. The Templeton Foundation's influence seems pretty obvious here.

18. **sunderpeeche**
July 11, 2006

Why don't you fund your own conference, free of Templeton Foundation influence? Recall the song from 1946 about the foundation of Brookhaven National Lab (~ Cold War + Big Science)

—x—x—

– "Take Away Your Billion Dollars," by Arthur Roberts (1946),

Up on the lawns of Washington the physicists assemble
From all the land are men at hand, their wisdom to exchange.
A great man stands to speak, and with applause the rafters tremble.
"My friends," says he, "you all can see that physics now must change.
"Now in our lab we had our plans, but these we'll now expand,
Research right now is useless, we have come to understand.
We now propose constructing at an ancient Army base,
The best electro-nuclear machine in any place.

"Oh – it will cost a billion dollars, ten billion volts 'twill give,
It will take five thousand scholars seven years to make it live.
All the generals approve it, all the money's now at hand,
And to help advance our program, teaching students now we've banned.
And as the halls with cheers resound and praises fill the air,
One single man remain aloof and silent in his chair,
And when the room is quiet and the crowd has ceased to cheer,
He rises up and thunders forth an answer loud and clear,
"It seems that I'm a failure, just a piddling dilettante,
Within six months a mere ten thousand bucks is all I've spent.
With love and string and sealing wax was physics kept alive,
Let not the wealth of Midas hide the goal for which we strive.
Oh — take away your billion dollars, take away your tainted gold,
You can keep your damn ten billion volts, my soul will not be sold.
Take away your army gen'rals, their kiss is death I'm sure.
Ev'rything I build is mine, and ev'ry volt I make is pure.
Take away your integration, let us learn and let us teach,
Oh, beware this epidemic Berkelitis I beseech.
Oh, dammit! Engineering isn't physics, is that plain?
Take, oh take, your billion dollars, let's be physicists again."

19. **Alejandro Rivero**
    July 11, 2006

    I had not seen the Panel, but bet Connes is able to bypass any reverend.

20. **Chris W.**

Interviews With Atiyah and Gell-Mann

July 12, 2006
Categories: Uncategorized

A correspondent wrote in to tell me about a wonderful web-site, called [People's Archive](). Their idea is to do in-depth interviews at a peer-to-peer level with the great thinkers and creators of our time. They've been doing this for a few years, only recently providing open access to much of the content on their site.

The two interviews of people closest to my interests are ones of [Sir Michael Atiyah]() and [Murray Gell-Mann](). The interviews are very long, several hours. So far I've made my way through the Atiyah interview (which is in 93 pieces), mostly just reading the transcript, and have poked around a bit in the Gell-Mann interview (which is in 200 pieces).

Atiyah is on just about every mathematician's list as one of the very few greatest figures in the second half of the twentieth century. He's also had a major impact on the relation of mathematics and physics. The interview essentially provides a long memoir of his life, concentrating on his mathematical research work, explaining in detail how it came about and how it evolved. It's truly wonderful, with all sorts of interesting stories, together with insights into mathematics and how it is done at the highest level.

The interview begins with his childhood in Khartoum, then discussing his later education in England, ending up at Cambridge where he was a student of Hodge. One story he tells (segment 21) is about Andre Weil's reaction when Atiyah showed him his work at the time he was a student. The segment is called "how not to encourage somebody." Atiyah also later on talks about his mathematical heroes, especially Hermann Weyl. Physicists often confuse Weil and Weyl, who were two rather different characters. They both did important work on representation theory with Weyl responsible for, among many other things, the representation theory of compact Lie groups, and the exponentiated form of the Heisenberg commutation relations (what mathematicians call the Heisenberg group). Weil was responsible for the geometric construction of representations of compact Lie groups (Borel-Weil theory), and a general theory of representations of Heisenberg-like groups (known as the Segal-Shale-Weil, or metaplectic representation).

Atiyah tells about the importance of his years spent at the IAS in the fifties and the people that he met there. It was one of the great meccas of mathematics at the time. He tells in detail the story of how the index theorem came about (segment 43), and the crucial role provided by the Dirac operator in linking together the analysis and the topology. The Dirac operator was rediscovered by him and Singer during their work. He also explains the important role from the beginning of equivariant versions of the theorem, in providing motivating examples and requiring the most general and deepest sort of proof.

During the 1970s Atiyah started to get deeply involved in interactions with physicists, and he recalls going to MIT to discuss instantons with them, meeting a young Edward Witten in Roman Jackiw's office there (segment 67). He describes in detail his interactions with Witten, especially his prodding of Witten that led to the discovery of the TQFT for Donaldson theory (segment 71), something that took Witten quite a lot of effort before he came up with the necessary twisting of supersymmetry to make this work. He also tells the story of the famous dinner at Annie's in Swansea where, in discussions with Atiyah and Segal, Witten came up with his Chern-Simons theory. The idea was so compellingly correct that Witten decided the next day to not give the talk he had planned, but to talk about this new theory born only the night before.

In his comments on the future (segment 74), Atiyah refers to the new ideas brought into mathematics from QFT as "high energy mathematics", and predicts that mathematics in the future will make crucial use of the sort of "infinities of infinities" that occur in QFT structures, but that mathematicians until recently have had no real idea how to approach. He also makes some interesting comments about what sort of problems it is best for graduate students to work on, and gives (segment 90) a wonderful description of the importance of beauty in mathematics and his own definition of it.

All in all, it makes fantastic reading, I hope the company that put this together will clean up the transcripts and put them out in book form.

I haven't had the time to go through all of the Gell-Mann interview, but it also contains all sorts of valuable history. One little-known fact that Gell-Mann mentions is that the SU(3) eight-fold way that he got the Nobel prize for came about because, after he had spent a long time trying to generalize SU(2)xU(1) unsuccessfully, a mathematics assistant professor (Richard Block) finally explained to him that what he was doing was trying to find a certain kind of Lie algebra, and the one he was looking for was the Lie algebra of SU(3).

Comments

1. **MathPhys**
   July 12, 2006

   Peter,

   You seem to be stuck in the 80's 😉 No physicist confuses Weil and Weyl any more. Seriously, thanks for the valuable link.

2. **Chris W.**
   July 12, 2006

   From Murray Gell-Mann's segment 21, [Viki Weisskopf. Mathematical formulas and physical theories]():

   > What I learnt from Viki was mainly an attitude which I've described in a paper that I presented in his honour called 'The Garden of Live Flowers'. He kept insisting on a pedestrian approach. Now, a pedestrian approach is not my approach. I like clean mathematical results and elegant demonstrations and so on and so on and so on. But nevertheless that was part of Viki's style that I was able to benefit from, and that was a sort of unpretentiousness: the idea that you shouldn't try to construct right away, ab initio, the ultimate theory of things.

   Given how fundamental physics has evolved in the last two decades there is a complicated irony in this reminiscence. By the way, has Gell-Mann had anything to say about string theory in the last few years?

3. **Belizean**
   July 12, 2006

   What a wonderful resource! I got to learn things about my old graduate advisor that I aways wondered about but was too timid to ask. Thanks for sharing!

4. **Paul Frampton**
   July 12, 2006

   I recently found the hours of interview with Murray Gell-Mann
   and watched it all as it is startling. The interviewer
   has Murray give countless insights not only about theory but other theorists. One example: at UCLA 30 years ago it was clear to me something had occurred between him and Schwinger who avoided Murray's ideas, a difficult task. See segment 106.

5. **Carl**
July 13, 2006

I'm a big worshipper of Schwinger, in particular his measurement algebra which dates to the late 50s. In fact, I started a website devoted to this, http://www.MeasurementAlgebra.com. I have to admit I didn't like hearing Gell-Mann accuse Schwinger of making an error in stealing someone else's work, for the sake of elegance.

To be human is to err. My own feelings is that Schwinger was on the right path with the Measurement Algebra, which dates to a few years before the incident discussed, but got off track when he converted it from a density matrix form to a spinor form. A recent argument for the density matrix form is here: (post #3 and replies) http://www.physicsforums.com/showthread.php?t=124904

There is no question that physics at the present time is in a certain amount of trouble. Did we get into trouble by excessive attention to elegance? Or was it failure to attend to the foundations of physics? In this, I think that Schwinger was right. It is the foundations of QM that were shaky.

But the Gell-Mann interview also reminds me of that physics is as much as social science as anything humans do. It is not that "physics" is in trouble, it is that the physicists have made no progress. Does repeating unpleasant truths (or lies) about personages who were slightly off the beaten path 50 years ago help advance physics?

When I get lost while driving, the way I get to where I want to go is to go back along the way I came, and look for a place where a mistake was made. In ignoring the complaints about the foundations of physics from the 1920s through 1950s, the string theorists are making the unwarranted assumption that the foundation they build upon is solid. It is in this that I think that Schwinger's best efforts were made, in pointing out the problems. Rather like Bohm.

Carl

6. **MathPhys**
July 13, 2006

I was quite thrilled to read what Gell-Mann had to say about the Abdus Salam/John Ward collaboration. I've never understood why Salam got the Nobel prize for electroweak interactions without Ward, given that they did the work jointly (the paper often cited as Salam's contribution to electroweak unification is a conference report on his joint work with Ward). I was very happy to read that Gell-Mann is of the same opinion.

Incidentally, does anyone know what became of John Ward?

7. **MathPhys**
July 13, 2006

I now know.

http://www.physicstoday.org/pt/vol-53/iss-10/p99.html

8. **Kyle**
July 13, 2006

> There is no question that physics at the present time is in a certain amount of trouble.

Hmm, I don't see this as true at all. Maybe your area of physics is doing poorly, but I see the discipline overall as doing quite well.

9. **D R Lunsford**
July 13, 2006

This is a fantastic site! I enjoyed Teller talking about his early interest in projective geometry – I remember proving that theorem that he said he was stumped by, algebraically, so that made me feel good! I find I still have a hard time listening to mathematicians run on 🙂 but listening to Teller, Bethe and Dyson is just wonderful. Also it was hilarious to hear Gell-Mann point out that going to MIT doesn't commute with suicide 🙂

-drl

10. **D R Lunsford**
July 13, 2006

This was also hilarious (Teller on Sommerfeld):

"I'm sorry to tell you I did not enjoy Sommerfeld. He was a bit on the high brow side and I can tell you one story about him that might explain my lack of enthusiasm. The story is about a very excellent American student who later got the Nobel Prize, van Vleck, who went as a young student to study in Munich. And there he was in the library, and in comes Sommerfeld. Excuse my German, I think you will understand it. Sommerfeld enters. van Vleck shows up and politely says- Guten Morgen, Herr Sommerfeld. He's rewarded with a none-too-pleasant grunt. Next time it happens Van Vleck says- Guten Morgen, Herr Professor. This time, Sommerfeld smiled a bit. On the following occasion, he said- Guten Morgen, Herr Doktor. Now, this time Sommerfeld said- Guten Morgen. But the last time Sommerfeld came in and van Vleck said- Guten Morgen, Herr Geheimrat. Well, Geheimrat means secret councilor. A very high title in Germany. And Sommerfeld looks at him- Aber Ihr Deutsch ist jeden Tag besser! But your German is improving every day!"

-drl

11. **Chris Oakley**
July 13, 2006

I have not looked at Gell-Mann's argument, but presumably it is on the lines of the following:

A = Going to MIT
B = Committing Suicide

AB = you commit suicide & your body is transported to MIT
BA = you go to MIT and then commit suicide

So $[A,B] \neq 0$

But either way you will end up dead at MIT, so I suppose that

<t2|[A,B]|t1> = 0

if t1 > max(T_MIT, T_suicide) or t2

12. **Chris Oakley**
July 13, 2006

… < min(T_MIT, t_suicide)

(I thought I'd got the hang of HTML tags, but maybe not)

13. **MathPhys**
July 13, 2006

Gell-Mann has such a low opinion of Schwinger.

14. **Tony Smith**
July 13, 2006

The People's Archive interview with Freeman Dyson (number 78) discusses Dyson's work on QED showing the equivalence of the Feynman and Schwinger approaches.
Dyson wanted to show Oppenheimer and the Princeton IAS the QED success.
Oppenheimer's reaction reminds me of the attitude of the superstring establishment.

Here are some excerpts from interview 78 with Dyson:

"… we met Oppenheimer and I wanted to talk about this in the seminar at the Institute … Oppenheimer wasn't enthusiastic at all. It came as a big shock to me that we'd done this wonderful stuff and I desperately wanted to tell Oppenheimer about it, that was the whole point in coming to Princeton. And Oppenheimer just brushed us off and said, "Well, you know, that's not leading anywhere,' …

"… This is of course a common situation; that the people who have failed to clean up a subject then don't believe that it can be cleaned up … And then if somebody comes along and says, "Look, it works," they don't believe.

"So that was how it was, and so we had a very hard time to get Oppenheimer's attention. …
All the old people … including Max Born and Heisenberg and Schroedinger … had radical proposals which turned out to be totally useless …

"Feynman … and … Schwinger .. and … I were conservative in the sense that we … actually made the mathematics work and got the right answers. And that came a surprise to Oppenheimer. It was very hard for him even to listen to it. …

"finally Uhlenbeck interceded with Oppenheimer … "Let's listen to Dyson," and so Oppenheimer put on a seminar series for me …".

The "radical proposals" of Born, Heisenberg, and Schroedinger remind me of superstring theory.

Sadly, it seems that today there is no Uhlenbeck who will listen to alternatives that work.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

15. **nigel**
July 13, 2006

"Incidentally, does anyone know what became of John Ward?" – MathPhys

See http://www.opticsjournal.com/ward.html , but that doesn't mention that John Ward had an argument in the 80s with Prime Minister Margaret Thatcher over Lord Penney and the design of Britain's H-bomb. After he had discovered the Ward identity, he got a job at Aldermaston circa 1955 and was set the task of designing a H-bomb (Britain had already tested the fission bomb).

According to the book 'Britain and the H-bomb' (by the official British nuclear historian Lorna Arnold), she interviewed Ward over the issue and he drew the blueprint for her that he had done for Penney in 1955. Penney chucked out Ward's design and went ahead with his own ideas which did poorly when tested in 1957. Ward quit in anger. However, Arnold says the blueprint Ward suggested was not exactly brilliant either, and he had done no supporting calculations to show it would work.

After the basic Teller-Ulam design was declassified in the 80s, Ward wrote to Britain's Prime Minister Thatcher claiming he had come up with the same design, but it had been suppressed by Penney, who got a lot of credit for ideas which did not always go off with a perfect bang. It created a bit of a scandal.

16. **D R Lunsford**
July 13, 2006

Dyson tells the following anecdote of Oppenheimer, which is really appropriate today:

"And then we met Oppenheimer and I wanted to talk about this in the seminar at the Institute, and somehow or other Oppenheimer wasn't enthusiastic at all. It came as a big shock to me that we'd done this wonderful stuff and I desperately wanted to tell Oppenheimer about it, that was the whole point in coming to Princeton. And Oppenheimer just brushed us off and said, "Well, you know, that's not leading anywhere,' and he had somehow got convinced that you couldn't do physics at all with these old methods. He considered this all old stuff and what physics needed was something radically new. This is of course a common situation; that the people who have failed to clean up a subject then don't believe that it can be cleaned up, so they're looking for something totally different. And then if somebody comes along and says, "Look, it works," they don't believe. So that was how it was, and so we had a very hard time to get Oppenheimer's attention. And I think Niels Bohr had a very bad effect on Oppenheimer too, because I mean Niels Bohr, at that time, was convinced that physics had to be radically different if it was going to work; and Heisenberg, all the old gentlemen of those days, they'd lived through this radical revolution of quantum mechanics which was so successful, they wanted to have something like that again. They thought a new revolution, like 1925, was needed. All the old people tried to do that, including Max Born and Heisenberg and Schrödinger, I mean each of them had radical proposals which turned out to be totally useless, and in the meantime it was the young people who actually were the conservatives; from this point of view even Feynman was a conservative. I mean he went back to the old physics and made it work, and that was what Schwinger did too, and what I was doing. So we were conservative in the sense that we used the old physical concepts of quantum electrodynamics exactly the same as Heisenberg and Pauli in the 1920s, and actually made the mathematics work and got the right answers. And that came a surprise to Oppenheimer. It was very hard for him even to listen to it."

-drl

17. **sunderpeeche**
July 13, 2006

Tony Smith –
"Sadly, it seems that today there is no Uhlenbeck who will listen to alternatives that work."

Where is a Dyson with alternatives that work?

FWIW Uhlenbeck didn't adapt well to the post-WW2 "big science" expt particle physics. He also didn't always listen to the new voices in the field of stat mech.

18. **D R Lunsford**
July 13, 2006

Tony – funny we should latch onto the same quote exactly! The entire Dyson interview reveals a fearless and honest thinker and is just downright inspiring.

-drl

19. **Tony Smith**
July 13, 2006

sunderpeeche said "… Where is a Dyson with alternatives that work? …".

Since that is a direct request for a specific alternative, I guess it is OK for me to say that my model gives reasonably-consistent-with-experiment values for force strengths, particle masses, the Dark Energy : Dark Matter : Ordinary Matter ratio, and more,

despite which I am blacklisted by the Cornell arXiv and either ignored or ridiculed when I have offered to describe my model at seminars (ignored by Perimeter/Smolin and ridiculed by Harvard/Motl).

If sunderpeeche would invite me to give a seminar about my model at a reasonable place and time, I would be happy to do so. (Since sunderpeeche is anonymous to me, maybe sunderpeeche's place is too far for me to go, but I would try within reason.)

Tony Smith

20. **Peter Woit**
July 13, 2006

Anyone who wishes to discuss Tony's work, please contact him privately, this is far off the topic here.

These interviews have a wealth of interesting material, but are very long, so it's time-consuming to read them all. Thanks to all for pointing out those sections that are striking in one way or another.

21. **Paul Valletta**
July 13, 2006

Peter, great links!

The era outlined by Atiyah at "Swansea" was really interesting, specifically as I was there. I do recall a number of Post-Grads were having a lot of problems with the talks, and there was a Grad revolt at hand. It's quite ironic that Witten felt that the re-arranged conference (I believe it was supposed to be held at a higher University rather than Swansea), was failing fast, and out of the dissent, Witten came up with his "revolutionary" insight!

Maybe Witten guessed the road ahead was peppered with "loopholes" and, as he was the conference's major Mathe-magician, produced a String/M-Theory "Miracle" ?

Thanks again for the really interesting thread.

22. **John Baez**
July 14, 2006

Peter writes:

Physicists often confuse Weil and Weyl, who were two rather different characters. They both did important work on representation theory…

Saying that they're "rather different" is an understatement. Let's not let anyone get confused:

Hermann Weyl was a mathematical physicist, and every physicist should know about him:

He gave the first precise definition of a 2-dimensional manifold, in his 1913 book *The Idea of a Riemann Surface*.

He introduced the term "gauge invariance" in his 1918 paper trying to unify general relativity with electromagnetism. A footnote to this paper by Einstein explained why this theory would not work – but later, after changing the group R to U(1), people realized that his treatment of electromagnetism as a gauge theory was very profitable.

His book *Space, Time and Matter* is a profound analysis of the basic concepts of physics. This book is the first place the modern definition of vector space was ever written down! It contains an excellent classification of tensors, tensor densities, and pseudo tensor densities, based on the representation theory of GL(n). If everyone read this, there would be far fewer arguments about various kinds of tensor-like thingies.

Weyl was largely responsible for introducing group representation theory into quantum mechanics, in his book *Group Theory and Quantum Mechanics*.

His book *The Classical Groups* systematized the use of Young diagrams for representations for the groups SU(n), SO(n) and Sp(n) – the special unitary, orthogonal and symplectic groups. He invented the term "symplectic"! (People had been using the term "complex", which is very confusing, so he translated it into Greek.)

His book *Symmetry* is a gem of science popularization that anyone can read – a study of symmetry in mathematics, physics, art, and nature.

He also did a lot of other work on Lie theory. He invented the Weyl character formula in Lie group representation theory. He also invented the Weyl relations: the exponentiated form of Heisenberg's canonical commutation relations, which you need for rigorous work on this subject.

A seriously cool dude!

Andre Weil was a number theorist, a draft dodger who was caught and jailed, and a member of Bourbaki. He shared an interest in philosophy with his more famous sister – Simone Weil.

He carried the analogy between number fields and function fields further than it had ever gone before, revealing that number theory is a branch of geometry. He came up with the Weil conjectures, which eventually led Grothendieck to etale cohomology. And he invented adeles – roughly the number-theoretic analogue of formal power series.

He did a lot more, but I'm getting tired….

23. **John Baez**
July 14, 2006

Peter writes:

> One little-known fact that Gell-Mann mentions is that the SU(3) eight-fold way that he got the Nobel prize for came about because, after he had spent a long time trying to generalize SU(2)xU(1) unsuccessfully, a mathematics assistant professor (Richard Block) finally explained to him that what he was doing was trying to find a certain kind of Lie algebra, and the one he was looking for was the Lie algebra of SU(3).

Richard Block is now a professor emeritus at my school, UC Riverside. He's an expert on Lie algebras over finite fields. He has a great house up in the hills overlooking the campus, and spends a lot of time gardening. He occasionally asks me questions about operads.

Besides pointing Gell-Mann towards Lie theory and SU(3), he was the first to have invented the Virasoro algebra… but not over the complex numbers: over finite fields. Unfortunately, he didn't tell any physicists about this. 🙂

24. **MathPhys**
July 14, 2006

John,
Did he get the central extension right?

25. **D R Lunsford**
July 14, 2006

JB wrote RE Weyl

He introduced the term "gauge invariance" in his 1918 paper trying to unify general relativity with electromagnetism. A footnote to this paper by Einstein explained why this theory would not work – but later, after changing the group R to U(1), people realized that his treatment of electromagnetism as a gauge theory was very profitable.

It's only an accident of 4d that the U(1) theory works – the electromagnetic scalar is already of the correct weight (in the sense of Weyl's geometry) and can live by itself in a gauge invariant Lagrangian, so that the essentially Weylian aspect of the geometry can be ignored and the geometry regarded as an external field living on Riemannian geometry. In other dimensions the volume element needed to construct gauge invariant integrals has weight other than 2, and this self-standing aspect of the electromagnetic scalar is lost.

In the sense of Weyl geometry the ie term standing in front of Am in the covariant derivative should be regarded as a conformal weight itself, that is in Weyl's theory the c.d. is

Dm = dm + N Am

where dm is the Riemannian expression for the c.d. and N is the weight of whatever D is going to operate on. In other words, the conformal weight of spinors has to be imaginary.

26. **Juan R.**
July 15, 2006

Chris W.,

After years claiming what "was" the correct version of string theory (i do not remember which one, heterotic?) now Gell-Mann is using a generic "action" in his histories formalism claiming that would be obtained from M-theory once known M-theory is 😉

Gell-Mann rudely critized antropic principle in his book the Quark and the Jaguar. I suspect that he maintains his views in the current Landscape trouble and the rest of nonsense.

Gell-Mann, as Glashow, also openly critizes the popular statement that string theory (or M-theory) is a TOE.

Juan R.

27. **John Baez**
July 16, 2006

Mathphys writes:

> Did he get the central extension right?

Yeah, Block got the formula right in the paper he wrote, which he used to keep posted by his office door. If you don't bother with the central extension, you just get the Witt algebra instead of the Virasoro algebra, and that's nothing special.

This abstract of a talk by Murray Bremner says that Block was the first to define the so-called "Virasoro algebra", but in characteristic p, while Gelfand and Fuchs were the first to define it in characteristic 0 (the case physicists care about).

28. **Stefan**
July 18, 2006

Hi Peter,

Just read your post here? Wondering… why is Atiyah so prominent? I know he did some heavy-duty stuff on K-Theory and the like, but what exactly did he do with gauge theories that should make us want to take note and read his works in detail?

By the way, his collected works on Gauge Theories (v. 5 of his Collected Works series) is well over $200; isn't there some alternative way(s) to get hold of his works?

Stefan

29. **Peter Woit**
July 18, 2006

Stefan,

Atiyah has done all sorts of interesting mathematics, but his greatest achievements have to do with the index theorem. The index theorem is a very deep unifying idea about mathematics, and one of the most important ideas of mathematics in the second half of the twentieth century. It links together topology, analysis, geometry and representation theory, all in a new and unexpected way. It's very much worth learning this story, and probably the best place to do it is via Atiyah's papers (both the expository ones and the more technical ones), since he is a masterful writer.

One big surprise was that the mathematics of the standard model is closely related to the mathematics involved in index theory, and Atiyah was deeply involved in working this out. Some of the things related to physics that he worked on from 1975 on include:

1. Construction of instanton solutions (ADHM)

2. Complex twistor-space techniques for understanding instantons.

3. Yang-Mills theory in 2d. The physics is rather trivial, but the mathematics that has come out of this is amazing.

4. Equivariant cohomology techniques for calculating some simple but non-trivial path integrals exactly in terms of fixed point data. Slogan is that in these cases the stationary phase approximation is exact.

5. Understanding of the whole story of anomalies in terms of the index theorem. The crucial idea is that of applying the families index theorem to families of Dirac operators parametrized by background gauge fields.

6. The whole idea of topological quantum field theory. Besides giving an axiomatic version, Atiyah was the first one to suggest that there should be a 4d QFT with Hilbert space Floer homology and observables Donaldson invariants, as well as a 2d QFT with observables Gromov-Witten invariants. Witten later constructed these QFTs, with some prodding from Atiyah.

Anyway, those are some of the high points.

I've heard rumors of a cheap Chinese paperback edition of his collected works. Absent that, unless you're well-off, this is what libraries are for.

This Week’s Hype

July 13, 2006
Categories: This Week's Hype

This week’s string theory hype is embedded in a story by Michael Schirber about the possibility of variation of fundamental constants that has appeared on msnbc.com, foxnews.com, and Slashdot. According to Schirber:

A popular alternative to relativity, which assumes that sub-atomic particles are vibrating strings and that the universe has 10 or more spatial dimensions, actually predicts inconstant constants.

According to this string theory, the extra dimensions are hidden from us, but the “true” constants of nature are defined on all dimensions. Therefore, if the hidden dimensions expand or contract, we will notice this as a variation in our “local” 3D constants.

It’s kind of funny to hear that string theory “predicts” that constants like the fine structure constant will vary in time. When Michael Douglas was here in New York giving a talk last year and was asked about predictions of the string theory landscape, he said that the best one was that the fine structure constant would NOT vary. His argument was that it couldn’t vary since effective field theory arguments would imply a corresponding variation in the vacuum energy, something inconsistent with observation. So string theory both predicts that the fine structure constant will vary, and predicts that the fine structure constant will not vary.

For more string theory hype, Michio Kaku now has a MySpace site, including a blog. He also has his own web-site, mkaku.org, which has recently been redesigned and now prominently features an offer of signed copies of his (softcover) books for $50.

Update: There’s an informed take on what the data about varying fundamental constants actually says from Rob Knop.

Comments

1. **fp**
   July 13, 2006

   Lubos, following Jacques Distler, wrote about the RHIC and that it already tests string theory. His argument is that one should not distinguish between strings used in AdS/CFT and strings used for a TOE, as you did previously.
   What do you think about his arguments or is this just hype again in your opinion?

2. **David**
   July 13, 2006

   Peter,
   Since you opened the subject wrt to Kaku, will it be possible to get an autographed copy of NEW once it goes on sale in the US? I collect copies of autographed science books.
   Best,
   David

3. **woit**
   July 13, 2006

   fp,

   And I was trying to ignore Lubos for a while…

   Chad Orzel on his blog made the perfectly accurate comment that RHIC would not test string theory, whereupon he was assaulted by the string theory hype and attack squad, including the usual Lubos behavior towards anyone who has anything negative to say about string theory.

   The idea that RHIC will “test string theory” is ridiculous hype, and Lubos’s refusal to distinguish between string theory on AdSxS^5 as used in AdS/CFT and string theory on R^4 x Calabi-Yau is just more of his usual nonsense designed to obscure the fact that one of these is a complete failure.

   While someday AdS/CFT ideas may give a real calculational method for QCD, and thus for the quark-gluon plasma, perhaps giving some real predictions about RHIC data, the subject is still very far from that point. The main problem is that AdS/CFT doesn’t apply to QCD, but to supersymmetric versions of the theory, and these have different degrees of freedom. Some people hope that even though AdS/CFT gets the spectrum wrong, and has the wrong degrees of freedom, for some aspects of high temperature QCD, there will be some sort of “universal” behavior and the fact that one isn’t dealing with the real QCD won’t matter. While someday this may get somewhere, at the moment as far as I can tell the subject is being seriously overhyped. If someone can point me to an unambiguous AdS/CFT calculation that makes a sharp, testable prediction about RHIC data, I’d be interested to hear about this.

4. **woit**
   July 13, 2006

   David,

   I won’t be selling autographed copies on the web-site, and have no idea how the publisher handles this (I’ve heard frightening rumors of authors locked in rooms with huge stacks of books and told they can’t come out until they’re all signed). On general principles I’ll be happy to sign people’s books though, without charge.

5. **Jeremy**
   July 13, 2006

   Oh Michio. I can’t believe you have a MySpace page.

July 13, 2006

> If someone can point me to an unambiguous AdS/CFT calculation that makes a sharp, testable prediction about RHIC data

What about the 'ideal liquid' (low viscosity) results referenced by Clifford?

8. **Peter Woit**
July 13, 2006

fp,

I've spent some time looking at the papers referenced by Clifford and others, without finding anything that looked like a sharp prediction that could be compared to RHIC data. I didn't look at all of this literature, and it's certainly possible I was missing something. If someone can point to a specific place in a specific paper that makes a sharp prediction, and to corresponding RHIC data, I'd be interested to know about this.

9. **Ryan**
July 13, 2006

Let us assign the abbreviation P to the statement "the fine structure constant will vary." Since string theory predicts both P and ~P, string theory therefore also predicts Q, where Q is any statement we want. String theory truly predicts everything… remarkable!

10. **anon.**
July 13, 2006

Peter wrote:

It's not a *hope*, it's an argument: QCD at high energies and temperatures is approximately conformal, and universal properties of AdS backgrounds should capture relevant information. See hep-th/0405231 for the calculation of viscosity by Kovtun, Son, and Starinets, and hep-ph/0312227 for discussion by Shuryak of the RHIC results and how they show surprisingly low viscosity. You might also want to look at http://www.admin.ias.edu/pitp/2005files/Lecture%20notes/Klebanov-strong.ppt, a lecture by Klebanov that can point to more literature.

Are there string theorists doing this work because they like the opportunity to connect to an experiment, which they otherwise wouldn't care about? Probably. But there are also real QCD experts who take this stuff seriously, Shuryak being one example.

11. **Peter Woit**
July 13, 2006

anon,

Thanks for the references. I'm not claiming there is nothing interesting going on here, just pointing out that the "RHIC tests string theory" claim seems to be overhyped. I understand the argument about approximate conformality, but is there also an argument about why the difference in degrees of freedom doesn't matter? Or estimates of what the deviation from this "universal" behavior will be for the real theory? That this difference doesn't matter, and that these deviations are small is what I was referring to as a "hope". Is there actually more of an argument?

From the references, it looks like AdS/CFT gives a conjectured lower bound on the viscosity, and the claim is that RHIC data can be interpreted as showing that this viscosity is within a factor of two of the lower bound. Is this right, and is this the closest to a confrontation with experiment that people have managed, or is there something better?

12. **Mike**
July 13, 2006

There is more and more hilarious stuff going on in physics, not just the string theory stuff. I was reading a book last night debunking "Intelligent Design". Maybe not such a bad thing to do — but Lee Smolin (whom I generally respect) had an article in this anthology about his ideas about evolution of the multiverse. Black holes "bouncing" into fantastic numbers of new universes, which reproduce themselves somehow with slight "genetic" variations, so the universes most fit for living systems end up reproducing and predominating. He even claims, sort of, that there is experimental evidence for this (other than the fact that we're here)! He uses the recent great advances supposedly made in quantum gravity in dealing with singularities. I guess this is the same theory that so far, to my knowledge, admittedly sketchy, can't give us a semiclassical Minkowski space! All of this to explain the embarrassment of the fact that we are here in a determinedly atheistic way.

It's all very interesting, and clever, and lots of fun, but utterly fantastical. By comparison, my nutty Bible-thumping ID-believing fellow-townsmen may not be as smart, assuredly not when it comes to science, but they sure are models of sobriety, and good sense!

13. **Joe Zhou**
July 13, 2006

Scientific American August has an article on Alain Connes and his "alternative" to string theory, how his (and Rovelli's) theory makes predictions at accessible energies whereas string theory does not.

14. **woit**
July 14, 2006

Joe,

I'll look for the article, haven't seen it yet. Presumably Connes is talking about his prediction of the Higgs mass. I've never found his version of the SM convincing, but at least he's sticking his neck out and making a prediction. If it turns out to be right, people will pay a lot more attention to his model. If it doesn't, he's in trouble.

I didn't know there was a joint Connes/Rovelli model, maybe this is a reference to purported LQG predictions?

Without seeing the article, I don't know how much hype it contains. I hope people working on alternatives to string theory will resist following the string theorists and overhyping their results.

15. **Joe Zhou**
July 14, 2006

Sorry for the confusion — the Higgs mass calculation does not involve Rovelli; his cooperation with Connes concerns quantum gravity and the emergence of time.

16. **Jean-Paul**
July 14, 2006

To anon.,
First of all, there is no evidence at all that RHIC produced quark-gluon plasma — you seem to be informed enough to read more than overhyped public announcements intended to keep it running (it's a historic pattern that amazing discoveries are claimed by experimentalists just before shut-downs). So read this abstract from (nucl-ex/0501009):
"However, the measurements themselves do not yet establish unequivocal evidence for a transition to this new form of matter. The theoretical treatment of the collision evolution, despite impressive successes, invokes a suite of distinct models, degrees of freedom and assumptions of as yet unknown quantitative consequence." What about this "suite of distinct models, degrees of freedom and assumptions"?
If RHIC really found QGP, it would not be canceled, believe me.

Concerning theory, do you claim that High T behavior of QCD is
the same as of Supersymmetric QCD? Ads/CFT and holography are based on symmetries following from supersymmetry. I don't think that you can make any statement about NON-BPS dynamics of QCD by using Ads/CFT, and I am not the only one.

So both experiments and theory are shaky. Just forget it…

17. **Jean-Paul**
July 14, 2006

To Peter:
I agree with (some of) your criticisms of ST. However, I am completely puzzled by your neutral position wrt to AdS/CFT. AdS/CFT has always been advertised (and you buy it) as an important step towards solving QCD, a problem that many theorists consider more important than quantizing gravity. A whole generation spent their most productive years working on it. After 9 years, it is clear that it is useful indeed for discussing unrealistic models with extended supersymmetry, but it has nothing to do with the real non-BPS dynamics of QCD. It's hard to believe that many theorists still consider AdS/CFT as something more than a mathematical curiosity proving once again that extended
SUSY theories have dynamamics completely determined by symmetry principles. After 9 years, don't you think that it's time to pull the plug?

18. **nitin**
July 14, 2006

Joe Zhou:

The August SA issue is not out yet (neither does anything about it, or more specifically the purported Connes-and-his-"string theory"-alternative, figure on the SA website). Please check your source, and if you can, provide a link, because I am interested to read about that "news" of yours.

19. **ObsessiveMathsFreak**
July 14, 2006

For more string theory hype, Michio Kaku now has a MySpace site, including a blog.

I think this can definitely be put down as a watershed moment.

20. **Kasper Olsen**
July 14, 2006

Dear Peter,

-Saying that "string theory both predicts that the fine structure constant will vary, and predicts that the fine structure constant will not vary" is wrong. Simply because Douglas is not identical to string theory (not even as string theory on AdS is identical to a YM theory…).

-And as Rob points out, the data cannot be used to conclude that the fundamental constants vary.

-Concerning the Quark Gluon Plasma, the RHIC fireball can be described as a gravity dual black hole. And then, since properties of black holes can be computed in string theory (in contrast to LQG for example), the shear viscosity divided by the entropy, can be predicted to be \eta/s = 1/(4\pi) = 0.08.

Regards, Kasper

21. **Ponderer of Things**
July 14, 2006

Someone might have commented on this already:

Nova PBS podcasts has two short (4min and 2 min) segments on string theory:
http://www.pbs.org/wgbh/nova/rss/nova-podcast-pb.xml

In the past they would simply interview Brian Greene – their website looks like a promotional vehicle for selling "Elegant Universe":

http://www.pbs.org/wgbh/nova/elegant/

Recent podcast, however, includes comments from Neil deGrasse Tyson, a director of Hayden planetarium, where he somewhat angrily comments on how string theorists always say that the experiment is just behind the corner – and so they were promising something concrete in 2-3 years for the past 20-30 years. Brian Greene responds.

They will have Glashow in one of the next podcasts – should be interesting….

22. **Peter Woit**
July 14, 2006

Kasper,

My point was just that the people hyping string theory are getting their story confused, with some saying it predicts one thing, some the exact opposite. My position on this has always been the same. String theory predicts nothing, nada, zip. Both Douglas's claim and the story in question are worthless hype.

As for the QGP, the problem is that the prediction you mention is for N=4 SYM, not QCD, and my question is how much of an argument is there that these will be the same. The second part of the question is whether there is a believable measurement of this parameter, and how it compares to the "prediction". From Klebanov's vague summary, I gather it looks different by a factor of two, but I'd be curious to hear from someone who knows more about this.

Jean-Paul,

AdS/CFT is certainly over-hyped, but not on the scale of string theory unification, which has conclusively failed after more than 20 years of hype, that continues to this day. It would be a very valuable thing for someone to write up a critical review of exactly what AdS/CFT has accomplished, and what it hasn't. This would be a very demanding task, since the literature is incredibly voluminous, and rife with mixing of what is a solid result and what is wishful thinking.

You can make a viable case that thinking about AdS/CFT and how to extend it to QCD may lead somewhere (although quite possibly understanding QCD requires completely different methods). This is different than studying complicated string theory "backgrounds", which is clearly a doomed enterprise, sure to lead nowhere.

23. **Kasper Olsen**
July 14, 2006

Dear Peter,

The same thing could be said about lattice calculations. QCD "is" not lattice-QCD, but the latter is presumably a good approximation to the former. Likewise, N=4 SYM can – in certain respects – be a good approximation to QCD.

But of course, we would prefer to do calculations in a non-supersymmetric background. One step at a time….

24. **Peter Woit**
July 14, 2006

Kasper,

You are writing nonsense. Lattice QCD IS QCD. To the extent it's an approximation, it's because it's a cut-off version and you have to take a limit, but this is true for just about any interesting QFT. N=4 SYM is a completely different theory than QCD, it has very different degrees of freedom and physical behavior. There's no parameter in the the theory that one can take to a particular value and get QCD.

25. **Kasper Olsen**
July 14, 2006

Peter, the "is" above refers to the fact that lattice-QCD is (among other things) a cut-off version of QCD on R^4. And as such an approximation. (Another reason being that most lattice calculations have not included quarks).

As an example, recent lattice calculations give a strange quark mass around 85 MeV as compared to the 150 MeV from phenomenology.

Are you claiming, that taking the continuum limit is trivial? Are you claiming that there are no finite-lattice spacing effects?

26. **Peter Woit**
July 14, 2006

Kasper,

To define a QFT like QCD, you have to do it by defining it with a cut-off, then taking a limit. That's the way an asymptotically free QFT works. Exactly the same thing is true in perturbation theory, or any other way one knows of for defining such a QFT. The cut-off is not an approximation, it's an intrinsic part of the definition of the theory.

Of course actually doing calculations is non-trivial, and you have to take the lattice spacing to zero carefully, understanding what errors are caused by stopping at a fixed lattice size.

Chiral fermions are tricky, but QCD is not a chiral theory. There are several ways of putting in fermions, this makes numerical calculations more difficult, but many groups are doing such calculations, and getting results consistent with experiment. I've never heard before the claim you're making that lattice calculations give results off by nearly a factor of two, and don't believe it. Please provide a reference.

27. **Xerxes**
July 14, 2006

According to the PDG, m_s falls between 80 and 130 MeV. If you take the lowest lattice point and the highest phenomenological point, you do get numbers like the ones suggested above. This says two things: (1) the strange quark mass is not very well known, (2) it's easy to lie by cherry-picking data.

28. **Gilbert Awad**
July 14, 2006

Hello prof. Woit,

Kasper is probably referring to work done by Akira Ukawa, published in late 2004. I remembered running into something like this a few months ago. The relevant quote would be at the end of section four (page 14 of the pdf file accessible from the URL below).

http://www.aapps.org/archive/bulletin/vol14/14_6/14_6_P11-15.pdf

And congratulations on the book. Can't wait to get a copy of the NA edition. The dust jacket for that edition is particularly elegant, especially with the "mirror image" WRONG in the title.

29. **Kasper Olsen**
July 14, 2006

Gilbert, correct – I didn't have the PDG at hand and remembered reading such numbers in the review.

I guess, even though you are doing theory, you should still carry it in your pocket. It's all so good for a late-night conversation at a local bar 😉

Cheers, Kasper

30. **Brett**
July 14, 2006

I wanted to mention a few points about lattice QCD, since there seems to be a bit of confusion about it. I am not a computational lattice person myself, but I have a number of friends who are, and I follow developments in the subject.

First, the quenched approximation (in which the dynamical quarks' contributions to the vacuum polarization are neglected) is pretty much gone. There are now many, many gauge configurations written to disk with 2 or 2+1 fully dynamical quark species, and groups around the world are making use of them. They have been used to make some remarkably precise calculations, but their general applicability is occasionally controversial, because of the second point.

The second point is that the Lagrangian used in lattice QCD is never just the QCG Lagrangian with a cutoff. That could come close to being useful if the lattice spacing was really small–much smaller than any other scale that might arise in a calculation. In order to get useful data at physically realizable lattice spacings (and one must actually use several lattice spacings and extrapolate to zero–this it how the continuim limit is taked), the actions that are used contain all sorts of extra terms and corrections. Generally, these additions are expected to be irrelevant, so that the theory approaches true QCD as the lattice spacing goes to zero, but that has not always been proved, and sometimes the changes to the action are downright controversial. The biggest problem comes from fermion doubling, which is related to the fact that the use of lattice necessarily organizes the momenta into Brillouin zones, and it's not always clear that the extra fermion "tastes" can be eliminated in a local fashion.

Finally, there are lots of things that lattice QCD cannot calculate usefully at all. I'm not sure what it would mean to "calculate" the strange quark mass, since this is usually an input parameter. (One might fix the up and down quark masses to 1/20-th of the strange quark mass, which is certainly an approximation, but it can be a highly useful one. Of couse, there are complications, since one can distinguish sea quark and valance quark masses, and the whole procedure is entangled with the extrapolation, but the basic idea is right.) A better example of what we cannot calculate on a lattice would be hadron-hadron scattering. The lattices in use today are simply too small to contain external scattering states. So lattice people are very careful to choose things (e.g. single-hadron properties, like masses and decay constants) that can be reliably calculated, although there are still sometimes problems with error estimations.

31. **Andy**
July 14, 2006

Chad has (I think) now retracted his statement that "RHIC does not test ST", and Clifford has thanked him for the retraction. Interesting.

32. **Peter Woit**
July 14, 2006

Gilbert,

Thanks for the reference. It seems to me that it shows that all calculations of observable masses are coming out right within expected errors. The strange quark mass is not something observable, so the discrepancy mentioned is not obviously significant unless you look into this more closely and make sure that you're comparing the same thing on both sides, and understand what the errors are on both sides.

Andy,

To be fair, the string theory attack squad was mainly complaining about Chad's remark that they weren't interested in RHIC and the data coming out of it. You could debate this point, but it wouldn't be useful. They do seem to have done a good job of beating Chad into submission in this case.

33. **Ponderer of Things**
July 14, 2006

Nova PBS series offers short podcasts featuring Brian Greene and Neil deGrasse Tyson, director of Hayden planetarium. Tyson mentions that string theorists tend to promise experimental confirmation that is "just around the corner" – maybe 2-3 years away, but that they have also been doing this for 20-30 years. Greene counters with a claim that he's never heard anyone say that, and perhaps string theorists were just joking.

It's a little surprising to hear Nova offer counter-argument, especially since their website looks like a vehicle for selling "Elegant Universe".

Coming up is the interview with Sheldon Glashow.

July 15, 2006

DEAR PETTER,

MICHIO KAKOS BLOG HAS AN ARTICLE ABOUT TESTING OF STRING THEORY USING GRAVITY WAVES AT LISA, DEVIATION OF NEWTON LAW – BUT ARE BOTH THESE NOT CLASSIKAL AFFECTS? IE, BY VARYING CLASSIKAL THEORY WE CAN GET THESE ONES. THERE IS NOTHING THAT STRING THEORY SAYS THAT IS NOT ALREADY SAID. THIS SEEMS TO BE TYPIKAL BEHAVIOR.

ALSO PLEASE TO BE COMMENTING ON THE ARTICLE IN THE AUGUST AMS NOTICES

http://www.ams.org/notices/200607/fea-marateck.pdf
ABOUT DIFFERENTIAL GEOMETRY AND FEYNMANN INTEGRALS. I HATE FEYNMANN INTEGRALS – WHY DO NOT THEY CONVERGE!!

PS I KNOW YOU ARE UPSET BECAUSE I USE ALL BIG LETTERS BUT I MUST FOR TWO REASONS. ONE, IT IS A PART OF MY PERSONALITY AND MAKES ME QUIRKEY AND MISTERIOUS AND ENIGMATIC. ALSO MY KEYBOARD IS BORKEN.

PPS ISRAEL GELFAND FOR ABEL PRIZE 2007!

36. **Peter Woit**
July 15, 2006

QWERTY,

Re Kaku and his "predictions", see

http://www.math.columbia.edu/~woit/wordpress/?p=219

The idea that LISA is going to test string theory is utter nonsense.

The Marateck article is a basic expository article on gauge fields for mathematicians. At the end it has some material about Feynman diagrams, but doesn't really explain anything much about them, or how they are related to the earlier material on gauge fields.

37. **Chris Oakley**
July 15, 2006

I see that Feynman is the 37 cent stamp. Personally, I would have preferred it if they had made him a 137.036 cent stamp. OK – it would make the arithmetic more complicated, but we could deal with that, couldn't we?

38. **D R Lunsford**
July 16, 2006

The Marateck article is just hot air, the entire thing is filled with factual errors of history, and is presented on the level of an ambitious and green undergraduate. I wish people would refrain from abusing Weyl and Dirac by refusing to comprehend them.

-drl

39. **Chris Oakley**
July 16, 2006

I could write an article on the lines of the Marateck one, and probably more interesting – i.e. not just cheerleading. Funny that I never get asked to do this.

July 16, 2006

Peter wrote:

The idea that LISA is going to test string theory is utter nonsense.

Last month I have collected some references related to this matter. I'm too busy to read them, but of course I am curious on them. And much more now, considering Peter's statement. Here is my selection:

* An interferometric gravitational wave detector as a quantum-gravity apparatus [gr-qc/9808029]
* Accessibility of the Pre-Big-Bang Models to LIGO [astro-ph/0510341]
* Observational test of holographic inflation [PRD, vol. 73, Issue 2, id. 023516]
* Gravity-wave detectors as probes of extra dimensions [astro-ph/0505277]
* The Primordial Gravitational Wave Background in String Cosmology [hep-th/9907185]

I do not know whether Peter Woit wants people to discuss them here, so if that is the case, you are invited to contribute here.

Thank you,
Christine

41. **MathPhys**
July 16, 2006

I just read that Michio Kaku is a comedian. I should have known that.

42. **D R Lunsford**
July 16, 2006

So Kaku goes to Dr. Woit and says "Doc, my string theory isn't doing so well" and Woit says, "Yeah, it's a very sick theory" so Kaku says "can I get a second opinion?", and Woit says, "Yeah, it's ugly, too!"

July 17, 2006

Seems like string theory has a high crackpot index…

49. **amazed**
July 17, 2006

Looks like we have a real high brow discussion going here of late. Perhaps we could get back to discussing approximations to QCD that were brought up earlier and Brett had a nice post about filling in some of the details. Does the statement that "lattice QCD IS QCD" hold water considering many of the things it does not take into account, and only certain regimes the approximations in lattice QCD hold? For instance what defines the utility or goodness of an approximation since as an example N=4 SUSY YM is more useful to calculating in QCD for the LHC than the lattice albeit our world is certainly not that full of supersymmetries at TeV energies. Of course we have to have some further discussion about N=4 applications in QCD such as what dixon et al do beyond the normal banter about AdS/CFT and whether it is or is not testing QG. Perhaps Peter could make a general post about QCD and various techniques in understanding QCD at a deeper level. Granted this would take us out of the whole joke fest we have going here but it would illustrate an important point many lay people don't understand. Different theories are useful for different energy regimes as well as different theories have sectors that can be used to calculate quanties better than in the original theory that is the "true" theory. Anyways if this isn't interesting to the rest of the commenters feel free to go back to the usual.

50. **Peter Woit**
July 17, 2006

amazed,

There were quite a few postings and discussions here in the past about twistor methods for doing perturbative QCD calculations, if there is anything new about this subject (and not just hype about N=4 SYM), I'd like to hear about it.

The problem with writing about QCD is that there seems to be relatively little new to say about it. I try to mostly write about news here, I don't really have the time or energy to do more in the way of making this an educational or expository site. But if there is something new about QCD, I'd be happy to learn more about it and maybe write about it here.

51. **Jean-Paul**
July 17, 2006

Here is a recent assessment of twistor techniques by Keith Ellis,
in a closing talk of QCD Moriond 2006 (hep-ph/0607038, page 9):
"So far the impact on real phenomenology is rather limited…"
He praises, however, "great intellectual excitment and an injection of personnel from formal areas".
What a nice compliment for the new QCD personnel!
By the way, twistor techniques should not be confused with string inspired/helicity/SUSY techniques used by Dixon et al very successfully over the last 15 years.

52. **QWERTY**
July 17, 2006

DEAR PROFESOR BAEZ

I AM NOT A CRACKPOT!! I AM A BIG ADMIRRER OF THIS WEEKS FINDS, IT IS VERY USEFUL. I AM VERY SAD THAT MY HEROE HAS CALLED ME CRACKPOT.

I MUST ADMIT THAT I AM MORE INTERESTING IN MATHEMATICS THAN IN PHYSICS BUT I FIND MATHEMATIC-PHYSIC BORDER IS MOST INTERESTING. I WILL WRITE ABOUT WHAT I WANT TO BE LEARNING SO YOU CAN SEE I AM NOT CRACKPOT AND I WILL BE PROOVED INNOCENT. SORRY PETTER FOR NOT WRITING ON THE TOPIC I WILL NOT DO IT AGAIN.

PLEASE TO BE WRITING IN THIS WEEKS FINDS ABOUT TWISTORS. THEY SEEM QUITE INTERESTING TO EVERYONE, CLASICAL PEOPLE AND QUANTUM PEOPLE AND EVEN THE STRING THEORY HERATICS. I UNDERSTAND THE IDEA OF WHAT IS A TWISTOR FOR MINKOWSKI BUT DO NOT UNDERSTAND HOW THEY CAN BE DEFORM IN GENERAL WHEN THE WEIL TENSOR IS DUAL TO ITS OWN SELF — I CANNOT UNDERSTAND KODAIRA DEFORMATION THEOREM AT ALL, VERY DIFFICULT! FROM A PHYSIC PERSPECTIVE WHY IS THE LIGHT RAY AND THE LIGHT CONE MORE IMPORTANT THAN THE POINT, THIS SEEMS A LITTLE VERY SILLY!! ALSO HOW DO MONOPOLES BECOME? THERE ARE MANY PAPERS ABOUT MONOPOLES AND TWISTORS. I DO NOT UNDERSTAND ANY LINK BUT THIS DOES NOT MEAN I AM A CRACKPOT, ONLY THAT I AM STUPID.

53. **Matthew**
July 18, 2006

Does the statement that "lattice QCD IS QCD" hold water considering many of the things it does not take into account,

Lattice QCD with 5 flavours of domain wall Fermions (for example) *is* QCD, in the continuum limit. Alas, we lack a computer to run such a beast.

Likewise, lattice QCD with 3 light flavours of staggered fermions, and 2 heavy flavours quenched is as close to QCD as we need to get.

In both of these cases there is nothing that isn't taken into account, though with the staggered fermions there is an ongoing theoretical issue.

and only certain regimes the approximations in lattice QCD hold?

Huh? The only "regime" that I know about where lattice QCD simply cannot be done is with non-zero chemical potential. And even that is basically a computational issue.

The problems with Lattice QCD these days are computation related. That is, we simply do not have the resources to run a realistic simulation (i.e. the first scenario I mentioned above). However, the staggered fermion approach, with various approximations for the heavy quarks has yielded real results, of genuine phenomenolgical interest. For a few recent results see hep-lat/0607011.

For instance what defines the utility or goodness of an approximation since as an example N=4 SUSY YM is more useful to calculating in QCD for the LHC than the lattice

Lattice people are busy computing things to compare to real experiments going on right now (cleo-c, belle, babar, D0, CDF, RHIC, etc.). The LHC is *well* into the perturbative QCD regime in any case. There are lattice calculations that could be done, however they're very complicatied (hadronization) and we probably lack the comptational resources.

Would it be practical to do something like "SETI At Home" with these calculations? I'm amazed that there are still computing problems in physics that can't be solved with a 1000-node Beowulf.

-drl

57. **Chris Oakley**
July 18, 2006

Danny – fine. The keyboard I am using at the moment (on a library computer in Oxford) is a bit old and disagreeable, so I am going to call it "PAULI".

Q: How many (less obnoxious) String Theorists does it take to change a light bulb?

A: Change the light bulb? Why? Playing games in the dark is so much better! You would be *amazed* at how brilliant some of the games we have devised are!

58. **Matthew**

July 18, 2006

drl,

Would it be practical to do something like "SETI At Home" with these calculations?

Probably not. Current computational bottlenecks are the speed of communication between nodes in a cluster, not the raw horsepower of the machine.

I'm amazed that there are still computing problems in physics that can't be solved with a 1000-node Beowulf.

There are many (many many many) problems of interest in computational physics for which a 1000 node Beowulf is nothing. Realistic QCD (i.e. with physically accurate light quark masses) is not feasible on any current computer, full stop. To solve complicated multiparticle states (say, to compute the nucleon-nucleon force from a lattice calculation) would require petaflop (or beyond) scale computers.

One trouble is the fermion update aglorithm critically slows down as you approach light quark masses. So lighter masses means massively more computer power is needed. Of course, we've got chiral perturbation theory, so you don't really need to go to the physical point. But even getting to within the validity of chiral PT is a challenge for modern supercomputers.

59. **CapitalistImperialistPig**
July 18, 2006

The article on Connes is a two page "Insight" piece on page 36 of the August issue, written by Alexander Hellemans. I learned from the article that renormalization was introduced by (among others) 't Hooft and Veltman, and that Connes has linked its mathematical justification to one of Hilbert's (solved) problems, and that the solution involved non-commutative geometry which "serves as a starting point to unify relativity and quantum mechanics." HTH you as much as it did me!

I also learned that Connes is the kind of guy who can walk through a riot without losing the thread of his mathematical conversation.

60. **urs**
July 20, 2006

> renormalization […] and that the solution involved non-commutative geometry

I am guessing that this refers to the Connes-Kreimer work.

61. **Juan R.**
July 22, 2006

D R Lunsford Says and Matthew,

Chemistry and biology are another two fields with entire problems without computational solving. Processors' flops are not the only problem, memory can be more a handicap. Usual chemical computations (TIE) needing of 2GB temporary files are hard to efficient managing by a supercomputer. More advanced methods (TDL) applied to basic chemical systems of interest need of 7 GB for storing equation, many more for solving it.

Juan R.

Center for CANONICAL |SCIENCE)

62. **Riofrio**
July 27, 2006

Hello, all. Did this start as an entry on changing constants? What does it mean if there is evidence from 2 independent methods that c is changing in exactly the amounts predicted?

Equivariant Cohomology

July 18, 2006
Categories: Uncategorized

The International Congress of Mathematicians will be taking place in Madrid relatively soon, in late August. One tradition at this conference is the announcement of the Fields Medals, and I'm getting embarassed that I'm not hearing any authoritative rumors about this (other than about Tao and Perelman); if you have any, please send them my way. One other tradition is to have speakers write up their talks in advance, with the proceedings available at the time of the conference, so already some write-ups of the talks to be given there have started appearing on the arXiv.

Last night, Michele Vergne's contribution to the proceedings appeared, with the title Applications of Equivariant Cohomology. On her web-site she has a document she calls an exegesis of her scientific work, this gives some context for the equivariant cohomology paper. She also is co-author of a book called Heat Kernels and Dirac Operators, which has a lot more detail on some aspects of this subject. Finally, there has been a lot of nice recent work in this area by Paul-Emile Paradan.

Equivariant cohomology comes into play when one has a space with a group acting on it, and it mixes aspects of group (or Lie algebra) cohomology and the cohomology of topological spaces. There are various ways of defining it, the definition that Vergne works with is a bit more general than the one more commonly used. It involves both differential forms on the space, and generalized functions on the Lie algebra of the group.

The beauty of equivariant cohomology is that it often computes something more interesting than standard cohomology, and you can often do computations simply, since the results just depend on what is happening at the fixed points of the group action. There's a similar story in K-theory: when you have a group action on a space, equivariant K-groups can be defined, with representatives given by equivariant vector bundles. Integration in K-theory corresponds to taking the index of the Dirac operator, and in the equivariant case this index is not just an integer, but a representation of the group. The index formula relates cohomology and K-theory, and one of Vergne's main techniques is to work with the equivariant version of this formula.

In the case of a compact space with action of a compact group, there's a localization formula that tells you how to integrate representatives of equivariant cohomology classes in terms of fixed point data. In many cases, this leads to a simple calculation, one famous example is the Weyl character formula, which can be gotten this way. New phenomena occur when the group action is free, and thus without fixed points. This was first investigated by Atiyah (see Lecture Notes in Math, volume 401), who found that he had to generalize the index theorem to deal with not just elliptic operators, but "transversally elliptic" ones. Such operators are not elliptic in the directions of orbits of the group action, but behavior of the index is governed by representation theory in those directions.

Vergne has been studying examples of this kind of situation, and it is here that generalized functions on the Lie algebra come into play. Integrating the kind of interesting equivariant cohomology classes that occur in the transversally elliptic index theory case over a space gives not functions but generalized functions on the Lie algebra. There's a localization formula in this case due to Witten, who found it and applied it to 2d gauge theory in his wonderful 1992 paper Two Dimensional Gauge Theories Revisited.

This kind of mathematics, growing out of the equivariant index theorem, is strikingly deep and beautiful. It has found many applications in physics, from the ones in 2d gauge theory pioneered by Witten, to more recent calculations of Gromov-Witten invariants. It leads to a mathematically rigorous derivation of some of the implications of mirror symmetry in special cases, and a wide variety of other results related to topological strings. My suspicion is that it ultimately will be used to get new insight into the path integrals of gauge theory, not just in 2 dimensions but in 3 or 4.

Update: Vergne has another nice new paper on the arXiv. It's some informal notes on the Langlands program which she describes as follows:

These notes are very informal notes on the Langlands program. I had some pleasure in daring to ask colleagues to explain to me the importance of some of the recent results on Langlands program, so I thought I will record (to the best of my understanding) these conversations, and then share them with other mathematicians. These notes are intended for non specialists. Myself, I am not a specialist on this particular theme. I tried to give motivations and a few simple examples.

It would be great if more good mathematicians wrote up informal notes like this about subjects they have learned something about, even if they are not experts. The notes are entitled All What I Wanted to Know About Langlands Program and Was Afraid to Ask.

Comments

1. **fp**
   July 18, 2006

   I guess the 'cosmology' in the 4th paragraph is a typo and should be 'cohomology'.

2. **Peter Woit**
   July 18, 2006

   Oops, many people might like an application of this to cosmology, but that definitely was a typo…

3. **doctorgero**
   July 19, 2006

   > …and I'm getting embarassed that I'm not hearing any authoritative rumors about this (other than about Tao and Perlman…

   Apparently, it is 'Perelman'. 🙂

4. **Authoritative Bigshot**
   July 19, 2006

   Bhargava.

5. **nonblogger**
   July 19, 2006

   I've noticed there are four slots for fields medalists' talks, so perhaps four medals. If indeed Perelman and Tao get one that's two left. Recent young EMS prize winners make up for a good shortlist
   http://www.math.kth.se/4ecm/prizes.ecm.html
   Looking at his recent publication record, I'd bet on Okounkov.
   There are also the lists of recent Clay Fellows http://www.claymath.org/fas/research_fellows/

and award winners
http://www.claymath.org/research_award/
I've looked at recent AMS prize winners but most seem too old.

6. **bobo**
July 19, 2006

what about Zhu and Cao? the 2 dudes who completed the proof of the poincare conjecture.

7. **comentator**
July 19, 2006

My bet is T.Tao,A.Borodin,G.Perelman (though the age limit could be a problem in Perelman case). This could be surprising that in such a short time between publication of a paper and vetting of it and the award of a prize is given in the case of Zhu and Cao.

8. **woit**
July 19, 2006

doctorgero,

Thanks, typo fixed.

About possible Fields Medalists:

Zhu and Cao: No way, and, knowing Cao, I'm pretty sure he's over 40 anyway.

Okunkov: Seems unlikely. In that field I'd think his Princeton colleague Rahul Pandharipande would be a more likely candidate.

Bhargava: Hmm, that actually sounds plausible. Maybe "Authoritative Bigshot" really is one…

9. **Harry**
July 19, 2006

Wikipedia claims Perelman is just 40 this year :

http://en.wikipedia.org/wiki/Grigori_Perelman

(Not sure to what extent it's reliable, though..)

10. **Zelah**
July 19, 2006

Who is A Borodin?

11. **Brett**
July 19, 2006

A great Georgian-Russian composer and chemist?

Or more likely, this guy: http://www.cs.toronto.edu/~bor/

12. **comentator**
July 19, 2006

Alexei Borodin teaches in Caltech. Representation theory.done groundbreaking work in group theory (big groups) aspects related to representation theory.

13. **Peter Woit**
July 19, 2006

Brett and Zelah,

The reference must be to Alexei Borodin, now at Caltech, see

http://www.claymath.org/fas/research_fellows/Borodin/

The list of Clay research fellows does probably contains many of the plausible candidates for the Fields.

14. **Matt**
July 19, 2006

There are also the prize winners from the 3rd ECM
http://www.emis.de/ECM3/prizes.html
Seidel, for his work on mirror symmetry and symplectic topology, and Gaitsgory, for his work on geometric Langlands, seem viable candidates. Since low dimensional topology/geometry always seems a popular subject, how about Zoltan Szabo?
Both Borodin and Bhargava are eligible to claim the prize four years hence. This could affect their bids – in 2002, only 2 medals were distributed even though Tao was also a favorite then.
Does anyone know who is on the medal committee this go-round?

15. **Anon**
July 19, 2006

"This kind of mathematics, growing out of the equivariant index theorem … leads to a mathematically rigorous derivation of some of the implications of mirror symmetry in special cases, and a wide variety of other results related to topological strings."

Could you elaborate on that? How is equivariant index theory used there?

16. **Peter Woit**
July 19, 2006

Hi anon,

This is a complicated story. Index theory itself hasn't been much used, but there has been a lot of use of equivariant cohomology and localization formulae. For some surveys of this, see Kefeng Liu's web-site

http://www.math.ucla.edu/~liu/

where he has various papers and surveys, including one by Yau, of the subject.

A lot of this goes back to work by Givental, you can find his papers at his web-site

http://math.berkeley.edu/~giventh/

17. **D R Lunsford**
July 20, 2006

Peter,

Isn't there a "for dummies" exposition of this stuff? How about putting it in historical context?

-drl

18. **Peter Woit**
July 20, 2006

Danny,

Sorry, I don't know of any really good simpler expositions of this material, especially for physicists. There is some literature in the context of TQFT and supersymmetric quantum mechanics for physicists, look at papers from the early nineties by Blau and Thompson. Unfortunately most of the physics literature doesn't really deal with the natural mathematical context for all this. Much of this is due to Atiyah, if you really want to understand this and its history, his collected works are a good place to look. But this is really not easy for a physicist to read and absorb.

19. **Johan Richter**
July 22, 2006

Is it decided already who will win the Fields medals? Or do they wait to the last minute to make that decision?

20. **Peter Woit**
July 22, 2006

Johan,

I'm sure it's already decided. I've heard the winners are notified some months in advance, so are those mathematicians chosen to deliver the addresses describing the work of the Fields medalists.

21. **Deane**
July 22, 2006

I am fairly certain that the Fields Medalists have already been chosen, but the names are a closely guarded secret.

If you look at the citation counts on Mathscinet, then, of the names posted here, Tao, Okounkov, and Pandharipande are way ahead of everybody else. Perelman is definitely on the short list, too. But we're all just guessing.

22. **Deane**
July 22, 2006

"It would be great if more good mathematicians wrote up informal notes like this about subjects they have learned something about, even if they are not experts."

Amen!

Terence Tao has lots of expository notes on his web site; the few that I've looked at are short and elegantly written.

The String Ideology

July 20, 2006
Categories: Uncategorized

If you want to get an understanding of the ideology that many string theorists subscribe to, you should check out Lubos Motl's [latest posting](). Besides the usual dismissal of non-believers as idiots, incompetents and crackpots (an attitude that unfortunately seems to be all too common among string theorists), Lubos does actually address some scientific issues.

There's nothing at all in what he has to say that actually makes any connection between string theory and the real world. The effort to find such a connection is completely ignored, including the work of the large part of the string theory community that continues to unsuccesfully work on this. No mention of "string phenomenology", the landscape, or anything of this kind. He chooses instead to address scientific issues in a resolutely unscientific way, basing everything upon faith and ideology, beginning with the opening part of his argument:

I will treat the "whole Universe" and "all of string theory" as synonyma because I am not aware of any controllable framework that would allow me to separate them sharply.

Most of the rest of the posting is a series of criticisms of other ideas that people have advanced as alternatives to string theory. At one, point, after criticizing John Baez and Urs Schreiber for their interest in 2-groups and gerbes, he makes clear what he sees as the proper way to approach new ideas about fundamental physics that one is not familiar with:

The previous paragraph also clarifies my style of reading these papers. The abstract has so far been always enough to see that these fundamental gerbes papers make no quantitative comparison with the known physics – i.e. physics of string theory – and for me, it is enough to be 99.99% certain (I apologize for this Bayesian number whose precise value has no physical meaning) that the paper won't contain new interesting physics insights.

This attitude makes life very simple. You don't have to bother doing the hard work of trying to understand what non-string theorists are doing. All you need to do is to read the abstracts of their papers, note that they aren't doing string theory, and then you can be sure you don't need to read any farther, because if it isn't string theory, it can't provide any interesting new insights into physics.

Lubos dismisses various ideas about string theory one after the other. Much of this is devoted to dismissing the idea that has led particle physics to many of it's biggest successes: that of looking for new symmetries or new ways of exploiting ones that are already known. He insists that:

we have learned that the gauge symmetries are not fundamental in physics.

with the idea being that because of dualities, the character of gauge symmetries is not fundamental but what he calls "social scientific". This argument doesn't make any sense to me. An equivalence of two different gauge theories is very interesting, but it in no way tells you that gauge symmetry is not fundamental. Making such an argument is like arguing that representations of Galois groups in number theory are not fundamentally important because of Langlands duality.

More seriously, Lubos does mention the philosophically trickiest aspect of gauge theories: the physical degrees of freedom are not parametrized explicitly, but as quotients by the gauge group action of a larger space of degrees of freedom. It's certainly true that this is how gauge theory works, and one can try and argue that one should just ignore gauge symmetry and work directly with gauge invariant degrees of freedom. In terms of representation theory, physical states are gauge-invariant ones, so one could hope to just work with these physical states. The problem is that in most interesting cases this isn't possible. The space of connections modulo gauge transformations is non-linear and in general can't be parametrized in a useful way. Working with the linear space of connections, which can be easily parametrized and understood, and then taking into account the action of the gauge group, is the method that actually works and has been hugely successful. All experience shows that fundamental theories are best understood using an extended space of states, together with a method for picking out the physical subspace.

After dismissing alternatives to string theory, Lubos finally gets around to explaining what he sees as the fundamental principle of string theory. Amazingly, it's the bootstrap philosophy, the failed idea that guided much of particle theory during the sixties and early seventies, before the advent of gauge theories and the standard model. The bootstrap philosophy is that symmetries are nothing fundamental, what is really fundamental are certain kinds of consistency conditions. All you need to do is impose these consistency conditions, and miraculously a unique solution will appear, one which describes the real world. In the sixties the hope was that the strong interactions could be understood simply by imposing things like unitarity and analyticity conditions, and that this would lead to a unique solution of the problem. It turned out that this can't work. While unitarity and analyticity properties are very useful and tell you a lot about the implications of a theory, they in no way pick out any particular theory. There are lots and lots (a whole landscape of them, even) of QFTs that satisfy the consistency conditions. There never was evidence for uniqueness, and the bootstrap philosophy was from the beginning built on a pipe dream and large helpings of wishful thinking.

The new version of the bootstrap that Lubos wants to promote goes as follows:

In the context of quantum gravity, many of us more or less secretly believe another version of the bootstrap. I think that most of the real big shots in string theory are convinced that all of string theory is exactly the same thing as all consistent backgrounds of quantum gravity. By a consistent quantum theory of gravity, we mean e.g. a unitary S-matrix with some analytical conditions implied by locality or approximate locality, with gravitons in the spectrum that reproduce low-energy semiclassical general relativity, and with black hole microstates that protect the correct high-energy behavior of the scattering that can also be derived from a semi-classical description of general relativity, especially from the black hole physics.

So, the idea is that, at its most fundamental level, physics does not involve simple laws or symmetry principles, just some consistency conditions (of a much more obscure kind than the analyticity ones of the original bootstrap). Lubos avoids the crucial question of how big the space of solutions to these consistency conditions is. All the evidence so far is that it is so large that one can't hope to ever get any predictions about physics out of it, and the string theory community is now divided between those who hope this problem will magically go away, and those who want to give up and stop doing science as it has traditionally been understood.

In 1973 the theory of strong interactions was heavily dominated by string theory and the bootstrap philosophy. The willingness of Veltman and 't Hooft to do the hard work of understanding how to properly quantize and renormalize non-abelian gauge theories ultimately led to asymptotic freedom and QCD. This pulled the plug conclusively on that era's version of the bootstrap. Perhaps sometime in the future, new hard work on gauge theories will lead to insights that will pull the plug on this latest version, which thrives despite conclusive failure due to the kind of unscientific ideological fervor that Lubos so perfectly embodies.

Comments

   July 20, 2006

   I read LM's blog maybe twice, decided it was rubbish and have not gone back. But now I'm reading (bits and pieces) of it over here. There is no escape. I am doomed.

   I think I'll commit ritual suicide. It won't solve anything, but at least I'll feel better.

2. **JC**
July 20, 2006

Peter,

What year did many people abandon the bootstrap stuff in favor of QCD? Was it gradual, or was it very sudden and quick?

3. **hack**
July 20, 2006

I wasn't there, but I believe there were some "dead enders" who continued publishing bootstrap stuff well into the 80's.

4. **Thomas Love**
July 20, 2006

Many years ago, a friend recommended that I read the Urantia Book. I put it down after I read this nonsense about electrons:
•
• " Mutual attraction holds one hundred ultimatons together in the constitution of the electron; and there are never more nor less than one hundred ultimatons in a typical electron. The loss of one or more ultimatons destroys typical electronic identity, thus bringing into existence one of the ten modified forms of the electron. "

I recalled that when I read about string theory. Urantia's ultimatons sound a lot like strings. So, was the string revolution inspired by the Urantia book? A lot of L.M. 's ranting sound like religious fundamentalism. Fundamenatlists don't read anything which challenges their beliefs, just like L.M.

5. **Peter Woit**
July 20, 2006

Actually if you look at the latest edition of "The Tao of Physics" it will tell you that QCD doesn't work, and the bootstrap was a big success, so there are probably still some really dead-enders out there.

By 1975 when I started at Harvard, gauge theory was what everyone there was doing, but Harvard had never really been a place where the bootstrap was very popular. You'd have to ask someone who was at Berkeley during those years how long it took them to come around to gauge theory.

To some extent, lots of people who had worked on the bootstrap and early versions of string theory just picked up where they had left off when string theory came back into fashion in 1984. There really only was a period of about 10 years (1974-1984) when QFT was completely dominant.

6. **not pw**
July 20, 2006

What year did many people abandon the bootstrap stuff in favor of QCD? Was it gradual, or was it very sudden and quick?

I'm not PW, but anyway, it was quick. BUT ….
The bootstrap stuff was not abandoned "in favor of QCD". The nuclear democracy idea was abandoned in favor of the quark model (with concomitant electroweak + QCD). This happened shortly after the J/psi November Revolution, after the discovery of additional resonances and D-mesons (charmed mesons), indicating a spectroscopy of bound-states.
The quark model could readily explain this. The acceptance of the Standard Model was rapid. It is true that bootstrap holdouts persisited into the 1980's but nobody paid attention.

7. **Brett**
July 20, 2006

I don't think the bootstrap was such a bad idea in the 1960s. If the only nice quantum field theory you've got to look at is QED, you could easily get the impression that that's all there is to gauge theory. QED is the only Abelian gauge theory; if you try to generalize QED by changing things around, you tend to either get nonsense or QED with a different set of parameters (possibly including a photon mass). So it was not unreasonable to think that maybe there just were not very many quantum field theories.

Also, before the discovery of asymptotic freedom in non-Abelian gauge theories and the development of lattice gauge theory, it wasn't obvious that quantum field theory was even something meaningful to discuss in the strong coupling regime. I've met people who say they worked on the bootstrap stuff not because they believed quantum field theory was really wrong, but because they didn't have the faintest idea how to apply it when the coupling constant was large. The discovery of asymptotic freedom, which opened up high-energy strong phenomena to perturbative treatments, was really unexpected. Antishielding is extremely counterintuitive, in large part because it seems to violate the idea of Le Chatelier's principle, that the dynamics of a system should work against disruptions. That principle holds (at least in spirit) not just for chemical equilibria, but also in classical E&M (in Lenz' Law) and in the screeing responsible for charge renormalization in QED. Perhaps people could have taken the hint from lower-dimensional models that antishielding was possible; however, the assumptions of the bootstrap model, while optimistic, were not so foolish, given what was known at the time they were formulated.

8. **Kea**
July 20, 2006

Hee, hee. It just gets funnier and funnier. Many of the talks here at the String theory Maths conference bear some relation to gerbes or tensor categories. I would love to see Lubos call these people crackpots!

9. **MathPhys**
July 20, 2006

't Hooft may have pulled the plug on the bootstrap, but he also introduced 1/N expansions which link gauge theories to strings, and lie at the heart of gauge/string duality, AdS/CFT duality, matrix models, and more beautiful ideas floating around nowadays.

I think we need to keep an open mind about these things.

10. **Peter Woit**
July 20, 2006

Brett,

It's not that I think the bootstrap program was so unreasonable, it's just that it was wrong, and wrong in very much the same way that string theory is (and also perhaps right in the way that string theory is, as a way of understanding strongly coupled gauge theory). If you look at Chew's writings from that era, there's a lot of the same kind of wishful thinking you see in string theory. Not knowing about asymptotic freedom of gauge theory, you could argue that the bootstrap was "the only game in town", but we're very lucky that Veltman didn't think this way, and worked on something else (despite lots of people telling him he was wasting his time). If the bootstrap had been even more dominant than it was, and Veltman and a few others had decided to work on it, we might still be doing bootstrap theory today.

11. **Shantanu**
July 20, 2006

Peter, have you seen any report or blog about
THooft fest ?
If so , maybe you could pointa link. the program is a mixture of interesting
talks in string theory, LQG, CDT, QCD, technicolor, grand unification.
would be interested in a hearing a report

12. **Peter Woit**
July 20, 2006

Shantanu,
I've heard a bit about the 't Hooft fest, was planning on writing about it soon, but hoping the organizers would put up slides for the talks.

13. **Arun**
July 20, 2006

Didn't someone [significant] say or write that the more different ways there are to express the same thing in physics, the more fundamental it seems to be?

14. **Adam C**
July 20, 2006

Didn't someone [significant] say or write that the more different ways there are to express the same thing in physics, the more fundamental it seems to be?

Something doesnt become more fundamental via transformation to something else unless in doing this transformation a new phenomena is explained.

15. **CapitalistImperialistPig**
July 20, 2006

I was a grad student in a Regge Pole department when 't Hooft pulled the plug on the bootstrap, but the bootstrap was motivated by intriguing ideas plus the desperation born from 25 years of QFT failure in the strong interactions. I think a suitable mileage marker for the end of the bootstrap might be when Gell-Mann went to Berkley, and noticing Chew in the audience, said some nice things about it.

Chew, GM said, replied with "Thank you, but I'm working on field theory now."

Peter didn't mention it, but LM saved a lot of his wrath for those who believe in a discretium. This is a much older war in physics, dating back to perhaps the seventeenth century. Boltzmann was, some say, persecuted to the pont of suicide by the anti-atomists. Ironically enough it was Einstein who drove the stake through the heart of continuous physics, both for matter and energy. Lubos is still fighting that battle, albeit on another front.

16. **CapitalistImperialistPig**
July 20, 2006

Also, the 1970's boostrap was hardly barren. It gave birth to duality and string theory.

17. **John Baez**
July 20, 2006

Brett writes:

> The discovery of asymptotic freedom, which opened up high-energy strong phenomena to perturbative treatments, was really unexpected. Antishielding is extremely counterintuitive, in large part because it seems to violate the idea of Le Chatelier's principle, that the dynamics of a system should work against disruptions. That principle holds (at least in spirit) not just for chemical equilibria, but also in classical E&M (in Lenz' Law) and in the screening responsible for charge renormalization in QED.

That's a good point! Were there actually people around who were clever enough to object to asymptotic freedom because it violated Le Chatelier's principle? I can imagine Feynman doing it, just to get people thinking.

In week94 I summarized Wilczek's intuitive description of asymptotic freedom as analogous to paramagnetism, where one atom with spin makes its neighbors want to line up with their spins pointing the same way. This may seem reasonable (since we're all familiar with a more drastic phenomenon along the same lines: ferromagnetism), but in fact it does seem to violate Le Chatelier's principle. What would seem more "reasonable" from the viewpoint of Le Chatelier's principle is diamagnetism, where a spinning atom makes its neighbors want to spin the *other* way, counteracting the influence of any magnetic field. Diamagnets screen magnetic fields; paramagnets antiscreen them.

But in fact, in volume II of his Lectures on Physics, Feynman argues that in classical physics, both diamagnetism and paramagnetism are impossible in thermal equilibrium:

> Feynman notes: "It is a consequence of classical mechanics that if you have any kind of system – a gas with electrons, protons, and whatever – kept in a box so that the whole thing can't turn, there will be no magnetic effect. [….] The theorem then says that if you turn on a magnetic field and wait for the system to get into thermal equilibrium, there will be no paramagnetism or diamagnetism – there will be no induced magnetic moment. Proof: According to statistical mechanics, the probability that a system will have any given state of motion is proportional to exp(-U/kT), where U is the energy of that motion. Now what is the energy of motion. For a particle moving in a constant magnetic field, the energy is the ordinary potential energy plus mv^2/2, with nothing additional for the magnetic field. (You know that the forces from electromagnetic fields are q(E + v x B), and that the rate of work F.v is just qE.v, which is not affected by the magnetic field.) So the energy of a system, whether it is in a magnetic field or not, is always given by the kinetic energy plus the potential energy. Since the probability of any motion depends only on the energy – that is, on the velocity and position – it is the same whether or not there is a magnetic field. For thermal equilibrium, therefore, the magnetic field has no effect.

So, both paramagnetism and diamagnetism can only be understood using quantum mechanics! For more on how quantum mechanics gets around the above argument, and how paramagnetism is related to asymptotic freedom, see week94.

18. **Tony Smith**
July 20, 2006

Peter's post said "… Lubos … sees as the fundamental principle of string theory.
Amazingly, it's the bootstrap philosophy …".

Maybe it is not so "Amazing" when you consider the PhD lineage:
Chew (founder of bootstrap) – Gross – Witten
and
the fact that Lubos is a devoted follower of Witten.

Tony Smith

July 21, 2006

Then again, maybe this is just a milestone in LM's own evolution into a right-wing, rude version of Fritjof Capra—someone who ceased to be a serious researcher decades ago, and whose outlook on particle physics (and physics generally) seems to be thoroughly ossified.

20. **ObsessiveMathsFreak**
July 21, 2006

I believe at one point, Newton proved that a "simple harmonic" gravitational force, proportional to 1/r, would lead to elliptical orbits. He wasn't satisfied, and went on to prove the case for 1/r^2 laws. A lot of the time in science, you've just got to keep on going the way you feel is the right one. A little ideology sort of drives you. Of course, it's important not to let it control you.

21. **anon**
July 21, 2006

Obsessive MF,

The key difference between stringers and Newton iscorrect predictions. He knew the distance of the moon and its orbital period, so using his equation a=(v^2)/r, he knew the strength of centripetal acceleration (gravity) at the Moon's distance. This was smaller than the measured gravity at earth's surface by the square of the number of earth radii that the Moon is away. Hence Newton empirically validated the inverse-square law theory.

People lament that Newton kept quiet and took 22 years to publish (1665-87), checking and improving his theories. Darwin took a similar period before publishing, under pressure. Why can't string theorists take the hint from these giants?

22. **P**
July 21, 2006

Dear mr Woit,

I must ask, why do you spend so much time on the outbursts from this man? Even for me, who only is a graduate student in string theory, it is quite obvious that he can not represent the string theory community as a whole. I think that for most people it should be quite obvious that his level of emotional identification, with the debate over string theory, has passed the acceptable limit. Thus, would it not be better to focus on more 'scientific' related stuff concering the progress (or non progress) of string theory? Atleast I, who enjoy many of your posts, would find that more educational.

Happy weekend!
P

23. **robert**
July 21, 2006

John Baez highlights the impossibility of dia- or any other sort of magnetism in classical statistical physics, so deftly explained by Feynman. This seemingly counter-intuitive result was first proved by Bohr in his Copenhagen thesis in 1911, and given a thorough going over in the guise of what van Vleck called, in a more gentlmanly time, Miss van Leeuwen's theorem. It's tempting to suppose that it was this finding that first set Bohr off on the road to quantum mechanics.

24. **Chris Oakley**
July 21, 2006

People lament that Newton kept quiet and took 22 years to publish (1665-87), checking and improving his theories. Darwin took a similar period before publishing, under pressure. Why can't string theorists take the hint from these giants?

They are. The only thing is that String theorists are publishing their results 22 years *before* they have anything of value to say. This is the same as Newton and Darwin, apart from the application of the Time Reversal operator.

25. **D R Lunsford**
July 21, 2006

Feynman's argument is specious, because the change in free energy is not

dG = -S dT + V dp

rather

dG = -S dT + V dp – M dH

in a magnetic field H. Thus it is entirely possible to discuss the equilibrium, in an applied magnetic field, of monatomic and diatomic iodine (one paramagnetic, the other diamagnetic) in the reaction

I I2

See Pauli, “Thermodynamics and Kinetic Theory of Gases”, Ch. 3.

These arguments that “X requires quantum mechanics!” are always wrong.

-drl

26. **LostHisMarbles**
July 21, 2006

I wondering the same thing about the quoted Feynman derivation. What about the magnetization contribution to the (Gibbs) free energy? DRL sums it up nicely.

27. **Peter Woit**
July 21, 2006

P,
Actually I’m trying to ignore Lubos as much as possible, but I do think this posting of his reflects the views of not all, but of a sizable proportion of the string theory community. Some string theorists (including one well-known one writing here on this blog) take the attitude that the only problem with Lubos is that he is “undiplomatic”, and it is extremely rare for them to publicly criticize him. From what I hear, many of his colleagues in Cambridge are quite supportive of him, some seem quite happy to have their views put out on his blog. He works regularly with, as he calls them, the “big shots” of this field, and claims in his postings to be reflecting their views, with no complaint from anyone on his blog that this is not true. His behavior is a huge embarassment to the string theory community, but this doesn’t seem to me to be a reason I should ignore it.

As far as I can tell, many of his attitudes are widely shared by other string theorists: the idea that string theorists are smarter than other physicists, that their critics don’t know what they are talking about, that there’s no point to reading non-string theory papers, that the possibility that string theory is wrong is so unlikely that it’s not worth thinking about, etc… There’s plenty of evidence that he’s far from the only one who thinks this way, and is just more up-front about it than others.

28. **ksh95**
July 21, 2006

Drl said:

> Feynman’s argument is specious, because the change in free energy is not

> dG = -S dT + V dp – M dH

huh? You just made Feynman’s point. M is the quantum mechanical variable.
And just for your own general knowledge. Calculating M for an ensemble of refrigerator magnets and calculating M for an ensemble of atoms or particles are two complety different calculations.

29. **Peter Woit**
July 21, 2006

drl, ksh95,

This is way, way off topic, enough.

30. **Hans de Vries**
July 21, 2006

John:

“In week94 I summarized Wilczek’s intuitive description of asymptotic freedom as analogous to paramagnetism,…”
–
Anti-shielding like effects do also occur with dielectric layers. Very actual are the new high k (high dielectric value) gates in CMOS transistors.

The coupling INCREASES if the very thin isolation layer (~1.2 nm) between the gate and the channel is replaced with a material with a HIGHER dielectric value. The same voltage on the gate will attract more charge-carriers in the channel instead of less.

This is exactly the opposite of what one would expect knowing the usual arguments about vacuum polarization and running coupling constants.

The higher polarized dielectric layer will have more charge carriers close to the channel pulling in more charge-carriers (of the opposite kind) into the channel. (Google for: high-k gates)

–
Regards, Hans.

31. **ks**
July 21, 2006

Hmmm… isn’t this exaclty the “swampland” program? Examining additional constraints on effective field theories that don’t necessarily describe ST but enable cuts in the landscape as well?

32. **David**
July 21, 2006

I have achieved a new first at least for me. I was banned by Lubos before I made any comment. I guess I’m beginning to understand the string ideology. If it’s possible that you might question or disagree don’t allow you to speak at all. This is not how I understand science. If this is off topic please delete it.

33. **Who**
July 21, 2006

I have achieved a new first at least for me. I was banned by Lubos before I made any comment.

that's impressive but I don't understand. did you not submit at least one comment?

34. **D R Lunsford**
July 22, 2006

Peter, off topic? We were talking ideology. I was talking physics, the kind I learned from Pauli, as opposed to hero worship, which is synonymous with ideology, in my book (cults of personality).

-drl

35. **John Baez**
July 22, 2006

Danny Lunsford writes:

Feynman's derivation shows that for a system of classical point charges in equilibrium, the magnetization M is zero.

This derivation breaks down when one allows current loops as primitive elements, as I point out in the addendum to week94.

36. **woit**
July 22, 2006

Since John started this, I'd encourage people to discuss this with him at his blog. Except, wait a minute, he doesn't allow comments there since moderating them is too much trouble….

37. **CapitalistImperialistPig**
July 22, 2006

Hmmm? Maybe I should start a thread on my blog for discussions too off topic for Peter's blog?

I appreciated John Baez's explanation and clarification.

38. **Peter Woit**
July 22, 2006

CIP,

Anyone who wants to host discussions I don't want to moderate here has my strong encouragement. But actually a better idea, if John sticks to his sensible decision not to host a place to discuss what he writes, would be for someone else to set up and moderate a forum for that purpose.

39. **wolfgang**
July 22, 2006

Not such a bad idea…
Perhaps I should set something like this up.

40. **Peter Orland**
July 22, 2006

If anyone is interested in the details of asymptotic freedom and paramagnetism…

A number of people derived asymptotic freedom by showing that the vacuum is a color-paramagnet back in the late 70's/early 80's. There is a nice review article about this by N.K. Nielsen in the American Journal of Physics, vol 49, page 1171. Nielsen uses heuristic arguments, but the same mathematics follows from the use of the background-field method.

If you turn on a color-magnetic field, gluons (actually fluctations around said background field) will make Landau orbits. The gluons have some (Landau) diamagnetism, as do any particles making such orbits. Since they have spin and a color-magnetic moment, there is also (Pauli) paramagnetism). This more than makes up for the diamagnetism. So the overall effect is that the vacuum is paramagnetic.

Spin-1/2 particles don't produce this effect, because with Fermi statistics, diagmagnetism wins out.

Paramagnetism means that the permeability of the vacuum at short distances is greater than one, for a strong field. In other words,
color-magnetic fields are screened at short distances. By constancy of the speed of light, the dielectric constant of the vacuum is less than one. This means that color-electric fields are anti-screened at short
distances.

41. **Peter Woit**
July 22, 2006

OK, I give up, there seems to be an irresistible movement to discuss paramagnetism here.

42. **Peter Orland**
July 22, 2006

I have a comment on the old boostrap idea. The original idea was to study model-independent on-shell properties of field theory. Then it somehow transmuted into an entirely different animal. If one views it as a tool for doing field theory, it has some successes. The problem was that it then became the Booststrap Hypothesis, which said you could find the S-matrix from a few simple assumptions crossing, symmeties and maximal analyticity – this is what turned out to be wrong.

Maybe the same is true of string theory – use it as a framework for the True System of the World, but don't take it seriously beyond that. I think this is the working philosophy of many people in the field, as it happens.

By the way, the Bootstrap works wonderfully for integrable quantum field theories in 1+1 dimensions. You can even study off-shell properties, through form factors.

43. **David**
July 23, 2006

To Peter Orland,

Yes, but in 1 + 1 a lot of things happen automatically because of dimensionality. For example 1 + 1 QED confines because in one spatial dimension the Coulomb potential is linear in the distance. The dynamics play no role in this confinement. On the other, hand 2+1 QED confines because notrivial tunneling instanton effects provide an effective photon photon interaction that changes the effective interaction into one that is linear with the distance. This was shown by Polyakov in 1977.

So, while it is interesting that the bootstrap isquite succesful in 1 + 1 D, one should not read too much into it. If it was useful in a higher dimensional theory where the dynamics were not so much restricted by dimensionality than when one has a single spatial dimension.

44. **Peter Orland**
July 23, 2006

David,

I am not sure how I should interpret your comments about confinement in this context, but you are absolutely right that the success of the boostrap in 1+1 dimensions is very special to that dimensionality.

I was only trying to point out that something useful arose from the bootstrap program – and it IS useful, since these 1+1-dimensional models are being applied to condensed-matter problems. There are some good articles on this by Bhaseen and Tsvelik and by Essler and Konik in the Ian Kogan memorial volume (all of which can be found on the web).

45. **Paolo Bizzarri**
July 25, 2006

It seems that no one is finding natural that after bootstrap we are using strings to pull up us…

46. **BJ Flanagan**
July 27, 2006

As is well known, Pauli was the original author of the phrase, "not even wrong."

Hitherto little-known is a recently translated correspondence between Pauli and Carl Jung, where the former argues for a unitary description of mind and matter, informed by quantum mechanics.

http://www.igpp.de/english/tda/pdf/paulijcs.pdf

The article begins with a fine discussion of symmetry.

This is all music to my ears, as I have long argued for this kind of thing, pointing to the symmetries and phase relations of such traditionally "mental" objects as colors and sounds.

I have also pointed to the fact, readily available to inspection, that colors define a projective vector manifold (Riemann, Weyl) which fibers over visual space — notions dismissed as "not even wrong" by certain persons, but which ought to be of interest to string theorists.

47. **Anthony Garrett**
July 29, 2006

Dear Peter,

Thank you for writing Not Even Wrong. Well said!

String theory does seem capable of reconciling general relativity and quantum theory and cannot therefore be consigned to la-la land. But its advocates overstate its promise to the point of irresponsibility. The typical first reaction of physicists to string theory, that it is ugly, seems to me to be healthy. String theorists remind me of drug addicts – once they are into it they see as wonderful something that others recognise as ugly and unhealthy. Perhaps they should be called "string addicts". Theory has outrun experiment and moved toward the realms of science fiction.

Is string theory really "the only [unification] game in town," as many claim? If general relativity and quantum theory do not want to go together then we should consider whether they have defects, before trying to enforce a shotgun wedding that carries those defects over into the marriage and its offspring.

Quantum theory has a basic flaw. Put a large number of electrons through a z-Stern-Gerlach apparatus and take those that emerge spin up. Now put these electrons through an x-Stern-Gerlach apparatus. Some will be spin up, some spin down and nobody in the world can say which. That's OK – the job of theoretical physics is to improve prediction. I have the highest respect for those who predicted and measured (g-2) to such accuracy. But the job is not ended, and it is not OK is to say that you may not ask what the next electron will do, and that henceforth you are allowed to predict only probabilistically. Unhappily that is the Copenhagen view, and it stands against the very meaning of what it is to be a theoretical physicist.

From the start of quantum mechanics it has been recognised that any underlying deeper theory must have strange qualities – so strange that many physicists deny they exist. Since Bell we can be more specific: any underlying theory must be nonlocal and acausal. (The order of measurement on two correlated electrons in a Bell setup is not Lorentz invariant; consider also Wheeler's 'delayed-choice' experiment.) Nonlocality is no big deal in physics – we have had 300 years to get used to it under the name "action at a distance" since Newton's theory of gravity (although subquantum nonlocality does not fall off with distance). Acausality is more alarming, but should it be so alarming as to make us give up and not even think about it? Logically, it is impossible to rule out a hidden variables theory – all that can be done is to rule out categories of hidden variable theories, such as local ones. Even the name 'hidden variables' is loaded since we can see their effect – what we can't do today is control them.

The challenge is to find a deeper theory that, with its extra variables suitably averaged (marginalised) over, reproduces the probabilistic predictions of quantum mechanics. We know that such a theory must be nonlocal and partly acausal. That is a tough assignment, but if you want easy problems you should stick to trainspotting. My worry is that nobody is trying.

How did the Copenhagen mind-clamp get into place? More than a century ago a similar debate took place between the atomists, and others who claimed that the jiggling Brownian motion of small particles seen under a microscope could not be predicted. The atomists won and physical prediction improved tremendously as atomic theory developed. To see why the debate went the other way at the next level down, a generation later, you must look beyond science at the culture it is embedded in. The findings of science are independent of culture but the doing of science is not, as Not Even Wrong recognises. I suggest that, at the time of the debate over atoms, there was sufficent belief that the universe was comprehensible for the scientific community to persist in looking for an explanation, but that by the time of the Copenhagen interpretation there was not. This belief stems from the Judaeo-Christian view, interwoven into Western civilisation, that the universe is comprehensible because it was created that way. (That is why science arose in the West rather than in another culture.) Similarly, the ancient Greeks had a prior faith that the skies were perfect but that terrestrial order was not – and the astronomy they developed was brilliant whereas their terrestrial physics was embarrassing. By the time of Copenhagen, the West had been under the influence of the secular Enlightenment for longer and was turning against the Judaeo-Christian worldview (church attendance was certainly falling); Eastern mystical ideas were received with interest, notably by several of the quantum pioneers.

So, rather than play with universes as string theorists do, I prefer to seek a theory that addresses a more humble question: where will the next electron go in my x-Stern-Gerlach apparatus?

Finally, the anthropic principle is not tautological and is clearly helpful when used correctly. In the 1950s Hoyle used the observed abundance of carbon, which is the basic element of life and is formed in stars, to predict a transition in its atomic spectrum (without which its abundance would be very different). He was later found to be right, and today we would call that anthropic reasoning. There are complementary categories in which we can consider why a theory has a particular feature, so that anthropic reasoning is not a threat to bottom-up research in cosmology or even string theory – all we need to do is get the reasoning right.

Anthony Garrett

(PhD in theoretical physics, University of Cambridge, UK, 1984, then three university postdoctoral contracts. Not publishing currently but writing a monograph on probability in physics.)

Anthony Garrett said "… the Copenhagen view … stands against the very meaning of what it is to be a theoretical physicist …
Logically, it is impossible to rule out a hidden variables theory – all that can be done is to rule out categories of hidden variable theories, such as local ones. …
We know that …[a successful hidden variable]… theory must be nonlocal and partly acausal. That is a tough assignment … My worry is that nobody is trying. …".

Actually Bohm did try (and substantially succeed) in formulating such a theory, but the reaction of the physics establishment (in the 1950s) to Bohm is similar to the reaction today of String Ideology proponents, such as Harvard Professor Motl, to any competing theories/models.
According to The Bohm biography Infinite Potential, by F. David Peat (Addison-Wesley 1997):
"… Max Dresden … read Bohm's papers … errors were difficult to detect … von Neumann's "proof" … did not rule out the sort of theory that Bohm had proposed. … Oppenheimer [said]…
"We consider it juvenile deviationism … we don't waste our time …" [by] actually read[ing] the paper …
Dresden … present[ed] Bohm's work in a seminar to the Princeton Institute …
The reception he received came as considerable shock to Dresden. Reactions to the theory were based less on scientific grounds than on accusations that Bohm was a fellow traveler, a Trotskyite, and a traitor. It was suggested that Dresden himself was stupid to take Bohm's ideas seriously. … all in all the overall reaction was that the scientific community should "pay no attention to Bohm's work" … Abraham Pais also used the term "juvenile deviationism". Another physicist said that Bohm was "a public nuisance" …".

The tactics of Bohr himself in support of the Copenhagen ideology have been described by Carver Mead in his book Collective Electrodynamics (MIT 2000), as follows:
"… Bohr gathered the early contributors [to]… Quantum Mechanics … into a clan in Copenhagen, encouraged everyone in the belief that they wre developing the ultimate theory of nature, and argued vigorously against any opposing views. … Bohr insisted that the laws of physics … are statistical in nature …[even though]… Statistical quantum mechanics … actively impedes our understanding by hiding the coherent wave aspects of physical processes. …
Einstein … believed … that the statistical nature of experimental results was a result of our lack of knowledge of the state of the system, and that the underlying physical laws can be formulated in a continuous manner. …
The disagreement culminated in a 1927 debate between Bohr and Einstein, refereed by Ehrenfest. Bohr was a great debater, and won the contest hands down.
A rematch was staged in 1930, and Bohr won again. …
At the time, there were no compelling experiments where the wave nature of matter was manifest in a non-statistical manner. …
Starting in the 1960s, … experimental demonstrations of numerous coherent, collective systems have … put us in a position to finally settle the Einstein-Bohr debate – with a resounding victory for Einstein. …

Bohr had won his debate with Einstein …[not by being correct but by]… an openly combative [technique]… the one who blinked first lost the argument … and the entire field adopted the style. … ".

Bohr's unreasonable, unblinking, combative style in attacking better models than Copenhagen survives today in the String Ideology style of Harvard Professor Motl and his ilk.

For some reasonable alternatives to Bohr/Copenhagen, see the works of Bohm and his followers, and the book by Carver Mead.

Anthony Garrett:

Quantum theory has a basic flaw. Put a large number of electrons through a z-Stern-Gerlach apparatus and take those that emerge spin up. Now put these electrons through an x-Stern-Gerlach apparatus. Some will be spin up, some spin down and nobody in the world can say which.

In 80 years of quantum theory, we don't have even approximate prediction of which electron will be spin up and which will be spin down. This is just a random effect. That's what quantum mechanics tells us, and I believe there is no any deeper theory behind quantum mechanics.

If you are worried (as I do) about the inconsistencies between QM and SR, I would suggest you to pay more attention to the other part, i.e., special relativity. The problem is that Lorentz transformations were derived for events associated with light pulses and non-interacting particles. We extend these transformations to all events in systems with arbitrary interactions. Is it logical?

50. **Anthony Garrett**
July 30, 2006

Hi Eugene,

One reason we don't have an exact or approximate theory telling us which electron will show spin up and which will show spin down is because Copenhagen has bamboozled the physics community into not looking for one. It then becomes a self-fulfilling negative mindset.

I want to know whether the next electron will show spin up or down. If you don't want to know, that is up to you, but isn't this the sort of question we are there to ask?

Bohm dared to look for hidden variables, though he didn't find them and his "quantum potential" was really an interpretation of quantum mechanics, since it could not generate any differing testable predictions. Today there are other such rationalisations, such as many-worlds. The key, though, is to find a theory that predicts where QM doesn't.

Since it's summer, lots of conferences going on:

The Institute in Princeton has its usual summer program designed to train graduate students and postdocs in string theory. The schedule and lecture notes are here.

On the opposite coast, with an opposite point of view about particle physics, there's the SLAC Summer Institute, which is on LHC physics. The program and lecture notes are here. One of the organizers, JoAnne Hewett, has a posting about this at Cosmic Variance.

In Australia there's a conference on the Mathematics of String Theory going on, with a satellite workshop next week in Adelaide.

Last weekend there was a conference entitled Under the Spell of Physics, in honor of 't Hooft's 60th birthday. Many of the talks sound interesting; here's the program, but unfortunately the talks are not online. From what I hear 't Hooft remains quite skeptical about string theory, Polyakov said that current ideas about how to apply string theory to nature are wrong, and the lack of progress in fundamental theory was a concern of many of the participants.

I've been thinking a lot about BRST recently, and happened to run across the Wikipedia entry for BRST Formalism. The entry had something I hadn't seen before, a banner announcing that "This article or section may be **confusing or unclear** for some readers, and should be edited to rectify this", and that the attention of an expert and a complete rewrite was needed. I have to say that I feel that way about most of the literature on BRST…

Soon to appear in the AMS Bulletin is an article by Sinai entitled Mathematicians and Physicists = Cats and Dogs?

The Cao-Zhu paper with a proof of Poincare/Geometrization is now out in paper copies of the Asian Journal of Mathematics, but still is not on the journal's web-site. I hear that someone who called them to ask about this was told that they're trying to make some money by selling the paper copies of this particular issue. Many libraries are now only paying for on-line access to journals like this, not sure what happens in this case. Today's Wall Street Journal had an article by Sharon Begley about the Poincare proof story.

Jim Weatherall, who was recently a physics student at Harvard, now works at the Center for Science Writings at Stevens with John Horgan. He has a web-site, which includes his paper on Effective Field Theories and the Pragmatics of Explanation.

Two reviews of my book are from Sabine Hassenfelder and from Science A GoGo.

FQXI was supposed to announce the winners of its Templeton-funded grants this past weekend, but still nothing on their web-site. It will be interesting to see what their choices are for fundamental research in physics that is not being supported by the usual channels.

Update: The FQXI web-site now says they'll be publicly announcing grants on Monday, July 31.

   YAKOB SINAIS ARTICLE IS DISAPPOINTING.

   THERE ARE SOME WONDERFUL ANECDOTES AND QUOTEATIONS, ESPECIALLY ABOUT AND FROM ISRAEL GELFAND!!

   BUT OVERALL IT SEEMS TO LACK SUBSTANCE WHEN MEASURED AGAINST SINAIS STATUE.

   AS FAR AS I CAN SEE IT SAYS
   1 PHYSISISTS ARE INTUITIVE BUT LACK RIGOR
   2 MATHEMATICS IS STILL IMPORTANT
   3 IT IS HARD FOR MATHEMATICIANS AND PHYSICISTS TO LEARN EACH OTHERS WAY OF THOUGHTS

   THIS IS COMPLETELY OBVIOUS, AND ISNT EVEN SAID VERY COHESIVELY.

   BUT ISRAEL GELFANDS BITING SARCASM QUOTES SOUNDS WONDERFUL, IT REDEEMS THE ARTICLE.

   THE ASIAN JOURNAL IS BEING VERY VERY EVIL AND GREADY, WE SHOULD BE ABLE TO SEE POINCARE PROOF ONLINE. ALSO IT DOES NOT HELP TO ADRESS THE CYNICISM ABOUT THE PROOF. ARE THERE ANY FAMOUS PEOPLE OF GEOMETRY (NOT YAU WHO SEEMS TO BE DOING POLITICS) WHO HAVE SCRUTINIED THIS PROOF?

2. **Garrett**
   July 21, 2006

   I like this introduction to BRST:

   http://arxiv.org/abs/hep-th/0201124

   Are there other good introductions out there on the arxiv or on the net? I think BRST is of foundational importance. And it would be nice to further develop a geometric understanding, especially in its application for nonabelian Yang-Mills fields.

   There are some hints in the earlier literature of a geometry behind BRST, with ghost fields literally added to connections in some sort of hybrid bundle, but my understanding is sketchy.

3. **Thomas Larsson**
   July 22, 2006

   A nice, brief introduction to BRST (or rather BV) from a mathematical perspective is Jim Stasheff's secret paper http://arxiv.org/abs/hep-th/9712157.

4. **Garrett**

July 22, 2006

The neat thing that's hinted at, at least for BRST applied to nonabelian gauge theory, is that the BRST operator, s, is a sort of exterior derivative (added to the exterior derivative on the base manifold) that acts in a discrete "direction", and the ghosts are the components of the connection in that direction.

Here's an introductory paper related to that point of view:

http://www.mathcs.emory.edu/~rudolf/localbrst.pdf

(And thanks for the paper you linked, Thomas.)

5. **anon**
July 22, 2006

I believe you can get a good intuitive understanding of BRST (although certainly not in its full generality) from studying Feynman diagrams. I think 't Hoof did some of this in his very early work on renormalization of gauge theories.

6. **Peter Orland**
July 22, 2006

Like a lot of people, I appreciated the original BRS work
since it can be used to generate a useful form of gauge-theory
Ward identities to prove renormalizability. Beyond that, BRST just seems a way of eliminating unphysical degrees of freedom.

The fascination with BRST by many people seems a little questionable to me, however. Some people actually think it is fundamental, but I can't see how this could be true. It is basically a perturbative supersymmetry. It doesn't work with a nonperturbative regularization – which means the lattice gauge theory (there is no other successful non-perturbative regularization). Herbert Neuberger wrote an interesting paper on this, some years ago.

BRST may be interesting mathematics, but its utility in much of physics is limited to to perturbation theory. This makes it an important tool, but not a path to a fundamental understanding of non-Abelian gauge theories. I am aware that it has a lot of utility in other areas, but I can't help suspecting that it can't be used beyond perturbation theory even in those cases.

7. **Peter Woit**
July 22, 2006

Hi Peter,

It certainly is true and interesting that you don't seem to need to gauge-fix in the lattice theory, but I still think there should be a non-perturbative version of BRST, and understanding it might teach one something interesting.

One reason for believing this is that one aspect of (quantum) BRST is something well-known to mathematicians: Lie algebra cohomology. The Lie algebra cohomology of a representation is just about by definition the invariant part of the representation. So, this is a mathematical gadget precisely designed to pick out the physical subspace in the Hilbert space of a gauge theory, and the existence of such a gadget should be a very general feature of the quantum theory, not dependent on perturbation theory. Whether one can construct it explicitly non-perturbatively is another question.

In the lattice theory, one picks out the gauge invariant subspace by integrating over the gauge group, and one can get away with this because for a finite lattice this is compact.

I'm not sure which Neuberger paper you're referring to. I'd be interested to hear more from anyone who knows of good references to papers where people try to do BRST on the lattice.

8. **Peter Orland**
July 22, 2006

Hi Peter,

I think the source of our disagreement is technical, not philosophical.
Ultimately what the lattice tells you is that the Lie group is more important than the lie Algebra. I think that there is something fundamentally wrong with trying to use Lie algebras to define gauge theory nonperturbative.

I can't prove my assertion, but I have several of arguments why it
is probably true. For example, strong-coupling calculations are the key to why QCD confines, at least for large bare coupling. Such expansions make no sense without a compact field degree of freedom.

Neuberger's paper is in the hep-lat archive. I think he actually
wrote several papers. In the first one he was trying to prove BRST, but
actually proved a no-go theorem in the second. My memory on
this is vague, unfortunately.

One possible way out – generalize BRST to compact spaces. If you
know some compact version of supersymmetry, perhaps it can be
dome.

9. **Peter Woit**
July 22, 2006

Peter,

You may be right, the difference between the Lie algebra and the group may be crucial. But even so, you should in principle be able to define the part of the Hilbert space invariant just under infinitiesimal gauge transformations. The part invariant under the gauge group should be a subspace of this. Understanding the difference between the two spaces would be interesting.

I think of BRST as Lie algebra cohomology, there are various versions of cohomology that use instead the full group. But in the compact case, they're really the same. Hmm, actually in the lattice case, since the group is compact, presumably one can show that, for a connected group, being invariant under the Lie algebra is the same as being invariant under the group. Have to think more about that…

10. **Peter Orland**
July 22, 2006

Well, that in a way is the point. Gauge transformations on the lattice
sit in a Lie group SU(N) to the power of the number of lattice sites.
This is crucially different from the Lie algebra. It is not just the fields
which are compact.

By the way, this is a bit of self-promotion (parties disinterested in the confinement problem should ignore it), but I have recently put out a paper on confinement in lattice gauge theory at weak coupling. The compactness of the gauge group is crucial there too, just as at strong coupling. The gauge theory is in 2+1 dimensions, the coupling are anisotropic, it's only SU(2), but it's the only case I know where things seems to work for unbroken non-Abelian gauge groups. None of
this will work unless the theory is on a lattice (and I think it does
work, if the theory is on a lattice).

OK, sorry about the advertisement, but I still think you need a BRST which is some sense is compact, otherwise important physics is missed.

11. **A knight who says ni**
July 22, 2006

>The Cao-Zhu paper with a proof of Poincare/Geometrization is >now out in paper copies of the Asian Journal of Mathematics, but >still is not on the journal's web-site. This sounds really strange.

The online access to the papers in AJM isn't free. So does this actually mean that people are not going to get what they are paying for?

12. **Peter Orland**
July 22, 2006

Peter,

By the way, there is a non-lattice way to define gauge theories
nonperturbatively in 2+1 dimensions, due to Karabali and Nair. They use a parametrization of the gauge orbits which is a kind of gauge fixing (someone showed this gauge fixing is closely related to background-field gauge). Strong coupling-expansions, done
by diagonalizing the kinetic term of the Hamiltonian are possible. There is a severe Gribov problem in generalizing this idea to 3+1, BUT…

Is there a BRST for Karabali and Nair's parametrization? I doubt it.
It seems worth looking into though…

13. **Peter Woit**
July 22, 2006

Knight,

I don't know what AJM is doing about this. Maybe they're sending paper copies to people who just paid for on-line access, maybe the paper will appear online, just later. My information that they are doing this to raise money is third hand, and not necessarily completely reliable. However I do have first hand information that the paper version exists (it's downstairs in our library), and that the on-line one doesn't., and that's kind of unusual.

14. **Kiff**
July 22, 2006

Is there any good introductory article which gives the big picture of BRST methods in general (as opposed to a case by case analysis) which isn't targeted to mathematicians?

15. **Moshe Rozali**
July 22, 2006

Peter Orland:

A couple of points that caught my attention:

1. When you say that BRST is perturbative, you mean it is only useful in perturbation theory, or that it is only defined perturbatively? The latter seems surprising to me. Maybe this is just then statement that on the lattice there is no need for gauge fixing?

2. Karabali and Nair work in the temporal gauge, and then use a clever parametrization of the gauge-fixed degrees of freedom, naively I would expect BRST to be more or less unaffected, even if the clever parametrization allows for some strong coupling results. On the other hand I am not sure what you mean in the statement that their parametrization is similar to background field gauge…

Thanks,

Moshe

16. **Aaron Bergman**
July 22, 2006

Nobody's mentioned the book by Henneaux and Teitelboim?

17. **Thomas Larsson**
July 23, 2006

The basic idea behind BRST applies more generally than to gauge symmetries. Whenever one has a complicated factor space, one can try to replace it by a sequence of simple spaces, such that the original space is recovered as the cohomology space H^0.

In BRST, one constructs the space of connections modulo gauge transformations in this way. In BV, one instead constructs phase space (even without gauge symmetries), as the space of histories modulo Euler-Lagrange equations. Just as one may coordinatize the space of connections module gauge transformations by fixing a gauge, one may coordinatize phase space by fixing a foliation – a history q(t) is specified by q and p = dq/dt at t = 0. But BRST teaches us that one obtains a cleaner and simpler description by cohomological means, where one does not have to make such arbitrary choices. Physics is hard as it is, without introducing spurious complications by hand.

One such complication, which has been discussed at length in connection with LQG, is the difference between the 3-diffeo and Hamiltonian constraints, which is an artefact of the introduction of a foliation. In cohomological and thus covariant formulations, both are part of the 4-diffeo constraint, because no foliation needs to be introduced.

18. **Peter Orland**
July 23, 2006

Moshe,

Formally BRST is fine in unregularized Yang-Mills. In perturbation
theory, it is still fine. If you try to define the theory beyond perturbation theory, Neuberger's theorem says (at least on the lattice) there are problems. My prejudice (and I stress that it is
only that) is that this makes BRST useless in understanding problems like quark confinement.

Karabali and Nair do more than a temporal gauge fixing. They
also solve Gauss's law. The resulting variables describe gauge
orbits. In this sense, they have a physical gauge condition, like
axial or Coulomb gauge, but with the Gribov problem eliminated. There are other ways to do similar things, but I was expressing doubt (not a proof!) that BRST is satisfied after this further gauge fixing.

My comment about background field gauge is a little technical.
It is the gauge in which a variation of the gauge connection
has vanishing covariant divergence. This was first discussed
by Babelon and Viallet around 1980. It is a useful gauge for
discussing orbit space geometry (inner products, curvature,….).

Peter O.

19. **D R Lunsford**
July 23, 2006

Peter said

The Lie algebra cohomology of a representation is just about by definition the invariant part of the representation. So, this is a mathematical gadget precisely designed to pick out the physical subspace in the Hilbert space of a gauge theory, and the existence of such a gadget should be a very general feature of the quantum theory, not dependent on perturbation theory.

This reminds me of the role of Lie derivatives in GR. Although unnecessary to formulate the theory, the Lie derivatives of this and that represent actual physical things, e.g. transport phenomena. I wonder if this is coincidental.

20. **Moshe Rozali**
July 24, 2006

Thanks Peter, I will have a look.

21. **Thomas Love**
July 25, 2006

I must agree with Qwerty's assessment: "YAKOB SINAIS ARTICLE IS DISAPPOINTING". Mathematicians and Physicists are not like cats and dogs, they are more like husband and wife (I'm not sure which is which), they often argue, but when they work together, the result can bring a new life into being.

22. **LostHisMarbles**
July 25, 2006

What is curious is that way back in the good old days, people like Newton were considered mathematicians (and natural philosophers). Newton worked on optics ~ designed the Newtonian reflector (and dabbled in alchemy). Gauss was a mathematician, yet the unit of magnetic field is named after him. Many famous mathematicians (Bernoullis, Lagrange, Laplace, etc) worked on problems of physics — witness the classic pdes = Laplace, heat, wave, all motivated by physics. The dichotomy (if that is the right word) between physicists and mathematicians seems to be a modern (20th century?) phenomenon.

If my own marriage is anything to go by, physicists are husbands. They are willing to be pragmatic about things. The wife will insist on every nitpicking detail.

23. **q2**
July 26, 2006

The rumors of AJM trying to make money by selling copies of the current issue seem to be corroborated by the bottom of [this](#) webpage, wherein we learn that we can have the issue for the low low price of $69.

I'm not sure what exactly online subscribers to AJM (or the other International Press journals for that matter) are paying for, since as near as I can tell all the articles seem to be freely downloadable by anyone.

Incidentally, Morgan and Tian's exposition of the proof of the Poincare conjecture can now be had for the low low price of $0 at http://xxx.lanl.gov/abs/math.DG/0607607

24. **anon**
July 26, 2006

"I'm not sure what exactly online subscribers to AJM (or the other International Press journals for that matter) are paying for, since as near as I can tell all the articles seem to be freely downloadable by anyone."

Since it is freely available online, that must reduce the number of printed subscription contributors to a few libraries. Hence the unit cost of printing is very high. It's down to the economy of scale: offset litho only becomes cheap when the total sales dwarf the high cost of film-setting (producing printing plates).

25. **A knight who says ni**
July 26, 2006

>I'm not sure what exactly online subscribers to AJM (or the other International Press journals for that matter) are paying for, since as near as I can tell all the articles seem to be freely downloadable by anyone.

Well, what about this then?

26. **q2**
July 26, 2006

>>Well, what about this then?

Well yeah, that was kind of my point…they *do* have an online subscription option, but I can't see why anyone would choose to buy one when nonsubscribers can download all the papers for free (granted, now with the exception of the Cao-Zhu paper).

Unless of course the idea is that when International Press decides for whatever reason to deny open access to some article (like Cao-Zhu) the online subscribers would still get it–but this seems like it would be too rare and unforeseeable to cause anyone to subscribe.

Whatever, it's not important.

27. **Anon**
July 26, 2006

There is also a Physics Reports review by Henneaux et al.

28. **MathPhys**
July 27, 2006

Latest on Poincare

July 27, 2006
Categories: Uncategorized

A new 473-page paper by Gang Tian and my colleague John Morgan that gives a complete proof of the Poincare conjecture based upon the argument outlined by Grigori Perelman (which carries out the program of my other Columbia colleague Richard Hamilton) is now available as a preprint on the arXiv entitled [Ricci Flow and the Poincare Conjecture](). This paper is in the process of being refereed and should ultimately appear as a book in the monograph series that the Clay Math Institute publishes with the AMS.

Morgan and Tian just provide a proof of Poincare, not the full geometrization conjecture. Other sources for worked out details of Perelman's argument are the [notes by Kleiner and Lott](), and the recent paper by Cao-Zhu that appeared in the Asian Journal of Mathematics. Cao-Zhu provide fewer details than Morgan-Tian, but do give a proof of geometrization. Until very recently the Cao-Zhu paper was only available in the paper version of the journal, for sale by International Press for $69.00. Yesterday the journal put the full paper on-line, and it's available [here]().

Latest rumor I hear is that the Fields Medal committee has definitely chosen Perelman as a Fields medalist, with the appearance of these detailed proofs using his arguments clinching the deal. However it remains unclear whether he'll show up in Madrid, or even actually accept the honor being offered him.

Update: There's an [article]() about this in this week's Nature.

Update: The September issue of the Notices of the AMS has an excellent [article]() by Allyn Jackson about this. Next week's Science Times is supposed to have an article by Dennis Overbye.

Comments

1. **Scott Aaronson**
   July 27, 2006

   I used to wonder: what would happen if mathematicians received the solution to a centuries-old open problem in the form of a coded message from an extraterrestrial intelligence? Would they put their other projects aside, and work together to decode the message? Would they understand the solution? Would they try to start a dialogue with the intelligence? Would they *credit* it (maybe even offering it a Fields medal), or would they treat it roughly like astronomers treat a gamma-ray burst? While we still don't know the answers to these questions, it's possible that we have more insight than we did a few years ago.

2. **woit**
   July 27, 2006

   Scott,

   A weaker version of this has already happened, with mathematics getting unexpected solutions to problems via coded messages from Edward Witten, who some have suspected of an intelligence extra-terrestrial in origin. Many mathematicians did put their other projects aside and worked together to decode the message. They did start a dialog with the intelligence, but it remains unclear whether they understood what he was telling them (see the two-volume IAS set on QFT that this dialog inspired, for evidence to argue the case either way).

   They definitely did credit the intelligence, and gave him a Fields medal.

3. **Deane**
   July 28, 2006

   Peter,

   Could you elaborate on what you mean by "Cao-Zhu provide fewer details than Morgan-Tian" and on what basis you make this judgement? If it's from reading the papers themselves, could you point to where this is apparent?

4. **woit**
   July 28, 2006

   Deane,

   I haven't done more than skim the papers myself and I'm no expert. That comment was based largely on the fact that the Morgan-Tian paper is much longer than Cao-Zhu, and yet doesn't cover as much (no geometrization), together with impressions I got (which may be mistaken), from talking to people who have looked more carefully at both papers. I'd love to hear here from an expert who could more accurately compare the two papers.

5. **Walt**
   July 28, 2006

   I've heard it suggested that both John von Neumann and Alexander Grothendieck were aliens, so Scott, I think your hypothesis has been amply tested. The real question is why are aliens interfering with the progress of mathematics? What is their purpose? Is it benign, or (as I suspect) sinister? What mathematical truths are they preventing us from discovering by distracting us in this way?

6. **Cynthia**
   July 28, 2006

   Peter,

   Using layman's language, would you briefly explain how the Poincare Conjecture might spill over into the foundations of theoretical physics?
   I would greatly appreciate your input/thoughts on this matter…

   Best,

7. **LostHisMarbles**
   July 28, 2006

So Perelman can receive a Fields medal without actually writing up a proper proof? Just an outline that others fill in? Could Wiles have won a FM if he had said (while age

8. **John Baez**
July 28, 2006

There's a fun Wall Street Journal article on Perelman and the Clay Mathematics Institute's million-dollar prize for proving the Poincare conjecture. It'll be interesting to see how they deal with the complicated mess that's been brewing. I don't think they expected someone working on such an important conjecture to not bother publishing in a refereed journal!

9. **Peter Woit**
July 28, 2006

Cynthia,

Sorry, but I don't really see any relevance of the Poincare conjecture to fundamental theoretical physics. With some effort one might come up with some very speculative idea along these lines, but there's nothing I'm aware of of this kind that there's any evidence for.

10. **Aaron Bergman**
July 28, 2006

It is kind of amusing that Ricci flow, the basis for Perelman's proof, shows up in the RG equations for a 2D sigma model, but as far as I know nobody has done anything with that.

11. **urs**
July 28, 2006

> It is kind of amusing that Ricci flow, the basis for Perelman's proof, shows up in the RG equations for a 2D sigma model, but as far as I know nobody has done anything with that.

I gather that the proof involves showing that the Ricci flow on any simply-connected 3-fold goes towards a fixed point which is precisely the 3-sphere.

Now, the plain 2D-sigma model on the 3-sphere is not conformal, since the 3-sphere is not Ricci flat. So are we really talking about the SU(2) WZW model?

12. **MathPhys**
July 28, 2006

There are paprs by I Bakas on Ricci flows from a 2D field theory point of view. My recollection is that he has to deal with gauge groups with generators that have continuous indices, or something that strange.

13. **Comentator**
July 28, 2006

In reference to John Baez post; The Clay Comitee already made it clear in its rules to determine the prize winner that. "It is discretionary to the comitee to award the prize even if the proof has not been properly published in a refeered journal as long as it survived the scrutiny period of at least two years".

14. **conjecturedepoincaré**
July 29, 2006

I conjecture that Grigori Perelman will be the first awardee to turn down the Fields Medal. If we assume such an occurrence, then one can infer that he will be absent in Madrid, when the IMU disciples/attachés meet.

It will be interesting to observe how a few hundreds of thousand of dollars (amounting in toto to more than a million) from the Clay Institute and IMU safes will get distributed in the months to come, amongst the few people who have worked on the proof. After all, awarding prizes and money has always been a real fuss, but sometimes arguably useful.

However, we take the opportunity to applaud the great intellectual triumph of this little group of people whose work have, for decades, been directed towards engineering mathematical techniques to solve one of the greatest problems in the realm of reason. And bravo Perelman!

15. **D R Lunsford**
July 29, 2006

Waldron vs. Woit – this was a cakewalk. "Marketplace for ideas" – what idiocy. Peter, speak more slowly and don't pull punches in these interviews!!

-drl

16. **D R Lunsford**
July 29, 2006

sorry the above was meant for the other thread

17. **Walt**
July 29, 2006

Why is everyone so sure Perelman will turn down the Fields? Did he say that?

18. **ObsessiveMathsFreak**
July 30, 2006

Wow. The paper is in fact quite readable. I predict two things resulting from this readability. One, it will be denounced by mathematicians as inadequate, and two, the proof will stand the test of time.

19. **ObsessiveMathsFreak**
July 30, 2006

I meant the Cao-Zhu paper, which contains clearer proofs, not the Tian-Morgan, whos prrofs seem much more reticent.

20. **nonblogger**
July 30, 2006

According to the ICM website
http://www.icm2006.org/press/bulletins/bulletin20/#poincare
"*Although Perelman himself, reluctant at least until now to appear at public events, will be absent, the subject will undoubtedly be the highlight of the congress*.".

Perelman is obviously aware of the impact of his work as he met many people during his lectures in the US, and clearly for him the ICM would be a waste of time (lots of media attention and no new maths or contacts). So not coming there only means he's not too much of a party animal, nothing wrong with that.

21. **conjecturedepoincaré**
July 31, 2006

Walt said:

"Why is everyone so sure Perelman will turn down the Fields? Did he say that?"

To answer your second question, as far as I know, Perelman did not say anything about whether he would accept or decline the award of a Fields medal. If there's a statement of his concerning this, to him at least, trivial issue, then you understand that I am unaware of it.

As far as I am concerned, I was just speculating his refusal of the Fields medal, and there are a few indications that he might actually do so.

1) He has already rejected at least one mathematical prize. In 1996, he refused to accept an award in Budapest, Hungary, from the European Mathematical Society.

2) I read on the wikipage about him that he is said to be "very unmaterialistic".

3) In an article ("On the verge of a solution") by Douglas Birch, which appeared in The Baltimore Sun (January 19, 2004), it is written (I quote):
"But the 37-year-old native of Leningrad, now St. Petersburg, doesn't seem interested in money or acclaim. While he could probably get a far more lucrative job in the West, he earns only about $200 a month at the Steklov Institute of Mathematics in St. Petersburg."

4) In a news announcement of The Abdus Salam International Centre for Theoretical Physics, I read (I quote):
"There is also some indication, as yet unconfirmed, that he will not accept the US$1 million prize from the Clay Mathematics Institute in Cambridge, Massachusetts, if it is offered."

These might, or might not, be taken to be true (to the extent that they come from the mouth of the mathematician, if at all, undistorted). Some uncertainty indeed!

After all, we all share the opinion that Perelman doesn't care much, if at all, about the prizes (Clay and Fields) and millions. He just needs to be left to do his work, like he's been doing in the last decade or so. He proved Thurston's Geometrization conjecture was true (with demonstration), that's what really counts in history.

I think that one pertinent and actually significant reason, in the societal context at least, of his refusal would be that he may be concerned that the talk, and possible eventual acceptance, of the prize moneys could make him a target of the Russian underworld. I don't think the society of mathematicians wants to risk this kind of thing to happen to one of its most able members.

So far, we know from the announcement on the ICM 2006 website (thanks to nonblogger for the link) that Perelman will indeed be absent. But this does not exclude the fact that a possible Fields medal could be awarded in absentia, if this can happen at all. Well, we will know in a few days' time!

22. **gunpowder&noodles**
July 31, 2006

ST Yau has a paper in the arxiv today in which it is pointed out that the Chinese were the first to invent pasta, gunpowder, magnetism, etc etc etc, and that it is long past time that they were accorded their rightful place at the head of etc etc etc.

23. **offended**
August 2, 2006

The previous comment is a libelous mischaracterization of Yau's talk. The commenter either (a) has an axe to grind against Yau, or (b) is a racist.

24. **Peter Woit**
August 2, 2006

Unfortunately this is a subject where a lot of people have axes to grind. Please don't do this here.

25. **Comentator**
August 2, 2006

I would suggest to wait for the validation of the proof presented by Perelman, and hence the paper by Cao and Zhu. and others. Remember that The Pioncare Conjecture is notorious for its technicalities and has stopped many great mathematicians in the past.
British Prof. Dunwoody's proof being the latest to come short.

26. **Fair**
August 2, 2006

Let be fair here: I respect Yau but not what he said in several of his interviews:
1) Someone won the Veblen under his influence on the committee;
2) in the Qiao Bao July 9 2006 issue, Chinese Weekend, he SAID THIS, "But the other group of mathematicians–Morgan and Tian Gan, they said they already had their paper, but it's been two months from now, if they have it, why not publish it? They said, their 400 page manuscript had been submitted to America's Clay Math Institute. I (this year) in late April asked this institute's director, his name is Carlson, he said he doesn't have this "manuscript", but only an "introduction".

27. **Agree with Fair**
August 2, 2006

That's true. Professor Yau once criticized the Chinese people for envying their people's accomplishment. He in that interview claimed that if these critics of Zhu and Cao's work can understand the paper of Poincare Conjecture, he would award them with 10000 dollars (or yuans?) However, on the other hand, he repels the work of another Chinese mathematician–Tian, work done jointly with Morgan. So much contradictions in his talks and interviews. Hope he is not a hypocrite.

28. **Sarah M**
August 2, 2006

So whose work in Poincare conjecture is THE SINGLE MOST IMPORTANT? I heard that Freedman, Thurston, Hamilton, Perelman and Smale have all worked on it. It seems it's just the Ricci Flow and Thurston's Geometrization that play the role in solving the problem. IF the tools are handily ready, then solving the Poincare Conjecture isn't like work on an extremely lengthy Olympiad math problem? Any ideas?

29. **Walt**
August 2, 2006

I think Smale's work only applies to higher dimensions, and doesn't help *at all* for the 3-d Poincare conjecture, but I could be wrong. Thurston sketched out a new way of looking at 3-manifolds, but his role somewhat analogous to Poincare's. Hamilton invented the key technique to prove the conjecture, but if his idea by itself was sufficient to solve the problem, then he would have done it himself.

30. **anon**
August 3, 2006

"A weaker version of this has already happened, with mathematics getting unexpected solutions to problems via coded messages from Edward Witten, who some have suspected of an intelligence extra-terrestrial in origin." – Woit.

Susskind says something similar about Edward Witten in a recent invterview see http://www.thestar.com/NASApp/cs/ContentServer?pagename=thestar/Layout/Article_Type1&c=Article&cid=1154082909559&call_pageid=1105528093962&col=1105528093790 which is an article in The Toronto Star by Siobhan Roberts:

"… at a public lecture at the Strings05 conference in Toronto, an audience member politely berated physicists for their bewildering smorgasbord of analogies, asking why the scientists couldn't reach consensus on a few key analogies so as to convey a more coherent and unified message to the public.

"The answer came as a disappointment. Robbert Dijkgraaf, a mathematical physicist at the University of Amsterdam, bluntly stated that the plethora of analogies is an indication that string theorists themselves are grappling with the mysteries of their work; they are groping in the dark and thus need every glimmering of analogical input they can get.

' "What makes our field work, particularly in the present climate of not having very much in the way of newer experimental information, is the diversity of analogy, the diversity of thinking," says Leonard Susskind, the Felix Bloch professor of theoretical physics at Stanford, and the discoverer of string theory.

' "Every really good physicist I know has their own absolutely unique way of thinking," says Susskind. "No two of them think alike. And I would say it's that diversity that makes the whole subject progress. I have a very idiosyncratic way of thinking. My friend Ed Witten (at Princeton's Institute for Advanced Study) has a very idiosyncratic way of thinking. We think so differently, it's amazing that we can ever interact with each other. We learn how. And one of the ways we learn how is by using analogy."

"Susskind considers analogy particularly important in the current era because physics is almost going beyond the ken of human intelligence.

' "Physicists have gone through many generations of rewiring themselves, to learn how to think about things in a way which initially was very counterintuitive and very far beyond what nature wired us for," he says. Physicists compensate for their evolutionary shortcomings, he says, either by learning how to use abstract mathematics or by building analogies.

"Susskind, for his own part, deploys more of the latter. Analogy is one of his most reliable tools (visual thinking is the other). And Susskind has a few favourites that he always returns to, especially when he is stuck or confused.

"He thinks of black holes as an infinite lake with boats swirling toward a drain at the bottom, and he envisions the expanding universe as an inflating balloon.

"However, the real art of analogy, he says, "is not just making them up and using them, but knowing when they're defective, knowing their limitations. All analogies are defective at some level."

"A balloon eventually pops, for example, whereas a universe does not. At least not yet."

31. **gunpowder&noodles**
August 3, 2006

The Chinese invented Pythagoras's theorem hundreds of years before Pythagoras. They were knitting woollen sweaters 6000 years ago when Europeans were wearing skins. They invented tiramisu 10000 years before the Italians, and were watching TV 20000000 years ago when Europeans had not even evolved eyes yet. No grounds for surprise that they proved Poincare first.

32. **Sarah Noah**
August 4, 2006

Perelman certainly deserves the Fields, I think only he and Grothedieck are the only two great mathematicians who do not pay attention to fame and glory, as I know. Does the proof of the geometrization automatically include a proof of the Poincare conjecture?

33. **Peter Woit**
August 5, 2006

Sarah,

I agree Perelman deserves the Fields. But there are plenty of other great mathematicians who don't seem to be very interested in fame or glory. Grothendieck didn't turn down the Fields medal, and his refusal to accept the Crafoord prize came when he was already isolating himself from the world in an eccentric fashion. In "Recolte et Semailles" he has harsh things to say about Deligne, which seem to be based on his feeling that Deligne was getting credit for his ideas.

Yes, geometrization includes Poincare as a special case.

34. **Jeremy Longman**
August 7, 2006

Peter,

Grigori Perelman carried out the program of Richard Hamilton with some new methods. Cao-Zhu's paper claims it grows out of the theories of Hamilton and Perelman and completes the proof of the Poincaré and the geometrization conjectures (from what I read, Perelman's papers seem to grow out of the work of Hamilton and others too). Cao-Zhu's paper is published in a refereed journal. Unless it is found that there are gaps or even errors in the Cao-Zhu paper, should the proof of the conjectures be considered as finished? If so, are the Kleiner-Lott paper and the Morgan-Tian paper appeared a little too late? Especially for the Morgan-Tian paper, it was posted on Arxiv one month after the publication of the Cao-Zhu paper.

Jeremy

35. **Lilian**
August 7, 2006

As concerning if Morgan-Tian's paper is too late, everyone knows they have been working on it and by the time Zhu and Cao were done with their paper, Morgan and Tian had their ready also. I think they were just trying to polish the paper but when they saw Cao and Zhu's came out, they believe it was time to have theirs published. That's my guess.

36. **Walt**
August 7, 2006

My guess is that since there's a gigantic mess for who gets credit for what, that everyone will just sidestep the issue, and call it the Geometrization Theorem or something like that. The Clay Institute doesn't have that out, of course.

37. **Peter Woit**
August 7, 2006

I believe Morgan-Tian went to the referees in May, before the Cao-Zhu manuscript was available, so their work was completely independent. Most of Kleiner-Lott was freely available on the web quite a while ago, long before they posted a version to the arXiv, and Cao-Zhu refer to this in their paper. Kleiner-Lott worked out many details of Perelman, but didn't write up a full proof of Poincare.

My own guess about how the math community will ultimately apportion credit for this is that the proof is based on Hamilton's program, that important new ideas were required to make it work, and that those are due to Perelman. It seems that Perelman's outline of a proof was essentially correct. Credit for working out the details of Perelman's proof will go to a sizable group of people, including Kleiner-Lott, Cao-Zhu and Morgan-Tian, but I'd be very surprised if the Clay committee considers this kind of work something that should be rewarded with part of the million dollars.

38. **Jeremy**
August 7, 2006

Peter,

What happens if Hamilton had claimed that he had given outline of a proof to the Poincaré and the geometrization conjectures in 1982, when he first introduced the Ricci flow approach, then he would leave it to the others to fill in the details (gaps)? Of course, he didn't. He went on to fill in the details and faced some serious difficulties. But if he did, would Perelman's work also be considered as filling the details?

Hamilton started the program. He did not finish it, probably because he didn't know how to fill in some the details. Is it possible that Perelman also didn't know how to fill in some of the details of his outline?

Perelman is a great mathematician. So is Hamilton. Their work has shown that. But it does not mean that they know how to complete the proof of the conjectures.

Kleiner-Lott devoted much of their almost 200 pages paper to fill in Perelman's gaps; Morgan-Tian devoted a large part of their more than 400 pages paper to fill in some of Perelman's gaps (not including geometrization); Cao-Zhu devoted a large part of their more than 300 pages paper to fill in some Perelman's gaps and some Hamilton's gaps (Cao-Zhu do have some of their own ideas to fill in Hamilton's gaps). Obviously, these are not small gaps. Are they?

Cao-Zhu, Kleiner-Lott and Morgan-Tian must have faced and solved many serious difficulties too. Kleiner-Lott did not write up a complete proof, but Cao-Zhu (for Poincaré and geometrization) and Morgan-Tian (for Poincaré) did. I believe that they all should share the credit with Hamilton and Perelman for completing the proof of the Poincaré conjecture. In fact, if there is nothing wrong in their papers. They are the ones who really completed the proof. Right?

As for the prize money. None of the U.S. based professors really need it. Do they?

39. **woit**
August 7, 2006

Jeremy,

Hamilton never claimed that he had an outline of a proof of Poincare that could be completed by filling in "details". The new ideas that Perelman came up with were not details, but original insights, mathematics not of a routine kind, but of the highest level. Perelman did claim that he had an outline that just required details to fill in, not any new insights. He could very well have been wrong. If so, Morgan/Tian and Cao/Zhu would have come to a point where standard techniques weren't enough to fill in the outline. As far as I know, this didn't happen, and Perelman's claims turned out to be correct.

As for the money, most people are of the opinion that they could use more. Perelman seems to be an unusual case and the story is that he doesn't want the money. I doubt Hamilton (or most other mathematicians) would turn it down.

40. **Jeremy**
August 9, 2006

Peter,

I cann't remember which professor said this: "anything that is proved is obvious, nothing is obvious before it is proved". Does this have any true in it? Can I replace "obvious" with your " of a routine kind"?

Money is such a distraction. I thought that keeping mathematics out of Nobel Prize is to keep mathematicians concentrated.

41. **Peter Woit**
August 9, 2006

Jeremy,

It's certainly true that after someone has come up with a new idea, it often looks "obvious" and it's hard to understand why it was so difficult to find it. But, in this case you can look at what people had to say before the ideas were there. As far as I know, before Perelman, Hamilton was not claiming he had an outline of a proof for Poincare that could be filled in with standard techniques. He and others could have pointed you to the difficulties with pushing through Hamilton's program, and identified exactly the places where no one knew of an argument that would work. After Perelman, everyone seems to acknowledge that he found possible ways around these problems, although at first no one was sure whether the details could be successfully filled in, as Perelman claimed (and was willing to often back up by providing details when asked for them). A pretty good definition of a non-obvious (or not of a routine kind) argument is one that the leading expert on the field (Hamilton) wasn't able to find despite working on it for quite a while.

Again, as far as I know, Cao-Zhu, Kleiner-Lott, and Morgan-Tian did not run into any problems in their work that they would describe as requiring the kind of original ideas that Perelman came up with.

42. **Janet**
August 10, 2006

Hi, Peter, saw the following question under your name:
Did Yau really claim that he was the one who solved the Poincare Conjecture? If so, that would be seriously misleading. # posted by Peter Woit : 20/6/06 12:14
http://rivelles.blogspot.com/2006/06/strings-2006-day-2.html

Here is my personal opinion and some facts plus other trivial interesting things.

There was an interview with ST Yau on Qiao Bao (Chinese Overseas Newspaper), the media has little or no comments on the Poincare Conjecture and its solvers. It was question and answer type. Yau did claim that he was ONE of those who contributed to the Poincare Conjecture. But he did NOT CLAIM that he solve it. However, in another interview and talk, in which he composed a very beautiful poem (at least it's interesting poem) that describes his efforts and fascination in Poincare Conjecture. For contribution percentage, he modified a little in the QiaoBao, he probably didn't make clear before that: CHINESE MATHEMATICIANS'S TOTAL CONTRIBUTION TO THIS WHOLE WORK [Poincare Conjecture? or Topology or Ricci Flow or Geometrization? I do not know] IS NOT LESS THAN 30%. Previously, I read on a newpaper that quoted as Cao and Zhu's work takes about 35% of the credit. But this is probably a loose statement and might not be what Professor Yau meant–but I dont know; and I don't know if he intended to mislead the Chinese media, to be fair. Well, Zhu and Cao, on the other hand, as well as many Chinese mathematicians are always low-pitched and being modest. Yau is the one who gave most if not all the talks and annoucements. in fact, what he says does not represent what many of the Chinese mathematicians think. And many of the Chinese Mathematicians do not even agree with them. And to those so called Chinese Academicians, as he calls them, Yau claimed that he would personally offered 10000 yuans or dollars to whoever is able to understand Cao and Zhu's work and the Proof of Poincare Conjecture at that moment.

Some people say since Professor SS CHERN passed away, Yau is the single most influential Chinese mathematician nowaday. It seems true. Another mathematician, Tian Gang seems to be very prolific and able too. Out of Curiosity, I looked up Math Genealogy and found out Professor Yau's students–most of them are very successful mathematicians on their own. I think Yau would probably get the Wolf Prize soon for this. After all, he's got Fields, Crafoord, Veblen, MaCarthy Fellowship such big ones, Wolf may be coming too. who know. Among all the Fields Medal winners, only Yau have so many successful students so far. Mathematical Monster–an nick name I once heard given to Professor Thurston for he's such a haughty genius and polymath that some, if not most, of us envy yet respect. Read this, ts interesting!
http://www.news.cornell.edu/chronicle/02/11.21.02/Thurston_profile.html
It's interesting to note that Thurston is one of the few who received the Alan Waterman Prize, the first one being Fefferman. Other receipients are Gang Tian, Edelsbrunner, Emmanel Candes, Friedman. But the only ones who are of the same rank as Thurston are perhaps the undisputed (genius and polymath): Bombieri, Charles Fefferman, (Bourgain?). However, all four of these geniuses do not yet have as many successful students as Yau, though Thurston has done way better than the other three genius-polymathes, and has Kerkoff, Gabai etc being the most outstanding ones. Probably geniuses are just like concentrating on their own work or maybe they have not met the right students and have high expectation for their students, who knows. Sometimes working with a genius can hurt one's feeling of being an ordinary scholar. But being an ordinary math student is also fun–nevertheless it's life that we live. But anyway, hey, less than 2 weeks left for ICM…I am so looking forward to it!!!Everyone says Terence Tao and Perelman are on the Fields Medal list, we'll see.

by the way, now we have so many prizes in math: Abel, Fields, Wolf, Shaw Prize, Crafoord, Shock, Alan Waterman, the New Gauss Prize etc. Can you tell us a little more about the significance of each? Which do you think is the single most prestigious that every math department respects? Anyone like to rank them in order of importance? It's nothing but some little fun. Thanks for your time.

43. **Michael Edwards**
August 10, 2006

William Thurston is the most approachable mathematician I've ever met, with the possible exception of John Horton Conway (when he's in a good mood). They do both expect that their interlocutors make the best effort they can to understand the matter under discussion; it would not surprise me if it is somewhat hazardous to give Thurston the impression that you are mathematically able and then disappoint him. Thankfully I never had that problem. 🙂

Cheers,
– Michael

44. **Walt**
August 10, 2006

I read a survey article by Yau on arxiv (sorry, I don't know the number) that seemed very level-headed, and did not in anyway exaggerate the contributions of himself, or Cao and Zhu. So I think there's nothing to this.

45. **Lilian**
August 10, 2006

Hi, Walt, I read that too. Unfortunately you will never find information like Janet posted in the Arxiv or any other Math Journal, Media etc in English. The talks and interviews are mostly in Chinese. In fact, even in Cao and Zhu's paper, they are being very humble and very excited about the work they are undertaking. They are truly exceptional mathematicians who have done some very important and valuable piece of work. They shall be praised for their work. But someone, don't remember whom, said: "(Yau) threw a monkey wrench into the question of who gets the credit." One can not get a whole picture of what is going on if she doesn't read a lot (not only in English) and follow closely. I don't know about the truth but just share my information here. Thanks.

46. **conjecturedepoincaré**
August 11, 2006

The September issue of the Notices is out, and has an article by Allyn Jackson about the Poicaré Conjecture ("Conjectures No More?: Consensus Forming on the Proofs of Poincaré and Geometrization Conjectures"). I haven't had the time to read it completely yet, so will not comment on it.

47. **Deane**
August 11, 2006

And watch for the article in the New York Times on Tuesday.

48. **nonblogger**
August 11, 2006

Another pre-ICM hint: Tao has put a more recent picture of himself on his webpage these days, and I can't imagine this is purely coincidental 😉

49. **Lilian**
August 12, 2006

Allyn Jackson's report is great!! Excellent reading!!

50. **Lilian**
August 12, 2006

By the way, how many fields medalists have been chosen this year? Tao, Perelman, who else would be a good candidate? I heard that there were going to be three of them?

51. **anonymouse**
August 12, 2006

Lindenstrauss, McQuillan

52. **Lilian**
August 16, 2006

Today's New York Times (Science Times Section) convers news on Poincare Conjecture! Worth reading! 8-15-06 Tuesday

53. **comentator**
August 16, 2006

In the las ICM the "sure" bets (that were not) were:
Tao, Borodin, so it is safe to say that in this time they could be amongst the winners and Perelman of course.

54. **Ghost of Marshall Hall**
August 16, 2006

Potential winners:

As mentioned: Tao, Perelman

Others (but likely some other time):
Green, Pandharipande, Knutson, Darmon

55. **Jeremy**
August 18, 2006

After collecting information from the Hamilton's paper (1982), Perelman's three papers (2002, 2003), Cao-Zhu paper (2006), Kleiner-Lott paper (2006), Morgan-Tian paper (2006), as well as the articles by Sharon Begley (The Wall Street Journal), Allyn Jackson (AMS) and Dennis Overbye (The New York Times), a theory of the winners and losers in the proof of Poincare conjecture and the geometrization conjecture has been formed. The theory is described as follows:

Theorem (Winners-Losers): There are winners and losers in the proof of Poincare conjecture and geometrization conjecture.

The winners are: Hamilton, Perelman, Cao-Zhu, NSF, JSG Memorial Foundation, NSF of China, Harvard University and Tsinghua University in Beijing.

The losers are: Kleiner-Lott, Morgan-Tian and Clay Mathematics Institute.

The biggest loser: Clay Mathematics Institute. ||

A complete proof of the Winners-Losers Theorem is given in the Appendix.

Corollary: Losers speak first. Winners speak last. ||

This corollary arrives naturally and it is even true in sports and politics.

Appendix

For later reference, we start by introducing the well-known Theorem of Publication.

Theorem: Publish after the publication of others on solving the same problem equals publishes nothing, i.e.

P(t) = 0 for t > t_(P of others).

Here P stands for publication and t is time. ||

Now we proceed to the details of the winner-loser theory.

Hypothesis: All statements and claims made in the Cao-Zhu paper, Kleiner-Lott paper and Morgan-Tian paper are accurate and correct. ||

The following is the proof of the Winners-Losers Theorem.

Proof

We first give proof of the winners.

Hamilton had the vision to first introduce the equation of Ricci flow to the proof of the geometrization conjecture and laid the foundation for the Hamilton program. He has many mathematicians believed in and participated in the program. Perelman agreed that his own work was to carry out the Hamilton program. Cao-Zhu also acknowledged that their work is part of the Hamilton program. The final proof of the conjectures has vindicated Hamilton's vision. Therefore, a winner. (Very likely, the Ricci flow equation will be renamed as the Hamilton Equation.)

Perelman shared Hamilton's vision and made the most critical contribution to push through the Hamilton program by bring in new ideas and new techniques, which made others realize that his claim to the proof of the geometrization conjecture, therefore the Poincare conjecture, could very well be true. Probably more importantly, the new techniques he developed will help the future development of mathematics. Although he left many less critical issues unsolved, some of those can be considered as details, the final proof of the conjectures has proved that his statement was accurate. Therefore, a winner. (The Poincare Conjecture will almost definitely be renamed as Perelman Theorem.)

Cao-Zhu worked on the conjectures in secrecy, except to the Harvard mathematicians. They used much of the Perelman's work, but did not limit themselves only on filling Perelman's details, which enable them to keep a broader vision in pushing through the Hamilton program. After combining other people's work with their new ideas, they could first publish a complete proof for the Poincare and geometrization conjuctures. Therefore, winners. (The geometrization conjecture may very well become Perelman-Cao-Zhu Theorem.)

Cao-Zhu has certainly pulled off a coup when the publication of their paper was first announced in April 2006.

NSF and JSG Memorial Foundation have been funding the work of Cao; NSF of China has been funding the work of Zhu. Obviously, funding winners makes them winners.

Harvard University supported Zhu's work; Tsinghua University in Beijing supported Cao's work. Winner's supporters are clearly winners.

Now we give proof of the losers.

Kleiner-Lott have been narrowly following Perelman's work, but posted their findings for everyone to use. Unfortunately, they lost their concentration on the larger picture, the relationship of Perelman's work with other people's work. Filling in Perelman details has been proved not to be easy. The announcement of the forthcoming Cao-Zhu paper in April 2006 has been a surprise and total shock. Unable to complete their paper in time and were very much aware of the implication of the Theorem of Publication, Kleiner-Lott posted their unfinished paper on the non-refereed arXiv at the end of May, a few days before the appearance of the Cao-Zhu paper. Kleiner-Lott still plan to publish their paper, but after the publication of the Cao-Zhu paper and the Morgan-Tian paper, (Morgan-Tian paper uses many Kleiner-Lott's results), the publication of their paper becomes much less meaningful considering the Theorem of Publication. Therefore, losers.

Morgan-Tian have also been narrowly following Perelman's work and busying on filling Perelman's details. At the April 2006 announcement of Cao-Zhu paper's publication, they haven't even filled the details for a part of the Perelman's work. Fully understood the implication of the Theorem of Publication, they sent a preliminary version (i.e. unfinished version) of their paper for refereeing in May, just before the Cao-Zhu paper's June appearance, to show that their work was independent. The final version of their finished paper was posted on the non-refereed arXiv more than a month after the publication of the Cao-Zhu paper. By the implication of the Theorem of Publication, there will always be suspicion that the final version of the Morgan-Tian paper has been inspired and has benefited from the Cao-Zhu paper. Therefore, losers.

The final version of the Morgan-Tian paper is more than 400 pages and only filled the details of a part of the Perelman's work. Among other things, it certainly has proved that "the details for a genius could be major problems for common men".

As the supporter of the losers, Clay Mathematics Institute is obviously a loser.

Finally, we give proof of the biggest loser.

Clay Mathematics Institute has a big treasure chest to back up its list of millennium prize problems. However, whenever the millennium problems are concerned, Clay Institute should support the mathematics community as a whole (support its conferences, workshops etc.), rather than support individual mathematician(s). Its role should be of a referee rather than a player. Once it starts to support individual mathematician(s), it may be viewed as playing favoritism. Perelman might very well consider that Kleiner-Lott and Morgan-Tian are taking advantages of his work, under the support of Clay Institute. Other mathematician may think that Clay Institute intended to give the prize to mathematician(s) of their choice even before the problem is solved. The prize money may then be considered as "tainted". The honor of the prize is therefore completely lost. The only thing that left is money. Giving out money that does not have widely recognized honor is truly meaningless. (There are people who really do not care about money!) Therefore, Clay Mathematics Institute is the biggest loser.

End of proof.

56. **Jeremy**
August 21, 2006

Should Clay Institute have supported Perelman?

http://www.telegraph.co.uk/news/main.jhtml?xml=/news/2006/08/20/nmaths20.xml

57. **Student**
August 23, 2006

Does anyone know Hamilton's opinion on the issue? Namely, Does he think that any of the "complete proofs" adds true substance to the solution?

58. **Lilian**
August 24, 2006

Hamilton gave a talk in the ICM, representing Perelman in receiving the prize. However, it seemed that he talked much about what he thought would work rather than describing what Perelman has done and the impact of his work. Probably he has taken ST. Yau's flattering 50% contribution to the Poincare Conjecture and did not view Perelman's contribution as important.

59. **woit**
August 24, 2006

Lillian and Student,

I don't believe Hamilton was "representing Perelman", rather that he was invited to talk about his own work, and this invitation was issued long ago, when the IMU still hoped to get Perelman to come and speak himself. From hearing Hamilton talk about this, I see no evidence that he does not view Perelman's contribution as important, quite the opposite. You'd have to ask him what he thinks of Cao-Zhu, I don't know. But I've always had the impression that he hasn't been all that interested in the project of filling in the details of Perelman's proof using Perelman's methods, preferring to see if he can use his own ideas to do some of the needed steps. He's a very original mathematician, and such a person generally wants to do things their own way.

60. **werdna**
August 24, 2006

In their New Yorker article, the authors write:

"Mathematicians familiar with Perelman's proof disputed the idea that Zhu and Cao had contributed significant new approaches to the Poincaré. "

They then went on to quote only John Morgan to support this statement. It would have been more helpful to hear comments by other mathematicians, not just someone from the Morgan-Tian camp.

61. **Student**
August 24, 2006

I am not technically capable of evaluating the involved works, but am curious to know what the "consensus" is among experts.

From what I read/felt, Morgan-Tian viewed their work as largely a community service — to help people understand Perelman's proof (and Clay to legally claim Perelman a winner — to have a peer reviewed publication, albeit not by himself); they didn't claim to have added anything substantial.

Cao-Zhu however did claim substantial technical contributions, althoguh it is interesting that they said that they made them not because Perelman was wrong, but because they could not understand how he could, so they took on their own.

The question is whether these "contributions" are substantial or not. Morgan thought they are not, but did not elaborate. and Yau seemed to think otherwise.

When the PR storm about "crowning achievement" was going on in China, Hamilton was actually visitng that country (for "personal reasons", as I heard — rumor has it that it involved a certain lady), and despite all the media fuss, he did not make any comment, other than that Cao and Zhu are excellent mathematicians. Being a close friend of Yau's and the perceived authority on this matter, his silence could be explained as a withhold of endorsement (of course, it is totally possible he is just uninterested, especially given the non-math mess surrounding this).

But then I read the abstract of Hamilton's ICM talk and it mentioned Perelman AND Cao-Zhu.

I agree that he probably wouldn't feel that Cao-Zhu is a big deal even if it has substance (after all, these are details…). But I am interested in knowing how he put it into the context. Did he think that the deal was done 3 years ago (although we wern't sure until now), or 2 months ago (with Cao-Zhu)?

Lilian — if you were at his talk, could you shed some lights?

62. **Jessica Lau**
August 25, 2006

Read Silvia Nasare and Gruber's elaborate portray of the Poincare Conjecture and Perelman. It's an excellent piece of work! Accurate information! Fair report!!
MANIFOLD DESTINY
A legendary problem and the battle over who solved it.
http://www.newyorker.com/fact/content/articles/060828fa_fact2
What it says in the article is very accurate. But critics and supporters of Yau and others may be unhappy about what it says there. Well that's the true story! I once read a review posted in this forum, reviewer was something like "Milnor the Giant" or something like that, that person is pretty fair and stood up to point out the unfairness and hierachy in mathematics community. It seems Yau is a fame seeker, well, different people may not feel the same way. But that guy's review is just interesting.

Perelman – Yau :The comparison very clearly establishes Perelman as a hero. He considered himself a disciple of Hamilton but only without Hamilton's authorization–I think it's a very modest yet somewhat souring comment that may has resulted from what Perelman felt about other people, in this case, Mr. Hamilton and Yau etc. As a Chinese myself, I deeply respect and admire Perelman yet feel a bit shameful of the other. Remember, not all Chinese mathematicians are like that. SS Chern, Loo-Keng Hua, Jingrun Chen, they are all humble and honest mathematicians.

63. **Herman**
August 25, 2006

Interesting report!! I think it's very fair, honest and accurate report too! A few quotes from Perelam in Nasar and Gruber's article:

"It is not people who break ethical standards who are regarded as aliens," he said. "It is people like me who are isolated." We asked him whether he had read Cao and Zhu's paper. "It is not clear to me what new contribution did they make," he said. "Apparently, Zhu did not quite understand the argument and reworked it." As for Yau, Perelman said, "I can't say I'm outraged. Other people do worse. Of course, there are many mathematicians who are more or less honest. But almost all of them are conformists. They are more or less honest, but they tolerate those who are not honest."

64. **Herman**
August 25, 2006

Yep! He's right!! Expository article only deserves at most a Steele Prize!! It's original ideas that open new field in research that's of upmost importantce! I agree with you Jessica!

65. **Herman**
August 25, 2006

"Politics, power, and control have no legitimate role in our community, and they threaten the integrity of our field," Phillip Griffiths said.

66. **Lilian**
August 25, 2006

Hi, Woit, I agree with most of your views, and that "(Hamilton) He's a very original mathematician, and such a person generally wants to do things their own way." But for the past ten years, he has not produced any significant results and his research hasn't gone any further. Well, it would still be very interesting to see his own way of completing the program!

Response to Student:

Well, I believe Hamilton would be far more delighted in solving the problem himself rather than being a spectator of it for ten years. ST Yau once played a recorded speech that Hamilton commented on Chinese Mathematicians (in particular Cao, Zhu and Yau)'s contribution to Poincare conjecture (and Differential Geometry) and Hamilton did not emphasize the importance of Perelman's contribution but Yau's suggestive ideas. In his ICM talk, he even stated that he and Yau were the main developers of Ricci Flow. Well, I really don't know how true that is. 1) What he said is true; 2) he just wanted to be nice to Yau or flatter him–you know, Yau is quite influential in today's mathematics.

Hamilton certainly made great contribution, but Perelman's may be more of a revolutionary type. What you guys think?

67. **Lilian**
August 25, 2006

One forum http://www.popyard.com/cgi-mod/page.cgi?cate=1&page=1&r=0 that I came across attacked Silvia Nasar's report! those are idiots. I am sure Nasar had received numerous harrassing emails from Yau's supporters!!

68. **Matheu**
August 25, 2006

There is an article on a Chinese newspaper, Science Times, based on an interview with Shou-Wu Zhang, a Professor at Columbia University. It contains some interesting Q&A between Zhang and S-T Yau. The following is a translation:

Zhang, "Can we call it Perelman-Zhu-Cao Theorem? "

Yau, "No. The contribution by Hamilton is the most, most important."

Zhang, "Should we call it Hamilton-Perelman Theorem?"

Yau, "No. Strictly speaking, Perelman's papers posted on the internet are just sketches of the proof. You can't say that he proved Poincare and Geometrization conjectures."

Zhang, "Should we call it Thurston-Yau-Hamilton-Perelman-Zhu-Cao Theorem?"

Yau, "That's correct. Although the name is a bit long, it gives indication of everyone's role."

[Note: I have edited this to fix it, the original version incorrectly dropped Perelman's name from the last list of names. PW]

69. **Student**
August 25, 2006

Folks, let's focus on math. Last time I checked, Yau is an American.

Again I am not working in this field, thus cannot judge if Silvia Nasar's report is "accurate" on otherwise. I did read on the web that some in the field is very critical to the report (this is secondhand, since I don't know the said commentator in person). This is complicated matter, so complicated that even experts within the field (in addition to those who have a stake) are still debating. I would not be surprised if Silvia Nasar's report reflects the views of some, but not others, in the field.

And precisely because of this complexity, I am very interested in the opinion of Hamilton's own. Not that he has devine power to judge others, but after all, this is his theory, even though he got stuck on it until Perelman showed up.

I feel a bit guilty that we have stretched the strig a bit too long on this one 🙂 But Peter has the advantage of being next to Hamilton (and Morgan), so maybe he can share with us something he overheard in the hallway 🙂

70. **Student**
August 25, 2006

This is from ICM Daily News:

[Quote]

Richard Hamilton (University of Columbia, New York, USA) finished his plenary lecture yesterday, the first of the ICM2006, by saying that he felt incredibly happy and enormously grateful to Grisha Perelman for finishing his work:"In this way we actually get a proof of the Poincaré Conjecture"

… …

Hamilton said that he had a "profound admiration" for Perelman's work, and that he would be "delighted to work with him in the future". He said that he had met Perelman personally, but he was not prepared to comment on Perelman's refusal to accept the Fields Medal conferred on him on Tuesday at the ICM2006. However, Hamilton did say that "it is not fair to criticize his position".

Hamilton was also asked abut the Chinese mathematicians Xi-Ping Zhu, from the University of Zhongshan (Canton, China), and Huai-Dong Cao, from the Lehigh University in Pennsylvania (USA), who last June published a paper in the Asian Journal of Mathematics. In the abstract of this paper the authors state that they present "a complete proof of the Poincaré and Geometrization Conjectures". Hamilton is sure that "there is no controversy" because both mathematicians

are “great researchers”. According to Hamilton, the
controversy surrounding the proof of Poincaré’s
Conjecture was caused by the press. He went on to say
that Perelman’s work “is difficult to understand” and at
some points even Perelman himself employs the term
“sketch”. “A sketch is an invitation to complete a finished
work, to find a way of doing it better. But no criticism is
implied in this, only the wish to help to solve a problem.
There is no controversy involved. Grisha is a model of
decorum and there is no dispute about who did what”.

… …

[/Quote]

Very diplomatic. Still no answer to my question, but I guess that’s all we could get out of him …

71. **tg**
August 25, 2006

Dear Lilian, Jessica Lau et al,

Re: Nassar and Gruber’s report.

I agree that the article in question is very entertaining and probably an accurate reflection of the events. However, I also believe that it exploits stereotypes against the Chinese as “technicians” and uncouth (the latter is my own word). It singles out Yau, connects him deeply with Chinese mathematics, while downplaying the fact that many mathematicians (and academics) act very similarly although in much less famous circumstances.

I and my colleagues on the “2006 Fields medal winners” forum of this blog have debated the relative merits of these points at length, so I kindly point you to the discussion there.

My purpose in introducing this link of discussion is to counter Lilian’s assertion that “attackers” of Nasar and Gruber’s report are “Yau supporters”. In my case, I support myself — I am of Chinese (descent) — as are you, Jessica Lau. Don’t you think that stereotyped attacks against a figurehead such as Yau (“figure head” — a position that Nasar and Gruber go at length to assert, although it is irrelevant mathematics involved) affect Chinese (and asian) opportunities in academics? I do.

I also kindly point you to September’s Notices of the AMS article (available online at http://www.ams.org/notices/200608/200608-toc.html)
where further discussion of the position of Asians in mathematics is discussed.

72. **Peter Woit**
August 25, 2006

student,

I’m not at all informed about Hamilton’s current views, know Morgan’s much better, but in neither case would it be appropriate for me to repeat things here they told me privately. I can say that everything I’ve heard from them is consistent with what they are saying publicly. Morgan worked hard for a long time on the project with Tian of writing up a complete proof of Poincare, and in the end found that Perelman’s sketch of a proof held up, you really can fill in all the details. As he told Nasar, he sees the Cao-Zhu version as also closely following the Perelman sketch.

As for Hamilton, ever since Perelman’s papers came out, lots of people have wanted to know if he thinks Perelman’s sketch can be completed to a true proof. My impression is that this is just a question he’s not very interested in, that he’s also not interested in getting involved in the politics of this, and he hasn’t wanted to talk to the press. He agrees that Perelman has come up with important new ideas, and I think what he is interested in is seeing what he can do by putting these together with his own techniques.

One interesting thing about the Nasar article was Perelman’s comment about how grateful he was to Hamilton for Hamilton’s openness, generosity, and willingness to share his ideas. Since he has been here at Columbia, Hamilton has often run a seminar, in which he discusses in detail his latest work in this area and shares with others what he has been figuring out. His contributions to research in this area go beyond what is just in his published papers.

73. **Student**
August 25, 2006

Thanks Peter. I particularly appreciate the comment about Hamilton.

74. **Matheu**
August 25, 2006

Peter, thanks. Could you please re-edit to remove my correction?

Now, from Morgan’s public talk, he says the following about the credit for proving Poincare conjecture, contradicting to what Yau said.

“Can we say that Perelman has proven the Poincaré Conjecture?
Yes, I would say and I will say today that Perelman has proven the Poincaré Conjecture. But one has to understand that he would not have done it without Hamilton’s work. Yet, in the culture of mathematics it is my view that the credit for proving the Poincaré
Conjecture should go to Perelman.”

75. **TruthSeeker**
August 26, 2006

From reading the NewYorker article, I did not get any impression about stereotypes that tg mentioned above, and neither did many others who posted here and elsewhere in the blog. Instead, I had the feeling that the authors were trying to write a hero-villain story with Yau being the bad guy and Perelman the hero, of course. His heritage was mentioned in order to give context to and help explain his behavior. (There is the quote, e.g., “Yau’s not jealous of Tian’s mathematics, but he’s jealous of his power back in China.”) So I thought it was necessary that the authors describe his Chinese roots.

However, I thought they were too eager to portray him as the villain that they failed to mention relavant, important details about his life. For example, it is well known that Yau has been passionate about fighting corruptive practices in academia in Communist China, to the point of being censored by the PRC. He is also known to be the rare scholar who insists on not taking a salary when lecturing or engaging in other scholarly activities in China, even though generous compensations must have been offered him, being who he is.

But such stories were not told in the article, because they would weaken their thesis that Yau was dishonest or manipulative. Whether he is dishonest or not in the handling of this Poincare incident, I do not know. It may very well be that he honestly thinks Perelman's proof is too sketchy and that filling in those details is far from routine or straightforward. Let the mathematical community take the time to go through all the manuscripts carefully, and let them give their most objective opinion, without the influence of politics. If it is determined that Yau is wrong (in his assessment), then I think he should apologize one way or another. We must give credit where credit is due.

76. **tg**
August 26, 2006

Dear Truthseeker,

You raise an important question with respect to the ways in which mathematicians (academics) assign credit, which I think deserves communal analysis, since it's often subjective. Here are a few (common) scenarios.

(1) "A" claims a solution to a problem, gives the statement of the solution (e.g., a formula) that is clearly brilliant and nonobvious, and by all checks (e.g., by computer) is correct, and says the proof is by induction, but leaves all the details out. "B", needing the formula finds no proof (and "A" will not respond to his questions about the proof) and goes about doing the induction. It's hard work, but eventually an induction proof works. Afterwards "A" says "I told you so". But where was he when the details were being worked out?

(2) Same as (1), except "A" doesn't claim to have a proof, but says _probably_ an induction works.

(3) "A" says he knows how to solve a problem but isn't there yet, and tells people his progress. "B" hears about "A"'s work and with hard work completes the proof.

(4) Same as (3) except "A" says he's done what he can do.

(5) The same as (1)-(4), except "A" and "B" are actually friends. They wonder whether it's appropriate to coauthor a paper together.

In all scenarios "A" clearly deserves credit, in my opinion. But what about "B"?

Personally, I think "A" is a jerk in scenario (1), but realizes that if he allows scenario (2) then he'll be a sucker, since mathematicians usually credit the person(s) who finish the job, and he wants all the credit to himself. As humans, we don't like people dishonestly exploiting other's hard work for their own fame — in which case maybe we should highly credit "B"'s work, since we wouldn't want to fall into, gasp, physics like rigor.

In (3), "B" is a usually regarded as a "thief", but in (4) he'll be given excellent credit as the "finisher".

In (5), they could fairly write a paper together, and the result would be the "A-B's theorem" for all time.

How do Perelman, Hamilton and Yau et al. fit into these scenarios?
No one doubts Perelman's contribution! But whether Yau et al deserve any credit depends (in the above scenarios) highly on what Perelman claimed know or not know.

One could argue that clearly it wasn't so obvious to even Perelman that he actually solved Poincare, or he would have dared to say so in his papers, right?

77. **Deane**
August 26, 2006

"One could argue that clearly it wasn't so obvious to even Perelman that he actually solved Poincare, or he would have dared to say so in his papers, right?"

In fact, in his third preprint, Perelman quite explicitly claims to prove the Poincare conjecture. He just doesn't call it the "Poincare conjecture". If I recall correctly, he calls it the "elliptization conjecture" (parallel to Thurston's "hyperbolization theorem"), but its statement is exactly that of the Poincare conjecture.

78. **tg**
August 26, 2006

Dear Deane,

I stand corrected then!

79. **TruthSeeker**
August 27, 2006

tg,

Questions about assigning credit and authorship can in some cases be tricky indeed. Even guidelines such as those issued by the AMS (see http://www.ams.org/secretary/ethics.html) are only that — guidelines. For example, their website says that researchers have the responsibility to publish "full details" of their (new) results. But the word "full" is not well defined. Did Perelman's papers, for example, contain full details? I think different experts will have different opinions on this matter. I guess that's why a committee called COPE (Committee on Professional Ethics) was set up by the AMS, an important function of which is to handle disputes. But even their final decision is only an opinion, a "best" judgment arrived at by examining the circumstances of the individual case and the existing practices and conventions of the field. And different fields do have different standards. (In chemistry, e.g., it is typical to automatically add an advisor's name to a graduate student's paper, regardless of contributions made, but this practice is much rarer in mathematics.)

Regarding the various scenarios you listed, let me offer my best opinion. In cases 1, 2, and 4, "A" cannot expect to publish his result by itself in a mathematical journal without a proof, even though his formula may be correct. If "B" comes up with a proof, I think he is obligated to list "A" as a co-author, assuming that the formula has not been published elsewhere before.

In the case of (3), B's behavior could lead to a poor reputation at best or plagiarism at worst (if he doesn't give proper credit in his paper containing the ideas of "A"). Ideally, he should have discussed his intention with "A" and work out some kind of a joint authorship.

You may want to look at other examples discussed in the COPE manual (http://www.ams.org/secretary/copemanual.pdf).

80. **Whu**
August 27, 2006

When reading this thread, I think one question has not been answered. Who should we blame for Dr. Perelman's feeling of be isolated?

In that article in "New Yorker" by Nasar, the author tried to convince audience that Dr. Perelman wanted to be isolated because of the dishonest or dictatorship of YAU. Is it true?

Dr. Perelman, who at least provided a schetch to prove Poincare conjecture, left the US in 2003 and stayed away from the math world since then. Yau and his students started their journey in 2004 funded by NSF, to investigate Dr. Perelman's proof. They completed it in May 2006. Assume YAU has attempted to take credits from Dr. Perelman. But this must have happened very recently in 2006. However, Dr. Perelman have the feeling of being isolated because of dishonest back in 2003 and beyond.

I, a teacher of chinese national, doubt the author's intention. I admire Dr. Perelman's terrific work and that of Yau too, about which I actually can only understand the first page of their papers. However, I feel uncomfortable that the author distorted the fact and made Yau a Godfather from Chinatown, which, seems to me, one of the strerotypes some in the US and Europe feel comfortable when thinking about China or anybody related to China.

81. **TruthSeeker**
August 27, 2006

I don't think Perelman attributed his sense of isolation to Yau, or at least not solely or primarily to him. It says in the article that "he mentioned a dispute that he had had years earlier with a collaborator over how to credit the author of a particular proof, and said that he was dismayed by the discipline's lax ethics." And, regarding Yau, he said: "I can't say I'm outraged. Other people do worse…" He seems to be saying that there are worse offenders in the math community.

82. **MathLover**
August 27, 2006

Peter,

Thanks for your blog and discussions here. I'm a math lover and of origin from China. The discussion about Poincare conjecture and Perelman has now a new dimension. Let me first quote two posts below:

Jessica Lau Says:

http://www.math.columbia.edu/~woit/wordpress/?p=434#comment-15043

"Perelman – Yau :The comparison very clearly establishes Perelman as a hero. He considered himself a disciple of Hamilton but only without Hamilton's authorization–I think it's a very modest yet somewhat souring comment that may has resulted from what Perelman felt about other people, in this case, Mr. Hamilton and Yau etc. As a Chinese myself, I deeply respect and admire Perelman yet feel a bit shameful of the other."

TruthSeeker Says:

http://www.math.columbia.edu/~woit/wordpress/?p=434#comment-15091

"I had the feeling that the authors were trying to write a hero-villain story with Yau being the bad guy and Perelman the hero.

However, I thought they were too eager to portray him as the villain that they failed to mention relavant, important details about his life. For example, it is well known that Yau has been passionate about fighting corruptive practices in academia in Communist China, to the point of being censored by the PRC.

Let the mathematical community take the time to go through all the manuscripts carefully, and let them give their most objective opinion, without the influence of politics."

I'm very thankful for TruthSeeker's remark about Yau's fighting against the corruption which has an intrinsic link to his own student Tian Gang. There is a big fight of corruption in China. Unfortunately, the corruption has swept out to academic and education areas as well. Goverment has shown only little effective control of the situation. Some (not all) scholars are corrupt; more severely, the system is corrupt. Tian is a part of this system. They promote and cover each other. It's a shame to hide this from the international community. Jessica, why not shame on yourself, you seem to enjoy the distorted report about Yau. I admire Perelman and Yau both.

I want to remind a story. Last year, an audit of an american firm (listed in NY) has lead to arrest of a high ranking corrupt officer in Chinese version of FDA. It seems that we shall push a similar pressure from outside to uncover the corrupt Chinese oversea scholars like Tian. There are several of them. Their images have damaged the fame of all other Chinese scholars. I can image, a tax audit will show they may hide their very high incomes from China.

Does Sylvia Nasser has interest to uncover it? Or shall we leave it to Dennis Overbye? It is not entertainment, it's more serious. Much more.

August 27, 2006

Morgan just declared that Perelman proved Poincare Conjecture in 2003. See the August 26 Daily News of ICM2006.

If we believe what Professor Morgan said, then what Yau did — he announced to the Chinese media that Chinese mathematicians gave the first complete proof of Poincare conjecture— is very bad. He should have known that such an announcement would cause controversy. Even worse, he accepted the paper by Cao-Zhu without stringent refereeing process and forbid the editors to read it.

85. **geometer**
August 27, 2006

"When reading this thread, I think one question has not been answered. Who should we blame for Dr. Perelman's feeling of be isolated?"

I do not think there is anyone here to blame (certainly not Yau; in fact, I doubt Perelman cares what Yau thinks of does).

"In that article in "New Yorker" by Nasar, the author tried to convince audience that Dr. Perelman wanted to be isolated because of the dishonest or dictatorship of YAU. Is it true?"

I do not see anything in the article that suggest the above. According to Nasar, Perelman explicitly say that "other people do worse", so this is not about Yau. I think, Perelman's reason is that, now that he is famous, he can no longer keep silent about what he thinks is wrong in math, while speaking up is not in his nature, so he has to quit.

86. **tg**
August 27, 2006

Dear geometer,

I can't be sure who Perelman blames for him leaving math. I don't think his "others do worse" remark exculpates Yau in his mind (or mine). Surely he (or perhaps Nasar and Gruber in their arguably highly biased article, written to appease the popular anti China sentiment in today's media) wants to come out saintly and would rather not explicitly say Yau is the cause of all (or much of) his problems.

It's worthwhile to emphasize that in the article reference is made to how Hamilton showed up late to a Perelman's lecture, or seemed indifferent. Perhaps Hamilton is also to blame in Perelman's mind (I speculate only based on the article, I don't know much about their dealings). Note, however, that this is internally consistent with Perelman's assertion that he is a disciple of Hamilton — what worse than to have that one special person who you think will fully appreciate your efforts seem less than caring?

His behaviour is consistent with an academic who feels under-appreciated and scorned. Of course, this is difficult for most of us to imagine — given the nice (for mortals) opportunities he was given in terms of academic positions in the US, well before his recent work. But maybe he expected even more. The standard conclusion now is that he proved that he did.

BUT, I want to write about another point of view on the unfortunate impact of Perelman's decisions to date. This is separate from the discussion of the controversial attitudes of Yau et al, which has received ample treatment in other comments.

Media, and future mathematicians are going to look at the model of Perelman for years to come. Do we really want the conclusion to be that mathematics is about the "lonely genius" who is incommunicative, terse, and eventually gave up on the pathetic subject that was thankless?

Frankly, if this is his attitude, I'd rather that he keep on doing (or not doing) his work from elsewhere — I'd rather not have him as part of any department I'm in (that being said, departments hoping to have him wouldn't be too interested in me!). I know various prestigious institutions would disagree — but I'd rather have faculty that are lecturing, developing graduate students, publishing, and in general contributing to the health of mathematics around me. I can always read his papers online.

The last thing the subject needs is for the public to think is that the Perelman model is what should be strived for. We have to constantly explain pure mathematics' virtue to the public, and to our peers, and to our financial sponsors. If we celebrate how to achieve this with a society of loners who hole up for a while and eventually (or probably not) create something, then I think mathematics is in trouble.

Imagine the following NY times article:

"XYZ a million year old problem got solved by this angry loner who hates everyone around him, and finally got his chance by ignoring and quitting math after proving he could solve what they couldn't. XYZ is this important math problem which is about donuts not looking like oranges. Mathematicians say that this could be relevant to black holes, but secretly many say that's just happy talk for the benefit of this article. Truthfully, an average engineering group at an average engineering department produces more relevant science for the work in a given year than XYZ will do for all of time. Finally, this problem would likely have been solved much earlier if there was more communication involved, but that's math.

Some-one-isomorphic-to-Sylvia Nasar-reporting"

87. **tg**
August 27, 2006

I think the "other people do worse" line is overplayed and can hardly exculpate Yau (in Perelman's mind). It can easily be interpreted as a public relations statement.

On the other hand, notice the article also points to the possibility that _Hamilton_ contributed to Perelman's disappointment. Specifically I speak of the passage concerning Hamilton's lack of keenness in Perelman's work.

In general, I don't agree with the model of mathematical research that the Perelman case exhibits. As a community, I think mathematics would be better off supporting and exhaulting collaborative, communicative academics than the "lonely genius" who rejects the field.

The fact that this lonely genius did manage to solve an old problem whose solution is only understood by a handful of people isn't an end that supports the means, in my opinion. Don't buy that nonsense about Poincare being relevant to black holes, or whatever. Any average engineering dept group probably produces more for this world and science in general than Poincare likely ever will. That's the bottom line when it comes to asking for public funding for our field.

If Perelman doesn't want to continue in mathematics, that's sad. But academic life is tough, and asks for many contributions beyond solving hard problems. He's been given plenty of opportunity and laudation at this point. I don't think it serves either mathematics or Perelman to massage him (or those who might sympathize with him) any further.

88. **Phil**
August 27, 2006

woit writes

"It's certainly true that after someone has come up with a new idea, it often looks "obvious" and it's hard to understand why it was so difficult to find it. But, in this case you can look at what people had to say before the ideas were there…."

Perfectly stated. That is key point.

89. **Moeen**
August 27, 2006

Given that there seems to be quite a debate over the quality of the recent article "Manifold Destiny," I thought it might be worth putting up my own points on it, so here goes:

Concerning the authors' supposed bias against the Chinese, I have to say when I first read the article I certainly didn't feel there was any bias of the sort in there, and was somewhat surprised to find commentators here claiming that. Looking at their comments, it seems like they're just read some parts of the article the wrong way and over-reacted.

For example, the accusation that the article stereotypes Chinese mathematicians as having strong technical skills is probably due to the quote by Griffiths referring to Yau where he says "He was not so much thinking up some original way of looking at a subject but solving extremely hard technical problems that at the time only he could solve, by sheer intellect and force of will." This isn't stereotyping, just pointing out what Yau's style of doing mathematics is. For example, the authors point out that Perelman's style is similar, and even compare him to Yau saying "Like Yau, Perelman was a formidable problem solver. Instead of spending years constructing an intricate theoretical framework, or defining new areas of research, he focussed on obtaining particular results."

Also, the authors aren't attacking the Chinese mathematcs community in pointing out Yau's status there. Their goal in this case is to show that Yau more or less wants to be the head of the mathematics community in China. Although Yau is an american, he seems to want to be seen as a hero for China. The authors state that "Yau believed that if he could help solve the Poincaré it would be a victory not just for him but also for China." and moreover:

Though Yau had not spent more than a few months at a time on mainland China since he was an infant, he was convinced that his status as the only Chinese Fields Medal winner should make him Chern's successor. In a speech he gave at Zhejiang University, in Hangzhou, during the summer of 2004, Yau reminded his listeners of his Chinese roots. "When I stepped out from the airplane, I touched the soil of Beijing and felt great joy to be in my mother country," he said. "I am proud to say that when I was awarded the Fields Medal in mathematics, I held no passport of any country and should certainly be considered Chinese."

Although Perelman does seem to fit the stereotype of the 'lonely genius,' the article seems to imply that was not his intention: In 1996, he wrote Hamilton a long letter outlining his notion, in the hope of collaborating. "He did not answer," Perelman said. "So I decided to work alone." The authors also point out that "Mathematics, more than many other fields, depends on collaboration," so they aren't supporting the 'lonely genius' model.

I've discussed the article with a few mathematicians, and they've said that the article was a bit 'gossipy,' but was factually accurate. Yau's negative behavior seems to be common knowledge in the mathematics community, and all the article did was make it public. None of them had anything negative to say about Tian.

It seems like Perelman left the community because he didn't want to get involved in the politics of it, which he saw as unethical, and this would no longer be possible given his current fame. It seems that given Perelman's reasons for leaving, the writers of the article probably wanted to give an example of this sort of unethical behavior, and Yau was the obvious choice. While Perelman's abandonment is somewhat unfortunate, I hope the mathematics community takes note and does something about this sort of behavior. I for one would not want to waste time having to deal with baseless accusations, character assassinations, and arguments over priority. This sort of thing is detrimental to research and the community.

Overall, a good article, which, despite being somewhat 'gossipy,' was well written.

Moeen Says:

"Concerning the authors' supposed bias against the Chinese, I have to say when I first read the article I certainly didn't feel there was any bias of the sort in there, and was somewhat surprised to find commentators here claiming that. Looking at their comments, it seems like they're just read some parts of the article the wrong way and over-reacted."

I trust you are honest when saying these. However, I would like to propose a conjecture here. Let us call it Nasar's Conjecture.

Nasar's Conjecture: Bias or stereotype of a doughnut size can be rendered into the size of a point in people's mind when it has been applied CNN flow.

Discussion of Nasar's Conjecture:

I and some of my friends found a trick American media always use when reporting other countries, especially China. Whenever the word "China" could not be avoided, it must be appeared in the report with phrases like "Communists, Human rights, claiming Taiwan and Tibet". For a country in Africa which US dislikes, the used phrase would be "corrupted, AIDS, civil wars, etc". This trick has been used in the extreme by CNN. Hence, we name it CNN flow.

Using this CNN flow, people without any knowledge about China or countries in Africa will naturally think "This is it over there", and hence bias no more when the word "China" is bound to "communist, human rights, abortion, take off human organ, invade Taiwan/ Tibet/Mongolia". However for people from China, the feeling is totally different.

I am sorry to introduce politics to this elegant and decent forum and I will not be upset if the editor decides to remove it. My point is: bias or not is up to each individual.

A sketch of a proof for Nasar's Conjecture:

Nasar's article portrays a bad guy, called YAU, who is dishonest, behaves like communist china, seeks fame and power crazily, promotes communist china insanely. In one word, really bad! While Dr. Perelman, a man from a remote planet, is the beloved and cutest kids we ever have.

A complete proof of Nasar's Conjecture:

Waiting for volunteers to fill in the gaps!

91. **Moeen**
August 28, 2006

Whu Says:

"A sketch of a proof for Nasar's Conjecture:

Nasar's article portrays a bad guy, called YAU, who is dishonest, behaves like communist china, seeks fame and power crazily, promotes communist china insanely. In one word, really bad! While Dr. Perelman, a man from a remote planet, is the beloved and cutest kids we ever have."

But the problem is you assume that the characterization of Yau's behavior, and Yau himself, is representing China in the article, whereas the authors are not doing this this but showing that Yau wants to be seen as the leader of mathematics in China. His behavior, while shown in contrast to Perelman, is specific to Yau, and should be seen in context of the Yau-Tian rivalry.

For instance, the authors make a point that Yau's behavior is characteristic of "the squabbles over priority which disfigure scientific history," which the authors quote from E. T. Bell's "Men of Mathematics." The authors give an example of this kind of squabble involving Poincare and Klein, and say:

"An exchange of polite letters between Leipzig and Caen ensued. Poincaré's last word on the subject was a quote from Goethe's 'Faust': 'Name ist Schall und Rauch.' Loosely translated, that corresponds to Shakespeare's 'What's in a name?'

This, essentially, is what Yau's friends are asking themselves."

The authors are not at fault if you insist on seeing things as if they're being portrayed from an american stereotype of Chinese behavior, and this discussion will also go nowhere.

92. **not a mathematician**
August 28, 2006

Perelman succeeded in proofing one more thing: when the goal is close, awarding prizes pushes scientists to exhibit their worst side. The Clay institute will have to choose if they support mathematics or speed races.

93. **tg**
August 28, 2006

Dear Moeen,

I was one of the people who felt Nasar and Gruber's article was "biased" (i.e., motivated to sell magazines to the vast anti-China sentiment reading the Newyorker, at the expense of asian mathematicians and mathematics more generally). I can tell you that I read their article quite carefully.

Obviously, all they said may very well be true, while still leaving a biased/stereotyping article, if they decide to leave out other facts or context. All I claim is that that is what they do, AND they had the motivation to do it. I've written more than enough here and elsewhere on this blog to describe how I think they do this.
I'd prefer, as a point of pedagogy to construct a non-China example to illustrate this point, but you can try your own, if you like, as an exercise.

The danger of racism/nationalism/sexism is its subtlety. Sometimes its hard to notice a particular brand unless you're dealing with it yourself. Part of the problem is many asians do not even recognize it affecting them, since they are told that they are already "overrepresented" as a minority in academics, so how could there be a problem? Perhaps with further discussion, such as the article written in September's Notices of the AMS, this will change.

94. **TruthSeeker**
August 28, 2006

An article may be well-written, factually correct, and still be an incomplete or one-sided representation of truth/reality. Surely a talented writer can skillfully select only a portion of facts available to him/her to weave a good story to achieve a certain effect.

Unfortunately, that's also how some scientists do "science."

Unfortunately, that's also how some scientists do 'science.' "

That's certainly true, and the article was a bit 'gossipy,' if you will. My main point, however, is that the authors were not racist or stereotyping. The characterization of Yau's somewhat egotistical behavior is specific to him alone; for example, none of the other Chinese mathematicians mentioned in the article are described that way.

If anyone believes otherwise you'll have to be more specific, or the discussion just degenerates into making accusations.

97. **atomistic machiavelli**
August 28, 2006

"Moeen Says:

The authors are not at fault if you insist on seeing things as if they're being portrayed from an american stereotype of Chinese behavior, and this discussion will also go nowhere."

When dealing with the dregs of defensive nationalism, with the opium smoke still hanging in the air, you find that parsing every phrase to quark dimensions is never sufficient.

Always expect that even smaller particles will be hypothesized and synthesized as necessary for the next round, until untestability is
securely in hand.

98. **ty**
August 28, 2006

How could SYLVIA NASAR AND DAVID GRUBER turn in their expense reports to their boss at the New Yorker magazine and to justify their travel expenses IF they failed to catch Perelman in person in his "dimly lit hallway of the apartment" and came home empty-handed?

How could SYLVIA NASAR AND DAVID GRUBER justify their travel expenses to their boss at the New Yorker magazine IF they failed to come up with some spicy stories and gossip materials to stir up the pot?

99. **Mike**
August 28, 2006

Anderson was quoted in the (New Yorker) article:
"Yau wants to be the king of geometry," Michael Anderson, a geometer at Stony Brook, said. "He believes that everything should issue from him, that he should have oversight. He doesn't like people encroaching on his territory."

Michael Anderson responded to The New Yorker magazine:

"The New Yorker article badly distorted my comments and
the quote given is very inaccurate and misleading. I've already
discussed it with Yau and expressed to him my apologies and disgust
at using my name in this respect. I tried to have the quote removed,
but was unsuccessful, partly because I was travelling in Europe while
all this happened very quickly and I had no time respond.
I spent a good deal of time talking with Sylvia Nasar
trying to convince her to avoid discussion of the Tian-Yau fight
since it is irrelevant to Perelman, Poincare, etc. But obviously I
was not successful. In this particular respect, I feel the New Yorker
has done a disservice to mathematicians.

Sincerely, Michael Anderson"

100. **James**
August 28, 2006

Dear Tg and Whu: Your views about the mainstream media's treatment of China may well be accurate, but either way, I do not see any reason to believe that this article was "anti-China", or that the authors acted on some presumed motivation to malign the country.

The article was about Perelman, and it can hardly be regarded as a selective choice of examples to pick the major controversy surrounding his results as an illustration of the causes of his disillusionment with the Mathematics community. Should the article instead have focused on some other minor dispute? Or not have been written?

I believe that if we regard nationalism and parochialism as undesirable traits, we should try to be the first to criticize our own countries and compatriots, rather than feeling personally responsible for defending them. As a foreigner myself, I know it can be difficult to resist the temptation to identify with my own nationality, but it is important to try, otherwise ugly scenes ensue – as anyone witnessing an international sports event can surely attest.

101. **Student**
August 28, 2006

Excuse me, but when did the New Yorker become a major math journal?

I would think that people who frequent here would be more interested in what the relevant mathematicians have to say than what reporters said. It apparently is still too early for the experts to have a consensus on how much each involved party has contributed, therefore what the New Yorker article said is really irrelevant — let's wait until Clay writes the check (even that could still be premature).

Perelman put it excellently: "If the proof is correct, then no other recognitions are necessary." Of coruse, he got the "everyone knows" part wrong …

Amen.

102. **Walt**
August 28, 2006

Student: And how is this expert consensus going to be communicated to the hoi polloi? In the Notices? Through word of mouth?

103. **Ken Dev**
August 28, 2006

I spent more than an hour in a bookshop today reading Sylvia Nassar's story on Perelman in the New Yorker. It was sad to read that he has decided to leave mathematics, a tragedy. Hope he changes his mind. Well, I know at least two people who refused the Nobel Prize [Literature and Peace]. What was disturbing about Nassar's article is the intrigue, backstabbing etc. by a Field Medalist, a famous Chinese mathematician against his own student, also a Chinese, who is now a Professor of Maths at Harvard. To the Professor's credit, he refuses to protest his teacher's behavior– he says it is the Chinese tradition.

I used to teach a very simple first year undergraduate course on visual topology, years ago, in a British University. Never did I think that a topic on topology will be such a sensational story 20 years later. Later on in my life, I switched to biology after arriving at MIT as a Visiting Scientist. We were all captivated by Watson's "Double Helix." In particular, it was absorbing to read how top scientists can be ordinary human beings with all their faults etc. Nassar's story reminded me of those events. Who knows, maybe, Ms. Nassar will write a book that will be made into film like, "A Beautiful Mind," on John Nash's life? What is needed is a very simplified description of how Poincare's Conjecture was solved by Perleman. All the articles that have appeared so far, including several in the NYT, do not quite get it. I hope someone succeeds in doing that. It deserves to be told, now that it took hundred years to solve it!

104. **woit**
August 28, 2006

I'm shutting down comments here. It's wasting too much time deleting the endless Tian vs. Yau nonsense that some people are trying to spam this blog with.

Conferences, etc.

July 27, 2006
Categories: Uncategorized

Lattice 2006, the big yearly conference on lattice gauge theory, is going on the week in Tucson. The program is here, and both plenary and parallel session talks are being posted. Georg von Hippel is blogging from the conference, his blog entries so far are here, here and here. One of the main topics is dynamical fermions, with a nice talk by Steven Sharpe. He discusses staggered fermions, which unfortunately come quadrupled with respect to what one wants, providing four "tastes" of fermions instead of a single one. The question then is whether one can get away with just taking the fourth root of the fermion determinant, which then makes the theory non-local. He concludes that this is not "Good" (i.e. having properties one would like even for non-zero lattice spacing), but it is not "Bad" (wrong continuum limit), it is just "Ugly" (for non-zero lattice spacing there are unphysical contributions, but these can be dealt with and made to go away as the lattice spacing goes to zero).

At the YITP in Stony Brook, a month-long workshop funded by Jim Simons on the String Landscape and the Swampland has begun this week. A schedule with links to audio of the talks is here. Today Cumrun Vafa is giving a talk on the beach about the Landscape and the Swampland.

The XXXIII International Conference on High Energy Physics (ICHEP), the big summer conference on high energy physics at which many HEP experimental groups announce their results, started yesterday in Moscow. Fermilab has a special web-page for abstracts from its experimental groups.

There's a review of Not Even Wrong by John Horgan in the August issue of the British magazine Prospect, entitled Stringing Us Along. Yesterday a short interview and discussion involving me and Daniel Waldram, a string theorist from Imperial College, was recorded by the BBC. I hear it was broadcast today on their "Today" radio program. Not sure how it came out after editing, and I can't really bear to listen to recordings of myself, but the discussion was perfectly polite, with no one calling anyone else names.

The August issue of Scientific American has an article about Alain Connes and his non-commutative geometry interpretation of the standard model. He continues to work on this topic, from what I hear most recently thinking about different versions of this idea that incorporate right-handed neutrinos. For some of his latest still quite speculative ideas about quantum field theory, see his recent lectures on Noncommutative Geometry and Physics, as well as other papers available at his web-site. In his version of the standard model the Higgs field has an unusual origin and one naturally gets a relation between the Higgs coupling and gauge couplings, but this is at some very high energy scale where the idea is that the use of non-commutative geometry will replace standard GUT ideas. To extract a prediction of the Higgs mass from this one has to make various assumptions, including a desert hypothesis (no new physics from 1 Tev up to the unification scale), so it's still unclear to me how solid a prediction this really is. For an example of a recent paper about this issue, see one by Knecht and Schucker.

Update: A commenter points to the website of MG11, the Marcel Grossman meeting. Videos of the talks are available. Alejandro Satz is blogged from the conference.

   check out 0854 "Everything you need to know about string theory"

3. **Zoe Marston**
   July 28, 2006

   Peter,

   What do you think the chatter will be in Moscow during the conference there this month about work about to begin at Cern? By the way, have you had time to review this month's Cern Courier? TThere is an interesting article about string theory, "Testing times for String Theory"?

   http://www.cerncourier.com/main/article/43/6/15

   What results would need to be produced by Cern for you to reconsider your position on the plausibility of string theory? Would also like your observations on the work being mounted in the Arctic to test String Theory.
   Jut waiting to see what happens next…
   Zoe

4. **Alex**
   July 28, 2006

   Radio clip is now at:

   http://www.bbc.co.uk/radio4/today/listenagain/thursday.shtml

   (0854 Everything you need to know about string theory.)

   It will only be there for a week.

5. **Chris Oakley**
   July 28, 2006

   I just listened to the audio clip. Here is an executive summary:

   PETER: String theory is 10 dimensional, but the world in 4 dimensional. There's no obvious, useful way to make it 4 dimensional, so it's a waste of time.

DANIEL WALDRAM: I don't agree with Peter. I like string theory and think it is good.

(If only they had had a worthy adversary like Lubos arguing the case for S.T.)

6. **Peter Woit**
July 28, 2006

Zoe,
That article appears to be several years old. It's standard hype about "braneworld scenarios". Such models can be constructed that would have observable effects at the LHC. But there's no evidence for them, and string theory doesn't predict anything about them.

I think I wrote a posting somewhere concerning the hype about "testing string theory" using the detectors in the Antartic ice. It's just hype.

If these brane-world scenarios do work out and involve a gravity scale in the TeV region, if string theory is the right theory of quantum gravity, there should be solid experimental evidence for it, and of course that would change my mind. I think this is extremely unlikely (and so do most string theorists…).

If there is big news at ICHEP, it would be because some experiment is reporting something new. I haven't heard of anything in particular.

July 28, 2006

Here's a direct link to the audio (RealPlayer file)

http://www.bbc.co.uk/radio4/today/listenagain/ram/today5_String_20060727.ram

A good interview Peter. It's just a pity that the producers didn't see fit to make it a little longer.

8. **boreds**
July 28, 2006

I liked the Today discussion. Always nice to hear the presenters struggling with something.

9. **nigel cook**
July 29, 2006

The BBC interview shows how string theorists take the fact that string theory is a failure, and then use that as a reason to continue trying. You have to admire their perseverance. (If it predicted anything, would they finally call it 'boring', and move on?)

Daniel's point is that string theory is interesting, exciting and 'beautiful' because it can't predict anything to help physics.

He then said that there is no real problem of suppression because people are totally free to do whatever they want (they merely lose grants, jobs, career prospects if they don't follow mainstream).

10. **jkowalskiglikman**
July 30, 2006

11th Marcel Grossmann meeting on gravity and astrophysics was held in Berlin last week. For those who are interested, videos of plenary talks are available at http://www.icra.it/MG/mg11/ (go to publications/conference livestream.)

I've been there, it was extremely hot (35C+ most of the days), and not very exciting scientifically. But some talks were really nice.

11. **Who**
July 30, 2006

JKG, thanks for the MG11 link. Ashtekar's talk was an obvious one for me to watch (I just did.) Any other especially nice plenary talks you want to mention?

12. **Zoe Marston**
July 30, 2006

Peter,
I think if you review the cerncourier again, you will find it is this month's. I honestly don't feel that it is at all dated, but thanks for your comments.
Z

13. **Jeremy**
July 31, 2006

Now don't go knocking good ol' Tuscon. There's lots of beautiful women there (especially in the ASU astrophysics department).

July 31, 2006

What's the deal with this FermiLab search beyond the Standrad Model?

==================

Researchers Pursue A Narrow Particle With Wide
Implications

Source: Northeastern University
Posted: July 30, 2006
http://www.sciencedaily.com/releases/2006/07/060730134836.htm

Northeastern University researchers Pran Nath, Daniel
Feldman and Zuowei Liu have shown that the discovery
of a proposed particle, dubbed the Stueckelberg Z

prime, is possible utilizing the data being collected in the CDF and DO experiments at the Fermilab Tevatron. The Stueckelberg Z prime particle, originally proposed by Boris Kors currently at CERN, Geneva, Switzerland and Pran Nath at Northeastern University in 2004, is so narrow that questions had been raised as to whether or not it could be detected.

This new research, published in the July issue of Physical Review Letters, confirms that it can. The results are of importance because the discovery of this particle would provide a clue to the nature of physics beyond the Standard Model and a possible link with string theory.

“It is exciting to know that the discovery of the proposed particle at colliders is indeed possible,” said Pran Nath, Matthews Distinguished University Professor of Physics at Northeastern University. “Physicists are always looking for what is next, what will lie beyond the Standard Model. These findings point us in the direction of those answers.”

Because of its extreme narrowness, the Stueckelberg Z prime particle resembles the J/Psi (charmonium) particle, whose simultaneous discovery in 1974 by Burton Richter and Samuel Ting earned them the 1976 Nobel Prize in Physics. However, unlike the J/Psi which is a bound state, the new particle is not a bound state but a proposed new fundamental building block of matter. What sets the new Z prime particle apart from all others is the mechanism by which it gains mass.

While in the Standard Model particles such as the W and Z bosons gain mass by the Higgs phenomena, the new Z prime particle gains mass by the Stueckelberg mechanism proposed by the Swiss mathematician and physicist Ernst Carl Gerlach Stueckelberg in 1938. While the Stueckelberg mechanism arises naturally in string theory, Kors and Nath were the first to successfully utilize it in building a model of particle physics.

“If the Stueckelberg Z prime particle were to be discovered, it could signify a new kind of physics altogether, a new regime so to speak,” said Nath. “The prospect is quite exciting.”

=== end press release ===

15. **Shantanu**
July 31, 2006

JKG thanks for the MG11 link. Peter, did you watch the talks on string theory at the MG11 link and what do you think?

16. **Peter Woit**
July 31, 2006

Shantanu,

I took a look at the program, but haven’t had the time or the interest to sit and listen to the talks. Too bad they don’t have transparencies on-line. I would be a bit curious to hear what Polyakov had to say.

17. **Shantanu**
July 31, 2006

Hi
Peter,
If you go to http://www.miklei.de/mg11/ramData/mgm-arch-24-2.ram
and fast forward to ~ 51st minute you can go straight to Polyakov’s talk

Templeton Funding for Physics Research

July 31, 2006
Categories: Uncategorized

The Templeton-funded FQXI organization has announced today the awarding of 30 grants totalling more than $2 million dollars for foundational research in physics. On the one hand I've always been dubious about this organization since it is funded by a foundation dedicated not to scientific research but to bringing science and religion together. On the other hand, given the sad state of some of current theoretical physics research, the idea of an organization with a different perspective coming in with new funding and the ability to encourage new ideas that are not getting attention seems highly promising.

The proposal summaries for the successful grants are often so vague that it's hard to tell what they are actually about, although presumably the full proposals give much more detail. FQXI seems to have succeeded in keeping the Templeton religious agenda at bay, with none of the grants trying to bring religion into science. But I have to confess I find the list of grants rather discouraging. FQXI will be funding several well-known string theorists, a group that has not exactly been starved of funding or attention in recent years. Some of the grants are for "multiverse" research, again something that I don't think physics desperately needs more of right now.

Almost completely missing from the list of topics awarded grants is high energy physics, or any foundational research into the standard model. Also very hard to find is any interest in further research into the new mathematical ideas that have come out of quantum field theory research during the last thirty years. In brief, what seems to me the most promising way forward for foundational research in physics, working on better understanding the standard model QFT and its mathematical context, doesn't seem to be something on the FQXI agenda. To be fair, I have the depressing suspicion that if I had to go through all the grant proposals submitted to them, I might not have been able to do much better in terms of coming up with promising things to fund.

Last week an interesting semester-long program on Non-commutative Geometry began at the Newton Institute in Cambridge, and some of the talks have already begon to appear on this web-site. The program will include a Templeton-sponsored workshop in early September on the topic of Fundamental Structures of Space and Time. Like FQXI, the workshop mostly seems to be free of religious influence, although there will be a public panel discussion on The Nature of Space and Time which will feature two clergymen.

Over at Cosmic Variance, Sean Carroll, who is at least as dubious about Templeton as I am, has a much more positive take on the FQXI grants. In the comment section FQXI associate director Anthony Aguirre points to a new mission statement at Templeton. At their web-site you can also watch a rather long video about this if you're so inclined, or see a list of upcoming conferences they sponsor on topics in science and religion (they're especially interested in cosmology).

Update: There's a story about this at Inside Higher Ed.

Comments

1. **Anthony Aguirre**
   July 31, 2006

   Thanks for your take on this. In terms of the particular projects funded, the truth is that FQXi does not have any particular scientific "agenda" (e.g., pro- or anti-string theory, etc.) or criteria other than what was stated in the Request for Proposals. Another panel would likely make different decisions, but I suspect not *very* different ones. If there are foundational, unconventional projects (or researchers) in high-energy theory that you see languishing for lack of funds, please encourage them to apply for the next round!

   best,

   Anthony

2. **Garrett**
   July 31, 2006

   Peter,

   There do appear to be a couple of funded projects focused on gauge theory, including this highly interesting and unusual one involving gauge theory and the structure of the standard model:
   Deferential Geometry
   Of course, my opinion may be biased. 😉

   Also, it looks like the institutional links under the researcher names actually point to the researcher home pages.

   There are quite a few funded projects on unconventional approaches to quantum mechanics — that seems an interestingly different point of interest than the standard fare.

3. **woit**
   July 31, 2006

   Hi Garrett,
   I should have mentioned that yours was the one proposal among the 30 about geometry and the standard model. Good luck with it!

4. **Garrett**
   July 31, 2006

   Thanks. And even more than luck, help is welcome.

5. **Chris Oakley**
   August 1, 2006

   If there are foundational, unconventional projects (or researchers) in high-energy theory that you see languishing for lack of funds, please encourage them to apply for the next round!

   Is this a joke, or what? As with the mainstream, a system based on mutual recommendation eliminates unconventional research by definition.

6. **Thomas Dent**
   August 1, 2006

Would you not say the two experimental proposals to look at the ‘constancy’ of the fine structure constant are to do with HEP?

And in theory we have Donoghue’s ’emergent gauge symmetry’ which would be very much at the heart of HEP.

7. **woit**
August 1, 2006

Thomas,

By HEP= high energy particle physics I meant the conventional meaning of studying particle interactions at high energies = short distances. The question of variation of constants on cosmological scales is a very different subject.

The Donoghue proposal is also more or less the exact opposite of the kind of mathematical investigation of the structure of gauge theories that I was talking about. He wants to throw away that whole structure as not fundamental.

8. **Wen**
August 1, 2006

The emergence of gauge bosons (as well as the emergence of Fermi statistics and gravitons) has been an active research area since 1987 in condensed matter theory. Many results were obtained, such as a unification of gauge interaction and Fermi statistics.
Just google “emergent gauge bosons”.

9. **D R Lunsford**
August 1, 2006

I can’t believe what people will pay for. FQXI (sounds like a southern radio station – “QXI in Dixie!”) is the IKEA of theory. Hidden variables in cosmology? Why not apply the Bell inequalities to colliding galaxies? Apparently this dude Lisi has figured it all out anyway so why bother?

The real question people should be studying is how the academic world collapsed under the dehumanizing weight of sex, drugs, and rock and roll.

-drl

10. **Brett**
August 1, 2006

Funding projects that look at possible time variations in fundamental constants is an extremely good idea. If the fine structure constant or the electron-proton mass ratio turn out to be time dependent, then this is an unambiguous indication of new physics. Moreover, unlike say, dark matter, time varying constants are relatively difficult to incorporate into the conventional frameworks that we use to describe physics. So the discovery of time variations would tell us a great deal about what kinds of changes are required if we are to understand the fundamental physics of the universe.

11. **JPL**
August 1, 2006

IKEA of Theory, indeed! I would suggest FQuiXi as a more commercial audiologo, though IT IS a southern radio station of sorts, if you think about it. Though that kind of money can surely buy a lot of sex, drugs, rock and roll and surf boards, I would say Templeton has managed to make science so silly and way out there that religion looks a lot more attractive! Not surprisingly, perhaps, most of these people work in institutions (my own included) that would insure them decent funding for better refereeing than what this list brings out without selling off their scientific honesty! No? Maybe I am the one who’s being naive…

12. **Who**
August 1, 2006

In reply to Wen
http://www.math.columbia.edu/~woit/wordpress/?p=436#comment-14002

Xiao-Gang Wen,
thanks for joining this discussion. Congratulations on your Foundational Questions award!
http://dao.mit.edu/~wen/

I agree with Smolin’s position that more support should go to those with the courage and intellectual independence to pursue approaches to basic problems that are not commonplace: in effect allocating to the individual track-record instead of to the entrenched program. Your condensed-matter type approach to the emergence of spacetime and fundamental interactions is an example of vigorous investigation off the beaten track.

Hopefully the awards will have a “multiplier” effect when departments at major universities see the FQX spotlight picking out individuals committed to bold original lines of research. Conceivably, some departments will be influenced to shift policy in awarding postdoctoral fellowships, and provide graduate students wider choice of topic.

D.R. Lunsford, any physics department in the US would be lucky to get “the dude Lisi” as a research fellow
http://arxiv.org/abs/gr-qc/0511120
Clifford bundle formulation of BF gravity generalized to the standard model
that is exactly the kind of research dude they should be looking for.

Just looking down the list of awardees, I see they are almost all attached to major academic institutions and it is spread out—not much clumping.

Michigan, Berkeley, Kansas, Massachusetts, London-Imperial, Yale, SantaBarbara, Perimeter-Waterloo, Illinois, Barnard, Harvard, Tufts, Louisiana, Oxford, Cornell….etc. …
(and of course MIT where X-G Wen is)

I really like the spread. It feels like a “democracy of the excellent” instead of a prestige pecking-order. And if they wanted to have a “multiplier effect” on the way departments think, then a wide spread was well calcuated. Congratulations to those responsible (Tegmark, Aguirre, and all who helped.) Lots more could be said—which I’ll leave to others.

13. **D R Lunsford**
August 1, 2006

Who,

massive shrug – quaternion disease. Most of us get past that stage while undergraduates.

None of the proposals listed on FQXI has a shred of physical interest. Big surprise.

-drl

14. **Garrett**
    August 1, 2006

    Thanks Who.

    DRL,

    The relationship:
    fermions -> spinors -> Clifford algebra -> quaternions
    seems pretty clear. Which step do you dislike?

    I'm kind of surprised to be the only guy on the list with a weird TOE. Makes me feel lonely. I'm curious what the 20 proposals that made the first cut from 172 to 50, but not the second cut from 50 to 30 were.

15. **D R Lunsford**
    August 1, 2006

    Garret,

    What you have is algebraic logic chopping with no real dynamical principle, and so no theory. But congrats on getting people to pay you for it. I looked at similar ideas in the early 90s and rejected them as a waste of time. V. Fock did similar work with the Dirac algebra in GR as far back as the mid 30s. That work is still valuable, but offers no new ideas – only Dirac on a Riemannian manifold.

    -drl

16. **Garrett**
    August 1, 2006

    drl,
    That's essentially correct — except this happens to be unusually successful algebraic logic chopping. And if I had the dynamics worked out perfectly, I wouldn't need time to work on it. In any case, this comment thread isn't the best place to discuss it. I'd be happy to talk elsewhere.
    Best,
    Garrett

17. **D R Lunsford**
    August 2, 2006

    Garrett,

    Yes not here. "The true metaphysics of y5 is hard."

    -drl

18. **Paolo**
    August 4, 2006

    In replay to Garrett,

    I do not know very much about the 20 proposals that did not make the second selection … but I do know "something" about some of those that did not make the first selection … in fact my project "Algebraic Quantum Gravity: Spectral Space-time via Non-commutative Geometry" (by the way: this was a project in "nc-geometry" +operator algebras+category theory) was immediately rejected without any explanation, apart from mentioning the fact that there were so many other much better proposals.
    I am actually very pleased to see that (at least for Quantum Gravity and TOE research) the funds went to some of the best experts in the field (some of them like C. Isham, L. Crane, F. Morkopoulou, O. Dreyer are some of the researchers that I admire the most).
    I am a bit disappointed to see that the grants (apart from Garrett's case of course!) actually went to people that are extremely famous, mostly with tenures and whose research programs do not need any particular help to get visibility, credibility … and most of all … funds …

    Considering the fact that the main aim of the Fqxi "foundation" was to support "out of box thoughts", "unconventional approaches" and even "research that would not be otherwise possible to fund" … I really find it difficult to see any relation with these words and "most" of the actual selected programs. The only natural pleasing answer is that … apart from those well-known names, already publishing heavily in the field, there are really no new thinkers that deserve to be supported.
    On one side, this is a really good news for universities in USA or UK … since they already got all the "interesting" people with the good ideas!
    On the other side, sincerely, I find it difficult to believe that there are no "original thinkers" in China, Japan, India, Korea (or "God forbid" … in some "developing" country …) that applied for a grant … and I find even more difficult to believe that they "do not" need support more that those selected!!
    I would have liked to know in advance that when I submitted my "low profile" project I was going to compete with Nobel prize level people looking for extra sources, through "mutual recommendation" … it could have saved me (and to many others) some precious time and probably some face!!

    In replay to the following phrase from Aguirre:
    "If there are foundational, unconventional projects (or researchers) in high-energy theory that you see languishing for lack of funds, please encourage them to apply for the next round!"

    For someone that is working (and probably trying his best to do some research) in difficult conditions of almost total lack of funds, heavy teaching load (with no real leaves, nor sabbatical) and in complete isolation (apart from an internet connection), it is a bit depressing to get this kind of answers … anyway thanks!

    In replay to Woit (and all the other people that have problems accepting funds from religious institutions … do they?):

    I really fail to understand the point here: I always considered spiritual and religious parts of life as natural as those related to art, literature, science and as a normal byproduct of human life (like breathing, eating, sleeping, enjoying conversation, play, music, knowledge ….).

I see that most of the complaints actually come from people with permanent positions or anyway with good jobs in American Academies and it seems strange that those people fail to recognize that they are actually sponsored by public funds coming from a vast majority of a “very religious” population and from an administration that is officially promoting not only “innocent” religious ideas, but also very much “radical and fundamentalist” approaches to religious life (let alone political practices!) … I would take their words seriously when they will change job … or change ideas!

Well … good luck to Garrett and to the other winners of the Fqxi awards.
And forgive me for a replay that is a bit “resentful”, but I could not resist 😉

Sincerely, Paolo

19. **Michael Edwards**
August 4, 2006

Although my sympathies (and congratulations on funding) lie with Garrett, my better judgment agrees with D R Lunsford that he’s off in the weeds. I think he suffers not so much from “quaternion disease” as from Lagrangian disease — the impression that what matters about a field theory is its (geometric and/or internal) symmetry algebra and its nominal Lagrangian as written in an introductory text. I recall getting a rude awakening from this illusion when I first tried to go from reading about non-Abelian gauge theories to trying to calculate anything in one.

I’m not a working physicist (or mathematician) and don’t claim to understand QFT even to the degree that a freshly minted Ph.D. from a second-rate university does, let alone people who can compute accurate QCD backgrounds for collider experiments. But you don’t really have to understand functional determinants and renormalization group flow to realize that the Lagrangian of an effective field theory may not look much like its Planck-scale antecedent. Take the example of Faddeev-Popov ghost fields (for mathematicians, more or less the Maurer-Cartan form on (the identity component of) the group of QCD SU(3) gauge transformations). They’re “unphysical” in the sense that they violate the spin-statistics theorem (among other things), so you rarely see them included in the headline SM Lagrangian — but good luck expressing anything quantitatively in QCD without them or their equivalent.

Is the entire fermion structure of the Standard Model just as “unphysical”, arising not from “algebraic logic chopping” of some set of geometrical objects but from something deeper such as the need to calculate past a wider redundancy in Fock space? I lack the techniques to state this question rigorously, let alone to answer it, but I can use it (along with other foundational questions about the QFT formalism) as a litmus test for ToE candidates. I’m looking for some combination of predictive and explanatory power, and I’m convinced that neither is to be found along lines of reasoning that focus narrowly on the symbols under the action integral.

So at best I think Garrett has wandered off in a different direction from the string theorists, and perhaps not as far (he is presumably not long-term dependent on “faute de mieux” grants for his livelihood). With apologies to Douglas Adams, the fundamental design flaws of his approach are completely hidden by its superficial design flaws. I say this having spent an unfortunate proportion of my life chasing similar dreams, and in hope that he will use some of the liberty that money buys to broaden his knowledge of how QFT calculations are actually made.

Cheers,
– Michael

20. **Christine Dantas**

Dear Paolo,

You summarize my impressions when I saw the list of awardees. I am somewhat relieved that my decision to not submit my project to the FQXi grants was a good one (at least I was able to spare myself of further frustrations), although I was confident that my project did meet their criteria. Well, let’s keep on going. You have my sympathy.

Best wishes,
Christine

21. **Kea**
August 4, 2006

Thank you, Paolo. I couldn’t have said it so well myself. Of course I wish all the awardees the best in their researches, but I was stunned when I saw the list. My proposal was on pseudomonads in a quantum topos style unification. I was rejected on the first cut because “the subject matter of the proposal didn’t meet the criteria of the fqxi guidelines”. I prefer people to be honest.

22. **Christine Dantas**
August 4, 2006

Kea wrote:

Yes, I also wish them all the best of course. I look forward to learn about the new developments and results that these investigations will lead.

Christine

23. **Anthony Aguirre**
August 7, 2006

Dear FQXi applicants, well-wishers, and naysayers:

Your comments on this forum are valuable to us. A few comments in return.

First, believe me, we would have liked nothing more than to have had \$20m to give away, and to fully fund all of the initial proposals we received. Cutting these requests tenfold was very difficult for the panels, and they did their best using exactly the same criteria provided to the applicants in the RFP document. Note also that some very prominent researchers had unsuccessful applications — and we hear from them too!

Second, the two-part application process was devised in part to save the community a substantial amount of time in preparing lengthy and ultimately-unsuccessful applications. This succeeded, but other than additional money there is no way to mitigate the frustration of most applicants going unfunded.

Third, it should be kept in mind that even for established researchers, getting funding for foundational projects is not — at all — easy. Usually this sort of work is done "on the side" while supported by other more conventional funding, and part of FQXi mission is to bring this side-work into the fore.

Fourth, since from the outset we took care to make FQXi open to researchers worldwide, we were actually disappointed in the rather small number of applications from outside North America and Europe. Certainly there was no bias against them — in fact, the favorable buying power of the dollar alone gives such applications (from India, for example) a substantial advantage in terms of cost-effectiveness. We think many more are out there, and we will redouble our efforts to get the word out to such researchers in future grant cycles.

Finally, we are indeed aware of the difficulty of judging the value of truly original research proposals — as we *must* do in order to make funding decisions. We are working on ideas and strategies for this, and welcome constructive ideas along these lines.

24. **Michael Edwards**
August 7, 2006

Garrett,

Judging from the comments to an earlier posting ("Various and Sundry", July 21, 2006), I may owe you an apology for assuming (based on the paper you linked above) that you were only interested in the stuff under the action integral. I agree with your comment there that BRST is of "foundational importance". The construction you are looking for, in which the BRST operator is extended to form the exterior derivative on a gauge bundle, is being discussed in the comments to "P. University Press", and there's a link there to a paper by Schuecker which may help kick-start a literature search.

When I get a chance, I will try to summarize concisely where the Faddeev-Popov ghost field fits (a standard result; see for instance Peskin & Schroeder) and how it can be extended to the Maurer-Cartan form on the space of right-invariant vector fields on the gauge bundle (probably also nothing new, but I haven't found it in the literature).

Cheers,
– Michael

25. **Garrett**
August 8, 2006

Paolo,
Sorry about your proposal. I was also surprised to see so many familiar names on the list — I figured there would be more dark horses from all over the world. The only consolation I might offer is that they don't appear to have funded any category theory projects. It's not hard to see the category theory star rising though, so don't give up on it.

Michael,
If the biggest flaw with my theory is having a nice Lagrangian, I'll be very happy. And Faddeev-Popov ghosts are at the heart of what I'm working on, and I am indeed very interested in the Maurer-Cartan BRST construction. I've seen it here and there, and even used it in my own work, but my understanding is sketchy. I'll go look in the other comment thread immediately. Also, it would be great to talk about this at
physics forums
which I think would be a practical and appropriate place to discuss it. I'd love to see your summary there. Please send me an email so we can talk about it:
gar at lisi dot com
I've been away at my sister's wedding for a few days, but I'm back now for awhile.

Anthony,
Thanks!!! If you do check back on this thread, I have a question:
When do you think FQXi will be opening up its discussion forum?

26. **Tony Smith**
August 8, 2006

Garrett and Michael Edwards mention ghosts, BRST, and Maurer-Cartan.
A useful paper about that is
Geometrical reinterpretation of Faddeev-Popov ghost particles and BRS transformations
by Jean Thierry-Mieg (J. Math. Phys. 21 (12) December 1980 (2834-2838)
whose abstract states:
"… A classical geometrical interpretation of the ghosts fields is presented. BRS rules follow from the Cartan-Maurer fibration theorem. The statistics of ghosts are explained and the effective quantum Lagrangian is derived without factorizing the volume of the gauge group. Topologically nontrivial ghost configurations are defined. …".
The body of the paper says in part:
"… the connection 1-form … describes at the same time both the Yang-Mills gauge particle and the Faddeev-Popov ghost particle. With respect to a section, i.e., a gauge being chosen, the connection actually splits into the sum of two components:
the gauge field … which is horizontal
and
the ghost field … which is normal to the section.
The exterior differential … also splits, and its component normal to the section is … the BRS operator.
… the Cartan-Maurer structural theorem, which states the compatibility of the connection with the fibration, implies the BRS transformation rules of the gauge and ghost fields.
Moreover, the ghost does not contribute to the curvature 2 form (field strength) and may be thus eliminated from the description of the classical theory. …".

August 8, 2006

Garrett:

The forums are on our current to-do list, and should hopefully be up in time for the fall.

best,

Anthony

28. **Michael Edwards**
August 8, 2006

Tony,

I think it's more accurate to say that the most fundamental form of the connexion on a principal bundle – a separation of the tangent space at each point into horizontal and vertical subspaces – is expressed as the Maurer-Cartan form (vertical projection) on the _bundle_. Its restriction to the vertical subspace is identified with the Faddeev-Popov ghost, because infinitesimal gauge transformations are the vertical subalgebra of the Lie algebra E of right-invariant vector fields on the bundle. ("Right-invariant" here means invariant under the right action of the bundle structure group, i. e., the gauge group.)

The connexion 1-form on the bundle pulls back on a local section to the "gauge" connexion 1-form on the base space. Because this pullback is defined using the connexion itself (it's dual to the "pushforward" of vector fields on the base space to "horizontal" vector fields on the bundle), you could say that it "splits out" the portion of the Maurer-Cartan form that acts on the horizontal subspace. But I would hesitate to use the word "normal" in this context because it doesn't have anything to do with metric structures or inner products. _Any_ connexion 1-form on the bundle is a projection from E to its vertical subspace, which is in turn the kernel of the "projection" (pushforward, really) of E to the tangent bundle of the base manifold.

Similarly, one can define an exterior derivative d_E: \Lambda^k -> \Lambda^(k+1) on the space of local-polynomial-valued alternating forms on E without essential use of a connexion on the principal bundle. The special case of a 0-form Q (e. g., a Lagrangian polynomial) yields the exact 1-form d_E Q, whose restriction to the vertical ideal of E is -s Q, where s is the BRST operator (I believe that the minus sign is the historical sign convention, if G&S and P&S are any guide). That's what is meant by the statement that -s is the "component normal to the section" of d_E, although "normal" is again somewhat misleading; the vertical ideal of E is well-defined irrespective not only of any metric-like structure but also of independent of the connexion.

The space \Lambda of local-polynomial-valued alternating forms on E, and the corresponding graded Lie algebra of derivations on \Lambda, is a powerful formalism for expressing the calculus of variations. The derivations on \Lambda can be extended to an even larger operator space via the wedge product and the Frölicher-Nijenhuis bracket. If I had to bet on a dark horse in the Theory of Everything stakes, I think this would be the mathematical formalism in which it ought to be expressed.

Cheers,
– Michael

29. **Garrett**
August 8, 2006

Nope. OK, Michael, can you send me an email and then I'll start a Physics Forums thread for this?

30. **Michael Edwards**
August 8, 2006

This is starting to feel inappropriate for Peter's blog, but I thought I should at least explain my comment on the Frölicher-Nijenhuis bracket and provide a reference.

Another term for a graded Lie algebra is "superalgebra", and the sheaf of alternating forms on a vector bundle is a classic example of a supermanifold. The subspace \Omega^1_* of \Lambda consisting of (vert E)-valued horizontal alternating forms on E can be given a Lie superalgebra structure via the Frölicher-Nijenhuis bracket, which coincides with the Lie bracket on 0-forms (i. e., polynomials taking values in vert E).

Better yet, the entire graded Lie algebra Der \Omega(vert E) of derivations on \Lambda, including (for instance) the BRST operator, can be identified with the direct sum of two copies of \Omega^1_*, one acting by contraction (the generalization of the inner derivative) and the other by Lie derivation (the generalization of the Lie derivative). See, for instance, this paper by Cap et al.:

http://citeseer.ist.psu.edu/cap94frlichernijenhuis.html

I think you might find that Der \Omega(vert E) is the Lie superalgebra of a supergroup of physical interest. This isn't the same thing as (the physicist's idea of) supersymmetry, because it doesn't involve spinors and doesn't establish any preferred relationship between particular odd and even elements of the algebra. One could try to mix form degrees of freedom of multiple ranks to get spinor fields via the Kähler route, but I think that's probably a dead end. Instead, I would expect you could exploit the isomorphism between (portions of) the _operator_ algebras on forms and on spinors in the course of BRST quantization.

I suppose that where this is headed is a generalization of the BRST quantization procedure to second class constraint systems. I wonder whether that would have any physical uses.

Cheers,
– Michael

31. **Michael Edwards**
August 8, 2006

Garrett,

I'm not really in the habit of online forums (I tend to drop in for a short while, use up my little store of insight, and go back to lurking) but feel free to write me at m.k.edwards at that webmail service that Google runs. Don't expect great things, though; I'm almost out of things to say already. 🙂 The rest is on the "P. University Press" thread, along with some pointers into the literature from Peter and Thomas that may take me quite some time to digest.

Cheers,
– Michael

32. **Tony Smith**
August 8, 2006

Michael Edwards mentions
"… Another term for a graded Lie algebra is "superalgebra" …"

and
mentions "… alternating forms … \Lambda …"
as
"… the mathematical formalism in which … the Theory of Everything … ought to be expressed.
ought to be expressed …".

I don't disagree with the general ideas, but as to more specific details I note that :

1 – Some graded Lie algebras are NOT "superalgebras", but are interesting Lie algebras that combine vectors, bivectors, and spinors, such as by the 5-grading
g = g(-2) + g(-1) + g(0) + g(1) + g(2)
where
g = E6 ————————————— the total Lie algebra
g(0) = spin(8) + R + R —————— the bivectors
dimR g(-1) = 16 = dimR g(1) ——— the (complexified) spinors
dimR g(-2) = 8 – dimR g(2) ——–– the (complexified) vectors

2 – If you want to include spinors, it is nice to extend beyond the exterior algebra \Lamda of alternating forms and go to Clifford Algebras and look at Clifford Modules, which are closely related to Dirac operators.

Also, with respect to my comment about Maurer-Cartan forms, BRS, etc,
my comment consisted of direct quotes from the paper of Jean Thierry-Mieg
at J. Math. Phys. 21 (12) December 1980 (2834-2838),
so any praise or criticism should be of Thierry-Mieg, and not me.

Tony Smith

33. **Michael Edwards**
August 8, 2006

Sorry for following up to myself (again) but this was too stupid to let stand:

> The subspace \Omega^1_* of \Lambda consisting of (vert E)-valued horizontal alternating forms on E …

This was a silly thinko. Horizontal forms on E annihilate vert E. I meant to write, \Omega^1_* is \Lambda(vert E, vert E), which is isomorphic to \Lambda(E, vert E) / Hor \Lambda(E, vert E). The horizontal forms constitute a subalgebra of \Lambda(E, vert E) and are defined independent of any connexion; presumably a choice of connexion can be used to select a unique representative of \Lambda(E, vert E) corresponding to an element of \Omega^1_*. Hey, look, another fiber bundle!

Anyway, I found the "standard" name for that connexion 1-form on the fiber bundle:
http://en.wikipedia.org/wiki/Ehresmann_connection
Whoever "Silly rabbit" at Wikipedia is, he's doing a bang-up job of overhauling their connection-related entries.

Cheers,
– Michael

34. **Michael Edwards**
August 8, 2006

Tony,

No personal criticism of you (or Thierry-Mieg) intended; it's just that the word "normal" gives me hives. I also have this irrational aversion to Clifford algebras, second only to my distaste for div, grad, curl and all that. This is part of the reason that I never made it as a physicist. But if you can find an elegant way to extend the Frölicher-Nijenhuis construction to Clifford algebras, I'm all ears.

Cheers,
– Michael

35. **Tony Smith**
August 9, 2006

Michael Edwards said "… But if you can find an elegant way to extend the Frölicher-Nijenhuis construction to Clifford algebras, I'm all ears. …".

For one example, consider hep-th/0112263
Geometric (Pre)Quantization in the Polysmplectic Approach to Field Theory
by Igor V. Kanatchikov

After using the Frolicher-Nijenhuis theorem with respect to a (Poisson-)Gerstenhaber algebra, Kanatchikov says
"… it was found suitable to work in terms of the space-time Clifford algebra valued operators and wave functions,
rather than in terms of nonhomogeneous forms and the graded endomorphism valued operators acting on them.
In general, a relation between the two formulations is given by the "Chevalley quantization"
map from the co-exterior algebra to the Clifford algebra …".

For details, see the paper itself.

Tony Smith
http://www.valdostamuseum.org/hamsmith/

36. **Michael Edwards**
August 9, 2006

Tony,

On a first reading, the Kanatchikov paper is about as clear as mud to me. I fail to see why you would want to "generalize the cotangent bundle" in the direction he chooses, I have no idea which objects are defined solely in terms of the bundle structure and which ones require a connexion or a local section or a metric or a complex structure or a Minkowski background or God knows what else for their definition, and the presence of the word "heuristically" in the abstract is a major turn-off.

I could tolerate all that in a model that reproduces real live phenomenology, but I refuse to participate in any universe whose fundamental dynamics involve the kind of hocus-pocus which permeates this paper – including "Chevalley quantization", which seems to be nothing but replacing a symbol that has a well justified commutation property with one that doesn't. Given that there is so much that I don't yet understand about the calculus of variations on objects whose geometrical significance I can grasp, I am going to have to leave the work of "Cliffordization" to someone else for the present.

Which is not to say that I'm not still all ears for a Clifford-Frölicher-Nijenhuis construction that I have a prayer of understanding. 🙂

Cheers,
– Michael

37. **woit**
August 9, 2006

Garrett, Michael, Tony,

I'm loathe to discourage people from discussing things related to BRST, it's exactly the sort of thing I think physics needs more of. But I think you'd be better off discussing this privately, for one thing you could exchange properly TeXed documents…

38. **Michael Edwards**
August 9, 2006

Peter,

No worries. I sent my little notation crib sheet (basically a drastically condensed summary of parts of G&S with extensions in the Frölicher-Nijenhuis direction) over to Garrett already, and we'll see how far we can get privately on BRST-ish lines of reasoning. If anyone else is interested in playing with these ideas, write at m.k.edwards at google's webmail.

Perhaps we'll hare off into the direction of perturbative cohomology. Applying BRST quantization to the Hodge theory of elliptic complexes sounds like fun. Some elliptic complexes, including the de Rham complex, can be defined without reference to a metric. However, you also need an elliptic operator to select a unique harmonic representative of each cohomology class, and its definition involves an arbitrary choice of metric. So the theory lives on a GL^+_n principal bundle; varying this metric to recover diffeomorphism invariance requires a BRST counterterm.

Anyone know offhand what happens to Atiyah-Singer when the Laplacian is actually a hyperbolic operator?

Cheers,
– Michael

39. **Michael Edwards**
August 9, 2006

I should have known that Ed Witten was there first:

http://projecteuclid.org/Dienst/UI/1.0/Summarize/euclid.cmp/1104161738

But he doesn't seem to have known at the time quite how to formally define "instanton moduli space" as the quotient space of cohomology classes and replace the singular Green's function of the elliptic operator with a metric-fixing term and its ghost counterterm. If I were a real mathematical physicist I would try to pick up where Witten left off.

Cheers,
– Michael

40. **Michael Edwards**
August 10, 2006

Amazing. I start reading Witten's paper, I see a lot of index slinging and heuristics and wildcat guesses, I start to question his reputation for mathematical brilliance – and then he proposes an elegant resolution of the problem posed for Hodge theory by working in the Minkowski signature component of the frame bundle: relate two inner products on the _Hilbert_ space, one positive definite and one Lorentz invariant, via the time reversal operation.

I won't clutter up Peter's blog with the implications but they're quite enlightening, as is the central assertion of the paper: a generally covariant quantum field theory is one in which the stress tensor is a BRST commutator. In fiber bundle language, such a theory lives on the unreduced GL^+_n frame bundle of an orientable manifold; the infinitesimal form of general covariance states that the Lie derivative of the Lagrangian with respect to any vertical vector field on the frame bundle is zero. That simply means that dL is a horizontal form on the frame bundle; i. e., the restriction of dL to the vertical ideal (aka the BRST commutator of L) is zero.

So even a totally heuristic approach to writing down a Lagrangian candidate will succeed in producing a "generally covariant" (under infinitesimal changes of metric, not general diffeomorphisms) theory, as long as its energy-momentum tensor (the variation of L with respect to a change of metric, calculated the hard way) coincides with the BRST commutator of some element \lambda of the exterior algebra on the fiber bundle. Although its index-slinging formula may be totally unrecognizable, \lambda will differ from L only by a BRST-closed form in \Lambda, i. e., one whose exterior derivative is a horizontal form.

That brings me back on topic for Peter's blog. A sufficiently brilliant mind wandering in the string theory wilderness for forty years is likely to discover that some candidate manifolds and Lagrangians are less intractable than others. This may result in isolated flashes of insight like Witten's that unleash a flood of interesting mathematics. The problem is not string theory but the string theory monoculture in which the majority of sufficiently brilliant minds are all wandering in the same wilderness. My mind is not in that class, so I selfishly wish there were more people of Witten's caliber wandering in my bundle-theoretic-topology wilderness, in hope that one of them will lead me out someday.

Cheers,
– Michael

41. **Michael Edwards**
August 10, 2006

Oh, now that's a neat way of looking at it. QFT and GR are the same theory of general covariance, just written in "Dirac-Feynman" gauge (gauge-fixing operator d+\delta) and “Einstein-Hilbert” gauge (gauge-fixing term R). I bet that someone sufficiently clever could parameterize this to interpolate between them, the same way that in QED one can interpolate between Landau gauge and ‘t Hooft-Feynman gauge using the \xi parameter whose name I can’t remember.

42. **Garrett**
August 16, 2006

The FQXi grant awardee pages now have links to technical abstracts, which are much more revealing.

43. **Michael Edwards**
August 19, 2006

Having commented here on the Frölicher-Nijenhuis calculus, I thought I would point out that there’s a good exposition available online. The PDF of a book-length follow-on to Kriegl and Michor’s work (as exemplified by the Cap et al. paper), published by Springer as “Natural operations in differential geometry”, is at http://www.emis.de/monographs/KSM/. It does a very thorough job on the Frölicher-Nijenhuis bracket and friends, including applications on gauge bundles.

The angle from which the authors approach Lagrangians is different from Schücker’s, and they do not draw his connection between the BRST operator and the restriction to the vertical ideal of the exterior derivative on the bundle. Consequently, they do not seem to have applied the Frölicher-Nijenhuis calculus to the space of local-polynomial-valued alternating forms.

Extending BRST in this direction is proving quite enlightening. The BRST operator seems to be more closely related to Lie derivation with respect to the (connexion-dependent) vertical projection than to the (connexion-independent) bundle exterior derivative. In a quite rigorous sense it is complementary to the “exterior covariant derivative”, i. e., Lie derivation with respect to the horizontal projection on vect[P]. This makes it very useful for expressing variational principles on principal bundles, since the generalized Stokes theorem applies properly to the bundle exterior derivative, not the exterior covariant derivative.

Cheers,
– Michael

Susskind on KQED

July 31, 2006
Categories: Uncategorized

Someone wrote in to tell me that KQED this morning had Leonard Susskind on to discuss string theory and his book The Cosmic Landscape. Most of the program consisted of him promoting his usual line about the string theory anthropic landscape and how the fact that string theory is compatible with anything makes it a wonderful and exciting new way to do physics. He claimed that there is no longer a substantive split among bright physicists about the landscape, that the only split is over people's emotional response to it.

There were quite a few strange things in the interview that have little to do with reality. Susskind repeatedly claimed that string theory has a great deal of experimental support, saying:

More and more the things that string theory seems to say seem to jibe and coexist with the things that physicists and cosmologists see in the laboratory.

Near the end of the interview, when asked to cite some experimental evidence in favor of string theory he said that yes there was a lot of evidence including:

1. The existence of gravity.

2. The existence of particles.

3. The laws of the universe.

Quite remarkably he then went on to announce that QCD is a string theory and take credit for it, saying that string theory was "invented by Nambu and myself as a theory of protons and neutrons, an extremely successful theory of protons and neutrons". According to Susskind, string theory provides "the whole explanation of protons and neutrons and nuclear physics" and that "heavy ion collisions are best described in terms of string theory".

One questioner asked him about LQG, which he characterized as a "half-baked theory" that was "similar to string theory but not quite the same" and that "even its proponents hope that it is another way of expressing string theory."

And what of criticism of string theory? Susskind deals with this with purely personal attacks. The interview began with the following:

Michael Krasny: *Let's talk first of all if we can about string theory since you're kind of called the father of it and all that, I know you've been humble on that score, but it's deserved. Challenges to it, now it's being challenged left and right… ill-defined, based on crude assumptions.. tell us.*

Susskind: *You're talking probably aout some of the books and blogs that have come out in very very big criticism of it. Well, I think one would have to say that some of it is due to a certain kind of grumpiness of people who…um..*

Well, for example, there's one fellow who failed as a physicist, never made it as a physicist, became a computer programmer, has been angry all of his life that he never became a physicist and that physicists ignore him, so he's now taking out his revenge by writing diatribes and polemics against string theory.

Somehow I suspect this is about me. For the record I'm a faculty member in the math department at Columbia, in an untenured position with title of "Lecturer", where my responsibilities include teaching, adminstering the department computer system, and engaging in research. Susskind sounds a lot more angry than I've ever been, and I certainly don't feel that physicists are ignoring me.

He goes on to attack Lee Smolin:

There's another fellow who has his own theory, I won't tell you who his name is or what his theory is, but he writes lots and lots of theories and his theories go glub, glub, glub to the bottom of the sea before he even gets a chance to put them out there. Physicists don't take him seriously, he's angry and so he's also writing a book complaining…

Just completely pathetic.

Comments

1. **Eugene Stefanovich**
   July 31, 2006

   Peter,

   thanks for the link. Correction: the interviewer's name is Michael Krasny, not David Krasny.

2. **CapitalistImperialistPig**
   July 31, 2006

   Holy shit! ST is taking on water fast if Susskind is morphing into Lubos Lite.

3. **Arun**
   July 31, 2006

   CIP,
   LOL!

4. **Peter Woit**
   July 31, 2006

   Eugene,

   Thanks, fixed.

5. **Hmm**
   July 31, 2006

Hey Peter,

Where are all the promised posts on your brilliant research ideas? We've been waiting and waiting and waiting and waiting….Surely you're bursting at the seams to tell us. Captain my captain, give us poor brainwashed masses a direction of research that will lead to concrete falsifiable predictions for physics, and we'll follow!

6. **J.F. Moore**
July 31, 2006

Yes, please tell us about your career as a "computer programmer". What a strange guy. It's like some people aren't aware that we are now living in a world where lies are discredited rather easily.

But are you serious that his second ad hominem is directed toward Smolin? If it's a joke I don't get it. If it's real, that's just scary. Is he that ego-driven or does he just want to sell his book that badly?

Is this like the gambling addict who doubles down because otherwise he must admit failure?

7. **Rickkkkkkk**
July 31, 2006

Hmm, Peter has made just as many falsifiable predictions as string theory(well actually more if you count his predictions of various Lubos meltdowns and the like) and as a bonus he's managed to do so without an attack squad or a hype machine. Well done Peter, bravo

8. **Paul Frampton**
August 1, 2006

My good friend Lenny on radio to promote his book does a good job.
1. Origin of string theory. My first postdoc was with Nambu starting
late summer of 1968 when I believe I was first to inform Nambu of the
Veneziano model. Within a couple of months Nambu had string theory,
in 1968, but did not publish it. My friends Holger Bech Nielsen
and Lenny himself did it independently. Chronologically Nambu was first.
2. Popularity of string theory. While it may be the most likely theory for quantum gravity it is probable there will be no data on quantum gravity for a long time so more particle theory papers should emphasize quantum field theory without gravity, by duality the same theory.
3. Lenny's "experimental evidence" for string theory showed poetic license but he was merely agreeing hastily with the interviewer as time ran out!

9. **D R Lunsford**
August 1, 2006

Um, hey Lenny, remember Veneziano?

-drl

10. **Eugene Stefanovich**
August 1, 2006

This interview would be funny if it were not so scary and medi-evil.

11. **hack**
August 1, 2006

Lenny can see his expiration date rapidly approaching and the result is not pretty.

12. **damtp_dweller**
August 1, 2006

"Let's talk first of all if we can about string theory since you're kind of called the father of it and all that…"

Sorry, did I miss the email in which it was announced that Leonard Susskind was "the father of string theory?"

Regardless of one's view of the theory, surely that title goes to several people, none of whom are Susskind? I'm thinking along the lines of Polyakov, Michael Green, John Schwarz, and, to an extent, Ed Witten.

13. **deloprator2000**
August 1, 2006

In a way I understand Susskind. Think about it he considers string theory as his "baby". He helped bring it into this world, he helped develop it to what it is now, for better or for worse, as such he will have an emotional attachment to it. To see string theory dismantled or criticized especially when you've dedicated your life's work to it, must be very difficult. I could just imagine at the turn of the century a leading "ether" theorist talking trash about some young punk named Einstein.

14. **Eugene Stefanovich**
August 1, 2006

hack:

Lenny can see his expiration date rapidly approaching and the result is not pretty.

If it were just Susskind alone… I am afraid that he is correct in pointing out that all the best and brightest, like Weinberg, Witten, Gross, etc., basically agree with him that there is no way around the swampland. Now we are all condemned to work on the swamp drainage project. Anybody trying to escape (Woit, Smolin, who else?) will be punished.

15. **Chris Oakley**
August 1, 2006

Susskind can say what he likes, but an anthropic Weinberg? *That* is hard to deal with.

16. **Stalin**
August 1, 2006

physicists that use these indimidatory methods can now prevent a scientific discussion, but will not remain influential after retirement.
Good luck to Berja Lubos.

17. **Lubos Motl**
August 1, 2006

Lenny's interview is nice. His description of two critics of physics is more personal than what I usually like, but its content is absolutely true.

I also think that Susskind's summary of the situation with the anthropic principle was fair – so "congratulations, Lenny" is the only thing I can say.

18. **MathPhys**
August 1, 2006

Paul Frampton,

Isn't true that Nambu wrote a paper, typed it himself in a hurry, as he was about to fly back to Japan, and it was circulated privately at the time?

I recall an early string theorist saying that the manuscript was so full of typos, they had to guess that Nambu frequently used his left hand shifted to the right, so many of his f's were are actually d's, and so forth.

Does anyone know if that manuscript is still around?

19. **MathPhys**
August 1, 2006

It's too bad that only Susskind is left to call himself "the father of string theory", as both Holger Nielsen and Nambu, both of whom are brighter and deeper physicists, are no longer in the limelight.

20. **Chris Oakley**
August 1, 2006

Good Morning Lubos,

Luckily I did not have a mouthful of coffee when I read your comment, otherwise it would have ended up sprayed all over the keyboard.

"His description of two critics of physics is more personal than what I usually like"

I assume that you meant "less" rather than "more".
Consult a Czech/English dictionary.

21. **boreds**
August 1, 2006

damtp_dweller

The statement about Lenny being the father of ST confused me when I heard it a while ago—but I think there is indeed a very early Susskind paper (1969?) on string theory as a model for the strong force. I don't think it's listed on SPIRES though, and I don't know why. I can try and dig out the journal reference but probably other people know it.

Anyway, he apparently lost interest in the subject for a while.

22. **Stefan**
August 1, 2006

Peter,

I came across Lubos's post on N.E.W. on "Mixed States". I read the criticism posted on his blog (17-page review of N.E.W) – well, most of it anyway; I then posted the following reply:

————————————————————————————–

Name: Anonymous

Dear L. Motl,

You recently posted your commentary on N.E.W. on "Mixed States". May I request a clarification (and if possible, elaboration) of the following remark:

"He ["P. Woit"] also assumes that string theory suffers from many problems whose absence has been [??] more or less [??] rigorously proved…"

When one writes "rigorously" does that imply "more or less"? Exactly what problems were enumerated and how were their absences RIGOROUSLY proved within string theory?

————————————————————————————–

The point of this exercise was: L. and such like will always bark, does that mean we should suspend our own work to respond to each and every diatribe they may (or can possibly) throw at us?

I don't believe he is taken as seriously by his peers as he takes himself… I don't mean that as an insult or a put-down, but the kind of ranting and raving he seems to enjoy engaging in does little service to the cause of science – or rational discourse, for that matter – as a whole.

Please ask him to reply to the community asap; if he is unable to do so satisfactorily we should take out that old "crackpot index" and ask him to read it thoroughly before he writes his next review / diatribe.

[He can write anything he wishes in his blog-journal – that is his own personal column.]

Stefan

23. **plank**
August 1, 2006

“Well, for example, there’s one fellow who failed as a physicist, never made it as a physicist, became a computer programmer, has been angry all of his life that he never became a physicist and that physicists ignore him, so he’s now taking out his revenge by writing diatribes and polemics against string theory.

Somehow I suspect this is about me.”

Maybe it’s about Chris Oakley, given that you are not a programmer by trade.

http://www.cgoakley.demon.co.uk/cv.html
http://www.cgoakley.demon.co.uk/qft/

Anyway, these comments (personal nature) are irrelevant.

24. **Chris Oakley**
August 1, 2006

Hi plank,

I wish that your theory was correct, but I doubt it.
First, Peter argues the case against S.T. more eloquently, more knowledgeably and at greater length. He has, after all, written a book on the subject, and secondly, he has a university post meaning that he is more likely to be taken seriously and will therefore be perceived as more of a threat.
On the subject of the book, have a look at LM’s 17-page “critique”, which proves (?) *inter alia* that LM has now mastered the difference between the English and American spellings of the word “colour”.

25. **ksh95**
August 1, 2006

Things like this are not good for HEP. Unfortunately (or maybe fortunately) the people holding the purse strings are rarely as stupid as some would like to think. And even worse than that, it doesn’t take a genius to see what is happening.

> “…what do you think of the people who criticize your theories…the one guy is a poo-poo head who smells and the other guy is a doo-doo brain with big ears…”

Any one with half a brain will spot emotional immaturity and non-scientific arguments a mile away.

26. **woit**
August 1, 2006

Paul,
What was bizarre about the Susskind interview was not his claim that he and Nambu were responsible for string theory, but his claim that they were responsible for a successful theory of the strong interactions, e.g. QCD.

ksh95,
The thing is, the interviewer didn’t ask Susskind what he thought of the critics of string theory, he asked him what he thought of the criticism of string theory. His failure to answer this, and his decision to instead go for personal attacks on the people making the criticisms, speaks volumes.

27. **King Ray**
August 1, 2006

Peter, excellent blog today. Keep up the good fight!

28. **Paul Frampton**
August 1, 2006

MathPhys:

You are confusing two different contributions by Nambu. By origin of string theory in 1968 I meant rewriting the Euler B function as an infinite number of SHOs. The later contribution in 1970 by Nambu was writing the string action as the area of the world sheet. He did type (with many typos!) some notes on that which I suspect is what you remember. That action was discovered independently by another Japanese theorist Goto in 1971.

Yoichiro Nambu is the deepest theorist of my 130 collaborators. I wrote one paper with him on string theory in 1970. Writing papers with Holger Nielsen was also remarkable for his exceptional creativity. I have never written a paper with Lenny but have talked with him about physics. We are on opposite coasts!

Peter Woit:

Nambu, though not Lenny, did contribute significantly to the birth of QCD.

29. **TomB**
August 1, 2006

I didn’t realise physicists have so much in common with structural engineers. As any structural engineer will tell you there’s only two kinda people – structural engineers and those that wanna be.

Come to think of it – its like the irish on St Patricks day.

Regards

TomB

30. **Peter Woit**
August 1, 2006

J.F. Moore,

It’s not a joke, that second piece really was about Smolin. I didn’t bother to transcribe it, but Susskind went on to make up some extreme statement and attribute it to Smolin, then use it to claim that no one could take Smolin seriously. Standard straw-man argument tactic.

31. **Mahndisa**

08 01 06

I had no idea things were so NASTY! It disturbs me that this type of dialog is occuring when learning should be the goal. Geesh! 🙁

32. **LDM**
August 1, 2006

“Well, for example, there’s one fellow who failed as a physicist, never made it as a physicist, became a computer programmer, has been angry all of his life that he never became a physicist and that physicists ignore him, so he’s now taking out his revenge by writing diatribes and polemics against string theory.”

The reality is that if Susskind thinks string theory has experimental support, then “failed physicist” is in fact a description of him, since string theory clearly has no such experimental evidence.

But then again, this goes to the heart of the matter. If Woit is correct, then there are a lot of string theorists, “physicists” if you will, that are not really doing physics.

33. **JPL**
August 1, 2006

“Near the end of the interview, when asked to cite some experimental evidence in favor of string theory he said that yes there was a lot of evidence including:

1. The existence of gravity.

2. The existence of particles.

3. The laws of the universe.”

My-oh-my! Isn’t the existence of Susskind enough evidence in favor of Strings and all that other “SUSSY kind” of theories? Who needs any more evidence? Give it up…

34. **John A**
August 1, 2006

> Near the end of the interview, when asked to cite some experimental evidence in favor of string theory he said that yes there was a lot of evidence including:
>

I trust you’re not paraphrasing this, but someone somewhere has inhaled when they shoudn’t have…

35. **Another Physicist Turned Programmer**
August 1, 2006

Susskind said: “Well, for example, there’s one fellow who failed as a physicist, never made it as a physicist, became a computer programmer…” I took offence to this because it’s arrogant and assumed that just because somebody doesn’t want to do the physics that’s being done in the market, he/she has failed in physics. More often than not, it is the failure of practising physicists to attract physics graduates with physics research that’s exciting and worth doing. Bearing in mind the low pay and hard work that must be endured by most practising physicists as compared to other careers, a physics graduate often faces a hard choice whether to remain in physics, or to switch career. With the current theoretical high energy physics job market being dominated by string theorists, it’s not surprising that a physics graduate who doesn’t believe in string theory (and other “hot” topics being offered in the physics job market) would choose not to waste the rest of his/her life doing something he/she doesn’t believe in. The “failure”, I believe, lies with the inability of current practising physicists to offer research which is believable. Theoretical physics has lost its way and only the die-hard stubborn believers of the current fads in physics (like Lubos) choose to remain. If this is a measure of their “success” in physics, I want no part of it.

36. **MathPhys**
August 1, 2006

Paul,
Thanks for the clarification. Do you know if Nambu’s notes (with typos) are available? I know he’s retired since a long time, but is he still in Chicago?

37. **Mark**
August 1, 2006

Peter, thanks for the great post and the link to the interview. The crux of the whole matter seems to me to be where Susskind says: “…quantum chromodynamics is a string theory…” and where in he then connects all of the experimental successes of QCD to string theory in general. While I am aware of some work in this direction, I was not aware that QCD was considered a string theory. Nor that any of its successes could be claimed as “MAJOR successes” for string theory. How close to the truth is Susskind? Do most string theorist agree with him? Or do they have other successes that they like to point to? Thanks again.

38. **Peter Woit**
August 1, 2006

Claiming the experimental successes of QCD as successes of string theory is just absurd. There are no experimental successes of string theory to point to.

Susskind's original work on string theory was designed to use it to provide a theory of the strong interactions, but this failed completely. We understand the string theory Susskind was a codiscoverer of, we understand QCD, and they're quite different theories. After the development of QCD in 1973, many people (including Susskind) worked very hard on trying to find a different string theory, one what would be a dual to QCD. One of the main insights of this period was that of 't Hooft, that things simplify at large N (=number of colors), and that this is the most promising case to look for a relation to string theory.

In 1997 Maldacena was able to come up with a proposed string theory dual not to QCD, but to N=4 (different N, number of supersymmetries) supersymmetric Yang-Mills. This led to a lot of hope that similar techniques would soon lead to a string theory dual of QCD, which is Yang-Mills with no supersymmetries. Nine years later, this still remains to be found. No one has a string theory dual to QCD.

Susskind is claiming to have the solution to a problem that is definitely not solved, one people have been working on for thirty years.

39. **hack**
August 1, 2006

This is rather amusing: Susskind has borrowed another page from the Motl playbook, apparently editing his own Wikipedia page. He deleted reference to his book's sales figures, and posted verbatim a lengthy, gushing review of his book.

40. **Paul Frampton**
August 1, 2006

MathPhys:

In "Dual Resonance Models" (Benjamin, 1974) Chapter 4 reference 23:
Y. Nambu, lecture notes prepared for the Summer Institute of the Niels Bohr Institute (SINBI), (1970). I did not keep a copy of this paper which explained the string action. In 1974 I had copies of all the hundreds of papers cited in DRM including it. In 1979 I jettisoned them all when DRM was remaindered and string theory seemed finished. The story does not end there. The same book twelve years out of date was reissued by World Scientific in 1986 and sold three times as many. How to explain that? Nambu moves between Chicago and Japan. He might have a copy.
Otherwise I cannot help. Sorry! Best regards.

41. **L. Riofrio**
August 1, 2006

"Never made it as a physicist, became a computer programmer.." That failure Bill Gates has written another book? (Disclaimer: The writer took a theoretical physics class from Susskind and received an A.)

42. **MathPhys**
August 2, 2006

Paul,

I have a copy of the original edition of your book.

Thanks.

43. **Peter Woit**
August 2, 2006

hack,

According to the latest version of Susskind's Wikipedia page, he and Michio Kaku are the co-discoverers of string theory, and his "Cosmic Landscape" book is a #1 bestseller.

44. **Chris Oakley**
August 2, 2006

I am surprised that Susskind's Wiki page fails to mention his other achievements, i.e. that he

• Developed a cure for cancer
• Found the *Lost Chord*
• Discovered Penicillin
• Invented Quantum Mechanics
• Determined the structure of DNA
• Invented the steam engine.

45. **MathPhys**
August 2, 2006

I just listened to Susskind's interview, and I found his claim (near the end) that string theory has had "lots and lots of great successes", then starting to talk about strong interactions, to be indeed very strange. It is simply technically inaccurate.

Incidentally, he also claims to be behind 1. the assertion that there is no loss of information in black holes, and 2. holography, both of which are definitely due to G 'tHooft.

46. **Haelfix**
August 2, 2006

1) The assertion that there is no loss of information in black holes.

Well, might as well chalk up 80% of the theoretical physicists living at the time when Bekenstein and Hawking made their inroads on blackholes, b/c it was more or less *the* question at the time. Picking one side or the other isn't exactly a great stride. You might ask who coined the question to begin with. Afaik, that comes from Roger Penrose but I might be mistaken.

If you want more specific details, I suspect you could pick any number of different authors who tackled the problem.

Incidentally it is still an open question, albeit one with a number of competing solutions (some of which say involve the the Strominger-Vafa calculations on stringy blackhole mechanics) and the plurality of people feel its no loss.

47. **Paul Frampton**
August 2, 2006

MathPhys:

Perhaps you should hang on to it. The 1974 book sold only 1200 but the
1986 reissue sold 4000+; the 1974 book has been widely stolen.
To answer your original query, the paper is reproduced in "Broken Symmetry" (World Scientific 1995). To the bemusement of my office mates Nambu would come to my postdoc office to tell me his thoughts.In 1969 he told me the action for the string. The dialogue went essentially like:
Frampton: " I have to say it is not completely obvious to me why that is the correct action." Nambu: "But, Paul, you know very well that the action for a particle is the invariant length of its world line" Frampton:" I understand! It is obvious that invariant area is correct." It is now discussed in textbooks.

48. **MathPhys**
August 2, 2006

Paul,

What can I say? Y Nambu is a great man. I wish someday he would write his autobiography, but I think he's too modest to do so

I just checked that the Benjamin edition of your book is where I thought it is!

I also just checked that my copy of "Dual Models", a collection of Physics Reports, edited by Jacobs and published by North Holland in the 70's is also where still there.

I bought it (brand new) for about $6.00 in 1982. There were about 10 copies in the warehouse where I bought it. North Holland dumped the whole edition because it was not selling. I wish I bought the whole lot.

49. **MathPhys**
August 2, 2006

As I leaf through physics reports on string theory from the 70's, I'm struck by the beauty and depth of string theory, even in those very early days.

I know that 30 years down the track, it still has no experimental evidence, that it works only in higher dimensions, that something is wrong about susy, that compactification is an unnatural idea, and above all, I'm totally put off by the arrogance and hype of people like Motl.

But there is something about string theory.

By comaprison, I'm afraid I find that LQG is not only half baked, as Susskind says, but at most 1 per cent baked. There is just no comparison.

50. **D R Lunsford**
August 3, 2006

MathPhys,

I too was struck by it when I came across it in the 80s – by its colossal ugliness and metaphysical pointlessness (sorry). That is – if the idea of matter had failed, then it was not the configuration of it that was responsible, rather, the very idea of an exacly localized "thing" of *any* dimension at all – and it was obvious how it would fail. Also, it was profoundly anhistorical – one, by dredging up Kaluza-Klein theory, which was rightfully dead (Pauli), and second, by ignoring the real problem in quantum theory, the idea of measurement. It was also totally opposed to the more geometrico of GR in spite of its pretensions. Not only was it never a real candidate for a "theory of everything" (who ordered that?), it was completely incompatible with BOTH GR and QM – it was, and is, a theory of nothing. What on Earth were people thinking to believe in such a theory?

-drl

52. **Lubos Motl**
August 3, 2006

Dear Stefan,

"more or less rigorous" means "rigorous" according to the standards of theoretical physics. This misunderstanding of yours is indeed another example of your breathtaking ignorance that all but guarantees that you will probably always be nothing more than a joke.

I wish you happy interactions with other idiots near the bottom of the sea.

Best
Lubos

53. **nigel cook**
August 3, 2006

"… it is now hard to set up a clear criterion for what is crackpotism (should I delete Lenny Susskind's comments if he decides to write in some day?)." – Peter, http://www.math.columbia.edu/~woit/wordpress/?p=128

I feel sorry for Professor Susskind having to finally respond to your criticisms of his theory, and doing it personally. His theory has received all the mainstream limelight for twenty years and he is promoting his very first book, criticisms are surfacing because now some people realise that it may not be the most helpful theory.

I watched him on TV somewhere and he is a really nice, down to earth person, actually he is an ex-plumber from New York who started physics a bit later when he went to college to do a gas installation course.

So if his string theory is full of holes and leaks, then he is the best person to fix it.

54. **hack**
August 3, 2006

'"more or less rigorous" means "rigorous" according to the standards of theoretical physics.'

Which more specifically means "can't be disproved with five minutes of hand-waving argumentation".

55. **David**
August 3, 2006

I can't help but notice that Motl again avoided the question that Stefan posed, i.e. what are the problems that Peter enumerated that Motl claims have been proved absent. If such proofs exist, Motl would do well to tell us about them rather than simply insult Stefan. Such a reply would strengthen string theory's position vs. Peter's criticism. Dare I suggest Motl adopts his position because he can't provide such proofs?

56. **Benni**
August 3, 2006

At a speech in munich I have asked Suesskind in person:
"When we are in the situation that string theory can describe any physics we want, would it not be better to accept this state of string theory and search for alternative theories?"
Suesskinds answer was:
"Yes of course. Of course. If you have one tell us of it"
I think this was a reasonable sentence.

57. **Thomas Larsson**
August 7, 2006

But there is something about string theory.

MathPhys,
There is something about CFT – it is the correct, and most likely the ultimate, theory of 2D phase transitions. This does not mean that it is the right theory of 4D gravity. Besides, it is not a theory of everything even in statphys, since it does not say anything about the physically more interesting 3D case.

P. University Press

August 1, 2006
Categories: Not Even Wrong: The Book

I really am trying to ignore Lubos, but there's just too much material…

Back in early 2004, after it became clear that Cambridge University Press was very unlikely to ever publish Not Even Wrong due to intense opposition from string theorists, I tried sending the manuscript (together with the Cambridge referee reports) around to a few other university presses to see if any of them would be willing to publish it. The response I got from two editors at well-known presses was positive comments about the content of the manuscript, but:

I think it's too controversial for a university press to publish.

from one, and from another

it is extremely unlikely that a proposal as controversial as yours would be accepted by the .

This made clear exactly how much of a "free marketplace of ideas" exists for debate about string theory within this part of the publishing world.

An editor at Princeton University Press wrote back after considering the manuscript for a week or two with a form-letter rejection informing me that "we must often forego formal review of promising manuscripts or proposals such as yours". I assume that, as I expected, the editor had discussed the manuscript with one of the local string theorists and thus been convinced not to pursue it.

With Roger Penrose's help, finally late in 2004 the British publisher Jonathan Cape bought the book, planning to publish it in Britain and sell the U.S. rights to an American publisher. During the first part of 2005 I worked a bit more on the book and it was copy-edited, and by the early fall the people at Cape were in negotiations with various possible US publishers, negotiations that I had little to do with. In November the editor at Cape told me that Princeton University Press had rejected the book as "too controversial". The next month US rights were sold to Basic Books.

I had no idea about this at the time, but it seems that someone had advised Princeton that the appropriate person to review this kind of manuscript and give an unbiased opinion about it was a Harvard string theorist with a well-known blog named Lubos Motl. Lubos has now posted his report, together with the proud claim that "a serious publisher whose name was edited used to scrap the project." He cleverly hides the true name of the publisher in question as "P. University Press".

The report makes clear what Lubos was going on about in some of the incomprehensible parts of his Amazon review. I responded to that review here, but couldn't even figure out a lot of what he was talking about there. With his detailed report with page numbers, this is now clear.

He was definitely on his best behavior. The report is not obviously a rant, and even includes some positive comments. He carefully went through the manuscript making many sorts of copy-editing suggestions (e.g. changing English spellings to American) and suggested a large number of rewordings of the manuscript that would make what it said agree with his vision of reality (but not mine).

Anyone interested can go through the report, compare it to the book and judge for themselves whether Lubos's extensive criticisms make much sense. Responding to his 17 pages filled with misinterpretations of what I wrote and tendentious claims about string theory is something I don't have the time or energy for, but I'll respond to his summary where he says that the book should be rejected because of its "many serious and elementary errors." He lists these as:

1. I don't know the difference between a GeV and a TeV. This is based on one typo, on page 32, where, after writing that the center of mass energy is at the LHC is 14 TeV, I mention that it might be possible to double this energy by doubling the strength of these magnets, and "28 GeV" is an obvious typo for "28 TeV". This typo is fixed in the US edition, thanks to the fact that he makes this argument against the book in his Amazon review.

2. He objects to my pointing out (page 179) that in a theory with broken supersymmetry the vacuum energy scale is too large by a factor of 10^{56}, wanting me instead to say that supersymmetry "improves" the vacuum energy problem with respect to non-supersymmetric theories by a similar size factor. What I wrote is correct.

3. On page 35 I mention that the neutrinos produced by a muon collider interact weakly, so will go through the earth and produce a radiation hazard when they emerge many miles away. Lubos claims that this is wrong, that "neutrinos with hundreds of GeV of energy interact strongly". This is nonsense. What he has in mind though is not really a "strong" interaction strength, but an electromagnetic interaction strength. He's right that at hundreds of GeV (way above the W and Z masses), there is electroweak unification, and the weak interaction and electromagnetic interaction strengths are similar. However, he seems to be making an elementary mistake: the neutrinos involved will be hitting a fixed target, so the energies involved will be much lower.

4. He repeats a mistaken comment that I once made on my blog about about SU(2) and SO(4), one that has nothing to do with what I write in the book. His excuse for introducing this is that on page 49 I refer to "axes of rotation" in 4 dimensions, complaining that I should have explained that in 4 dimensions rotations are specified by choosing not a one-dimensional axis, but a two-dimensional plane. It's quite true that I was simplifying things, not explaining that in N dimensions an "axis of rotation" is N-2 dimensional. Explaining that more carefully was not something I wanted to get into. Perhaps he's right that it would be better if I put "axes" here in quotes to keep people from making the wrong assumption that he's making.

5. He finds something wrong with the fact that even though I explicitly say that the physical Hilbert space is the trivial representation of the gauge group, I speculate that understanding the non-trivial representations of gauge groups is an unsolved mathematical problem whose solution might tell us something interesting about gauge theory. This is clearly labeled as speculation and perfectly accurate as written.

Anyway, now I know why Princeton rejected the book, although I still have no idea who put them up to choosing Lubos as a referee.

For more about Lubos and the controversy over string theory, there's an article in the Frankfurter Allgemeine Zeitung (in German). Lubos comments that "virtually all well-known theoretical physicists" think as he does, but that only he (together with Susskind) is willing to fight compromise with very stupid people and crackpots like me. He warns "to the polite big shots: the more silent you will be the more loud the blunt opinionmakers such as Susskind or your humble correspondent will have to be."

Comments

1. **Chris Oakley**
   August 1, 2006

   Anyway, now I know why Princeton rejected the book, although I still have no idea who put them up to choosing Lubos as a referee.

   I find this puzzling too, as sending *Not Even Wrong* to Lubos is a bit like sending *The Da Vinci Code* to Torquemada.

At the end of the day, though, publishing is a *business* … even without any referee reports it was obvious that you had the credentials to write such a book, and the question really was, would people buy it? And as *The Da Vinci Code* proved, even things that are arrant nonsense can sell if they are controversial.

2. **LostHisMarbles**
August 1, 2006

Just a brief comment about particle beams AFTER they go through particle detectors ~ "radiation hazard". (One can have in mind neutrino beams.) The beamlines are typically angled to that the beams go flying up in the air and enter the atmosphere and outer space. This is certainly the case at Fermilab, where the beamlines are angled upwards. By the time the neutrinos etc clear the FNAL boundary, they are in the air above any homes outside FNAL. (No skyscrapers there.) No radiation hazard. I believe there is a no-fly zone where airplanes stacked for O'Hare do not fly, to avoid their electronic instrumentation being hit by the beams. I have no doubt the ILC or a muon collider will be designed the same way. Someone from FNAL can comment in more detail.

3. **woit**
August 1, 2006

Chris,

University presses are funny businesses, not completely driven by the profit motive. It is generally part of their mission to have high intellectual standards and sometimes publish things that might not make much sense financially. In the case of my book, the controversial nature would suggest that it was likely to sell better than much of what they publish and might make them some money. The argument against publishing it would be that it didn't meet their intellectual standards, and this is what a reviewer is supposed to provide an evaluation for.

4. **Aaron Bergman**
August 1, 2006

Geez. My review is ony 11 pages right now….

(Which I will finish up eventually, but right now I'm focussing most of my time on Hochschild cohomology.)

5. **Lubos Woit**
August 1, 2006

well, at least now you can be sure that lubos wasn't lying when he said that he has read your book.

6. **Santo D'Agostino**
August 1, 2006

Lubos Woit,

It is dishonest to comment on a MANUSCRIPT and claim that it is a review of a BOOK.

7. **Kea**
August 1, 2006

Anyway, now I know why Princeton rejected the book, although I still have no idea who put them up to choosing Lubos as a referee.

Maybe they support the book, and were cleverly using their position to garner great publicity for your book via Lubos!

8. **Tommaso Dorigo**
August 1, 2006

Peter,

I have to say that, while I do think it is a proven fact that the trouble your manuscript faced when trying to become a book is almost entirely due to the string mafia, I also believe that the point you seem to make at the start of the post above is prone to criticism: you seem to imply that when somebody says "this book is too controversial" (s)he means "this book goes against the mainstream thinking of the big mushrooms and it would bother them".

I think there are two separate issues. We agree on the mafia, but I think (some) University Press editors might be honest when they say they prefer to avoid publishing divulgation material which is so focused on criticizing a theory en vogue.

The fact that there was quite a bit going on under the tables during the review process of course might make the above detail irrelevant, given the direct attempts at having the book rejected. But in principle, UPs might be right if they think scientific controversy is better solved at the blackboard than in a media fight… Indeed, controversy usually sells well, as somebody pointed out above – but UPs are right in ignoring that. You said it – there aren't just business issues there.

That, of course, does not mean the book wasn't needed or useful… Quite the opposite. Thank you for writing it!

T.

9. **LDM**
August 1, 2006

Form Lubos review: *I find it completely necessary to mention the names of Andrew Strominger and Cumrun Vafa – the authors of the pioneering work that has shown that string theory gives the right value for the black hole entropy.*

What was actually discussed by Strominger and Vafa: *The Bekenstein-Hawking area-entropy relation $S_{BH}=A/4$ is derived for a class of five-dimensional extremal black holes in string theory by counting the degeneracy of BPS soliton bound states.*
http://arxiv.org/abs/hep-th/9601029

This is definitely not the same as what is suggested by Lubos — that the result applied to all black holes (whether charged, uncharged, or rotating) — which we know was the original Hawking result. In fact, read the Strominger and Vafa paper, look at the result, and you see it does not apply for uncharged (electric charge) black holes…It also relies on the conjectured existence of Axions and that the black hole has large Axion charge.
Sadly, the same tremendously overstated misrepresentation appears on Vafa's own web page:
http://www.physics.harvard.edu/people/facpages/vafa.html
Among these one can name the discovery of Strominger and Vafa that the Bekenstein-Hawking entropy of a black hole can be accounted for by solitonic states of string

theory and also the relation between geometry and field theories that arise through string dualities, a topic known as "geometric engineering of quantum field theories".

The Lubos review is neither objective or balanced…but that is not new for him.
What is disturbing is the thought that Princeton may have actually relied upon his review.
But don't worry, DOVER will pick up N.E.W. and re-print is as a classic 🙂

10. **Peter Woit**
August 1, 2006

Tommaso,

You may be right that part of the concern with "too controversial" is a fear of more heat than light being shed. In any case it's hard to know really what is behind editor's decisions. They're often not going to give truly honest reasons in a rejection letter, for lots of reasons, including simple politeness.

In this case though, from going through the process with the editor at Cambridge, I think I can see the problem that university press editors faced when considering the book. The book makes strong claims that some very accomplished (as well as powerful) people are wrong about something, and the issues involved are both highly technical and understood by relatively few people. The editors involved don't have the background to be able to decide for themselves how good my arguments are. When they ask experts, they find non-string theorists willing to support what I have to say, and string theorists often vehemently claiming I don't know what I'm talking about.

They end up in a very uncomfortable position of having to decide whether to put some of their reputation and the reputation of their institution behind me, without being able to be sure whether I'm right. In addition, these presses often have some faculty body that has to sign off on publication decisions, so the editor has to worry about whether he or she can convince them also. Not an easy decision to make.

So, I'm not too surprised that these university presses didn't want to get involved. I am surprised that Princeton University Press did decide to get involved to the extent of commissioning a review, then chose someone obviously inappropriate to do this.

11. **CapitalistImperialistPig**
August 1, 2006

Peter,

No doubt there are many of LM's comments that are trivial or even silly, but a few have apparent substance. I'm thinking of the critique of your statement on p 159 of the manuscript "string theory is not a background independent theory." I looked at the relevant chapter of Polchinski, and he does indeed claim that ST is not restricted to just one background. Could you clarify this issue?

Do you plan respond to his more substantive points?

12. **Peter Woit**
August 1, 2006

CIP,

I hadn't planned on going through Lubos's whole document and responding to all it, I just don't have the time, and mostly I don't think it would be very enlightening.

As for the "background-dependent" business, you could consult extensive battles over this between string theory and LQG proponents on this blog and elsewhere (don't even think of starting this up again Who or Aaron…).

The fact of the matter is that to even write down at all what you mean by a string theory, you have to first choose a background. Different backgrounds give different physics. This is what I mean by "background-dependent". What I wrote is completely accurate. String theorists have an argument, that infinitesimal deformations of the background space still leave you in the same theory, just a different state.

One could go on and on about this issue, it quickly gets confusing because string theorists love to mix up what is actually known and corresponds to something they actually can understand and write down, and what they don't understand, but hope to be true, with various degrees of evidence for the hope.

I really, really, really don't want to try and moderate the N'th unenlightening discussion of this issue here. If people absolutely can't restrain themselves, go ahead and provide a link to a discussion of this somewhere else that you agree with. Just don't try and fight out the issue here.

13. **Energex42**
August 1, 2006

Hey, I saw it in Amazon.com that Lee Smolin is coming out with a new book in September. Curiously it is about String theory as well. Not to worry, I will buy both.

14. **Bee**
August 1, 2006

Hi Peter,

I read Lubos review. I found it very nice actually. If I think of some reviews I receive on my papers, this is a very well founded, reasonable, though biased list. I can't avoid having the impression that the publisher was only looking for a confirmation that the book would be too controversial, otherwise the mentioned points could easily have been revised.

@Energex,
Lee's book is not about string theory. It's about the trouble with physics. Reading Peter's last post, it seems that's gotten more of a trouble with physicists lately.

Best, B.

15. **Kasper Olsen**
August 1, 2006

Dear Peter,

You're saying that: *"different backgrounds give different physics. This is what I mean by "background-dependent".*

Could you please make more precise the definition of the term "different backgrounds"?

(1) Are you claiming that the background g'_{ij} = exp(2)g_{ij}, for example, will give different physics from the background g_{ij} ?

(2) And are you claiming that the sum over topologies (of the world-sheet) is not determining the interactions (of the superstring)?

(3) And – in relation to (1) and (2) – in analogy that only "background independent" formulations of, for example, QCD are relevant?

(4) And that *string field theory* is not a background independent formulation of string theory (in the sense to be defined above)?

Cheers, Kasper

16. **woit**
August 1, 2006

Kasper,

1. No
2. That has nothing to do with this question.
3. That has nothing to do with this question.
4. Yes

17. **C**
August 2, 2006

Is it possible that Lubos' role in the review process was the result of a misunderstood joke?

Publisher A (doesn't read blogs): Who should we get to review this?
Publisher B (reads blogs): (sarcasm) Of course, we should get Lubos Motl from Harvard.
Publisher A, impervious to sarcasm, sends manuscript the next day.

18. **anonymous**
August 2, 2006

About neutrinos: they produce radiation hazards in TeV-energy muon colliders because 1) muons decay to neutrinos; 2) TeV neutrinos interact with matter LESS strongly that electrons, photons etc, so that building the collider underground is not enough to shield neutrinos: they exit making occasional showers.

PS: how many books had a Harvard professor as spell checker?

19. **Kasper Olsen**
August 2, 2006

Dear Peter,

I forgot to make precise that the first question is not (1), but (0), or:

(0) Could you please make more precise the definition of the term "different backgrounds"?

and I don't hope you'll answer

0(1). No,
or
0(2). That has nothing to do with this question.

In saying that background A is different from background B, one must have a way of classifying different – and consequently equivalent – backgrounds, or – loosely speaking – a metric topology on the space of backgrounds. For example, I would use a metric where background

A' = exp(2) A

is at zero distance from background A.

cheers, Kasper

20. **Stefan**
August 2, 2006

Hi Peter,

Peter, with a heavy heart I must state my dismay and disappointment with your actions – in regards to your various opponents, so far.

Lubos – with all his grandiose utterances – is nothing more than a rambler. (His own utterances will testify amply to that.)

When will you – if ever(??) – start discussing physics again?

If, at any time you do, please follow on:

I have been trying to find some useful information on the topics we discussed upon earlier:

1) Dirac operators, and

2) Gauge fields.

Landmark texts / works?
Do you by chance happen to know the standard references to consult? (Textbooks, Arxiv, etc.)

I am also trying to purchase the text by Jouko Mickelsson: Current Algebras and Groups.

Finally, do you happen to know what the following texts are primarily studied for:

1) Gauge Fields: An Introduction to Quantum Theory – L. D. Faddeev, A. A. Slavnov;

2) Gauge Fields and Strings – A. M. Polyakov;

3) Quantum Field Theory: From Operators to Path Integrals – Kerson Huang;

4) Operator Methods in Quantum Mechanics – O. L. de Lange, R. E. Rabb;

Thanks,
Stefan

21. **ocnote**
August 2, 2006

LM writes on his blog: "People, including those with degrees, tend to trust the media, and because the media have been producing crap about physics most of the last few years, it more or less means that most people who rely on media inevitably believe this crap."

You don't think Lubos means the media-hype around string theory, do you?

22. **Arun**
August 2, 2006

I'm wondering whether delaying Peter's book has increased its impact, because as each year goes by, the claim of progress becomes less plausible.

23. **Anonymous Coward**
August 2, 2006

Stefan,

When did you ever get the impression that Peter knows anything about cutting-edge physics? He never did and doesn't now. Thats why he has this blog–the only way to make a name for himself, which is much easier than actually doing research. He keeps promising to talk about physics, but never does, because he has nothing interesting or substansive to say. You should check out his (in)famous ideas on the embedding of SU(2) into SO(4) to see the calibre of great ideas he thinks up. This isn't meant to be insulting to Peter, only explanatory. He has much more fun knocking down people who are seriosuly working for years on interesting difficult ideas, especially when it requires no intellectual effort of him. Thats why almost no real theorists–string theorists or not–respects or even pays any attention to him. If you're interested in substansive physics discussions, ignore blogs and the mediocrities and crackpots they attract altogether. Peter has been promising to tell us about his fantastic ideas for research for a long time now, and I predict it will never happen.

24. **woit**
August 2, 2006

Kasper,

I have no idea what the precise set of consistent string theory backgrounds is or what the correct metric on it is, and I don't think anyone else does either. But as far as anyone can tell, there are many of them, they give different physics, and you have to choose one before you can even write down what your theory is and try and see if you can extract any physics from it.

Stefan,

There are by now hundreds of places you can read the basics of gauge theory and find out what the Dirac operator is. Some of the books you mention contain this, there are many others. You first need to understand quantum Yang-Mills theory at the level of the books you mention. Another one that is highly readable is Pierre Ramond's QFT book.

Once you understand that, then I'd suggest learning about the mathematical context of these things. I keep encouraging people to read Atiyah's expository articles. The Mickelsson book you mention is much more advanced than the other books, but also highly worth reading, it's a much more research level document.

AC,

You know, you anonymous pluckers really should try and find at least one more mistake I've made in what I've written here and in the book. I'm sure among the by now thousands of pages of stuff there's at least one more.

25. **King Ray**
August 2, 2006

Peter, keep up the good work. I think your criticism of string theory is contributing more and doing a greater service to physics than all the string theorists combined. They have no aesthetic compass.

26. **David**
August 2, 2006

Peter,
I have now finished reading the UK version of NEW. As someone who works in the molecular/chemical end of science (among other things) and not in HEP, I found the book difficult in spots. However, by the end I thought you had given a clear overview of your position on the current state of theory in HEP. The essential arguments are there. If the string folks want to say that's not correct and explain why, then that should help understanding in the field. WRT to Lubos, I don't think you should expect much. Based on my interactions with him, I find that he is not interested in the reasoned discussion of scientific issues. He's only interested in telling people that his view is correct and everyone else is wrong because they're too stupid to see that he's always right. A particular thing that I find annoying is his over and over misquoting someone and concluding the person is stupid based on his misquote. In summary, I think NEW is thought provoking and thus adds something positive to HEP discourse. I think a full and frank discussion of these issues will make HEP a stronger field. I hope that happens. As you mentioned, last week, if some of the braneworld models that may be testable at the LHC are supported, you'd modify your views. That's what a scientist does. Hopefully other people will take note, and adopt a similar attitude. NEW, the book, is, I think, a very positive contribution.
Best,
David

27. **Juan R.**
August 3, 2006

I do not usually reply anonymous postings but will reply this one.

Anonymous Coward said,

> When did you ever get the impression that Peter knows anything about cutting-edge physics? He never did and doesn't now.

Right! I do not remember Peter Woit (not other here) claiming that. I remember string theorists claiming that they are making the TOE (i.e. claiming that they know anything about anything).

> Thats why he has this blog–the only way to make a name for himself, which is much easier than actually doing research.

Right again! This is reason that string theorists wrote so many popular books, give talks for outsiders, submit articles to generic magazines, give interviews to media. Unfortuntately, after 40 years there is none serious work about string theory, none prediction, none explanation of misteria of SM and GR…

> He keeps promising to talk about physics, but never does, because he has nothing interesting or substansive to say. You should check out his (in)famous ideas on the embedding of SU(2) into SO(4) to see the calibre of great ideas he thinks up.

Would i remember you how many wrong stuff is said each day by string theorists? None serious physicist working in quantum measurement takes Brian Greene ideas about the topic seriously (Dyson was very clear about this a few years ago). There is more…

> He has much more fun knocking down people who are seriosuly working for years on interesting difficult ideas, especially when it requires no intellectual effort of him.

Do you mean that serious people who claim that string theory predicts gravity (Witten), that string theory is the language God wrote the world (Motl), that the CC is explained by the antrophic principle over a quasi-infinite Landscape (Susskind)?

Hum, when you ask Witten how string theory predicts gravity he replies that really is a postdiction, when you ask Motl about derivation of some known stuff in physics he replies insulting (as usual in him because string theory predicts/explains nothing), when you follow details of the Susskind approach you coincide with Gell-Mann: absurd.

> Thats why almost no real theorists–string theorists or not–respects or even pays any attention to him.

I know that string theorists -and others- usually do claims without basis. Could you provide any reference or statistical data for your claim please?

> If you're interested in substansive physics discussions, ignore blogs and the mediocrities and crackpots they attract altogether.

Then why are you writting here?

> Peter has been promising to tell us about his fantastic ideas for research for a long time now, and I predict it will never happen.

I do not know, nobody knows. However, is not that the history of last 40 years of research in string theory? During 40 years we receive claoims about all kind of fantastci stuff could be done from string theory and how M-theory would revolutionate our views about space and time? result?

1) String theory is unable to explain data can be explained with common theories as SM and GR. String theory is compatible with nothing of this world.

2) Nobody knows M-theory is (if it really exists).

3) Since string theory cannot explain stuff as CC using scientific method the scientific method is abandoned by metaphysical cuasi-religious stuff (instead abandoning string theory nonsense).

Juan R.

28. **Mahndisa**
August 3, 2006

08 03 06

Hello Peter:
Congratulations on your book reviews etc. And I am curious about what you or anyone else thinks about Mr. Thiemann's newest paper on AQG? Pls pardon me if you have already written about this. I asked Lubos, but to no avail. I don't think my knowledge is developed enough to analyze the paper thoroughly, perhaps you or someone else can? Thanks.

29. **Peter Woit**
August 3, 2006

Mahndisa,

I took a quick look at the papers, they look interesting, but to really understand them would take a lot more time, since I'm no expert in this area. I hope to find the time someday to read them more carefully.

30. **Mahndisa**
August 3, 2006

08 04 06

Thanks for the response Peter. I have a feeling, a thorough analysis of that set of papers will take a lot of time yet;)

31. **Kasper Olsen**
August 3, 2006

Dear Peter

Now, if what you are saying, that

I have no idea what the precise set of consistent string theory backgrounds is or what the correct metric on it is, and I don't think anyone else does either.

is true, then

(1): how can you claim, that

there are many of them, they give different physics

????

and related to my question above, which you considered irrelevant to the discussion,

(2): if your statement, that

you have to choose one before you can even write down what your theory is and try and see if you can extract any physics from it.

is true, then are you applying the same critisism to theories like

QCD, or **QED**

????

Cheers, Kasper

32. **woit**
August 3, 2006

Kasper,

This is about Lubos's claim that I'm wrong to say that string theory depends on a choice of background, this has nothing to do with QCD and QED. You're trying to start up a different argument that has already taken place here many times.

Your attitude seems to be that string theory is background independent since you don't know what the possible backgrounds are or how to calculate anything in them. I suppose that's a consistent point of view…

33. **Kasper Olsen**
August 3, 2006

Dear Peter,

I think my question (2) was relevant for the reason implied above, but of course it is up to you if you want to answer the question (2), or not.

And whether Lubos claims this or that has nothing to do with my question – actually, *I'm just trying to follow your line of thinking*;

and I think it would be relevant to get an answer to my question above:

(1): how can you claim, that

there are many of them, they give different physics

??

But of course, I haven't read your book yet…

best, Kasper

34. **Michael Edwards**
August 4, 2006

This comment is too long and has too much math in it, but I thought readers might be interested in an elaboration of Peter's "wrong" ideas about subgroups of SO(4). Disclaimer: I am not a working mathematical physicist, just a hobbyist with an unfashionable interest in physics on 4-dimensional manifolds of Euclidean signature and complicated topology.

If I've read the infamous "SU(2) embedded in SO(4)" error correctly ("Wick Rotation", Feb 28, 2005), it's not even (all that) wrong. Yes, if you insist on viewing SU(2) as an _invariant_ (normal) Lie subgroup of SO(4) and imposing a _group_ structure on SO(4)/SU(2), then you do have to choose one of the "chiral" SU(2) subgroups. In this case, the quotient group is unambiguously SU(2)/{+/-1} ~ SO(3) with generators drawn from the "opposite" chiral subgroup. But that's not the only way a quotient of Lie groups can enter into physics. If all you want is a finer fibration of a principal bundle with an SO(4) fiber, then it's not important to have a group structure on the quotient space, and you can choose any Lie subgroup of SO(4) as the (sub-)fiber.

Peter's later comment about an "anti-diagonal" SU(2) is indeed erroneous, in that the generators "orthogonal" to the diagonal SO(3) don't form a closed Lie algebra. And for this reason, I think the "diagonal" SO(3) isn't a terribly helpful starting point if you want to wind up with an SU(2) that you can identify with the electroweak SU(2)_L. But there's another way to implement the spirit of his original post, which is to look at the manifold structure of SO(4) / (subgroup containing SU(2)_L) and ask what the action of the remaining generators on this manifold looks like.

This matters when you try to express, say, a Chern character on a 4-manifold M in terms of a more complex bundle over M than the ordinary frame bundle. Why would you want to do this? Because we have much more powerful analytical techniques for systems phrased in terms of complex fields than for those phrased in terms of real fields, and this more complicated bundle structure may contain a central U(1) that we can identify with the "i" of complex analysis.

For instance, you could take an individual chiral generator — call it I (in a convention in which the "generator" is the actual Lie algebra element and not the matrix I/i) — and consider the non-normal Lie subgroup G1 equal to the centralizer of I (isomorphic to SU(2)xU(1)/{+/1} ~ U(2)). We can't put a Lie group structure on SO(4)/G1. But we can form a principal bundle with total manifold F ~ SO(4), fiber G1, and base manifold F/G1 ~ SU(2)/U(1) ~ S^2. The quotient is done along the orbits of the right action of G1, which also makes sense _globally_ on other objects with a global SO(4) right action — such as the SO(4) principal reduced frame bundle P of a 4-manifold M of arbitrary orientable topology. So you can look at the whole frame bundle as a principal G1-bundle E, globally diffeomorphic to P, over a bigger base manifold

N=P/G1, locally diffeomorphic to (U \subset R^4) x S^2.

This 6-manifold N is in turn an associated SO(4)-bundle over M with fiber S^2, trivially reducible to an SO(3)-bundle since the generators of the SU(2) with opposite “chirality” to I (let’s call it SU(2)_L) all act trivially on the fiber. In general you can’t find a global section of this associated bundle, i. e., a smooth mapping from each point on M to a point on the fiber over M; if you could, then you could reduce the structure group of P to G1. But you can ask how a connexion on the original fiber bundle acts on the S^2 fiber of the associated SO(3)-bundle N and on the G1 fiber of the new principal bundle E.

We were able to reduce the structure group of N to SO(3) because both the left and right actions of SU(2)_L act trivially on its fiber S^2. So does the right action of the U(1) with generator I, as long as the quotient on SO(4)/G1 is taken from the right; but the left action of exp(It) on SO(4) doesn’t follow the same orbits as the right action. And because the fiber bundle structure of SO(4)/G1 is not trivial (it’s related to the Hopf map SU(2)/U(1) ~ S^2), we can’t reduce the structure group of E to SU(2)_L. Although the right action of G1 on an individual fiber of E looks like U(2), and we can certainly define a left action of the central U(1) on that same fiber for the purpose of constructing an atlas on E, this left action does not coincide with the left action of G1 as a subgroup of SO(4) on the original bundle structure P.

This complicates the mapping of fields of geometric origin on P to fields on E, which are (potentially) more analytically tractable. For instance, a connexion on the original fiber bundle P, viewed as a lift of the space of tangent vector fields on M to the space of right-invariant tangent vector fields on P, is more like a left action than a right action (in the sense that, if point p \in P has coordinates (x_i, g_i) in a given coordinate patch, and the right-invariant vector field v has the coordinate expression (v_i, g_i a) at p for some element a in the Lie algebra of G, then at R_g(p) = pg = (x_i, g) it has value not (v_i, g_i g a) but (v_i, g_i a g)).

So from the point of view of gauge couplings, i. e., the connexion on the original frame bundle, the original SO(4) splits into an SU(2)_L that acts on the fiber of the new G1-bundle and an SO(3) that acts on the “compactified” S^2; the latter also acts on the central U(1) of the G1 fiber in a way that varies depending on where you are on S^2. Except that’s probably not the right way to define a connexion on E that is in some sense induced from the connexion on P; instead, you want to go back to the idea of a connexion as a family of horizontal subspaces of the tangent spaces at various points of the bundle, and ask whether there is a consistent way to extend the 4-dimensional horizontal subspace at a point p \in P to a 6-dimensional horizontal subspace at the corresponding p \in E. The answer is yes; although the right actions of the other two SU(2)_R generators are associated with vector fields on each fiber of P which are not invariant under the right action of the U(1) in G1, the plane they span is.

Enough math. Looking back at Peter’s original idea, it is tempting to identify SU(2)_L with the weak SU(2) and seek a (not necessarily trivial) relationship between the central U(1) and the hypercharge U(1). As he proposed, there is also a resemblance that I won’t go into right now between the SO(3) action on S^2 and the SO(3) of spatial rotations on the original bundle; and analytical results (if any) will probably involve spinors and Wick rotations, not so much because the geometric objects sort neatly into spinor representations (they don’t) but because that’s a useful way to implement “gauge fixing” of the diffeomorphism group of M.

Does this have anything to do with the fundamental reality underlying the Standard Model? Maybe, maybe not. But it seems to me to be a perfectly sensible starting point for an interesting mathematical excursion. And having audited and enjoyed a string theory course not so long ago, that’s more or less how I feel about string theory, too. It’s just not science — not until it has some combination of predictive and explanatory power with regard to the observed universe.

Cheers,
– Michael

35. **John Gonsowski**
August 4, 2006

Michael, given Peter’s recent comments, your math filled post about Peter’s ideas might be more common in the future of this blog. That 4 in SO(4) is a Clifford Algebra vector and why more people don’t play with a vector for their spacetime is beyond me. If you want a ten dim spacetime then John Baez’s SO(10) paper seems like a nicer starting point than string theory. If you want to naturally get to spinors then SO(8) and its triality seem nice, even string theory noticed this years ago before getting farther and farther from the real world. One can also do nice things with SO(8) and fiber bundles. That some kind of vector-spinor triality might exist down at SO(4) is a nice idea. Finding little math errors does not always make the general idea wrong.

36. **woit**
August 5, 2006

Kasper,

Go talk to any “string phenomenologist” working with the state of the art of techniques for trying to get physics out string theory. What they do is pick a background of some kind and try and calculate something. Different backgrounds give different results.

37. **Kasper Olsen**
August 5, 2006

Dear Peter

Go talk to any “phenomenologist” working with the state of the art of techniques for trying to get physics out of quantum field theory. What they do is pick a background of some kind and try and calculate something. Different backgrounds give different results.

cheers, Kasper

38. **woit**
August 5, 2006

Michael,

Many thanks for the long comment. The kind of geometry you’re talking about is exactly what I had in mind in the comments you’re referring to. The “off-diagonal” SU(2) comment was a misguided attempt on my part to say something over-simplified about the geometrical set-up that you describe in detail.

The space you call N is also known as the (Euclidean) twistor space. a CP^1 bundle over the four manifold M. It’s the bundle over M whose fiber at a point is the space of orthogonal complex structures on the tangent space at the point (more precisely, those compatible with the orientation). As you note, the frame bundle P of M gives a principal U(2) bundle over N. It is this U(2) that I’d like to identify as the electroweak U(2).

Again, as you note, the problem with this is that this is a U(2) bundle over N, not M, and one has to deal with this somehow, and I don’t know of a really satisfactory way of doing so. You could just locally pick a section of N (in general you can’t do this globally), but then you have another sort of field to worry about. The SU(2) part of the U(2) doesn’t depend on this, but the U(1) does, which creates a problem.

One other issue here is that this is all Euclidean, and how to set up the analytic continuation to Minkowski signature has to be sorted out. In essence, the hope is that somehow under analytic continuation the boost part of the local Minkowski frame transformations becomes something that can be interpreted as an internal SU(2) symmetry.

My suspicion is that this somehow has to do with an old conceptual problem that many people have commented on (Yang, Penrose, Baez and others): there are several complex structures being used in QFT, and it is not clear why they can all be identified as acting by the same "i". One kind of complex structure comes from space-time symmetry, it's used crucially to distinguish between positive and negative frequency, and thus to characterize the vacuum state. Another inherently different complex structure is the one on the fibers, the "i" that generates U(1) gauge transformations. I'd like to think that maybe the use of the space of all local complex structures gives a new way of thinking about this problem, but I haven't seen my way through this.

At some point in thinking about this many years ago I reached the conclusion that I needed a better, more abstract, way of thinking about path integrals, especially for fermi fields, before it would become clear if the ideas above could be used. Still working on that….

39. **woit**
August 5, 2006

Kasper,

OK, so you agree with me that I was correct to write in my book that string theory depends on a choice of background.

You obsessively want to make the argument that string theory is in the same state as QFT, even though this is obviously not the case. One makes testable predictions, the other doesn't. I've gone over this a hundred times here, and doing it the one-hundred and first time is clearly going to be a waste of time. But the bottom line is extremely simple to state: QFT phenomenologists can calculate many things that can be compared to experiment, and, if they don't start making their models baroquely complicated, they make solid predictions that can be tested. String theory "phenomenologists" can calculate very little in their models, and even to force this very little to agree with experiment, they have to make their models so complicated they make don't make testable predictions.

40. **Aaron Bergman**
August 5, 2006

String theory does not depend on the choice of background. The low energy observed physics depends on the choice of a vacuum. Just like in any other theory with multiple vacua.

41. **woit**
August 5, 2006

OK, Aaron, I knew you wouldn't be able to help yourself.

You should mention that it's not just the low energy physics that depends on the background, but the high energy physics also.

All known ways of writing down string theory depend on first choosing a background (yes, even AdS/CFT, where the asymptotic behavior is the background). At this point I recall, what you like to do is to say that string theory is just analogous to gauge theory, it's just we only have a gauge-fixed version. Problem with this argument is that observable physics doesn't depend on the gauge, whereas observable physics of string theory does depend on the background (which most people not schooled in string metaphysics would describe as being background dependent).

If you have something new to say about this, go ahead, but if it's going to be the same argument, please just link to one of the versions elsewhere.

And who, don't even think of joining in. Unless you have something really new to say on this topic, any comments arguing about this will be mercilessly deleted.

42. **Kasper Olsen**
August 5, 2006

Peter,

I don't know what you wrote in your book since I haven't read it yet. So I can't say that I agree with you.

And actually, it is not true that I "want to make the argument that string theory is in the same state as QFT". Of course not. My question was not related to phenomenology directly. Actually I think it was quite simple:

> (2): if your statement, that
>
> *you have to choose one before you can even write down what your theory is and try and see if you can extract any physics from it.*
>
> is true, then are you applying the same critisism to theories like QCD, or QED ????

Maybe you'll just need to make more precise what you mean with the concept of "background independence"; And then the question was I don't think you answered yet was:

> Now, if what you are saying, that
>
> *I have no idea what the precise set of consistent string theory backgrounds is or what the correct metric on it is, and I don't think anyone else does either.*
>
> is true, then
>
> (1): how can you claim, that "there are many of them, they give different physics" ????

So I don't want to repeat the discussion of whether string theory makes any "real predictions" or not; the discussion would be much simpler if I had read your book 😉

best regards, Kasper

43. **Aaron Bergman**
August 5, 2006

Actually, what you say is not how I think about it, but as per your request, those interested can see here. Enjoy!

44. **Kasper Olsen**
August 5, 2006

Dear Aaaron and Peter,

Of course the question about a choice of background is different from the one of a choice of vacuum.

My question (2) was related to Peter's criticism of string theory in that you choose a background (much like in many other theories); but as we all know the resulting physics is background independent; so his critisism seems to be formulated in a way that confuses things.

My question (1) was related to the fact that the concepts of a choice of background and vacua also is confused; surely different points in the string theory landscape give rise to different physics – different cosmological constant etc. etc.; the background g' = exp(2) g is equivalent to background g (as Peter agreed) and not a different vacuum, or related to the question of "giving different physics".

Kasper

45. **Peter Woit**
August 5, 2006

"as we all know the resulting physics is background independent"

You're confusing what is known to be true with what many people would like to be true.

In any case, this is not even conjecturally true in the case of what people expect for generalizations of AdS/CFT. The string theory explicitly depends on a fixed asymptotic background. Different asymptotic backgrounds give different physics.

46. **Kasper Olsen**
August 5, 2006

Dear Peter,

Sorry, maybe not all…. And, are my questions above answered in your book, NEW ??

Best regards, Kasper

47. **Peter Woit**
August 5, 2006

Kasper,

No, the book doesn't deal with every piece of wishful thinking common among string theorists. All it does is accurately describe what the current state of knowledge in the field is.

Yes, yes, I finally did get some more copies of the book recently, and you're on a list of people to send a copy to…

48. **Michael Edwards**
August 6, 2006

Peter,

It's great to have the "twistor" connection to the literature about this and similar constructions. I've read a bit about twistors in Minkowski space but hadn't identified this particular construction with Euclidean twistors. Is there a good book in this area that focuses on geometrical and topological applications? (My idea of "good book" on manifolds runs to Goeckeler & Schuecker and Choquet-Bruhat; I learned differential geometry originally out of Dubrovin but was later turned on to differential forms and fiber bundles by Bill Burke and tend to prefer that language.)

What I like about the construction in terms of the frame bundle is that it makes clear that you can have a global U(1) right action on certain geometrical objects on any orientable 4-manifold, without postulating additional structure on the base manifold. It also shows how you can get "compact" dimensions with geometrical significance, in addition to the "macroscopic" dimensions of the base manifold, without a lot of handwaving about why some dimensions are macroscopic and others aren't. Depending on what you're trying to calculate, you may be able to work entirely on the U(2) bundle over N and quotient out the redundant degrees of freedom at the end, never having to deal explicitly with the lack of a complex structure on the original base manifold.

I do not worry about continuation to a manifold of intrinsic Minkowski signature because I am exploring the premise of complete diffeomorphism invariance, in which geometry is interesting only as a way to express topology in terms of local fields. The Minkowski signature isn't intrinsic to the manifold; it comes of choosing boundary conditions on the set of acceptable coordinate systems in which t->-inf and t->+inf are fundamentally different from spacelike infinity.

Picture a 2-torus M covered, except for a 1-dimensional "skeleton" consisting of two intersecting circles, by a single contractible region. The maximal atlas on the 2-torus contains a diffeomorphism between some coordinate region U \subset R^2 and this region of M. Choose a diffeomorphism between U and the complex plane C, and remove the origin and the negative real axis. In terms of radial coordinates rho and phi, define t = log rho and x = tan phi/2. The entire t->-inf boundary of this R^2 coordinate system converges toward the origin; the x->+/-inf boundary converges toward the negative real axis; and the t->+inf boundary converges toward the "skeleton". The t->+inf boundary is fundamentally different from the others; its intrinsic geometry contains "kinks" that capture the topological difference between the 2-torus and the 2-sphere. Euclidean rotations of this coordinate system do not preserve this difference but Lorentz boosts (pure shears along the light cone axes) do.

Now add two dimensions and a vastly more complicated topology. The premise remains the same: one R^n coordinate system covering all of an orientable manifold M except for a (n-1)-dimensional skeleton (actually, a simplicial complex of dimension not exceeding n-1) plus a trivial coordinate anomaly, in this case arising from recoordinatizing U->Q->R^4. (There's nothing magical about the quaternions here; they're just a convenient way to get to an R^4 system with the desired boundary conditions.) The skeleton is at t->+inf, and t->-inf converges to a single point on the manifold, connected by a line segment to a point on the skeleton; all of spacelike infinity winds up on this line segment.

None of these boundaries are special in terms of the intrinsic geometry of the manifold; one could just as easily have picked any other maximal coordinate patch in the atlas on M and transformed it using the same U->Q->R^4 trick. But the t->-inf and t->+inf boundaries are certainly special in the coordinate system, and the Poincare group preserves this distinction. I consider this quite sufficient reason for a completely diffeomorphism invariant theory to have the global causality structure and Poincare-invariant phenomenology with which we are familiar from QFT. And for dessert we get primordial asymptotic homogeneity and an entropic arrow of time.

Remember, I'm not saying this has anything to do with physics. This obviously isn't the whole spacetime story; it doesn't address microcausality, it doesn't explain why gravity looks so much like intrinsic geometry on a Minkowski background, it doesn't tell you the price of tea in China. But it adds to my interest in in Wick rotation as a way of making contact between QFT actions and partition functions in Euclidean space. Not to mention an interest in finding the portion of the SM gauge spectrum that couples chirally somewhere in the frame bundle over a Euclidean 4-manifold.

I also have some thoughts on path integrals and fermions, which it will take me a bit longer to write down at finite length. They were inspired by the identification of the

Faddeev-Popov ghost field with the Maurer-Cartan form on the group of QCD gauge transformations. I am handicapped in expressing these ideas by an inadequate grasp of the theory and lingo of Virasoro representations, which seem to be the way that field theorists with a solid mathematical background look at this. Any recommendations on texts?

Cheers,
– Michael

Of course, I meant H for the quaternions. I had originally written C^2, changed it during an editing pass, and had a momentary brain lapse. I'm a bit out of the habit and not copy editing as carefully as I might (there are glaring typos in the earlier post too).

Michael,

I learned about the Euclidean version of the twistor construction from Atiyah. He used it right at the beginning of the modern interaction between math and physics to study instantons. Using it relates questions about self-dual connections to questions about holomorphic bundles. See his short book "Geometry of Yang-Mills Fields", in vol. 5 of his collected works.

The Virasoro algebra is the centrally extended lie algebra of diffeomorphisms of the circle. There's a huge literature about this by now. The group of gauge transformations is something different, but related. For the circle, it's a loop group, with the central extension the Lie algebra is an affine Kac-Moody Lie algebra, and there's again a huge literature. For spaces of higher dimension than a circle, very little is known about the representations of either gauge groups or diffeomorphism groups. One place to start reading about this is Jouko Mickelsson's book.

OK, then perhaps Virasoro representation is not the hook into the literature that I'm looking for. What I'm really after is a way of describing the Lie algebra cohomology of the diffeomorphism group of a compact orientable 4-manifold.

There's an elegant way of combining the BRST coboundary operator with the covariant exterior derivative relative to a fixed connection to get a covariant coboundary operator on the gauge bundle. This can be used to construct a Lie algebra of graded derivations in which the "scalar functionals" are the space of Lagrangians (viewed as polynomials in the field degrees of freedom and their derivatives at a point, as in Ward identities) and the inner derivatives are taken relative to the direct sum of the Lie algebra of tangent vector fields on the base space and the Lie algebra of infinitesimal gauge transformations. The Maurer-Cartan form on this space is quite interesting.

I shouldn't attempt to spell this out in more detail without LaTeX, but does it sound like one of the directions that cohomology has taken since Stora? Does it have anything to do with equivariant cohomology?

Cheers,
– Michael

August 6, 2006

What I'm really after is a way of describing the Lie algebra cohomology of the diffeomorphism group of a compact orientable 4-manifold.

To simplify things, one should start infinitesimally and locally. Extensions of the algebra of polynomial vector fields by modules of tensor fields were classified by Dzhumadildaev – my review math-ph/0002016 is online. Two of the extensions are closely related to the higher-dimensional generalizations of the Virasoro algebra, which arise in lowest-energy representations.

Michael,

There's work by mathematicians on the Lie algebra cohomology of vector fields that goes under the name "Gelfand-Fuks cohomology". Bott wrote some beautiful expository papers on the subject, see vol. 3 (I think, the one on foliations) of his collected works.

The BRST related ideas you mention are among the things about this I've always found confusing and have never quite sorted out for myself, especially the relation to equivariant cohomology.

54. **Thomas Larsson**
August 7, 2006

Definition of Gelfand-Fuks cohomology can be found here.

A clarification: an extension of a Lie algebra L by its module M is an element in H^2(L,M). Dzhumadildaev (Z Phys C 72 (1996) 509-517) classified this for L = vect(n) and M a tensor module. Gelfand and Fuks only considered n = 1 and M the trivial module (Gelfand-Fuks cocycle = Virasoro algebra).

August 7, 2006

TL, there should be a way of saying this physically, as in, "the part of curvature not coupled to matter is the Weyl conformal curvature" etc. There may be an obvious intepretation I'm ignorant of..

56. **Thomas Larsson**
August 7, 2006

DRL. Sorry, but I specifically tried to answer a question on Lie algebra cohomology, without claiming any connection to physics.

OTOH, demanding a kinematical Hilbert space with a well-defined action of the diffeomorphism algebra dictates that QFT must be modified in a certain way; details can be found in the [ArXiv](). Unfortutely, what is written reflects my understanding as of 2004 and is flawed in several respects. If I stop wasting my time reading blogs, I might eventually manage to write things up.

57. **Michael Edwards**
August 7, 2006

Thomas,

Your ArXiv papers are definitely proving rewarding reading. There is, however, an aspect of your handling of the BRST operator that is not clear to me.

A textbook description (e. g., section 12.3 of Goeckeler & Schuecker) of Stora's solutions to the Wess-Zumino consistency condition exhibits a linear representation W on the space Pl of Lagrangian polynomials of the total Lie algebra E of right-invariant vector fields on the gauge bundle. On a trivial gauge bundle, E is the semidirect product of the vector algebra and the gauge algebra over M. On a non-trivial gauge bundle, infinitesimal gauge transformations still form a "vertical" ideal of E, but the "horizontal" vector algebra does not form a subalgebra. The coordinate expression of the Lie bracket on E necessarily involves a "fixed" (background) connexion on the gauge bundle, but that's not fundamental to the construction; it's just a way of expressing a right-invariant vector field on the bundle space in terms of a vector field on the base manifold plus an infinitesimal gauge transformation.

Identifying Pl with the space \Lambda^0 of 0-forms on E taking values in Pl, the Ward operator W(e) may be identified (up to a sign) with the Lie derivative wrt e on \Lambda^0. This Lie derivative looks exotic, involving a lift of the vector algebra (the infinitesimal diffeomorphisms) from the base manifold to the gauge bundle by means of a fixed connexion, ensuring that the commutators in the Lie bracket on E can be patched together on the overlaps of a local trivialization. This Lie bracket should not be confused with the Lie bracket of vector fields on the base manifold; the curvature of the fixed connexion appears in the Lie bracket of two horizontal algebra elements.

Now, given a Lie bracket on the total algebra E and a Lie derivative on the space of Pl-valued 0-forms over E, we can axiomatically construct the complete algebra \Lambda of alternating forms on E and the graded Lie algebra of derivations relating them. The "exterior derivative" operator d_E in this construction can be identified (up to a sign) with the BRST coboundary operator, and in fact the 1-form d_E L coincides with -Q L on the vertical ideal of E. d_E is nilpotent by construction.

Now, is -d_E the Koszul-Tate operator referenced in 0501043? (I'm having a hard time relating the language of canonical quantisation to the functional setting in which I'm used to seeing BRST-related constructions such as the Faddeev-Popov ghost.) If so, how does your approach to quantisation result in a change to the BRST operator that breaks nilpotence?

Cheers,
– Michael

More notes on the above, in hope that one or more of the folks who have been so kind as to suggest readings in cohomology will recognize this as a standard line of reasoning.

It turns out that most of the above construction is available in the first five sections of Schuecker's 1987 paper:

http://projecteuclid.org/Dienst/UI/1.0/Summarize/euclid.cmp/1104116716

His construction of the graded Lie algebra of derivations in section 6 is, however, significantly different from what I have in mind. He also doesn't particularly emphasize that the fixed auxiliary connexion is only a device for identifying the "horizontal" portion of an algebra element in a particular local trivialization, and that the actual graded Lie algebra of derivations on \Lambda is independent of this connexion. Nor does he spell out that the full coboundary operator (in his notation, d + s) is an extension of the BRST coboundary to the full algebra of infinitesimal diffeomorphisms + infinitesimal gauge transformations; maybe in his construction it's not (I haven't checked).

Perhaps for these reasons, Schuecker points out the resemblance of the "(algebraic) Faddeev-Popov ghost" to the Maurer-Cartan form but does not extend it to the full Maurer-Cartan form on E. The latter has some very interesting properties that I may comment on later (when I decipher some of my old notes).

In my construction, the Lie derivative on \Lambda with respect to an element e of E is of degree 0, the inner derivative with respect to e is of degree -1, and the exterior derivative (coboundary) is of degree 1, just like in ordinary differential forms. The inner derivatives with respect to elements of E form a Grassmann subalgebra of the graded algebra of derivations on \Lambda, which I am tempted to relate to the Grassmann algebra of which fermions carry odd representations.

I hedge a bit here because, if this has any relationship to physics, the fermions of low-energy phenomenology probably are not objects of a single rank in this Grassmann subalgebra. There could be some terms in the "fundamental" Lagrangian that arise from topological densities, expressed using objects of well-defined rank. Other terms are artifacts of functional quantisation in a non-diffeomorphism-invariant "gauge", involving fields whose algebraic properties (like those of the traditional Faddeev-Popov ghost) are chosen so that the added term in the Lagrangian forms an operator trace of the Jacobian of the gauge-fixing term. I would expect the eigenfields of the mass term in the effective Lagrangian (wherever it comes from) to be a mix of fields of these two types.

Is this clear enough to be boring yet? 🙂

Cheers,
– Michael

Michael, it might be better to continue this off-topic discussion privately, rather than pushing Peter's hospitality further. My email address is on my eprints. However, let me just end with some general comments.

What I'm doing is not strictly equivalent to QFT. To obtain a well-defined action of the diff algebra, which is impossible in QFT proper, I first replace all fields by their Taylor series. This introduces an additional datum: the expansion point. Whereas infinite Taylor series are independent of the base point, truncated ones are not, and this dependence remains in the form of anomalies after quantization, even when the truncation is removed.

The existence of new anomalies shows that passing to Taylor data makes a substantial difference. I think this is a good thing, because we know that QFT is incompatible with gravity. By considering a structure which is close to QFT, but essentially different from it, this no-go theorem might be avoided.

Our main similarity is that we both use cohomology, but this is a very general mathematical technique, applicable in many situations. My work is largely modelled on the antifield approach, as formulated in chapter 17 of Henneaux and Teitelboim. However, since I want to do canonical quantization, I need an honest Poisson bracket rather than an antibracket, and therefore my starting point is not the space of histories, but rather its phase space. A flaw in my paper is that I get an overcounting for the harmonic oscillator. To correct this, one must add an extra constraint which identifies momenta and velocities.

Thank you for making me aware of Schuecker's paper. I have never managed to understand them properly, and I have long been confused about their relation to my extensions. AFAIU, there is none. In particular, I do consider vector fields on the base manifold, without a reference connection A^0.

60. **Thomas Larsson**
August 9, 2006

to understand them properly

them = conventional gauge anomalies

61. **Michael Edwards**
August 9, 2006

Thomas,

My (obviously very amateur) take on anomalies is that they happen when you try to write down a theory about objects that live in quotient spaces of group actions on fiber bundles using index-slinging notation and you don't get it quite right. This tends to come of using heuristics like "give this symbol algebraic properties which make the term in which it appears come out gauge invariant", "the horizontal element is the one normal to the vertical subspace", or "this field must be a boson because it's a Lorentz scalar" instead of sweating blood over what it's doing there in the first place.

We've all grown up with this situation because quantum mechanics _works_ even though it doesn't make any bloody sense. Heck, it started long before quantum mechanics: I lost confidence in the formal correctness of what I was doing in the physics classroom the first time I saw a Lagrange multiplier, and to this day I can't look at a partial derivative without wincing. The Lie derivative _means_ something. A partial derivative has no more intrinsic meaning than ten in the ones column carried to one in the tens column.

Until you slog your way through to BRST quantization, gauge covariance is just a heuristic. For me at least, putting Schücker's chapter on anomalies side by side with Peskin & Schroeder's explanation of "BRST symmetry" led (eventually) to an "a-ha" moment: if you want a theory with local causality, and the fundamental objects of your theory live on a big honkin' principal bundle with irreducible global structure, then you'd better define your theory there, because that's the _only_ space on which the Lie derivative looks like a local operator. The rest of the apparatus – differential forms, Clifford algebras, Wick rotation, Feynman diagrams, contour integrals – is long division for postdocs.

Your work has my respect (though not yet my comprehension) because it investigates how real calculations with imperfectly known initial conditions can be truncated without losing the answer in imperfectly cancelled anomalies. I couldn't compute a QCD background if my life depended on it. A formalism with all the elegance and explanatory power in the world is of little use if it can't make contact with phenomenology, and "we can't prove that the SM can't be obtained as our effective field theory" is a poor second to a theory with added predictive power. Personally, I would be very satisfied with a theory that doesn't make any "new" predictions but does liberate grad students from index-slinging and the rest of us from piffle about the philosophical implications of discontinuous spacetime at the Planck scale.

Cheers,
– Michael

Reviews and Errata

August 2, 2006
Categories: Not Even Wrong: The Book

The August edition of Seed magazine is out on the newstands, and it contains a joint review entitled "No Strings Attached" by Charles Seife of my book and of Lee Smolin's The Trouble With Physics. The article and magazine issue are not online at the moment. The latest issue of Physics World contains a review by Gordon Fraser, entitled String theory gets knotted.
