@Scott,

The question about the physics at the horizon can be asked in two ways: one way for the hypothetical universe where AdS/CFT is true and describes black holes, and the other way for our universe with the laws of physics that we already know and have tested. For obvious reasons, the second version is more interesting and important. The no-nonsense answer there is to reject (1) and get a peaceful in-fall through the horizon and await eventual spaghettification near the singularity.

By now, the case for this point of view will have already been made, I'm sure, in the talks by Bill Unruh and Bob Wald.

15. **Michael Welford**
August 23, 2013

I've been viewing to Hawking podcast from fuzzfire and the sound quality is TERRIBLE. I have just enough time to wonder aloud whether the other skeptical voice (Unrah) will subject to similar distortion.

16. **Peter Woit**
August 23, 2013

Michael Welford,
I took a look and also soon gave up trying to listen to that. Perhaps a transcription could be arranged…

17. **Peter Shor**
August 23, 2013

@Igor Khavkine:

But if you admit that (1) is the correct answer and black hole evaporation is not unitary, you've just refuted one of the main contributions of AdS/CFT, the crown jewel of string theory. Who wants to do that?

18. **Scott Aaronson**
August 23, 2013

Igor Khavkine:

Yes, Bill Unruh just gave a talk today where he advocated rejecting (1) *extremely* forcefully and entertainingly! (Unfortunately I fly back today and will miss Bob Wald's talk.)

But while I don't understand some of the assumptions bandied about at this workshop (especially those coming from QFT), I *do* understand how central unitarity is to physics' current conception of the world, and what a drastic step it would be to get rid of it. So AdS/CFT or no AdS/CFT, string theory or no string theory, I certainly understand not wanting to give up on unitarity without an extremely hard fight.

(Incidentally, in my summary of the AMPS paradox, I forgot to say something. As I understand it, what AMPS added to the simple logical argument that I outlined was really to make the consequence (4) more "concrete" and "vivid"—by describing something that, in principle, you could actually do to the Hawking radiation before jumping in, such that after you jumped in, if there *wasn't* anything dramatic that happened—something violating local QFT and the equivalence principle—then you'd apparently observe a violation of the monogamy of entanglement, a basic principle of quantum mechanics. Probably the bare logic (1)-(4) was known to many people before AMPS. I certainly knew it, but I didn't call it a "paradox," I just called it "I don't understand black hole complementarity." 🙂)

19. **brian**
August 23, 2013

Any women at KITP besides Eva?

20. **Scott Aaronson**
August 23, 2013

There were maybe 4 or 5 other female students and researchers.

21. **Lee Smolin**
August 23, 2013

Dear Peter and Scott,

The argument Scott summarizes requires that the evolution be unitary as seen by an observer at infinity.

\\

The view that 1) -so modified- is wrong has a straightforward justification consistent with everything we know about both general relativity and quantum theory. This is the hypothesis that quantum gravity effects eliminate the singularity and so quantum evolution proceeds to a non-classical region of spacetime to the future of where the singularity would have been. The evolution as observed by an observer at infinity will not be unitary if that new region doesn't reconnect with infinity, but no principle of quantum mechanics is violated. The evolution as a whole can be unitary even if there is no observer who can reconstruct a pure quantum state from their observations.

\\

This commonsense solution has been discussed since the 1970's. There were some papers raising issues about remnants but as we discussed in detail with Hossenfelder in our paper arXiv:0901.3156, those are not convincing.

\\

The lesson in my opinion is that the key issue in quantum black holes and the information problem is not at the horizon, it is at the singularity. It is unreasonable to expect any new physics at horizons where the curvatures are small, but necessary to find new physics at the approach to singularities. The focus on the firewall problem is in my view a consequence of insufficient appreciation of this point. It can be seen as a reducto for the assumption that the problem can be resolved without investigating how quantum gravity effects eliminate the singularity and taking on board the consequences of the resulting evolution to the future of where the classical singularity would have been.

\\

Thanks,

Lee

22. **Anonyrat**
August 23, 2013

Scott Aaronson,

They say quantum states for the blackhole with firewalls exist but are generally not accessible by external observers. Specifically they say in their model:

> • The evolution of a black hole does not dynamically develop a firewall (even after the Page time). An infalling observer who does not perform a special manipulation to his/her environment always sees a smooth horizon.
>
> • It is not possible for an observer to see a firewall even if he/she performs a very special measurement on Hawking radiation emitted earlier from the black hole. Such a measurement cannot change the fact that he/she will see a smooth horizon.
>
> • If a falling observer can directly measure a mode entangled with the stretched horizon as he/she falls through the horizon, then he/she may see a firewall. This, however, does not violate the equivalence principle; the same can occur at any surface
> in a low curvature region.

So I guess they are saying that (4) is mistaken.

23. **Peter Shor**
August 23, 2013

Lee:

As I understand it, the problem with assuming that all evolution is unitary (considering both the interior and the exterior of the black hole) is that from the point of view of an outside observer, nothing ever falls into the black hole, so from this observer's viewpoint, evolution over the entire universe (which just consists of the exterior of the black hole) is not unitary.

24. **Bob**
August 23, 2013

Scott:

> DimReg: No, it's completely different from EPR. EPR is about entanglement

I wouldn't dismiss DimReg's comment so quickly. The ER=EPR conjecture of Maldacena and Susskind (arXiv:1306.0533) is an attempt to resolve the firewall paradox by making something like DimReg's comment precise. The starting point is the thermofield double formalism of Israel (1976). One introduces a second copy of the physical Fock space. The two copies are then related to the black hole interior and exterior, and they are entangled in just the right way to be consistent with complementarity and black hole thermodynamics. We make peace with the apparent non-locality of:

> (4) by applying some suitable unitary transformation to the Hawking radiation of an old enough black hole before you jump into it, you ought to be able, in principle, to completely modify what you experience when you do jump in—an apparent gross violation of locality.

because the Hawking radiation you acted on was EPR entangled with the black hole interior.

25. **Igor Khavkine**
August 23, 2013

@Peter Shor: 😉

@Scott: If everything in the world was unitary, there would be no place for things like the Lindblad equation. Similarly, for the same reason that a room with an open window is allowed to violate unitarity, so is the exterior of a black hole at intermediate times after its formation. On the other hand, at very long times (where "complete evaporation" is supposed to take place), there is nothing but a HUGE question mark. And a question mark does not a paradox make. Lee has made a similar point above.

26. **DimReg**
August 23, 2013

Scott,

Thanks for clarifying, that makes more sense! For some reason, I got the impression that it was all about entangling internal and external states.

27. **Chris Cesare**
August 23, 2013

@Igor: The Lindblad equation does describe non-unitary evolution of a quantum state, but this non-unitarity is not fundamental. As I understand things, it typically arises because you trace out the Hilbert space of an environment (like some thermal bath) which interacts with your system of interest and that you don't have a way of measuring precisely in practice. In principle, you could include the evolution of the bath in your description and recover unitary evolution. There is currently no reason to expect that this "in principle" statement is not correct, and I think this is what Scott was referring to in his reply.

28. **Scott Aaronson**
August 23, 2013

Lee Smolin: Thanks for the comment. I agree that baby universes are an option, although I can't comment on the merits of specific scenarios. (Unruh mentioned baby universes in his talk as another alternative to information loss, though he didn't dwell on them.) Preskill also made the point that, with all this fuss about the horizon, strikingly little was being said about the singularity—in order to motivate his and Seth Lloyd's proposal (building on Horowitz and Maldacena's), which *does* involve the singularity.

While I'm obviously far from an expert, where I think I part ways from you and Unruh is on the following. We're pretty sure black holes have an *entropy*, which goes like the area of the event horizon in Planck units. We're pretty sure that, from an external observer's perspective, infalling stuff gets "pancaked" on the event horizon and scrambled beyond recognition, never making it through to the interior. Finally, we're pretty sure that the external observer ultimately sees the black hole evaporate, through Hawking radiation that emerges (appears to emerge?) from the horizon. To me, these facts would seem like an intolerable coincidence, if the black hole didn't have microstates—"stored," one wants to imagine, on or near the event horizon—and if the Hawking radiation didn't carry away the information about those microstates. Otherwise, what a waste for Nature to "come so close" to upholding unitarity, only to chicken out at the last moment! 🙂

29. **Igor Khavkine**
August 24, 2013

@Chris Cesare, you have elaborated my implicit point about the Lindblad equation. For a black hole, the role of the "environment" or "bath" or even more precisely "whatever degrees of freedom are neglected" is exactly played by the interior of the black hole.

@Scott, as a frequent voice of reason in a ocean of doofocity, I hope you re-examine the certainty with which two of the statements from your last post are held: "the external observer **ultimately** sees the black hole evaporate" and "black holes have an **entropy**" (where "entropy" is specifically used in the sense of log(Omega)). Snag… I have to run and can't expand on this at the moment! I mention only that anyone interested in black hole physics should personally critically examine the arguments for how these claims have been arrived at.

30. **Greg Egan**
August 24, 2013

Scott wrote:

> We're pretty sure that, from an external observer's perspective, infalling stuff gets "pancaked" on the event horizon and scrambled beyond recognition, never making it through to the interior.

This account isn't just observer-dependent, it's *coordinate*-dependent! There are plenty of respectable coordinate systems that an external observer can use in which it's false.

In contrast to the "pancake" picture, it's an objective fact (proof here) that if a stationary external observer drops something into a black hole, after a finite amount of proper time has elapsed for that observer, it will be physically impossible for them to chase after the infalling matter and catch it before it crosses the horizon. (Ditto for the infalling matter reaching the singularity — even if you're feeling suicidal, once you drop something you have a finite time to go after it, before you lose any chance of ever touching it again, even inside the hole.)

About the strongest objective statement I'm aware of that favours the "pancake" picture is the fact that — in the idealised case where you can detect arbitrarily red-shifted light — there is no upper bound on how long it might be before a stationary external observer receives radiation emitted from a given piece of infalling matter. But the red shift factor grows exponentially, so I'm not sure that this counts for much, even in principle.

31. **Lee Smolin**
August 24, 2013

Dear Scott,

Thanks, but either I don't understand your argument or else it is circular. What do you suppose happens to the singularity as well as to the quantum state of the star whose collapse formed the black hole in the first place? If the singularity is eliminated then the Hilbert space in the future is a direct product of a factor spanned by observables which describe degrees of freedom to the future of where the singularity would have been and a factor spanned by observables external to the horizon. The evolution onto this product can be assumed to be unitary but (I feel silly telling you this) it cannot be when restricted to either of its factors. Hence the observer at infinity describes a density matrix gotten by tracing out the degrees of freedom in the baby universe inaccessible to them.

Isn't this a completely reasonable option, especially because it avoids the otherwise paradoxical implications of the firewall argument?

The pancake is a non-sequitor: why does it matter what information does or doesn't get to infinity or when, if infinity is not the only place information goes to? So to refer to it seems to assume what you are claiming to demonstrate.

Many thanks,

Lee

32. **wolfgang**
August 24, 2013

@Lee

as your wrote, your proposal is not new and thus its problems are known.
One problem of simply allowing a non-unitary evolution in the exterior is that
particle physics becomes non-unitary as soon as you (have to) include virtual black holes.

33. **Lee Smolin**
August 24, 2013

Wolfgang,

That is not a convincing argument and it is partly addressed in the paper I mentioned. The basic point is that there is no reason one has to include contributions from "virtual black holes." When one looks at it carefully it becomes not at all clear what would be meant by that in a well defined background independent formulation of quantum gravity. The intuition that any process should have large or even divergent contributions from "virtual black holes" is based on an incorrect use of effective field theory, as discussed in section 4 of the paper with Hossenfelder I mentioned above.

Another reason is that there is no reason to think that horizons make sufficient sense in terms of quantum geometry at the Planck scale to give meaning to the semiclassical intuition of a virtual or Plank scale black hole. If quantum geometry is discrete at Planck scales then there are no horizons, curvatures or singularities at those scales and no way to give meaning to a Planck scale black hole. There is no contradiction in believing that quantum gravity is simply unitary at small scales while real astrophysical black holes create baby universes.

Thanks,

Lee

34. **Peter Shor**
August 24, 2013

Wolfgang:

What is anything fundamentally wrong with including virtual black holes, and making particle physics non-unitary? While it is much more difficult to think about, and nobody seems to have a specific satisfactory theory of how non-unitary particle physics might work, I don't think there is any reason to believe such theories couldn't exist.
Particle physics could be non-unitary at the Planck scale, and have some built-in quantum error correction properties which keep it unitary at observable scales. For a two-dimensional condensed matter model for something like this, Google "Kitaev honeycomb model".

35. **Peter Shor**
August 24, 2013

Lee:

Your quote "there is no contradiction in believing that quantum gravity is simply unitary at small scales while real astrophysical black holes create baby universes." is reminiscent of the early quantum physicists' division of physics into the "microscopic", where quantum effects are important, and the "macroscopic", where classical physics holds. We now realize that this was a big mistake.

Regards,

Peter

36. **geromes**
August 24, 2013

My guess is that the firewall problem is due to an idealization. A lot of fuzz is made about the role of the BH singularity and physics at infinity – both I regard as just unphysical.

My suggestion: One should think about an appropriate analogue model realizable in the laboratory. There have been interesting suggestions to measure the Hawking effect in black hole analogues in Bose-Einstein condensates, for instance. There should be no violations of unitarity in such systems, right ? It would be interesting to see a firewall analogue in a Bose-Einstein condensate :-). Googling suggests to me that such models have not been worked out yet. Oh, by the way, such lab systems are full of surprises, e. g. bosenovas.

37. **wolfgang**
August 24, 2013

@Peter Shor

>> I don't think there is any reason to believe such theories couldn't exist
sure, but until it is written down and works, I prefer to go with the findings of Scott and Harlow-Hayden that Alice cannot actually perform the calculation necessary to create a paradox …

38. **Bill**
August 24, 2013

Peter, I think you would be interested in reading this post by a world class mathematician (anonymous, but so I am told) on the interaction between string theory and mathematics. I wonder if your assessment agrees with his?

39. **Peter Woit**
August 24, 2013

Bill,
I'm generally sympathetic with the views of that blogger, whoever he or she might be. But that's a large and complicated topic completely unrelated to this posting. Anyone who wants to discuss it should do it over at that blog.

40. **Jim Graber**
August 24, 2013

To reduce it to a slogan: Give up Black Holes, Save Unitarity
Baby Universes were mentioned, but I think the idea of replacing black holes deserves much more serious study than it has received. The problems discussed at the recent "Black Holes Complementarity Fuzz or Fire?" workshop emphasize only some of the serious problems with the black hole concept. I realize the workshop was predicated on acceptance of the black hole concept as well as the general accuracy of the Hawking radiation paradigm, but neither of these ideas has a strong experimental support. Gravitationally collapsed objects similar but not identical to black holes could alleviate many issues if they were unitary and did not involve either horizons or singularities.

41. **Scott Aaronson**
August 24, 2013

Jim Graber:

"I realize the workshop was predicated on acceptance of the black hole concept … Gravitationally collapsed objects similar but not identical to black holes could alleviate many issues if they were unitary and did not involve either horizons or singularities"

Actually, several speakers (including Stephen Hawking, who's been saying similar things since he conceded the information loss bet in 2004; and Samir Mathur and several other "fuzzball" people) explicitly advocated replacing black holes by some kind of unitary "black-hole-like object." Though fwiw, my preference would be simply to DEFINE "black hole" to mean "that entity, whatever it is, that behaves from the outside more-or-less like the black hole of classical GR."

42. **Peter Shor**
August 25, 2013

@Wolfgang: my characterization of what Harlow-Hayden is saying is that "Nature is inconsistent, but because we only have limited computational power, we will never be able to catch Her in an inconsistency, so we might as well pretend that She's inconsistent". I really don't think this idea holds up to close inspection.

43. **Peter Shor**
August 25, 2013

That last "inconsistent" should be "consistent".

Of course, this is essentially what Bohr's Complementarity Principle said before people worked out the mathematical justification behind it. But there is something fundamentally different about hiding "inconsistencies" with the Uncertainty Principle and hiding them with computational complexity.

44. **wolfgang**
August 25, 2013

@Peter Shor
>> there is something fundamentally different about hiding "inconsistencies" with the Uncertainty Principle and hiding them with computational complexity

I see it the other way around: One reason I found Scott's talk so amazing is because it suddenly hit me how fundamental computational complexity really is.
Of course, Scott was preaching this on his blog for long time …

45. **Stephen**
August 25, 2013

Apologies – this is wholly off-topic.
Does anyone know if the "unification" of the couplings in SUSY still holds in view of the latest LHC results ? I've been hunting around for some time now and couldn't find anything. Also, how unique are the "unification" solutions i.e. are they a generic feature of SUSY at a mass of X TeV ?

Sorry for going off topic… I shan't post on this again. Hopefully the question will anyway be of use to a lot of people reading this blog.

46. **Eric**
August 25, 2013

Dear Stephen,

Yes, the gauge coupling unification of the MSSM still holds after the latest LHC results. In fact, the gauge coupling unification works better for heavy squarks and sleptons in the 5-10 TeV range.

47. **Stephen**
August 25, 2013

Hi Eric,
Thanks.

Is there a ref for this ? (Apologies to Peter – no more posts from me on this).

48. **Peter Woit**
August 25, 2013

Stephen,
One recent reference is this
http://arxiv.org/abs/1212.6971

When thinking about whether different versions of the MSSM do a better or worse job of coupling constant unification, you probably should remember that you're talking about a theory with more than a hundred undetermined parameters to play with….

49. **Scott Aaronson**
August 25, 2013

Peter Shor:

> Nature is inconsistent, but because we only have limited computational power, we
> will never be able to catch Her in an inconsistency

No, I don't think that's what Harlow and Hayden are saying at all. It's more like: "yes, semiclassical field theory might have to break down and get replaced by a consistent quantum theory of gravity, even in a low-energy regime where physicists thought that QFT would work fine. But if the breakdown would take something like ~2^10^60 years to reveal, then maybe we don't have to worry all that much, if our goal is to reassure ourselves that we already more-or-less understood what happened at low energies."

50. **Scott Aaronson**
August 25, 2013

Lee Smolin and Greg Egan: Thanks for the comments and clarifications.

When I referred to "pancaking" (my choice of image, and maybe a bad one), I mostly had in mind a series of lectures that Lenny Susskind gave at PI, where he described the process by which quantum information is believed to get rapidly "scrambled" at or near the horizon, even giving detailed quantitative bounds on the rate at which the scrambling is thought to take place. So my impression was that, even independent of AdS/CFT and so forth, we knew something about the "rapid mixing" that a faraway observer would believe to take place, just because of the extreme temperature in the stationary frame at the stretched horizon, or something like that. If so, then the argument wouldn't be circular, since nothing in it would presuppose that the information ultimately comes out, but it would nevertheless support the intuition that it does come out. But maybe I took Lenny's calculations about the mixing near the horizon to be better-established than they are.

I forgot to mention an additional reason why I'd personally be happy if the information comes out of the hole, rather than into a baby universe. Namely, I would like the laws of physics to uphold the holographic entropy bound, that the total number of qubits in any bounded region should be upper-bounded by the region's surface area in Planck units. But if the interior of the region could contain a "portal" to another universe of unbounded size, then isn't the universality of that bound called into question?

So, here's a question for either or both of you. Suppose that, for whatever reasons, I thought that upholding unitarity was a *very* big deal—maybe an order of magnitude more important than any other principle at stake in the black hole debate. And suppose that by "unitarity," I meant that an observer in *our* universe should in principle be able to reconstruct the infalling qubits (even if after 2^10^60 years or whatever), rather than that the qubits should continue to exist in a baby universe. Then my question is: could LQG (or spin foams, or other non-string quantum gravity approaches) give me what I wanted? Or do you regard the information's falling into baby universes as essentially a *prediction* of LQG?

51. **wolfgang**
August 25, 2013

@Scott

>> if the breakdown would take something like ~2^10^60 years to reveal

maybe I misunderstood the Harlow-Hayden paper, but I thought the main point was that Alice can (most likely) not complete the calculation before jumping into the black hole (and thus create a contradiction) – however, Charlie , remaining (infinitely long) outside the b.h. finds no issue with unitarity.
This seems different to me than what you just wrote.

52. **Eric**
August 25, 2013

Peter W,

In regards to your statement about gauge coupling unification, this happens generically within a 1-3% so long as the superpartners are not too heavy. This not very sensitive to the number of parameters in the MSSM. The 1-3% percent discrepancy is usually attributed to unknown GUT threshold corrections, although the discrepancy does appear to be smaller for heavier squarks. For example, see http://cds.cern.ch/record/478820/files/0011356.pdf

53. **Marcus**
August 25, 2013

Scott, there was what I think is a fairly important LQG paper in Physical Review Letters 110, 211301 (2013) by R. Gambini and J. Pullin. I've only seen the version they posted in February on arxiv.
Pullin presented the paper in July at the GR20 conference. It was the lead item of the main Loops session. Ashtekar spoke in a GR20 joint session with string and pheno people (Bob Wald, Don Marolf and Gary Horowitz also took part) which was specifically about BH evaporation and the same stuff as the KITP conference. In doing so Ashtekar drew on this type of fairly unambiguous Loop BH result.
http://arxiv.org/abs/1302.5265
Loop quantization of the Schwarzschild black hole
Rodolfo Gambini, Jorge Pullin
(Submitted on 21 Feb 2013 (v1), last revised 10 May 2013 (this version, v2))
We quantize spherically symmetric vacuum gravity without gauge fixing the diffeomorphism constraint. Through a rescaling, we make the algebra of Hamiltonian constraints Abelian and therefore the constraint algebra is a true Lie algebra. This allows the completion of the Dirac quantization procedure using loop quantum gravity techniques. We can construct explicitly the exact solutions of the physical Hilbert space annihilated by all constraints. New observables living in the bulk appear at the quantum level (analogous to spin in quantum mechanics) that are not present at the classical level and are associated with the discrete nature of the spin network states of

loop quantum gravity. The resulting quantum space-times resolve the singularity present in the classical theory inside black holes.
4 pages, Revtex, version to appear in Physical Review Letters
============
Here is the abstract of Ashtekar's July 2013 talk at GR20, in the special joint session on quantum mechanics of BH evaporation
ABHAY ASHTEKAR (20+5 MINUTES)
TITLE: Quantum Space-times and Unitarity of BH evaporation

There is growing evidence that, because of the singularity resolution, quantum space-times can be vastly larger than what classical general relativity would lead us to believe. We review arguments that, thanks to this enlargement, unitarity is restored in the evaporation of black holes. In contrast to ADS/CFT, these arguments deal with the evaporation process directly in the physical space-time.
==endquote==
You asked Lee and Greg if they regarded info into new expanding region as essentially a prediction of loop/spinfoam. Hopefully they will answer or you can figure out from what i just quoted. As nonexpert I would say YES essentially a prediction. AdS/CFT cannot be right if it sticks with a single asymptotic region ("boundary") while a hole develops in bulk. That is top.change. In Loop it leads to bounce and new expanding region which would have its OWN asymptotic region.
Therefore boundary acquires new component and boundary observables algebra must be enlarged. "Firewall" kerfluffle is probably just nature warning us that boundary has been enlarged (by baby universe) and only a part of info is coming back out to us in Hwkg radiation. My best guess as non-expert.

54. **Marcus**
August 25, 2013

Here is abstract of Jorge Pullin's talk at the main Loop session of GR20. It was the first paper of the session. He presented the February Gambini Pullin result.

Complete quantization of vacuum spherically symmetric gravity
Pullin J
We find a rescaling of the Hamiltonian constraint for vacuum spherically symmetric gravity that makes the constraint algebra a true Lie algebra. We can implement the Dirac quantization procedure finding in closed form the space of physical states. New observables without classical counterpart arise. The metric can be understood as an evolving constant of the motion defined as a quantum operator on the space of physical states. For it to be self adjoint its range needs to be restricted, which in turn implies that the singularity is eliminated. One is left with a region of high curvature that tunnels into another portion of space-time. The results may have implications for the current discussion of "firewalls" in black hole evaporation.

http://gr20-amaldi10.edu.pl/userfiles/book_07_07_2013.pdf see page 218 of file.

He is saying they get a new expanding spacetime region from where the singularity used to be. It's pretty unambiguous. And he notes possible implications for the "firewall" discussion.

55. **Cosmonut**
August 25, 2013

A very interesting discussion indeed.
From what I can gather, the firewall paradox is deeply connected to quantum gravity (?).

But string theory claims to be a successful quantum theory of gravity. (From what I know, the successful quantization of gravity is said to be one of the "well established" triumphs of string theory, unlike the landscape nonsense).

In that case, why doesn't ST provide a clear resolution to the firewall paradox ?

Apologies in advance if this has been discussed elsewhere.

56. **Lee Smolin**
August 25, 2013

Dear Scott,

Thanks very much for your question. Let me be clear first of all, there are so far no exact results in full LQG (ie the full 3+1 d spacetime diffeo invariant QFT) as to the fate of black hole singularities. What there are are results about models which reduce the full diffeo gauge symmetry to 1+1 dimensional diffeo symmetry. These give different results, so there is no clear message except that there may not be a single universal answer.

The region to the future of the resolved singularity can reconnect with infinity after a period of evolution through quantum geometries that have no classical description. In this case you get what you want. This is shown in detail in LQG analyses of the 1+1 dimensional CGHS model by Ashtekar, Tavaras and Varadarajan, arXiv:0801.1811, recently studied also by Ashtekar, Pretorius and Ramazanoğlu: arXiv:1011.6442 and arXiv:1012.0077. I am surprised that these papers are not better known.

A different kind of 1+1 model is studied by Modesto who found evidence for a bounce leading to new asymyptotic regions as discussed also above by Marcus in his discussion of the recent very interesting model of Gambinii and Pullin.

The picture seems to be that while the elimination of singularities is universal the fate of the resulting quantum region to the future of the resolved singularity depends on details of the dynamics of the quantum geometry and hence requires detailed computations of models such as I've discussed.

I want to reply too your general comments, I'll do that in a later message.

Thanks,

Lee

57. **Lee Smolin**
August 26, 2013

Dear Scott,

The issues you raise are subtle, partly because there is not a formulation of QFT on curved spacetime that shares the coordinate and diffeomorphism invariance of classical GR. So at the very least beware of claims and intuitions based on one choice of coordinates. The thermalization of Hawking radiation appears to be fully explained by projecting out a subsystem of an entangled pure state. Remember these are free fields-there are no interactions of the modes at the horizon with each other-so there is no physical basis for rapid mixing. The other system the Hawking photons are entangled with are modes that fall through the horizon and are approaching another boundary-the singularity in Hawking's original calculation and whatever is post=singularity when the singularity is resolved. That is the physics as we best understand it.

I’d like then to address your statement: “ Namely, I would like the laws of physics to uphold the holographic entropy bound, that the total number of qubits in any bounded region should be upper-bounded by the region’s surface area in Planck units.”

That is a statement of what we can call the “strong holographic bound”. We can distinguish it from a weak form of the holographic bound (hep-th/0003056) which might be stated, “the total number of qubits measurable on any surface should be upper-bounded by the region’s surface area in Planck units.”

I would argue that all the evidence we have is that the weak form is correct. I give several arguments in hep-th/0003056 for the weak form over the strong form as best explaining the evidence we have from Bekenstein and Hawking’s original arguments as well as since. Moreover, recent work deriving black hole thermodynamics from quantum gravity by Bianchi, both perturbative (arXiv:1211.0522) and non-perturbative (arXiv:1204.5122) shows that the black hole entropy is best understood as an entanglement entropy. I would suggest that this be taken seriously as it is the only calculation of the BH entropy that gets the 1/4 right without any parameter fixing for a generic non-extremal black hole.

Thanks,

Lee

58. **Brian**
August 26, 2013

Scott, the sentiment is ok, but one must choose between other universes (ridiculous, of course) and the (quantum) ‘universes’ of other observers. In the latter case, one might say that unitarity was preserved for any given observer, but in the context of black hole information one probably needs to account for multiple observers. There could easily be (non local) information that violates unitarity, but then that does not necessarily conflict with your view, if you modify the wording.

59. **Mitchell Porter**
August 26, 2013

Lee Smolin, a number of people have examined those papers by Bianchi and they say that he is not counting black hole microstates, that it’s just a version of the original Bekenstein-Hawking calculation.

60. **Jim Graber**
August 26, 2013

Scott,
Thank you for your reply.
“”Actually, several speakers (including Stephen Hawking, who’s been saying similar things since he conceded the information loss bet in 2004; and Samir Mathur and several other “fuzzball” people) explicitly advocated replacing black holes by some kind of unitary “black-hole-like object.”” “
I am happy to see Mathur’s fuzzball proposal getting more serious attention. I have followed it for many years, and had read many of the earlier papers, but I was not up to date on all the more recent papers.
As to Hawking. I could not find a published paper clearly advocating an object without horizon or singularity. I tried, but could not understand his Fuzz or Fire workshop talk, so I don’t know if he mentioned it there. (Maybe a transcript or a paper will emerge later?)
I reread his concession paper arXiv:hep-th/0507171 and scanned his more recent work, , but I didn’t find a clear endorsement of such black hole replacements. If a good reference where Hawking supports an unconventional black hole replacement exists, I would like to hear of it.
Jim Graber

61. **Lee Smolin**
August 26, 2013

Mitchell,

If someone has an objection to the claims of Bianchi’s papers I’d be glad to discuss in detail, as I’m sure would also Bianchi. Indeed he has spent a lot of time in discussion with people who were originally skeptical, some of whom conceded in the end he was right.

In any case please explain your statement as on the face of it its confusing. First of all there are two papers by Bianchi, which one are you referring to, the perturbative or the non-perturbative one? Second, please explain what you mean by “a version of the original Bekensteiin-Hawking calculation?” I don’t know what that could refer to as the two of them did very different things. In any case both were semiclassical and treated the metric geometry classically, which Bianchi’s first paper is clearly not.

Many thanks,

Lee

62. **Peter Woit**
August 26, 2013

Mitchell and Lee,
This is starting to give me bad flashbacks to endless 2006 blog comment arguments about LQG vs string theory black hole entropy calculations, which seemed to me highly unenlightening. Claims about what “a number of people” say about this definitely are not enlightening. Unless this has a lot more to do with the discussions at the KITP workshop than it seems, it would be best to just give references here to good sources of information about this question.

63. **Mitchell Porter**
August 26, 2013

I meant Hawking’s semiclassical calculation, not Bekenstein’s. The claim is that a true explanation of black hole entropy should involve state counting, and that Bianchi’s 1204.5122 does not. There was a discussion of this at [Bianchi’s entropy result…] when the paper first appeared.

I had not seen the later paper, 1211.0522. I now gather that the philosophy of the two papers is as follows. 1204.5122 should not be regarded as a microscopic explanation of black hole entropy, it really is just the Hawking semiclassical calculation in a LQG framework. It’s 1211.0522 which proposes a microscopic picture, based on entanglement entropy. For a non-LQG counterpoint to that discussion, I suggest 0905.0932, e.g. section 2.5.

The thread on Bianchi’s work that I just mentioned is still open, and would be a suitable venue for continuing with this topic.

64. **Scott Aaronson**
August 27, 2013

Jim Graber:

Here's the relevant paragraph from Hawking's concession speech.

"Information is lost in topologically non-trivial metrics like black holes. This corresponds to dissipation in which one loses sight of the exact state. On the other hand, information about the exact state is preserved in topologically trivial metrics. The confusion and paradox arose because people thought classically in terms of a single topology for spacetime. It was either R^4 or a black hole. But the Feynman sum over histories allows it to be both at once. One can not tell which topology contributed to the observation, any more than one can tell which slit the electron went through in the two slits experiment. All that observation at infinity can determine is that there is a unitary mapping from initial states to final and that information is not lost."

I should confess that I don't understand this argument (and apparently I'm not alone — even Preskill, to whom Hawking conceded, said he didn't understand it!). But Hawking does seem to be clearly asserting that the solution to information loss involves there being a nonzero amplitude for the black hole never forming in the first place. (Though an obvious issue is that he doesn't say how *large* the amplitude is: if it were nonzero but exponentially small, that wouldn't seem to help much.)

65. **Jim Graber**
August 27, 2013

Scott,
Thanks very much!
I read that paragraph and didn't pick up that it is a reference to a black hole substitute which is topologically trivial. In my book, that should eliminate both the singularity and the so-called "horizon" which is more like a "brink". That is my favored configuration, so this pleases me very much.
But in my thinking, the topologically trivial configuration should be dominant.

66. **jd**
August 27, 2013

Are there relevant ideas in PRL 110, 101301 (2013)?

The paper is available for free download.

67. **Peter Woit**
August 27, 2013

I see Scott Aaronson has a blog posting about this now, at
http://www.scottaaronson.com/blog/?p=1508
so if you want to discuss these issues with someone who actually was at the workshop and knows what is going on, Scott's blog is your best bet.

68. **Peter Shor**
August 28, 2013

To me, the amazing thing is that the theory of black hole complementarity was taken seriously by a lot of people for two decades before AMPS showed that this theory doesn't hold water (at least, not as it was originally presented). I suspect that the moral is that if somebody writes physics papers with very few equations, lots of words, and a moderate amount of handwaving, you should ignore them (unless they are named Einstein).

It really seems to be a case of *The Emperor's New Clothes*. As Scott Aaronson says on his blog:

> I didn't call it a "paradox," I just called it "I don't understand black hole complementarity"!

I don't believe he was the only one who thought he didn't understand it.

69. **Friedwardt Winterberg**
September 3, 2013

The conclusion that a black hole is at the event horizon surrounded with a wall of fire by the disintegration of infalling matter was first proposed in an article I had published in 2001 in Zeitschrift fuer Naturforschung 56a, 889 (2001). My paper had the title "Gamma Ray Bursters and Lorentzian Relativity". It is Lorentzian relativity which resolves the black hole information paradox, with no information loss or violation of unitarity. In Lorentzian relativity SRT and GRT remain extremely good approximations for energies small compared to the Planck energy. My paper is cited in "An Apologia for Firewalls" by Almheiri, Marolf, Polchinski, Stanford and Sully: arXiv:1304.6483v2 [hep-th] 21 jun 2013.

70. **martibal**
September 7, 2013

Lee,

> If someone has an objection to the claims of Bianchi's papers I'd be glad to discuss in detail.

There is a point that is puzzling me, and which is also puzzling me in Bianchi's computation: in your paper GR as the equation of state of SF, you consider a *finite* piece R of the near horizon region observed by a family of accelerated observers. You further require that R has the *Unruh property*, namely that there exists a state in the Hilbert space associated with R which is thermal with temperature $a/2\pi$ (a being the acceleration of the observer). I do not really understand in which context this assumption makes sense. More precisely:

1. In the framework of algebraic quantum field theory [AQFT], we have shown with Rovelli in Class. Quant. Grav . 20 (2003) 4919-4932 that a uniformly accelerated observer in a finite double-cone region of space-time of size L sees the vacuum at a temperature which, at first order in 1/L, equals the Unruh temperature $a/2\pi$. But our result heavily relies on:

a) an extended acceptation of the KMS condition as a *local equilibrium condition;*

b) the requirement that the qft under investigation is *conformally invariant*. Otherwise (e.g. for a massive theory), it is a longstanding open problem in AQFT whether there exist observers in a finite region of spacetime for which the vacuum state is indeed thermal (technically speaking: unlike the Wedge case, the modular group associated to a non-conformal qft defined on a finite region of Minkowski spacetime may not have a geometrical action).

2. Besides AQFT, there are some proposals for an "Unruh temperature for finite lifetime observers". For instance J. Louko (see e.g his work with Satz here) considers a finite-time interaction of an Unruh-de Witt detector with the vacuum. As far as I can remember, it is not clear at all that one finds a temperature equal to the Unruh temperature at first order in the time of interaction. There is for instance a non-trivial dependence in the shape of the function describing the switching on/off of the interaction.

—

So it is not so obvious to me what the Unruh property for a *finite region of spacetime* means, even at first order in the size of the region.

In your paper you use the result of Bianchi who showed that R was Unruh. From what I understand following various discussions with people expert in these thematics, the idea is to assume that an observer stationary near the horizon *locally* sees the same vacuum as the one seen by an eternally accelerated observer in the Rindler Wedge. What I do not understand is why this is enough to justify that the finite region is Unruh ? My point is the following: in the Wedge, the computation of the Unruh temperature does not relies only on the fact that the Unruh-de Witt detector interacts with the vacuum, but also that this interaction is integrated all along the trajectory of an eternal observer, that is from $\tau=-\infty$ to $\tau=+\infty$ (similarly in AQFT: to obtain the Unruh temperature one has to consider the algebra of local observables associated to the whole Wedge, not to a sub-region of it).

—
Alternatively, the notion of "local equilibrium state" is far from obvious.
For instance Buchholz and Solveen have extensively discussed it, and proposed a definition different from the one we used with Rovelli (and again, in this context the meaning of a *finite* Unruh region is not so obvious to me).

—
Of course I am not claiming that these objections invalidate the BH entropy computation. But it seems to me that the the proof the finite region R is Unruh is based on some "hidden" assumptions that are not completely clear.

Sorry for the length of the message, but I would be interesting to hear your opinion on these points.

SUSY 2013

August 31, 2013
Categories: Uncategorized

The big yearly SUSY conference, SUSY 2013 has been going on in Trieste this past week. From the experimentalists, the news is just stronger limits: no hint of SUSY anywhere in the LHC data. From the theorists, the reaction to this news has been pretty consistent: despite what people say, not a problem.

According to John Ellis, everything is fine, with MSSM SUSY preference for a Higgs below 130 GeV vindicated and successful SUSY predictions for the Higgs couplings (that they should be the same as if there were no SUSY). According to Ellis, we just need to be patient, and he has CMSSM fits preferring 2 TeV gluinos.

However, if you look at Savas Dimopoulos's talk the MSSM gets a grade of D-. He argues that the LHC has shown us that the answer is the Multiverse, and that split SUSY with its fine-tuning gets a grade of A. The grade inflation in particle physics is pretty dramatic: you now can get an A without your theory having the slightest bit of experimental evidence.

Nima Arkani-Hamed's talk was about SUSY in 2033, which in his vision will be pretty much the same as SUSY in 2010. Remember all those things the LHC was supposed to find but didn't? Well, now the argument is that they're really there, but we will need a 100 TeV collider to see them. If all goes well, in 2033 such a machine will be under construction, and SUSY 2033 could feature all the SUSY 2010 talks retreaded, with 1 TeV gluinos moved up to 10 TeV.

One of Arkani-Hamed's slides ~~makes me worry that the LHC results have caused him to begin to lose his marbles. He~~ claims that if one doesn't see new physics like SUSY at the 100 TeV machine, in his view

> this would be 100 times more shocking and dramatic than ~~no~~ *nothing but* Higgs at the LHC

Even wilder claims came form Gordon Kane in his talk, where we're told that particle theorists giving "negative" talks because of the LHC results have:

> no knowledge of LHC physics, Higgs physics, supersymmetry, phenomenology, etc.

According to Kane, we not only have seen the tip of the iceberg of a unified string/M-theory, but actually have the whole iceberg. The ingredients are all in place for what he sees as a similar experience to the 3 year period in the 1970s when the Standard Model emerged and was experimentally vindicated.

Tommaso Dorigo points out that there was one SUSY 2013 talk that in his humble opinion was a good candidate for the IgNobel, see here (warning, NSFW).

On a more positive note, at the conference production of compactified Calabi-Yaus was finally conclusively demonstrated.

Update: Nathaniel Craig has some recent lectures on The State of Supersymmetry after Run I of the LHC. The emphasis is on examining the consequences of failure of pre-LHC assumptions about SUSY based on simplicity and naturalness. Out of 60 or so pages, only one is devoted to the models favored by Arkani-Hamed and Dimopoulos, string-theory based models are not even mentioned.

Comments

1. **Bee**
   September 1, 2013

   I once had to sit through a talk where "Susy" was depicted by Betty Boop. Gives you a totally new perspective on what the guys are after.

2. **emile**
   September 1, 2013

   I went through Nima's slides (so few this time!). The talk is essentially a sales pitch for the next big machine. I wouldn't say that his statement on what would be most shocking (no Higgs vs no BSM up to 100 TeV) is crazy as Peter suggests. If I can play devil's advocate and give one example: I've known many theorists (though they were always a minority) who thought that the breaking of EW symmetry had to be dynamical in nature. Now in the last 15 years, the measurements have been pointing more and more away from such an explanation but that possibility was still alive. It was one of the solutions to deal with the problems associated with a fundamental scalar i.e. you remove it from your theory. So… perhaps Nima would have been surprised but not that shocked if there was no fundamental scalar but he would be shocked if the Universe was really fine-tuned (although with split SUSY he has certainly considered such a possibility…). Anyway, I don't think it is crazy. One slide I did not understand is the one that follows the introduction of the e+e- collider where he writes "kills all anthropic explanations". Anybody understand what he meant there?

3. **Peter Woit**
   September 1, 2013

   Emile,

   He wasn't saying no BSM at 100 TeV would be more shocking than no Higgs, he was saying it would be "100 times" more shocking. It's this insistence on going over the top into wackiness that is, well, kind of shocking.

   I'm not interested enough in anthropic explanations to figure out exactly what scenario he had in mind that "kills all anthropic explanations", but given the "100 times" claim, I'd guess that it's yet another over-exaggeration of something.

4. **Pawl**
   September 1, 2013

   Well, implicit in Arkani-Hamed's talk is a great truth: experiments drive physics, and at the moment theoretical work on what the fundamental questions he's interested in is unconvincing.

   Besides the technical over-the-top comment Peter pointed to, there's what to my mind is a more basic concern: "… we've attracted the best minds on the planet to work on the hardest… problems in all of Science." Someone who says this may be (probably is) perfectly sincere, but it does raise concerns about how well he understands other fields of science or the people in them.

5. **Neil**
   September 1, 2013

Those colorful Calabi-Yau 3D prints are great! I definitely want one. It is nice to know that string theory has finally produced something tangible.

6. **Pawl**
   September 1, 2013

   [addendum to my previous comment]

   Or, I should add, other, non-scientific, disciplines.

7. **scotty**
   September 1, 2013

   Does someone know if Arkani-Hamed also gave some advice to today's young physicists what to work on during the next three decades of their careers, until 100 TeV data may arrive (if we are lucky)?

8. **Jon Orloff**
   September 1, 2013

   What happens if the taxpayers decide that it's not worth building a 100 TEV collider? That could happen if there isn't a much better reason than put forth than the airy stuff I have seen so far.

9. **george ellis**
   September 2, 2013

   Pawl is absolutely right:

   "… we've attracted the best minds on the planet to work on the hardest… problems in all of Science."

   So all those people in quantum optics and nanoscience and molecular biology and neuroscience and climate change don't compare intellectually with us. We are the elite, and their problems don't compare with ours…..

   Do physicist really have no concept of the extraordinarily complexity of the problems neuroscientists are trying to deal with? Or the incredible achievements of the molecular biology revolution?

10. **Peter Woit**
    September 2, 2013

    My apologies to Nima, it seems that I misread and misquoted his slide (thanks to a helpful reader for pointing this out). His claim was that no BSM at 100 TeV would be 100 times more shocking than no BSM at LHC energies, NOT that it would be 100 times more shocking than no Higgs at the LHC. Read accurately, its a wild exaggeration, but not the crazy-talk of my misreading.

11. **Dan D.**
    September 2, 2013

    @george ellis,

    It seems to me that this is a fairly common (though hopefully not too widespread) attitude among scientists of *any* discipline, to view one's own field of being of primary importance, or at least more important than those "lesser scientists" in [pick a scientific field]. It's also true when one broadens to philosophy and mathematics, for example. You'll see mathematicians looking down their noses at physicists for not being sufficiently mathematically rigorous, you'll see physicists deriding philosophers for discussing problems that *gasp* may not have any answers in physics (this in particular seems to be in vogue as of late), and on the flip side you'll see philosophers criticizing physicists for not researching the really "deep" problems. And so on. I think this is simply the tribalism of human nature manifesting itself within academia, which is no excuse, of course. It's not necessarily a bad thing (the tribalism, that is), until it gets to the point when no effort is made to apply any intellectual rigor to understanding other "tribes", even to the point of demonizing them (as is common for climate scientists these days, from people who should know better). Whether Arkani-Hamed's slide in question was really betraying this sort of elitism on his part, or was simply a bit of innocent pride in his own field (nothing wrong with this), is something only he could answer, I would think.

    More on topic, as a non-particle physicist, I found Arkani-Hamed's overall argument for a 100 TeV collider convincing enough. I think such should be built if only for the passion of needing to know "what's over the next mountain". I guess I'm too much of an idealist :).

12. **Dan D.**
    September 2, 2013

    Quick clarification, I meant it seems to be disturbingly common for climate scientists in particular to be demonized even by other scientists these days, which is unfortunate for the field, even if some of the individuals within it arguably deserve it from time to time.

13. **Bernhard**
    September 2, 2013

    "According to Ellis, we just need to be patient, and he has CMSSM fits preferring 2 TeV gluinos."

    It is interesting to compare this claim with an older one (http://www.nature.com/news/2011/110228/full/471013a.html):

    "I'm wouldn't say I'm concerned," says John Ellis, a theorist at CERN, Europe's particle-physics lab near Geneva, who has worked on supersymmetry for decades. He says that he will wait until the end of 2012–once more runs at high energy have been completed–before abandoning SUSY."

    Assuming this was semi-accurate…

14. **emile**
    September 3, 2013

    Regarding the idea that the best minds are working on physics problems: this reminds me of a list by Joe Lykken on the top 10 reasons why physicists are better than biologists. One of the reasons was: Physicists used to be smarter and more arrogant than biologists, now, they are just smarter.

    Regarding the favoured regions of the CMSSM moving with time: this happens by construction. The real question is how is the goodness of fit evolving with time?

15. **Anon**
September 3, 2013

After the 14 TeV run with 10 times more data if LHC finds nothing fine tuning would then be at 1% level. Currently fine-tuning is probably at about a 5-10% level. If there is a natural solution to the fine-tuning problem, isn't it much more likely that it will be found at 14 TeV run than being found only at 100 TeV? Intuitively, shouldn't the probability of finding a natural solution to the hierarchy problem grow exponentially (or rapidly) smaller with the amount of fine-tuning?

How can Nima make this assessment that it would be 100 times more surprising to find nothing at 100 TeV? Doesn't sound logical to me….the 14 TeV run has not even started yet and its importance should not be undermined.

16. **P**
September 3, 2013

Peter,

Nima's ~ 100 times more surprising argument seems pretty standard. The COM energy picks up a factor of 10 compared to LHC, which then gets fed into the quadratic divergence of the cutoff.

No need to restart the scientific argument regarding naturalness in this thread, but I think honesty requires someone pointing out that *most* of the community disagrees with you that this is unimportant; i.e. "Wild exaggeration" are your words, and many would disagree.

Cheers,
P

17. **Anon**
September 3, 2013

P —

What is standard is that at 100 TeV you can establish fine-tuning to a factor of 100 more than at LHC — ie we can show that Higgs mass is 0.01% (or worse) fine-tuned compared to being 1% (or worse) fine-tuned at LHC14.

But why would a discovery of finetuning of 0.01% be 100 times more surprising/shocking than discovery of a fine-tuning of 1%?….when the real shock is that there is fine-tuning of Higgs mass. We have a renormalizable theory that could be good all the way up to the Planck scale and it does not by itself allow us to be shocked by some artificial naturalness/finetuning standard like 0.01% (or equivalently 100 TeV machine).

Where do you produce a small unnatural number like fine-tuning of 0.01% to set a standard for naturalness?

Note that there are naturalness explanations based on approximate chiral symmetries for small Yukawas that could be like 0.1, 0.01, 0.001, 0.0001 and even 10^-5 in the standard model. Similar chiral symmetries and arguments are at work in SUSY theories to protect the Higgs/Higgsino masses. And LHC would show beyond any doubt show that such a naturalness argument has failed in the case of the Higgs and hierarchy problem.

18. **Peter Woit**
September 3, 2013

P,
Others have weighed in, but the obvious point is that making degree of shockingness linear in the degree of fine-tuning, instead of, say, logarithmic, is, well, the kind of thing you would do if you like exaggeration.

In general, I think if you have a hypothesis that something should be order 1, and experiment bounds it at .01, it's more conventional to start questioning your hypothesis than to announce that a bound of .0001 would be 100 times more shocking.

19. **The Vlad**
September 4, 2013

Peter:

Do you understand what Craig meant by the second part of the quote "there are many valid reasons to favor supersymmetry, some of which are only strengthened by what we've learned so far at the LHC"?

Do you think he was alluding, as he later writes, to the claim that "[SUSY] predicts the Higgs mass to lie below 135 GeV, in good agreement with observation"?

Assorted News

September 4, 2013
Categories: Multiverse Mania

- This past weekend I was up in Boston and attended quite a few talks at the Gelfand Centennial conference at MIT, in honor of the 100th anniversary of I. M. Gelfand's birth. Abstracts of the talks are available, but most of them were blackboard talks, not being recorded as far as I could tell. I've been starting again on my project to learn more number theory, so found Matt Emerton's and Akshay Venkatesh's survey talks especially helpful.
  There was one long afternoon program of recollections of Gelfand and his seminar from a long list of speakers, which went on into the evening banquet. This was being recorded, so video will perhaps appear some day (Gindikin's contribution was on video, available here). Another long afternoon session dealt with Gelfand's mathematical legacy, again perhaps at some point there will be video available of this.
- In mathematical news, speakers at next year's ICM have now been announced, for both the plenary and the various sections. Those interested in tea-leaf reading can consider for themselves what this new information says about who will get a Fields Medal next year. They might also appreciate this.
- A Fields Medal is worth just 15,000 Canadian dollars. If you can claim some relation to physics, much better to have your friends get to work nominating you for a $3 million fundamental physics prize. Online nominations for 2014 are here, and the news is that the three finalists for the $3 million will be announced this November. The Selection committee will be the 11 previous theorist winners of the $3 million prize plus three LHC physicists from the experimental side. The FPP also has some news here about what some of the LHC experimentalist prize winners have done with the money.
- Historically unparalleled payments to the stars of the field seem to be part of a larger societal pattern, as well as a much grimmer picture for young non-stars. The situation on the theorist side is not news, but Adrian Cho at Science magazine has a story about the extremely ugly job prospects facing young LHC experimentalists, with the title After the LHC, the Deluge.
- In case you weren't aware of this, see here for an explanation of why The STEM Crisis is a Myth. One thing in that article I'd never seen before is Alan Greenspan's explanation of why we need more H1B visas: the inequality problem in the US is due to overpaid computer programmers, and these plutocrats can be dealt with by importing low-wage labor to take their jobs.
- Finally, for the latest in multiverse mania, New Scientist has Death by Higgs rids cosmos of space brain threat (and an editorial about how this shows the Higgs is not "boring"). I knew there was no way they could resist Sean Carroll's new paper dealing with the question: Can the Higgs Boson Save Us From the Menace of the Boltzmann Brains?. Sean has more about this here, and Jacques Distler has a discussion here which I think accurately reflects the views of physicists outside certain West Coast enclaves:

  > Normally, I wouldn't touch a paper, with the phrase "Boltzmann brains" in the title, with a 10-foot pole. And anyone accosting me, intent on discussing the subject, would normally be treated as one of the walking undead…
  >
  > This is plainly nuts.

  I confess that this kind of thing completely mystifies me. Carroll is an intelligent, well-informed, and almost always reliably sensible sort, with a keen devotion to the battle for scientific rationality against the forces of religion and obscurantism. But he likes to pair this with an enthusiasm for pseudo-scientific multiverse wackiness that Distler's "nuts" describes pretty well. Very weird, and if you want to know why I keep referring to "mania" in this context, this is a good example.

   "… what some of the LHC experimentalist prize winners have done with the money."

   Bravo for Incandela and Virdee. We are still waiting to know about the rest though.

2. **CU Phil**
   September 5, 2013

   It looks like Sean Carroll will be giving a physics colloquium at NYU in October, so maybe you'll get a chance to hear about this straight from the horse's mouth.

3. **Alex**
   September 5, 2013

   You say there's no STEM crisis, but in August of 2008 somebody from my university's office of instructional technology told me to my face that the economy will collapse if we don't get every available warm body into STEM. A few weeks later the banking system melted down. I wish I had taken his pious sermon more seriously.

   Next you'll try to tell me that there's no experimental evidence for string theory!

4. **Peter Shor**
   September 5, 2013

   Unless it's changed, the plenary speakers and the Fields Medals are chosen by two different committees who don't talk to each other, so information theoretically, the list of plenary speakers doesn't give any information about the Fields Medalists that isn't already public knowledge.

5. **X**
   September 5, 2013

   I'm a bit surprised by this reaction to the Boltzmann brains paper. One way to resolve the BB paradox is to put a finite lifetime on the universe. A metastable Higgs phase does that. These two statements seem unremarkably standard physics, so what's the big problem? My reaction to the paper was more "Duh, isn't this obvious? Who's trying to get a publication out of this?"

6. **El-Coco**
   September 5, 2013

   Gelfand wrote some amazing introductory primers to elementary topics in mathematics. I wish other top talents would do the same. Perhaps they believe it a waste of their time, but Gelfand's little books changed a lot of lives (mine included).

7. **Peter Woit**
   September 5, 2013

El-Coco,
At the conference I think Gelfand's widow Tatiana mentioned that she was working on getting out an elementary geometry textbook written with him.

A couple links I should have included in the posting:

http://www.israelmgelfand.com/index.html

and Tanya Khovanova's toast at the banquet

http://blog.tanyakhovanova.com/?p=470

8. **Peter Peterson**
September 5, 2013

Peter, you already had a pretty prolonged discussion about STEM, and I commented there also. I hold you in high respect in anything related to physics and mathematics. However on this topic both you and the author of an article are very wrong. I am sure there are more than these two articles, but there are many more on the opposite side of the issue. The crux of the matter here is as always not quantity but quality of STEM workers. Or, in other words, a need to find a few diamonds in a pile of rubble.

9. **tt**
September 5, 2013

we need more skilled economists, not STEM workers

10. **z**
September 6, 2013

In terms of STEM research jobs, there will always be a job shortage since most science is done via a finite number of federal grants that eventually produce PhDs with a multiplicity factor greater than unity. Even if you increase the amount of money for grants, this model is still has no equilibrium solution. H1Bs however are not usually PhDs, but programmers and thus mostly only drive down wages for BA/BS-level jobs. Computer programmers _are_ overpaid compared to other high skill work, like say, science teachers or community college professors — and it is dictated by supply and demand.

There is also another STEM crisis, but it's not about degrees or credentialism, but that the general public is highly deficient understanding quantitatively and logically how the natural world works.

What needs to happen is that every college student, regardless of major, needs to know how to program, know calculus-based physics that includes thermodynamics and E&M, and take a biology course that teaches evolution. I find it unbelievable that people can graduate college without this basic knowledge, when I had it taught to me in a public high school. I am aware some undergraduate programs do this, but it needs to be more widespread as I think it's the 21st century equivalent of a 19th century classical/liberal arts education.

11. **T.G.**
September 6, 2013

According to the results of these two polls, the Fields medalists will be Bhargava, Avila, Lurie and one more not from the list in the first poll.

12. **Alex**
September 6, 2013

Peter Peterson-

In regard to quality of STEM grads, there are at least three distinct things going on:
1) Are the graduates smart (whatever that means) and rigorously trained to think through hard problems? I would argue that laments about "new grads these days" are probably timeless, but if there is any truth to them then efforts to increase quantity might actually be hurting quality.

2) Is their training relevant to the needs of industry? This is more of a problem of the disconnect between academia and industry than a problem of quantity. There is indeed "not enough", but it's a lack of grads with the right training, and increasing the raw number of grads without changing their training would not help.

The second problem requires faculty to take a hard look at curricula, projects, internships, etc. Adopting the latest edu-fad buzzwords is not what's really important here. What's important is us making a connection with industry and understanding what they need.

3) Industry seems less interested in investing in training, so the days of "Hire a smart grad and then train them to do what our company does" is gone. They want us to produce people specific to their needs. Depending on how broadly they define those needs that might be fine, but we can't design one degree program per job opening. We need to construct degree programs a bit more broadly than that.

I don't see any problems here that require greater quantity. What they require is a refocusing of educational efforts, and some effort by academia and industry to meet each other half-way.

13. **Wyman**
September 6, 2013

Were there a real shortage of qualified workers in STEM disciplines then employers would be forced to raise wages and actually provide training. Giving that the trend is broadly in the opposite direction on both counts, I'm not sure how anyone could conclude that there's a shortage outside of some specific positions. Really, a labor shortage of any sort without growing wages is just nonsense.

14. **davetweed**
September 7, 2013

Alex: there's an even deeper issue with your point 3. If you take the (reasonable view) that the best people to teach area X are those with some degree of experience in X (which isn't to deny that sometimes the best practitioners are hopeless teachers, but that teaching something one only knows about through being taught to teach it doesn't work that well), then universities can't be a good way to produce people trained for jobs in company Z because most of what university people do when not teaching (research) is very different from what employees in company Z do. (The few exceptions — eg, law schools where the professors are also practicing lawyers/judges — tend also to produce the graduate populations that companies complain least about.)

If companies want people who are tailored to their environment then they have no alternatives to doing training, whether it's "on-the-job training" or getting substantially more involved in degree level teaching. (To be fair, quite a few companies do actually do good on-the-job training, sometimes taking people without university degrees if they feel the training of a degree doesn't help them.) Unfortunately the prevailing atitude of many companies/business organsiations seems to be that they want a certain output from degrees without contributing significant input.

15. **Yatima**
September 7, 2013

> I'm a bit surprised by this reaction to the Boltzmann brains paper. One way to resolve the BB paradox is to put a finite lifetime on the universe. A metastable Higgs phase does that.

As you no knowledge about how "the universe" looks after "the metastable Higgs phase" has done its job, this doesn't resolve anything at all.

16. **Art**
September 7, 2013

Keep in mind that the STEM article you quoted appeared in the IEEE Spectrum mag. IEEE is a professional organization and has long desired to be the electrical engineering equivalent of the American Medical Association, controlling the supply of its members to keep their wages high. Nothing wrong with that; the point is that they have a big dog in this fight, so *caveat emptor* .

17. **Tom**
September 7, 2013

@Art said:
" … IEEE is a professional organization and has long desired to be the electrical engineering equivalent of the American Medical Association, controlling the supply of its members to keep their wages high. … "
— — — — — -
I've been an IEEE member for some 30 yrs. I've not encountered or observed any such systematic policies from IEEE. If anything, it's tended toward the opposite.

OTOH, my main interest in IEEE is their technical publications, conferences, and opportunities for professional networking. The "leadership" of the various IEEE divisions seem to be academic or research-oriented engineers with too much time on their hands. I admit — I tend to tune them out.

18. **Visitor**
September 7, 2013

"Carroll is an intelligent, well-informed, and almost always reliably sensible sort, with a keen devotion to the battle for scientific rationality against the forces of religion and obscurantism."

Carrol also seems to be engaged in an attempt to advance himself as Michio Kaku's successor in the trash media. Hence such puerile foolishness as equating cooking eggs with doing cosmology. I'm not sure if he will ever be "The Fried-Egg Cosmologist" in the same way that Stanton Friedman is "The Flying-Saucer Physicist" but, as the lottery slogan has it, hey, you never know.

19. **srp**
September 7, 2013

Another (though least important) reason for trying to invest in advanced accelerator concepts: Some of the proposed AAC technologies have complementarities with more-applied areas (e.g. possibly building tabletop soft X-ray lasers). Anything that reduces the gap between the working technology used in particle physics and the problems of other fields can only improve the employment situation.

20. **CIP**
September 7, 2013

In the future, physicists will be expected to wear the livery of their patrons.

21. **Alex**
September 7, 2013

I don't know about IEEE specifically, but my experience has been that most professional societies in STEM whole-heartedly endorse "We need more students in STEM! We need more students in STEM!" Some of it might be the self-interest of their academic members, but I think most of it is the psychology of regarding one's profession as Important. Electrical engineers love electrical engineering, they think it's important, anybody who cares enough about it to get involved in IEEE probably loves to share their enthusiasm for engineering, so their psychological leaning will probably be to encourage interest among the young.

22. **Peter Woit**
September 8, 2013

Visitor,
Actually, while I'm sure he'd love to take over Kaku's role in the media (and maybe already has), Carroll is generally much more sensible in his public discussion of physics. He mainly seems to go over the top on multiverse-related issues, sometimes going beyond what Kaku ever tried (e.g. writing wacky scientific papers).

23. **Mike**
September 8, 2013

The subject of STEM workers and H1B visas is always frustrating – reports from everywhere seem to come out that we have a shortage of technical people and there are jobs for the taking out there – we just need more grads in the science and engineering field. In the meantime, we should just increase H1B visas. Most of these reports can be traced back to lobbying groups that support the clamoring of corporations that will play any game to get those high-paying jobs down into the "acceptable range" as seen by economists and accountants who immediately see a better balance sheet for the companies they work for when any labor cost drops. It seems like our economy has suffered enough at the hands of people who's idea of math is add, subract, multiply and divide (and maybe some watered-down calculus they had to suffer through in business school)!

24. **Mark**
September 9, 2013

"Peter, you already had a pretty prolonged discussion about STEM, and I commented there also. I hold you in high respect in anything related to physics and mathematics. However on this topic both you and the author of an article are very wrong. I am sure there are more than these two articles, but there are many more on the opposite side of the issue. The crux of the matter here is as always not quantity but quality of STEM workers. Or, in other words, a need to find a few diamonds in a pile of rubble."

But when many industry jobs requiring STEM people pay peanuts why would they attract the best and brightest? In the uk science jobs in industry are very badly paid from what I can see (similar salaries to relatively unskilled jobs – when I see how much money other highly skilled professionals are paid its quite a gulf….) – thats probably why a lot of physicists go and work in banks, or move to other countries offering higher salaries relative to the cost of living.

In fact I would have to take a significant pay cut to take a science job in industry in the UK, so if I ever leave my university research group it won't be for a STEM job in the UK.

As far as I can see we have two problems:

(1) We produce far too many STEM people compared to jobs
(2) STEM jobs can't get the good STEM people, because the best are attracted to other careers or countries with much better pay and conditions, and so perhaps are left with the dross from (1)

25. **John Urbanik**
September 9, 2013

As one of those so called over paid programmers I've been around long enough to see that H1B's (and L1's) are nothing more then attempts to lower the standard of living here in the US to other coutnries. At first companies tried to off-shore work. Then came on-shore/off-shore teams. These attempts all failed for verious reasons.

Companies soon realized that they only alternative is to say there is a shortage of skilled workers here in the US. What they really mean is there is a shortage of skilled workers in the US willing to work for $20K per year. BTW over paid to these 'economists' is anything above $50K per year.

26. **srp**
September 9, 2013

@Mark: Low wages only keep the more talented out of a field if the more talented are unable to demonstrate their superiority in some observable way. Marginal chefs and novelists are quite ill-paid, but there is no shortage of talent in those fields making good incomes. Neither field has strong entry restrictions. (On the other hand, neither field has the inherent oversupply of new workers by grant requirement that STEM has.)

In some fields, supply creates its own demand, e.g. lawyers suing, doctors referring, possibly active money managers trying to outperform the market. In some technological areas "arms race" dynamics have the same effect–radar and electronic countermeasure experts making work for each other, semiconductor manufacturing technologists at rival firms pushing each other to speed up miniaturization, biomedical engineers struggling to come up with better medical devices than their rivals, etc.. Nothing like that kind of dynamic operates in particle physics, which implies the field has to generate demand by 1) popularization and 2) doing "physics appreciation" classes at the high school and undergraduate levels.

27. **tt**
September 9, 2013

" Low wages only keep the more talented out of a field if the more talented are unable to demonstrate their superiority in some observable way." or if they can make more money doing something else.

28. **Mark Decker**
September 11, 2013

Speaking of Kaku's role in the media: Charlie Rose had him on this morning and played back an interview segment from a few months ago showing his (now erroneous) prediction for the 2013 hurricaine season. I guess that's the risk you run when switching from discussing extra dimensions to meteorological predictions since meteorological predictions can be tested.

29. **T.G.**
September 13, 2013

Peter,

Check out this economics paper, especially, the summary on page 33, and figures and tables on pages 33-35. They show that the rate of output of the Fields medalists declines noticeably in the post-medal period, and medalists are pursuing topics that are far less likely to be related to their pre-medal work. One cool statistic stands out:

Average age at death of Fields medalists: 74
Average age at death of "contenders": 60.5

"Contenders" are mathematicians who were awarded at least one of six other mathematics prizes (the Abel, Wolf, Cole Algebra, Bôcher, Veblen, and Salem Prizes) but were not awarded the Fields Medal, and who had above-median per-year citations during the eligibility period for the Fields Medal.

30. **T.G.**
September 13, 2013

Here is an article about that paper.

31. **Peter Shor**
September 15, 2013

Something that bothers me a lot about that study is that to decide who were the contenders for the Fields Medal, they look at the Abel and Wolf prizes, which are typically awarded much later in the medalist's career. I think this post-selection biases the entire study. Suppose contenders for the Abel prize are (a) people who had a great early career and won the Fields medal and (b) people who weren't quite good enough for a Fields medal at 40, but who had a great late career. Including category (b) in the study biases it towards people whose output doesn't decline after 40.

The study should be redone just looking at people who won the Cole, Bôcher, Veblen, and Salem prizes at the age of 40 or younger.

32. **AndreasK**
September 15, 2013

" A question immediately arises: what exactly are the
medalists doing with their time in the post medal period?"

well the answer immediately arises that they were at least not writing questionable, obviously flawed economics papers on cultural subjects they have little or no understanding of. Possibly Mr. Borjas should spend instead more time on writing further papers on the necessity of reducing immigration rates to the US, or does he try to manifest 'intellectual mobility'?

"The harmful effects of immigration will not go away simply because some people do not wish to see them."

http://www.theatlantic.com/past/docs/issues/96nov/immigrat/borjas.htm

33. **Peter Shor**
September 15, 2013

My thoughts: the authors of that paper have PhDs in Economics from Columbia and Princeton, and are employed at two reasonably–well-respected institutions of higher learning.

The word "statistics" is derived from the word "state", because the science of dealing with data is fundamental for running a government and an economy.

And the paper contains what looks to me like an absolutely elementary fundamental in statistics.
This is very scary.

34. **Peter Shor**
September 15, 2013

Oops … I meant to write absolutely elementary fundamental **error**.

35. **Bill**
September 15, 2013

Peter Shor,

I agree, they probably thought that all these awards are equivalent. They could have asked mathematicians at Harvard (where the paper was written) to tell them more about these awards. Or, perhaps, they did ask, but nobody knows anything about statistics at Harvard math?

36. **Peter Shor**
September 17, 2013

The "age at death" statistic is also suspect. The first Fields Medal was awarded in 1936, the first Bôcher prize in 1923, first Cole prize was given in 1928, the first Veblen Prize in 1964, and the first Salem Prize in 1968, the first Wolf prize in 1978 and the first Abel prize in 2003.

Many of the Veblen and Salem prize winners haven't yet had enough time to die of old age.

This could, of course, be compensated for by using the proper statistics. The authors didn't.

37. **Bill**
September 17, 2013

I thought that only mathematicians who already died were counted to compute the "age at death"? The increase of lifespan over the last half a century, probably, can not explain such a big gap by itself.

38. **Peter Shor**
September 18, 2013

Hi Bill: Suppose I compare the age at death of a bunch of mathematicians born in 1920, and a bunch of mathematicians born in 1950. I guarantee you that the average age of death of those born in 1950 is less than 63.

Assuming the Veblen and Salem prizes are given to mathematicians at the age of 40, then the average year of birth of a Vablen or Salem prize-winner is around 1950.

I have no idea whether the Veblen and Salem prize-winners being born later on average will skew the average age of death of contenders 14 years younger, but the authors clearly should have take these correlations into account.

39. **AndreasK**
September 18, 2013

whilte there seem to be other 'oddities' in the study (Wolf- and Abel-prize/non-Fields winners seem to be considered irrespective of age restrictions while non-Fields-winners of Cole-, Veblen-, Bocher- and Salem prize seem to be considered as 'contestors' only if winning one of the prizes before the age of 40, the Salem prize is referred to on one and the same page as a determinant for being 'contestor' and as non-determinant because 'less prestigous' [footnote]), the main problem for me seems to be the questionable use of 'productivity measures' in cultural affairs like mathematics in general. The very first sentence in the abstract of the study already symbolizes the direction of the ideology: mathematics as a means to increase 'economic growth', the use of technoid terms like 'knowledge generation', the always re-occuring term 'productivity'.

Having said this I do indeed believe that the mathematical community, by being oblivious to the widespread introduction of 'industrial measures' into mathematical culture, paved the way for western representants of 'state institutions' to come up with articles like the above which, under the disguise of criticising 'wealth effects on labour productivity' actually aim to put a dubious light on mathematics in general, since depicting the most prestigous members of its community as 'lazy and/or experimenting and/or 'striking out" post-Fields-medaillists means more or less depicting the whole culture as in tendency prestige-governed, narcissistic and irresponsible.

I wonder if anyone ever wrote such papers on prize winners in the field of art or literature, but clearly a public or state institution being seriously interested in 'production rates' of Nobel laureates in literature before or after receiving the prize is quite hard to imagine, quite in contrary to mathematics obviously. So what went wrong?

40. **Bill**
September 18, 2013

Peter Shor, you are smarter than I am. But we already knew that.

41. **Shantanu**
September 18, 2013

42. **Peter Shor**
September 19, 2013

Bill … this is getting off-topic, but I think more undergrads should take a course in statistics like the one I took from Gary Lorden at Caltech, where he illustrates with examples many of the mistakes you can make by blindly applying statistical tests. If I'm smarter than you in this respect, it's largely due to him.

Perimeter Institute and the crisis in modern physics

September 9, 2013
Categories: Uncategorized

Maclean's has been publishing a very nice series of articles about Perimeter Institute by Paul Wells. These include one about Jacob Barnett, a 15 year-old who is now studying in a master's level graduate program (Perimeter Scholars International) there. Another piece, about other students in the program, is here. It discusses one somehow oddly familiar story, of a "young man with dark hair…seems too cool for school", born in Iran, but educated in Canada, on his way to a promising career in particle theory, Nima Afkhami-Jeddi. There's also yet another piece, with a wonderful description of the bistro at Perimeter.

In the most scientifically substantive piece, entitled Perimeter Institute and the crisis in modern physics, Wells describes PI director Neil Turok's welcome speech this year. Here are some quotes from Turok:

> Theoretical physics is at a crossroads right now…In a sense we've entered a very deep crisis.
>
> You may have heard of some of these models…There've been grand unified models, there've been super-symmetric models, super-string models, loop quantum gravity models… Well, nature turns out to be simpler than all of these models.
>
> If you ask most theorists working on particle physics, they're in a state of confusion.
>
> The extensions of the standard model, like grand unified theories, they were supposed to simplify it. But in fact they made it more complicated. The number of parameters in the standard model is about 18. The number in grand unified theories is typically 100. In super-symmetric theories, the minimum is 120. And as you may have heard, string theory seems to predict 10 to the power of 1,000 different possible laws of physics. It's called the multiverse. It's the ultimate catastrophe: that theoretical physics has led to this crazy situation where the physicists are utterly confused and seem not to have any predictions at all.
>
> The data just fits so perfectly with Perimeter's mission. If it had turned out to be complicated and messy — 10 new particles at CERN and all kinds of funny evidence for models of inflation and stuff in the sky — one would have to say the future of theoretical physics does look pretty messy and complicated. Perimeter would be just one of 100 such institutes.
>
> But given that everything turned out to be very simple, yet extremely puzzling — puzzling in its simplicity — it's just perfect for what Perimeter's here to do. We have to get people to try to find the new principles that will explain the simplicity

Turok's perspective on the current situation is great to hear. It's wonderful to see this kind of admission that the evidence is now in that particle theory has been barking up the wrong tree, coupled with a vigorous position that looking for new principles is where the future lies. My only comment would be that Turok might want to think about bringing in to Perimeter more mathematicians, since if physicists are going to look for new principles, they might need some new mathematics.

For another similar take on the current state of theoretical physics as it faces up to the fact that our simplest theories of particle physics and cosmology are working all too well, see Adrian Cho's Boxed In at Science magazine.

In the US, HEPAP was meeting last week to discuss the Snowmass workshop and the process for going forward with recommendations about the future of HEP. There was a report from the DPF Panel on the Future of High Energy Theory. It had nothing about the intellectual crisis that Turok and others see in the field, with the only crisis addressed the difficult budget situation, leading to cuts in grants. The panel recommends that theorists continue to get two full months of summer salary, and argues that "salary caps" limiting the size of these payments should not be lowered.

Update: Physics World has something about this, with the headline Perimeter Institute welcome speech reignites the string wars.

Comments

1. **Jess Riedel**
   September 10, 2013

   My guess is that the crucial insight will be more philosophical/interpretational than mathematical. Likewise, the Lorentz transformations were discovered and analyzed *in the context of electromagnetism* almost 2 decades before Einstein came up with special relativity. My vague impression of Perimeter is that most of the folks there would agree, although I certainly can't speak for them. But sure, bring on the mathematicians. Maybe their impressiveness will counter-balance the stigma of quantum foundations.

2. **Shantanu**
   September 10, 2013

   Peter, if you compare the list of seminars and other talks at PI now vs many years
   back, when it was formed, earlier there used to be lots of talks on non-trendy topics
   and including by people who usually don't give talks elsewhere.
   whereas nowadays most of the seminar are on the usual fad topics.

3. **Noname**
   September 10, 2013

   "[…] might want to think about bringing in to Perimeter more mathematicians, since if physicists are going to look for new principles, they might need some new mathematics."
   Well, this might be a bit premature, don't you think? What branch of mathematics do you think it will be needed? Fortunately you are not the Perimeter's director!

4. **Peter Woit**
   September 10, 2013

   Noname,

   "premature"? Do you think that if the crisis in theoretical physics gets worse, that will then be the time to call in the mathematicians?

   I'm not sure why you find the idea of a few mathematicians amongst the hundreds of physicists at Perimeter so threatening. Actually, I hadn't realized that Perimeter now has Mathematical Physics as one of its nine research areas. Between that and Nima Arkani-Hamed's interest in motivic Galois theory, the inroads of mathematics at

Perimeter may already be more advanced than I realized.

One thing I think we can both agree on is that it's very good that I'm not the director of Perimeter. For one thing, I don't have much in the way of good ideas about who they should hire. As for promising fields of mathematics, given the huge past success of symmetry arguments in fundamental theory, there's a name for the field of mathematics that deals with such symmetry arguments (representation theory), and that would be one obvious place to consider.

5. **Foster Boondoggle**
September 10, 2013

"nature turns out to be simpler than all of these models"

This seems like a very strange thing to say. It sounds like Turok thinks we've found everything out already, and it's not complicated! In context, he's talking about the combined discoveries of Planck (strong confirmation for the Lambda-CDM concordance model) and the Higgs, more or less capping the particle zoo of the Standard Model without providing any clues (yet) to what lies beyond. But to call this "simple" seems a misuse of the word. 3 generations of fermions? "Who ordered that?" A light scalar: how does that work? Another scalar that drives inflation. What is it? Stable probably heavy non-baryonic dark matter and a non-zero cosmological constant 10^-120 times its "natural" value. What are they? And how does all this hang together into a coherent whole? This is simple?

The crisis is the gap between the limits of the methods that served so well since the 1930s and the energies that we need to investigate. In the face of that gap, theorists are doing what they can. But they're not just confused – as Turok notes in the fuller context, they're depressed. He goes on to say things promoting the PI as a route to fulfillment, which is part of his job, so one can forgive his rhetoric. But what's your excuse? You wear your schadenfreude on your sleeve. It's an entirely worthy thing to mock hype, which you do ably. But it seems perverse to take pleasure in the hopelessness of so many who've been at the forefront of discoveries and theoretical inventions that have taken us so far, and are now stymied.

6. **Peter Woit**
September 10, 2013

Foster,

To my mind, Turok is just making the obvious point that we don't have any good ideas about how to get beyond the SM, that the heavily oversold ones of the last 30 years were always too complicated to be plausible, and now in addition have had their hopes for some experimental confirmation shot down, thus the "crisis".

My reaction to what Turok has to say is not "schadenfreude" at all, but optimism to see someone influential making these obvious points that I and many others have been making for years. He's quite right that the theory community should acknowledge the situation and act accordingly, not by being "depressed" that the unpromising ideas many had been working on are getting shot down, but by looking for something new to try. To be blunt, I have little sympathy for those "depressed" that the techniques they know and love have run out of steam and no ideas or interest in coming up with others. People working in this area are smart and capable of doing many things with their lives, and if they don't see anything worth doing in this field, they should move on to a different one and open up space for those who do have ideas they want to work on.

7. **Thomas Larsson**
September 10, 2013

Hehe. It is encouraging that people like Turok starts to acknowledge the crisis in physics. After another ten years of crisis, maybe people will even start to look into new non-trivial extensions of gauge and diffeomorphism algebras 🙂

But then again, whom am I kidding. We all know that the ultimate goal of theoretical physics is to worship Ed Witten by chanting magic and mystery.

8. **chorasimilarity**
September 10, 2013

When I was a kid I was sleeping with a CERN print and I was explaining the Hawking radiation to my friends by impersonating a black hole, eating cherries and spitting the kernels. Later I got converted to mathematics. Now, my impression is twofold: on one side, there's a lot of new math which could benefit to physicists and on the other side, boy, understanding biology is far more interesting and challenging than physics.

9. **Autism Skeptic**
September 10, 2013

Is there any legitimate evidence that Jacob Barnett is actually autistic. Highly intelligent, unusually behaving, late-talking, children are quite often misdiagnosed as being autistic when they are not autistic at all. Maybe Jacob Barnett got caught up in the Autism Dragnet.

11. **fuzzy**
September 10, 2013

if i was a teacher in math, i would say that the counting is wrong, and even the evaluation of the perimeter is doubtful.

in fact, taking a renormalizable gauge theory su(3)xsu(2)xu(1) with sm content, the number of parameters is 20 not 18 (3 mixing, 1 phase, 9 masses, 3 parameters in the scalar sector, 3 gauge couplings, 1 strong cp phase). and i doubt that a reasonable counting of the parameters of a grand-unified-theory can be done, without declaring the theory that you want to discuss.

but what is worse is the statement "If you ask most theorists working on particle physics, they're in a state of confusion."…. "most theorists"? when, for god sake, mankind made a step forward in theoretical physics using polls?

12. **Peter Woit**
September 10, 2013

fuzzy,

I suppose one can argue that dimensional transmutation allows one to trade one of the gauge couplings for a choice of mass units, and the strong cp phase getting somehow set to zero isn't really an undetermined parameter but a structural aspect we don't understand. That would give the 18. A more serious problem is that this count doesn't include neutrino masses and mixing angles.

13. **Anon**
September 10, 2013

The strong CP phase has to be experimentally determined in the standard model and we only have good bounds on it — but we may yet discover that it is non-zero in the improved sensitivities of neutron and other EDM experiments in the next 5-10 years. So it is a bonafide parameter.

In the Higgs sector there is only its mass and VEV — so 2 parameters.

And then there are the neutrino mass and mixing parameters as well, but maybe these are being considered as beyond the standard model parameters.

14. **fuzzy**
September 11, 2013

hi friends, let me insist, assuming we are theorists. if we can agree on counting, maybe we can do physics.

the parameters ought to be counted by using the rules of the game. and the rule of the game are three: "gauge invariance, renormalizability, selected representations".

with these rules

1) neutrino masses are out from sm. this proves that the sm is not correct, but this is another story that does not pertain to the "counting of parameters in the sm".

2) the scalar potential contains a constant, that has to be counted (you can call it the cosmological constant, if you want to call it somehow)

3) the theta term is a honest gauge-invariant term, it is also there in the heap of parameters. all we know from experiments is that, assuming that the sm is correct, it is small.

the fact that we want to understand neutrino masses, cosmological constant, reason of conservation of cp in strong interactions (and we don't) does not change the counting of the parameters in the sm.

(apart from disagreement, i do not understand one of your arguments peter: if you consider dimensional transmutation, you do not change the number of parameters; alphas or lambdaqcd makes always one, from the point of view of counting)

15. **Bobito**
September 11, 2013

The mainstream of physics is still condensed matter and optics. There is no crisis there, rather constant and impressive progress. You do a disservice speaking of a "crisis in physics" when you mean something like a "crisis in particle physics" or a "crisis in high energy physics" (both probably still too overbroad).

16. **vmarko**
September 11, 2013

Fuzzy,

"2) the scalar potential contains a constant, that has to be counted (you can call it the cosmological constant, if you want to call it somehow)"

Please, please don't call that parameter the "cosmological constant". At the very least, calling it that way is very bad terminology, as people might confuse this parameter with the actual experimentally observable cosmological constant.

Adding to your rules of the game, I'd just note that:

(a) gravity is to be considered BSM (due to your renormalizability requirement) and consequently there is no cosmological constant (the real one) in the SM,

(b) the constant parameter in the action is completely unobservable within the SM, and should not be treated as a bona fide parameter.

The additive constant in the SM action (or any other flat-spacetime theory) can couple only to gravity, which is BSM by definition. Without gravity, this parameter is not observable, and can be freely set to anything you want, including zero. So it can be removed from the SM with no difficulties, and it should not be counted as a proper parameter.

And again, please don't call it the cosmological constant — the *real*, observable cosmological constant is a parameter in GR, it measures the non-flatness of spacetime, and has absolutely nothing to do with the constant parameters in flat-spacetime theories like the SM.

Best, 🙂
Marko

17. **fuzzy**
September 11, 2013

marko i agree that it is better to say that the sm has 19 *observable* (or potentially observable) parameters.

i am instead confused by the statement that the cosmological constant is purely gr; perhaps you mean that gr is a self consistent theory that does not need the sm, and we can use some simpler treatment of the matter when doing cosmology?

thanks again! 🙂

18. **vmarko**
September 11, 2013

Fuzzy,

We're getting off-topic here, but since you asked…

"i am instead confused by the statement that the cosmological constant is purely gr;"

Why is that confusing? The cosmological constant is a parameter in Einstein equations of GR (and some other models of gravity, but let's not get into that), and is being measured through its gravitational effects. One particular effect of nonzero CC is that the Minkowski flat spacetime is not a solution of Einstein equations.

On the other hand, the SM is defined precisely in flat spacetime, which means that it ignores both GR and the CC itself. The SM action is defined up to an arbitrary additive constant, which cannot be measured in any SM experiment, and is therefore usually set to zero. Being introduced in flat spacetime, this constant has a priori nothing whatsoever to do with the CC.

Now, if one couples GR and SM (classically only, quantization has lots of issues), the arbitrary constant from the SM sector and the CC from GR sector sum up into a single resulting parameter, which is also called CC. Experimentally, the CC has been observed to be positive (by gravity-related measurements), leading to the acceleration of the universe. While one could in principle say that the free parameter from the SM gives a contribution to the observed constant, there is no other way to measure that parameter on its own (non-gravitationally). Therefore the easiest thing to do is to set it identically to zero, and have only one parameter to be called CC — the one which was present in GR from the beginning.

I hope now it is more clear. 🙂

"perhaps you mean that gr is a self consistent theory that does not need the sm, and we can use some simpler treatment of the matter when doing cosmology?"

I did not try to say anything about the self-consistency of GR, SM, cosmology or otherwise. 🙂

Best, 🙂
Marko

19. **Peter Woit**
September 11, 2013

Please, enough about the CC…

20. **imho**
September 11, 2013

Lets be fair. I see some in the HEP community stubbornly refusing to acknowledge reality… but I see many other prominent names doing exactly what Peter (and many others) have been suggesting. That is, looking for more fertile ground. What do you think this whole firewall business is about? Have you paid attention to Witten's work the last few years? Many of the saner minds in hep -are- looking for new approaches and directions. We should not expect a public mea culpa as that could harm all of science funding. But we should "privately" acknowledge and encourage the change of tack.

21. **Noname**
September 11, 2013

I'm just curious to know what Peter would do if SUSY is discovered in the next LHC run. In my opinion the only honorable reaction would be to close down this blog. Peter, if you answer, please don't say this will never happen. I'm interested in your reaction if it does happen.

22. **Peter Woit**
September 11, 2013

imho,
I disagree with you that this is a discussion that should only be held privately to protect funding. What has actually been happening over the past decade or so is that as the problems with string theory and SUSY have become more apparent, the refusal to publicly admit this, and the choice to start adopting multiverse pseudo-science instead, has damaged the interest of HEP theorists immensely. Look at it this way, if you're a non-HEP physicist trying to decide whether to hire in HEP theory, having HEP theorists saying that past ideas haven't worked out, but they're moving on and trying to find new ones is not a strong case to hire them, but it's something. If instead you're being asked to hire people who refuse to admit that what they've been working on doesn't work, you've got a very strong case not to hire them. I think Turok has it right: make lemonade.

Noname,
Unlike some physicists, I don't have a problem with the fact that sometimes I'm wrong about things. If the LHC sees the kind of SUSY that I don't think has ever been very promising, I'll have been wrong, and will discuss this not just privately, but publicly. I'll also be fascinated to try and understand the implications of what the LHC does see. If it turns out it's a complicated SUSY effective field theory of some random point in the string theory multiverse, and none of the various ideas about representation theory and physics that I've been thinking about go anywhere, I'll give up and do something else with my time. This might become a blog about number theory and Shimura varieties…

23. **Geoff**
September 11, 2013

Peter –

I'm not sure if you had a chance to listen to all of the video of Turok's welcome for the new students. A bit later in the video he says that what string theorists are really doing is playing around with different pieces of mathematics. So perhaps when Perimeter hires a string theorist, there really are hiring mathematicians.

24. **imho**
September 11, 2013

Hi Peter, we should hold a public discussion to what benefit? The public discussion over the last decade has been helpful no doubt, but it seems to me we're seeing power law behavior at a critical point. A new phase is coming. Is it still useful to air dirty laundry when most everyone agrees there was a problem and many are taking steps to correct said problem. Shouldn't we keep in in the family? Or perhaps we need to make a distinction between those changing tack and those stubbornly steering towards the iceberg… Maybe I'm wrong.

25. **Peter Woit**
September 11, 2013

Geoff,
Problem is that mostly string theorists aren't mathematicians or doing mathematics. Some of them are and that's great, but the assumption that string theory=mathematics is just wrong (as an extreme example, consider the string theory anthropic landscape).

Actually I see that Perimeter divides things in a reasonable way, with a “Mathematical Physics” research area and a “Quantum Fields and Strings” research area, with only some of the QFT+string theory people listed in both.

26. **Cliff**
September 11, 2013

Im completely flabbergasted at the things Turok thinks he’s justified in saying. As Foster rightly points, he speaks like someone who’s had some kind of divine revelation of the solutions to all nature’s problems. The known problems with the Standard Model in 2013 are just the exact same problems that were known in 2003, and Neil Turok is in no position to declare the solutions to these problems “simple” or “complex” or anything else, because they remain *unsolved* problems!

Besides being confused about the difference between fundamental and effective field theories, the difference between parameters and vacua and “laws of physics” (confusions all also promoted by this blog) Neil’s main thesis is also complete nonsense. There is only exactly one thing that could be called a “crisis in physics” and its really more of crisis in economics: the fact that substantially novel data costs on the order of $10 billion or more to obtain. There is no “crisis” in having a description of nature that works perfectly well up to the energies that can be accessed by such a machine (if that is the case, which is far from certain). There is no “crisis” in having accumulated detailed parametrizations of as many scenarios as possible that are known to be consistent with all existing experimental data. And certainly there is no crisis that will be solved by stopping theorists from constructing new models.

Its natural that some people will find that the most powerful BSM ideas unpalatable to their intuition, and theres nothing wrong with that. But if this intuition is grounded in truth then there will be some other framework from which we can derive QM, GR, Yang-Mills, the Higgs mechanism, and every other major component of empirical reality, and that framework will have nothing to do with SUSY or strings. Well I would be very interested to learn that you’ve found such a completely new framework, but I don’t think we ever will, because I think that intuition is obviously wrong. But in either case, for now, thats all it is: intuition.

27. **donald**
September 11, 2013

Fiber Bundles! That’s where it’s at!

28. **fred**
September 11, 2013

Thanks for the post. I also agree that more mathematical physicist (people like Wigner) who has mathematical vision and physics intuition can be really useful. I also agree that string theorist can not replace mathematicians in the field. To my understanding they just play with this and that, not necessarily having the deep mathematical vision.

Additionally, as a person who was in the field, I would say I did not see much flexibility in accepting new ideas. I am sure the next Einstein is already changed his field to “finance” or something else.

For a fundamental breakthrough, I believe that we need more mathematicians, more open positions, more passion, and less dogmatism.

29. **Bob Jones**
September 12, 2013

“the assumption that string theory=mathematics is just wrong (as an extreme example, consider the string theory anthropic landscape).”

Calm down about the multiverse! Hardly anyone is even studying that stuff. Probably around 80% of the papers on hep-th are looking at formal, mathematical problems in QFT and string theory. You’re so obsessed with this multiverse business that you’re completely ignoring the reality of this subject.

30. **Bernhard**
September 12, 2013

Bob Jones,

The multiverse stuff might not be in the hep-th front line
(and here I have serious doubts… check this out: http://arxiv.org/find/all/1/all:+multiverse/0/1/0/all/0/1)
, but in any case certainly is in the of the spotlight of the outreach arena, which is the “welcome card” of our field. Almost every popular book and article mentions it, it appears on TV in several programs, the list is unending. And, it seems to me that the number of bullshit hep-th papers is increasing and not decreasing. A sign of the times is to see a talented fellow like Sean Carrol writing some crazy article about “Botltzmann brains”.

Peter might be more concerned than the rest of the field, who so far seems to just ignore as an embarrassment not worth mentioning. Whether ignoring will make it go away or make it worse (increase bullshtiness in hep-th), time will tell.

31. **Peter Woit**
September 12, 2013

Bernhard/Bob Jones,

The multiverse was only being mentioned here as an extreme example, no need for more discussion of it here. More to the point, my comment was about string theory, and Bob Jones responds by arguing about “QFT and string theory”, which, if you care about what words mean, is something different.

If anyone has some actual data on what fraction of hep-th articles are about string theory and are of the sort that a mathematician would describe as serious mathematics, that would be interesting. Otherwise though, enough…

32. **Bob Jones**
September 12, 2013

String theory is not mathematics, I agree with you about that. But it’s still *mathematical* in the sense that most of the time string theorists do not even attempt to postulate new physics. Instead, string theorists are generally interested in conceptual questions in quantum gravity and applications to formal problems in quantum field theory. They’re not coming up with new laws of physics but deducing consequences from the theories that are already known to be relevant for describing nature.

33. **JK**
September 12, 2013

Although it is good to hear someone from the Theoretical Physics community admits to the current crisis, one is tempted to think it might not be an accurate reflection of what physicists at PI believe. I have met with several PI faculty members and students. They generally and mostly (not exclusively though) expressed a snobby attitude. I believe members of the String Theory group at PI must be convinced that String Theory is the way, otherwise they would abandon it. If Turok is really serious about working on finding a solution to the current crisis, then a plan for adopting new directions should be implemented. One thing could be hiring mathematicians, like you suggested. I also think it would be very useful if there are more practical projects invested in, for instance projects that can provide theoretical predictions verified by EXPERIMENT. To my knowledge there is one or maybe two theorists at PI working on problems that may (?) connect to experiment. PI can express greater interest in Condensed Matter Physics and AMO Physics. For now, I feel probably the most useful work at PI is in the context of Mathematical Physics. Also, there could be projects held in connection with the philosophy of physics. After all, philosophy and physics were connected for a long time.

I would be interested in your opinion, Peter.

34. **LogicFan**
September 13, 2013

My gut feeling, somewhat along the lines of what Jess Riedel and JK allude to, is that the crisis will be solved not by physics but by philosophy. I do not know intellectual history well, but certainly we have found ourselves in this position before–apparently stymied, unable to progress. Yet our problems were, in time, solved by a deep, simple, and in retrospect obvious philosophical insight. Whether it's the Copernican Revolution or Einstein's insight into (e.g.) the relativity of time, cleverness or technical skill didn't do the trick. Instead, it was a willingness to think "outside the box" and against the orthodoxy.

If I were a physicist, I would study intellectual history to identify situations similar to the one we find ourselves in now. Then I would examine how those situations were eventually resolved, with an eye toward the general philosophical outlook, the conceptual leaps, etc. that were involved. That would not provide us a solution but at least would suggest the approaches and persons likely to succeed.

On these grounds, string theory strikes me as dubious. It strikes me as similar to the ill-fated effort to explain the geocentric orbits of the planets through ever more complicated mathematical systems of epicycles upon epicycles. Contrast this to Einstein; he didn't invent any new mathematics at all as far as I am aware. Instead, he took from Lorentz, and then from Riemann. But he just had that fundamental philosophical insight that was right for the time.

35. **fuzzy**
September 13, 2013

hi LogicFan, i agree with you, and would like to add a thing.

a trivial principle is that we should not support an idea in which we are not convinced, but it is much easier to avoid confrontation with ideas and with people, and rather, accept "this" since it is fashionable, "that" since it gives me a grant, or since the research center where it is studied is so respected, etc.

we need critical and open discussions among physicists! if a colleague working in condensed matter, or astrophysics, is not convinced by the validity of a certain plan or idea concerning particle physics, this is a good reason to reduce fundings. i mean, physicists should take responsibility of a serious and responsible community, we cannot accept self-referencing.

the usual objection i receive to this description is "it cannot be so"! but please, go to any specialized conference in strings or susy and tell me how many people come to progress in science or to understand something new, and how many to participate in the social event. (tip: one of the two numbers is usually zero)

coming back to the discussion of turok, i do not like his ideas. as i argued above, he is not taking theory seriously, because one cannot speak so loosely: "the sm has 18 parameters" (and as we discussed, this is not true: the parameters are 20, 19 of them are observable) or worse "this class of theories has 100 parameters, the other has 120" (which theories!!?? nobody cares of what he is speaking of???)

i highly dislike his argument "things are puzzling for its simplicity and this justifies our institute", since I am also a fan of logic, and this argument has nothing to do with logic, it is pure rhetorics! for me, what it is really puzzling is not that some people are free to discuss anything they want, but rather, that nobody ever asks them "but where all your predictions of yesterday have gone? what is your contribution to the physics?"

36. **Peter Woit**
September 13, 2013

JK/LogicFan,

Experimental condensed matter and AMO physics is pursued by most physics departments in the US and Perimeter's mission is explicitly to try and do something different. I also don't know of any promising ideas about experimental HEP or cosmology work that are not being already actively pursued.

As far as philosophy goes, since its founding Perimeter has had much more involvement in that (via Lee Smolin, for instance) than just about any other physics institute I know of. This is also a topic that has been well-funded in recent years (see the Templeton-funded efforts in "Philosophy of Cosmology" as an example). I'm a skeptic about prospects for this sort of thing, but one should try everything….

37. **Bob Jones**
September 13, 2013

"If I were a physicist, I would study intellectual history to identify situations similar to the one we find ourselves in now."

I have nothing against philosophy, but this idea that physics is going to be saved by some "simple, and in retrospect obvious" philosophical insight is just ridiculously naive. Physicists are well aware that progress may require radical new perspectives. However, progress also requires some understanding of how our current theories work and what sorts of extensions they admit. We're not going to make progress by sitting around and trying to imagine ways in which the current situation might be similar to that one that existed in the time of Einstein.

"It strikes me as similar to the ill-fated effort to explain the geocentric orbits of the planets through ever more complicated mathematical systems of epicycles upon epicycles."

You can always count on some layperson comparing string theory to epicycles on this blog, and it always exposes ignorance. One of the implications here is that string theory is some sort of ad hoc construction that can be modified in any possible way. On the contrary, many people are interested in string theory precisely because of its uniqueness properties. The comparison to epicycles also suggests that string theory might be abandoned some day. It should be obvious to any honest person with minimal knowledge of the subject that string theory is here to stay. Even if it doesn't provide a successful theory of everything, it's taught us a lot about how quantum gravity works conceptually, and it's one of the main tools of theoretical physics.

38. **Martin**
September 13, 2013

Looking at history, its not philosophy that physics needs, but relevant experiments. Theoretical physics should go back to phenomena that can be observed in experiment. String theory and quantum gravity are of course attractive to mathematically inclined physicists, but these topics do not bring physics any further. Sad, but true.

39. **A.J.**
September 13, 2013

@Martin:

I agree completely that what theoretical _particle_ physics needs right now is new data (and lots of it). However, I see nothing wrong with studying string theory and quantum gravity within the context of mathematical physics. We've learned a good bit about the mathematical structure of quantum field theories by doing this. For example, Seiberg & Witten's demonstration of confinement in an interacting 4d QFT and Komargodski & Schwimmer's proof of the a-theorem

Bob Jones and others are completely right that most people who study string theory are working on this sort of thing, not on the multiverse and similar sorts of nonsense. It's unfortunate that we spend more time discussing this garbage than we do talking about real advances in scientific understanding. But what do you expect? Real advances in scientific understanding are rare and frequently difficult to understand, while nonsense is easily produced and easily discussed. What would you choose if your living depended on getting people's attention?

(Question for Peter: Are you really doing the world a favor by bringing this stuff up all the time? I wouldn't be surprised to learn that your blog probably has a wider readership than the many/most of the press releases and pop sci articles you find. Is it possible that you're effectively feeding the trolls by covering this stuff?)

40. **LogicFan**
September 13, 2013

Bob Jones, in my judgment the comparison between string theory and epicycles is apt. Our disagreement about this is not due, it seems to me, to my "ignorance"; rather, I think that you are committing logical errors. That said, if it were due to my ignorance, I would likely not be aware of this fact; we all posses a degree of epistemic self-blindness. In the end, one of our positions will be vindicated, and one will not.

As an example of your logical error, we can accept both your criticisms and yet still maintain the insight that string theory is like epicycles in the relevant way. That is, the objection is not that string theory hasn't been useful, or that it isn't "here to stay", as you put it, but that it appears to be the wrong *type* of theory. The argument runs as follows:

1) There have been numerous points p1 . . . pn in history (not including the current crisis) in which physics has found itself stymied, apparently unable to make progress.
2) For each of these p1 . . . pn there eventually was found a solution, s1 . . . sn, respectively.
3) Each of the s1 . . . sn share common traits T1 . . . Tm. Among these is that the key insight, what really made the solution possible, was a deeply conceptual, "philosophical" insight. None of the T1 . . . Tm is that the key insight, what really made the solution possible, was an increase in mathematical complexity and technical cleverness. (If there was an increase in mathematical complexity and cleverness, it did not enable the discovery but rather was a side-effect of it.)
4) String theory contains no deeply conceptual, "philosophical" insights. It does contain many increases in mathematical complexity and cleverness.
— —-
5) String theory is unlikely to be correct.

That's the argument, anyway. An intellectual historian could weigh in on the truth of the premises.

Another logical error that you commit, which string theorists commit frequently, is that you seem to think that all of us who disagree with you are stupider than you. That's both a error in reasoning and factually false. You may well be smarter than me, but how smart can all these string theorists be if they keep committing simple, symbolic logic 101 errors in their reasoning?

41. **Peter Woit**
September 13, 2013

LogicFan/Bob Jones,
Sorry this exchange has reached the point of zero worthwhile content, I'll delete any attempts to pursue it further.

42. **Rauha**
September 13, 2013

Epicycles shouldn't be compared to string theory. Its degrading.

The ptolemiac model was one the the most succesful scierntific theories ever. It made predictions, there were observations and it even had practical uses.

43. **Peter Woit**
September 13, 2013

AJ,
Actually, I'm regularly resisting writing about string theory related nonsense in pop sci articles. Just today there was
http://www.newscientist.com/article/mg21929342.800-supergoop-universe-offers-a-window-into-glassy-physics.html
which tells us that
"Welcome to the supergoop universe. This hypothetical reality derives from string theory, which allows for a large number of possible universes, each with different physical laws."
which I have no intention of discussing.

The reason that the media is full of multiverse nonsense is not because of my blog, but because very prominent people in the physics community are aggressively pushing it. As long as this is going on, I think there needs to be someone pushing back and making clear the problems with this point of view. I don't see anyone else doing this. By the way, are you calling Sean Carroll, Nima Arkani-Hamed, Savas Dimopoulos, Lenny Susskind, Andrei Linde, Steven Hawking and Frank Wilczek trolls?

I think we agree that some string-theory motivated research is good mathematical physics. The problem is that as long as people refuse to admit that parts of the string theory research program are a failure, there's an associated failure to be able to distinguish between unpromising things whose motivation is a failed idea and more promising ideas.

44. **A.J.**
September 13, 2013

* By the way, are you calling Sean Carroll, Nima Arkani-Hamed, Savas Dimopoulos, Lenny Susskind, Andrei Linde, Steven Hawking and Frank Wilczek trolls?*

If the shoe fits.. (Also, less than half of those people are string theorists. Perhaps it's cosmologists you have a problem with? Or Palo Alto residents?)

As for the goop, that's a classic example of gee-whiz pop-sci writing doing a discredit to an interesting scientific analysis. Interested parties should read the paper instead. No mention of the term 'universe', and the authors make it quite clear that they think the main use of these models is that they exhibit features analogous to those seen in real world condensed matter systems. Not much different from thinking about the Ising model as toy model for salad dressing.

45. **vmarko**
September 13, 2013

There seem to be many different interpretations of what Turok actually said. But after I watched the actual video, it seems to me that he was asking for one thing every physicist would just love to have, but none do so far — a working theory with a smaller number of free parameters.

The Standard Model has 18-20 or so parameters (depending on how one counts), and creating a BSM theory which has a 120 or 10^500 free parameters is obviously not a step forward. What Turok was asking for is that we need to formulate a BSM model which *reduces* the number of free parameters in the SM. This can be done only by figuring out and formulating some deep principle that nature obeys, which would be powerful enough to establish relationships between existing parameters, thereby explaining some of them in terms of the others.

The only example of a model that even remotely comes close to this goal is the noncommutative SM developed by Alain Connes and his collaborators, which AFAIK features one extra equation relating the particle masses in the SM (IIRC, it has one free mass parameter less than the SM itself).

Also, we should all keep in mind that Turok was addressing very young freshmen students, so his words should be understood within that context. He was giving a lecture to students about what is important in hep-th research, and what it means to make a prediction — to cover as much as possible of the experimental data, with more concepts and less free parameters to be adjusted.

One of the most vital things that a hep-th researcher should know is to distinguish the physical concepts that nature satisfies from the mathematical formalism used to express those concepts. Students should be aware that we need new principles, rather than more complicated formalisms. The state of the art today is that formalisms are abound in hep-th, while concepts are very few and hard to come by. Turok is very right to call this a crisis.

And it's not just about the lack of new experimental data, it's also about lack of understanding of the already existing data. String theory has 10^500 parameters to fit the data, SUSY models have 120 or more parameters to fit the data, the SM apparently fits all data with just 18-20 parameters. The real challenge is to make a theory that will fit all data with *less* than 18 free parameters. Only *that* would constitute a real progress in understanding nature. Everything else is just formalism, bells and whistles, cosmetics, and free-parameter-fitting.

HTH, 🙂
Marko

46. **fuzzy**
September 14, 2013

hi marko, i do not insist on the counting, but only on the issue that we should respect the valid principles, and "gauge principle" is what i had and i have in mind, with my pedantic counting. i note that grand unified models are gauge theories, i.e., theoretical constructs based on valid ideas. their exploration cannot be said to be complete. the reason why they have been largely ignored in the last 10 years or so is the so called "naturalness principle", that i do not think deserve as much respect as "gauge principle" (i know that other people disagree with me here). from the counting of turok, the grand unified theories do not deserve credit because they have "100 parameters". i think this is a superficial statement, just as the counting of the sm parameters, without considering what the sm is: a well defined gauge theory. i think this kind of opinions can mislead freshmen students. with friendship 🙂

47. **Urs Schreiber**
September 15, 2013

A.J. is right.

48. **Shantanu**
September 16, 2013

OT: Peter : any comments from any of the talks from the firewall conference
at KITP? I watched Bill Unruh and Bob Wald's talks where they were critical of ADS/CFT
and they were met with some hostility from string theorists

Trust the math?

September 11, 2013
Categories: Uncategorized

The last few days have seen some new revelations about the NSA's role in compromising NIST standard elliptic curve cryptography algorithms. Evidently this is an old story, going back to 2007, for details see Did NSA Put a Secret Backdoor in New Encryption Standard? from that period. One of the pieces of news from Snowden is that the answer to that question is yes (see here):

> Classified N.S.A. memos appear to confirm that the fatal weakness, discovered by two Microsoft cryptographers in 2007, was engineered by the agency. The N.S.A. wrote the standard and aggressively pushed it on the international group, privately calling the effort "a challenge in finesse."

The NIST has now, six years later, put out a Bulletin telling people not to use the compromised standard (known as Dual_EC_DRBG), and reopening for public comment draft publications that had already been reviewed last year. Speculation is that there are other ways in which NIST standard elliptic curve cryptography has been compromised by the NSA (see here for some details of the potential problems).

The NSA for years has been pushing this kind of cryptography (see here), and it seems unlikely that either they or the NIST will make public the details of which elliptic curve algorithms have been compromised and how (presumably the NIST people don't know the details but do know who at the NSA does). How the security community and US technology companies deal with this mess will be interesting to follow, good sources of information are blogs by Bruce Schneier and Matthew Green (the latter recently experienced a short-lived fit of idiocy by Johns Hopkins administrators).

The mathematics being used here involves some very non-trivial number theory, and it's an interesting question to ask how much more the NSA knows about this than the rest of the math community. Scott Aaronson has an excellent posting here about the theoretical computation complexity aspects, which he initially ended with advice from Bruce Schneier: "Trust the math." He later updated the posting saying that after hearing from experts he had changed his mind a bit, and now realized there were more subtle ways in which the NSA could have made number-theoretic advances that could give them unexpected capabilities (beyond the back-doors inserted via the NIST).

Evidently the NSA spends about $440 million/year on cryptography research, about twice the total amount spent by the NSF on all forms of mathematics research. How much they're getting for their money, and how deeply involved the mathematics research community is are interesting questions. Charles Seife, who worked for the NSA when he was a math major at Princeton, has a recent piece in Slate that asks: Mathematicians, why are you not speaking out?. It asks questions that deserve a lot more attention from the math community than they have gotten so far.

Knowledgeable comments about this are welcome, others and political rants are encouraged to find somewhere else. There's a good piece on this at Slashdot…

   September 11, 2013

   Interesting to note how little things have changed from the time of the Church Committee. From page 2:

   "At the same time, we must insist that these agencies operate strictly within the law. They were established to spy on foreign governments and to fend off foreign spies. We must know to what degree they have turned their techniques inward to spy on the American people instead. If such unlawful and improper conduct is not exposed and stopped, it could, in time, undermine the very foundations of freedom in our own land.

   So the committee intends to hold public hearings, not only on the domestic abuses of the CIA, and the FBI, but on the improper activities of such other Government agencies as the Internal Revenue Service, the Post Office, and the National Security Agency."

   September 12, 2013

   I think Benjamin Franklin said it most clearly:
   "They who can give up essential liberty to obtain a little temporary safety, deserve neither liberty nor safety. "

   I believe we are well into the 'deserve neither liberty nor safety' side of things now. I don't feel very safe, or liberated in light of the revelation of our government's new homeland pastime. The Yahoo CEO is now saying they were basically threatened into submission. The silence on this issue is deafening because 'speaking out' as you put it is now a crime.

3. **Joseph Zizys**
   September 12, 2013

   Just a run of the mill ignoramus here, but I would be very surprised if any significant advances in number theory pertaining to crypto have been made secretly by the NSA. It is just hard to imagine, regardless of how much money they spent, that anyone could really develop in a vacuum like that. How many genuinely promising young mathematicians have "disappeared" to work exclusively for the NSA? And I don't just mean "this kid might make a good grad student for that idea I had last year" promising, I mean Hardy promising if not Ramajunan promising. How many Terry Tao's are whisked away each year by the NSA to push the field forward in secret? It seems far more likely that good old fashioned spycraft, politics and manipulation of standards bodies will be the way to compromise standards and institutions now and in the future, rather than fundamental mathematical research somehow pursued in secret rooms by nebulous "geniuses" who where somehow missed by the universities of the world for long enough to be hoovered up by the NSA.

4. **Bobito**
   September 12, 2013

   Mathematicians who work for the NSA have blood on their hands just like those who used to work to build bombs. Let's stop giving these funding hungry leeches respect and promotions. They are working to destroy what remains of democratic society.

5. **Joel Rice**
   September 12, 2013

crypting is peanuts compared to mapping out the social networks. And if the devices attached to providers are just splitting off the fiber, then they get all the raw stuff anyway. And now it is reported that Israel is getting raw feed – we don't even know who gets to play with all this stuff.

6. **Jeff M**
   September 12, 2013

   I think it's important to remember that what is being talked about here is not the NSA making some sort of mathematical leap which allows them to break encryption, but rather the NSA inserting weaknesses into the encryption scheme from the start. Certainly that would involve doing some tough math, but it's a different sort of thing then breaking an existing encryption scheme. I doubt very seriously that the NSA has figured out how to factor large numbers in polynomial time. Anyone remember the movie "Sneakers?"

7. **Jeff M**
   September 12, 2013

   Joel,

   The raw feed does you no good if it's properly encrypted, that's the whole point of https: You can protect yourself, use PGP for email, Tor to browse, etc. Any traffic you have with the web using https is safe (unless the NSA HAS figured out how to factor very large numbers in polynomial time :-), though of course anything password protected (like say your FB page) is hackable unless you're very careful about passwords.

8. **wolfgang**
   September 12, 2013

   @Jeff M

   nothing on your list is safe from the NSA.

   PGP: It seems the NSA can break key up to length 2048 and most passwords are not very safe to begin with.

   Tor: The NSA can do end-point correlation analysis and recently an FBI attack compromised a large number of exit nodes.

   https/SSL was explicitly mentioned as one of the protocols undermined by NSA.

   As for your FB password: The NSA does not even need it because the large US web companies cooperate with them anyways.

9. **Peter Woit**
   September 12, 2013

   Joseph/Jeff M,
   I think if you look into this carefully (and this is what Scott Aaronson started learning after his initial posting), you'll find that the situation is much more complicated than you think. The problem is not as simple as "have NSA mathematicians made revolutionary advances such as polynomial time factoring?". The implementation of standard encryption algorithms is quite a complicated story, and the possibility of NSA mathematical advances that exploit weaknesses in the implementations (either unintentionally there or introduced by the NSA through their abuse of the NIST processes) is very real.

   For any particular encryption algorithm, the story of possible attacks on it can be quite complicated. One should also keep in mind that when you see "https", telling you that some sort of encryption is going on, that doesn't tell you which algorithm is being used. From experience, I can assure you that the question of configuring which SSL encryption algorithms are supported and used on a webserver is not a trivial one.

10. **Jeff McGowan**
    September 12, 2013

    Peter et al

    I'm sorry, I really doubt the NSA can break RSA if it's properly done. There are hacks which attempt to get around the polynomial time problem, and as Peter points out https can mean different things, some of which are better than others. Passwords are very hackable, unless you're very good about it, and as Wolfgang says Tor is only so good, it just means they have to spend a lot more time to get in, and odds are they can't get nearly as much. That said, anything you do like that means the NSA has to devote much more time to you. Wolfgang, what's your reference for the NSA being able to hack 2048 bits? That would seem to me to be too much…

11. **wolfgang**
    September 12, 2013

    @Jeff McGowan

    Bruce Schneier, who has seen the Snowden documents, wrote on his blog:
    "We're already trying to phase out 1024-bit RSA keys in favor of 2048-bit keys. Perhaps we need to jump even further ahead and consider 3072-bit keys."
    He later published a new public key of length 4096.

    Btw Symantec now owns PGP and is a company known to cooperate with the NSA.
    If you use PGP you should use a program compiled from the original source with a compiler you fully trust.

12. **Jeff McGowan**
    September 12, 2013

    Wolfgang, thanks, I'm going to have to look into this. And you're right about PGP and sources,on the Mac at least you can just compile the GNU version yourself…

13. **John Urbanik**
    September 12, 2013

    Spending money and employing mathmaticians is a good thing. Like all military and secret technology if they have come across some radical new math it will eventually become known to all and then all of us can benefit.

14. **Cplus**
    September 12, 2013

Phil Zimmerman, who originated PGP cryptography, left the company when Symantec took over in 2010. Last year he founded a start-up to provide secure communication.
It is worth recalling that last month, he terminated the email component of his service because even he could not assure privacy in the existing legal and technological system.
It will take years at best before a legal and technological framework can be created in which realistic privacy will be possible, which is most likely to emerge from the open source world.
Zimmerman's analog of Moore's law: the ability of computers to track us doubles every eighteen months.

15. **gs**
September 12, 2013

Evidently the NSA spends about $440 million/year on cryptography research, about twice the total amount spent by the NSF on all forms of mathematics research.

When I got pulled into the military during the Vietnam War, I didn't end up carrying a rifle through a rice paddy. Neither did a fellow soldier who had gotten drafted out of a highly ranked graduate program in mathematics.

According to the Mathematics Genealogy Project, he has written his thesis. I see nothing else definitive about him online.

No conclusion can be drawn from this single instance, but I wonder how many other mathematicians have, in a sense, gone missing.

16. **David Derbes**
September 12, 2013

Maybe some mathematicians were not visible long enough to go missing. If you've seen the film *Zero Dark Thirty* the fictional character Maya (a composite) is described as having been *recruited out of high school*. Whether this is believable or not I do not know; if so, the question arises: How could the talent spotters have found her? There are all manner of Math Camps and competitions (at least one of which if I recall correctly is openly sponsored by NSA) that might in principle identify very talented young people, and perhaps even provide tuition and mentoring in math, in exchange for national service for a period of 3 or 5 years. NSA made a half-hearted pass at me in college; I was doing physics, Russian, Greek and math. The chair of the Slavic Languages department told me (1973) about an exam I might want to take one Saturday, offered by NSA. I declined.

17. **Philip Gibbs**
September 12, 2013

GCHQ like to use code cracking competitions to attract "curious, tenacious and creative candidates who have the intellectual ability, though not necessarily the practical experience or qualifications" They launched a new one yesterday see http://www.gchq.gov.uk/Press/Pages/solve-cyber-secret.aspx

This tactic may net some talented young mathematicians before they publish or start a doctorate.

18. **milkshaken**
September 12, 2013

SSL gets cracked by NSA through man-in-the middle type of attacks, by employing fake certificates – no nimble math magic there.

19. **Haim**
September 13, 2013

The NSA employs more mathematicians (between 10 and 20 000) than the rest of the world combined. It is also well known that the NSA knows more about number theory than the rest of the world combined.

The back doors in its algorithms are known in expert circles since more than a decade. They are used by European cryptography producers as sales argument to convince customers not to buy American cryptography products. And indeed, no European country does so, for any sensitive equipment (communications to embassies, military encryption). What the NSA does in return is also known since decades (hiring spies as technicians in these companies, etc).

The naiveté of the doubters here is appalling.

20. **Jim Akerlund**
September 13, 2013

Peter,

In the interests of full disclosure, what has your brush been with the NSA, if one exists? I know sometimes you bring up math related subjects for the social relevance. Is that the reasaon your writing about this?

21. **Geoff**
September 13, 2013

Apparently, getting recruited out of high school isn't entirely unheard of.

http://www.forbes.com/sites/stevenbertoni/2011/09/21/sean-parker-agent-of-disruption/4/

22. **Peter Woit**
September 13, 2013

Jim,
I've never had any contact with the NSA that I know of (although, from what one reads, presumably like everybody else I've had a large amount of contact with them that I don't know about…). This posting was just meant to inform others about something that seems to me an issue that should be of general interest in the math and physics community.

I saw some place quote me as an "expert" on this, and I'd like to make clear that that is not at all the case. I know a little bit about the mathematics involved and about computer networks, but have no expertise on either topic.

23. **Geoff**
September 23, 2013

"Meanwhile, over in Building 5300, the NSA succeeded in building an even faster supercomputer. "They made a big breakthrough," says another former senior intelligence official, who helped oversee the program. The NSA's machine was likely similar to the unclassified Jaguar, but it was much faster out of the gate, modified specifically for cryptanalysis and targeted against one or more specific algorithms, like the AES. In other words, they were moving from the research and development phase to actually attacking extremely difficult encryption systems. The code-breaking effort was up and running.

The breakthrough was enormous, says the former official, and soon afterward the agency pulled the shade down tight on the project, even within the intelligence community and Congress. "Only the chairman and vice chairman and the two staff directors of each intelligence committee were told about it," he says. The reason? "They were thinking that this computing breakthrough was going to give them the ability to crack current public encryption."

24. **Chris W.**
September 25, 2013

See this September 23 interview with Bruce Schneier in *Technology Review*:

> **Schneier**: We're not there yet, but already we've learned that both the DEA and the IRS use NSA surveillance data in prosecutions and then lie about it in court. Power without accountability or oversight is dangerous to society at a very fundamental level.

Susskind: String theory not a complete picture of how quantum gravity works

September 16, 2013
Categories: Uncategorized

For the latest on quantum gravity, readers might want to look at talks from some events of the last couple weeks. At the new ICTP-SAIFR theoretical physics institute in Sao Paulo, a school on quantum gravity has talks available here, with a follow-up workshop here. At Stanford last week the topic was Frontiers of Quantum Gravity and Cosmology, in honor of Renata Kallosh and Stephen Shenker.

Matt Strassler was at the Stanford conference, and he blogs about it here, describing most of the speakers as "string theorists" who are no longer working on string theory, and most of the quantum gravity talks as not being about string theory (this is also true of the ICTP-SAIFR workshop). I don't really understand his comment

> Why has the controversy gone on so long? It is because **the mathematics required to study these problems is simply too hard** — no one has figured out how to simplify it enough to understand precisely what happens when black holes form, radiate particles, and evaporate.

since the problem isn't "too hard" mathematics, but the lack of a consistent theory (which he makes clear later in the posting).

Most remarkably, he described the talk by Lenny Susskind, one of the leading promoters of string theory, as follows:

> Susskind stated clearly his view that string theory, as currently understood, does not appear to provide a complete picture of how quantum gravity works. Well, various people have been saying this about string theory for a long time (including 't Hooft, and including string theory/gravity experts like Steve Giddings, not to mention various experts on quantum gravity who viscerally hate string theory). I'm not enough of an expert on quantum gravity that you should weight my opinion highly, but progress has been so slow that I've been worried about this since around 2003 or so. It's remarkable to hear Susskind, who helped invent string theory over 40 years ago, say this so forcefully. What it tells you is that the firewall puzzle was the loose end that, when you pulled on it, took down an entire intellectual program, a hope that the puzzles of black holes would soon be resolved. We need new insights — perhaps into quantum gravity in general, or perhaps into string theory in particular — without which these hard problems won't get solved.

For many years now, the most influential figures in string theory have given up on the idea of using it to say anything about particle physics, and results from the LHC have put nails in that coffin, removing the small remaining hope that SUSY or extra dimensions would be seen at the TeV scale. The "firewall" paradox seems to have made it clear that string theory-inspired AdS/CFT doesn't resolve the problem of non-perturbative quantum gravity, leading to renewed interest in other approaches. This leaves string theory now as just a "tool" to be used to study topics like heavy-ion physics. Things don't seem to be working out very well there either.

Comments

1. **P**
   September 16, 2013

   Per usual, overly negative and pessimistic.

   Matt's treatment is quite fair, though, also per usual. I'd recommend readers of your blog to look at his for a more balanced approach.

2. **lun**
   September 16, 2013

   As an orthogonal issue, but one related to something you discuss on this blog often, by the calibre of speakers and topics discussed, and the _level_ of the discussion, this conference could have been at the IAS, yet it is nearly entirely organized and financed by a "BRIC" country.
   Employment in an institute as prestigious as the ICTP (or, say, the Tata institute in India) is likewise becoming equivalent to employment in a large research level university in the US and Europe.
   Could this be the answer to the abysmal situation in the "first world" job market in theoretical physics? Moving to a country such as India or Brazil could become a realistic alternative to leaving physics for young people interested in basic science.
   Since employment in these institutions follows somewhat different administrative rules w.r.t. the US system, this could also lead to a research program that is less dependent on senior-initiated fads a la landscapes and firewalls.
   Could BRIC countries rescue theoretical physics?

3. **Bernhard**
   September 17, 2013

   lun,

   the "somewhat different administrative rules w.r.t. the US system" these institutions follow is a complete nightmare. If you want a job in a public institution in Brazil you have to have abundant time to waste to follow the endless and also saturated process of the so-called "concursos". Ah, and be prepared to speak fluent Portuguese by the time you apply, you won´t go far there with just English. I think we are slightly off-topic so let me stop here.

4. **Pete**
   September 17, 2013

   Background: the concurso is a long (all day, occasionally two) exam, usually written in Portuguese and then read out by the candidate to the committee, set by the university to which you apply on (usually fairly general) topics of their choice. If you apply lots of places, this takes a lot of time…

   The institutes (as opposed to the public universities) often don't do the concurso, rather their hiring tends to be very much US-style. You'll be expected to teach in Portuguese at some point, but you probably have at least a year to learn, and it's not hard (especially if you know Spanish, of which it's pretty much a dialect).

   Also the public universities (especially the better ones) are starting to let people do the concurso in English. You'll still need to be competent to pass, and you'll need to commit to learning Portuguese fairly soon. But the system isn't especially overloaded. If you know stuff outside your specialisation reasonably well, you can pass the concurso. If you only know stuff outside your specialisation at second-year undergraduate level though, either you have to cram once the topics are released or you will not pass.

   On the other hand, at a university the teaching load isn't especially nice, unless you like teaching evening classes for the part-time students (of course, if you really get into the culture then the class ends about the time you want to go out, get a meal and go on the town; and you won't be teaching before lunch the next day). And you probably don't want to have children there otherwise life gets too complicated.

5. **Bernhard**
September 17, 2013

Pete,

"But the system isn't especially overloaded."

It is not specially overloaded if you compare with the normal situation in HEP. And specially if you want to be in a center – the research situation outside the centers is not as nearly as decent. And about the "concurso", the form varies from university to university with places like CPBF having much more specific exams. There, by the way, it is a terrific place to work, with zero teaching obligations. But a piece of this cake is in my opinion as hard (or as easy) as getting a position in Europe. The rest is "easier", but not as nearly as interesting.

All in all, if you look at Brazilian faculties, there are usually 99% Brazilians working there. The situation might change a bit, but I doubt it in any drastic way in the near future.

Peter, sorry for highjacking the discussion – my last comment about this…

6. **Hernán Meier**
September 17, 2013

Folks,

Well this is my first post, but if you are considering to do a Ph.D in an underdeveloped country at the same level of top institutions in developed countries you can consider the Balseiro Insititut in Argentina (www.ib.edu.ar) it´s considered the best Physic and Nuclear related institute in Argentina and maybe the entire Latinoamerica.
Moreover, with the plus to be located in Bariloche city (Tahoe is awful compared to that place)
The main problem is the mathematical level they ask you to have the entry.
Hernán

7. **Arjun**
September 17, 2013

"Since employment in these institutions follows somewhat different administrative rules w.r.t. the US system, this could also lead to a research program that is less dependent on senior-initiated fads a la landscapes and firewalls.
Could BRIC countries rescue theoretical physics?"

I am from India and got my PhD at an US institution in theoretical physics. I can say with confidence that this would be a very bad career move—to try to move to India—even if you get a faculty position at TIFR or IISC or HRI. For one, you will be paid much much lower than what your colleagues pursuing private sector jobs will be earning in India, in Indian rupees. And unlike in the US where even as a physics graduate student you have access to pretty good standards of living, you will find yourself struggling to provide yourself and your family with basic luxuries. While you will be allocated a govt. built apartment within the campus itself, it will be of very dismal quality.

Not to mention the hierarchy nightmare over there in India. Indian culture is traditionally hierarchical. This coupled with the colonial history has resulted in a deeply hierarchical society. So your seniors will drive your research agenda. Moreover to get a faculty position over there you have to be "known" by these seniors and also be "liked" by them.

A few colleagues made such moves tempted by the recent "boom" in Indian economy and the promises of the govt. to put more money into research. One colleague told me to never, never come back to India; another said that he's decided to settle for it even though he knows he'll not do world-class research.

And given the fact that the economy is now tanking (much talked about in both Indian and international media these days), it remains to be seen if the funding promises will be fulfilled or not. Given my experience with India, most probably not!

8. **Peter Woit**
September 17, 2013

Well, at least string theory has given us this:

http://www.youtube.com/watch?v=2rjbtsX7twc

9. **Marcus**
September 18, 2013

Tim Blair! McGill, MS advisor was string theorist Alex Maloney. Totally awesome you must watch this, only 8 minutes. Thanks, P.W.

10. **Marcus**
September 18, 2013

correction: Tim Blais (aka "acapella science")

11. **abg**
September 18, 2013

[off-topic] The best Brazilian universities (USP and Unicamp) can still hire without "concurso" and knowledge of Portuguese (which is not a Spanish dialect!), but only English. However it is rare.

Also, there exists some kind of "intellectual communism" in Brazil, such that all professors are treated equally, in every aspect, independent of the quality of the work which they do. Once someone is approved in a "concurso", he or she can do absolutely nothing and still maintain his or her position. It is very difficult to fire a public worker in Brazil. And the result is a bunch of incompetent people occupying jobs positions, while the stimulated and talented scientist must stop his research to study for a "concurso".

12. **NumCracker**
September 20, 2013

@abg

Actually, it is a “pseudo intellectual communism” once you forget about the probatory time before getting tenured. On the other hand, research grants are attributed on the basis of productivity as anywhere in the developed world. Also, I recommend people interested in moving to South to write to Nathan Bercovits @IFT … he is an american, with high qualification standards in ST, which decided to do such a wise move some of guys here are describing. Nathan seems happy at IFT/ICTP and is still very productive here in Brazil. Would I start a PhD/Posdoc in HEP in South Hemisfere it would be there.
Regards

Num

13. **abg**
September 21, 2013

[Off-topic] I do not think that the probative stage helps very much. Indeed, once someone is approved in it he or she can do practically *no research* at all and have a guaranteed position (recall that the duration of a probative stage is around 2 years, and most academicians will work for 2 or 3 decades!). Even worse, a docent can be continuously promoted in Brazilian public universities but can never recede.

And about the research grants, it is true that it is based in productivity, but it is not necessarily a good thing since it is extremely normative! For example, the article in which Cesar Lattes changed completely the field of particle physics (he was one of the discovers of the meson pi) would have the same value as any article published in any magazine independent of the quality of the work; and it would have 1/2 of the value a published textbook, again independently of the its quality.

It would be better if the universities here could negotiate the grants and even in the academic position freely, that is, without any rigid governmental bureaucrat legislation, like many universities around the developed world (this is the case of USP and Unicamp, but is is an exception).

Let me finish by saying that, *however*, there exists brilliant scientists working at now in Brazil, and they are very product in a broader sense. See, for instance,

http://arxiv.org/find/math-ph/1/au:+Rodrigues_W/0/1/0/all/0/1

14. **abg**
September 21, 2013

Another remark: Nathan Jacob Berkovits works at UNESP, which is a state university of São Paulo, like USP and UNICAMP. I would say that these 3 SP’s State Universities are more or less an exception to my comments above.

15. **NumCracker**
September 21, 2013

@abg

While our exchange is completey off-topic it may be helpfull for some enthusiasts wanting to definetely move, or just doing a pos-doc, bellow the equator 😉 So I intend to finish my collaboration by just saying that other interesting (exceptional) federal institutions are: UFRGS, ITA, UFABC, UFRJ, UFMG, UNB, UFPE, CBPF. In addition, researchers have decent computational infrastructure provided by SINAPAD/MCT and free-access to a huge national base of scientific periodics (by CAPES.)
The really accurate numbers are 4 years before getting tenured, 35 years of service before retiring. The average salary is about US$ 50k up to 100k depending on the hierarchy. Even after tenured, one just progress on such carrer by commitment and effective productiveness during decades. One would expect to spend at least 8h/w by lecturing, but more realistically one would consider about 12h/w. It is not a quite dynamic scientific environment as (*part of*) Europe or USA, but with that salary (and a properly chosen place to live) life is surely nicer.
Best,

Num

16. **abg**
September 22, 2013

I agree with the information in the latter post, which are indeed accurate. Except a detail: it is in fact possible to be promoted in a public university in Brazil without (a high) productivity, but just with sufficient “time of service”, that is, being associated in the university for a time long enough.

Finally, if some academician is interested in coming to Brazil to work in any (public) university, I recommend the reading of the following blog, maintained by a Brazilian logician, who wrote (and still write) a lot of things about the life in science here: http://adonaisantanna.blogspot.com.br.

Physicists Discover Geometry Underlying Particle Physics

September 18, 2013
Categories: Uncategorized

Today's Slashdot tells us that Physicists Discover Geometry Underlying Particle Physics, a story that is based on an excellent article, A Jewel at the Heart of Quantum Physics, by Natalie Wolchover at the new *Quanta Magazine* sponsored by the Simons Foundation.

As you might suspect, the Slashdot headline is simply nonsense. What's really going on here is some new progress on computing scattering amplitudes in a very special conformally-invariant QFT, one not known to "underly particle physics". This is a long story, one going back to Roger Penrose's work on twistors from the late 1960s. In recent years this has been a very active and successful field of mathematical physics research, with a large group last year putting out Scattering Amplitudes and the Positive Grassmanian, which showed how to express some amplitudes to all loops in terms of volumes of geometric objects defined as subspaces of a Grassmanian. Mathematicians who want to see some speculation about the relation of this to other areas of mathematics should take a look at section 15 of that paper.

The more recent news is that Nima Arkani-Hamed and his ex-student Jaroslav Trnka now have an improvement on that calculational method, which uses the volume of a particular such geometric object they call the "Amplituhedron". There's no paper yet, but you can watch recent Arkani-Hamed talks about this here or here (the last from yesterday). How this ended up with the ridiculous Slashdot headline is pretty clear, as Arkani-Hamed with his trademark enthusiasm promotes this work as a road to revolutionizing physics, getting rid of locality and unitarity as fundamental principles, finding emergent space-time, maybe emergent quantum mechanics, etc (while admitting that what has been accomplished is just step 0 of step 1 of a multi-step program). From this, one gets to the rather excessive Quanta headline about a "jewel at the heart of quantum mechanics", ensuring that the next stage of publicity (e.g. Slashdot) will launch the hype level into outer space, escaping any relationship to reality.

For the details of what this really is, the Quanta article gives a good overview, but you need to consult the long paper and recent talks to dig out a non-hyped version of what the real recent advances are. I'm nowhere near expert enough to provide this, hope that if this turns out to be as important as claimed, surely there will soon be lots of expositions of the story from various points of view. In the meantime, best perhaps to pay attention to what Witten has to say on the topic:

> The field is still developing very fast, and it is difficult to guess what will happen or what the lessons will turn out to be.

Update: Here are some slides about the Amplituhedron from Trnka (hat-tip to George Ellis).

Update: Scott Aaronson has come up with an even more dramatic advance, the discovery of the Unitarihedron, which includes the Ampltituhedron as a special case, just "a single sparkle on an infinitely greater jewel". See his posting The Unitarihedron: The Jewel at the Heart of Quantum Computing, where he unveils this new theory.

Update: See comments here by Lance Dixon and this paper for an alternative approach to computing planar amplitudes in this theory, one not using the "amplituhedron".

Update: Congratulations to Kosower, Dixon and Bern for the award of the Sakurai prize for their work on amplitudes.

Update: Dixon has a guest post about this topic at Sean Carroll's blog.

Comments

   September 18, 2013

   I found this article on Reddit! So I came over to see if you had smacked it around like it was a puppy slobbering all over your shoes…

   Thx! My takeaway is its interesting, possibly important, but still just another angle to await further actual results..

2. **george ellis**
   September 18, 2013

   Here's a set of slides about it:

   http://www.staff.science.uu.nl/~tonge105/igst13/Trnka.pdf

3. **Lamont Granquist**
   September 18, 2013

   Can anyone give a brief explanation of "maximally supersymmetric Yang-Mills theory" at an undergrad level?

   It sounds sorta like the spherical chicken/cow of higher dimensional quantum field theories. I got a bit excited by the Quanta Magazine article until I hit that sentence and realized it was probably still all wrapped up with supersymmetry and string theory at its core…

4. **Peter Woit**
   September 18, 2013

   Lamont,

   What's being referred to is the "CFT" in the AdS/CFT correspondance, the QFT that is supposed to be dual to a certain string theory. It's a very interesting 4d QFT, conformally invariant and the subject of a huge amount of attention, but not directly related to the QFTs of the Standard Model.

5. **CIP**
   September 19, 2013

   I wonder if you aren't leaving out the most special thing about this result. In this special case, all those annoying extra guage degrees of freedom go away. They have been a nuisance to many smart people for a while.

6. **nasren**
   September 19, 2013

   What struck me about this article is that it seems to heavily involve twistors and yet Penrose gets no mention whatsoever. But Witten does, rather irrelevantly. One is left in no doubt which side of the Atlantic is having its curry favoured.

More destructive boosterism.

7. **Mitchell Porter**
September 19, 2013

This work descends from Witten's 2003 invention of twistor string theory.

8. **P**
September 19, 2013

Nasren,

You're wrong. Witten is very relevant to this story. Penrose is relevant, too, but not as relevant as Witten for this particular line of research on scattering amplitudes. Witten's paper

hep-th/0312171

is one of the most cited in this amplitude business, and he is the W in BCFW, which was a crucial paper.

You don't have to be so critical! And if you're going to be, at least get your facts straight first.

9. **nasren**
September 19, 2013

I stand corrected.

10. **twistor**
September 19, 2013

@ Lamont Granquist & others who might not know what "maximally supersymmetric Yang Mills" is:

Take a look at the rather nice explanations of Matt von Hippel:

http://arstechnica.com/science/2013/05/earning-a-phd-by-studying-a-theory-that-we-know-is-wrong/

or his rather excellent blog:

http://4gravitonsandagradstudent.wordpress.com/a-theorists-theory/

11. **chorasimilarity**
September 19, 2013

After browsing the interesting slides, I was struck by the repeated "not known to mathematicians". I am a mathematician and I don't have any precise idea about what exactly those amplitudes are. However, as far as I understand after a quick browsing of the slides, my understanding is the following: with a goal which I don't grasp, they attach some "forms with logarithmic singularities" to geometric data coming from affine parametrizations of points in convex polygons in projective spaces. (No wonder that some grasmannian type spaces appear and that some geometric constraints are expressed as the positivity and invariance of parametrizations.) Then they make sense of some, impenetrable to me, calculation by reformulating it in graph rewriting terms. Maybe is not at all related, but that's what I do as a mathematician (impenetrable physics goal aside). Affine parametrizations of such convex polygons are particular examples (yes,mathematician, sorry) of what I call emergent algebras, i.e. one-parameter deformations of idempotent right quasigroups (that's related to Yang-Baxter, of course), and their graph rewriting version is called graphic lambda calculus. A friend noticed some days ago that the identity (13.1), p. 94 [arxiv:1212.5605]() looks very much alike my graphic beta move [arxiv:1305.5786]() (or better [web tutorial]()), which is the graph rewriting version of the beta reduction in lambda calculus. So, maybe, with excuses for what could be a completely unrelated rant, but maybe some of it is not unknown to mathematicians.

12. **anewcommenter**
September 19, 2013

@chorasimilarity: I think the "not known to mathematicians" line is somewhat hyperbolic. Two of the co-authors, Goncharov and Postnikov, are mathematicians, so the lower bound for "number of mathematicians who know this" is 2, if not higher. Goncharov, in particular, has done quite a bit of work dealing with polylogarithms, algebraic cycles and Feynman diagrams.

13. **P**
September 19, 2013

@anewcommenter:

The claim in the talk that I saw was that the amplituhedron, not the positive Grassmannian, was new to mathematicians. The latter is definitely not new. Since the paper isn't out and we don't know the precise definition of the amplituhedron, it's hard to say for sure whether or not it is known to mathematicians; hearsay is the best we can do.

That being said, Nima's mathematician friends would likely know if such objects exist in the math literature. It's not unheard of that physicists stumble upon something that mathematician's haven't seen yet, e.g. mirror symmetry. Perhaps we have again stumbled upon something new . . .

14. **lun**
September 19, 2013

Considering that this is a theory in the planar limit, and the scattering amplitudes are all on-shell, what reason is there to assume that there is no qualitative transition between Trnka's step 1.1 and "grand vision"? (slide 2 of http://www.staff.science.uu.nl/~tonge105/igst13/Trnka.pdf)
could all this not be a mathematically elegant way to codify conformal invariance, unitarity, and energy-momentum conservation, rather than a "radical reformulation" of a generic QFT?

15. **Beelzebud**
September 19, 2013

So as a layman on the subject, let me see if I've distilled the media hype to what is really going on here.

They've found a replacement for Feynman Diagrams? Is that the meat and potatoes of this announcement?

16. **Peter Woit**
September 19, 2013

CIP,
I don't think gauge symmetry is just a nuisance, it's part of the deep structure of our best theory (and an integral part of the modern point of view on geometry). Yes, it creates all sorts of problems in a QFT, but you could also see these as opportunities. Anyway, I think I've gone on about this before, and should again sometime, but it's a complicated story for which simplistic sloganeering isn't very interesting.

lun,
Yes, that's a real question. What people have found here is the solution to a very special problem, and from this claiming evidence for a revolutionary reworking of the foundations of physics seems very premature. There's a huge amount to be done to understand the significance of why these specific amplitudes can be expressed in this form.

Beelzebud,
Yes, in a very specific, highly symmetric toy theory they have a way of getting scattering amplitudes without summing the usual Feynman diagrams. Quite interesting piece of mathematical physics, but I suggest taking Witten's advice:
"it is difficult to guess what will happen or what the lessons will turn out to be."

17. **Thomas**
September 20, 2013

Just a very naive question:
If one can do everything on-shell, no virtual particles any more, what is left of q.m., e.g. the uncertainty principle ?

18. **Peter Woit**
September 20, 2013

Thomas,
That's not so naive. Part of Arkani-Hamed's program refers to maybe even replacing QM, with QM "emergent". This kind of exact formula indicates that something may be going on here like a classical approximation being exact.

19. **Thomas**
September 21, 2013

Peter,
thanks for your answer.
Having seen the video, my hunch is that something really "deep" is going on here, but I guess one has to wait and see how things develop further.

20. **anewcommenter**
September 21, 2013

@P:

I was being a bit tongue-in-cheek in that comment. Of course the amplituhedron is a novel thing to have come out of the work, and I trust that the authors have verified that it is new, to the best of their abilities.

However, I also wanted to object to assertions like your analogy to mirror symmetry. This is quite unlike mirror symmetry – which, to my limited knowledge, appeared seemingly unbidden from physics – in that there are mathematical precursors to Arkani-Hamed et al. (as well as work done in parallel and independently, such as the work of @chorasimilarity) that are brought together in that work.

In particular, I mentioned Goncharov's work on Feynman diagrams and polylogarithms, because there have been glimpses of computational efficiency emerging from the work of people studying that locus of ideas, cf. Kreimer and others. This has been something that some mathematicians have found to be exciting for at least the past few years now.

21. **Peter Peterson**
September 21, 2013

Thank, you, very interesting subject that I was not aware of – Amplituhedron articles.

22. **Lance Dixon**
September 21, 2013

19 years ago, people stopped using Feynman diagrams to compute perturbative scattering amplitudes in N=4 SYM, and began using unitarity. That was also the beginning of the focus on the analytic properties of the loop integrand — the object which the amplituhedron is describing for N=4 SYM in the `planar' limit of a large number of colors. Ironically, this year the loop integrand has become obsolete for computing at least the simplest nontrivial amplitudes in this planar N=4 SYM theory. See arXiv:1308.2276, in which the 3-loop 6-point amplitude was computed, as a function of the external data only (all loop integrals having been performed). The loop integrand was bypassed entirely. Certain boundary information necessary for the construction was supplied from a source (the operator product expansion and integrability) that can be tapped to all orders in the coupling, so the method is very robust.

23. **Lun**
September 22, 2013

Lance thank you very much for the clarifications.
For non-experts can you also specify
a) to what extent can one be hopeful that
these results can be generalized beyond
CFT
b) I take it this goes beyond on-shell scattering amplitudes
Is that correct? How relevant are such
calculations to efforts to probe N=4 is integrable?

(Conversely if it is not integrable would
You expect such methods to fail?)
Thanks

24. **Lance Dixon**
September 22, 2013

Lun: a) unitarity for the loop integrand works in any theory, CFT or not. It's used in QCD calculations for the LHC, for example. The CFT in question (N=4 SYM) is very special, without a doubt, so you can go much further than in (say) QCD. The complete four-loop four-point integrand is known, for example, whereas 2 loops is the current limit for the QCD 4-point amplitude.

The limit of this CFT where the number of colors is large (planar N=4 SYM, corresponding to only drawing the planar Feynman diagrams) is even more special, however. Its amplitudes can be mapped to "polygonal Wilson loops" – which you can visualize as a polygonal rigid wire frame tiled with Feynman diagrams. Related to that, there is a symmetry that is like conformal symmetry, so that the answers only depend on a subset of the variables you thought they did. In fact the scattering of 2->2 gluons, or 2->3 gluons is totally fixed by this symmetry (up to constants). So the first nontrivial scattering is 2->4 (the 6-point amplitude). Also, integrability should only hold in the planar limit.

b) Everything I was talking about was with the aim of determining on-shell scattering amplitudes. However, they are closely related to the spectrum and other properties of the gauge-invariant composite operators of the CFT. The operator dimensions and operator product coefficients of the CFT appear as you take limits where the scattering amplitude degenerates or factorizes (where that wire frame assumes some singular limiting form where two or more edges become parallel). In fact, such limits simultaneously provide information to fix the answer for the generic, non-limiting case, and also test the source of that limiting information – which includes integrability and further assumptions. So yes, the fact that there is a consistent solution tests integrability. And if the approach failed at a given point, it could indicate a failure of integrability (or of some other assumption, so one would have to figure out which). So far, no failures though!

25. **4gravitons**
September 22, 2013

Just to clarify for Lun on point b), in case this was the source of the confusion: Nima's diagrams are "on-shell" in the sense that they represent things on the inside in terms of on-shell rather than the off-shell states that Feynman diagram methods use. That's just a feature of the particular way he sets things up, it doesn't have anything to do with whether the incoming and outgoing particles are on-shell or off-shell.

When people talk about amplitudes, they're generally talking about processes where the external particles are on-shell. There are other terms (correlation functions in particular) for the more general case.

26. **Peter Woit**
September 22, 2013

Thanks Lance,
I've added a note to the posting with a link to the paper that you mention. If there are other sources you'd recommend for people who want to learn more about this, let me know.

27. **johnnyythelowery**
September 23, 2013

http://www.youtube.com/watch?v=2rjbtsX7twc

The lyrics are going to have to changed….again!!!!

28. **Lance Dixon**
September 25, 2013

Thanks for adding that note, Peter. Our approach to planar N=4 SYM works hand in hand with the boundary data (from the OPE and integrability) provided by Benjamin Basso, Amit Sever and Pedro Vieira in their papers 1303.1396 and 1306.2058. In brief, they use the polygonal Wilson loop formulation of the problem. They solve the problem of exact, factorizable scattering for a system with one time dimension and one space dimension, which is roughly the direction along an edge of the polygon. Once they have that 2-d scattering matrix, they find a solution for a pentagonal Wilson polygon in terms of it. Then they build all other polygons (in a certain limit) out of their pentagons. The cool thing is that when they solve a certain part of the problem, they do so to all orders in perturbation theory in the 't Hooft coupling, thanks to the exact 2-d scattering matrix (which in turn is thanks to integrability).

29. **Anonyrat**
September 30, 2013

If we don't have to sum up Feynman diagrams but only have to compute volumes of the Amplituhedron, then the Feynman-diagram-inspired picture of the vacuum as a seething cauldron of virtual particles may be an artifact of the method of computation. Doesn't this cast a different light on the alleged non-naturalness of the value of the cosmological constant?

Love and Math

September 19, 2013
Categories: Book Reviews, Langlands

Edward Frenkel's new book Love and Math is now out. It's a must-read for those who share the interests of this blogger, so go get a copy now.

The "Love" of the title is much more about love of mathematics than love of another person, as Frenkel provides a detailed story of what it is like to fall in love with mathematics, then pursue this deeply, ending up doing mathematics at the highest level. Along the way, there are lots of different things going on in the book, all of them quite interesting.

A large part of the book is basically a memoir, recounting Frenkel's eventful career, which began in a small city in the former Soviet Union. He explains how he fell in love with mathematics, his struggles with the grotesque anti-Semitism of the Soviet system of that time (this chapter of the story was published earlier, available here), his experiences with Gelfand and others, and how he came to the US and ended up beginning a successful academic career in the West at Harvard. I remember fairly well the upheaval in the mathematics research community of that era, as the collapse of the Soviet system brought a flood of brilliant mathematicians from Russia to the West. It's fascinating to read Frenkel's account of what that all looked like from the other side.

Russia at the time had a vibrant mathematical culture, but one isolated from and quite different than that of the West. Many of its most talented members had rather marginal positions in official academia, and their community was driven much more by a passion for the subject than any sort of careerism. Frenkel comes out of this background with that passion intact, and it shines throughout his book. In some other ways though, he's more American and less Russian than just about anyone I know. Part of the Russian mathematical culture has sometimes included a certain cynicism and vision of great mathematics as an esoteric subject best closed to outsiders, with little interest in communication with the non-initiated. I confess to a personal sympathy with the cynicism part (as any reader of this blog has probably figured out) but no sympathy for obscurantism about mathematics research.

Frenkel's sunny optimism and cheerful enthusiasm for his subject and life in general is very American, and in his writing he often gets through to melt the cynical part of this reader. What's really wonderful though is his dedication to the cause of the opposite of obscurantism, that of doing the hard work of trying to explain mathematical insights to as wide an audience as possible. His book is packed with mathematics and physics, full of enlightening explanations of difficult topics at all different levels of mathematical sophistication.

Perhaps the most remarkable part of the book though is the way it makes a serious attempt to tackle the problem of explaining one of the deepest sets of ideas in mathematics, those which go under the name of the "Langlands program". These ideas have fascinated me for years, and much of what I have learned about them has come from reading some of Frenkel's great expository articles on the subject. To anyone who wants to learn more about this subject, the best advice for how to proceed is to read the overview in "Love and Math" (which you likely won't fully understand, but which will give you a general picture and glimpses of what is really going on), and then try reading some of his more technical surveys (e.g. here, here and here).

The Langlands story is a complex one, but it starts with a very deep and beautiful idea that brings together different parts of mathematics: one way to think about number theory is to think of rational numbers as rational functions on a space, the space of primes. One then ends up seeing all sorts of parallels between the study of Riemann surfaces and number theory. Frenkel explains this in detail, including André Weil's description of a "Rosetta stone", a translation between aspects of number theory, aspects of Riemann surface theory, and yet a third intermediate parallel theory, that of algebraic curves over a finite field.

He goes on to explain the subject of "geometric Langlands theory", the transposition of the Langlands program from the number theory to the Riemann surface case, creating a whole new area of mathematics, one with deep connections to quantum field theory. The book includes extensive discussion of discoveries by Witten and others linking duality in four-dimensional quantum field theory to the fundamental mysterious Langlands duality in the geometric Langlands case. Frenkel has been in the middle of these developments and is the ideal person to tell this story.

The connection between these ideas and two-dimensional quantum field theory seems to me to be a subject for which we have so far only seen the tip of an iceberg, with much more to come in the future. One part of this that I don't think Frenkel discusses is early work by Witten (before geometric Langlands was formulated) giving explicit analogies between 2d qft and reciprocity laws in number theory. For more about this, see Witten's 1988 Quantum field theory, Grassmanians and algebraic curves, or a more recent paper by Takhtajan. Working on writing up the material about the harmonic oscillator and representation theory from my last year's course has gotten me interested again in the number-theoretical version of that particular story. Unfortunately I don't know a really readable reference, hope some day to write something myself once I have a better understanding of the subject.

So, I heartily recommend this book to all with an interest in mathematics or its relation to physics. If the "Love" of the title has you hoping for a tale of romance between two people, you're going to be disappointed, but you will find something much more unusual, a memoir of the romance of mathematics and its relation to the physical world.

Comments

1. **Michał Kotowski**
   September 19, 2013

   His last name is Frenkel, not Frankel (you misspell it 3 times in the post).

2. **Peter Woit**
   September 19, 2013

   Thanks, fixed.

3. **Paulo Guerra**
   September 19, 2013

   …

   "Frenkel's sunny optimism and cheerful enthusiasm for his subject and life in general is very American…" (!!!)

   No comments.

4. **Peter Woit**
   September 19, 2013

   Paulo Guerra,

OK, I probably should have said “used to be very American”, things have changed somewhat in this country in recent decades…

5. **Michael Welford**
September 19, 2013

Amazon lets you peek at the end material for this book!!! It’s not so frighteningly advanced as you might suppose from Peters talk about ‘geometric Langlands’ and ‘Riemann curves’.

If you get straight A’s in calculus while barely opening your textbook, then this book looks like a good book to measure yourself against. See how many chapters you can get through before you finally bog down. Of course if you describe yourself as, for instance, a Frenkel-chapter-12 you’d better be prepared to back it up, because the math nerds will be gunning for you.

I’ll be waiting for a paperback edition.

6. **Anonymous**
September 19, 2013

Hard to digest… I thought that geometric Langlands is one of the most esoteric subjects closed to outsiders?

7. **Peter Woit**
September 20, 2013

Anonymous,
Yes, geometric Langlands is one of the more difficult areas of mathematics to understand, because it brings together some very deep and not completely understood ideas. Frenkel’s more technical expository papers are by among the most accessible things to read, but there is no royal road, this subject is very demanding. That he’s trying to explain it at a popular book level is a very remarkable feat.

8. **Anonymous**
September 20, 2013

Many fields of mathematics have deep ideas and difficult problems. The reasons why some areas are considered more deep and difficult are purely psychological and cultural. Some of these areas close themselves to outsiders to perpetuate the myth of greatness. Just like string theorists, mathematicians working in these areas enjoy getting all the admiration. This includes prestigious awards, positions in top schools and publications in the best journals for making even the slightest progress on some famous problem. Brilliant mathematicians working in these areas are no more brilliant than top mathematicians in many other areas who unfortunately are often judged by a different standard.

9. **Armin Nikkhah Shirazi**
September 20, 2013

Peter,

Based on Paulo Guerra’s name (which does not sound typically American) I surmise that his “no comments” comment was a subtle criticism of the implication of your claim that “sunny optimism and cheerful enthusiasm” exclusively characterize American culture, not this was once the case and may not be so any longer.

Thank you for the book review, though.

10. **Ponder Anew**
September 20, 2013

“…The organic unity of mathematics is inherent in the nature of this science, for mathematics is the foundation of all exact knowledge of natural phenomena. That it may completely fulfil this high mission, may the new century bring it gifted masters and many zealous and enthusiastic disciples!” –David Hilbert 8.8.1900.

I came to mathematics late in life but I have certainly developed a love affair with it; it’s seeing the problem all the way through, the clarity of vision that oftentimes seems to take eons to obtain, which is so addictive – similar to those bursts of creative insight which lead to novelty in so many fields! This is the first time I’ve encountered this “geometric Langlands” entity and it sounds quite fascinating; I wonder, is it the solution to the enigma regarding the unity of mathematics and the intimate connection between mathematics and physics? Of course, to date, I don’t have the knowledge base required to tackle such a book but perhaps one day the Love will lead me there . . .

11. **Peter Woit**
September 20, 2013

Armin,

A bad idea for me to be trafficking in national stereotypes at all, of course they are of very limited significance and dubious value, but, in any case, plenty of other national stereotypes include even more optimism than that of Americans. In terms of stereotypes, from IP address you’re right, but these days “Paulo Guerra” is a pretty American name…

12. **Peter Woit**
September 20, 2013

Ponder Anew,

Frenkel is known for referring to the Langlands story as a “Grand Unified Theory of mathematics”, with some justice. The connections to physics make the unification theme even more impressive.

13. **Mathematician**
September 20, 2013

Thanks for the review. I’ve ordered the book.

14. **anon**
September 21, 2013

Grand unified theory of nothing. The last time this Frankel quote came up on this blog, David Ben-Zvi wrote (July 24, 2008): ‘Of course Frenkel’s comment on the “grand unified theory” is tongue in cheek, but in any case he was referring to the entire Langlands program, not just to its geometric aspects.'

15. **Chris Austin**
September 22, 2013

If Frenkel thinks he can "popularize" maths by making a movie that puts forward the worse-than-silly propositions that there exists a "formula for love", and that after discovering this "formula", he has no alternative but to kill himself, why should anyone think there is anything more to his "deep" maths than the emperor's new clothes?

16. **uair01**
September 22, 2013

Michael Welford says:
Of course if you describe yourself as, for instance, a Frenkel-chapter-12 you'd better be prepared to back it up, because the math nerds will be gunning for you.

I wonder where this book lies between:
1) The "Road to reality" where I got to chapter 10 and from there I had to read "in between the equations" (just as Mr. Penrose suggests).
2) This interesting number theory book (Fearless symmetry) which I read in its entirety.

I still wonder how many people buy those books. They're too difficult for the common public but are (I assume) too trivial for the specialists. But it's very sympathetic of the authors to present "unadulterated" science.

One author (forgot name) once wrote that: "every extra formula halves the possible audience".

1) http://www.amazon.com/The-Road-Reality-Complete-Universe/dp/0679776311/ref=sr_1_1?ie=UTF8&qid=1379850599&sr=8-1&keywords=road+to+reality
2) http://www.amazon.com/Fearless-Symmetry-Exposing-Patterns-ebook/dp/B005K46YVU/ref=sr_1_1?ie=UTF8&qid=1379850665&sr=8-1&keywords=fearless+symmetry

17. **Peter Woit**
September 22, 2013

Chris Austin,
One more reason for reading the book is that there's a chapter about the film and what he was trying to do with it. One can like, dislike, not care, about his film (for options other than "not care", you might want to read what he has to say), but I don't see how this has anything to do with the issues about mathematics. I don't see any reason why doing great mathematical work should correlate at all with whether one's art-film project is wonderful or misguided.

uair01,
The book is not like Penrose's, which was a graduate level textbook disguised in the cover of a popular book. It's much closer to "Fearless Symmetry", which covers related mathematics, at a similar level. The difference is that Frenkel's book is not written at all at a specific level aimed at an audience with a certain background. Much of the book is a memoir that could be enjoyed by anyone with zero knowledge of math and zero interest in learning more. Of the rest, a lot is explanations of mathematical ideas at a popular level, with no equations. In parts though, he's getting into ideas that it's just not possible for people without a lot of background to follow. Those will be understandable by people with some sophisticated math training, but for the average person will just be a glimpse at something they're not going to really understand (but such a glimpse might give them some insight into what math at this level is like).

18. **Shantanu**
September 25, 2013

Peter, OT.
Nobel prize annoucement in 2 weeks. Any guesses?
Will it be awarded for Higgs discovery?

19. **Marco Masi**
September 26, 2013

I'm no longer sure that falling in love with math is healthy for everyone. It is fine for mathematicians, but for physicists it can be dangerous. I once used to be it too until I realized that it distracted me from understanding better the foundations of physics and the deeper meaning of some of its principles. In a certain sense I believe this is one of the causes of today's failure in theoretical physics to go beyond the SM.

Quick Links

- The new issue of *Nautilus* has a wonderful story about Yitang Zhang, called The Twin Prime Hero, which includes a long interview with him. Zhang's remarkable mathematical career includes several years working at a Subway in Kentucky. His sucessful work on the twin prime conjecture (see here) was done over four years, working seven days a week without almost any breaks, while teaching two classes at a time.
- This year's Physics Nobels will be announced October 8, Nature has a story here. For non-HEP physics, I have no ideas about likely winners. For HEP, of course the Higgs is the big news. Personally I think they should give the award to CERN + ATLAS + CMS, but that would require changing their tradition of not making this award to groups. Seems like a good time to change this. On the theory side, in some sense it is Weinberg-Salam that has been vindicated, and they already got the prize for this. If one wanted to give a prize for the general idea of the Higgs mechanism, I've argued that Anderson should be included (see here).
- This weekend the IAS will host Dreams of Earth and Sky, a celebration of Freeman Dyson's 90th birthday, see more here.
- I'm not going to the Dyson-fest, but am looking forward to seeing the film Particle Fever this weekend at the New York Film Festival.
- Next weekend it will be not physics, but math, as I'll be at the Simons Foundation day-long program on October 5, Celebrating the Mathematics of Pierre Deligne. Recently I've been spending some time watching Deligne's lectures from this past spring at the IHES, available in high quality video here.
- The only mention of Bohemian Gravity! here was in a comment a while back, and I hadn't added more, since this has gotten attention from hundreds of other sources. But of course it really is great and deserves all the attention and more, so if you're the only reader of this blog who hasn't checked it out, do so now.
- Frank Wilczek has been very active on Twitter recently, and a directory of some of his recent writings is here. According to this tweet, he has plans at some point to break out of the 120 character limit.
- Latest news from the LHC is here. Work is on schedule for January 2015 first beams at a higher energy of 13 TeV.
- For an example showing that some basic technical questions about the Standard Model are still poorly understood and deserve a lot more attention, see Michael Creutz's talk on Chiral Symmetries and Lattice Fermions at this recent QCD conference, as well as the preprint version here.

Update: In case you don't get enough material from me here explaining what the problem is with the "multiverse", Sabine Hossenfelder has more here.

   September 27, 2013

   Yes, a Nobel for CERN+ATLAS+CMS would be the right thing to do.

2. **Thomas**
   September 28, 2013

   It would be great if you write about the talks at the Deligne conference!

3. **Bill Cheswick**
   September 29, 2013

   Thanks for mentioning the dyson fest. I Immediately signed up and went, and it was excellent. It is the first time the entire Dyson family was in one place.

   Best new concept for me: iron helide. Freeman analyzed the crystal structure of this "compound" on the surface of a neutron star.

   The presentations were streamed, but don't seem to be online. I hope they make it.

4. **Ponder Anew**
   September 30, 2013

   I read about Yitang Zhang awhile back; it's an interesting story. In a vein remotely similar to the Yitang Zhang story is the story of Jacob Barnett, a 15 year-old autistic boy studying at the Perimeter Institute (http://www2.macleans.ca/2013/09/01/jacob-barnett-boy-genius/). His story reminds me a bit of the Kit Armstrong story in that both boys are mathematical "geniuses" and both have really extraordinary mothers!

   October 8, 2013

   Other possible contenders for the physics prize – Nick Holonyak for the LED. It was the fiftieth anniversary of his discovery last year.

   Thomson-Reuters have suggested Marcy, Mayor and Queloz for discovering extra-solar planets. I admit that I have been wondering for the last few years if exoplanets could be in the running, but the names they suggest are wrong. If they do give it for exoplanets it will be to Wolszczan, Mayor and Queloz. Wolszczan found the first exoplanets -around a pulsar – and Mayor and Queloz found the first around a sun-like star. Marcy came on the scene afterwards. If the award is given for exoplanets, however, expect a possible debate that makes the one concerning the MRI prize look quite tame. The history isn't anywhere near as clear as most accounts make it seem – some people think that exoplanets were found before the pulsar planet ones – and many of the claimed exoplanets aren't very robust.

7. **Mike Creutz**
   October 18, 2013

   Someone just pointed out to me the above comment on my Trento talk. I said some outrageous things there and was surprised I didn't get more of a reaction. Among others:
   Partially quenched chiral perturbation theory is wrong
   Matching lattice masses with msbar is not sensible
   These are both mainstays of some lattice groups. It appears this was the wrong audience, which cared mainly about the infrared behavior of the gluon propagator.

I also just stumbled on the extensive 2008 discussion here of my ranting. On this topic communication has completely collapsed.

Why m_H= 126 GeV?

September 26, 2013
Categories: Uncategorized

This week in Madrid there's a conference going on with the title [Why m_H= 126 GeV?](). It brings together HEP theorists working on "Beyond Standard Model" physics, with the majority of the participants from Western Europe, especially Spain. As part of the workshop they did a [survey](), getting about 50 responses. Among the results:

- For the question "Do you think that String Theory will eventually be the ultimate unified theory?", 27% said Yes, 73% No, with the Nos breaking up into 27% just "No" and 46% "No, but it is a step in the right direction".
- For a question about the hierarchy problem, the three opinions that got the highest numbers were pretty much split evenly among them: "Low energy SUSY solves the problem", "Anthropics solves the problem", and "There is no such problem."
- Opinion was evenly split on whether the LHC would or would not find non-SM behavior of the Higgs, and 60-40 in favor of the LHC finding some non-SM new physics.

If you're at all interested in what the current mood and thinking is in this part of HEP theory, you should definitely take a look at the video of this evening's discussion section, moderated by Joe Lykken. It included extensive debate about the questions raised by the survey and what people's answers meant. At the end there was a short interesting discussion about AdS/CFT and its relation to string theory, with Michael Douglas arguing that AdS/CFT should be thought of as an improved version of the renormalization group, with no necessary connection to string theory. String theory and SUSY only come into it by providing certain examples where you can do explicit calculations in the dual theory. By the way, I've heard a rumor that Douglas is going on leave from his physics job to work at the Simons hedge fund Renaissance Technologies.

Among the talks so far on-line, you might want to take a look at Alessandro Strumia's Is Naturalness Natural, for an example of the sort of thinking that denies the dichotomy of "low energy susy or anthropics". As the survey showed, this insistence on other alternatives has at least 1/3 support, and Joe Lykken mentioned that he was in this category.

Michael Dine's talk on Alternative Futures for Particle Physics starts off with slides about Neil Turok's comments on the "crisis" in the field, and shows this blog entry. He then goes on to give a string theory landscape/anthropics-based point of view on prospects for BSM physics. At the end of the talk there's some pushback from the audience, with one questioner describing Dine's anthropics as "a kind of sleeping pill, so you convince yourself that you are smart", calling this "theology" not physics.

Dine describes my blog entry he showed as one that personally insults him, something that certainly wasn't intentional. He's not mentioned at all, but I gather he's unhappy about my description of the material in the slides of Sally Dawson's HEPAP presentation

Dine was chair of the committee that produced this report on The Future of U.S. Particle Theory and it's well worth reading for a detailed overview of the current state of HEP theory research in the US, especially from the more phenomenological end. Like the slides though, I'd describe it as mostly avoiding dealing with the intellectual crisis that Neil Turok was describing. Even though Dine was the chair of the committee, there's nothing in its report about his favored road ahead (the landscape and anthropics). I'd guess that the committee members felt that when trying to get support for HEP theory from other scientists or government funding agencies, talk of crisis-level problems with conventional wisdom was to be avoided, but even more so any mention of the string theory landscape and anthropics.

Update: For the latest on the landscape, see Michael Douglas's talk on The string landscape and low energy supersymmetry. At the beginning of his talk he notes that "most people seem to have given up" on this, and from the talk itself it's easy to see why. Actually, Douglas himself seems to be giving up. I've heard more about his move from physics to finance, which began last fall when he went on leave to work at the Rentech hedge fund. Evidently this fall he is not coming back to the Simons Center, but staying at Rentech, leaving his academic position. Rumors are that one reason he gives for leaving is that there is not much of interest going on in HEP theory these days.

   September 27, 2013

   Michael Douglas is right about AdS/CFT. The idea of holography is quite general and doesn't require string theory. It can also be realized entirely within quantum field theory where you can show that a topological field theory (which is similar to a gravitational theory since it is "generally covariant") can be equivalent to a conformal field theory on a lower number of dimensions.

2. **CU Phil**
   September 27, 2013

   Hi Peter,

   This isn't the first time I've heard that AdS/CFT is independent of string theory (which seems true from what I know, but I don't feel qualified to rule on that), but the first time I've heard that it should be thought of as an improved version of the RG. Do you know any more detail about what he means there?

3. **Thomas Larsson**
   September 27, 2013

   The almost inconsistent SM parameters have an interesting analog in statistical physics. In the 1940s Onsager showed that critical exponents have to satisfy certain inequalities. Twenty years later people realized that these inequalities are in fact equalities, i.e. critical exponents are on the border of inconsistency. The underlying reason is scale symmetry.

   By analogy, the fact that the SM Higgs mass is on the verge of inconsistency could be a sign that a symmetry principle is at work here too. If so, there probably isn't any BSM physics to be found, apart from gravity which is a different matter altogether.

   Hence the null results from the LHC could actually turn out to be quite exciting.

4. **Ray**
   September 27, 2013

   @Peter Have you seen the recent blog post by Andreas Karch in Lubos's blog? http://motls.blogspot.com/2013/09/guest-blog-on-applications-of-holography.html
   Any thoughts?

5. **Peter Woit**
   September 27, 2013

   Ray,

Well, one thought is "why would anyone sensible want to appear as a guest on Lubos's blog?"…
But, beyond that, seems like a reasonable discussion, although just dealing with one side of the story, reasons for optimism about doing things with this set of ideas. If you want to discuss it though, you really should discuss with Karch, not me.

CU Phil,
I'm not sure exactly what Douglas had in mind, but in AdS/CFT, the fifth dimension has an interpretation as an energy or distance scale, and people have used that to discuss various ideas about a "holographic renormalization group".

6. **Anon**
September 27, 2013

Peter,

Thanks for pointing these talks and videos. A lot of the talks seem to say that there is already evidence for fine tuning or unnaturalness at 1% level (some even have it at 0.1%). That is pretty interesting. Maybe after a few years of data from its 14 TeV run, LHC can establish fine-tuning at a 0.1% level…

7. **Anonymous**
September 27, 2013

0.1% fine tuning wouldn't be completely implausible in the context of the "dimensionless factors should be ~1" naturalness argument. Would something like 1/(8pi)^2 show up on anyone's naturalness radar?

8. **Shantanu**
September 27, 2013

Peter thanks for the link to this video. extremely interesting.
Joe Lykken seems to agree with you about string theory. The discussion about inflation and quantum gravity was also quite interesting.
I disagree with Slava that there is no alternative to inflation.

9. **Tommaso**
September 27, 2013

If you liked the survey, please post your own answers at the comments thread of my blog post on the matter, here:
http://www.science20.com/quantum_diaries_survivor/confidence_new_physics_and_susy_dropping_stone-121294 . And specify whether you are a particle physicist… It would be nice to compare the views of HEP physicists and the rest of the world !

T.

10. **Giotis**
September 28, 2013

Douglas' propositions regarding AdS/CFT and HS gauge theory are weird at least. HS gauge theory is String's theory backyard and can be only understood only as a limit of it.

For an analysis on a conceptual level of the gauge/String correspondence the interested reader is redirected to the following classical paper by Polyakov:

http://arxiv.org/abs/hep-th/0110196

11. **John**
September 28, 2013

@Giotis String theory is also argued to be a spontaneously broken phase of HS theory.

12. **Giotis**
September 28, 2013

It's still String theory which possesses this HS gauge symmetry i.e. its tensionless limit; the tension generation breaks the symmetry and the tensile String theory emerges.

13. **Rick Ryals**
September 28, 2013

I'd say that some degree of congratulations is in order, Peter. The rats are starting to abandon Hook's fantasy ship in droves!

14. **Noah Smith**
September 28, 2013

I've heard a rumor that Douglas is going on leave from his physics job to work at the Simons hedge fund Renaissance Technologies.

Yay for Stony Brook's anchor firm!!

15. **Noah Smith**
September 28, 2013

Dear string theorists: Your field is dying. Come to Long Island and work in quantitative finance while you figure out your next career move! 🙂

16. **fuzzy**
September 28, 2013

great title, "why higgs mass is 126 GeV?"; i like this way to organize workshop! next ones could be, why omegaLambda=0.692, why theta13=9 degrees, and many more to follow… we have a lot of useful occasions of discussion, why we speak of a crisis of HEP? (that could be another title, in fact)

17. **uair01**
September 28, 2013

All those bright theoreticians going into finance is genuinely scary. Not only will finance have more capital and political power than everyone else, but no one else will be able to understand what they are doing. Not only tougher, but also smarter than the rest of us. Something like "chess-boxing" masters. Resistance is futile.

🙂

18. **Noah Smith**
September 28, 2013

Pretty much! But since both quant finance and string theory are basically just ways for us to keep our smartest people active and occupied until we have something useful for them to do, we might as well have the smart people make money while they wait! 😉

19. **OMF**
September 29, 2013

> Not only will finance have more capital and political power than everyone else, but no one else will be able to understand what they are doing.

>Implying that finance understands what it is doing in the first place.

20. **CU Phil**
September 29, 2013

I think the people taking pleasure in this rumour about Douglas are being moderately nasty and entirely misguided. In a field that is subject to lots of hype, Douglas has always struck me as a very honest, level-headed, sound physicist.

21. **Peter Woit**
September 29, 2013

CU Phil,
I agree that personal criticism of Douglas is out of line. With string theory unification stuck in the dead end of the landscape, it's eminently reasonable for him to decide he'd rather do something quite different with his life. What he's doing is actually a lot better for the field than sticking around not doing much in a permanent position, since it opens up a job for someone else. One could criticize on scientific grounds his decision to promote (and continue promoting as in his talk) the string landscape as a viable rather than dead idea (and I have), but that's a scientific, not personal criticism. The world is full of wonderful, admirable people who I happen to disagree with about something or other.

22. **CU Phil**
September 29, 2013

Hi Peter,

FWIW, I wasn't talking about you. You've always seemed to treat Douglas as an honest, well-intentioned guy who you happened to disagree with. It was people celebrating this as "rats abandoning the ship" that irked me — even if that was something to be celebrated, the ship seems to be better off with people like Douglas than without them.

23. **Chris Oakley**
September 30, 2013

> Pretty much! But since both quant finance and string theory are basically just ways for us to keep our smartest people active and occupied until we have something useful for them to do, we might as well have the smart people make money while they wait

So there are people who know better than the smartest people what the smartest people should be doing – but they are not themselves the smartest people – ? That sounds like a contradiction. There are different kinds of smartness. Although I had little success in getting academic posts, in 1984 I was at least smart enough to see that String theory was a blind alley. If more theorists had shared my insight a huge waste of time and effort would have been avoided. In the area of quantitative finance, any market professional could have told the quants building models that repackaged sub-prime mortgage bonds to create AAA tranches from junk – a group that, on paper, looked incredibly smart – that the models were fundamentally flawed because diversification cannot be used to reduce risk in volatile markets as in these circumstances all correlations become either 1 or -1. See *The Big Short* by Art History major Michael Lewis for a good analysis of this. So in this situation too the "smart people" did something seriously not bright.

24. **Bernhard**
September 30, 2013

"For a question about the hierarchy problem, the three opinions that got the highest numbers were pretty much split evenly among them: "Low energy SUSY solves the problem", "Anthropics solves the problem", and "There is no such problem."

I am surprised by the fact that so many indeed believe "there is no such problem" since I haven´t seen any prominent theorists defending this point of view. I guess it is the sort of thing people secretly think for themselves but fear criticism of people in the high chain of command (like Arkani-Hamed). With the LHC results and the pressure on SUSY, I guess maybe people will begin to speak more freely about it.

In fact I know of no good paper (a review would be particularly useful) that discusses this particular point of view. I am curious to know if others do (if so, please share).

(disclaimer: I have no intention to discuss the hierarchy problem per se here for the thousandth time).

25. **Visitor**
September 30, 2013

"In the area of quantitative finance, any market professional could have told the quants building models that repackaged sub-prime mortgage bonds to create AAA tranches from junk – a group that, on paper, looked incredibly smart – that the models were fundamentally flawed because diversification cannot be used to reduce risk in volatile markets as in these circumstances all correlations become either 1 or -1. "

It WAS incredibly smart. The quants and the market professionals and the rest of those pigs made incredibly big amounts of money, and everyone else got incredibly screwed and had to pay for it. And then we had Derman telling us how he never, ever even suspected that, as a quant, he was not working for Eleanor Roosevelt, and how shocked – shocked! – he was to learn that not all the profits were going to UNICEF.

How inspirational was that!

26. **Peter Woit**
September 30, 2013

Please, enough generalized finance bashing, which is pretty much off-topic (no, whatever you think of Renaissance Technologies, they weren't responsible for the mortgage-backed securities mess).

27. **Anon**
September 30, 2013

Anonymous —

In MSSM that solves the hierarchy problem, it is factors of order 1 (or for some terms maybe of order 0.1) that multiply SUSY breaking scale terms M_SUSY^2, to give the contribution to Z mass (m_Z ~ 100 GeV). If M_SUSY becomes order 1 TeV this is 1% fine tuning (~m_Z^2/M_SUSY^2) and if its 3 TeV its 0.1%.

The naive 1/(8 \pi)2 factor which is in front of the Planck scale (UV cut off scale) in standard model for estimating quadratic divergence due to loop effect, does not multiply the scale that is expected to solve the hierarchy problem.

28. **Anonymous**
September 30, 2013

What I am saying is, even if it turns out that the MSSM is a correct effective theory of nature, it would remain mysterious why SUSY had to be broken at all. A more enlightened theory might be able to show that, ah, of course, it must be the case that "m_Z = m_SUSY/8pi" (or something like that; I mean a theory that can relate m_Z and m_SUSY perhaps in the style of the relation between m_Z and m_W in the SM), explaining the breaking and resulting in the apparent "fine tuning" of 1/(8pi)^2, which would not be fine tuning at all, being a very reasonable not quite ~1 constant.

The argument is intended to be that 0.1% fine tuning is equivalent in my eyes to 50% "fine tuning", because mundane constants like 1/(8pi)^2 are no less "natural" (dimensionless constants are naively expected to be ~1…) to me than 1/sqrt{2}, say. Heck, even 1/(64pi)^4 doesn't ring naturalness alarm bells for me (again, I can easily imagine that some future theory could show that SUSY breaking must lead to exactly this level of fine tuning). My standard for natural is "is it conceivable that a future theory predicting a relation between these parameters, which today we must take to be free, would give such a small ratio". I have pretty low standards for that threshold.

29. **Noah Smith**
September 30, 2013

So there are people who know better than the smartest people what the smartest people should be doing – but they are not themselves the smartest people – ? That sounds like a contradiction.

Not if you believe in the "wisdom of crowds"… 😉

30. **Anon**
September 30, 2013

Anonymous — This does not happen in MSSM but in principle there could be some new solution to hierarchy problem where there is a small coefficient like you say between the scale of new physics and the weak scale and then there would not be fine-tuning — but I dont think such solutions have been found yet.

If nature actually uses such a solution, I think it would probably apply directly to standard model (SM) without need for SUSY….so it does not require one solution of the hierarchy problem (namely, SUSY) to lower the Higgs mass down from Planck scale to SUSY scale and another solution between SUSY and weak scale.

It would be very useful if someone came up with a mathematical proof that within the framework of the usual QFT and SM, the solution for hierarchy problem must be at the weak scale or else there will necessarily be fine-tuning.

31. **paddy**
September 30, 2013

Relative to factors or 2 and PI and sqrt(2) etc..I recall Sidney Coleman recalling in a lecture that in his oral of some some sort he attempted to wave his hands at such factors…only to have one of the committee (R.F. for short) say to the young Sidney: "If you don't understand where the 2's and PI's go…you don't understand it at all."

32. **Peter Shor**
October 2, 2013

The argument for the existence of the hierarchy problem essentially assumes we roughly know the Bayesian prior probability distribution on the parameters of the QFT. If we believe that the Standard Model (and any low-energy extensions of it) is just an effective field theory, and we don't know anything about the underlying structure, then all this discussion of fine-tuning and the hierarchy problem is highly speculative.

33. **Bernhard**
October 2, 2013

Peter Shor,

While finding your argument quite interesting, I am not sure I follow it completely (my gut feeling is that I´m not alone). Any reference where this is discussed a bit more detailedly?

34. **Tommaso**
October 3, 2013

Dear Peter,

I agree with what you say, and I would add that since any pdf chosen as a Bayesian prior depends on the choice of variable (it will change by the Jacobian if we change variable), that choice is a further assumption one is implicitly casting into the problem.

Cheers,
T.

35. **anonymount**
October 3, 2013

"The argument for the existence of the hierarchy problem essentially assumes we roughly know the Bayesian prior probability distribution on the parameters of the QFT. If we believe that the Standard Model (and any low-energy extensions of it) is just an effective field theory, and we don't know anything about the underlying structure, then all this discussion of fine-tuning and the hierarchy problem is highly speculative."

Well, sounds reasonable, but tuning arguments are very much common-sense ones, and they have been successful previously in a number of well known cases. Your criticism would apply equally well to those.

36. **Bernhard**
October 3, 2013

Tommaso,

Would you consider writing a blog entry about this? The hierarchy problem is one of the most taken for granted problems in HEP, with little to none questioning about its validity. I must say that I have been searching for papers discussing just what it´s being stated here, without success.

After I read your comment, Peter Shor´s comment was suddenly clearer, but I (and I believe many) would benefit from reading your take on this. As you know, let not overestimate most physicists knowledge of statistics which I am sure is, on average, way below yours.

Just an idea, think about it….

37. **anonymount**
October 3, 2013

Bernhard, you can read this: arxiv.org/pdf/1307.7879.pdf
Is the clearest and sharpest you can find.

38. **Bernhard**
October 3, 2013

anonymount,

Many thanks!

Particle Fever

October 1, 2013
Categories: Favorite Old Posts, Film Reviews, Multiverse Mania

Yesterday I got a chance to see Particle Fever, the long-awaited film about particle physics. It's at the New York Film Festival, where there will be another showing on Wednesday, although tickets are already sold out. Oliver Peters was also there, and has a detailed review.

My own reaction to the film was kind of schizophrenic: most of it I thought was fantastically good and I really hope it finds distribution and gets widely seen. On the other hand, some of it I thought was a really bad idea. First though, the really great aspects of the film.

The main structure of the film is built around the discovery of the Higgs at the LHC, starting at a point back around 2006 or so. Theorist David Kaplan is the person most responsible for the idea of the film and getting it made, and there's footage of him visiting the LHC while ATLAS is being installed, getting shown around by Fabiola Gianotti, who later was to become ATLAS spokesperson. This part of the film shows very well the scale of the effort represented by the LHC and its detectors, as well as giving some idea of the physical environment experimentalists work in (both the huge experimental halls and the areas around them, as well as control rooms and crummy office spaces). There's good use of high quality graphics to give some basic insight into what is going on. Interviews with a few ATLAS physicists add a human face to the story and explain the motivation that drives people to do this kind of work.

The cameras were also there for first beam back in 2008, as well as to capture people's reaction to the depressing news of the accident a few days later that set the whole project back by a year. There's wonderful footage of the scene late in 2009 when first collisions finally occurred, with Beethoven's Ode to Joy providing a very appropriate soundtrack. I especially liked the scenes of a young postdoc (Monica Dunford) carrying her laptop around, elated to show everyone plots with data from the first collisions.

The last part of the film is dominated by the July 4, 2012 discovery announcement, doing a wonderful job of showing the media frenzy as well as the joy and excitement of the entire HEP physics community at that time. All in all, if you want to get someone turned on to high energy particle physics, or just convince a young person that a career in science is an attractive idea, the CERN footage in this film should do the job better than anything I've seen from even the highly competent CERN press office.

Theorists provide a parallel track throughout the film, with focus on Kaplan, ~~his advisor~~ Savas Dimopoulos, and Nima Arkani-Hamed. All of them are highly eloquent on the topic of the significance of fundamental HEP physics research. It is made clear that the fact that the LHC is not seeing SUSY or other new particles is a big problem for theorists like these who have devoted their careers to models of new physics that was supposed to show up at the LHC. In one scene Dimopoulos and Riccardo Barbieri are discussing the matter, with Barbieri saying he has wasted 40 years working on such things, and will soon be retiring. Dimopoulos says that in his case it's just 30 years, but insists there is still two years to go (until the full-energy LHC) before really giving up. The relation of all this to the Higgs is not made clear.

As for the really bad idea, it's the introduction of the multiverse into the theory part of the film. Kaplan is shown claiming that the multiverse predicts a 140 GeV Higgs, based on this paper of Yasunori Nomura and Lawrence Hall (who was Arkani-Hamed's advisor). This is at a time when there were experimental hints of a 140 GeV Higgs. After they went away, and the mass came out at 125 GeV, the "prediction" is forgotten, but a long segment still has Arkani-Hamed going on about the CC and arguing for the multiverse. Just before this segment though, Dunford the experimentalist is shown Skyping with the filmmaker, warning them "Don't listen to theorists". At the film showing, Kaplan and Arkani-Hamed were there and answered questions at the end. One of the first questions (not from me…) was from an audience member who asked why they had put the material about the multiverse in the film, even though it had no real link to the Higgs or the LHC experiments. Arkani-Hamed admitted that the 140 Gev prediction was tenuous, there was no "sharp" link of the multiverse to the Higgs, and that no way is now known to get predictions out of the multiverse idea or test it. Kaplan explained that the intention was to make an "experiential" film, focusing on what theorists were talking about and thinking about, without getting into really trying to fully explain the scientific issues. The problem with this is that the film comes through as promoting the Dimopoulos/Arkani-Hamed view that no SUSY means a multiverse, without showing any challenge to such an argument.

In any case, it's a beautifully done film, on a great topic. I hope it soon gets widely distributed, although perhaps with some sort of warning tag attached.

   While we are talking about LHC:

   Google adds Large Hadron Collider tunnel to Street View

   "Google has dragged is Street View imaging kit to Switzerland, then lugged it beneath the earth to capture images of the tunnel containing CERN's Large Hadron Collider (LHC)….

   Sadly the images don't quite let you be the atom, instead offering the chance to trundle through the LHC's long and monotonous tunnel. Perhaps more insightful are some of the incidental sights: CERN's surprisingly grubby, some of its walls weren't poured by artisanal concrete-wranglers and there are plenty of places that look overdue for a fresh coat of paint.

   The image trove can be found here.

2. **Marcel van Velzen**
   October 1, 2013

   It's a shame ignoring the two physicists who were brave enough to write already in 2009: "This results in $m_H=m_{\rm min}=126$ GeV, with only a few GeV uncertainty". Basically assuming no new physics up to the Planck scale: http://arxiv.org/abs/0912.0208 With only a few GeV uncertainty!

   Even if they got lucky (which I don't believe) THEY WON. Yes Mikhail Shaposhnikov and Christof Wetterich won and nobody else. Get used to it!

3. **franco zoccheddu**
   October 1, 2013

   May you tell me how (or when, or where) to see "Particle Fever"? I live in Italy, and would like my students to see the film. Will it be in theatres next months? Will it be translated for other countries? Hard asks, I know… so thank you for any answer of yours!

4. **Shantanu**
   October 1, 2013

Peter, what do you think about the Wetterich/Shaposhnikov paper?

5. **Peter Woit**
October 1, 2013

franco,
As far as I know, the film has not yet found a distributor, so there aren't plans yet for it to be in theaters.

Shantanu,
I'm no expert on the topic, my main thought about Wetterich/Shaposhnikov is that I'd like to hear from experts. From what I've seen, the sort of thing they are discussing deserves a lot more attention, about 10^500 times more than the landscape. It would have been a great idea for the filmmakers to interview them or someone else with serious ideas about the Higgs, rather than to feature Dimopoulos/Arkani-Hamed and the multiverse.

6. **Tim Tait**
October 1, 2013

(Minor) Correction — Kaplan's advisor was Ann Nelson of UW.

7. **Peter Woit**
October 1, 2013

Tim Tait,
Thanks. My misunderstanding of something said in the film. I gather Kaplan worked as a postdoc at SLAC with Dimopoulos, not as a student.

8. **Gordan Krnjaic**
October 1, 2013

Marcel,

The Shaposhnikov/Wetterich paper is certainly interesting, but ever since LEP, we've had indirect (but inconclusive) evidence to suggest that the Higgs should be in the 120 GeV ballpark. Given this prior and the hundreds of Higgs mass predictions out there, it's not so surprising that one of them would land on ~ 126 GeV.

9. **Marcel van Velzen**
October 1, 2013

Hello Gordan. Basically I agree with what you wrote, but no one should make a claim of correctly predicting the Higgs mass (especially after it has been measured) in some fancy theory without mentioning the ones who were closest to the correct value with a 2.2 GeV error margin, reasonably ahead of time and who used very little new physics (far less than most of the correct/incorrect Higgs mass predictions with much larger error margins). If you want to make this into a claim game, at least mention the winners.

10. **Ray**
October 1, 2013

Take a look at this paper called Higgs Mass Predictions: http://arxiv.org/abs/0708.3344.
All masses from 100-300 Gev are represented with quite a few around the 126 GeV value. In fact there was a crackpot paper which predicted 126 GeV based on four color theorem. Clearly if you exhaustively sample the whole parameter space you are bound to get lucky sometime.

11. **paddy**
October 1, 2013

On the Mikhail Shaposhnikov and Christof Wetterich prediction or postdiction: is not the question "Is their reasoning deserving of attention?" Like PW I await somebody knowledgable enough to say yea or nay.

12. **Columbia**
October 1, 2013

I am not an expert on asymptotic safety, but the Shaposhnikov paper has a few obvious issues. First is that the revised prediction is closer to 129 GeV, which is a special place theoretically for a number of reasons quite independent of asymptotic safety. Second is that it simply doesn't answer all the important cosmology questions. Like what is dark matter, why so little antimatter, what is the inflaton. It doesn't explain particle generations, flavor or CP, or the group structure of particle physics, and it still in principle involves a great deal of finetuning. One can go on…

The problem is that any attempt at an answer for those questions will in principle change the value of their Higgs prediction. The authors are aware of this, and have released some minimal proposals which all have their own problems (like Higgs inflation). So I mean its far from a panacea at this time, but it deserves some more work

13. **Shantanu**
October 2, 2013

Columbia,
Having no connection to dark matter is not a reason to dismiss a theory. Note that despite what you hear inalmost every HEP talk, there is not a single shred of evidence from
astrophysical observations that dark matter has anything to do with particle physics.
Also as I have mentioned several times, whether inflation happened or not is still an open question.
Also I don't think supersymmetric models address baryogenesis

14. **FNesti**
October 3, 2013

"…Kaplan, his advisor Savas Dimopoulos, and Nima Arkani-Hamed"

I don't get what these people have to do with the Higgs – how dare they speak instead of the fathers of the field? Weinberg, Higgs, Glashow, Anderson, etc.

As a theorist, I'm quite ashamed of this crap.

15. **fuzzy**

October 4, 2013

The director should have considered as characters also those who originally contributed to this field, right so! Possibly those mentioned by FNasti, or alternatively, Leonard Nimoy–depending on how one defines what "this field" is.

16. **FNesti (not FNasty thanks :))**
October 5, 2013

Dear fuzzy

yes – the question of what "this field" is, is not a naive one, it contains the essence of the point. I may define a field as a topic plus the researchers working on it, with their respective ranking of academic achievements.

Thus, without cutting any freedom of speech, I believe one should not be considered a possible spokesperson in a field if there is someone else much more entitled to it (no matter how smart one may be, or the number of citations).

This point, which is a point of scientific integrity, I think is unsafely missed in Peter post.

Overall this operation, as the multiverse issue, is evidently an opportunistic push of a new slogan and of a group of people in the public arena (scientific and general public) by exploiting a great experimental discovery. As such I think it should be recognized.

As for Leonard Nimoy,

McCoy: Think, Spock – what's happening on your planet right now?
Spock: My people are barbarians… warlike barbarians.

17. **fuzzy**
October 6, 2013

this is it, the noble race of particle theorists was Vulcanian and now is almost completely degraded into Romulans. But enough for kidding, I agree with you fully, FNesti:

I join your "je accuse". I am defending since long this view, that we should call physics the physics. If you publish a paper with 5K citations, saying that gravity is modified at the mm scale, and this is not, it is a serious problem that requires assessment of the field. We cannot continue to speak of physicists, as if it was a god-given title: we have to speak of what is physics and what it is not. maybe you remember, "not even wrong".

18. **Yatima**
October 6, 2013

Off-topic but apparently the latest congressional pratfall consists in banning "the Chinaman" from entering NASA premises:

US scientists boycott Nasa conference over China ban: Nasa facing backlash from US researchers due to rejection of Chinese nationals from conference

Nasa is facing an extraordinary backlash from US researchers after it emerged that the space agency has banned Chinese scientists, including those working at US institutions, from a conference on grounds of national security.

Nasa officials rejected applications from Chinese nationals who hoped to attend the meeting at the agency's Ames research centre in California next month citing a law, passed in March, which prohibits anyone from China setting foot in a Nasa building.

The law is part of a broad and aggressive move initiated by congressman Frank Wolf, chair of the House appropriations committee, which has jurisdiction over Nasa. It aims to restrict the foreign nationals' access to Nasa facilities, ostensibly to counter espionage.

Will this be "enhanced" to other institutions (when they are not in "shutdown" mode?) My cynical me says "sure".

19. **Goran**
October 8, 2013

I strongly support what FNesti and fuzzy are saying about the danger of slogans in physics. Here they led to the incredible claim that if nothing new is found at the LHC, it will be proof of the multiuniverse (I keep seeing Pauli turning in his grave). This tragicomic argument reminds me how some in the fifties concluded that there could be dinosaurs on Venus.

The argument goes like this (as recalled by Carl Sagan in http://www.youtube.com/watch?v=Cj5A0rKI0Ag) : one can't see a thing on the surface of Venus, because it's covered with a dense layer of clouds. Clouds are made of water, therefore Venus must have a lot of water, thus the surface must be wet and there's probably a swamp. If there's a swamp there's ferns, if there's ferns… maybe there's even dinosaurs. In summary:
Observation: You could not see a thing.
Conclusion: Dinosaurs.

When I present this in my public lectures or colloquia, people laugh like crazy, especially physicists. And yet, amazingly enough, if you substitute 'dinosaur' with fancy words such as multiuniverse or landscape, it is often taken seriously by the same people who laugh at the above 'science'.

Why Are There Still So Few Women in Science?

Normally I avoid writing about the topic headlined here, not because it's not of interest or not important, but because the usual discussions it attracts seem to me ideologically-driven, containing far more heat than light. The New York Times Magazine however has just published [an excellent article](#) on the subject, by [Eileen Pollack](#). Pollack describes in detail her experience as a physics student at Yale, including that of having a senior thesis supervised by the great representation theorist Roger Howe. This includes her decision not to go on in the field, with this description of the perception of the Princeton graduate program:

> By the start of my senior year, I was at the top of my class, with the most experience conducting research. But not a single professor asked me if I was going on to graduate school. When I mentioned shyly to Professor Zeller that my dream was to apply to Princeton and become a theoretician, he shook his head and said that if you went to Princeton, you had better put your ego in your back pocket, because those guys were so brilliant and competitive that you would get that ego crushed, which made me feel as if I weren't brilliant or competitive enough to apply.

I think Pollack very much gets it right, including emphasizing many of the subtleties of this problem, and urge anyone interested in this to read the article. A couple comments though about two aspects of the issue she doesn't really address.

- There is a serious effort at an institutional level to have an impact on this problem, but it takes place mostly only at specific points where the institution can measure what is happening. In particular, in my experience academic departments do take seriously the issue at the point of the graduate school admission process, with often a careful attempt to identify promising female applicants. This isn't at all inconsistent with Pollack's story, which explains why she didn't even apply to graduate school.

  At the point of hiring faculty, university administrations often provide serious incentives to departments to hire women (i.e. by providing faculty lines that can only be used for female or minority candidates). Again, this is often past the point where the problems Pollack identifies have already worked to make the number of viable female candidates small.

- Pollack repeats the claim of a serious shortage of students in STEM fields:

  > Last year, the President's Council of Advisers on Science and Technology issued an urgent plea for substantial reform if we are to meet the demand for one million more STEM professionals than the United States is currently on track to produce in the next decade.

  something which is actually only a shortage of talented people willing to work for low wages. She opens her article with the all-too-plausible results of a Yale research study showing that

  > Presented with identical summaries of the accomplishments of two imaginary applicants, professors at six major research institutions were significantly more willing to offer the man a job. If they did hire the woman, they set her salary, on average, nearly $4,000 lower than the man's.

  This is good evidence that attitudes (women's as well as men's, since they were just as biased) remain a problem. But Pollack doesn't comment on the absolute value of the salaries chosen as typical ($26,508 for a lab manager with a science bachelor's degree), which is less than what a typical Starbucks barista makes here in New York (see [here](#), where my location automatically gives the NYC data). Part of the story may well be women's differential willingness not only to deal with competitive ego-crushing Princetonians, but also abusive, badly-paid working conditions for many parts of the science job market. If the pay, hours and coffee are better at Starbucks (and your co-workers are nicer…), lots of people are going to reasonably make the decision to work there instead.

Update: As anyone could have predicted, allowing anonymous comments on a topic like this soon becomes untenable. On a more positive not, [Sabine Hossenfelder's reaction to the NYT article](#) is highly recommended.

Update: From Fabien Besnard

> I'm in a special position with respect to this question, since my institution, l'école polytechnique féminine was formerly for girls only. Up to the 1980's, the vast majority of french female engineers were formed in this "grande école".Then, since the other grandes écoles were gradually more and more open to girls, the EPF began to be perceived not as "the engineering school for girls", but "the engineering school for girls who can't go anywhere else".It reacted by opening itself to boys, while keeping its name "féminine". Few boys came at first, but the proportion gradually rose, until a point where the EPF was not anymore perceived as a "girl only" institution. Then the boys massively came. There is a now about 60% boys among the students, a proportion which is roughly constant for the last 10 years.
>
> The proportion of girls is still the highest in a school of engineers, and when you ask a student why she came, a very frequent answer is that it is precisely because she knew there would be many other girls. Another interesting aspect is that among the top 25% of the students, the proportion is rather inverse : 60 % of the best students are girls. The reason is that the best among the girls could have applied to one of the more selective "classe prépas" but refrained to do so for fear of being confronted to a stressful environment, with a lot of competition and… boys. Many of them seem to underestimate their chance of success in such an environment.
>
> Lastly, in the final year of our formation (which is the fifth), the students must choose an option that will largely determine their future career. We offer a wide range of choices, from aeronautics to medical engineering and computer sciences. It is a fact that girls do not evenly distribute themselves among these different options. However, there is a fair amount of girls in each one of them.
>
> So my experience largely confirms that the "negative feedback" effect of having too many samples of a single sex in a class acts as a magnifying glass on the small differences of taste between boys and girls, which nevertheless do exist. Also, the girls tend to underestimate their talents.

1. **CIP**
   October 3, 2013

   But this mostly ignores the fact that women have suceeded very well in lots of fields filled with giant egos and mysogynistic males, like law, medicine and pop music. The real question is what makes the situation in physics different.

2. **tt**
   October 3, 2013

   those fields all pay better ?

3. **Low Math, Meekly Interacting**
October 3, 2013

You would do well to solicit women in physics and mathematics, and only women in physics and mathematics, to comment on this post. Otherwise, you are right to avoid the topic. The discussion is inevitably both depressing and uninformative. With a female contingent feeling safe to open up simply state their impressions and experiences without being grilled over them, you might well still end up depressed, but you have a chance to actually learn something.

4. **Peter Woit**
October 3, 2013

LMMI,
Excellent advice. Please, women with something to say about this are highly encouraged to comment. Men, on the other hand, are equally highly encouraged to first reflect on whether or not they really know what they are talking about if they feel compelled.

5. **she physicist**
October 3, 2013

In my opinion, the main question asked in the article was answered in the book Pitagora's Trousers. Yes, as the book amply demonstrates, the physics as done by teams of men is a sort of unisex religious congregation where women trespassers are regarded as disturbances of the holy male soul.
As a female physicist who has worked both in a former communist state and the US, I encountered the most (in fact, the only) adversity and prejudice in the US academic environment.

6. **Koray**
October 3, 2013

I am a man, so I don't know what I am talking about. But, this post's last article makes an excellent point: perhaps there are few women in STEM because they know better. I sympathize with women who hear discouraging remarks and face discrimination, and I don't dispute their experiences, but I don't think anybody cares whether the men in those fields treat each other also like crap.

Everybody knows Steve Jobs' reputation. He'd totally crush the even the best of his people. Perhaps these fields are generally hostile & unrewarding (pay, social life, etc.) to everybody, so it takes the kind of person more commonly found among men to stick with it despite the abuse.

7. **Bill**
October 3, 2013

Those in power must encourage women at the highest level. For example, giving the Fields Medal to a woman would do more good for mathematics in the long run than "getting it right" (whatever that means).

8. **Jerry Moore**
October 3, 2013

I read this article about an hour before finding your post here. I agree with your analysis, it is a very well written article, but also has those groaners about the 1 million STEM "shortfall" and blithely mentioning the shockingly low salaries, although I wonder how much of the latter is because the people being polled were faculty, who are used to paying grad students?

Currently I have a female relative who is considering engineering as a college major. I want to encourage her, but also let her know what she faces (at least the salary issue isn't so bad). What a shame that such a thing has to be a mixed message, and that like the young women quoted in this article "we don't care what people think" is a necessary attitude.

9. **LV**
October 3, 2013

As a female physics graduate student from Canada, I thought I'd chime in with my (very positive) experience. In my last year of undergrad, when I was feeling particularly awful (who doesn't when they are panicking over exams while also trying to figure out what to do with their life?) I had several profs ask me in utter bewilderment why I wasn't applying to graduate school, and then offer to be my supervisor. Then, during my Masters, I had the most encouraging supervisor, the sort of professor who takes his teaching and mentoring responsibilities very seriously. Halfway through, I was feeling particularly inadequate and unable to do the work, but I felt comfortable enough to talk to him about my concerns, and it was thanks to him that I decided to continue on to do my PhD. I don't know if maybe the climate in Canada is different from in the US, or if I just managed to luck out, but I just wanted to point out that there are definitely physicists out there who are very supportive of their students, whether or not they are male or female. Emphasizing the good this does could maybe encourage others to start taking mentoring seriously as well. So many students I know drop out because their professors did not pay attention to them, did not take the time to provide access to data and information, and did not send them to conferences or schools where they could collaborate with and learn from others in their field.

10. **X**
October 3, 2013

I wonder if solutions to the problems of bias might be more welcomed if they weren't specifically indicated as being against sexism. Plenty of people are going to argue that they know they're not sexist, but no scientist would try to argue "Blinding isn't necessary for this experiment, because I know I'm not biased." There are plenty of biases (race, class, gender, attractiveness, social connections), and we could stamp out the lot at once using standard techniques that remove systematic error.

11. **Curious Wavefunction**
October 3, 2013

I think we need enough women in physics to set off a positive feedback loop; this seems to have happened in biology where the initial concentration of fuel "seeded" the next generation. Plus the article's point that culturally women seem to be much more discouraged to go into physics rather than biology seems very relevant. So is the point that both American men and women themselves seem to think of looks and intelligence in a woman as mutually exclusive properties. This has to change.

12. **averageGuy**
October 3, 2013

There's a blog set up that describes women's experiences being a professional philosopher and the amount of wretched sexism and misogyny they experience (http://beingawomaninphilosophy.wordpress.com/). Jordan Ellenberg blogged about it and asked if the situation was similar in mathematics. Izabella Lada chimed in and said that it was comparable. I imagine the same thing can be said of physics as well, and I would guess that one of the main issues with women avoiding STEM professions. Just from anecdotal experience, I am a male software developer, and I have a surprisingly large number of female colleagues (~60%), but they all hail from different countries that encourage women to participate in STEM-related subjects. Not a single American. It's not hard to see that the issue is specific to our cultural attitudes towards women and what their place is in society.

13. **another woman-physicist**
October 3, 2013

I see as a great problem the aging male majority in physics, which is still in charge (and getting even older by the minute). They have grown in time when there were even fewer women around in the field and they never learned to relate comfortably with women in professional setting. The fact that they feel uncomfortable with female students means that these students will not get sufficient encouragement or mentoring. We will be stuck with these unfortunate old guys attitudes for yet many years to come.

14. **Hack**
October 3, 2013

I have seen chauvinist pigs in action and it cracks me up that the supposedly brightest and most educated people on the planet are still a bunch of neanderthals! Those neanderthals should enter the 21st century, maybe they need to go back and take Sociology 101.

No I am not a woman, but I have seen women get marginalized quite often and drop out of graduate school or decide to leave their field after they graduate.

15. **Hack**
October 3, 2013

Sorry, have to add one more thing, if you have not noticed that women get marginalized in the sciences, you must either be at an extraordinary department (where it doesn't happen) or have your head in the sand.

16. **M**
October 3, 2013

A statistics from the European Union shows that women are the majority in soft sciences (such as psychology) and are the minority in hard sciences (physics, mathematics, engineering…), where success criteria are more objective. The difference increases in countries (such as Sweden) where people have more freedom to follow personal preferences.
The reason of the difference is simply that males and females have, on average, different interests, as confirmed by sociological and biological studies. The "gender" ideology that postulates no sexual differences and wants to explain differences with discriminations is wrong.

17. **lun**
October 3, 2013

While this topic is superficially different from the main thrust of this blog, some parallels do come to mind.
Most theoretical physicists will swear up, down and sideways that their field is the most meritocratic on earth, that it is truly the community of the smartest people in the world (as Arkani-Hamed put it in the lecture you blogged about a few posts ago) united in pursuit of the most basic problems in existence, and nothing except ability matters.

When you point out that this ultra-meritocracy is less diverse than Wall Street and most country-clubs in New York, theoretical physicists tend to get very uncomfortable and defensive, but not budge about the supposed meritocracy of theoretical physics. Many will never ever admit it, but quietly do believe that if there are few women and blacks in physics, it is ultimately because for whatever reason they are not good enough (Wink wink, what could this reason be? This is a great illustration of how "political liberalism in the abstract" and a desire for positive social change "in one's own backyard" can be very different things).

Fair enough. Except it is amusing that "the most intelligent and meritocratic people on earth" have made practically zero progress on all of the profound questions they spent the last 30 years pursuing! In fact, the people being defensive about physics ethnic/gender lack of diversity and people being defensive about string theory are often the same (there are, to be fair, quite a few commendable exceptions).

Is there a relation between the two phenomena? While the factors in lack of diversity in STEM are many and non-trivial (the article above is very good), group-think, self-selection (quality-by-reference-and-citation), a one-dimensional view of intelligence (intelligence=problem solving ability within the framework set by the senior people) and a view of academia as a rat-race contributes to both amplifying any pre-existing lack of intellectual diversity and enforcing group-think with regard to a particular idea.

An academic structure a bit more intellectually diverse and a bit less of a pressure-cooker would probably become more socially diverse too, for better or for worse.

18. **Peter Orland**
October 3, 2013

I once heard that the situation for women in astrophysics was better than in physics as a whole. Can any woman astrophysicists verify (or vehemently contradict) this statement?

19. **Kavanna**
October 3, 2013

Often, this situation is grasped at the wrong end of the stick.

Let's not underestimate the "bullheaded stupidity" factor, which males in their 20s exhibit to a greater degree than do females of the same age. How many of those male students will make it to tenure-track positions, much less tenure? The majority will drop out, either from their doctoral programs, or later on the academic career track. My experience is that the female students simply size up the academic job market better and sooner than do their male counterparts. They finish with either a bachelors or, often, with a masters, then leave academia for better and less chancy opportunities elsewhere.

This reality is closely related to the push to get more STEM graduates and immigrants, to allow employers to hire a continuing flow of younger and lower-salary workers, rather than be forced to hire older and more experienced workers at higher salaries.

That said, there's no doubt that prejudice is still a factor, although far less than 40 years ago. Much of it is a function of age, also abundantly confirmed by my own experience. Senior faculty under 60 or 50 are less prejudiced in the way described in the posting. It also varies significantly by field; for example, chemistry and biology have more women in them at the career level. But more women are attracted to those fields as students in the first place.

20. **Anon**
October 3, 2013

M above says it perfectly: "The reason of the difference is simply that males and females have, on average, different interests, as confirmed by sociological and biological studies. The "gender" ideology that postulates no sexual differences and wants to explain differences with discriminations is wrong."

How true. Most women I know are totally disinterested in science and would rather die than work in a field they consider completely boring. As ever, men get the blame, but this is nothing to do with discrimination. Women prefer doing other things.

21. **Peter Orland**
October 3, 2013

Anon,

"Most women I know are totally disinterested in science and would rather die than work in a field they consider completely boring."

So are most men. So what? Anecdotal evidence is a great debating tool, but it can't be used to establish facts (and there is nothing you said above which is factual). For that you need statistics.

22. **CU Phil**
October 3, 2013

This comment thread has developed in the most predictable manner possible.

23. **Z**
October 3, 2013

The situation is slightly better in astronomy, but only observational astronomy. There are very few distinguished or even tenured female astrophysics theorists (and the ones I know work at NASA as research scientists, where supposedly bias is less tolerated or overt than universities).

Then there is the whole LGBT issue which isn't even being commented upon in this discussion. I know of one physics/astronomy graduate student that is biologically male but psychologically female and is undergoing hormone therapy. I have been asked by one older male faculty member "what" this person was at a conference, with their face aghast. LGBT people, as far as I know, are nonexistent in tenured physics/astronomy faculty even compared to women and far far more needs to be done to recruit and retain them.

24. **averageGuy**
October 3, 2013

@Peter Orland: Agreed. Not only that, but if we are going to value anecdotal evidence then we should rely on the testimony of women because they are the group of people who are being pushed out of STEM occupations. From the article, women say the following:

pg 2:

Another student was the only girl in her AP physics class from the start. Her classmates teased her mercilessly: "You're a girl. Girls can't do physics." She expected the teacher to put an end to the teasing, but he didn't.

Other women chimed in to say that their teachers were the ones who teased them the most. In one physics class, the teacher announced that the boys would be graded on the "boy curve," while the one girl would be graded on the "girl curve"; when asked why, the teacher explained that he couldn't reasonably expect a girl to…

pg 3:

After the tea, a dozen girls stayed to talk. "The boys in my group don't take anything I say seriously," one astrophysics major complained. "I hate to be aggressive. Is that what it takes? I wasn't brought up that way. Will I have to be this aggressive in graduate school? For the rest of my life?" Another said she disliked when she and her sister went out to a club and her sister introduced her as an astrophysics major. "I kick her under the table. I hate when people in a bar or at a party find out I'm majoring in physics. The minute they find out, I can see the guys turn away."

And I'll stop quoting because I'll end up quoting the entire article. Frankly I find it a bit disturbing that women's first-hand testimony is being dismissed so callously.

25. **Peter Woit**
October 3, 2013

Please all, unfortunately I agree with CU Phil. Unless you've got something particularly insightful to say about this, please restrain yourself. The phenomenon of men convinced that their voice must be heard on any topic is actually part of the problem.

And bringing in other hot-button topics that are not really relevant and guaranteed to draw dumb arguments is not helpful (no, I don't think the solution to the gender-diversity problems in science is that we need to do more to encourage biological males, but just the ones interested in gender transformation).

26. **srp**
October 3, 2013

Based on the original post, most problems in the field would be solved if physics departments served lattes in addition to their other functions. Or perhaps a chain of CERN cafes?

27. **Jeff M**
October 3, 2013

Just a couple of reasonably well informed (I hope) comments. I'm chair of a math department, I've been involved in a bunch of searches. I don't think the issue can much be that women don't go into physics because they realize that there's no future in academic physics – while the job market in math isn't great by any stretch, it's much better than physics and we have the same problem finding women. In my experience plenty of places are trying, but not so much at the highest levels. A "critical mass" of women somewhere really good would definitely help, it already has. Carolyn Gordon has been at Dartmouth since I was in grad school (a long time ago in a galaxy far far away) and she has produced a ton of great female students, many of whom have stayed in academia. A few of them are at research 1 schools. Lipman Bers (my thesis grandfather) had about 50 PhD students, 15 or so were women (he was active from the 40s to the 80s, mostly at NYU and Columbia, top schools). A number of them (Tilla Klotz, Linda Keen, Lesley Sibner at least) went on to have students of their own.

28. **LogicFan**
October 3, 2013

This is indeed a problem, including in my field, philosophy. It is a problem which thankfully we are all waking up to. There is not much research on the reason for the gender imbalances, and I think figuring out, empirically, why women are not present in equal numbers should be the first step. We have little data on the problem in philosophy, but that which we do have suggest that we "lose" women at the undergraduate level, before they declare their major. We don't know why this is the case.

One totally unhelpful approach is to ask only "women in physics and mathematics, and only women in physics and mathematics, to comment on this" and then to regard that as "Excellent advice". That is terrible advice. This is a problem that confronts our professions as a whole, and the solutions are going to come from the professions as a whole. I certainly agree with Peter Woit's assessment that discussions like these become "ideologically-driven", but that's partly owing to a lack of diversity of opinion. The idea that only women know why there are so few women in science is ridiculous (e.g. some of the leading researchers on gender imbalance are men).

One important question to address is this. I tend to think that the reason we lose female philosophers at the pre-major declaration level is that women do not find the career attractive. In just the same way that women do not find being a plumber an attractive career. If this is true, whose interest are we serving in promoting greater equality? It may be, as lun interestingly observed, that the academic mission may benefit from greater gender diversity. I believe this to be true in philosophy. But then we are not doing it for the sake of women. This may be unobjectionable, but it does imply that the women are the means rather than the end.

29. **Anonyrat**

In response to CIP:

Women in law in the US: (PDF file)
http://www.americanbar.org/content/dam/aba/marketing/women/current_glance_statistics_feb2013.authcheckdam.pdf

While they're doing better than women in physics, it isn't yet a bastion of equality.

Likewise, women in academic medicine in the US: (PDF file)
https://members.aamc.org/eweb/upload/Women%20in%20U%20S%20%20Academic%20Medicine%20Statistics%20and%20Benchmarking%20Report%202011-20123.pdf

Seriously, pop music? In any case, women went through their difficulties there as well. e.g., (powerpoint)
http://virtual.clemson.edu/caah/women/ws301/ppt/wopopmus/Women%20in%20Pop%20Music.ppt

It is still within living memory that women could not join the Musicians' Union.

I suppose physics is on the lagging edge of society as far as opportunities for women are concerned.

30. **Peter Woit**
October 4, 2013

I'm deleting all of the flood of incoming comments from men explaining that the answer to the question of the title is just that women are stupider than men. Sorry, but such a discussion is great for getting people worked up, but never leads to any insight about anything,

31. **usually `amused' but not this time**
October 4, 2013

"In particular, in my experience academic departments do take seriously the issue at the point of the graduate school admission process, with often a careful attempt to identify promising female applicants."

At my university (somewhere in Asia) we had an outstanding female undergraduate student. She completed the 4 year maths honors program in 3 years, and still graduated as the top student of that year. To put this achievement in perspective, at this university we are able to recruit some of the best students from China and elsewhere in the region thanks to our many undergraduate scholarships (approx 30-40 per year). The standard of these foreign scholarship students is very high, most of them are very ambitions and motivated, so graduating as the top student in that group is quite an accomplishment.
Besides that, she demonstrated ability to do maths research at a high level: The research problems she solved for her undergraduate thesis led to 2 publications in the quality maths journal C.R.Acad.Sci.Paris, joint with her advisor. (Her advisor gave her the problems, she solved them.)

I and others strongly encouraged her to apply to top universities for PhD, telling her that she belongs at such a place (which she clearly does). (I'm not her thesis advisor but know her from other contexts.) But there was no need to encourage her because she was already very motivated to do exactly that. Her dream was to do PhD and postdocs(s) at top universities in USA and then get a maths faculty position at one of the best universities back in China.

Well, she applied to Princeton, Harvard and other top universities for PhD and was turned down by all of them.

Her reaction was to assume that it was because she just wasn't good enough to be admitted to those universities. While she she had 2 publications in a quality maths journal, the students who get admitted to Princeton etc probably have 5 or 6 such publications as undergraduates, right?

I'm puzzled about why it didn't work out for her, considering that we've had (male) students admitted to top universities for PhD in the past and her accomplishments are better then theirs. One factor could be that her undergraduate thesis advisor is a non-famous person and I have doubts about his ability to do a good job with the recommendation letter. But that shouldn't matter if the selection committee is really making "a careful attempt to identify promising female applicants". Relatively weak recommendation letters for strong female applicants is the most obvious thing to identify and adjust for.

Another thing that makes this disappointing is that, despite the hype, the average PhD student at Princeton etc is really nothing special. E.g. many of the physics PhD students can't manage to publish a paper on their own in PRL, and some of them can't even do research without having their hand held/riding on a coattail…. It's ridiculous that the talented female student in this case is probably going to go through life thinking that she wasn't good enough for Princeton while the reality is that she is probably better than the majority of the PhD students who were admitted there.

32. **NumCracker**
October 4, 2013

The title is quite biased. There is still so few women in HEP physics, not in Science in a broad context.

33. **woj**
October 4, 2013

Our 8 year old daughter has joined CAGIS (Canadian Association for Girls In Science)

http://www.cagis.ca/

This is from their website:
Many years of research throughout Canada and the United States has shown that girls begin science education at a disadvantage and fall behind in school, not because of lack of interest, but because of lack of exposure. A recent University of Michigan study found that giving girls hands-on science activities helped close the gap.

34. **Andrew Foland**
October 4, 2013

So I'm a man, but would like to pass along a talk by a woman that helped me at least understand some things: http://www.cfa.harvard.edu/cfawis/kathryn_johnston.pdf

(I think you might even have mentioned this talk before, Peter)

35. **Kavanna**
October 4, 2013

My experience of divergent science careers of men and women in other countries is limited and somewhat out of date. But it's worth relating.

European countries gave me the impression of being divergent themselves. Germany seemed moderately negative for women, France quite negative, Britain and other northwestern European countries modestly positive, with Spain and Italy the most positive (surprisingly). I don't know much about eastern Europe.

One commonality between France and the US is that, at least in the universities, the culture is very hierarchical, with a rigid pecking order, and a long path to getting a tenured position. The other systems seem less rigid. Contrary to what many Americans think, the US academic system is one of the world's most rigid, as many scientists (mostly male) have related to me over the years. The rigidity has an effect on everyone, but differentially more so on women. The French system is famously rigid.

Everyone should also think about science outside academia, in government and industry. The sex differences are generally less, sometimes strikingly so. We spend too much time obsessing about academia, instead of seeing how odd academia is.

36. **Peter Woit**
October 4, 2013

Also being deleted: all the people who want to go on in general terms about the "nature of men" or the "nature of women" and how they are different. Hardly anyone I know well fits into such mindless categorizations, and these have nothing really to do with the specific experiences and issues raised in the article I linked to.

37. **Anonymous Math Faculty**
October 4, 2013

To "usually amused":

I've served on the graduate admissions committee for a top mathematics program in the U.S., and one of our hardest problems is evaluating applications from China. The recommendation letters are all uniformly glowing, and all the applicants do very well on the GRE. So the only things we have to go on are the grades, which it seems really only tell us anything useful for the top few schools in China (and apparently not even then if the applicant is "well-connected").

38. **Anonyrat**
October 4, 2013

Some posts on Alexandre Borovik's blog (in Peter Woit's Math Blog list) are relevant.

39. **Lynne Jolitz**
October 4, 2013

Peter,

I am a Berkeley physics alumna. I also have a daughter who is completing her senior year at Berkeley in physics and mathematics (double major) and preparing for graduate school. She is also President of the Society of Physics Students chapter at Berkeley, so she interacts with many physics majors, men and women.

Because we have both gone through the program, we have shared many perspectives on how things have changed for women in physics and how things have stayed the same.

One thing we both agree upon is that the Berkeley physics department is, overall, receptive to women, with women in both leadership and research positions. When I was a student, there were few women but they were actively recruiting. Now there are quite a few women at the professorial and graduate student level.

But socially, physics has not improved among the students. Even though there are many women physics majors, it was difficult for my daughter to convince women to join in SPS activities, such as faculty-student lunches and special seminars. "Are there any other women involved?", would be the usual tentative question. The fear of being the only woman in a sea of men (many of whom are still very immature and vulgar — even in front of faculty) has made it unattractive to many women.

I saw the exact same problem (and we *did* have only a handful of women) in physics when I was at Berkeley. It was especially acute in plasma physics. I ended up as the only woman student in my senior year plasma physics course due to the difficulty of the course and the winnowing effect of small numbers (my professor, though, was an absolute gem and did not allow any misconduct in his class). I ended up doing all my upper division lab work alone because I could not get anyone (all men) to be my lab partner even though I was an excellent lab student. I never was invited to a study group, and I did all my problem sets in the library alone.

Unlike the other few women in the major, I had the support of family and an active entrepreneurial life outside the university. I made an effort to attend seminars (both in physics and CS), ask questions, and meet faculty and people in industry so I would not feel isolated nor uncomfortable at being "the only woman in the room". This has served me well in my career in Silicon Valley.

It is through seminars, courses and events like faculty-student lunches where students, men and women, develop the relationships to get advice and encouragement towards graduate school. My daughter is working to encourage both professional interest *and* civility with the encouragement and assistance of faculty, but she says it isn't easy.

Bullying at the undergraduate and graduate level is a severe problem, and misogyny and harassment is a common attack point to undermine perceived rivals. I don't claim this is induced by the study of physics, but instead this is an ugly reflection of our society. To ignore it or belittle it (the old "toughen up" nonsense) degrades the professionalism and scholarship of any program and should not be tolerated.

Ironically, I was also Treasurer of the Computer Science Undergraduate Association at Berkeley at the time and there were plenty of women in that "male" major (approx 40%) who would tell me about immense amounts of harassment and vulgarity, yet they endured it because CS was an exciting field. Now the percentages are reversed, so the progress in physics and math has been met by a drop in CS and engineering.

CS and engineering, frankly, never did deal with their "woman" problem. The "toughen up" approach to harassment and bullying was endured while it was a lucrative career option, but it was never a sustaining one.

I love physics. And I loved my experience in the Berkeley physics department. It gave me the tools and the courage to look at problems and solve them in new and innovative ways.

I would hope we will continue to face openly that bullying and contempt for individuals studying physics based merely on their gender, their race, or their beliefs is damaging to physics, to scholarship and to our society.

October 5, 2013

I think it should also be mentioned that the quoted anecdote took place in or before 1978 according to the article.

41. **usually `amused' but not this time**
October 5, 2013

Anonymous Maths Faculty,

Thanks for responding. The situation in this case is a bit different from what you seem to be imagining. I understand the problem you mentioned since I have to deal with it myself when assessing PhD applications from China. But ours is not some random unheard of university (and not even in China). We are in the top 100 in the world in a couple of rankings, and our best maths/physics graduates regularly get admitted to top universities for PhD. In the past we have had students accepted at Harvard, MIT, Berkeley, Stanford,…(I don't remember hearing of anyone accepted at Princeton but there might be someone).
So when our top graduate, who happens to be female, doesn't get accepted for PhD at any top university, even though her accomplishments are clearly superior to our other graduates who were accepted at top universities in the past, then it is very puzzling… Especially in light of the claim that there is "a careful attempt to identify promising female applicants".

You mentioned the problem of assessing students from foreign universities – glowing references from faculty you haven't heard of, and stellar grades in academic systems whose standards you aren't familiar with – and I understand the difficulties that causes. But I think you know the quality of the maths journal C.R.Acad.Sci.Paris… This student had 2 publications there from her undergraduate thesis research (as I mentioned)… So your excuses are void in this case.

In your experience, how many publications in quality maths journals as undergraduates do the successful PhD applicants to top universities have on average? (My guess is less than 0.5.)

Isn't it true that, when assessing PhD applications to top universities, recommendation letters from famous people at illustrious institutions trump demonstrated research ability as documented by publications in quality maths journals as an undergraduate? This is a significant consideration for the general issue of gender bias and other biases, since recommendations depend a lot on the "gut feeling" of the writer, in which all kinds of biases can manifest themselves. On the other hand, quality research publications are a much more objective indicator of the quality of the candidate.

Isn't it also true that the "careful attempt to identify promising female applicants" in PhD applications to top US universities is intended for American female students from elite undergraduate institutions in cases where they are less confident and/or motivated, causing them to do less well than male peers, but does not include highly motivated and confident foreign female graduates who massively outperformed their male peers and published papers in quality maths journals as undergraduates, etc.? For those foreign female applicants it's business as usual as far as gender biases go, right?

42. **anonymous**
October 5, 2013

Question for usually `amused' but not this time:

Did any slightly less qualified students from your university get accepted to the same top graduate programs in the same year that the woman who was rejected did? Sometimes schools accept fewer students in general, especially foreign, during economic dips. Depending on the year, it's a possibility. That said, the situation you describe sounds like a quite unfortunate failure of the system.

Anyway, speaking as a man, I think I agree most with woj that the main problem is lack of exposure. This imbalance begins long before college. And by the time students get to college, how many physics survey courses cover what physicists actually do? Pre-meds learn about springs and pulleys and levers and spherical cows in a vacuum. Actual physicists learn about (and actively study) dark energy and dark matter and Bell inequality violations and non-Abelian anyons, and… People (and by that I mean Americans) grow up in a society where physics is considered a boring subject, where only (white) men have the time and privilege to concern themselves with – nay, are expected to be responsible for – the boring stuff that nobody else wants to waste his or her life doing. Thankfully my many female labmates and collaborators (integrating through the years even two open lesbians and a bisexual) have seen through this social construct. They are at once totally excellent at physics and totally girly or at least comfortable with who they are. And I assume that springs and pulleys are as equally boring to them as they are to me.

43. **Paul**
October 5, 2013

I am in the MIT math department. Do you have an outstanding female undergraduate student who you've taught personally (!), and who would do great in our PhD program? Email me in early January and give me the applicant's name, so I can double-check. Nothing specific to us, I'm sure it would work elsewhere as well.

44. **anonymous**
October 5, 2013

Here's another way of framing the argument I said about lack of exposure. How many times do parents think, "My child is a girl, so she's probably not interested in visiting the science museum this weekend"? You would hope that her science classes in school would counteract this tendency. Then again, how many science teachers at the elementary or middle school level know anything at all about dark matter? Not many, I imagine, because their education major didn't require it. So young students end up learning that physics is either something esoteric that Newton, Einstein, and a few other great, white men have already solved, or just a bunch of boring springs and pulleys. This is a safe approach for an elementary science teacher who doesn't want to be confronted with students' questions about dark matter that the teacher can't answer.

I believe it would be much more helpful to portray physics as a list of mind-boggling open questions that are so difficult that only diverse, multi-gender, multi-racial, international collaborations can solve them. Really? We only understand a small fraction of the universe? I personally can grow up to be one of the team players who discovers the rest of the universe? And I can even levitate frogs and shoot lasers at shiny objects along the way? This approach might be outside the comfort zone of the existing pool of elementary science teachers who like to give their students the illusion that they know everything. But I believe it's the right way to do it, especially because it has the benefit of being true.

With this new approach, once there are enough "seeds" at an earlier level, you can eventually reach a critical mass of women by the time you get to the college or professional level. Sure, there might be some remaining bias against hiring, for example, a pregnant woman. But at least with enough women around in general (and enough of the old, white men dying off) the bias will be at a level more comparable to what exists in other fields.

45. **vmarko**
October 5, 2013

IMO, there are apparently at least two diferent effects at play here. One is the society-level bias, discouraging females from getting interested in physics via a passive gender stereotype images all arounsd us. This starts from an early age, and continues throughout life, making too few women getting professionally involved in physics to begin with. The second effect is the professional bias in academia, that happens to that already small number of women who did get involved in physics.

We can fight against the latter inside academia, but the former needs to be addressed at the level of global society, which is much more inert, and needs much more time to fix.

Best, 🙂
Marko

Email me in early January and give me the applicant's name, so I can double-check. Nothing specific to us, I'm sure it would work elsewhere as well.

This is without a doubt the most disgusting comment I have ever read in this blog. Someone willing to bend the rules because an applicant is female.

All this talk of too few women somewhere always evolves into this. Special access to people that just can't cut it and want to game the system through sociological excuses.

BTW Peter, remove this again and I will post it again, and again, and again. I will never let go because quite frankly, this is too bad to just ignore.

Beyond the God Particle

October 6, 2013
Categories: Book Reviews

There's a new popular book about high energy physics coming out this week, Beyond the God Particle, by Leon Lederman and Christopher Hill. The authors are unapologetic about the "God Particle" terminology, coined by Lederman back in 1993 for marketing purposes, which for better or worse is now a fixture in popular accounts of the Higgs.

The new book isn't really a general introduction to the subject, but is focused on two pretty much unrelated subjects. The first is the actual physics of the Higgs field, with a long and detailed explanation of chirality and the way in which interaction with the Higgs field provides particle mass terms. This is great material for anyone who has been subjected to endless attempts at explaining this as the Higgs being like molasses, or a room full of people, or any number of other metaphors that don't really explain anything. Lederman and Hill go way beyond this, with a much more extensive and serious discussion, while still staying away from using equations. For someone who wants to understand as much as possible about what "particles get mass from the Higgs" means without looking at a Yukawa term in a Lagrangian, this is the place.

The second main topic of the book is Project X, Fermilab's proposed new high-intensity proton linac that would provide beams suitable for studying rare decays, neutrino physics, potential muon storage rings, and new sorts of fission reactors for nuclear power. This is pretty much the centerpiece of plans to try and keep US in the game of cutting edge experimental HEP physics. As far as the energy frontier goes, the situation at the LHC is explained, with the argument made that on that front, all there is to do now is to wait and see, with 2017 the date by which the authors expect to have a verdict about whether there is new physics to study at the TeV scale. Only once this is in do they see an informed decision about a new high energy machine to be possible. As far as the last 30 years of theorist's claims about BSM physics, they're dismissed with:

> Our fellow citizens often get confused about what big science is trying to do, perhaps because of what we tell them, usually in the media. For example, all too often we hear that colliders are built "to discover extra dimensions," to "confirm string theory," "to discover supersymmetry." False! Colliders are built to uncover *whatever is happening* in nature at the shortest distances, and not to accommodate the agendas of various sects of theorists.

Throughout the book there's a vigorous argument that science in general and HEP in particular deserve far more financial support from the public than it is getting. On the whole I'm in agreement, but I do think the authors go over the top at a couple points. The short discussion of cosmology is HEP-triumphalist:

> The great discoveries, such as the "gauge principle" shared by all forces in nature, allowed us to speculate about "grand unification" and led to the idea of "cosmic inflation" and canonized the field of cosmology. Suddenly cosmology became respectable. The leading cosmologists are all particle physicists.

The argument for the societal value of scientific research dismisses economists as "eggheads" too dense to realize that there's a simple answer to the question "What makes economies grow":

> The answer is almost obvious, yet it took more than 200 years from Adam Smith's *The Wealth of Nations* to figure it out. The answer is (drumroll): *economies grow because of investment in science!* Basic science, applied science, all science. All scientific research pays a handsome dividend, and the more science the better.

Given the current dysfunctional US government, funding valuable new tools like Project X will be a challenge. Lederman will be at the front of the charge to make this happen, and this book is one weapon for the fight ahead.

Comments

1. **LA**
   October 6, 2013

   authors*

2. **Z**
   October 6, 2013

   It can't be a coincidence the timing of this book is the same week as the physics Nobel announcement. Do Leon Lederman and Christopher Hill know something we don't?

3. **Peter Woit**
   October 6, 2013

   LA,
   Thanks. Fixed.

   Z,
   I doubt it. But who knows, maybe the publisher's marketing people chose the release date to coincide with the announcement, just in case…

4. **uair01**
   October 6, 2013

   The answer is (drumroll): economies grow because of investment in science!

   I totally agree, but just one question (and I'm serious, not trolling):
   Is HEP not too far removed from anything earthbound to ever be of practical use?

   I know the examples of theoretical mathematics suddenly becoming practical (cryptography). I realize that building HEP "playthings" will produce a lot of spin-off in (computer) engineering. I would agree that just searching for "big answers" is valuable on its own. But do you really expect that we will ever use the results of HEP research in something practical? (Like using abstract physics for quantum computing?) If so, what would be the first HEP result to produce some results that could be used business-wise?

5. **Peter Woit**
   October 6, 2013

   uair01,
   The main problem with finding direct applications of possible new HEP physics discoveries is that they typically involve particles with very short lifetime. It's hard to imagine what useful you could do with a Higgs particle (even if you could easily produce lots of them) given their lifetime of 10^-22 seconds or whatever. But, if a new

stable particle was ever discovered (for instance, conjectured dark matter), then one might very well find practical uses of such a new form of matter.

Neutrinos are stable, and maybe one can imagine discovering something new about them which would make them more useful. Already, here's an idea http://www.math.columbia.edu/~woit/wordpress/?p=4646

6. **K**
   October 6, 2013

   Project X is in danger since some time.
   The US budget is not the only problem. The director at Fermilab
   has recently changed and the new one hates Project X, so….

7. **Peter Woit**
   October 6, 2013

   K,
   If the FNAL director hates Project X, what do you suppose his vision for the future of FNAL is?

8. **Mathematician**
   October 6, 2013

   I only buy books with the word "God" in the title if they are written by Richard Dawkins.

9. **srp**
   October 6, 2013

   Leon Lederman is a great salesman and I start out with an emotional bias in favor of investment in HEP. But you do have to worry that at some point you're doing the equivalent of building giant stone statues on Easter Island. Given the small size of the HEP budget relative to the economy, that conclusion seems far away to me. The fact that very intelligent people want to work on these projects and are willing to put up with low salaries and job security to do it also suggests that the social cost is low relative to the benefit. But sometimes the enthusiasts' arguments prove too much, as Lederman seems to in the quotation provided in this post.

   It does baffle me why there is no community push for real money and manpower to be spent on investigating advanced accelerator concepts, a policy which would make sense on the scientific, technical, economic, and marketing levels. It's like asking for money to build history's largest Yankee Clipper instead of experimenting with steamship technology. Harder to sell, more expensive, and less likely to be productive in the end.

10. **Peter Shor**
    October 6, 2013

    @srp: The LHC has just started, and isn't even at its full strength yet. It seems to me that there's lots of time to wait before starting to spend real money on the next collider (either in terms of advancing collider technology, or making detailed plans for one we know how to build).

11. **Tim May**
    October 7, 2013

    OK, to fund XHEP (the extreme HEP beyond the LHC, costing perhaps 10-50 times more, etc.) or to not fund it.

    But as someone who worked for Intel in the 70s and 80s, and now invests in high tech, the connections between HEP and electronics/computers/etc. were pretty much gaseous even in the late 50s.

    The energy scales tell the story. Electronics is happening at non-nucleonic energies.

    The Bevatron in the 50s was already outside these scales, by a wide margin.

    Detectors? Computers? Networks? The WWW itself? Second order effects.

    I think the stuff on this blog is fascinating. I think cosmology, fire walls, etc. is really great stuff, to talk about and think about. Maybe in some distant century we'll be able to to test these theories. Maybe even some telescopes (a lot less expensive than a 500 TeV machine) may turn up something interesting. But arguing that a new accelerator should be built to smash things together at 100-500 TeV, costing the GDP of a European country or two, and saying it may help with economic growth is just not well-supported.

    –Tim May

12. **jd**
    October 7, 2013

    Some decades ago a Nobel prize winner in HEP theory talked individually with several of us and recommended that we not pursue a career in HEP theory. Instead he strongly encouraged us to engage in finding new directions other than just building the next large accelerator. He felt that the current course was not sustainable. I agree, although I did not anticipate that there would be three or so larger and larger machines. I did not follow his advice as I was not interested in HEP at all. Just as I do not believe in unlimited population growth, this brute force approach to HEP experiments makes little sense to me.

    I have noticed on these HEP blogs that little attention is paid to the wish lists of other areas of science and to the large dollar amounts involved.

    NIF 7.5B to date, 300-400M/yr continuing
    ITER 20B for construction
    DEMO and K-DEMO similar to ITER

    LIFE and HiPER similar to NIF
    Nuclear physics facilities – the field is struggling
    Uranium facility at Oak Ridge – I think 6B
    Fission reactor research
    Big telescopes
    Light sources
    NASA

This list can probably be added to. I am sure each area has arguments for support.

13. **M. Wang**
October 7, 2013

I'm sorry, but very very few people in the real economy would agree that science is a main driver of economic development, much less the main driver.

Different schools of thoughts may have different opinions on what the answers should be to the question: what makes economy grow, but there are three factors that will appear with the greatest frequency: engineering technology, infrastructure and division of labor. The science behind building an iPhone had been understood for decades, but the technology still took the genius of Steve Jobs to get right. Better roads and better telecom cost trillions of dollars but create values many times that by increasing the participation of people, land and resources in the economic network.

So, infrastructure allows full utilization of resources everywhere, and superior tools resulting from superior technology improves productivity. The final driver of economic progress is greater division of labor, which allows greater specialization that in turn leads to higher quality and greater creativity. This requires the right legal and social environments as well as efficiency of scale.

As for pure science, take HEP for example, the economic return is minuscule. Once the research frontier gets past stable and semi-stable particles (like muons), no technology can be built out of it. Its only connection with the real economy is now in form of stories being told. This is the fundamental reason why string theorists can get away with their ever shifting stories. Can you imagine iPhone depending on field theory or beyond?

To say science is what makes economy grows is an ultimate conceit of an egghead. It does not help the cause of science; in fact, it shows the public how detached from real lives these eggheads are. In a sophisticated modern economy, there is plenty of room to justify spending on science as the pursuit of truth just like arts as the pursuit of beauty. To make grandiose but ultimately unfounded claims is counterproductive.

14. **Yatima**
October 7, 2013

I can only agree with M. Wang. HEP at least should be considered a peculiar form of art, coupled to "industrial policy" (i.e. subsidies and political bling), which may have some trickle-down benefits to systems engineering. Still better than the rabid destruction of value that a project like the F-35 is, but let's not go there.

15. **srp**
October 7, 2013

@Peter Shor: The point of AAC is to explore for much cheaper ways to get to higher energies. The amounts needed to do technology exploration would not be on the scale of building an actual accelerator, and if the work panned out then there would be the option to get way more bang for the buck. Of course, you might find out that none of these advanced concepts are feasible.

16. **Jens**
October 7, 2013

M. Wang,

It can be argued that the World Wide Web is a spin off from HEP, as it was originally created to allow HEP scientists share data more easily. This sort indirect economic return may be what Lederman has in mind.

17. **piscator**
October 7, 2013

>>Can you imagine iPhone depending on field theory or beyond?

Yes. GR is a field theory, and if you can imagine an iPhone using GPS then you can imagine an iPhone using field theory.

In any case, HEP as an international and collaborative enterprise is not expensive on the scale of government expenditure. Compared to budgets like health, defence or social security it is a rounding error. HEP is a few per cent of the science budget, which in turn is a very small fraction of the overall budget.

18. **Michael Gogins**
October 7, 2013

Mr. Wang:

"Different schools of thoughts may have different opinions on what the answers should be to the question: what makes economy grow, but there are three factors that will appear with the greatest frequency: engineering technology, infrastructure and division of labor. The science behind building an iPhone had been understood for decades, but the technology still took the genius of Steve Jobs to get right. "

This does not refute Peter Woit's argument that basic science drives the economy. All it does is say that it takes a long time to realize the payoff.

Also, of course, it is by no means predictable WHAT basic science research will end up paying off economically.

This is a situation where if one does what is fun or interesting or satisfies one's curiosity, one's descendents receive a fabulous economic reward, whereas if one tries to identify targets for purely economic investments with short-term returns, for example by publicly funding only engineering research, one impoverishes the grandchildren by comparison.

19. **imho**
October 7, 2013

Hi M Wang. I understand what you think you are saying, but it seems to me you really have no idea what you're talking about. Of course the iPhone depends on field theory. Condensed Matter Physics is full of Quantum Field Theory and has been directly responsible for almost the entirety of electronics. Every optical device ever constructed requires a Classical Field Theory tour-de-force. Chemistry, Materials Science and Engineering, Electrical Engineering, etc, etc depend completely and utterly on Science. Go to any large company and research the background of the "Engineers" who build all of these products, check out the R&D departments. You will find Physicists, Mathematicians, Chemists, Biologists. To even think that science is not (at first order) directly responsible for the majority of today's economy is laughable.

I think perhaps you meant a small minority of Physicists – who constitute a minority of a minority of scientists – engage in research that isn't directly related to economics. But even that's arguable since Wall Street hires HEP theorists like Wal-mart hires cashiers.

20. **Peter Woit**
October 7, 2013

Re: "Peter Woit's argument that basic science drives the economy"
I should make it clear that this isn't my argument, it's that of Lederman/Hill. Their form of it I described as "over the top", since I think they are over-simplifying a complex issue. I don't believe that all science, at all times, funded in any amount, necessarily pays dividends. This oversimplification is a rather convenient one for scientists to believe in, since it allow one to evade what can be a difficult issue. In the case of experimental HEP research, I do think the amounts spent on it can easily be justified, but you have to work harder than just saying that it's science, and more funding for science is always justified.

21. **lun**
October 7, 2013

M. Wang wrote:
"Different schools of thoughts may have different opinions on what the answers should be to the question: what makes economy grow, but there are three factors that will appear with the greatest frequency: engineering technology, infrastructure and division of labor. The science behind building an iPhone had been understood for decades, but the technology still took the genius of Steve Jobs to get right. "

Let me correct on you this: It took the marketing, business ability and luck of Steve Jobs to make the iPhone the worldwide brand it is. The technology for mobile communication was finessed by many many engineers of many companies, but was ultimately developed, on the software side, by people like Dennis Ritchie of the basic science institution of Berkeley (who died 2 weeks after Jobs and was completely ignored by the US press, despite his contribution to computing being MONUMENTALLY higher than Jobs's), and on the hardware side by big lab (NASA, Bell labs etc.) engineers. A lot of them working on fundamental science related projects, like accelerators and space exploration.
Of course, unlike Steve Jobs, such projects are in practice "open source", anyone can take advantage of their results. So you do not see the profit in the economists balance sheets: the profit gets distributed and multiplied across all society, including Apple or whoever is built the Linux-box which I am using to type these lines. Google might be a better example… except it was started by people doing "basic science" (Computer scientists at Stanford),and, despite all its questionable corporate practices, does retain a lot of basic science's ethos (it produces a lot of open-source software and runs a basic science program, admittedly not in particle physics).

I hope Peter forgives my cheesed-off tone here. Whenever the US press uses "Genius" and "Einstein" in the same sentence as Jobs and Zuckerberg, I literally want to puke. And to bring this on-topic, the problems described in Peter's blogpost are exactly due to this: If the latest corporate wheeler-dealer is the "genius" but the paradigm-shifting researcher is the irrelevant burden on the economy, of course science will wither. As a scientist, I have my own experimental prediction of how the economy will follow after that.

25. **M. Wang**
October 7, 2013

I appreciate your replies to my first comment. Let me clarify a few issues.

When most people talk about "driving the economy", they mean certain and quick causality relationship that a policy can be built on. The first problem with science trying to take credit here is that it is highly uncertain and always several steps removed from actual applications. Of course, everything that goes into an iPhone was once a top of cutting-edge science, but to make it to the real application takes decades of efforts from many groups of engineers and designers. Only the last group get to bask in glory. You may call this unfair, as all engineering begins with science. To that, Keynes once said, "But this long run is a misleading guide to current affairs. In the long run we are all dead." Likewise, in the beginning we weren't born yet.

The second problem is that good science is almost always open source, and therefore what the economists call a public good. It is well known that public goods always get shortchanged.

Let me take a step back and remind everyone that economics is amoral. Contribution to economic growth is not necessarily good for mankind. Take HEP theory for example, by far the greatest contribution to GDP coming out of the field in recent decades has to be the series of fictions parading as popular science books written by Brian Greene, but this is hardly a good thing, particularly since science is supposed to be the pursuit of truth and must stake its claim of worth as such in the long run.

As for JohnB's idea of invading economics, I am all for it. The current bunch of leading economists are mostly free-market fundamentalists that pushed the US government to pursue unchecked growth in finance, directly leading to the Great Recession of 2008 that cost the world tens of trillions of dollars. The others like Paul Krugman think every problem can be solved by printing more money, even after the FED has already done so to the tune of $4t in 5 years. With competitions like these, people who can at least follow basic logic and common sense will be welcome replacements.

26. **Z**
October 7, 2013

Thomas Larsson: it depends on what you define as "practical", on what timescale, and how many connections to get to "practicality".

For example, the air show detectors that detect UHECRs certainly use the quark model in their analysis of decay products to accurately reconstruct events and estimate cosmic ray fluxes at various energies. Now, UHECRs, and indeed the galactic cosmic ray flux is the basis for carbon 14 dating, calibrated to proxies such as tree rings. Ergo, the quark model helps us date things more accurately (or detect close by supernovae, including those in the past). Is that practical enough?

However, the idea that science should or does have economic benefits is unsettling to me. Economics is a social construct and description of reality, and not really fundamental to happiness, strength or longevity of an intelligent species. One could define the economics of science differently in term of "human capital and knowledge", since it's an entirely arbitrary construction.

27. **martibal**
October 7, 2013

Sorry it is s bit out of topic but this is fascinating and – I hope – deserve one more message (and it provides one more argument than "GR for GPS" to explain that yes, fundamental physics is useful): how are UHECR used to calibrate C14 dating ?

28. **Z**
October 7, 2013

Not UHECRs specifically but most of the cosmic ray flux high in the atmosphere is protons or neutrons above 1 GeV, with about an order of magnitude lower number of mesons. Measuring the flux (via ballons, satellites and surface-based detectors) is important in estimating the formation rate of Carbon 14: 14N + neutron -> 14C + 1H that then feeds in dendrochronologic or historical calibration for dating. The cosmic ray detectors in their construction and data analysis, especially the higher energy ones, all have assume the standard model of particle physics via GEANT4 etc.

Incidentally, Tritium with a half life of ~12 years is also formed via cosmic rays like 14C, and can be used to date watery substances like wine.

29. **Chris W.**
October 7, 2013

Consider a paraphrase—or generalization—of the famous remark by Keynes [emphasis added]:

> The ideas of economists and political philosophers, both when they are right and when they are wrong, are more powerful than is commonly understood. Indeed the world is ruled by little else. Practical men, who believe themselves to be quite exempt from any intellectual influence, are usually the slaves of some defunct economist. Madmen in authority, who hear voices in the air, are distilling their frenzy from some academic scribbler of a few years back. I am sure that the power of vested interests is vastly exaggerated compared with the ***gradual encroachment of ideas***.

The trouble is, so many ideas are bad, and still have influence. At its best, science counteracts that. At its worst, it contributes to the problem. Sloppy declarations like "the more science the better" don't help.

30. **Thomas Larsson**
October 7, 2013

Z, I would define practicality like Faraday – I don't know what it is good for, but I'm sure that you will find a way to tax it. I don't see that your quite contrived example is generating much tax revenue.

Tim May gets it exactly right when he emphasizes the energy scales. EM and QM may be esoteric, but they are esoteric on terrestial scales, and therefore have terrestial applications. Quarks are relevant at much higher energies, and hence have few, or any, applications on earth. The energy frontier today is of course even much further way from terrestial conditions.

31. **martibal**
October 8, 2013

Z thanks for the explanation ! By knowledge of C14 dating was that of the exercises of second year at university.

32. **jd**
October 8, 2013

Z has connected the standard model and quark model to radiocarbon dating, as examples of the practicality of HEP. Wikipedia has a long entry on radiocarbon dating and a number of references. Just google on "radiocarbon dating". I only skimmed some of this material (there is a lot and I am lazy). The question is how many times do the words "quark model" and "standard model" (the HEP standard model) appear in this material?

33. **Christopher Hill**
October 8, 2013

Thanks for the review and the commentary. Our book is released today
and is being shipped at amazon.

On the economic front I must refer you to Warsh's book: "Knowledge
and the Wealth of Nations." It's pretty emphatic: science and technology drive economic growth. Solow's model could calibrate the post-War boom and it was driven (80%) by science, mainly the impact of the quantum theory– and that still holds today (we imply no insult to those economic "eggheads" and we express our gratitude to them for figuring it out, e.g., to be able to give a quantitative measure such as "80%"). We don't like to oversell the world-wide-web but it did come straight out of HEP, straight out of CERN at the same time the SSC was cancelled in the US. It required the paradigm of HEP to develop it. It is probably worth $10 Trillion, globally, per year.

Look, you either go into the lab to develop a product (Edison) or you go there to discover laws of nature (Fermi, Einstein). The latter approach produces greater and more lasting effects, *but all science driven economy happens through spin-offs* . HEP's impact is no different–via spin-offs that wouldn't happen any other way. Look at Roentgen, who was merely exploring the "rays" coming from gas discharge tubes, accidentally discovering X-rays. Within weeks he had turned this into the leading medical imaging technology….but that was a "spin-off" of the pure intellectual pursuit of knowledge. It's always a spin-off when it's driven by pure science.

We're on the cusp of some pretty big spin-offs from HEP. SCRF's (Superconducting RF cavities) may be the next big thing (DOE has spent over $600 million to develop them for electron linear colliders, but they promise a wide range of applications in the general economy, from cleaning smoke flues, to producing Tc-99 at hospitals for med imaging, etc. etc.). Furthermore, Accelerator Driven (sub-critical) Reactors, that are much safer than conventional nukes, can burn thorium (the world has over 100,000 years worth of thorium, vs 100 years of U235, and it produces only short-lived waste, no plutonium, no weapons grade materials etc.). These would be amongst the spin-offs of Project X. The development of Fermilab's Tevatron magnets led to the nickel-niobium wire that made MRI machines possible. I've always thought we should have superconducting power "highways," and the necessary tech is on the shelves at Fermilab ready to go, but it would require government initiatives to make it happen.

But yes, Project X is in some trouble. Our new Director of Fermilab, Nigel Lockyer, has to grapple with budget constraints that may simply be unmanageable if we try to move forward on Project X. As we tried to emphasize in our book, austerity can often be a bad policy. It's an easy sell to the folks back in one's Congressional district, but by cutting basic science budgets you deny economic growth to future generations. We are seeing that in the USA, and it looks like it will only get worse.

34. **Rez**
October 8, 2013

I hate the nickname “god particle”.

35. **Thomas Larsson**
October 8, 2013

Christoffer Hill, you don’t seem to have noticed the point about energy scales. QM applied to the eV (solid state, chemistry, optics) or keV (nuclear) scales has many applications, because such states of matter are readily manufactured on earth. The LHC is about the TeV scale, which is only relevant in supernovae or the Big Bang. That will never have applications on earth.

The www is a wonderful invention, even if I am not convinced that it will survive myself due to resource depletion. It could not have come into being without military research creating the Arpanet turned internet. So we should increase military funding to get more spin-offs…

36. **Peter Woit**
October 8, 2013

Christopher Hill,
Thanks for writing in with the comment.

Thomas Larsson,
You’re the one ignoring Hill’s point emphasizing spinoffs. In the case of future HEP facilities, I think everyone agrees that direct applications of any new physics are very, very much a long shot, but spinoff applications of new technology developed for Project X are quite plausible, with Hill giving specific examples.

37. **tt**
October 8, 2013

Thomas Larson,
another data point: lightning gets electrons up to 100 MeV
http://www.agu.org/pubs/crossref/pip/2012JA017535.shtml

38. **Thomas Larsson**
October 8, 2013

Peter. In my mind, there is a big difference between cases when the science itself has applications, and spin-off effects that don’t really have anything to with the science.

Some physics examples:

Röntgen: The *physics* of X-rays has medical applications.

80% of post-ww2 growth driven by science: Solid-state *physics* is used in electronics.

Nuclear: For better or worse, nuclear *physics* defeated Japan and gave us CO2-free electric energy.

Spin-offs:

HEP created the www (and Tim Berners-Lee is not a physicist).

Military science created the internet.

Space science create cool material like kevlar.

The core mission of these fields are different. HEP should uncover the building blocks of matter, the military should go to war, and space science should explore space. From my perspective, it is a big difference between spin-off effects and the science itself being useful.

39. **srp**
October 8, 2013

Historians of science and technology have long moved beyond the simple model of basic science–>applied science–>useful technology because there are many, many examples where the technology comes first. For example, steam engines, gasoline engines, etc. Just about everything Edison did. Many useful medical discoveries, including vaccination. The science often flows in later, systematizing and greatly enhancing the envelope of what a given technology can do.

On the flip side, you also have to give credit to basic science for inventions that wouldn’t have even been attempted without a general scientific knowledge that something might be possible, even if the specific breakthrough occurs in more of a trial-and-error mode than science–>solution mode. I think (though I could be wrong) that a lot of work on masers and lasers was like that–inspired in basic terms by quantum physics, but not simply calculable from first principles, with some experts believing it to be impossible.

40. **CFT**
October 8, 2013

@Peter,
There actually has been an increasing awareness in economic circles that advancing technology has been causing many jobs to vanish due to automation technology. While you can say the newer technologies are more ‘efficient’, they also employ fewer people and thus shift the wealth into fewer hands, require fewer highly skilled individuals to operate the increasingly idiot-proofed automation with each passing year, which makes for an ever shrinking work force with which to power the economy. There is also the economic reality that a highly skilled individual in the United States can have their job outsourced to a third world country for a pittance due to the wonders of ever increasing telecommunication technology. I think Lederman and Hill are pretty divorced from reality, and haven’t the slightest idea of how a real world economy works. Hopefully, neither of them will ‘help’ run the economy further into the ground.

41. **Geoff**
October 8, 2013

Here’s an interesting perspective on the growth of the internet which – according to Larry Smarr – was driven in no small part by computational physicists (numerical relativists) trying to gain supercomputer time.

http://vimeo.com/6982439

42. **Chris Austin**
October 11, 2013

@uair01:

Is HEP not too far removed from anything earthbound to ever be of practical use?

A conceivable discovery of experimental HEP that could have major technological implications would be the discovery of baryon number violation, together with some means of catalysing proton decay or baryon-baryon annihilation. The catalysis of proton decay by magnetic monopoles in certain grand unified models was considered by Rubakov and Callan 30 years ago – here's a recent study. The experimental discovery of such a process could improve the prospects for practical interstellar travel, by making it possible, in principle, for a rocket engine to convert a substantial fraction of the rest mass of ordinary matter to the kinetic energy of light decay products such as charged pions, and to utilize a significant fraction of that kinetic energy for propulsion. The LHC experiments are actively searching for both baryon number violation and magnetic monopoles, see e.g. here and here.

Various News

October 7, 2013
Categories: Uncategorized

- First a sad piece of news, via commenter Bob Jones. It seems that David Kazhdan, a well-known representation theorist, was hit by a truck Saturday morning while bicycling in Jerusalem. He's in the hospital, with his condition described as "very serious". I hope he manages to recover soon from this accident.
- On a much happier note, I spent Saturday at the Simons Foundation attending a day-long program celebrating the work of Pierre Deligne. More technical talks were in the morning, with Goncharov giving a talk on this material, and Illusie discussing the mathematical significance of several letters he had received from Deligne.

  Deligne's contributions to mathematics are immense, and go way beyond his many published works. Quite a few mathematicians have received letters like the ones Illusie discussed, laying out all sorts of new ideas. Some of these ended up getting worked out in detail by students and others, with Deligne's name not necessarily attached. To this day, Deligne continues to send highly helpful hand-written letters about mathematics to people, although I understand that these days they arrive not by snail mail, but as a scan sent by e-mail by a secretary. These letters make up a huge resource for mathematics, perhaps someday a way will be found to archive them and make them more widely available.

  In the afternoon, Brian Conrad and Ravi Vakil gave some very good more general talks, with one theme the Weil conjectures that Deligne was responsible for finishing the proof of. The day ended with reminiscences of Deligne from Illusie, Saint-Donat, and Dennis Sullivan (since Sullivan couldn't be there, his contribution was read off a cell-phone by Jim Simons).

  Contemplating Deligne's remarkable career is rather awe-inspiring. For more about him, a good place to start is this page at the Simons Foundation, which includes videos of an interview of Deligne by Robert MacPherson. See also this recent piece by Illusie, which makes the point that one of Deligne's achievements was to bring together two great but disparate currents in mathematics, the abstract algebraic geometers around Grothendieck, and the representation theorists working on what is now called the Langlands program.

- For yet more unification of mathematics and physics, last week the Mathematical Institute at Oxford hosted a conference on Number Theory and Physics, associated with talks celebrating the Institute's new building (see here and here). Witten's slides are available here and here, a blog posting by Bruce Bartlett is here.

  Via Jordan Ellenberg and Mathbabe, there's the news that Andrew Wiles took the occasion of the building opening ceremony to warn about the abuse of mathematics by the financial industry. By the way, the new building is described as housing 500 mathematicians and staff, which seems to me truly huge, quite a bit bigger than any other math institute I know of.

- A journalist at Science magazine got not just one, but 157 open access science journals to accept a bogus completely incompetent paper. One could take this as conclusive evidence for the problem with open access journals, except that he didn't try this also on conventional journals, and many believe that they too would publish something just as bad.
- Brian Leiter has a discussion here of some data here about the fraction of philosophy Ph.Ds that are able to get tenure-track jobs. I had always thought that academic philosophy Ph.D.s were likely to have even worse job prospects than theoretical physicists. If you believe these numbers at all though, your job prospects as a philospher are dramatically better than similar numbers for physics theory Ph.D.s. My guess is that, at least in the US, theoretical physics Ph.D.s have very roughly a 20% chance of finding a permanent academic position, while the data here shows 60% of similar philosophy Ph.D.s with permanent positions. If you're in a physics theory Ph.D. program, and at all interested in the philosophical side of the subject, perhaps you should immediately look into changing departments.
- As always, multiverse-mania shows no signs of slowing down. For the latest, see articles in the new issue of Nautilus here and here.
- Just a few short hours until the 2013 Physics Nobel announcements, with speculation raging about what the Nobel committee will do about the Higgs discovery.

Update: It's Englert and Higgs for the Nobel. I still think that, for a prize recognizing the theorists who figured out the Anderson-Higgs mechanism, there's a name missing in that list.

Comments

1. **Jeff M**
   October 7, 2013

   It's clear why the job market in math is so much better than physics, since we teach so many service courses, and don't have to rely on majors. I'm confused as to why it would be so much better in philosophy though, unless it's supply, are there many more physics Ph.D.s? At my university the math department has 31 full time faculty, if you eliminate stats and math ed, there are 13 pure math folks. The philosophy department has 7, and physics is 5.

2. **Kuas**
   October 7, 2013

   I hope the Nobel committee finally does the right thing and awards the physics Nobel to Gordy Kane for correctly predicting the Higgs mass. It's been a long time coming and Gordy isn't getting any younger.

3. **pa**
   October 7, 2013

   i think the odds of getting a job doing theoretical physics are way higher than 20%. sure, it's not easy but in my experience, people who did reasonable phds and werent burned out during their postdocs all get jobs within 4 – 5 years after their phd. i'd estimate the odds being closer to 60-70%, with it being 80 – 90% if you remove those who start postdocs feeling really burned out.

   the jobs might follow fads though.. topological phases or graphene or some fad in biophysics.. but people do get hired doing theoretical physics all the time in the US.

4. **kevin dowd**
   October 7, 2013

   I liked the Nautilus piece.

   October 8, 2013

   "Open access" is a terrible name for "author pays". Let's stop letting unscrupulous publishers like the AMS getaway with this doublespeak.

6. **Andrea**
October 8, 2013

One piece of news you may have missed is that the Dannie Heineman Prize for Mathematical Physics has been awarded to Greg Moore this year for "eminent contributions to mathematical physics with a wide influence in many fields, ranging from string theory to supersymmetric gauge theory, conformal field theory, condensed matter physics and four-manifold theory."

Hugely deserved, by any objective measure.

7. **Eli Rabett**
October 8, 2013

At the risk of starting a riot, let Eli point out three things about the philosophy job market.

First, the level of support for philosophy doctoral students is much lower, not a lot of personal fellowships/research assistantships. Many in the softer arts go out an get jobs between masters and doctorates, etc.

Second, philosophy professors don't have or need large teams to support their lifestyle as is the case for high energy experimental groups

Third, in the US there are a lot fewer international students of philosophy who graduate and stay, competing for jobs.

All of these factors limit the number seeking positions in philosophy.

Of course, what physics and philosophy have in common, is given the small number of undergraduate majors, many places are trying to wipe out the departments leaving only service courses.

8. **DPB**
October 8, 2013

The BBC are reporting that the Nobel prize has been awarded to Peter Higgs and Francois Englert.

http://www.bbc.co.uk/news/science-environment-24436781

October 8, 2013

… and here is the press release.

10. **amused**
October 8, 2013

The "open access" journals scene seems more than a little sinister… I was almost sucked in recently after getting solicited by the "Journal of Physical Mathematics" – normally I would ignore, but in this case the message was semi-personalized and when I took a look at the editorial board there were respectable people on it, including someone I know a little bit. On the one hand sending a paper there makes no sense – why would anyone pay to publish a paper in a new journal with unestablished reputation rather than publish for free in an established and (supposedly) reputable journal? It could only make sense if someone wanted to boost his/her number of publications with low-quality papers that wouldn't be publishable in a reputable journal.
On the other hand, if the people on the editorial board were serious about trying to build up this journal, and one of them had been responsible for my "invitation", then maybe I should submit something there…
However, googling the publisher led to this wikipedia article, from which it is clear that this shouldn't be touched with a ten foot pole!

According to the wikipedia article, one of the delightful practices of this open access publisher is to list people on editorial boards without their consent, and then decline to remove them when they ask… Presumably that explains the respectable-looking editorial board in the case above.

Another thing, my "invitation" mentioned a 20% discount on the publication fee if I submitted the paper by a certain date..but there is no information either in the email or on the journal website about how much the publication fee actually is… Apparently it is only revealed after the paper is accepted.

11. **amused**
October 8, 2013

Another interesting article about the open access journal scene
here. It seems that besides the legitimate OA publishers there is now a substantial group of bogus publishers who are basically operating a scam. (This aspect doesn't seem to have been mentioned in the Science article.)

12. **Peter Woit**
October 8, 2013

pa,

Where do you get your numbers? If you look here
http://www.physics.utoronto.ca/~poppitz/Jobs94-08
you'll see there are around a dozen people getting HEP theory faculty jobs each year for the past few years. Do you really think this is 60-70% of the number of Ph.Ds in the subject each year?

Secret Codes of the Multiverse Debunked

14. **Aquiles**
October 9, 2013

I do not think Anderson would have deserved it.

First, his work on symmetry breaking was not explicitly related to weak interactions, not even to particle physics.

Second, Dr. Anderson did all he could to avoid the Higgs particle to be discovered.

(and third, he already got a Nobel)

It would have been really absurd to have Anderson added to yesterday's list.

15. **Lun**

Regarding the maths/physics/philosophy intersection
What do you think of the recent sciam article
About the interpretation ambiguity of QFT??
http://www.scientificamerican.com/article.cfm?id=physicists-debate-whether-world-made-of-particles-fields-or-something-else

16. **Peter Woit**
October 14, 2013

Lun,

I read that but couldn't get much out of it. I guess I just don't see that there's an "ontology" problem with QFT, that "it does not tell us what a photon or quantum field really is". At the level the author seems concerned with, we have a precise definition of the QFT, and to me, that's what it really "is". I can't fathom what sort of answer to the question of what a "quantum field theory really is" the author would find satisfactory. Yes, obviously it's not a "field", it's not a "particle", and it's not any other word or combination of words in the dictionary. But I don't see what the problem is the author wants to solve. One could point specifically to details of the definition and identify things that one finds unsatisfactory about that, but I don't see that happening in this article.

Nobel for Englert and Higgs

October 8, 2013
Categories: Uncategorized

Congratulations to Francois Englert and Peter Higgs, awarded the 2013 physics Nobel prize this morning. Evidently the prize announcement was delayed because they were unable to reach Higgs by phone. Surely he wasn't unaware that today was a day he might be getting an early morning phone call…

The Higgs discovery last year was one of the great milestones of fundamental physics research and it would have been very odd for the ~~Nobel committee~~ Swedish Academy of Sciences to not recognize it with a prize this year. I do think though that the way they chose to do this is not ideal, for a couple reasons.

The first is that this was foremost an experimental achievement, but the experimentalists and their work remains unrecognized. The thousands of physicists and engineers of CERN, LHC and ATLAS have accomplished something amazing by working together, but this makes them somehow ineligible for the Nobel. As far as the Nobel goes they make the mistake of running their collaborations relatively democratically, without a "great man" (or "great woman") who could stand out and be awarded a prize.

Another issue with today's choice is that if you do want to emphasize a model of scientific research where advances come from a specific "great man" theorist, in this case they've left out the greatest one involved. The specific model tested at the LHC was not that of Englert and Higgs, but the one that Weinberg and Salam already got a prize for. The new prize is for the general mechanism, but this is something that was first understood by Philip Anderson a couple years before Englert and Higgs. For some details of the history, see here. The argument is often made that Anderson's model was not relativistic, but this is a phenomenon for which relativity is not relevant, something which Anderson understood.

The Nobel prize announcement comes with a detailed discussion of the history, which discusses extensively Anderson's work. It makes the argument that relativity was a crucial issue, and summarizes the situation with:

> This was a very important step forward showing that one could indeed have massive vector particles without having a massless mode, but it did now show how the same phenomenon would work in a relativistically invariant theory. Anderson concluded by saying "We conclude then, that the Goldstone zero-mass difficulty is not a serious one, because we can probably cancel it off against an equal Yang-Mills zero-mass problem."

Weirdly, this paragraphs contains a crucial typo. I assume they meant to write "it did not show" instead of "it did now show".

The authors refer to what is usually called the "Higgs mechanism" as the "BEH Mechanism", but it seems to me that if you want to insist on adding more names to the usual terminology, "Anderson-Higgs" would be better.

As far as the Nobel goes, Anderson already has one, given for other work, and maybe this is one reason he was left out this time (although getting multiple Nobel prizes is not unprecedented). Congratulations to him and the LHC experimentalists today, as well as to Englert and Higgs.

Update: Jon Butterworth has some similar comments at the Guardian, especially about the "lone genius" model for progress in science.

Update: For more from Anderson about his work on this topic, see interviews by Chandra, Coleman and Sondhi at the AIP oral history site here. One of the things I find most surprising about this history is that Brout was in close contact with Anderson during this period, but does not refer to Anderson's 1963 paper in the original Brout-Englert paper, or in later discussions of the history (see here). Here's Anderson's account:

> during this period I was in fairly close contact with Bob Brout. Later on, one of the co-inventors of the Higgs mechanism is Brout with Francois Englert. Bob spent several summers with us down at Bell and I know that I talked many of these things over with him. So he was definitely one of my sources for knowledge about particle physics, along with John Ward to a much, much lesser extent. Therefore, when I was recently helping edit one of the accounts of the recent Nobel Prize and noticed that they ascribed the idea, they call it Higgs, Brout, Englert, which I'd never heard, I realized that actually Brout and Englert had a fairly considerable influence on the whole development(must have gotten their ideas from me). So I had thought that it just fell into a black hole and Higgs reinvented it and everybody called it the Higgs mechanism because of that, but in fact, it is in the linear chain of what eventually led to t' Hooft and Veltman. So I was quite happy with that.

Update: John Preskill comments "The emphasis on finding a relativistic model may be misplaced, though. Anderson understood the mechanism well."

Update: There's an interesting story here about the final decision process and the delay in the announcement. Evidently the way things work is that the Nobel Committee (see here for members) proposes up to three candidates. The Royal Swedish Academy of Sciences meets at 9:30 am, debates the matter, makes a decision, with the announcement of the decision scheduled for 11:45 am. Earlier today though, something unusual happened, requiring delay by at least an hour (~~maybe two, one source says the announcement was at 13:45~~ it was at 12:45). Supposedly Higgs was not reachable by phone, but that seems unlikely to have been the cause of the delay since it was known in advance that this would be the case. The press story quotes the academy's permanent secretary as giving as reason "There were many people who had a lot to say".

Unfortunately the rule is that deliberations are kept secret for 50 years, so I'll be long gone before it is known what happened at this meeting today.

Update: It took two days, but the Swedes finally fixed their typo. Now Anderson "did not show how the same phenomenon would work in a relativistically invariant theory."

Update: C. R. Hagen, the "H" in "GHK", sent me the following commentary on the document about the prize put out by the Swedish Academy.

> It is difficult to take seriously the document put forth by the Swedish Academy which purports to explain the basis for their Nobel award.
>
> **"Scientific Background on the Nobel Prize in Physics 2013**
>
> **The BEH-Mechanism, Interactions with Short Range Forces and Scalar Particles"**
>
> http://www.nobelprize.org/nobel_prizes/physics/laureates/2013/advanced-physicsprize2013.pdf
>
> Plainly and simply stated its unnamed author(s) does not understand the mechanism which they are attempting to explain to the physics and world communities. The report in dealing with the Brout-Englert paper reads "The Goldstone theorem holds in the sense that that Nambu-Goldstone mode is there but it gets absorbed into the third component of a massive vector field."
>
> This assessment clearly demonstrates a total lack of understanding of the mass generation and Goldstone avoidance mechanisms associated with spontaneous broken symmetry. In fact as shown by Guralnik, Hagen, and Kibble (GHK) in 1964 the missing longitudinal mode of the vector meson comes from one of the two scalar particles in the model (the other being the so-called "God Particle" recently alleged to have been found at the LHC).
>
> There is no way to explain this incredible blunder by the Swedish Academy. In their desire to marginalize the GHK paper they have failed to understand its real contribution and have certainly failed to comprehend that the Coulomb gauge analysis of that work makes totally credible and understandable the route whereby the expected Goldstone boson is eliminated from the physical sector.

-C.R. Hagen

Comments

1. **Bernhard**
October 8, 2013

   Yes, I agree leaving Anderson out of the picture is unfair, but for political reasons – cutting the throat of the SSC, being unsympathetic to HEP experimentalists, being an anti-particle physics voice, already having a Nobel, etc – they decided to leave him out. I guess this is understandable, since awarding him the prize would generate a huge polemic, something Swedes are not very keen on…

   That said, I think their choice is not bad at all . Giving the price to the experiments could only be achieved giving it to the whole collaborations – without citing any specific names. It could be done of course, but giving it to the collaboration´s spokespersons would have been even a worse choice.

   Then, considering the discovery was sort of a (monumental, but still) confirmation.. it´s not crazy to award the theorists.

   If ATLAS, CMS or other LHC-experiment discover BSM physics (especially if unpredicted) then they will have to face how to solve these dilemmas, but for now I can see why they chose not to do it.

2. **Brown**
October 8, 2013

   Guralnik, Hagen and Kibble take notice, saying you didn't read prior work doesn't cut it as far as getting the Nobel is concerned.

   Anderson is debatable

   This reminds of the similar Gallo/Montagnier "controversy" regarding HIV.

   Again the Nobel went to the right people.

3. **Walt**
October 8, 2013

   I assume that one consideration is that Higgs and Englert are more likely to die suddenly in the next year than are the staffs of ATLAS and CMS.

4. **tulpoeid**
October 8, 2013

   About the phone call, since there is an official statement by him I guess he got it the day _before_, as it always happens. Personally I thought that the delay took place to tip experimentalists to return to their offices and leave the champagnes down, but luckily I was wrong 🙂

   About the rest, I wonder why we have to remind ourselves the 3 persons rule each year. Although I hope that "persons" will turn to "entities" for the first time really soon. (Think lhc, atlas, cms.)

5. **AcademicLurker**
October 8, 2013

   Given the number of potential candidates, should we be reading any significance into the fact that they chose to award the prize to only 2 people instead of 3?

6. **D**
October 8, 2013

   Robert Brout (1928 – 2011). R.I.P.

7. **Michael Jennings**
October 8, 2013

   Theoreticians don't usually get Nobels until there is experimental confirmation of their work. This year was the first year in which they could reasonably be given the award for this reason. However, as they are very old, there was something of a hurry if they were to get the award at all.

   On the other hand, the experimentalists involved in this are much younger. There is plenty of time to give them an award in some future year, possibly after more work can be done in figuring out who exactly to give it to.

   I don't think the choice to give the award to the theoreticians reflects any more than this.

8. **anon**
October 8, 2013

   Am I the only one who is slightly relieved that our hordes of LHC data analyzers won't be lording it around the corridors today with their 0.01% of a Nobel prize?

9. **Peter Woit**
October 8, 2013

   AcademicLurker,
I suppose you could read this a serious dis to Anderson, as in "unlike some other people we could mention, there was room for you, but too bad."

   anon,
Yes.

10. **vmarko**
October 8, 2013

I think that the Nobel was given for the theoretical prediction, rather than experimental confirmation/discovery. The same thing happened in 1957, when the prize was given to Yang and Lee for the prediction of the parity violation, rather than to madame Wu and others who have actually measured the effect.

If Atlas and CMS groups eventually measure some BSM effect that nobody has predicted so far, that will probably be considered a “new discovery”, rather than “confirmation of a theoretical prediction”. They could get a Nobel for that new thing, but not for the discovery of the Higgs particle.

At least that is my guess about the thinking of the Nobel committee. 🙂

Best, 🙂
Marko

October 8, 2013

Higgs was not sleeping next to the phone: [Dr. Higgs — the J. D. Salinger of physics — has already let it be known that he will not be available in any form on Tuesday.]

12. **Kavanna**
October 8, 2013

Good for Dr. Higgs.

Leaving out Anderson is debatable, although understandable. Kibble is the other one who might have been considered. The others often mentioned were not as early or as seminal.

13. **martibal**
October 8, 2013

Experimentalists at CERN already got the fundamental physics prize, which is almost 3 times the amount of money of the Nobel. Did any voice raise at this time to regret that none of the theoreticians of the Higgs mechanism were awarded ?
Also, without the scope of discovering the Higgs boson, what would have been the justification to build LHC ?
(these two questions are real questions, I am not being sarcastic).

14. **GoletaBeach**
October 8, 2013

Higgs gets out an about a whole lot more than Salinger. He has lots of close friends. Nice to see Ken Peach quoted, for example.

Nobel Prizes aren’t ever perfect… No-Bell to Hewish, Hahn not Meitner, etc. To err is human, and the prize committee is merely human.

A vast amount of experimental work over the last 40 years has filled the tables that parametrize the Standard Model. A certain segment of those parameters indicated a light Higgs and led to the persuasive arguments that caused the designs of CMS and ATLAS (good em calorimeters & lepton id).

The only prize that really matters is getting the physics right both empirically and theoretically.

BTW, nice discussion of Migdal & Polyakov in the Nobel Citation. Pretty good discussion of precision electroweak & LEPII as well. I felt a commitment to fairness in the Citation.

15. **fuzzy**
October 8, 2013

the role of gauge invariance for a qed was noted 3 years before the paper of weyl

16. **Z**
October 8, 2013

Maybe Kibble et al will get their prize in next year’s three slots. Is it too soon to speculate? (Yes)

17. **Nathalie**
October 8, 2013

The Nobel Prize is not awarded by the Nobel Committee but by the Swedish Academy of Sciences.

18. **srp**
October 8, 2013

It used to be that the physics Nobels were for recent work and the economics prizes were lifetime achievement awards for old guys. Now the timelines are crossing.

19. **Peter Woit**
October 8, 2013

Nathalie,
Thanks. This made me aware that the Nobel Committee just proposes laureates, it is the Swedish Academy of Sciences that makes the final decision and award.

20. **Neil**
October 8, 2013

I will leave it to others to opine whether omitting Anderson on merits was justifiable. But if he was omitted because “he already has a prize”, then the whole process is a travesty.

21. **gs**
October 8, 2013

1. I starting reading this site for the soap opera back when the string community was in full denial about the experimental situation. My understanding of the science may be little better than a layman's.

2. Having said that:

In 1977 Anderson shared the prize with Mott and Van Vleck despite being from the following generation. Maybe Anderson was chosen at that time because John Slater had died in 1976.

Sounds like a bit of karmic balance (but afaic Anderson unquestionably deserves recognition at the Nobel level).

22. **Ray**
October 8, 2013

It shouldn't be forgotten that both Brout and Higgs are Europeans whereas Guralnik, Hagen and Kibble are Americans. I suspect that European bias played not too small a part in the decision. I have seen a lot of Europeans referring to the Higgs mechanism as the BEH mechanism long before this. (Kiritsis's "String Theory in a Nutshell" does this consistently.)

On a different note Sasha Polyakov and Sasha Migdal discovered the Higgs mechanism independently of the Western physicists around the same time. This was all the more impressive considering that they were both teenagers at that time. No one in Russia took their paper seriously and of course they probably had no effect on Western science. In Sasha Migdal's words, "For the whole two years 1964 to 1966 JETP refused to publish our work with Sasha Polyakov "Spontaneous Symmetry Breaking of Strong Interaction and Absence of Massless Particles" where we (correctly!) argued that vector mesons of the Yang-Mills Theory must acquire mass by absorbing zero mass Goldstone particles. We were stomped to the ground at every seminar we tried to present this work at. The most disturbing thing was that nobody would even argue with us on the subject — the mere mention of "Spontaneous Symmetry Breaking" caused healthy laughter, which ended the conversation. Independently this effect was discovered and published by Higgs and rightfully is called Higgs Phenomenon." (From http://alexandermigdal.com/prose/paradise1.shtml)

I find it very intriguing that nobody even mentions this fact whenever this controversy breaks out.

23. **Peter Woit**
October 8, 2013

To be honest, I've never understood the argument for Guralnik-Hagen-Kibble, or Migdal-Polyakov. The Migdal-Polyakov paper was submitted for publication November 30, 1965, more than a year after all the others, and very specifically was about the strong interactions. It's an interesting independent development, but it would be absurd to award it a prize for the Higgs.
Guralnik-Hagen-Kibble, despite a campaign to claim that they did everything independently and better, explicitly refer to and discuss the earlier Brout-Englert and Higgs work, denying themselves priority. I just took another look at their paper, and noticed something I've never seen before: it ends with the sentence "preliminary investigations indicate that superconductivity displays an analogous behavior". This is remarkably clueless, given Anderson's work, which they would have known about if they'd looked into the relation to superconductivity at all.

That said, European chauvinism may have had a small part to play in denying a piece of the award to Anderson, although his views on the SSC and his already having a prize are probably more important factors. I just reread the "scientific background" paper released today, and remarkably it seems to me that it could just about as easily be read as justifying an Anderson prize as not. Also remarkably, it still contains the crucial typo giving the opposite conclusion to the one intended about the relation of his work to the relativistic case. This is very odd, since I would have guessed that paragraph would have been among the ones read most closely by those using it to make or justify a decision.

24. **Visitor**
October 8, 2013

To me, awarding a Nobel Prize (or any other prize) to an organization is indistinguishable from awarding it to the *administrators* of that organization.

25. **Peter Woit**
October 8, 2013

Visitor,
Well, in the case of ATLAS and CMS, those running the organization are the scientists themselves. I suppose that if they had a less-democratic policy of appointing one scientist CEO, those two people would now have Nobel Prizes. In that case though, I think the difference between giving a prize to the collaboration and a prize to the CEO would be noticeable.

26. **Tom Weidig**
October 9, 2013

>> Guralnik, Hagen and Kibble are Americans.

As far as I know Kibble is British. He has been a professor at Imperial College for decades. When I did my Master's there and talked to him, he came across to me being English.

27. **A.**
October 9, 2013

Peter Woit,

The announcement was at 12:45 CET (I'm in CE and watched it).

There was a question posed immediately after the announcement about why no experimentalists were awarded the prize. If someone managed to grab the video and has a link to it, I'll translate the answer.

28. **Bernhard**
October 9, 2013

According to NBC, the next chapter is clear:

http://www.nbcnews.com/science/after-nobel-whats-next-particle-physics-supersymmetry-8C11360835

29. **Bernhard**
October 9, 2013

…. and here more on the internal dispute that caused the delay:

http://www.thelocal.se/50690/20131009/

30. **fuzzy**
October 9, 2013

i guess that nbc assumed the correctness of the following statements:

"Theorists believe that the SM most probably is but a low-energy approximation of a more complete theory. If this were not so, quantum mechanical corrections to the Higgs mass would drive mH towards the Planck scale – unless "unnatural" cancellations occur"

let's analyze them. the higgs mass is known. it is not even similar to the planck mass. then, *assuming* the above statements are correct, we conclude that the sm is only a low-energy approximation of a more complete theory.

not difficult to see the mistakes. the sm is a renormalizable theory (veltman and 't hooft). its parameters are known after we measure them. there are no quantum mechanical corrections that "would drive" anything inside the sm, as instead stated by the royal academy.

if one wants to discuss another theory, why not? e.g., the supersymmetric models do not predict its mass scale; it has baryon- and lepton-number violating effects that are not seen; it do not predict anything that is measured. not clear to me why we need to discuss it in the "outlook" of such an important document.

31. **El-Coco**
October 9, 2013

Peter, you've got to think positively. You could easily be alive and well in 50 years.

32. **Håkan Eriksson**
October 9, 2013

The citation for the prize this year was: "for the theoretical discovery of a mechanism that contributes to our understanding of the origin of mass of subatomic particles, and which recently was confirmed through the discovery of the predicted fundamental particle, by the ATLAS and CMS experiments at CERN's Large Hadron Collider"

I hope people realize that the last part naming ATLAS and CMS collectives is unprecedented. Such recognition of third parties have not been done before. So it's pretty unfair to say the experimentalists and their work remains unrecognized.

33. **Bernhard**
October 9, 2013

Håkan Eriksson,

I agree. The fact that ATLAS and CMS are two separate entities perhaps even played a role on the impossibility of awarding the experimentalists directly (like they were two other "persons) and the solution was to recognize them in the citation. I´m sure this was a headache for the academy. The third solution I guess would be to award CERN, as representative of both experiments, but this also not ideal, since CERN is a lab that represents other LHC experiments, not only ATLAS and CMS.

34. **Aquiles**
October 9, 2013

The BaBar and Belle experiments were also mentioned in the 2008 Nobel press release… (and by the way, even the then-future LHC is mentioned)

35. **Bernhard**
October 9, 2013

Aquiles,

Yes, but this carries much less weight than the Nobel citation.

36. **Peter Woit**
October 9, 2013

Bernhard/fuzzy,

I also noticed the rather odd appearance of SUSY and "naturalness" at the end of the scientifc document. No mention there though of the other big achievement of the LHC, the negative results about SUSY.

At least we can all be happy that this didn't make it into the prize citation, which I suppose could have been for the "discovery of the first of five predicted fundamental particles, by the ATLAS and CMS experiments at CERN's Large Hadron Collider."

37. **Columbia**
October 9, 2013

Anderson's ideas were a little too vague too award a Nobel prize too. Although I have no doubt he had all the major elements in place, and would have found it himself if he had bothered to flush out the material.

I'm a little surprised that Goldstone wasn't picked. In some sense he's the odd man out, now that the prizes for Nambu, Weinberg et al, and the Higgs selection is complete.

His work is arguably much more theoretically important and universal than the messy details of the Higgs mechanism perse. It's important to note that all three groups were specifically looking for a method around the Goldstone theorem and was the main motivations for those papers.

38. **Shantanu**
October 9, 2013

Peter: the announcement was at 12:45 (not 13:45)

39. **Moe**

October 9, 2013

Guralnik compares the papers here in this video. Whether you agree with all his points, I give him credit for comparing the three PRL papers. I have not seen other comparisons by the original 6 and find that he demonstrates his knowledge on the topic better than others – certainly "My Life as a Boson" speech.

http://www.youtube.com/watch?v=WLZ78gwWQI0

40. **Jim**
October 9, 2013

We live in an age in which scientists are a lot more media savvy than they ever were and will willingly rush to embrace opportunities to promote themselves and their work. I admire Peter Higgs' decision to shun the media (he's 84 years old, after all). I had the privilege to meet him in August 2011, when speculation of an imminent discovery at CERN was rife. He told me that, in the event of overwhelming attention from the media following an announcement from the Royal Swedish Academy, he would simply unplug his phone and refuse to answer his doorbell. I'm not the least surprised that the Academy couldn't get him on the phone yesterday. For those hungry for his reaction, however, he will be giving a press briefing at the University of Edinburgh at 11am (GMT) on Friday, 11 October. The briefing will be webcast from http://www.ed.ac.uk.

I have to say I'm a little concerned about the outbreak of rather nationalistic sentiments in the comments on Peter's blog post. Are some American high-energy physicists are still carrying the mental scars of the SSC experience, after all this time? As Tom Weidig has pointed out, Tom Kibble is British (I believe he was born in India). Also, although Robert Brout was working with Francois Englert in Belgium in 1964, he was born in New York in 1928. Had he lived (he sadly died in 2011, after a long illness) he would have surely shared the Nobel Prize with Englert and Higgs.

41. **Sebastian Thaler**
October 9, 2013

Meanwhile, John Horgan has put his own characteristically pessimistic spin on this news: http://blogs.scientificamerican.com/cross-check/2013/10/08/could-nobel-prize-for-god-particle-be-last-gasp-for-particle-physics/

42. **Kavanna**
October 9, 2013

After all, Peter, we could still be alive in 50 years, still wondering when supersymmetry will be found.

Nonetheless! After about 85 years, the Standard Model, beginning with the Dirac and Klein-Gordon equations and ending with the discovery of the Higgs boson, is now fully cooked.

43. **Peter Woit**
October 9, 2013

Thanks Jim,
The reaction of Higgs to the media attention is admirable. As for

"Are some American high-energy physicists are still carrying the mental scars of the SSC experience, after all this time?"

I fear the answer is definitely yes, and to some extent there's good reason, since the effect of this event on US experimental HEP was disastrous and still being felt.

44. **SUSY**
October 9, 2013

If LHC discovers SUSY particles, who gets awarded the Nobel?
If direct dark matter detectors discover dark matter, who gets awarded the Nobel?

45. **FNesti**
October 9, 2013

Peter, fuzzy
mentioning the current spectrum of naturalness-related BSM theories has the twofold aim of 1) praising the current mainstream theoretical ideas, which gives a reassuring impression of seriousness of the community; 2) using again these theories for the real closing: motivating the request for a future machine.

Evidently, we can not ask (as Lederman) for a change in attitude: i.e. that experiments must be made *to see, not to look for.*

I just came across a piece by Galileo, which just discovered the Milky-Way was made of stars (! and not of milk) _after_ building the telescope.
And he concludes: through this instrument, one can see clearly that all discussions, century-long worry of philosophers, dissipate with the certitude of valid experience, and we are freed from sterile debates.

… attraverso il cannocchiale si può vedere in modo così palmare che tutte le discussioni, per tanti secoli cruccio dei filosofi, si dissipano con la certezza della sensata esperienza, e noi siamo liberati da sterili dispute.

I'd say, evidently history has some recurrent patterns 🙂

46. **Neil**
October 9, 2013

If LHC discovers SUSY particles, who gets awarded the Nobel?
If direct dark matter detectors discover dark matter, who gets awarded the Nobel?

Well, dark matter should be easy because it was hypothesized on the basis of evidence. So Rubin alone since Zwicky is dead.

47. **Marco Masi**
October 10, 2013

"The thousands of physicists and engineers of CERN, LHC and ATLAS have accomplished something amazing by working together, but this makes them somehow ineligible for the Nobel. As far as the Nobel goes they make the mistake of running their collaborations relatively democratically, without a "great man" (or "great woman") who could stand out and be awarded a prize."

.
But the “great man” (or woman) would finally be only the group leader. And in what sense would these be “great”? The group leaders of these research teams are great team managers, great policy makers and fund raiser (and I don’t mean that to be a negative trait, such kind of people play an important role in big science), but they are not (or are seldom) scientific geniuses, and are even not necessarily those who contribute at a scientific level. Eventually the Nobel policy should change towards the idea of assigning the prize also to a group or an organization as a whole. But the idea to favor the corporate minded personality over all the other scientists, amounts to a form of subtle idolatry of the manager type figure in science with which I definitely disagree with.

48. **A.**
October 10, 2013

We don’t really have to wait 50 years to find out about the Nobel deliberations; seeing the presentation which was apparently made to physicists on the Nobel committee (we’ve just seen the slides in a separate presentation), makes it clear that Anderson’s role was downplayed because he didn’t prove the statements he made about the relativistic generalisation of his results, while Weinberg’s contribution was downplayed because of his disagreement with Englert on renormalisability (Englert being right in the end, of course.)

49. **Marty**
October 10, 2013

The idea of awarding a Nobel prize to large collaborations doesn’t seem quite right to me. I don’t mean to downplay the great work and very significant findings of the CMS and Atlas teams. Certainly the discoveries themselves are in a class of Nobel-worthy discoveries; their importance is not at issue. My disagreement lies more in what would be a significant departure from recognizing individual achievement, something I thought was the intent of Nobel prizes in science.

Thus far, whenever a Nobel was shared among multiple individuals, care was taken to ensure that each individual did Nobel-worthy work. If the current tradition were relaxed a bit so that, say, the prize could be awarded to up to five people, I’m confident each recipient would have done Nobel-worthy work. At what number of co-recipients does this idea of individual worthiness break down? I don’t know, but I feel sure it would break down with far fewer than the thousands of individuals comprising the CMS and Atlas collaborations.

Can anyone honestly believe that each person in the Atlas collaboration, for example, deserves a Nobel prize for their individual work? Each grad student who pulled cables, kept an eye on the instruments in the control room, and wrote code to generate test data for event analysis software? Members of the collaboration who have devoted essentially all their energy looking for hints of SUSY or extra dimensions? If the collaboration were to receive a Nobel, all members would be treated as equally worthy of the Nobel regardless of their role. This doesn’t seem right to me — by treating everyone as equally important, as anonymous cogs in the Atlas or CMS teams, it cheapens the efforts and achievements of those who worked very hard and played an outsized role in the discovery while unduly rewarding those who played no significant role at all.

I don’t think that awarding a Nobel to a spokesperson or other proxy for a collaboration is a good idea either, as others have pointed out. Perhaps we have reached a time when some of the most important discoveries will involve large collaborations with no single individuals playing such a large role that they deserve a Nobel prize. And that’s OK — not every huge discovery has to get a Nobel if doing so would depart from the intent of awarding individual achievement.

50. **Bernhard**
October 10, 2013

Marty,

I understand and sympathize with your concern, since if they were to distribute 6000 little Nobel medals, the seriousness and prestige of the Nobel would pretty much evaporate.

However, I think that is not the idea behind awarding an organization, no more than it was not the idea to distribute the 2012 Nobel Peace Prize among all EU citizens. The idea is to simply to acknowledge the achievement of the institution, which only exists when all its members are taken together and makes no sense otherwise. It is not like saying that each member of ATLAS or CMS would each win 1/6000 of the Nobel.

About what each people do in a collaboration, that´s tricky. Even people searching for SUSY, in many cases, contributed crucially to this discovery. All members of ATLAS and CMS have “detector duties”, without which the Higgs discovery would have been impossible. I don´t think the data analysis is the hardest part – it´s one part, an important part, but if all other duties are not taken just as seriously just forget about doing the histograms.

About spokespersons I am as you, fiercely opposed to the idea of awarding them, but indeed, I would have no problem with them going to Stockholm for the ceremony, for the sole reason that at some point a human being needs to pick up the prize in the name of the organization . It is (at least to me) a very, very different thing however, if the Nobel diploma writes down the name of the spokesperson or of the organization.

The cash is unimportant in this case – 8 million SEK could be used to finance a dinner among the collaboration members (perhaps not in Geneva, not sure would be enough there).

51. **Terry**
October 10, 2013

The Nobel “history” is really quite nasty and just wrong…this view is from some famous physics folks you would never think would complain. Frankly many lies in this “history” giving credit to BE and H papers – it even claims that EB and Higgs had the same potential. Show me the potential in the papers!

http://www.nobelprize.org/nobel_prizes/physics/laureates/2013/advanced-physicsprize2013.pdf

Downplays everyone but BEH – especially Anderson and GHK.
For GHK they are particularly careful to ensure there work is downplayed. (It is as if ULB wrote it)
*Puts GHK in “other contributions” and uses several techniques to downplay the contribution
*Positions GHK in this “history” after some Soviet paper which came out in 1967
*States how the Soviet paper was clearly independent (but does not say that for GHK, basically implies it was not independent)
*For GHK each sentence was structured to downplay their paper
*Gives dates to show GHK was after others
*States it was the same model as BEH
*GHK citations of BEH was noted (does not mention that H referenced BE)
*States GHK explains detail of Goldstone avoidance but conclusions were “essentially the same”
*Never returns to the GHK paper throughout the document

The academy must have really felt the need to downplay Anderson and GHK. This paper was carefully constructed to really hammer the others and manipulate thinking with lies and half-truths.

Would be great to know who the "primary author" was for this "revised history"

52. **papers**
October 10, 2013

The *Physical Review* is making the BE and H papers publicly (free) available for download. Only BE and H not GHK. Read them and look up the potentials and anything else you like.

53. **young experimentalist**
October 11, 2013

sure this was before my time, but didn't rubia get the nobel prize for the UA1 discoveries? were times that much different back then, that there was a "great man"?

54. **Chris Oakley**
October 11, 2013

young expermentalist,

Yes indeed, but as the politicians are less willing now than then to fund HEP research, any CERN director needs to be even greater now. The problem with the whole area is that measuring progress and achievement is much harder than, say, most industrial or medical research. In the first case it can be measured by the company making more money and in the second by people being more healthy. In HEP the whole world relies on a handful of experts to inform them, who, not wanting to put themselves on the line, then further delegate the task to the Nobel committee. I would not like to be one of them.

55. **Bernhard**
October 11, 2013

young expermentalist,

I believe that one of the things that have changed is how close the alleged leader is close to the physics analyses. In the case of Rubbia or even Lederman in 1988, they were very close and active to the scientific results. I believe however, that even in their case, it would have made sense to give the prize to the collaborations, but indeed their leadership was very important. I, for example, don't swallow at all what Lederman wrote about his own deserved credit in the neutrino experiment in "The God Particle", but if I were to, than he deserved the prize.

The closest thing we have today regarding the roles Rubbia and Lederman had are , to some extent, the group conveners, but they change with the wind and would be very strange to just award one of them. Furthermore, the most difficult thing in the case of the LHC experiments, IMO, was the detector design – after that, the methods that were used to discover the Higgs were known. It did not need any epiphany from nobody in particular to see it.

All in all I think the Nobel policy of giving group leaders too much credit has been damaging. Take for example the pion discovery. It is undisputed that Cesare Lattes was the the main researcher (and by the way he first author of the Nature article) regarding the pion discovery, but it was actually Cecil Powell, the group leader, who got it. This was not a good idea then and it should not be a good idea today either, specially when the role of the spokesperson has detached itself even further from the analyses.

56. **Terry**
October 11, 2013

They three (BE, H, GHK) are all available from the PRL milestones paper site.

October 11, 2013

Young experimentalist:

Read 'Nobel Dreams' by Gary Taubes. Beg, borrow or steal a copy (it is out of print now). But if you are a HEP experimenter, and you want to read about a great experimental discovery together with lots of juicy stories about how those collaborations worked….

58. **greatmen**
October 11, 2013

Carlo Rubbia was very much a (or the) driving force to push (persuade?) CERN to implement stochastic cooling and convert CERN's existing SPS Super Proton Synchrotron, which was a fixed target machine, into a p-pbar collider, which would have the energy reach to produce the W and Z bosons. And Rubbia headed the UA1 collaboration to build the required detector. (Note that there was also a UA2 collaboration.) So Rubbia was much more than simply a group convener. Lederman won jointly with Steinberger and Schwartz, and note that the experiment was at Brookhaven Lab in 1962 (not Fermilab), a fixed target experiment using the AGS synchrotron. The collaboration size was much smaller, and the leaders formulated the basic idea of the expt, designed the apparatus, analyzed data, etc. ~ much more than simply being a group convener. In fact Sam Ting's collaboration (the J of J/psi) was about the same size, and indeed Ting won (joint with Richter) ~ not his entire staff. (The collaboration size was maybe six people?)

Nevertheless, the notion of awarding the Nobel Prize only to the team leader is controversial and questionable and not a good idea.

59. **Marco Masi**
October 11, 2013

Marty, there is nor reason (apart from tradition) why the Nobel prize must necessarily recognize only the individual achievement, especially when everyone knows that it wasn't. Médecins Sans Frontières (MSF – "Doctors Without Borders") received the Nobel peace prize as an organization in itself, but no one began to believe that every individual working at MSF is a Nobel laureate. I think it is a false problem, and don't see why that can not be applied in physics too.

60. **orgs**
October 11, 2013

To date, only the Peace Prize has been awarded to organizations. Also, the limitation to not more than three individuals is an arbitrary rule, made by some committee in the early days of the prizes. Actually, Alfred Nobel's will had in mind only one person per prize. So be grateful that the current limit is at least three, not one.

61. **Tom**

October 11, 2013

An essay by Sean Carroll a couple days ago, criticising the Nobel practice of restricting prizes to maximum of 3 people:

http://www.nytimes.com/2013/10/09/opinion/no-physicist-is-an-island.html
"No Physicist Is an Island"

62. **Peter Woit**
October 11, 2013

Looking at Nobel's will on the Nobel website, it states that the prizes are for

"those who, during the preceding year, shall have conferred the greatest benefit on mankind."

then going on to specify that the benefit to mankind he had in mind was a discovery in physics, chemistry or medicine, or a work of literature, or peace-making. From this, the ATLAS/CMS collaborations would fit precisely the terms of the physics prize, since they had the most important discovery in physics in 2012. Englert and Higgs don't fit at all, since their work was not last year, but 48 years ago, something completely different than what Nobel had in mind.

It is in the later specifications that "person" in the singular is used. This was violated long ago by the decision to allow prizes for three people in the scientific fields, and organizations in the peace prize. I don't see how allowing a prize for a collaboration of scientists is any more a violation of Nobel's intent than the current rules. So, arguments that it is Nobel's will that is the problem here just don't hold water.

The problem with not allowing prizes to collaborations is that it rules out many parts of experimental science, only allowing prizes when experimental collaborations are organized by having an identifiable "leader" (or, up to three of them). Having a system where large parts of the experimental side of science become ineligble for the prize I doubt is what Nobel intended. There's also no reason to believe that he felt that experiments needed to have a "leader" who would be the one to get prize recognition. On the whole, arguments against giving prizes to collaborations seem to be coming from theorists, who, since they work alone or in small collaborations, have obvious reasons to prefer a system where their form of organization is the one to be rewarded.

63. **Gog the Mild**
October 11, 2013

Apologies if this has already been mentioned, but apparently Professor Higgs learnt about his award from a neighbour in the street. BBC – http://www.bbc.co.uk/news/uk-scotland-24493400 . This also has some quotes regarding his take on allocating credit for the theory.

64. **will**
October 11, 2013

There are many ways one can read Nobel's will. That's how lawyers make their money after all … Thomas Edison probably conferred more benefit on mankind than any winner of the physics prize, yet Edison never won (and quite likely was never nominated). The invention of the incandescent lamp (aka "light bulb"), the phonograph, electric utility company (was it in Menlo Park? I think his lab was there), many other things. Steve Jobs also conferred great benefit on mankind and also deserved to win, and most likely Jobs was also never nominated.

Fritz Haber did win, for chemistry, for his invention of the Haber process (today the Bosch-Haber process) to fix nitrogen from the air to make ammonia. It is an important industrial process for the chemical (or fertilizer) industry. It also enabled Germany to fight WW1 (because the British had blockaded supplies of saltpeter from Chile). Was Haber's work a benefit to mankind? I believe Haber won a Kaiser Wilhelm Medal for his services to the German war effort (and he was shocked when he was later dismissed from his professorship because he was a Jew). But the Bosch-Haber process is to this day an important industrial process.

I think no one would argue that awarding the Nobel Prizes (in the sciences) to collaborations violates the spirit of Nobel's will. Also the restriction to three individuals.

Basically, it boils down to the concept of how science was practiced in Nobel's day. The rules were formulated within the paradigm of how scientists practised research in those days. Who would have dreamed in those days that physics experiments would take years to plan and build and cost billions and require teams of thousands? And who knows how science will be practiced a hundred years from now? I can easily imagine that significant contributions will be made by robots or suchlike, and there will be debates as to whether the prizes should be awarded to robots. A robot might even make the critical discovery, in some team. Who can say?

65. **Marty**
October 11, 2013

Bernhard and Marco,

Thank you for your perspectives. Both of you seem to take the Nobel Peace prize as a precedent for awarding a prize to group. Maybe that is a reasonable model for rewarding collaborations. It would certainly be desirable and appropriate to somehow recognize the significant achievement of the detector teams in finding the Higgs, beyond an "honorable mention" in a paper by the committee that discusses this year's award.

However, it still seems that awarding the physics prize to Atlas+CMS would require a significant departure in thinking about what a Nobel in science signifies. I interpret Peter's helpful quote from Nobel's will, *"those who, during the preceding year, shall have conferred the greatest benefit on mankind"* (ignoring the "preceding year" part), as an intent to reward the person (now "no more than three people") who made the discovery, i.e., a collection of identifiable individuals. But this interpretation doesn't seem to match my understanding of what Bernhard was thinking, which was that one should think of the collaborations as abstract institutions that made the key discovery rather than a set of individuals each of whom individually deserves 1/6000 of the prize.

The peace prize is qualitatively different from the science prizes, which I think should be assessed before using it as a model for rewarding a scientific collaboration. For example, peace itself is an idea rather than an objective condition (a police state may look outwardly "peaceful" even though its citizens may live in constant fear), and the best way to achieve it is very subjective (e.g., "peace through strength" versus peace through respect and accommodation versus …) and hence intrinsically political. Scientific discoveries, however, must be very concrete to earn a Nobel. I would have thought that rewarding an organization for promoting peace also makes sense when that organization is a group of highly motivated individuals working toward a common goal (and often at significant personal risk), but it's hard to see how the award to the EU is consistent with that viewpoint, given that (in my understanding) many EU citizens strongly dislike the institution…

One way to continuing the tradition of awarding Nobel prizes in science to individuals, while also accommodating the growing importance of large collaborations in bringing about significant scientific discoveries, is to create a new prize (not necessarily awarded annually) for that purpose. Such a prize could be for all of the sciences where Nobels are currently awarded so that, say, physics could get it one year, medicine another year, etc. Not that anyone is likely to care that I think this could be a good idea…

66. **Marty**
October 11, 2013

Oops, a bit of vagueness slipped into my last paragraph. The “new prize” I was suggesting would be specifically for rewarding scientific collaborations.

67. **Shantanu**
October 11, 2013

Btw, first time I checked publication list of Higgs on inspire and didn’t know that in 60’s and 50’s he also worked on GR and canonical formulation (or something like what people working on LQG do nowadays). Didn’t see this mentioned in any news articles.

68. **Uninvolved Swede**
October 12, 2013

According to Swedish media the delay was caused by internal debate on whether to also reward CERN, which they decided not to since organizations are not eligible according to current Nobel Foundation by-law. Though, I suspect they will change that relatively soon. The speculation in the comments here about European bias is rather silly, if there is any at all (which I highly doubt) I suspect there would be just as much anti-European sentiment as anti-American here in Sweden. (Despite efforts by the EU most people here still think of themselves as Swedes or Scandinavians rather than Europeans.)

69. **Peter Woit**
October 12, 2013

Uninvolved Swede,

Thanks. The conjecture of a possible award to CERN as the third winner makes a lot of sense. It would explain why the detailed history has so much about CERN and the LHC experiments, why a third place was left open when it could have been given to Anderson, why there was lengthy discussion that morning making a delayed announcement necessary, and why there is explicit mention of the experiments in the citation.

70. **Peter**
October 15, 2013

A quote in the APS News (Oct. 2013) article about the demise of SSC 20 years ago.

– Among the most vocal detractors was Nobel Laureate Philip Anderson, a condensed matter physicists who bemoaned “the almost irrelevance of the results of particle physics not only to real life but to the rest of science.”

71. **aps news**
October 16, 2013

To put a more positive spin on things, read the poem in APS News bottom p4
http://www.aps.org/publications/apsnews/201310/upload/October-2013.pdf

72. **Bernhard**
October 17, 2013

Joao Magueijos (Imperial College) has a rather aggressive anti-Nobel opinion.

http://www.publico.pt/ciencia/noticia/o-nobel-da-injustica-1609163

The article is in Portuguese, but worth reading it with google translate (not too bad):

I translated two paragraphs here:

“Nobody likes to be accused of being a bad loser, but sometimes true courage lies in having the courage to criticize when you lost. The Nobel Prize has long since lost touch with reality, specifically in physics. Science is an increasingly collaborative and collective effort, even in the theoretical areas. Where the contribution of each one begins and ends is becoming increasingly less obvious.”

And:

“One conclusion we can draw from all this: the Nobel Prize, with its anachronistic rules, is unable to represent fairly the nuances and historical details of any scientific discovery. What happened to my colleague (Kibble) is a tremendous injustice, and worse it will be when the prize is awarded to the scientists at CERN , where the Higgs particle was detected. Thousands of people from over 100 countries contribute, but then only the leaders will receive recognition, as it is tradition in these cases. As a rule, these leaders are more politicians than scientists. There are even those who say they are the worst representatives of these huge groups, invoking the quote “shit rises to the top”. If the Nobel Foundation did a raffle between the doctoral students, there would be more integrity.”

73. **shinosuke**
October 20, 2013

With all due respect to Phil Anderson, to whom my discipline, Condensed Matter Physics, owns a great deal (and I certainly believe that he deserves more than one Swedish prize), I find a strange kind of “symmetry” with Anderson failing to get the 2013 Nobel together with Higgs and Brout and the case of Jaques Friedel in 1977.

Indeed, that year Anderson got the Nobel together with van Vleck and Mott “for their fundamental theoretical investigations of the electronic structure of magnetic and disordered systems”. In Anderson’s case, besides his famous work on localization in disordered semiconductors, the mention is also for another of his important contributions, namely the “Anderson model”. The latter describes the behavior of a magnetic impurity in a metallic host. The model was mathematically described and solved (within a mean-field approximation) by Anderson in Phys. Rev. 124, 41–53 (1961).

It might be not known to many in the HEP community, but the mechanism that the model captures had been described much earlier (with words, but in detail) by Jaques Friedel in Can. J. Phys 34, p. 1190 (1956). It is hard to believe that Anderson was not aware of Friedel’s work since, at the time, the number of Physicists working on Solid State problems was rather small and they met regularly. But to his own merit, Anderson was the first to formulate these ideas mathematically, thus lying the foundations of fields such like the so-called Kondo problem, Heavy fermion materials, and other strongly correlated electron phenomena. Of course, it would have been nice to have seen the Nobel committee change the rules back in 1977 and expand the number of winners from three to four or even more… but where is the limit?

Latest From Langlands

October 11, 2013
Categories: Langlands

Robert Langlands will be speaking at Yale in a couple weeks at a day-long Mostowfest of lectures in honor of Dan Mostow. His title is "The search for a mathematically satisfying geometric theory of automorphic forms" and he has already posted some notes for the lecture. A much longer set of reflections on the same topic was finished late last year and published in a volume in memory of Jonathan Rogawski. It's available at the IAS Langlands site as A prologue to functoriality and reciprocity: Part 1. There's no part 2 yet, but an earlier version of the full document is here, based on some lectures by Langlands in 2011 at the Institute, one of which is available on video here.

In all of these, Langlands is struggling with various ideas about "geometric Langlands", meaning analogs of the Langlands program in the case of Riemann surfaces instead of number fields or function fields (functions on a curve over a finite field). One approach to this question, starting with Beilinson and Drinfeld around 25 years ago, has been extremely active and I've often written about this here. For the latest from this point of view, you can consult Dennis Gaitsgory's web-site here. Langlands doesn't find this often very abstract point of view to his taste, so has been trying various more concrete things. In particular, he's quite interested in the connection to quantum field theory. I don't think he's actually found a satisfying line of attack on this problem, but it's fascinating to see what he's thinking about. There are all sorts of very deep questions in play here about the relationship of quantum field theory, representation theory, number theory and algebraic geometry. Langlands himself describes what he has as just "still provisional reflections on the geometric theory", and says about his upcoming lecture:

> The best I can offer in the way of a geometric theory with which I would be pleased is a sketch of the principal difficulties to be overcome. There are many. The importance for me is the very strong analytic flavour of the theory I hope to construct or see constructed.

Comments

1. **lazy eye**
   October 12, 2013

   Do we know what exactly Gaitsgory et al. have achieved in the direction of geometric langlands ?

   On an other topic : I hope we will soon get a "latests from ABC" post, I think i'm not only speaking for myself when I'm saying that its crazy that we have no information whatsoever on how the reading of the proof is going !

   Love your blog !

2. **Peter Woit**
   October 12, 2013

   lazy eye,

   Glad you like the blog!

   The latest from Gaitsgory et al. on geometric Langlands that I know about is this
   http://arxiv.org/abs/1302.2506
   which outlines a proof of the "categorical" version of geometric Langlands, for the case of GL(2). There is a school on the topic planned for Jerusalem in March
   http://www.math.harvard.edu/~gaitsgde/School14/
   This has become a large subject though, and there may very well be more interesting things going on using these ideas than that focused on the conjectured equivalence of categories.

   Unfortunately, from the QFT point of view, I don't think there's much activity.

   On Mochizuki, I think the situation remains that most experts have given up as hopeless the task of making their way through the details of his papers. He has a relatively new "panoramic overview of Inter-universal Teichmuller Theory"

   http://www.kurims.kyoto-u.ac.jp/~motizuki/Panoramic%20Overview%20of%20Inter-universal%20Teichmuller%20Theory.pdf

   but I think this doesn't provide the kind of detailed outline of a proof that experts are looking for.

   One interesting question I don't know the answer to concerns the status of refereeing of Mochizuki's papers. I've heard rumors some of them have been submitted for publication, haven't heard what happened. It does appear that he has been going through them with the help of Go Yamashita and others, checking things and making periodic revisions, see
   http://www.kurims.kyoto-u.ac.jp/~motizuki/news-english.html
   It's undoubtedly a problem to find referees who feel competent and willing to go through the papers and understand exactly what is going on well enough to judge whether the details were correct.

Last Links For a While

October 20, 2013
Categories: Uncategorized

In a few days I'm heading to East Africa for a couple-week long trip, planning to be in Uganda on November 3 for the (short) total solar eclipse that day. This will be followed by a few days in London, then back here with regular programming resuming around November 11. While away I'll shut off the commenting system, since I'm hoping to not have internet access during most of the trip.

Here's some short items that might be of interest:

- For the latest from CERN about SUSY, see this overview from ATLAS. The bottom line is quite simple: zilch, in every channel examined. Limits on a gluino mass are about 1.2 TeV, and there seems little prospect of much change until 2015, when results at 13 TeV start to come in. A naive extrapolation says that ultimately the LHC should be able to set limits on gluino masses of up to 2 TeV. Pre-LHC, the limits were about 300 GeV (from the Tevatron). I don't know anyone who is optimistic that it will turn out that the 62.5% energy jump in 2015 will find something when the 400% energy jump didn't (and the theoretical arguments for SUSY implied that it should have already been seen at the Tevatron).
- Steven Weinberg has an article about the current state of cosmology and particle physics, entitled Physics: What We Do and Don't Know. About string theory he has this to say:

  > String theory is attractive because it incorporates gravitation, it contains no infinities, and its structure is tightly constrained by conditions of mathematical consistency, so apparently there is just one string theory. Unfortunately, although we do not yet know the exact underlying equations of string theory, there are reasons to believe that whatever these equations are, they have a vast number of solutions. I have been a fan of string theory, but it is disappointing that no one so far has succeeded in finding a solution that corresponds to the world we observe.

  The main reason for disappointment about string theory is not that a solution corresponding to the SM hasn't been found, but that the theory predicts nothing at all. All indications are that the dead end that string theory has hit is not that (if one could actually figure out what the theory is…) of no SM solution, but that of so many solutions that you can get anything you want. Unfortunately Weinberg seems to be of the "if a fundamental theory predicts nothing, that's too bad, but maybe how the world works" camp, rather than the more standard "if a fundamental theory predicts nothing, it's a bad fundamental theory" camp. He goes on to argue that we may have to just give up on fundamental physics and be content with this theory that predicts nothing:

  > Such crude anthropic explanations are not what we have hoped for in physics, but they may have to content us. Physical science has historically progressed not only by finding precise explanations of natural phenomena, but also by discovering what sorts of things can be precisely explained. These may be fewer than we had thought.

  Back in 1977, in the wake of the great advances of the Standard Model, Weinberg famously made the statement that:

  > The more the universe seems comprehensible, the more it also seems pointless.

  Presumably the universe is still pointless, but now the argument seems to be that it's also incomprehensible.

- Unlike Weinberg, Frank Wilczek hasn't been a fan of string theory. From a recent interview:

  > 3. Is String Theory a dead end? Is there news coming, regarding scientific advances, or experimental confirmations?
  >
  > Many very smart people continue to work on string theory, and I expect that they'll continue to do interesting work, in mathematics if nothing else. Whether they'd be more productive doing something else, is another question. It is unfortunate that in the early days people got carried away, and promised much more than the theory
  > could reasonably be expected to deliver.

  and about anthropics:

  > It is the scope of anthropic reasoning that's debatable. I hope we can avoid appealing to it very much in fundamental physics, but time will tell.

- According to the Stony Brook newspaper though, based on information from Michael Douglas, all is well with string theory:

  > String theory has done quite well so far in explaining all of the forces of the universe. The theory has matured, and so have the mathematical equations it has produced. An equation describing the universe is considered successful if it is symmetrical. What that means is if the equation is taken apart and its components rearranged, it should still produce the same conclusion. If the rearrangement of an equation does not yield the same result, it is deemed unstable and not a good descriptor of the universe or its forces.
  >
  > The equations that have stood up to the test of symmetry have predicted the existence of particles that help bridge the gap between general relativity and quantum field theory. For example, string theory predicts a particle called the graviton, thought to be a closed loop string that is responsible for the gravitational force…
  >
  > Gravity is weak.
  >
  > String theory not only predicts the particle that constitutes gravity, it also helps describe why it is so weak…
  >
  > Currently, the ability to test the predictions from string theory is very limited and some have said that this roadblock is impossible to overcome.
  >
  > Douglas thinks otherwise.
  >
  > The next phase of this theory will likely take a lot of hard work and fresh ideas. String theory has made enormous strides in the relatively short amount of time that it has been around, and it is thought by many to be the most promising of the so-called "theories of everything."
  >
  > In a few more years, who knows what exciting advances could be in store?

  The article doesn't mention Douglas's decision to stop working on string theory and go to work for a hedge fund.

- The Financial Times has its own take on the current state of fundamental physics research, with an article on The new physics.
- Also at the Financial Times is a good survey of Physicists and the financial markets, describing various current activities of physicists now working in the financial industry.

- Harvard University Press has just released a new book by Steve Nadis and S.-T. Yau, a history of the Harvard math department entitled A History in Sum: 150 Years of Mathematics at Harvard. It concentrates on the period 1825-1975, and I enjoyed it quite a bit. It ends right about the time I arrived there as a student, so covered history that I never had known much about.

  Harvard's role as a mathematics research institution began with Benjamin Peirce, who taught there from 1831-1880. It only started to become a world-class institution around 1900, with young faculty who had gone to Germany for their training. The book covers a fairly long list of great 20th-century Harvard mathematicians (including George David Birkhoff, Morse, Whitney, MacLane, Ahlfors, Gleason, Mackey, Zariski, Brauer and Bott), and makes a serious attempt to explain some of the mathematical ideas they developed. As a result, a large part of the book is not just history, but actual exposition at a popular level of a wide range of mathematics, together with quotes from many other prominent mathematicians about the significance of the ideas.

  If you're interested at all in the history of mathematics, this book is well-worth finding a copy of.

- David Appell has an article about the SSC, the major disaster for US HEP research. Next year should see a book on the topic by Michael Riordan, *Tunnel Visions: The Rise and Fall of the Superconducting Super Collider*.
- The Simons Foundation Quanta magazine continues to put out many high quality stories about science, with one of the latest an article by Natalie Wolchover about experiments searching for neutrinoless double beta decay, which would indicate a Majorana neutrino mass term.
- The SETI institute has a series of SETI Talks, available on YouTube, with the latest featuring Joe Polchinski on Black Holes and Firewalls.
- The Boston area Joint Math Colloquium this week with have Edward Frenkel speaking on The Langlands Program and Quantum Physics. Afterwards you can go up to Harvard Square and get him to sign a copy of his new book.

   "The main reason for disappointment about string theory is not that a solution corresponding to the SM hasn't been found, but that the theory predicts nothing at all. "

   His disappointment, or yours?

2. **Peter Woit**
   October 20, 2013

   Visitor,
   I don't think it's just my opinion that string is disappointing because it can't predict anything. Surely Weinberg would also agree this is a cause for disappointment. I'd be curious what he thinks though of the possibility of a string theory landscape that has a SM solution, but so many others that one can't extract a prediction about anything out of it. Would the existence of this SM solution remove the disappointment, and he would then be happy with a non-predictive theory? I kind of doubt it.

   This is the problem with the point of view he's selling at the end. If you have a testable theory that predicts that certain parameters (e.g. the CC) are enviromental, that's one thing. But an untestable theory that predicts nothing is a different story, and can't be saved by trying to argue that all the things one might hope to use as tests are just environmental. Right now string theory is in the second category, with no prospects for entering the first.

3. **johnnythelowery**
   October 20, 2013

   Going to Africa?: There is a great series on Netflix which aired in the UK on TV called 'Long Way Down' where two guys (one, an actor you might know—Star War's Ob1kenobe) ride motorcyles from top of Scotland to Cape Town. It presents a videoblog view of the various countries of Africa and the topology of the various countries. The series is different than anything before about Africa. Eye opening.

4. **johnnythelowery**
   October 20, 2013

   You say String theory predicts nothing at all, which is a fascinating observance. but see here in the same posting; Douglas claim's that it predicts the Graviton? So, there seems a conflict with your preposition.

5. **Peter Woit**
   October 20, 2013

   johnnythelowery,

   I'll just quote Lisa Randall about that prediction: "yes, string theory predicts gravity, ten-dimensional gravity…"

6. **Yatima**
   October 21, 2013

   I feared that "Physicists and the Financial Market" would be enragingly content-free with "physics!!" mysticism, Physics Envy and the obligatory mention of "black swans" but it's actually a nice introduction.

   Oxford university's J Doyne Farmer builds "Crisis": *The project is an attempt to do in economics what is common in physics, to build an agent-based model not from a mathematical formula or theory but from the ground up, by simulating the interactions of all the component parts. "The failure to embrace things like simulation has inhibited progress in economics," Farmer says. "Physics, meteorology, chemistry, biology, even other branches of social science have got major impetus because of serious use of computers as a simulation tool."*

   It's about time, but it has as much to do with physics as does simulation of large-scale neural networks: which is to say nothing at all, except that papers may exhibit differential equations. However, I fear that the model will be "value-neutral" and not factor in things that traditionally make the worst rise to the top. A EU-financed project that models "political entrepreneurs" who wreak havoc while selling crony-capitalist enrichment schemes in the nice flashy box of "Keynesianism"? A *likely* outcome.

7. **morris**
   October 21, 2013

   Peter Woit,

As an aspiring physicist, born and currently living in Nairobi, Kenya am excited to hear of your planned trip to East Africa. If you do happen to pass through Nairobi, a group of us, currently studying at Nairobi University would be happy to meet and show you around. We would be honoured to meet a practising physicist at the frontier of knowledge. Your blog has been an inspiration to most of us young aspiring theoretical physicists. Karibu East Africa.

8. **Bee**
October 21, 2013

It's not that string theory doesn't predict anything. At the very least it predicts string excitations. It's just that the things that it does reliably predict aren't presently possibly to test experimentally. Alas, the same could be said about pretty much all other approaches to quantum gravity. The reason people are 'disappointed' is not that it's a bad theory, but that it's been oversold. The pendulum will swing again once people notice that LQG also doesn't 'predict anything'… And then they'll all end up doing qg phenomenology :p

Have a safe trip 🙂

9. **vmarko**
October 21, 2013

Bee,

"The pendulum will swing again once people notice that LQG also doesn't 'predict anything'…"

My guess is that the majority of us already know this. The difference is that nobody is trying to advertise LQG as a "theory of everything", "the only game in town", "*the* solution of the QG problem" etc. 🙂

Best, 🙂
Marko

10. **vmarko**
October 21, 2013

Peter,

"The main reason for disappointment about string theory is not that a solution corresponding to the SM hasn't been found, but that the theory predicts nothing at all."

I have noticed lately that people working in string theory have changed their opinion on what ST actually is — it is a *formalism*, rather than any particular theory. In a sense, they now consider ST on par with QFT, which is also just a formalism, and has no serious predictions to give by itself. The word "theory" in the name of both is a misnomer.

Only when one specifies a particular landscape solution in ST, or a particular gauge group and a set of fields in QFT, does one get a theory (or more precisely, a model) that has some concrete predictions.

This change in the point of view by string theorists apparently does away with the "no predictions" criticism — namely, now ST is not even *supposed* to give any predictions, until one provides additional input which picks a particular model within ST. As far as I can see, this new point of view actually makes some sense out of ST. What's your opinion on this?

Best, 🙂
Marko

11. **Avattoir**
October 21, 2013

Is there an equation that predicts the chances of a blog becoming invaded by Von Misians?

12. **Jason Starr**
October 21, 2013

You misspelled "Peirce".

13. **Peter Woit**
October 21, 2013

morris,

Thanks so much for the offer! I wish I could take you up on it, but unfortunately the only time I'll be able to spend in Kenya this trip will be changing planes in Nairobi airport.

14. **Peter Woit**
October 21, 2013

Thanks Jason, fixed.

15. **wolfgang**
October 21, 2013

>> when results at 13 GeV start to come in
I assume you mean 13TeV ?

16. **Per Östborn**
October 21, 2013

You often hear that QFT and string theory are analogous frameworks or formalisms, that none of them are predictive theories per se. I'm an outsider to the field, and Peter may be tired of the entire discussion, but I try to orientate, and I wonder if the following fundamental distinction is proper:

in the QFT approach you build a theory step by step by adding fields, altering the gauge group, and so on. At each step in the construction you may have a unique theory that makes unique predictions what to see and not to see in the next experiment. If this experiment does not agree with the theory, you just add another building block, or adjust parameters.

In contrast, in string theory you begin with a unique theory (ideally), having a vast, possibly infinite number of solutions. Each new experiment makes it possible (in principle) to exclude large chunks of solution space, but regardless how many experiments you make, there may still be so many solutions left that conform with all experiments so far that the outcome of the next experiment is not restricted at all. In this sense string theory may therefore forever lack predictive power. You may have to make an infinite number of experiments to nail the correct solution.

17. **fuzzy**
October 21, 2013

among the various opinions on string theory, i think that it should be fair to remind those of glashow's and feynman. maybe, one could admit that these chaps have been much more long-sighted of those who needed the lhc, before they can begin to think …

(enjoy your travel, peter!)

18. **Kent**
October 21, 2013

Thanks for the links, Peter.
There is enough reading material linked to here that it will keep me busy for the two weeks you are offline.

19. **Peter Woit**
October 21, 2013

wolfgang,
Thanks! Fixed.

vmarko,
This is an FAQ, I really need to get back to updating the FAQ I started for the blog, maybe later today..

Also an FAQ to put in the answer to is my response to claims like the one Bee mentions about seeing string states as a prediction. Very short version: what about M-theory?

20. **Michael Zeiler**
October 21, 2013

Peter, good luck on eclipse day. I'll be in Gabon. Lots of eclipse maps, including detail maps for Uganda, are on my web site at http://eclipse-maps.com/Eclipse-Maps/Gallery/Pages/Annular-total_solar_eclipse_of_2013_November_3.html For those in the eastern US/Canada/Caribbean, you also get a good show – a partial solar eclipse at sunrise. Details at http://eclipse-maps.com/Eclipse-Maps/Gallery/Pages/Annular-total_solar_eclipse_of_2013_November_3_files/HSE2013_Americas.png

21. **Bernhard**
October 21, 2013

vmarko,

Here is an old comment from Peter, that I believe addresses your question, to some extent:

http://www.math.columbia.edu/~woit/wordpress/?p=4065&cpage=1#comment-98564

22. **vmarko**
October 21, 2013

Bernhard,

Thanks for the link! It took a bit of time to read up the context of that conversation, but now I see. That Peter's comment should really be put into the FAQ.

Best, 🙂
Marko

23. **P**
October 21, 2013

Hi Marko,

Your comment is quite reasonable, though I think it's safe to say that this isn't really a new perspective.

The hope in the 80's was that there would be a unique string vacuum. Now we know there is a landscape of string vacua — each vacuum comes with a low energy effective action, and things like the gauge symmetry, spectrum, can be computed. People have been viewing the situation this way for at least ten years.

Cheers,
P

24. **Tim May**
October 22, 2013

Good luck on your trip!

I'm enjoying the book you recommended, Frenkel's "Love and Math." Some very nice explanations of some abstract math. (As a kid, I loved Gamow's "One, Two, Three…Infinity" and books of that type. So books like Frenkel's are a real treasure.)

I'm slightly less negative about string theory in recent years. I started reading your blog, and then your book, after finding a lot of the string theory, M-theory popular accounts way too "hand-wavy."

Also, the hype about string theory seems to have lessened a bit. Unfortunately, the hype deficit seems to be made up for with the hype about the multiverse.

Nevertheless, I'm looking forward to going to Lenny Susskind's talk on black holes tomorrow (Tues, 4:15 pm, see site for details) at Stanford. He's a great speaker, most would agree, and his recent work on the AMPS conjecture doesn't veer off much into the multiverse stuff.

–Tim May, California

25. **Peter Woit**
October 22, 2013

I've added quite a bit more material to the "Frequently Asked Questions" part of the blog, some of which addresses the question from vmarko, as well as Bee's comment about string theory being predictive at high energy.

26. **Simple biologist**
October 22, 2013

Peter,

the new FAQ "Doesn't string theory make predictions at very high energy?" has a broken link.

Link on the the words "see this posting" doesn't work.

27. **Peter Woit**
October 22, 2013

Simple biologist,

Thanks! fixed.

28. **Bernhard**
October 22, 2013

There is another broken link on "Where and when did news of the Higgs discovery first appear?" (the first one).

Also, on "Why do you say string theory is unfalsifiable? Doesn't it predict quantum mechanics?" maybe you could link also to this comment:
http://www.math.columbia.edu/~woit/wordpress/?p=5358&cpage=1#comment-136521

It is the same thing you are saying on the FAQ, but I personally prefer your choice of words on the comment: "The falsifiability criterion is intended to refer to distinctive aspects of a theory that differentiates it from others, not generic properties common to all known theories."). In fact this whole post + comments are relevant to someone looking into this.

29. **Peter Woit**
October 22, 2013

Thanks Bernhard, I've taken your suggestion.

30. **vmarko**
October 22, 2013

Peter,

"I've added quite a bit more material to the "Frequently Asked Questions"…"

It's a good read, thanks!

P,

"People have been viewing the situation this way for at least ten years."

Indeed, as I have just figured out by reading through oldish blog discussions. 🙂 Apparently this is news only to me. 🙂 I've known about the landscape problem for a long time, and I figured that it was a problem that needed to be solved for ST to work. But only recently have I heard that the "landscape problem" was spinned as a "landscape feature" of ST (outside of the context of multiverse&antropics, that is).

Apparently I am not socializing with enough string theorists to be in touch with old news. 😉

Best, 🙂
Marko

31. **James**
October 23, 2013

While you are in Uganda, you should definitely try make it down to see the Mountain Gorillas in the Virunga Volcano region. (if not in Uganda, then just across the border in Rwanda, where I saw them, and I have heard is a better experience) It's the experience of a lifetime. The bus trip from Kampala is extraordinary in and of itself. You can, and I might advise to, make reservations ahead of time.

32. **Dan**
November 10, 2013

> I don't know anyone who is optimistic that it will turn out that the 62.5% energy jump in 2015 will find something when the 400% energy jump didn't

Well, after all the Higgs discovery at LHC needed a 10-20% energy jump from the previous LEP

It’s too soon to declare supersymmetry a tragedy

October 22, 2013
Categories: Uncategorized

Well, maybe one more before I leave…

Tom Siegfried, last heard from telling us that Belief in multiverse requires exceptional vision, now has two new pieces at Science News (here and here) arguing that the failure of the LHC to see SUSY is not really a big problem for SUSY proponents. You see, it’s only a problem if you believe physics theories should be simple and if you believe in naturalness. According to Siegfried, what the LHC is telling us is that you just have to give up on one of these, with your choices now:

1. Give up on simplicity. Just announce that SUSY is fine and solves the naturalness problem, but we’re not seeing it because it’s not the MSSM (which adds more than a hundred parameters), but something really, really complicated, so complicated that it manages to show up in such a way that the LHC experiments can’t see any evidence of it. Believe this, and you can still believe in SUSY, no need to face the tragedy of an idea you’ve done so much to promote getting killed by heartless experimentalists.
2. Give up on naturalness and have the exceptional vision to believe in the multiverse. Then you can fine-tune your SUSY particles up to very high energies and make them unobservable. Again, you’re free to keep believing in SUSY, writing articles and books about it, etc., despite the negative experimental results. The advantage of this option is that you don’t need to make your SUSY complicated, it can just be the MSSM, so you keep simplicity. Of course, once you accept fine-tuning, you could get a whole lot more simplicity really easily: just throw out SUSY and stick to the SM….

Comments

1. **Justin**
   October 22, 2013

   Woit,

   While I sympathize with you on supersymmetry, the death of the theory does raise an interesting question: if not supersymmetry, then what? So, if you were a young researcher who is tired of the obsessive pursuit of a theory which has been experimentally made very unlikely, then what might this student work on if he/she wants to do particle theory?

2. **Peter Woit**
   October 22, 2013

   Justin,
   That one’s a FAQ I don’t have time to write about now. And also, no satisfying answer. It’s not hard to come up with interesting things that we don’t understand about QFT, and personally I think we have just scratched the surface of the relation of QFT to mathematics, but there aren’t ideas around that give a clear path to making progress on getting beyond the SM. In general I think students have to rely on finding advisors who can guide them to interesting things to work on, but while doing this, best to be aware that this is now a difficult business and that lots of people don’t have any promising ideas to work on.

3. **svik**
   October 22, 2013

   Is not that the discovery “that all is fine tuned” and we don’t need the extra baggage.

   But what does it mean?

   Even predators and prey must be fine tuned to work as it does.

   Have a good trip. Watch out for the bugs. Keep small bill for bribes.
   My coworker was there a year ago…. building schools, etc.

4. **Shantanu**
   October 23, 2013

   Justin,
   As Peter recently mentioned its surprising why very few people are working on asymptotic safety. almost no one is working on QFT in curved space time. but probably there are more examples.

5. **Anon**
   October 23, 2013

   Hi Justin — The hierarchy problem is not the only challenge for particle physicists — for example there is the strong CP problem.

   There may be a larger lesson that LHC is teaching us – that the mainstream thinking among high energy physics community need not be natures thinking for addressing outstanding problems. Also that the mainstream thought process can be delusional.

   Thus putting the faith in SUSY for hierarchy and axions for strong CP, as the mainstream particle physics community does, may not necessarily be the direction a young and bold researcher should take today. Historically nature has not necessarily endorsed mainstream scientific thinking. Just because the present day particle physics appears mathematically more sophisticated, it doesn’t mean big names in the field aren’t being mislead and aren’t misleading.

6. **CU Phil**
   October 23, 2013

   FWIW, the recommendation given by some very well-regarded HEP faculty here to several very smart undergrads as they went off to grad school was “don’t do HEP theory”. So there’s that.

7. **Tom**
   October 23, 2013

   believe believe believe is the most used word … so why not believe in an old man sitting behind the clouds?

8. **vmarko**
   October 23, 2013

   This is, IMO, the most convincing argument for SUSY from Siegfried's article:

   "After all, isn't a supernova better than a nova? Supermodel better than a model? Superman better than Clark Kent?"

   Unbelievable.

   Best, 🙂
   Marko

9. **Peter Woit**
   October 23, 2013

   Thanks to all for the suggestions about the trip. Leaving soon, so will shut off comments for the duration.

10. **Kavanna**
    November 7, 2013

    "Super," indeed. Supersymmetry may yet be proved right, but implemented in some way, both the symmetry and its breaking, that we never thought of. Certainly, the whole approach so far has been driven by two considerations that might be a tad myopic: the need to solve the weak-grand/gravity hierarchy problem, and the assumption that everything is understandable in perturbation theory or extensions thereof.

    Maybe the hierarchy problem and grand unification are collaterally solved by something else that's driven by some other consideration, like the cosmological constant — just to pick something not completely random.

    It is good to hear that senior HE theorists are turning students away from string theory and related problems. Certainly, the way misguided senior theorists have dominated the field for the last 20+ years has been destructive. At this point, we should want only those few who are both really determined and not under the sway of a generation-and-a-half of failure. Those not interested in "high" theory should try astrophysics or something else where mind and sense are connected. Let's encourage everyone to leave the Platonic never-never land of mental masturbation.

11. **Kavanna**
    November 7, 2013

    P.S. I don't mean to denigrate mathematics with that final remark. Math doesn't have to be connected directly to counting and measuring in the real world. But as Peter has often pointed out, to qualify as serious, the math should be rigorous and precise, whether it has an obvious immediate application or not.

Back to the Usual

November 6, 2013
Categories: Uncategorized

I'm now back to regular internet access, in London for a few days after a trip to East Africa, where I managed to see the November 3 total solar eclipse through light clouds from a location in Northern Uganda. From checking various news sources, it looks like the main pieces of HEP-related news that I missed weren't very surprising:

- The LUX experiment reported stronger limits on WIMP dark matter, ruling out various claims for evidence of such dark matter particles at relatively low mass. For more about this, good sources are Resonaances, Matt Strassler, and Tommaso Dorigo.
- The $3 million Fundamental Physics Prize as usual identifies "Fundamental Physics" with string theory, with the announcement that the nominees for the 2014 prize are 5 string theorists (Polchinski, Green/Schwarz, and Strominger/Vafa). I confess that I can't figure out exactly how this prize process is supposed to work. The announcement says that the nominees get a "Physics Frontiers Prize", a shot at the $3 million, and

  > Those who do not win it will each receive $300,000 and will automatically be re-nominated for the next 5 years.

  What I don't understand is that Polchinski already got such a nomination and prize last year (and the $300,000 consolation prize for not getting the $3 million). It seems that he is getting another identical prize this year, with another $300,000 or $3 million. On the other hand, the only non-string theorists ever to win this prize (last year's condensed matter group Kane/Molenkamp/Zhang) didn't get a second one this year, and it's unclear if they still have a possible $3 million payday in 2014. Perhaps the rules are different for string theorists, the idea being that you just can't give too many prizes for string theory.

  I'll bet that Green/Schwarz will be the 2014 winners, on the grounds that if you're going to hand out lots of prizes for working on the superstring, its co-discoverers should be among the first in line. While this means that Polchinski will only get a second $300,000, it's in his interest to lose as many times as possible before winning.

  As for the $100,000 prizes for young researchers, this year was different than last year. The winners (Cachazo/Minwalla/Rychkov) were two Princeton Ph.Ds and one ex-Princeton post-doc, whereas last year is was one Princeton Ph.D and all three were ex-Princeton post-docs.

- In other news, Max Tegmark, known for his work on the multiverse, is running a "Project Einstein", which has found 400 theoretical physicists and mathematicians who have agreed to have their genes sequenced. The idea is that they are "math geniuses", but no one seems to know what will be done with the genetic data for these geniuses. It's unclear who these "geniuses" are, but we do know that one person who was asked and declined was Curt McMullen. His reaction to this project was what I suspect was a common one:

  > "I thought it was strange that it was called 'Project Einstein', which seemed designed to appeal to the participants' egos," he says. He asked the project's staff and the New England Institutional Review Board, which approved the study, to explain how results would be used. "The uniform answer to my questions was that 'we are not responsible for how the information is used after the study is completed'," he says.

  If Project Einstein identifies a common gene among its participants, and uses the knowledge to breed a race of übermenschen, they may find they have selected not for unusual mathematical genius, but for unusual ego.

Update: I realized there's one other remarkable thing about the six winners of the "New Horizons in Physics Prize". Besides all having a close Princeton connection, none of them has a job in the US. It seems US physics departments are not buying what Princeton is selling right now…

Comments

1. **svik**
   November 6, 2013

   I don't think there is a math gene(s).
   The common denominator is being unwanted and a social outcast, this causes us to turn to the love of math as an escape. Yes it is so with most scientists.
   ….
   Now if a math gene is found I support math men should only marry the sisters of other math geniuses. Then in 60 years we will have a new breed of mathies that can finally prove or revoke string theory. 🙂

2. **Kimmo Rouvari**
   November 6, 2013

   Automatic nomination for the next five years doesn't mean that the nominee will be automaticly among those three front runners.

3. **David M.**
   November 7, 2013

   Peter,
   About the Fundamental Physics Prize, I would definitely agree there is a Princeton/String theory bias, although I don't necessarily think that its a bad thing. I don't see anyone on that list who does not deserved to be honored. Their work is invaluable for our understanding of QFT and quantum gravity even if String Theory does not describe nature.

   My question to you is, who would you choose to be given such an award? I mean with the current purpose of the award, to honor physicists whose work is of paramount theoretical import, but may not be directly connected to experimental physics and/or is underappreciated by the general public.

   I don't ask this as a challenge, I'm not implying these are the only people who should be honored. I'm asking because when I think of people who should be given such an honor these are the names I would think of first and I'm genuinely curious.

4. **Peter Woit**
   November 7, 2013

   Kimmo Rouvari,

   Maybe you're right that's how it works. Kind of odd though, since anyone can nominate anyone on-line, being automatically nominated for five years isn't very meaningful. If that's how it works, one wonders why a non-string theory nomination was at the top of the list last year, didn't make it this year.

David M.,

One obvious name would be Roger Penrose's. He's the one responsible for the twistor techniques at the heart of the whole amplitudes business. Do you think hostility to string theory might have something to do with why he's not $3 million richer?

The overall problem with these prizes is that they are based on an extremely narrow vision of what "fundamental physics" is, both intellectually and geographically. Furthermore, this is a narrow vision that has been extremely unsuccessful over the past few decades, with one reason for its failures precisely this narrowness.

5. **Bee**
November 7, 2013

übermenchen -> übermenschen

6. **Peter Woit**
November 7, 2013

Thanks Bee, fixed.

7. **Armin Nikkhah Shirazi**
November 7, 2013

David M,

It seems to me that your perspective is so deeply entrenched in the current paradigm that the central issue escaped you completely. The issue does not center around whether the current nominees are deserving of honor or not but around the fact that the name of this award clearly would lead one to believe that it is given for major advances in fundamental physics, but that it is given in actuality only for major advances in just one subfield which, moreover, still awaits experimental confirmation; the prize is not what it purports to be.
Also, it seems to me that calling a string theory prize a fundamental physics prize is a slap in the face of all the theorists who have actually made what would be rightfully regarded as outstanding contributions in fundamental physics which happen not to be related to string theory (or only indirectly so). I think that instead of talking about these theorists in the abstract, it is more effective to actually name some of them, and indeed you requested a list of names.
So, with apologies to Peter here is my own subjective list of living non-nobel laureate theorists who I think would make terrible candidates for a string theory prize but outstanding candidates for a fundamental physics prize (I almost certainly omitted many other highly deserving physicists but that would only further make my point):

1. Freeman Dyson (Many contributions)
2. Roger Penrose (Many contributions)
3. George Zweig (Independent discovery of quarks)
4. Jim Peebles (Prediction of CMB)
5. George Sudarshan (Sudarshan-Glauber P representation, Quantum Zeno effect)
6. Yakir Aharonov (AB effect, Weak Measurement Theory)
7. Simon Kochen (Kochen-Specker Theorem)
8. John Clauser/Michael Horner/Abner Shimony/Richard Holt (CHSH inequality)
9. Gerald Guralnick/ Carl Richard Hagen /Tom Kibble (Higgs Mechanism)
10. Jeffrey Goldstone (Goldstone theorem)
11. N. David Mermin/Herbert Wagner (Mermin-Wagner Theorem)
12. Ludvig Fadeev (several eponymous results in QFT)
13. Hagen Kleinert (significant expansion of domain of applicability of path integrals)
14. Rudolf Haag (Haag's theorem)
15. Martin Reese (Cosmology)
16. Jakob Bekenstein (Black Hole Thermodynamics)
17. William Unruh/Paul Davies/ Stephen Fulling (Unruh Effect)
18. Richard Arnowitt/ Stanley Deser/ Charles Misner (ABM Formalism)
19. Yoshio Koide (Koide formula)
20. Toichiro Kinoshita (precision QFT computations)

I'll let you compare this list with that of the current nominees and draw your own conclusions.

8. **A String Theorist**
November 7, 2013

You write "It seems US physics departments are not buying what Princeton is selling right now" but I think you have it completely backward. To my personal knowledge most (perhaps all?) of the winners had job offers in the US, but the landscape (no pun intended!) has really changed in recent years. Frankly, there is very little that US academic institutions can offer compared to many of the top places outside the US. Considerations across the board, from salary, to research support, to funding possibilities, to the quality of available graduate students and postdocs, to the increasing ability of young researchers to stay in their home country (if they choose to), lead many to the conclusion that the US is certain no longer "the place to be" for theoretical physics. As a theoretical physicist as a US institution, I'm happy that great opportunities are becoming available outside the US, but on the flip side I'm saddened to see the decline in the US.

9. **Philip Gibbs**
November 7, 2013

Armin Nikkhah Shirazi, your list includes many great achievements but the rules insist that the prizes "Should recognize major achievements, with special attention to recent developments." I don't see anyone on your list whose work is both major enough and recent enough compared to those recognised so far.

10. **jim**
November 7, 2013

The thinking motivating "Project Einstein" is the reason you never let theorists touch your equipment.

11. **Kavanna**
November 7, 2013

Armin's list is great and shows that, while Nobel Prizes can recognize greatness, they just as often miss it, for whatever reason. A classic fun game is to name the great writers who didn't receive the Literature Prize.

US physics departments are not buying what Princeton's selling — a correct statement for the last 5-6 years. It's not just opportunities opening up elsewhere; those have been there for a while. Thankfully, US physics faculties are no longer scrambling for crumbs from the Princeton table. Better late than never.

12. **Kris Krogh**
November 7, 2013

Philip Gibbs,

"I don't see anyone on [Armin Nikkhah Shirazi's] list whose work is both major enough and recent enough compared to those recognised so far."

Are you familiar with Aharonov's work? It's true the AB effect is not recent, but his work on weak measurements is, and is currently having a major impact.

13. **Armin Nikkhah Shirazi**
November 7, 2013

Hi Phil,

Well, what does the statement "Should recognize major achievements, with special attention to recent developments" actually mean? It seems to me that under a liberal interpretation, one could, for example, even take Dyson's contribution from the late 1940's to be a major achievement "with special attention" to the discovery of the Higgs boson. The nobel committee certainly had no qualms about considering a theoretical discovery made almost 50 years ago as compatible with the specification in Alfred Nobel's will that the prize be awarded to "those who, during the preceding year, shall have conferred the greatest benefit on mankind."

But, let me not play this game and just partially agree with you. I think that some, but not all, of the achievements may be difficult to square with a reasonable interpretation of that (in my opinion highly ambiguous) sentence. However, even then I don't see how your argument challenges the point that what is being called a fundamental physics prize is in reality a string theory prize, unless you are suggesting that the only recent significant theoretical discoveries come excusively out of string theory. I hope that is not what you mean to imply, for if you do, then it reflects that you are just as guilty of the narrow vision and-pardon me for expressing this because I truly have great respect for you-hubris as what allowed something like this to happen in the first place.

14. **Jeffo**
November 7, 2013

Based on the picture accompanying the Nature article, I'd say it's more urgent that we identify the "bad-fashion-sense" gene!

15. **David M.**
November 7, 2013

Armin,
In your original list I do agree that many physicists you mention deserved to be honored, but like Phil mentioned they did their most important work a while back, pre 1980s typically. I know there are plenty of people out there who deserved a nobel but thats outside the parameters of the debate. And there are physicists who deserve to be honored for important work done in the past 30 years, Mikhail Shifman, Randall & Sundrum, and Xiao Gang Wen come to mind. I said the people listed were the first to come to mind not the only ones!

I also have to say I disagree with the characterization that US institutions are some how no longer hiring people from princeton. If you check out the particle theory rumor mill for 2013 you'll see that 7 people offered jobs either got their Ph.D at Princeton or did a postdoc there. Thats out of 17 so ~41%.

16. **Philip Gibbs**
November 7, 2013

Whoa Armin! You are putting an awful lot of words in my mouth. I never said or implied anything about whether the current distribution of prizes is too narrow.

I do think the string theory prizes are merited but I agree that there are other recent areas of fundamental physics that could be included. The problem is that the whole area has been fractured down the middle by the string wars. If Milner had started out giving the prizes to Smolin, Rovelli etc we might now see all the prizes going to people connected to the Perimeter Institute instead of Princeton. That's just the way the field is at the moment.

17. **JHe**
November 7, 2013

Dear Phil,
The link at your name is blog.vixra.com. It should be blog.vixra.org. It must be your mistake.

18. **Peter Woit**
November 7, 2013

A String Theorist,

I don't doubt that the 6 prize winners could have found some sort of job in the US, but I think the evidence is that there was less enthusiasm for hiring them in the US than in the other places they ended up. In mathematics the best young US-trained mathematicians are aggressively recruited by US institutions, which do very well in competing with offers from other countries. My impression is that US physics departments are now rarely willing to do this kind of recruiting in string theory.

David M.,
I haven't checked your numbers, but in any case I didn't intend to claim there's some sort of prejudice about hiring anyone with a Princeton connection, the reference was to string theory, and plenty of theorists with Princeton connections work in quite different areas.

19. **Peter Woit**
November 7, 2013

One person contacted by "Project Einstein" forwarded me the e-mails they sent. They didn't call it "Project Einstein" in the e-mails, and said nothing about what they planned to do with the data other than to collaborate with Tegmark on some sort of data analysis to "uncover the genetics of mathematical reasoning and abstract thought". This person's reaction to the request for his genetic material was that he really was only interested in providing it in the time-honored standard biological manner, but it seems that wasn't what "Project Einstein" had in mind.

20. **IM**
November 8, 2013

Among the recipients of the New Horizons in Physics Prize,
Slava Rychkov's work, cited as
"for developing new techniques in conformal field theory, reviving the conformal bootstrap program for constraining the spectrum of operators and the structure constants in 3D and 4D CFT's"
is entirely on field theory
(though he has earlier worked on string theory, and CFT results may
be relevant for AdS/CFT).
See https://sites.google.com/site/slavarychkov/
for his ongoing work.

21. **Peter Woit**
November 8, 2013

IM,
Thanks. Actually, none of the new young prize winners are really doing string theory, in the sense of having a significant connection to the quantized theory of strings. There is though some subfield of theoretical physics that one could best characterize only sociologically, as "those topics discussed at Strings 20XX", which these days mostly don't have to do with strings. This field deserves a name, but I don't know what to call it, and people often call it "string theory". Calling it "Formal QFT" as opposed to "Phenomenological QFT", has the drawback that it implies that there is no non-phenomenological qft work that isn't part of this subfield, which is far from the truth. The other problem is that this is highly time-dependent, these days you can for instance be doing twistors or hydrodynamics and fit in here, but at previous times that would very much not be the case.

22. **John**
November 8, 2013

Concerning the prize for young researchers, I wonder why nobody mentioned an apparent conflict of interest: Witten-Gaiotto, Seiberg-Komargodsi, Polyakov-Rychkov,… It's like having parents in the selection comittee.

23. **layman**
November 8, 2013

corrections:

1.) US is not buying: you have no idea what you are talking about and which job opportunities some of the laureates had. I would call some of the offers I know people had quite aggressive and generous. It is just that nowadays some institutions outside of the US (mostly private ones) can easily compete even with the best offers from Harvard and Princeton… And why not settle in Europe, where the food is much better and the health care much nicer? 🙂

2.) The list of Mr Armin: 90% of the people you mentioned do not fit the definition of the prize either because they have not done something which is significant enough or because they have been inactive for 20 years. Also you have a typo: ABM->ADM.
The 10% who fit the definition of the prize may very well get it in the future, I dont see why not. You also missed many deserving cosmologists and condensed matter physicists.

3.) Penrose does not fit the definition of the prize, which is why he will never get it, regardless of his achievements. Other people who hate string theory may well get it because they do fit the definition.

4.) Many of the other comments here reflect deep ignorance of what is going on. Also not being able to understand the rules of the prize by reading the 2 online paragraphs does not bode well for being ever able to understand modern physics (but I guess we already knew that).

24. **Peter Woit**
November 8, 2013

layman,
Why does Penrose not fit the definition of the prize (for his work on twistors + singularities in GR?)?

If string theorists are as attractive to US institutions as people in other fields, why do you think US institutions are ending up with many of the best young mathematicians, but not the string theorists? Back in the late 1980s there were many US departments trying to hire in string theory, making the best offers in the world (e.g. Rutgers). Can you point to even one US physics department that now has hiring a string theorist as its top priority?

And, by the way, do you think the perception that string theorists are insufferably arrogant people who go on endlessly about how anyone who disagrees with them is stupid and ignorant might have anything to do with why these departments aren't hiring string theorists?

25. **layman**
November 8, 2013

The ease with which you make claims which are as bold as they are wrong is astonishing. I hope that the standards you apply when you do research are slightly higher. It is you, not me, who said " It seems US physics departments are not buying what Princeton is selling right now… ." You had not a single bit of knowledge on any of the personal circumstances of the laureates, about the offers they had from elsewhere (which are sometimes more attractive salary-wise than the salary of any two young mathematicians anywhere in the US combined!), and about the offers they may or may not hold now. Yet, in spite of that, you made a bold claim and drew a far-reaching conclusion from that claim based on zero understanding of the data and the circumstances.

Let me also assure you that some people among the six had offers from the US far exceeding salary-wise the salary of ANY single young mathematician in the US.

I think it is not surprising that a person would react arrogantly to claims made with such confidence but with so little actual knowledge. I think it is much more arrogant to feed (presumably) thousands of your readers with wide speculations framed as universal truths. On the other hand, maybe your readers deserve to be treated liked that 🙂

To further demonstrate how pathetic this discussion is, let me please mention the four Fields medalists of 2010, Elon Lindenstrauss, Ngô Bảo Châu, Stanislav Smirnov, Cedric Villani. Now let us test your theory that the US attracts bright mathematicians by checking how many of these 4 had a permanent job at the US at the time they got the medal. Answer: 0/4. It is true that at least 2 of them spent ample time in the USA before or after the medal, but they did not have a permanent job there and most of their time was spent outside of US soil. I would say the situation is remarkably reminiscent of the physics prize. Also 2/4 are very closely tied with Princeton. So it seems that also in math the US is not buying what Princeton is selling.

I think at this point I am flogging a dead horse, but regarding your other questions:

"Can you point to even one US physics department that now has hiring a string theorist as its top priority?"

I am not based in the US, and unlike you, I am not discussing matters with which I have no intimate knowledge so I don't have an answer. I just know that many hep-th people are getting extremely generous offers from many places in the US. So I assume it is a very high priority.

"Why does Penrose not fit the definition of the prize (for his work on twistors + singularities in GR?)?"

The prize is not awarded to people who did *great* stuff in the early 70s and after that either decoupled or became lunatics. The emphasis is on people who are still active and are doing good and sensible things. Unlike Penrose, Hawking got the prize and fits the definitions quite well (he was an avid participant in the modern discussions about the information paradox and the wave function of the universe).

26. **layman**
November 8, 2013

Also many of Penrose's results are in collaboration with Hawking, who later did much more important and *fundamental* things than twistors or the classical singularity theorems. So if one has to give the prize to one of the two the choice is obvious. Especially that it is a FPP and not a prize in mathematical physics.

So unfortunately, despite the monumental effort of the impressive hive mind here, nobody came up with a single name of a clearly more deserving FPP laureate than the existing ones. Sure, there are many people who deserve, but no evidence points to the fact that the selection is biased. (BTW, even though we are talking small numbers here, the PU and IAS seem to be comparably dominant among the Fields medalists as the FPP, and in both cases many of the laureates just spent time in IAS or PU, and then moved elsewhere, often not on US soil.)

27. **Anonymous Lurker**
November 8, 2013

Layman:

Where does it say that a recipient of the Fundamental Physics Prize does it say that the recipient still has to be active? I looked at the web, and didn't see this criterion anywhere.

Hawking's citation says "For his discovery of Hawking radiation from black holes, and his deep contributions to quantum gravity and quantum aspects of the early universe." If the prize is supposed to be for recent work, why did they not mention any of his recent work?

And is Alexander Polyakov still active? He got the prize last year, he's 68, he was certainly a great physicist, but it doesn't look to me like he's done that much in the last few years.

28. **Peter Woit**
November 8, 2013

layman,

From what you write it's clear you have no idea what kinds of salaries the best young mathematicians in the US can command (they're every bit comparable to the what the best young physicists are offered, the star system is not just in physics). As for my comment about what US departments are not buying, it's simply a fact. Your argument is just that they're not buying because they can't afford to pay the price. I don't believe this because I'm well informed about the mathematics job market, what the competition for the best people is like, and who is paying what. All the evidence I've seen is that the market in physics is not that different.

The Fields medalists you mention are different in a lot of ways (one of which is that this is a distinction universally recognized by the math community, whereas Milner's prize is a very different story). The market for Fields medalists is highly competitive, with US universities willing to pay top dollar for them. Ngo chose an offer from Chicago after his Fields medal, and, while I don't know the details, I don't think low salary offers from US institutions is the reason the other three have chosen to stay where they are.

As for Hawking/Penrose, I don't see how twistors aren't a truly fundamental idea, it's one of the bases for the modern work on amplitudes, every bit as significant as the string theory-related advances that many of the FPP winners got their prizes for. Being an "avid participant in the modern discussions about the information paradox and the wave function of the universe'" seems to me to have nothing to do with whether one should get a prize for anything or not. Referring to Penrose as a "lunatic" is worthy of Lubos, you should try and get a grip. I'm no fan of some of Penrose's recent ideas, but they're no sillier than the M-theory multiverse business that Hawking has been writing books pushing.

29. **A String Theorist**
November 8, 2013

Expanding on my comment above: it's interesting that you mention Rutgers, Peter, because one of the appealing aspects of Rutgers in those days (I don't know if its still true?) is that they could offer string theorists 1/2 teaching load (that is, one course per calendar year).

In my comment above, where I mentioned some of the factors that make some positions outside the US so appealing, embarrassingly I forgot to mention the Holy Grail! Several (perhaps all? I'm not sure) of the six New Horizons winners have non-teaching positions! Zero! No physics department in the US can offer that, and it is priceless.

30. **Bob Jones**
November 8, 2013

I think it's only a matter of time before Strominger and Vafa win this prize. I'm was actually surprised that they didn't win it the first time around.

I'm also surprised that no one has mentioned 't Hooft. He seems to be the perfect candidate for this.

31. **paddy**
November 8, 2013

@ A String Theorist
Is it a good thing that academic institutions do not require teaching? This was my second thought after facetiously thinking: Thank heaven they won't be teaching.

32. **Philip Gibbs**
November 9, 2013

On the subject of Project Einstein, John Baez has said on Google+ that he will participate and gave some details about the consent conditions. I think the traits and circumstances that lead to people becoming maths or physics leaders is too broad for such a small sample of genomes. They might do better if they concentrated on people who showed early signs of ability, e.g. those who did well in maths olympiads. There is also the Personal Genome Project http://www.personalgenomes.org/ with more general aims which is being conducted in a way that has a better chance of success.

33. **layman**
November 9, 2013

Indeed, no teaching is one of the main perks institutions overseas can offer (there are many others). It is not that US institutions are not trying, 99% of them just cant make attractive enough offers.

Most people prefer to have a slightly lower salary than to have to teach every semester.

"I don't see how twistors aren't a truly fundamental idea, it's one of the bases for the modern work on amplitudes, every bit as significant as the string theory-related advances that many of the FPP winners got their prizes for"

Twistors is simply a "notational" tool (i.e. kinematical) there is nothing truly deep about this. Hawking's semi-classical computation is deep, far-reaching, and very truly important.

34. **Thomas Larsson**
November 9, 2013

For those who don't think that work done during the 1980s is recent, consider this:

In this excerpt of the will, Alfred Nobel dictates that his entire remaining estate should be used to endow "prizes to those who, during the preceding year, shall have conferred the greatest benefit to mankind."

Seems to me that pretty much every Nobel winner was disqualified, except perhaps Rubbia and van der Meer, and Bednorz and Müller.

35. **Shantanu**
November 9, 2013

Peter and others, something OT/old news.
Found the videos the conference Cosmo 2013 in Cambridge.

http://www.ctc.cam.ac.uk/activities/cosmo2013/programme.php
In particular the talk by John Ellis, in which he argued that the Planck
data supports Starobinsky model of inflation which begs for supersymmetry.
shantanu

36. **Mitchell Porter**
November 9, 2013

"layman" said

"Twistors is simply a "notational" tool (i.e. kinematical) there is nothing truly deep about this."

It's just an accident that they gave us the twistor string and the amplituhedron?

37. **Peter Woit**
November 9, 2013

layman,
The idea that twistors are just a notational innovation is very funny. You seem to be arguing that major prizes can't go to new ideas about "kinematics", which I guess would explain why Einstein was never awarded a Nobel for special relativity.

Interesting to see that the young prize winners have gone from making twice as much as people in the US to taking less money in exchange for having to teach less.

From experience, I think anyone who insists on never teaching is making a big mistake. Teaching a subject is the best way of really understanding it deeply.

38. **Low Math, Meekly Interacting**
November 9, 2013

An absolute requirement for determining heritability of a complex trait is controlling for variance. Soliciting DNA from a bunch of math whizzes does not strike me as a particularly effective sampling protocol. If by "not crazy" Rothberg means "compared to wiping my backside with my surplus of $100 bills" I suppose that would be accurate enough. While basic statistics seems to have failed Dr. Tegmark here, I bet he could calculate the odds that there exists a copy of himself that stumbles on the "math gene" by pure chance on some branch of the wavefunction.

39. **Peter Orland**
November 9, 2013

"An absolute requirement for determining heritability of a complex trait is controlling for variance. Soliciting DNA from a bunch of math whizzes does not strike me as a particularly effective sampling protocol."

Indeed. It a was notion Einstein and other twentieth-century humanists had deep disdain for.

40. **Pawl**
November 9, 2013

Two comments:

(a) The notion that "many of Penrose's results are in collaboration with Hawking" is at best highly misleading. It was Penrose who was, far and away, most responsible for the development of the deep geometry of causal structure, including the first singularity theorem. Penrose's results completely transformed the way people thought of the field. Hawking really came along later.

(b) It's evident that the prizes have been awarded in a remarkably narrow way, and this really makes one wonder what the Selection Committee's perspective on physics is.

41. **Peter Orland**
November 9, 2013

I meant to write:

Indeed. It also a was notion Einstein and other twentieth-century humanists had deep disdain for.

42. **Simple biologist**
November 9, 2013

"An absolute requirement for determining heritability of a complex trait is controlling for variance. Soliciting DNA from a bunch of math whizzes does not strike me as a particularly effective sampling protocol."

The whole idea is ridicilous, but the quoted part isn't really problematic. There exists already plentiful amount of sequenced human genomes and the number is growing. Majority (almost all?) of it is availeable on free and publicly availeable databases. No need for bigger sampling protocol.

They could always just sequence math wizards and use "normal" sequenced genomes from other sources for control and variance.

43. **Armin Nikkhah Shirazi**
November 9, 2013

In response to my list above, some people have pointed out that the contributions of most of the people on the list had either not been recent or significant enough to merit the FPP. At first, I was not going to protract a discussion of this issue because comparing scientists' achievements is an awkward business of dubious taste, but "Layman" 's claim that ".. nobody came up with a single name of a clearly more deserving FPP laureate than the existing ones" is so unbelievably pompous that I feel it cannot stand without a detailed, evidence-based rebuttal.
Before I give my rebuttal, I want to emphasize that I mean in no way to belittle the FPP laureate's distinguished achievements, I only want to show that "Layman"'s claim, besides being unbelievably arrogant, may be shown by evidence to be false.
The 2013 FPP Laureate is Alexander Polyakov. His citation reads:
"for his many discoveries in field theory and string theory including the conformal bootstrap, magnetic monopoles, instantons, confinement/de-confinement, the quantization of strings in non-critical dimensions, gauge/string duality and many others. His ideas have dominated the scene in these fields during the past decades."
The contrapositive of the claim by David M., Phillip Gibbs and "Layman" is that Polyakov deserved the FPP because unlike any (or most) of the people on the list, his achievements were 1) sufficiently recent and/or 2) sufficiently significant.

Let us test for recency:
The first relevant work on conformal bootstraps of which I am aware seems to be
Polyakov, A.M., "Non-Hamiltonian approach to conformal quantum field theory" Soviet Physics JETP, Vol. 39, p.10 (1974)
The first relevant work on magnetic monopoles of which I am aware seems to be
Polyakov, A.M., "Particle spectrum in quantum field theory", Journal of Experimental and Theoretical Physics Letters, Vol. 20, p.194 (1974)
The first relevant work on instantons of which I am aware seems to be
Belavin, A.A., Polyakov, A.M., Schwartz A.S. , Tyupkin, Yu. S. , "Pseudoparticle solutions of the Yang-Mills equations", Physics Letters B, Vol. 59, p. 85 (1975)
The first relevant work on quark confinement/de-confinement of which I am aware seems to be
Polyakov, A.M. "Quark Confinement and topology of gauge theories", Nuclear Physics B, Vol. 120, 3, p. 429 (1977)
The first relevant work on the quantization of strings in non-critical dimensions of which I am aware seems to be
Polyakov A.M. "Quantum geometry of bosonic strings", Physics Letters N, Vol. 103, p. 207 (1981)
The first relevent work on gauge/string duality of which I am aware seems to be
Polyakov A.M. "String Representations and hidden symmetries for gauge fields", Physics Letters B, Vol. 82, p. 247 (1979)

Phillip Gibbs gave no cutoff threshold for recency, David M. gave one of 30 years, "Layman" gave (indirectly) one of 20 years. The most recent of the above publications is 32 years old. The others are all pre-1980's.

Let us now turn our attention to significance. This is a highly contentious matter because it is so subjective. Different people have different criteria for significance, and unless everyone agrees on the same set of criteria, there will be endless discussion without resolution. We are scientists not philosophers, so I think we should confine ourselves to the one criterion that is entirely uncontroversial in terms of determining the value of a fundamental idea in science: Whether it has been empirically confirmed. If anyone thinks that there exists a more important criterion in the evaluation of a fundamental scientific idea than empirical confirmation, you are welcome to make your case.
Let me now ask the following questions:
1) Has the conformal bootstrap been empirically confirmed?
2) Have `t Hooft-Polyakov monopoles been empirically shown to exist?
3) Have BPST instantons been empirically shown to exist?
4) Have quantized or any other kinds of strings been empirically shown to exist?

Compare this now to the following questions (remember, we are treating this apart from recency):
1) Has QED been empirically confirmed?
2) Have quarks been empirically shown to exist?
2) Has the CMB been empirically confirmed?
4) Has the Aharonov-Bohm been empirically confirmed?

I think this is sufficient to demonstrate just how ludicrous "Layman"'s above claim is, but I doubt that he will concede because it is quite clear to me that he did not arrive at this position because of any evidence but because he has an emotional commitment to the position he holds. One encounters this most often in political and religious debates, and (thankfully) less often in scientific debates. A hallmark of people who argue in the absence of supporting evidence is that they resort to various fallacies, such as
1. Ad hominem ("Many of the other comments here reflect deep ignorance of what is going on.")
2. Innuendo ("I hope that the standards you apply when you do research are slightly higher")
3. Obfuscation by Introduction of irrelevant considerations ("Layman"'s fields medalist "Argument")
4. Misrepresentation ("Twistors is simply a "notational" tool").
However, "Layman" did give one correct argument. He correctly pointed out my typo, that it is ADM, not ABM and I thank him for that. I just wished he would make giving substantive arguments the rule instead of the exception.

November 9, 2013

Armin Nikkhah Shirazi says: [good stuff elided]

Hear, Hear!

45. **lun**
November 9, 2013

Hoping to find a "genius math gene" is, without exaggerating, a thousand times more crackpot than anything relating to the string landscape. And much more dangerous. It really does not help that otherwise reputable scientists are willing to lend respectability to such crackpottery.
Anyone who doubts that, check out
this and
this. Or do some research on the Flynn effect.

46. **layman**
November 9, 2013

1) Has the conformal bootstrap been empirically confirmed?

Yes. It is known for some years now that the conformal bootstrap equations do
postdict the critical points of 3d Ising and He_3 and others. They also predict many new 2nd order transitions.

2) Have `t Hooft-Polyakov monopoles been empirically shown to exist?

Yes. In condensed matter physics monopoles were found, of the type 't Hooft-Polyakov envisioned.

3) Have BPST instantons been empirically shown to exist?

Yes, long ago, for example, in 3d.

4) Have quantized or any other kinds of strings been empirically shown to exist?

No.

Note that almost all the achievements above are very well deserved and have not been already celebrated by many other major prizes.

1) Has QED been empirically confirmed?
Yes, and it is completely irrelevant to celebrate this pre-history in the 21st century. All the people responsible for this are either dead or in their 90s.

2) Have quarks been empirically shown to exist?
Yes, and the same comment as in 1) applies.

3) Yes. This should be recognized.

4) Yes, but it is too old (more than 60 years).

47. **amused**
November 9, 2013

It's an amusing exercise to contrast the views of the people who awarded the latest round of Milner prizes with the views in the recent document "The Future of US Particle Theory: Report of the DPF Theory Panel" (arXiv:13106111) which includes a substantial fraction of string/BSM theorists among the authors. It contains a summary of significant advances in recent years (as well as predictions for where the action will be in the future) – presumably quite relevant when considering which recent developments might be worthy of a big prize.

Curiously, the dominance of string theory in the Milnor prizes is not mirrored by dominance of ST in the description of significant advances in this document… In fact it gives the impression that important advances have occurred across a range of different areas, including some obscure and unheard of ones (unheard of at least to readers of blogs, popular science magazines and the NY Times). E.g. an area called lattice gauge theory, in which, according to the document, "astounding" progress has occurred over the last decade.

It's completely understandable though that, regardless of whatever advances have occurred in such areas, they can't come into consideration for a prize such as Milnor's, since it would involve honoring the contributions of people not working at or connected to Princeton, Harvard and the other few institutions to which such prize winners must belong. Giving such a prize to people outside of those institutions would be a hideous offense against the natural order of things – unthinkable!

48. **kashyap vasavada**
November 9, 2013

Layman writes outrageous words like "lunatic" for such a great mathematical physicist Penrose. If he believes Penrose should not get FPP that is perfectly OK. But he has no business calling Penrose lunatic. I am reasonably sure layman is very ordinary physicist and will never get FPP or nobel prize!! May be there should be a rule that one has to give his/her real name in the blogs. Such people are cowards who hide under pseudo names , so they can say any thing they like without any possible penalty.. I have always used my real name.

49. **piscator**
November 9, 2013

Look, this is clearly a Princeton prize. The area the so-called New Horizons prize is awarded in is 'mathematical physics topics of interest to IAS/Princeton particle theory faculty', and the best indicator of getting a prize is being a protégé
of said faculty. And I think if layman finds it hard to think of more deserving awardees of the FPP he should just learn some more physics -as in, the subject about describing this world. In any case, based on various sources it appears that some of the original FPP prizes were essentially self-awarded. Within the professional particle theory world I haven't met anyone yet who thinks these Milner prizes are a positive thing

50. **Low Math, Meekly Interacting**
November 9, 2013

S.B. – One needs to seriously consider what traits and background are likely required to hold a physics or mathematics professorship at a top-tier university, and if it's possible to control for selection bias such that the signal:noise allows one to reliably identify alleles that would be responsible for innate quantitative ability in the general population. I'm guessing the answer is a resounding no. I don't see how using a random selection of public-domain genomes as a baseline could help.

51. **Bob Jones**
November 10, 2013

Armin Nikkhah Shirazi,

Your last post makes no sense. Polyakov's prize citation mentioned "quantization of strings in non-critical dimensions" and "gauge/string duality", and your response was "Have quantized or any other kind of strings been empirically shown to exist?"

It's obvious from your question that you have no idea what kind of strings we're talking about here. The term "non-critical" means that these are not the superstrings that are used to model elementary particles. Here we're talking about lower dimensional theories that are important for theoretical reasons. For example, Polyakov has done a lot of work on Liouville theory, a two-dimensional conformal field theory theory which is important in a variety of toy models of quantum gravity. It makes no sense to ask whether such a theory has been empirically tested.

In the context of gauge/string duality, the strings just provide a mathematical reformulation of gauge theory. We know that the particles of the standard model are well described by gauge theory, so these strings are definitely relevant for describing nature. It makes no sense to ask whether they have been empirically observed.

52. **Peter Shor**
November 10, 2013

At some point soon, they will run out of worthy candidates that have any connection whatsoever with Princeton. I don't think they're anywhere close to running out of string theorists, though.

53. **tristes_tigres**
November 10, 2013

I wonder, does the origin of prize money bother any of the recipients? Perhaps, that explains the size of the prize. Harder to refuse on ethical grounds if the sum is irregularly large.
NYT reported that Lawrence Summers was forced out of the Harvard presidency in some part due to the unease of the faculty over his role in Russian "economic reforms" of the 90s. So there's a real possibility of some recipient refusing to play supporting role in Mr.Milner's recasting himself as respectable philanthropist. Not any of string theorists so far, though. No impractical Grisha Perelman-like characters there.

54. **venp**
November 10, 2013

Re "Project Einstein": Genome-wide association studies are common these days in studying possible genetic causes of medical conditions. You take, say, 400 persons with type 2 diabetes and compare their genome with that of 400 healthy individuals and see if a gene mutation exist in the diabetics but not the others. I suppose the next step in the "Project Einstein" is to send 400 letters to some of us non-geniouses for the second sample. I certainly hope I don't get one of those:)

55. **Armin Nikkhah Shirazi**
November 10, 2013

Layman,

I guess a big difference between you and I is that if somebody asked me: "Have black hole event horizons ever been empirically observed?" It would have never occurred to me to answer by saying :"Yes, analogues of the black hole event horizon have been empirically observed in microstructured optical fibers.", but evidently this is the kind of answer you are quite comfortable with giving.
Do you see what is wrong with it? I'll help you: It is not an answer to the question asked, but an answer to related but distinct question: "Have relations that characterize black hole event horizons been empirically observed in other systems?"
And so it is with your answers to my first set of questions: As far as I can tell, in all of your answer you presented analogues, usually in condensed matter, as if they were the real thing.
Now, I don't think that you are so uneducated so as to not be able to tell the difference. But if that true, then it is hard to escape the conclusion that you conflated the two questions on purpose, the purpose being to convince people that those theoretical predictions have the same empirical standing as the theoretical predictions of, say, quarks and the CMB.
So, while I do think that your last post is a vast improvement over your previous posts in respect to the quality and tone of your arguments (credit where credit is due) it has not yet changed my impression that you are trying to fit facts to a position at which you have arrived because of an emotional commitment, not because evidence led you to it. I wished you would make a sincere attempt to reflect on what I am saying, but in my experience this kind of appeal usually falls on deaf ears.
The reason I disagree with your assessment of the second set of answers is that it fails to take into account a purely psychological effect that tends to bias us against fully appreciating the most significant achievements in fundamental physics.
When children first learn to read, they read letter by letter, but as they become proficient, the individual letters "disappear", so to say. They no longer "see" the individual letters, only the words. This is universal phenomenon that happens with anything that serves as a building block for higher level concepts, and in particular with our most fundamental scientific concepts. But just because we no longer "see" them, it doesn't mean that they don't "dominate" our thinking (to use the FPP citation word in the last sentence) in every aspect of research in the relevant field. We just fail to appreciate it on an ongoing basis because this is a psychological shortcoming of us humans, and I think your use of the term "pre-history" reflects just such a psychological bias.
Also I believe this has quite a paradoxical consequence: If, say, the theory of quarks were *less* well established empirically (say, we had only condensed matter analogues available as empirical evidence), then its discoverers would seem *more* eligible to for an FPP because their theory was not yet established enough to fade into the background. To me that is just perverse, we should not in effect penalize scientists precisely because they have made contributions that are far more outstanding than those of the rest of us.

Bob Jones,

Let's see: I wrote a long post in which I raised numerous issues, and you declare "Your post makes no sense." because you object to one issue? Do you really believe this is a reasonable thing to say? I don't think you need hyperbole to raise your objection, especially since actually I think you have a point. That question was originally two questions, one pertaining to quantized strings and one pertaining to superstrings, but because they sounded too similar, I decided to combine them into one question, even though, as you point out quite correctly, they are different kinds of concepts.
That was careless of me, and you are right to criticize me for that. Thank you.

Now concerning your last sentence: "It makes no sense to ask whether they [i.e. quantized strings] have been empirically observed."

If someone asked me, say: "Have gauge potentials ever been empirically observed?" my answer would be "Gauge potentials are not the kind of objects that can be directly observed, however they are associated with other objects (e.g. fields) which can produce observable effects, and such effects have been observed in association with certain gauge potentials." I would *never* say "it makes no sense to ask whether they have been empirically observed" because that would immediately provoke the follow-up question : "Then why do they have anything to do with physics?", and quite rightly so.
Now, I realize that you used this language because you are trying hard to make me look like someone who doesn't know what he's talking about, but it would seem in your

own interest to try to avoid inadvertently contributing to the growing perception that string theorists are detached from physics.

Peter,

I just noticed the allegations raised by “John” in the post above. Is this true? If it is, it is quite simply shocking. Have you blogged about this? If it is true and you did not blog about it, why not? I can’t imagine that you would not have known about it.

Armin

56. **Peter Woit**
November 10, 2013

Armin,

Yes, it’s true. As for blogging about it, that’s exactly what I was doing when I wrote this blog entry, John was just providing more detail…

57. **Bob Jones**
November 10, 2013

Armin Nikkhah Shirazi,

It’s not really clear what you’re willing to accept as answers to your questions. In the AdS/CFT correspondence, the strings capture the physics of strongly coupled gauge theories, so they’re certainly relevant for understanding the physics that we observe in particle accelerators. In this way, Polyakov’s work on string theory has led to plenty of new insights about observable phenomena.

There are other ways in which one might answer your question. For example, a lot of recent work in theoretical physics, now recognized by Milner prizes, studies strings that propagate not in spacetime but in an auxiliary mathematical space called twistor space. It makes no sense to ask whether such strings have been directly observed, but this sort of work has led to important new techniques for computing scattering amplitudes in gauge theory, including techniques that are being used right now at the LHC. I should also point out that in condensed matter physics, there are many applications of two-dimensional conformal field theory, and such a theory can always be thought of as a theory that describes strings propagating in the target manifold.

Note that these are all *formal* applications of string theory. In general, it makes no sense to ask whether a formal mathematical concept has been empirically observed. Thus it is meaningless to ask whether a noncritical string has been observed in an experiment. It’s like asking whether differentiable functions have ever been observed. Of course you can ask more generally whether a formal concept has any empirical manifestation, but it was not at all clear that that’s what you meant by your original question.

58. **An observer**
November 11, 2013

I am sympathetic to some of what you write. However, I don’t know why you entered this unseemly discussion about job offers in the U.S. It is simply true that at least some of the people on the new horizons list, had offers with *tenure* from top places in U.S. (eg Harvard.)

It would be better to phrase your point in a neutral manner, rather than engaging in these personal arguments, when you don’t know what personal circumstances and motivations got people to settle where they are.

59. **Peter Woit**
November 11, 2013

An observer,
I wasn’t making a personal argument about anyone, and the details of what job offers any one of these people has had is irrelevant. My point was just that the fact that none of them ended up in the US is statistically significant evidence for a lack of enthusiasm by US physics departments for hiring in this area. There are plenty of other indications of this (e.g. the rumor-mill), I wouldn’t have thought it was a controversial observation at all.

60. **Marcel van Velzen**
November 11, 2013

Who cares who gets this price. It is Milner’s money and he can do with it what he likes. Because it’s so much money it seems interesting but it really isn’t. It’s just Milner’s way of buying himself into theoretical physics.

61. **vmarko**
November 11, 2013

Marcel van Velzen,

If everyone had the same opinion that you have about the prize, there would be no problem at all.

However, if you win the Milner’s prize, and afterwards that fact helps you land a better position at some university (as happens with Nobel and Fields prize winners), then it is a problem.

The issue with Milner’s prize is not the money, but the implications for the academia that it can bring.

Best, 🙂
Marko

62. **Marcel van Velzen**
November 11, 2013

Marko: “If everyone had the same opinion that you have about the prize, there would be no problem at all.” that is why I expressed my opinion 🙂

63. **Curious Wavefunction**
November 11, 2013

Not only does the Fundamental Physics prize identify fundamental physics with string theory, but it also identifies fundamental physics almost exclusively with theory rather than experiment. I wonder if Robert Millikan or Albert Michelson would have been nominated for this prize had it been around then.

64. **Philip Gibbs**
November 11, 2013

Curious Wavefunction, There was the special FPP given to representatives of LHC, ATLAS and CMS.

65. **GooGoo**
November 11, 2013

I liked McMullen's comment! Well said.

This "Einstein Gene" business reminds me of the letters from "Who's Who of High School Students" explaining they want to include such a brilliant and wonderful person as yourself. By the way, of course you will want to buy the (not inexpensive) volume….

A possibly relevant fact to all this is that I met a relative of Einstein, who certainly possessed the Einstein gene, but evidently this was a gene for niceness rather than the gene for math or physics.

I would hazard to guess that William Shockley would be behind this project, after of course including his own person as one of the donors, but then again he must have passed on to other universes by now.

On to the Millman prize: I can't help but wishing that some billionaire would use their money in a way which would actually benefit the science. It is quite right that although zero teaching is not a good idea for most, too much teaching, especially of the repetitive variety, can kill your research and your love of the subject. Thus, what could really be of help is a shotgun approach of many small grants funding reduced teaching loads, including sabbaticals. Arguably the money would be much better spent in this way than by heaping yet more rewards on the same few names (i.e. the star system). These people already have great positions, and in the best cases are motivated by a real love of science and not by yet more money.

66. **David Nataf**
November 12, 2013

There is an unhealthy obsession on this board with prizes. It reveals how the better solution is simply to do away with all prizes.

67. **Typhoon**
November 12, 2013

All this talk of prizes reminds me of the following aphorism:

"Prizes are like hemorrhoids, sooner or later every a**hole gets one."

68. **Laymammal**
November 12, 2013

The Nobel in Physics has exclusively been given to theorists only after their theory has been confirmed by experiment. In the future, the Nobel in Physics may have to alter its criteria to theories which are mathematically consistent both internally and consistent mathematically with confirmed theories like QM. The Genius of Strings is that it's internally consistent and also consistent with almost Every possible theory that may be confirmed.

69. **CFT**
November 12, 2013

Ok, because this 'Project Einstein' is even being considered at all makes me cringe. Why on earth would anyone like Einstein (in particular since he was a Jew) even want his name associated with a eugenics breeding program considering who was actually trying to do such breeding during the first half of the 20th century? Call it for what it is. Eugenics. And for those who need to be reminded what that really is;
*
eu·gen·ics
noun plural but singular in construction \yü-ˈje-niks\
: a science that tries to improve the human race by controlling which people become parents

Full Definition of EUGENICS

: a science that deals with the improvement (as by control of human mating) of hereditary qualities of a race or breed
*
It appears that stupidity and evil dressed up as science never goes out of fashion. I think anyone who wants to connect the name 'Einstein' with such contemptible research objectives should consider having themselves gene sequenced for a 'Fascist' or 'complete idiot' gene, then be surgically neutered in order to gain a first hand empathy and understanding of what they were advocating.
I would also ask anyone with a whit of common sense (rather than what goes for pure mathematical ability apparently) to consider the implications of what would happen if said such 'Einstein' project actually succeed by some dumb luck. What would the product of such a project think (mathematically or otherwise) of the idiots who wanted to control his/her very being, not by loving acceptance, nurture, argument, or education, but by the objectives of animal husbandry? I'd much rather prefer we keep the like of Khan Noonien Singh inside Pandora's little bottle of cautionary fiction, and be extra careful not to spill.

70. **birdie**
November 12, 2013

Eugenics that eliminates intelligent female genes, and selects for arrogant groupthinkers. Yeah, that will work.

71. **Marcus**
November 12, 2013

CFT you just lost it. If some couples or individuals want to try to have extra intelligent or, say, musically talented children that is certainly their right. It is a personal choice and represents individual liberty–in this case the freedom to use available scientific studies and methods to try to improve the life of one's offspring.

By using words like "stupidity" and "evil" and "Fascist" you are in effect using hate speech to limit individuals' personal rights and liberties by harshly disapproving propaganda. Since a government mandate is not the issue the word "eugenics" is irrationally applied–since it has the connotation of state mandate interference with reproductive choice. What you are doing resembles fundamentalists who use rhetoric to stir up hatred against doctors who perform abortion, so that abortion clinics eventually get firebombed, or shut down on technical grounds by legislatures.

So please cool it with the irrational outrage against reproductive choice.

72. **vmarko**
November 12, 2013

Marcus,

"If some couples or individuals want to try to have extra intelligent or, say, musically talented children that is certainly their right."

Assuming that project Einstein is successful in finding a "math gene" (whatever that may be), how would your couple of individuals go about making their child extra intelligent? The parents either do or do not have the gene, they have no choice in the matter. And if they manipulate their genetic material to introduce the math gene artificially, that's very close (if not equivalent) to eugenics.

Either way, the "math gene" most probably doesn't exist. There is overwhelming evidence that capacity for doing math is not hereditary, or otherwise we would already have several Fields medalists or Nobel winners from the same family by now (Milner prize notwithstanding)… 😉

Best, 🙂
Marko

73. **Marcus**
November 12, 2013

Hi vmarko,
I have no interest in arguing about whether math ability is heritable. To me it seems even a bit off topic. I just couldn't let CFT's over-the-top hate speech about reproductive choice pass.

For you, apparently, the word "eugenics" has no connotation of state-control. According to your example "eugenics" can be a matter of individual couple's choice when they are getting ready to have a baby.
That kind of eugenics is increasingly common these days where heritable factors have been identified, and I think of it as morally neutral. As long as you are clear about what you mean I have no problem with what you say. Just don't foam at the mouth about it, OK? :^D

74. **Anonyrat**
November 12, 2013

You can read the first college-level textbook on eugenics – "Applied Eugenics", by Paul Popenoe and Roswell Hill Johnson published in New York, 1918, here:

https://archive.org/details/appliedeugenics19560gut

Left as an exercise to the reader: trace the effects of those ideas on modern US politics.

75. **Yatima**
November 12, 2013

CFT says:

Ok, because this 'Project Einstein' is even being considered at all makes me cringe. Why on earth would anyone like Einstein (in particular since he was a Jew) even want his name associated with a eugenics breeding program considering who was actually trying to do such breeding during the first half of the 20th century?

Please do not open this particular can of worms as there are very, very disturbing ideas being bandied about and actually actively acted upon by the "state" of a certain Middle Eastern country at the present time, which drives me to despair in the human race. Though it confirms that people are mainly driven by self-aggrandizing aggressive myth, not history or introspection. Einstein must be spinning so fast he is probably dragging the frames around his grave.

76. **Peter Woit**
November 12, 2013

Enough about eugenics and related hot-button political issues, although I realize that the "Einstein Project" does bring them up. Unfortunately there doesn't seem to be much news in math or physics, but I'll try and find something to change the subject…

77. **chiz**
November 12, 2013

I'm puzzled as to what a "math gene" would be. There is evidence, from neurology and linguistics, that our brains are wired for number, and that small numbers are treated differently from large numbers, so there is clearly something genetic going on with regard to a number-sense. But that's not the same thing as a math gene. I can hardly be the only person who, on having told friends and family that I was doing a degree in maths, was then faced with friends and family assuming that I was good at arithmetic and would, say, be the ideal person to be treasurer of a local club. Do you really need a number-sense to do muck around with group theory or Fourier transforms? My best guess is that you need a capacity for abstract, or, even, very abstract thought.

In any case, even if there is a math gene, it doesn't automatically follow that it will show up in genome sequencing or that it is heritable. Genetics and heritability have become decoupled over the last decade.

78. **Marcus**
November 12, 2013

Peter:
"Enough about eugenics and related hot-button political issues, although I realize that the "Einstein Project" does bring them up. Unfortunately there doesn't seem to be much news in math or physics, but I'll try and find something to change the subject…"

A propos changing the subject, have you thought any about the paper just posted by Roberto Percacci, Astrid Eichhorn and Pietro Donà?
"Matter matters in asymptotically safe quantum gravity".
Evidence supporting that approach to quantum gravity is bad news for SUSY and extra dimensions, it turns out. Here's the abstract:
"We investigate the compatibility of minimally coupled scalar, fermion and gauge fields with asymptotically safe quantum gravity, using nonperturbative functional Renormalization Group methods. We study d = 4, 5 and 6 dimensions and within certain approximations find that for a given number of gauge fields there is a maximal number of scalar and fermion degrees of freedom compatible with an interacting fixed point at positive Newton coupling. The bounds impose severe constraints on grand

unification with fundamental Higgs scalars. Supersymmetry and universal extra dimensions are also generally disfavored. The standard model and its extensions accommodating right-handed neutrinos, the axion and dark-matter models with a single scalar are compatible with a fixed point."

79. **Philip Gibbs**
November 13, 2013

Describing a project to look for genes related to intelligence as eugenics is like calling an experimental test for relativity an act of nuclear war. I think Einstein would have appreciated the difference.

80. **Bernhard**
November 13, 2013

Here:

http://www.theguardian.com/science/2013/nov/12/stephen-hawking-physics-higgs-boson-particle

Not a "extra, extra" news, but perhaps something to change the subject.

81. **CFT**
November 13, 2013

@Yatima,
I did not intend to open a can of worms, or offend actually, but I did wish to call it for what it was. I am also fully aware my existence is only possible because someone was not given license to tinker with my DNA to suit their preferences of who I should be, flaws, quirks and all.
@Peter, Please let me respond to Marcus, I don't mind him taking his shots as long as I can respond in kind to his labeling my arguments with 'over the top hate speech'.
@Marcus,
Deciding to have a child and exposing them to music or mathematics in hopes they will gain an appreciation for such subjects is one thing; The child will be making a choice (exerting their liberty, and their freedom if you will) if they decide to pursue such a discipline. Deciding you are going to exert absolute control over another person's gender, sexual predisposition, politics, height, intelligence, and abstract intellectual pursuits and hobbies is quite another thing… with horrifying implications. Considering who has been deemed unworthy of existence over the years in the pursuit of said "improvement", I find your use of the words 'liberty' and 'freedom' quite ironic and disturbing, since you are advocating the right to basically predetermine a potential child's nature (or soul) to your 'choice' and not allow them the right to determine their own preferences or desires. I'm also quite certain many world governments would also love to make use of such a capability to make certain some of their own additions were added to your list of improvements in the name of 'the greater good' and benefit of society.
*
Please take your seriously misplaced 'hate speech' comment and file it where the solar photons don't directly interact. Disagreement with a person or concept is not 'hate speech', a 'thought crime' or whatever academically approved politically correct jargon you want to use to silence discussion or debate. If you haven't, try to read '1984' before you pull any more newspeak out of your hat and see if it's really the way you want to go, and possibly go watch the movie "Man of Steel" for entertainment, noting the plotline entirely revolves around a child conceived without a genetically predetermined disposition or societal function. I found it remarkable that the super intelligent parents of the 'superman' figured out that their own species relentless desire to control every last aspect of intelligent life in the name of scientific perfection and social harmony was the cause of their civilization's stagnation and downfall. Krypton had given up on the uncertainty of teaching and learning in favor of the predictability of genetic programming. People don't learn and grow very much when they are given little or no choice in what their preferences are and what they do, so Mr. and Mrs. El decided to break with their world's engineered fate and let their son choose his own destiny, for himself to decide what kind of a man he was going to be. By doing so, Lara and Jor El affirm a concept of that so many people seem to have forgotten. The right to choose, freedom and liberty, did not begin with or end with the parent, nor are they the sole property of one generation to lord over the next, they are the birthright of the child as well.

82. **Peter Woit**
November 13, 2013

Really, enough. Part of the problem here is that the "Einstein Project" doesn't seem interested in explaining what they will do if they find the "math genius gene"…

83. **David Nataf**
November 13, 2013

Peter, I am guessing that the long term goal would ge to use it as a guide in undergraduate and graduate admissions where it would probably be more accurate than GRE scores.

Also to select which nine year olds can go to math camp.

84. **paddy**
November 13, 2013

Peter,
For two days now I have been thinking this chain is indeed "back to the usual".

85. **Kimmo Rouvari**
November 13, 2013

@Peter Have you made any (toy) models of your own? Certainly that would qualify as a great new post and topic. It would be extremely educating to hear what kinds of thoughts and ideas contemporary professionals have in order to create TOE, other than ST.

That's just my 2 cents.

86. **Hendrik**
November 14, 2013

Peter, a good topic for a post would be the ResearchGate website. It seems to be rivalling the ArXiv.

87. **Mathematician**
November 14, 2013

Hendrik, you cannot possibly be serious. ResearchGate keeps sending me fraudulent emails purporting to be from my co-authors, trying to trick (phish) me into "confirming" the details of papers. With these kinds of scammy tactics, I wouldn't touch that website with a stick.

88. **Hendrik**

November 15, 2013

Dear Mathematician, well you should Google it first before you make up your mind. Almost everyone in my subfield of mathematical physics belong to it (have profiles on it), and many very well-known mathematicians are on it.

89. **Mathematician**
November 15, 2013

Hendrik, I don't believe you. ResearchGate is very obviously a scam outfit.

When ResearchGate founder Ijad Madisch says things like "I want ResearchGate to win the Nobel Prize", nobody should be surprised by ResearchGate's sociopathic practices.

90. **Oldster**
November 16, 2013

Mathematician: " ResearchGate keeps sending me fraudulent emails purporting to be from my co-authors, trying to trick (phish) me into "confirming" the details of papers."

I've received many requests from ResearchGate to "confirm" papers as my work, but in every case, when I look at the details, I find one of the authors on these papers shares my last name and first initial, even though it's not my work. I simply click on the button that tells them it's not my work. It seems to me that ResearchGate is making a very innocent mistake here, using some computer program to scan for my name on papers, and not filtering the results as carefully as a human searcher might. That's not a "scam", it's just a somewhat simple scanning program …

91. **Mathematician**
November 16, 2013

Oldster, your experience is not relevant to the discussion because you know you are not an author of the quoted paper, so you won't fall for the scam. That's just like when you get an email about suspicious activity in your account at PQR bank, when you know you have never even had an account at PQR bank. But other recipients who do have accounts at PQR bank may fall for a scam. Your comment does confirm though that the emails seem to be automatically generated. It also shows people are too apt to attribute innocent motives to nefarious conduct.

My experience, which is typical, is this. For i=1,…,n I have received an email purporting to be from my coauthor ABC_i to paper XYZ_i. Now ABC_i is indeed my coauthor on paper XYZ_i, as ResearchGate has factually correctly "scraped" from some source. But if I am to take this email at face value then my coauthor (and colleague/friend/etc.) endorses and is involved in ResearchGate and has made a conscious choice to reach out to me personally, via this email, to suggest I become involved too. In reality, ABC_i knows nothing of this email, and may never have even heard of ResearchGate. Despite the fact that the email clearly states that it is from my coauthor ABC_i, it is in fact sent by ResearchGate in a deliberately fraudulent attempt to deceive me about the true nature of the email, and to trick me into becoming involved based on the apparent endorsement of ResearchGate by my coauthor ABC_i to paper XYZ_i (for i=1,…,n).

There is no doubt in my mind that ResearchGate has intentionally set out to deceive the academic community. They have even used their claims of large numbers of participants (who've been tricked into joining, if the numbers are real at all) to attract millions of dollars in investment. I think the FBI or SEC should investigate these guys.

Academia should avoid ResearchGate like the plague.

92. **Oldster**
November 16, 2013

Mathematician:

I agree I haven't received such emails, even where I have a paper with a coauthor which ResearchGate has managed to locate, and query me about. I have received emails stating that other researchers from my institution ("Retired") have joined ResearchGate, and asking if I wouldn't like to talk to them. Since "Retired" is a very broad "institution", the emails are a little ridiculous, but hardly malicious. Everything I've seen so far seems to fit into such categories. I have used ResearchGate to message authors for a copy of their paper, and then forgotten about it when I heard nothing back for a long time.

Unless I receive something like you describe, I can't really comment on your experience, except to say nothing like that has happened to me. I suggest you complain to ResearchGate directly if you feel they're abusing the site. If that happens to me, I will do that, because I've found the site is otherwise useful for legitimate contacts from time to time …

"If Project Einstein identifies a common gene among its participants, and uses the knowledge to breed a race of übermenschen, they may find they have selected not for unusual mathematical genius, but for unusual ego."

Kudos. I wish email sigs were still trendy.

Various Topics

November 15, 2013
Categories: Uncategorized

- Mathematician Sasha Beilinson has a letter to the editor in this month's AMS Notices calling on the AMS to sever all ties with the NSA (right now it manages NSA grants, and runs ads from the NSA in the Notices). Beilinson compares the NSA to the KGB of the former Soviet Union. For discussion of the Beilinson letter, see here.
- Beijing now has a Center for Future High Energy Physics, with Director the ubiquitous Nima Arkani-Hamed. The inaugural conference of the Center will be next month, on Future High Energy Circular Colliders. Nature has an article on the topic this week, Physicists plan to build a bigger LHC, about proposals to build a 100 TeV pp collider, with a possible electron-positron collider Higgs factory using the same tunnel. For the latest on TLEP, the proposal for such a Higgs factory at CERN, see here.
- I was in London a few days too early for this, but this week the Science Museum there celebrated the opening of its exhibition about the LHC with an event featuring Stephen Hawking. The Guardian has a report here. Hawking seems to think the LHC may see evidence for M-theory:

  > "There is still hope that we see the first evidence for M-theory at the LHC particle accelerator in Geneva," said Hawking. "From an M-theory perspective, the collider only probes low energies, but we might be lucky and see a weaker signal of fundamental theory, such as supersymmetry.
  >
  > "I think the discovery of supersymmetric partners for the known particles would revolutionise our understanding of the universe."

  As is often the case in stories like this, the wording about evidence for string/M-theory is rather odd. We're told:

  > As yet there has been no incontrovertible experimental evidence to show that M-theory is correct.

  but "no incontrovertible experimental evidence" is a peculiar way of phrasing "absolutely zero experimental evidence of any kind whatsoever."

- For an interview with Shiraz Minwalla, one of the winners of this year's Milner prizes for young researchers, see here.
- Edward Frenkel's new book, Love and Math, has been getting quite a few good reviews, with the latest from Jim Holt in the New York Review of Books.
- Finally, your best source of fascinating mathematically-related graphics is surely going to be John Baez's new Visual Insight blog.

Update: One more. The Perimeter Institute announced yesterday the funding (half provided by the Krembil Foundation) of two new chairs in theoretical physics. These will be held by two young mathematical physicists: Kevin Costello and Davide Gaiotto. As far as I know, the hiring of Costello away from Northwestern is the first time Perimeter has hired someone with a pure mathematics background. It's good to see them moving in this direction.

Update: More about the new Perimeter chairs here. The article discusses the fact that this is a change of direction towards mathematics:

> The choice is a strategic shift and a gamble for the 12-year-old institute, which is in a global tug-of-war for talent and looking to grow its profile as a centre for high-level thinking on some of the deepest questions in the universe.
>
> Although math is the working language of physics and equations cram every available blackboard at Perimeter, Dr. Costello's hiring, to be announced Saturday, will mark the first time the institute has sought a pure mathematician for its faculty….
>
> "There's something about the situation in physics today which makes it especially important to bring in high-powered mathematics," said Neil Turok, the institute's director.

   Concerning prizes, honors, awards, I recommend David Mermin's Reference Frame article, Physics Today 42,1,9(1989). This sickness in science has only gotten worse since then.

2. **Lowell Boggs**
   November 15, 2013

   Sasha Beilinson's opinions are understandable given his history. But sometimes things are just true without our being able to prove it. Despite valiant failed attempts to prove it, 1 + 1 still remains 2. Similarly, the KGB were the bad guys. The NSA are the good guys. It is just true.

   Yes, we should abandon the bad mathematical theory and practice that the NSA inflicted on the world of security algorithms, but no we shouldn't take them all out and shoot them. They were trying to prevent terrorism — the loss of life inflicted on innocents by crazy people.

   Do we see large scale theft of financial records because of their actions? N. Do we see good governments toppled? Do we see our personal foibles broadcast on YouTube by the NSA? No. We see Al Quaida disappearing into the backwater of history? Yes.

   Should we applaud the NSA for perpetrating fraud? No. But should we sit around wringing our hands over their lies and improprieties? No. That chapter of their efforts is over. Snowden saw to that. I'm glad he waited so long to render their efforts ineffective. I hope that the NSA are as effective with their future endeavors as they have recently been in protecting me and mine from airplane bombs.

   The NSA are the good guys. They have been doing an excellent job of preventing unnecessary deaths and the hands of lunatics.

   I might not be able to prove this, but it is true.

   I am not a spammer. My opinions are my own and they are heartfelt.

   (By the way, I really love your blog. I am doing my best to keep my mouth shut most of the time.)

3. **Peter Woit**
   November 16, 2013

   There are many obvious differences between the KGB and the NSA (for one thing, the NSA has technological capabilities the KGB could only dream of…), but please, if you just want to argue that the KGB was bad and the NSA is good (or vice-versa), do this somewhere else. Beilinson is raising a specific issue about the role of the mathematics community in the NSA controversy, and thoughtful discussion of that topic is welcome.

4. **Xu Jia**
November 16, 2013

I really don't think Nima Arkani-Hamed has any vision on how to explore the very high energy. He doesn't even have a correct vision on what would be seen @14TeV. The best plan for the future would be Chinese government approves a TLEP Higgs factory and Europe focuses on the high luminosity. This is the only chance that we could see the HHH channel open before 2030, the presence or absence of which would be a huge hint for modelling of the Higgs sector. However, this can not happen because they won't pay for a ring not bringing a long anticipated Nobel Prize. We should wait for Europe, patiently.

5. **Dave Miller in Sacramento**
November 16, 2013

Peter,

Strangely enough, had my career taken a slightly different twist, I might have played Ed Snowden's role: from the mid-eighties through the mid-nineties I worked, for several years as an employee and then as an independent consultant, for a contractor for the intelligence community.. I hope that, if I had ever run into the sort of illegalities that Snowden exposed, I too would have blown the whistle. Fortunately, I didn't, or I'd now be brushing up on my high-school Russian!

I'm inclined to agree with Beilinson, though of course even if the AMS accepts his suggestion, the result would only be symbolic.

It seems to me that any serious discussion of the issue would have to range far beyond intelligence gathering and the NSA per se: if the US is going to pursue the sort of wide-ranging interventionist foreign policy that we have pursued since 1940, then organizations like the NSA are inevitable, and such organizations are inevitably going to cross the line from time to time.

I doubt you or the AMS wants to get into that sort of debate about long-term US foreign policy!

I see no way in which either the current AMS policy or the reversal suggested by Beilinson can reasonably be considered neutral. Furthermore, the intelligence community has lots of interesting, decently-paid work for mathematicians and theoretical physicists, and there is no way that they will find a shortage of candidates to fill those positions.

From all of this, I conclude that the AMS will simply ignore Beilinson's suggestion.

But perhaps he will stimulate a few bright people to start thinking seriously about the deeper implications of US foreign policy.

Dave

6. **Peter Woit**
November 16, 2013

All,

Sorry, but I'm just going to delete any comments about the NSA issue that aren't about the relevance to the math (or physics) community. I'm not able or willing to moderate discussions of US foreign policy here.

7. **paddy**
November 16, 2013

Peter,
Damn..was just about to dig my dog eared copy of Leben des Galilei out of my stacks.

8. **Jim Akerlund**
November 16, 2013

I just read the n-category article and that article raises the issue of NSA/GCHG and them employing mathematicians. But I have also been reading articles of other countries doing smaller versions of the same thing. So, Beilinson raises the concern over what U.S. mathematicans should do, but I am seeing this as more along the lines of what the worlds mathematicians should do in each others respective countries. Maybe if the U.S. mathematicians figure out a cogent response then the rest of the worlds mathematicians can follow along or do something better.

9. **Roger**
November 16, 2013

If the AMS is going to sever ties with the NSA for undermining privacy, then maybe it also ought to cut ties with Google, Facebook, and a long list of others.

10. **Andrea**
November 18, 2013

Just an amusing coincidence, the Hamilton and Galilei chairs will be held by an Irish-born and an Italian respectively.

11. **Don Murphy**
November 19, 2013

Thank you for recommending Edward Frenkel's book, Love and Math, on this blog a months or so ago. It was uplifting, well written, and very understandable. Even the mathematics presented in the book was clear. It was best book I've read of its type and I felt joy at its conclusion. His description in the beginning of the book of how math is generally taught, "What if at school you had to take an "art class" in which you were only taught how to paint a fence? What if you were never shown the paintings of Leonardo da Vinci and Picasso? Would that make you appreciate art? Would you want to learn more about it? I doubt it. You would probably say something like this: "Learning art at school was a waste of my time. If I ever need to have my fence painted, I'll just hire people to do this for me." Of course, this sounds ridiculous, but this is how math is taught, and so in the eyes of most of us it becomes the equivalent of watching paint dry. While the paintings of the great masters are readily available, the math of the great masters is locked away."
Frenkel, Edward (2013-10-01). Love and Math: The Heart of Hidden Reality (p. 1). Basic Books. Kindle Edition.

12. **Geoff**
November 21, 2013

There was a discussion not too long ago when some people on this blog seemed skeptical that the NSA was able to recruit people at a very young age, never to be heard from again in the academic community. While that may happen on rare occasions, what seems much more likely is involvement thru the Institute for Defense Analysis:

http://cryptome.org/2013-info/09/nsa-ccr/nsa-ccr.htm

Taking a look at where they draw on talent is interesting (anyone from current graduate students, to current as well as emeritus faculty)

http://www.idaccr.org/info.html

There have been high profile examples of this, not the least of which is this guy:

http://en.wikipedia.org/wiki/James_Harris_Simons

And from the computer science side, it appears they were also able to draw on this talent:

http://en.wikipedia.org/wiki/Donald_knuth

With people like that, and the computational resources at Oak Ridge, I'm pretty sure they could break just about anything.

13. **theon**
December 7, 2013

About mathematics at the PI:
Psychologists think that the deep problems of physics will be solved by better psychology.
Philosophers think that the deep problems of physics will be solved by better philosophy.
Mathematicians think that the deep problems of physics will be solved by better mathematics.
But I, said the fool, I am a physicist; I think that the deep problems of physics must be solved by better physics.

Anderson 90th

November 17, 2013
Categories: Uncategorized

Philip Anderson's 90th birthday is coming up next month, and Princeton will host a workshop commemorating the event. Witten and Wilczek will give talks on the Anderson-Higgs mechanism, for which Anderson recently was not awarded a Nobel Prize (for the history of this, more here).

Princeton condensed matter theorist Shivaji Sondhi has an article here about the role of Anderson in the Higgs story, rightly emphasizing "the remarkable intellectual unity of modern physics."

Many have speculated that a reason for Anderson not getting a piece of this year's Nobel Prize was his public opposition to the SSC project back in the 1980s. He was far from the only physicist opposing the project, since there was widespread concern that in the Reagan-era environment of budget-cutting, devoting large sums to an HEP project would mean reduced funding for the rest of physics. Anderson has a letter in the latest APS News about this. For a summary of his concerns about the SSC, see this opinion piece from 1987.

One thing that exacerbated conflict between HEP physicists and others at the time were claims about "spin-offs" from building large accelerators, with some people claiming that HEP physics was responsible for MRI machines. Anderson recalls:

> As I was leaving the committee room behind Steve Weinberg, the particle physicist who had testified for the SSC, one of the senators accosted him and effusively thanked him for his role in the development of MRI, which had been instrumental in treatment of a relative. Since close friends and I had been responsible for most of the basic research underlying MRI's superconductiing magnets, this was a bit of a bitter pill for me to swallow.

For Weinberg's point of view on this, see here, where he writes:

> The claim of elementary-particle physicists to be leading the exploration of the reductionist frontier has at times produced resentment among condensed-matter physicists. (This was not helped by a distinguished particle theorist, who was fond of referring to condensed-matter physics as "squalid state physics".) This resentment surfaced during the debate over the funding of the Superconducting Super Collider (SSC). I remember that Phil Anderson and I testified in the same Senate committee hearing on the issue, he against the SSC and I for it. His testimony was so scrupulously honest that I think it helped the SSC more than it hurt it. What really did hurt was a statement opposing the SSC by a condensed-matter physicist who happened at the time to be the president of the American Physical Society.

In recent years the hot topic in the string theory end of HEP theory has become "AdS/CMT", the attempt to apply AdS/CFT ideas to condensed matter theory models. Anderson at nearly 90 is still dealing with HEP hype, see this from the April issue of Physics Today.

Comments

1. **jd**
   November 17, 2013

   Is it true that AdS/CFT is a conjecture that is not proven?

2. **Bernhard**
   November 17, 2013

   Sure Anderson was not the only, but he was the most high-profile physicist against the project testifying (I would say more than the APS president, as a Nobel-laureate). I find the message on this link you gave from Weinberg (which I didn't know) a bit in contradiction with his book (Dreams of a Final Theory). I would say that to the very least Weinberg misleads the reader to blame Anderson quite heavily for the SSC fiasco there. The problem is that he discusses the SSC in the middle of a chapter about reductionism where Anderson is quoted a few times as example representative of the opposition. Here two related passages from the book:

   "In the middle of the spectrum of antireductionists there is a group that is less disinterested and far more important. They are the scientists who are infuriated to hear it said that their branches of science rest on the deeper laws of elementary particle physics."

   Note: at this point Weinberg was not directly talking about Anderson, but it is clear Anderson was among those who Weinberg had in mind:

   "Chief among the physicists who are unhappy about the pretensions of particle physics is Philip Anderson of Bell Labs and Princeton, a theoretical physicist who has provided many of the most pervasive ideas underlying modern condensed matter physics (the physics of semiconductors and superconductors and such). Anderson testified against the Super Collider project in the same congressional committee hearings at which I testified in 1987. He felt (and I do, too) that research in condensed matter physics is underfunded by the National Science Foundation. He felt (and I do, too) that many graduate students are seduced by the glamour of elementary particle physics, when they could have careers that would be more scientifically satisfying in condensed matter physics and allied fields. But Anderson went on to claim that "… they [the results of particle physics] are in no sense more fundamental than what Alan Turing did in founding the computer science, or what Francis Crick and James Watson did in discovering the secret of life."

3. **Low Math, Meekly Interacting**
   November 17, 2013

   It may be semantics, but Anderson's assertions about how "fundamental" sundry phenomena may be is the only thing I've ever read by him that I've disagreed with on a conceptual basis (the SSC is something else entirely). I love "More is Different" dearly, and I would love to believe in "new laws" hidden in complexity. But I can't see why they should exist. And there is nothing fundamental about the structure of DNA. What may have the appearance of being "fundamental", to life at least, is that it must somehow encode information about itself. An almost offhand comment in Watson & Crick's paper is by far the most interesting thing in it, wherein they speculated about the information content of the sequence of nucleotide bases. This was foreseen by Schrödinger, in his "aperiodic crystals", and "What Is Life" got Watson interested in molecular biology. However, "it from bit" strikes me as far more "fundamental" than the information content of self-organizing systems. Numerical simulations increasingly bear this out.

   I've always wondered if some kind of misguided "envy" was the root cause of all the trouble. If so, it was tragic. I envy the power of physics all the time, but I'd be incredibly foolish to try to lay some kind of claim to such power for myself. Then again, I'm surely no Philip Anderson.

4. **Anonymous**
   November 17, 2013

The most ironic is that now, with the benefit of hindsight, we know that Anderson was right, althought not because of one of the reasons he listed.

Just imagined what if instead of one, we had two extremely expensive particle accelerators with nothing to show but the Higgs?

5. **Mathematician**
November 17, 2013

Anonymous, your comment doesn't make any sense to me at all. Could you please explain.

6. **Peter Woit**
November 18, 2013

Bernhard/LMMI,

I don't think the philosophical argument over what is "fundamental" really had that much to do with the Weinberg/Anderson disagreement over SSC funding. The worry that SSC costs would crowd out other funding for science was widespread. Even mathematicians were worried about this, and I remember having to point out to some of them that the SSC cancellation would just mean less total money for science, not more money available for math research. Until seeing Anderson's letter, I hadn't known about the MRI issue, how galling it was to condensed matter physicists worried about their funding to see HEP physicists getting credit for this.

Mathematician,

I assume "Anonymous" is referring to the SSC and the LHC, but it's interesting to consider where we'd be if the SSC had gone forward. If so, I very much doubt CERN would have built the LHC. They would likely have run LEP much longer, and after an SSC discovery of a 125 GeV Higgs, would possibly have upgraded LEP (along the lines now being discussed of a "LEP3") to reach energies where it could study the Higgs, somewhat of a "Higgs factory".

7. **Bernhard**
November 18, 2013

Peter,

I agree with that. My point was only that Weinberg was between the lines, intentionally or unintentionally, blaming Anderson the SSC failure on that book. The fact that he chose to consistently quote Anderson over and over as someone "unhappy about the pretensions of particle physics" and then saying that Anderson testified against the project (all in the same chapter, it is irrelevant that it happened to be reductionism) and later that the project was cancelled leaves one strongly believing it was his fault. If that was not Weinberg's intention he should have clarified, the way he he did on the link you provided. Furthermore, the fact that the project was cancelled by the House of Representatives and that Anderson testified only for the Senate (which I also didn't know: note that Weinberg's expression is "congressional committee") is not a detail that he cold have left out. How many read that book and thought Anderson played a larger than he actually did on SSC's cancellation I don't know, but I include myself among the ones fooled.

8. **Mathematician**
November 18, 2013

PW, right, if SSC is built, then CERN would do something different.

But what puzzles me is Anonymous's phrase "with nothing to show but the Higgs". Surely scientists want to ultimately find out what's true. The accelerators will find what's there to be found (in their energy range) and it's up to nature what's there to be found, whether it's one particle or none or many. If it's a surprise to some theorists then so be it. At least now they know. But it would have been better if SSC had been been built so that 15(?) years ago they would have known that the Higgs particle was there and other hypothesized particles were not there. A lot of theorists could have saved many years chasing false leads in the absence of experimental data. So having "nothing to show but the Higgs" is just fine.

9. **Art Brown**
November 18, 2013

Professor Woit, Professor Anderson's argument against SSC assumed a fixed science budget, but I infer from your comment above that the SSC would have been funded entirely with new money. 25 years on, is there any evidence either way?

10. **Low Math, Meekly Interacting**
November 18, 2013

I agree that the argument of who got what slice of the pie was at the root of opposition to the SSC. But if characterizing HEP as no more "fundamental" than other branches of science was not meant to reinforce the notion that it was no more deserving than other branches, what was the point of mentioning it?

11. **venp**
November 18, 2013

Bernhard,
"How many read that book and thought Anderson played a larger than he actually did on SSC's cancellation "
I read the book and I lived through it, there is no mistake the Prof. Anderson was
the most prominent opponent of the SSC regardless of which congressional committee he testified in. And the most vociferous, I would add, with the possible exception of Rostum Roy.

12. **Bernhard**
November 18, 2013

venp,

Thanks, that is more in accordance with what I've got from Weinberg at the time.

In any case, if what you are saying is true, which is what I thought it was true all this years, than Anderson is not taking responsibility. But I don´t think the distinction between the congressional committee he testified publicly and the one who actually cancelled the project not being the same is a detail.

13. **Peter Woit**
November 18, 2013

Mathematician,

I agree. “Nothing but the Higgs” is a fundamental discovery about how nature works in a new energy range. That some people unreasonably promised potential discoveries of extra dimensions and superpartners that never were going to happen isn’t that relevant, the LHC would have been built without that hype. The SSC cancellation did however set back HEP by decades. In an alternate universe where it was funded, we’d now not only have a Higgs discovery, but probably a Higgs factory running in the LEP tunnel for many years, and a lot of information about both Higgs physics and whatever else might be there in the factor of 5 energy range from the 2012 LHC to the SSC. I think it’s going to be quite a few decades before we get to the point we would be at now if the SSC had been funded.

Bernhard,
I’m not sure the question of Senate vs. House committee makes much difference, and I also don’t think the testimony of either Weinberg or Anderson influenced much the ultimate decision, which had a lot more to do with the politics of where large sums of money were going to get spent. From what I remember of the time, Anderson is right that quite a few physicists and other scientists (I’d suspect possibly even a majority of non-HEP physicists) would have voted against SSC funding if it was up to them, out of a justifiable fear that SSC money was not all “new money”, that it would crowd out funding of other fields. Recall also that the projected cost of the SSC kept growing, and it seemed plausible that cost overruns might cause problems for the rest of science funding.

What I think Anderson doesn’t take into account is that while many of his colleagues agreed with him, he’s always been unusually willing to speak his mind and is a very distinguished figure, so was much more quotable than others. Weinberg is probably right though that opposition from a single out-spoken figure like Anderson was less damaging than that from the president of the APS, who could be seen as representing a much wider opinion.

14. **piscator**
November 18, 2013

I don’t know exactly what happened then, but Nobel prize winners have more influence than just what they say in front of a committee. There are private soundings and opinion-forming which also play a big role in decisions.

And regarding MRI, I think completely anecdotal and uncheckable evidence from someone with such a personal stake in this should be treated with the weight of a Goldstone boson…or maybe am I meant to call it an Anderson-Goldstone boson now?

15. **Peter Woit**
November 18, 2013

piscator,
I think you’re right that private lobbying was likely more influential than public testimony. From what I know of Anderson though, he was likely saying exactly the same things privately and publicly.
The MRI issue is not something Anderson just came up with, it was a major issue in the debate at the time, see for example “Can Big Science Claim Credit for MRI?” in Science magazine here
http://www.jstor.org/stable/2879150
which tells about the arguments over this exact issue.

16. **TimG**
November 18, 2013

Bernhard wrote:
“Sure Anderson was not the only, but he was the most high-profile physicist against the project testifying (I would say more than the APS president, as a Nobel-laureate).”

If the APS President in question is Nicolaas Bloembergen, then he was also a Nobel laureate.

17. **Casey Leedom**
November 19, 2013

My memory of what was reported in the papers and other news sources at the time is that one of the biggest issues with the SSC was that the government was either going to build it or the International Space Station, but not both. The SSC represented money that was going to be spent almost entirely within one state, Texas, while the backers of the ISS were able to lobby Congressional Members of many states by farming out pieces of the ISS all over the US.

18. **Bernhard**
November 19, 2013

Peter,

“I’m not sure the question of Senate vs. House committee makes much difference”.

OK, I’m not an American and my idea of how this all works is perhaps not so accurate. Is curious though that Anderson mention it as the first argument in his defense.

TimG,

Thanks. I always assumed the Senate hearings happened in 1992, but I went to check and indeed they took place in 1991.

19. **Low Math, Meekly Interacting**
November 19, 2013

Interesting footnote here:

http://econ.williams.edu/files/www.jstor_.org_stable_pdfplus_27757780.pdf

–
“Nicolaas Bloembergen testified in 1991 that neither superconducting magnets, the superconducting magnet industry, nor magnetic resonance imaging had come primarily from the development of accelerators, adding in a follow-up letter to an official at Fermilab that was entered into evidence in a Congressional hearing in the spring of 1992 that “MRI woud be alive and well today even if Fermilab had never existed.” To Anderson, “the saddest sight of all is to see officials of the Department responsible for our energy supply deliberately misleading Congress and the public with these false claims, and to see my particle physics colleagues, many of whom I admire and respect, sitting by and acquiescing in such claims.”
–
Incredibly saddening little turf war all around, that. And all quite aside from the the true worth of the SSC. Incredibly saddening.

20. **Peter Shor**
November 19, 2013

It seems to me that Anderson has been made something of a scapegoat, and that the blame for the cancellation rests at least as much with the HEP community, first for the original cost estimate for the SSC being less than half its true cost, and second for subsequently being incompetent at politics.

It's certainly true that Anderson's opposition didn't help, but blaming him rather than trying to figure out what the HEP community should have done better isn't going to help get better results in the future.

21. **Low Math, Meekly Interacting**
November 19, 2013

I've believed for a long time that Anderson et al.'s testimony served to put a fig leaf of legitimacy on something Congress wished ardently to accomplish anyhow to score political points. That said, the focus and tenor of the whole debate on what branch of physics should get funded how much and why was, to me, a tragic development.

22. **Eli Rabett**
November 19, 2013

Up until the SSC, the HEP community had been remarkably successful in finding new money for its projects, indeed the large sums that they generated had something of a trickle down effect on other fields, so everyone left them alone. At the time of the SSC it was obvious that the game had changed, if for no other reason than the huge cost, but also the limits on R&D funding due to the federal budget squeeze at the time. The SSC was going to negatively affect all other science funding, thus the us against them.

23. **arp**
November 19, 2013

Given how difficult it was to get the LHC up and running with access to more modern technology, is it reasonable to believe that the SSC could have been completed on schedule, on budget, and at its promised specs?

24. **paddy**
November 19, 2013

1) arp says above what I always wondered.
2) these were theory folk arguing for an instrument..not just the importance of what could come of the result but that it would work in anything close to the time frame and budget that was proposed.
3) and why do you all ignore that Weinberg was bought and payed for?

25. **GoletaBeach**
November 20, 2013

Reading the Science article on MRI was just depressing. A deputy secretary of energy (not an actually particle physicist) makes an inflated claim. A nobel laureate (Bloembergen) and Robert Park pounce on him and attack all particle physicists. Jeez.

Felix Bloch & Edward Purcell (Purcell is a particular hero to many experimentalists, particle & otherwise) got the Nobel Prize for what we now call MRI, not Bloembergen or Anderson. Indignation by B & A is just misplaced.

The development of MRI into a useful reliable research tool was the work of many, many folks, and without doubt a few strands of the quilt come from experimental particle physics. Denying that is as ignorant as saying the whole MRI field comes from particle physics.

Meanwhile, anyone noticed the proliferation of light sources in the world, and how `small science' groups flock to them? Don't ever hear from the SSC-opposers anything about how important particle physics was to the development of light sources, or even the simple fact that many of the light sources are on the grounds of former particle physics labs, like SLAC. Certainly there are no particle physics labs that are operating in former experimental condensed matter facilities!

BTW, I met face-to-face with Anderson and asked him one-on-one about his opposition to the SSC. He said he couldn't stand the SSC because of all the `spear chuckers' (direct quote) who supported it. His opposition was visceral and the scientific overlay was merely window dressing.

26. **Kavanna**
November 20, 2013

The problem wasn't Reagan-era budget cutting, which happened in the early 80s, before the SSC was proposed. The problem was the dawning post-Cold War era, when HEP had an uncertain future. In the early 90s, there was a strong push to reduce federal deficits — the era of Perot and "read my lips." The SSC had enough political cover under Bush Sr. to keep going, being based primarily in Texas. When Clinton replaced Bush in 1993, the SSC lost that cover. (The SSC was canceled in the fall of 1993.) It became the political equivalent of a large, lumbering beast on the Serengeti, spotted by packs of smaller but swifter predators.

The obvious strategy, barely considered, was internationalizing the project, to include foreign scientific efforts, especially the Japanese. (The Japanese were riding high at that point, at the end of 30 years of rapid growth. Our trade and federal deficits were mainly their surpluses.) But that was all seen too late. The cancellation of the SSC was a disaster for HEP in many ways, not least in the way that it created a vacuum later filled with hot, exponentially expanding string/M-theory hype.

27. **Eli Rabett**
November 21, 2013

Having built Pound boxes, let Eli tell you that knowing the physics of NMR was not the problem but making superconducting magnets was as is clear to anyone who ever did NMR with an iron core monster. Bloch and Purcell were the first observers, but MRI depended on the availability of supercons, which is what Bloembergen and Anderson were talking about. Oh yeah, and among other things, having the Cooley Tukey FFT algorithm (also Bell Labs)

To climb down further into the weeds, the SSC got caught up in Gramm Rudmann Hollings and the Budget Enforcement Act of 1990 which set caps on spending, including a cap for scientific research. It is that in particular which set the condensed matter, and HEP physicists against each other.

28. **cthulhu**
November 24, 2013

(coming in late…)

Kavanna has it exactly correct – the demise of the SSC was Texas-bashing politics as a thin excuse to "cut the fat out of the budget." I was working in north Texas aerospace at the time; when several co-workers left for the SSC to do stuff ranging from mechanical design to IT, it seemed likely to me that they would be back in a few years – unfortunately I was right.

29. **chiz**
November 26, 2013

PW: *In an alternate universe where it was funded, we'd now not only have a Higgs discovery, but probably a Higgs factory running in the LEP tunnel for many years, and a lot of information about both Higgs physics and whatever else might be there in the factor of 5 energy range from the 2012 LHC to the SSC.*

Of course, its also possible that in this alternate universe with a SSC that we might have discovered that the 125 Gev particle isn't a Higgs but is instead something that the theorists never predicted.

30. **I_Was_There**
November 29, 2013

Just a few hopefully clarifying points:
1. The SSC vs International Space Station funding that year in Congress is telling. The sometimes emotional opposition against the SSC in the House and Senate was bipartisan just as was the support. Opponents in the House were led by members such as Jim Slattery (D-KS), Sherwood Boehlert (R-NY) and Dana Rohrabacher (R-CA). A day after the vote finally killing the SSC, the ISS funding for that year was approved by the House by (if memory serves) one or two votes with Boehlert and Slattery voting to continue the ISS. It is well known that Vice President Gore spent real time lobbying for the ISS and he opposed the SSC. (Slattery is the disingenuous person who went on ABC's Primetime Live to publicly accuse the SSC team of misusing and abusing federal funds based on spending a few bucks to buy a few fake plants for a few offices in a largely windowless old warehouse rented to .. save money; Slattery also cited as an example this misuse of funds by physicists who deemed themselves privileged because a few times during all-day meetings, the lunch was "catered" which turned out to be ordering a few cold cut sandwich plates from a local supermarket so the meeting participants could work through lunch! Boy, did Sam Donaldson leap all over that to spew smoke where there was no fire.)

2. Dr. Anderson's opposing influence was indeed heavily felt from his private comments as well as his public comments. During that time, I spoke directly to a staffer in Sen. Ted Kennedy's office who cited Anderson's views as a primary factor leading Sen. Kennedy to oppose the SSC.

3. While the concern about science funding for other well-deserving research areas/projects seemed real, the fact is that the SSC funding had nothing tangible to do with condensed matter research funding, and terminating the SSC funding that year had *zero* effect on non-HEP funding or reducing the deficit. The money was simply re-programmed to other "water projects" that were within the same purview of the House appropriations committee dealing with the SSC.

4. The comments about the MRI and superconducting magnets are missing a key point. No doubt the basic research is being cited more or less correctly, and there is no doubt that MRI happens with or without HEP and the big accelerator labs. However, especially after BNL and Isabelle, a key contribution made by experimental physicists and engineers was actually making good superconducting magnets before anyone else did, and the need for all that superconducting cable for the Tevatron absolutely did accelerate the development of more cost effective cable fabricated commercially.

Those are facts. I could list more, but any revisionism that Dr. Anderson did not play a prominent role in being one of several important scientists to influence the opposition to the SSC is simply that — self-serving revisionism when it's now pretty obvious that the SSC would have succeeded probably at least a decade before the LHC.

31. **jd**
November 30, 2013

I_Was_There completely misses the point on the savings from the cancellation of the SSC and I suspect he knows it. At the cancellation two billion had already been spent and the tunnel was a quarter finished. The project was heading for at least a factor of two overrun that would have had to come from somewhere. That overrun was saved. As to better superconducting cable, well whoopie and I thank you, but the MRI machines would still have been built. At the moment the MRI technology is heading toward new wire technology that does not relate to that used in HEP. Maybe you guys can lower the cost of your next big machines from using that. Maybe not. But I am a little sick of all this hype on the benefits of the spinoffs. You cannot justify the building of the big machine from their spinoffs. If the spinoffs are what is important, fine. Do all the research for the next big machine and build prototypes of all the technology but do not do any construction. We then get all the spinoffs and save the majority of the cost.

32. **I_Was_There**
December 1, 2013

JD has turned around my comments, so I feel forced to reply that:
1. I never justified the construction or cost of the SSC based on the spinoff of superconducting cable. There is not one word in my comment to that effect. I explicitly stated that "there is no doubt that MRI happens with or without HEP and the big accelerator labs. " I was only clarifying the role that HEP had at that time in developing superconducting magnets and how that progressed the commercial developments toward dropping the cost of the cable at a faster rate. That was only in response to a couple of the earlier comments. That's a fact whether JD likes it or not.

2. There is also no doubt the final cost was going to be 2x or more the initial cost. My guess at the time was 2.5-3x the initial $5-6B estimate. Compare that with other big projects in defense and non-defense, and especially with the ISS. I did not miss any point about the "savings" of cancellation, including about the federal budget in the ensuing years.

3. Finally, the original topic here was the effect that Dr. Anderson had as a publicly prominent scientist opposing the SSC, and my comments were meant to respond to that topic. Perhaps I should not have included a couple of the contextual comments regarding the overall tone and politics of the debate. JD is of course entitled to his opinion, too.

33. **Peter Woit**
December 1, 2013

I Was There,

Thanks for the comments, which were interesting and helpful.

About Anderson, there's no question he was a prominent opponent of the SSC, and had some effect, although one can argue about the size of this effect, and what would have happened in a counterfactual world without him (personally, I think the SSC would still have been canceled, with the growing cost a huge factor). It seems he's mainly annoyed to be portrayed as the only such opponent of the SSC, when the fact was that there were significant others.

34. **Eli Rabett**
December 2, 2013

Just to point out that ISS had a huge Texas footprint through Johnson. What NASA did do was give a piece of meat to a whole bunch of states, but Texas had the prime.

Progress on Twin Primes

November 20, 2013
Categories: Uncategorized

There's a new paper out on the arXiv last night, Small gaps between primes, by James Maynard, which brings the bound on the size of gaps between primes down to 600. This uses some new methods, beating out the Polymath8 project, which has been improving Zhang's original bound of 70,000,000, getting it down to 4680.

To follow the Polymath8 project, the place to look is Terence Tao's blog, here. They're working on a paper, with the current draft version available here. This is a remarkable collaborative project bringing together a sizable group of mathematicians in an unusual way.

For more about this, see this expository article by Andrew Granville, which is pre-Maynard. At Quanta magazine, Erica Klarreich has an excellent long popular article telling the story to date, including that of Maynard's new result.

Comments

1. **kdl**
   November 20, 2013

   Interesting to know if Zhang didn't publish his twin primes work back in May, Maynard's paper would still show as it is now 6 months later, would it be an even BIGGER twin primes breakthrough as well just by now?

2. **Nick M.**
   November 21, 2013

   Thanks, Peter, for the update. I've had a number of things going on in my life at this time, and I haven't had the opportunity to stay abreast of the latest developments in the twin prime conjecture. Even though number theory isn't my primary interest in mathematics, every mathematician has a soft spot in his/her heart for what Carl Friedrich Gauss described as the "Queen of Mathematics".

3. **Pete**
   November 21, 2013

   Maybe more to the point, Maynard can not only show a better bound on lim inf gaps between one prime and the next (the next big excitement will be when that gets to single digits, we're still over 100, and in some sense that's not so much nicer than Zhang's 70,000,000) but he can show that there is a finite bound on lim inf gaps over any given m primes – this wasn't thought to be on the table. Roughly, we knew bounded gaps between primes conditional on a (still) unproved `good behaviour' conjecture (Elliott-Halberstam); Zhang's theorem is powered by Zhang's observation that you don't need the full strength of that conjecture, and you can actually prove (with a lot of work) what you do need. But even assuming the full E-H conjecture we couldn't get much below trivial lim inf gaps containing multiple primes before now (Goldston and Yildirim claimed something like this ten years ago, but there was an error that looked unfixeable: Maynard, roughly speaking, fixed it).

4. **TonyK**
   November 23, 2013

   Andrew Granville has updated his expository article to include Maynard's results. See http://www.dms.umontreal.ca/~andrew/CEBBrochureFinal.pdf.

5. **paddy**
   November 23, 2013

   @TonyK
   Thanks for the link. Makes good reading on a cold stormy afternoon.
   @PW
   Fascinating stuff even for an old experimental physicist.

Controversy over Yau-Tian-Donaldson

November 25, 2013
Categories: Uncategorized

The last posting here was about an unusually collaborative effort among mathematicians, whereas this one is about the opposite, an unusually contentious situation surrounding important recent mathematical progress.

What's at issue is the proof of what has become known as the "Yau-Tian-Donaldson" conjecture, which describes when compact Kähler manifolds with positive first Chern class have a Kähler-Einstein metric. This is analogous to the Calabi conjecture, which deals with the case of vanishing first Chern class. Progress by Donaldson on this was first mentioned on this blog here (based on his talk at Atiyah's 80th birthday conference in 2009). Last fall a proof of the conjecture was announced by Chen-Donaldson-Sun, with an independent claim for a proof by Gang Tian, see here. I wrote a bit about this last winter here, after the details appeared of the Chen-Donaldson-Sun proof, and that posting gives some links to expository articles about the subject.

I had heard that there were complaints about Tian's behavior in this story, including claims that he did not have a complete proof of the conjecture and was not acknowledging his use of ideas from Chen-Donaldson-Sun. Recently this controversy has become public, with Chen-Donaldson-Sun deciding to put out a document (linked to from Donaldson's website) that challenges Tian's claims to have an independent proof. The introduction includes:

> Gang Tian has made claims to credit for these results. The purpose of this document is to rebut these claims on the grounds of originality, priority and correctness of the mathematical arguments. We acknowledge Tian's many contributions to this field in the past and, partly for this reason, we have avoided raising our objections publicly over the last 15 months, but it seems now that this is the course we have to take in order to document the facts. In addition, this seems to us the responsible action to take and one we owe to our colleagues, especially those affected by these developments.

I should make it clear I'm no expert on this mathematics, so ill-equipped to judge many of the technical claims being made. The Chen-Donaldson-Sun document is giving one side of a complicated story, so it would be useful to have Tian's side for comparison, but I have no idea if he intends to respond.

On a more positive note, perhaps this controversy will not interfere much with future progress in this area, as Donaldson and Tian are jointly organizing a Spring 2016 workshop on this topic at MSRI.

Update: I hear from Tian that he has recently written a response to the Chen-Donaldson-Sun document, which is available here, and he may at some point write some more about this. Anyone who has read the CDS side of this should also take a look at what Tian has to say in response.

Comments

1. **An.**
   November 25, 2013

   If you carefully read this linked document "On some recent developments in K\"ahler geometry", the accusations sound pretty serious. Also, they did a great job presenting the evidence, which all looks very convincing. Basically, they claim that most key arguments were copied by Tian without any reference after their preprints were posted. From first to second version of Tian's paper on arxiv, several missing or wrong arguments were replaced with the ones almost identical to theirs, and still there are some gaps left (probably because he can not continue copying ALL their arguments). Why would somebody who had such a great career do something to taint it like that?

2. **srp**
   November 25, 2013

   In Hollywood, entities suing one another on one issue often collaborate simultaneously on others. Let's hope similar compartmentalization works for the jointly organized workshop mentioned in the post.

3. **An.**
   November 25, 2013

   Of course, if you look at Tian's let's say top ten most cited papers, it is clear that this was probably one of his favorite pet problems. This might somewhat explain his behavior. Also, wouldn't it be better to call it in the post the Yau conjecture, since this is primarily how CDS call it in their document (they mention that *sometimes* it is called YDT conjecture). Well, at least one good side effect of this controversy is that we can safely assume that there will never be a paper by the trio Sun-Tian-Donaldson.

4. **Peter Woit**
   November 25, 2013

   An.,
   From what I can tell "Yau-Tian-Donaldson conjecture" is pretty standard terminology. I suspect the reason CDS are avoiding it is just Donaldson's adherence to standard academic practice of authors avoiding use of their own name to describe things in their papers.

5. **An.**
   November 25, 2013

   Peter, this doesn't stop Tian from using it, as well as the Cheeger-Colding-Tian, in his paper. I noticed that he also mentions Hermi***tian*** a lot.

6. **Daniel Mathews**
   November 25, 2013

   As mentioned in CDS document, Tian posted his paper in two versions. The first one posted on Nov. 20, 2012 has only 32 pages. The sencond one on Jan. 28, 2013 has 47 pages. What they didn't mention is there is a third version posted quite recently on Oct. 18, 2013 at http://www.bicmr.org/~tian/?page_id=8, which has 61 pages. The fact is, Tian has been correcting and adding more details for his paper in the past year, while CDS has not changed a word in their papers. What can one conclude from this simple fact?

7. **Kent**
   November 25, 2013

One can't conclude anything at all from that simple fact. He could be adding and correcting his papers because they were incorrect or incomplete at first. Or, perhaps his paper was correct and complete at first, but he is making additional progress. But the fact that there are multiple versions of his paper, on its own, proves nothing. It all depends on the details.

8. **theoreticalminimum**
   November 25, 2013

   An.:

   Hermitian is absolutely fine. French mathematicians & physicits use *hermit**ien***. Apparently, this whole hermitian-vs-hermitean pseudo-pedantry is only an issue in some English-speaking milieu, which is rather funny.

9. **Mathematician**
   November 25, 2013

   Tian's reply can be found here:

   http://www.bicmr.org/~gtian/?ddownload=315

10. **An.**
    November 25, 2013

    theoreticalminimum, it was a joke (about Hermitian).

    Tian's response is reasonable overall, but the response to accusations in Section 3.2 avoided the main issue, namely, why did the proof of Lemma 5.8 went from 25 lines in the first version of his paper to 10 pages in the second version, with the proof now identical to CDS (even though Tian claims he never read it).

    On the other hand, after reading Tian's response, I feel that the CDS document focuses on minor details and does not explain what was the BIG NEW IDEA that Tian stole from them. After all, it is hard to imagine that Tian didn't know some minor details about the topic he has been working on for decades.

11. **Phil**
    November 26, 2013

    Maybe there is not a single big new idea. The obstacles have been there and been known to experts for many years. There are many possible ways to solve the problem, and none of them seems to work at first sight. You have to try and try, test and test. The new idea is that some guy Jimmy finally find one of the ways works, and if he told the outline to an expert Tom who had worked on this problem for many years, Tom could fill in most of the details, if not all. But you cannnot say that Tom didn't know this outline. He just didn't know that this outline works.

12. **Curious**
    November 26, 2013

    There is another post written by a third person:
    http://blog.sciencenet.cn/blog-87484-721241.html

13. **Peter Woit**
    November 26, 2013

    Curious,
    I saw the document from Sen Hu you link to a few months ago, decided at the time that it wasn't a good idea to mention it on the blog. This was because it seemed rather one-sided, and it was not clear at all that it was written by someone expert enough in the technicalities and their history.

    The Chen-Donaldson-Sun document did seem worth mentioning, since, while it may be one-sided, it's an authoritative representation of the views of some of the principals in the the story. I'm glad to see that Tian has also given his point of view. Hearing what they have to say directly from both sides involved in this is a lot better than getting a one-sided argument from some third party. So, at this point I don't see anything particularly useful about the Sen Hu document.

14. **Peter Woit**
    November 26, 2013

    I've deleted several comments here, in one case at the request of the original commenter. Please do not use this comment section to engage in attacks on people, especially not taking advantage of anonymity.

    People arguing over priority issues is not very edifying, but at least in this case we're hearing directly from the people involved giving their point of view on these issues.

15. **Grinch**
    November 29, 2013

    It is too bad to see such wonderful mathematicians spatting in public about priority.
    Indeed, we are blessed in many unusual ways in life; it can be regarded as a real blessing to be neither smart nor knowledgeable enough to work in certain areas!

    More seriously, a practical way to avoid this sort of problem is to avoid "problem-solving" altogether in favor of posing new questions which you try to answer at least partially yourself before someone else can jump onto it. But once you do publish or speak publicly about it, you have to let go of it and let your "baby" walk on her own feet! And part of the problem here seems to be Tian's unwillingness to let his beautiful baby go off on her own….

    Another related approach is to try to come up with new theories.

    A third is attitude: to not be so worried if someone else does have "priority", if you do "rediscover" something. This is inevitable in today's world. Try to unhook yourself from the disappointment; if you reinvented it, it means you are on the right track!
    Furthermore, don't be discouraged: inevitably you came up with some new angle, you just have to see what it is! Of course, be generous in your citations. No one ever lost anything by over-citing others. Err in that direction! Upsetting someone is stupid and unnecessary- and unjust. Be bigger than that….

    And most importantly: recognize that
    the process was just as much fun, and having fun with it should be the first and ONLY point of doing mathematics. (However, never, ever admit that truth publicly or to a granting agency-this is a closely guarded secret of mathematics!)

The best mathematicians I have known- coincidentally the ones most universally loved- focused on the beauty of the math itself, and also realized the beauty of the human mind, and human personality, in its many and varied (and often difficult) forms.

There is a caveat to this idealism: we all need a job, we all need grants. But one hopes that is a corollary of good work and good ideas and that it doesn't become the main point. Too much focus on credit, money, power leads to self-destruction and damage to a community one loves, and which one should be working to build. Life is a rich mixture of beauty, ugliness, generosity, selfishness, jealousy, compassion, justice, unfairness. We can choose what to focus on, which tendencies in ourselves and others to encourage. If we get paid to think, to do something we love, we should never forget how lucky we are, compared to the vast majority. And we should also remember that the mathematics itself doesn't care one iota: it will go on being beautiful, despite the flaws of its discoverers.

16. **Noah Smith**
December 1, 2013

Sad to see this kind of priority dispute still cropping up in math.

17. **Mitchell Porter**
December 2, 2013

Noah: how does the better world look and work – it's always clear who was first? no-one cares who was first?

18. **Noah Smith**
December 3, 2013

Well, we seem to have a lot fewer of these disputes in recent decades. Is that an illusion? If it's real, it's probably due to better information dissemination making it clearer who was first. But also probably due to more credit-sharing (i.e. fewer people caring who was first past the post, as long as people did the work independently).

So, both.

19. **Mathematician2**
December 6, 2013

"Grinch", your remarks are exceedingly cruel. The reality is that altruism (in mathematics research and elsewhere) sometimes has very negative consequences for the altruist, and comments like yours serve only to throw salt into the wound. I used to talk openly about my ideas, was generous with co-authorships, etc., but started realizing that I kept getting burnt. In one case, after a talk by a former collaborator, I explained to him (and his collaborator on that talk), how to generalize their result. I was simply being generous. I was shocked when I later got a paper to referee by those two guys, with the result I told them, but not even an acknowledgement that I told them. When I discussed the situation with a senior colleague, they berated and belittled me with the implication, like "Grinch"'s, that it would be contemptible for me to finally stick up for myself for once, and that I should shut up and accept the paper, which is exactly what I did, I was so browbeaten.

I really wish that mathematics research (and other activities) were a utopian, happy cooperative endeavor that people did for the pure joy of it. But it's just not that way. There are too many aggressive ambitious people out there, and if you are the generous altruistic type, you just get walked all over. Personally, the only way I could deal with that type of environment, was to avoid it completely and work in isolation. I would have loved to have been part of a happy cooperative mathematics research community, but I found that in my area, it doesn't exist.

Quantum Mechanics and Representation Theory: talk and book progress

November 27, 2013
Categories: Quantum Theory: The Book

Last week I gave a colloquium talk at the Texas Tech math department, slides are here if you're interested. One motivation for the talk was to advertise the book project I'm working on, which gives a lot more detail about these topics if you find something interesting in the slides.

The current state of the book is visible here. There are 31 chapters done, about another 5 to go. I also need to go through the entire thing again and reconcile various choices of convention that currently are not necessarily consistent. I plan to get back to work on this in a couple weeks after fall classes are over here, have something like a finished draft of a book done around February. The next project will be to get back to what I was writing long ago on Dirac cohomology and make some more progress with that.

For the next few days though, will be taking it easy, and eating turkey. Happy Thanksgiving to all!

Update: The volume of the Feynman Lectures on Physics devoted to quantum mechanics is now available freely online here. This is a masterful introduction to QM from the perspective of a great physicist. What I've been writing in some sense is intended to function best as a supplement to this and an explanation of how it is related to some basic concepts in mathematics.

Comments

   FM, he gave you a BOOK, for crying out loud — and you knitpick?

3. **Per**
   November 28, 2013

   Hey,

   This book looks really interesting. Thanks for putting the draft online,

   Per

4. **Peter Woit**
   November 28, 2013

   Florin,

   I should have provided this link:
   http://www.math.columbia.edu/~woit/brstdirac.pdf

   As I mentioned, next plan is to get back to work on this…

5. **Cplus**
   November 28, 2013

   The dual of your title, Representation Theory for Physicists, may claim equal validity.

6. **kashyap vasavada**
   November 28, 2013

   I would like to know if your book would clarify foundations of QM or help with the perpetual debate on its interpretations.

7. **Yair**
   November 28, 2013

   I think the use of the Feynman statement as the motivation for the colloquium is inaccurate.

   Feynman was not referring to a lack of understanding of the mathematical tools.
   He was rather referring to issues like the non intuitive nature of QM.

8. **Ray**
   November 28, 2013

   How come none of the equations in the book are numbered? Also you should replace hand drawn figures by figures produced in latex.

9. **Avattoir**
   November 28, 2013

   Book needs a sexed-up title to goose sales: one suggestion, to get the ball rolling about the hat: Where there's a Weyl there's a Woit. (Logic suggests those might be reversed; but this is about marketing, dammit!).

Another – The Big Lie Updated; or – Quantum Mechanics: Lies, Embedded Lies and Mathematics.

10. **Florin Moldoveanu**
November 28, 2013

Thank you Peter, I will study the reference in detail.

11. **Adam**
November 29, 2013

I am currently an undergraduate studying physics, and am taking Quantum Field Theory for the first time. Through this class, I really have gotten a feel for how important representations of lie groups really are. As far as I can tell, however, most undergrad physics majors – unless also advanced math majors – seem to pick it up as they go, which is really odd. Representation theory arguably contains the most important mathematical tools used in modern physics, save for say calculus… Point is, this book will help fill a gaping void in the literature for young students of physics – just some words of encouragement.

12. **Chris Oakley**
November 29, 2013

I agree with Avattoir. How about this for an opening sentence: "For decades the worst kind of populist bullshit has been peddled in quantum mechanics s0-called text books."

13. **Peter Woit**
November 29, 2013

Cplus and Adam,

Thanks, I do hope this is as useful to physicists trying to understand representation theory and some of the mathematics behind quantum theory as it might be to mathematicians trying to understand quantum theory. I should find another title for it, although I'm not going to follow Avattoir's suggestion…

14. **Attempting to be useful**
November 29, 2013

Your books seems to be pretty good. As a math person that took some grad physics courses, however, my recollection is that what I missed most was physical intuition.
So, my suggestion is to add some remarks on the following:
(1) at what scale do you need quantum mechanics to describe motion? (something like what is done in the Feynman lectures in physics)
(2) what is a lot of energy or little energy – what sort of process and behavior you can see at different energy levels?
(3) Which particles exist?

Basically, I think mathematicians tend to focus too much on the math side of any given scientific theory. Hence, they will most likely look at the book as a small subset of representation theory – and as such, they might think that it would be more profitable to read a book on representation theory instead. It is crazy, of course, that many of them would think like that – so, if you give them a concrete grasp that there are some real objects out there, you may end up waking up some sleeping beauties.

15. **Peter Woit**
November 29, 2013

Ray,
The book is still a long ways from a finished product, latex makes it look much more finished than it is. It definitely needs better and more graphics, and probably equation numbering.

kashyap vasavada,
There's nothing really about interpretational issues, although there is somewhat of an argument that QM is really founded on certain kinds of mathematical ideas, so in that sense is making an argument about foundations.

Yair,
Feynman was contrasting QM to classical physics, including the fact that they seem to have radically different formalisms. I'd argue that representation theory does give some "understanding" of the QM formalism, giving a sort of answer to questions like "why are observables self-adjoint operators?", which is the sort of question I think Feynman had in mind as "no one understands" the answer to.

Attempting,

Thanks for the comment. I may try and add more material like you suggest (there will be some in the last chapter on the standard model). Giving some real physical insight though is difficult, I think what I've written would best be used in conjunction with a standard physics text, supplementing but not replacing it.

16. **Chris W.**
November 29, 2013

Loosely related to the question of what Feynman meant: See [this new post] by Steve Hsu.

17. **Emanuel Quant**
November 30, 2013

Peter,
I am struggling with the understanding of the physical relevance of unitary inequivalent representations.
You say:
"In the case of quantum field theory one has an infinity of inequivalent irreducible representations of the commutation relations to consider, one source of the difficulties of the subject."
It seems to me that this issue is not fully settled yet. What is your opinion ?

18. **Peter Peterson**
November 30, 2013

Hi Peter,
I liked your presentation of QM for mathematician – the version from couple of years back. This is a great continuation, as a physicist, I am a bit challenged by a very matter of fact presentation that expects basic mathematical knowledge, that physicists often try to get away without.

Just a question – I was trying to search for word Clifford, just to verify how much in depth you go there (again, a great introduction here, but with expectation of having necessary mathematical background would challenge a number of physicists, and I suspect should be expected basic knowledge for a mathematician). My search did not work that well, because 'ff' in Clifford is using a special (I assume Unicode?) character (I cannot paste it here, edit box will not let me). It is probably intended.
Again, I like your book a very much.

19. **Peter Woit**
November 30, 2013

Emanuel Quant,
I don't think that it's a problem that can be "settled", it's a real aspect of the mathematics of qfts, partly responsible for making the subject much more difficult than quantum mechanics of a finite number of degrees of freedom.

Peter Peterson,
The treatment of Clifford algebras, spinors and their relation to fermionic quantization is one thing that's in the notes, but not so well known (to physicists or mathematicians). I don't know of a really good, easy to follow treatment of these topics elsewhere, so I hope what I've written will be useful.
The "ff" issue is about the handling of "ligatures", I'm not sure what source you are having the searching problem with. For more about this issue, see here
http://english.stackexchange.com/questions/50660/when-should-i-not-use-a-ligature-in-english-typesetting

20. **Art**
November 30, 2013

Title contest? Avattoir sets a high standard, but how about "Giving the Lie to Feynman"? A marketer's dream…

21. **Peter Peterson**
December 1, 2013

Hi Peter,
You likely read the following books:
1. Clifford Algebra to Geometric Calculus A Unified Language for Mathematics and Physics (Fundamental Theories of Physics) By D. Hestenes, G. Sobczyk
http://www.fishpond.com/Books/Clifford-Algebra-to-Geometric-Calculus-D-Hestenes-G-Sobczyk/9789027725615
2. New Foundations for Classical Mechanics (Fundamental Theories of Physics) by David Hestenes http://www.amazon.com/Foundations-Classical-Mechanics-Fundamental-Theories/dp/0792355148
3. Geometric Algebra for Physicists by Chris Doran, Anthony Lasenby. http://www.amazon.com/Geometric-Algebra-Physicists-Chris-Doran/dp/0521715954/ref=sr_1_1?s=books&ie=UTF8&qid=1385925080&sr=1-1&keywords=doran+and+lasenby
4. The Berezin Calculus by Paul Robinson – http://www.google.com/url?sa=t&rct=j&q=&esrc=s&source=web&cd=1&ved=0CCsQFjAA&url=http%3A%2F%2Fwww.ems-ph.org%2Fjournals%2Fshow_pdf.php%3Fissn%3D0034-5318%26vol%3D35%26iss%3D2%26rank%3D1&ei=noybUtTIE4fxoATvqoDAAg&usg=AFQjCNE9kLrL24OG59Kvzf2ql7WLSjOxbg&bvm=bv.57155469,d.cGU&cad=

There are a lot of shorter articles and studies if you search.
Hestenes started applying and promoting Clifford/Grassmann framework as a consistent approach to all areas of physics a few decades ago. There were multiple attempts to teach physics based on this geometric (Clifford) approach, even though in my opinion, notwithstanding the claims by proponents that geometric algebra approach makes understanding physics easier, the prerequisite is understanding of geometric algebra, which I suspect adds a more challenging preliminary step than the traditional approach. Doran Cambridge group has a very nice gauge theory of gravity based on this approach (see: http://arxiv.org/abs/gr-qc/0405033v1), among many other things.
In any case, you may already have an opinion on most if not all that I referenced, would be interesting to read your opinion, even just a short comment.

22. **Peter Woit**
December 1, 2013

Peter Peterson,

I've always thought that the spinor/Clifford algebra point of view on geometry ultimately will have something to do with how to unify internal and space-time symmetries, but I don't think any of the attempts to do this tried so far really work. Much of the "geometric algebra" stuff is purely classical, but what I think is most fascinating is the way it shows up in quantization of fermionic variables. Of the things you mention, I'm not specifically familiar with those sources, but I've looked at closely related things off and on over the years.

What I've tried to put into this book is a good reflection of what I see as the important mathematical ideas, together with how they show up in basic ideas about quantization. There will be some more of this in the chapter I'm in still writing about quantized spinor fields. Once I've finished this, there are some ideas there I think worth pursuing, will try and write more about them at some later point.

23. **vmarko**
December 1, 2013

Peter Peterson:

"[…] http://arxiv.org/abs/gr-qc/0405033v1 […]"

I don't know about the whole geometric algebra approach, but what I see from the above article is the following:

(1) The authors introduce the geometric algebra by essentially rewriting the tensor calculus in the spinorial representation of SO(3,1). They just use a somewhat unconventional abstract notation to hide spinor indices. Apparently no mention is being made that this is equivalent to an already existing body of knowledge in a different notation.

(2) The authors do not appear to understand the difference between symmetry localization and introduction of interactions. They claim that localization of Poincare symmetry should be enough to generate gravity, criticize conventional (Kibble/Hehl/others) approach for having an extra step of saying "spacetime is curved", and then go on to perform both of these steps in their own approach, without recognizing what they do. In the end they advocate that their approach is better and that it leads to Einstein-Cartan gravity. However, from what I saw, it is quite equivalent to the standard approach.

(3) The authors make some explicitly incorrect statements regarding the localization of Poincare symmetry, such as that there is no way to disentangle translations and rotations, criticizing the conventional localization approach. They even cite Kibble and Hehl papers (from 1961 and 1976 respectively) to back that up. However, they seem to be unaware of the more recent literature where it was shown that this disentangling can indeed be done and that there is no problem with the conventional approach.

I don't want to sound like a referee here, but IMO the authors have not done their homework, and I don't trust any conclusions of that paper. Moreover, I don't see any benefit of introducing the geometric algebra language for this whole ordeal.

My advice on reading this paper: nothing interesting, move on.

HTH, 🙂
Marko

24. **D R Lunsford**
December 2, 2013

Thanks for the book. Fills a gap. Will sit next to Weyl when I have the print edition 🙂

-drl

25. **Mtor**
December 3, 2013

Hello Prof. Woit
You have a very beautiful book there. With all the theory you could easily add a chapter of "applications " containing elegant solutions of QM problems using representation theory. I´m thinking, for example, about the Onsanger solution or the Kauffman solution of the 2D Ising model or in general problems that can be stated clearly in a mathematical way and can be solved neatly using representation theory.

26. **lun**
December 3, 2013

OT but IT for this blog, perhaps you can comment on the latest stringy PR fad,
http://news.sciencemag.org/physics/2013/12/link-between-wormholes-and-quantum-entanglement
The hyerarchy between the quality of the evidence (very thin if you read both the original paper by Maldacena and Polchinski and these PRLs) and the "splash" in the academic press is remarkable even by string theory standards

27. **Peter Woit**
December 3, 2013

Mtor,
Thanks! Unfortunately there are many, many such applications, and I want to keep the length of this book to a reasonable size (below 400 pages).

lun,
Arguments about entanglement/holography/black holes seem to be one of the major industries today among particle theorists. None of this seems to address any issues I find interesting so I'm mostly trying to ignore it, and have no intention spending the time necessary to follow these arguments well-enough to comment on them here knowledgeably. I suspect there's plenty of hype to be deflated there, but someone else will have to do it….

28. **Peter Peterson**
December 4, 2013

Vmarko,
Thank you for reviewing the Arxiv post. You are much better qualified than I am to evaluate the merits of the approach, and reading the books I quoted, I noticed a number of 'leaps of faith', mostly in Doran's case. Lasenby, if I am not wrong, cooled down to the idea over time. What was appealing to me though if one could come up with formalism as the authors claimed, where they could operate in flat spacetime it would lead to some new insights.

However, I agree that yes, Doran and group try to apply the geometric algebra formalism to everything that is already known (but not much, if anything, new) just as another mathematical tool that would lead to the same result in a more straightforward way. Which opens a question that is never answered: what spacetime property makes macroscopic interactions behave to follow this mathematical abstraction. Meaning, if mathematics can indeed be formalized to include all types of interactions, which was not proven yet. The beauty of geometric (Clifford/Grassmann) product application and scalability to any number of dimensions in a way consistent with Lie group symmetries is aesthetically pleasing, if anything else.

29. **Lowell Boggs**
December 4, 2013

Thanks for posting the reference to the Feynman lectures. Your book is beyond my abilities, but you regularly post lots of interesting information that I actually can appreciate and learn from. Thanks!

Best of luck on the success of the book.
Lowell

News from CERN

December 5, 2013
Categories: Experimental HEP News

Here's a roundup of recent CERN-related news:

- The status of the LHC and the LHC experiments was discussed here yesterday. The LHC shutdown is more or less on track, first beams at 13 TeV total energy Jan. 2015, physics starting April 2015.
- Both ATLAS and CMS have announced new data on tau-tau decays of the Higgs, providing stronger evidence for this signal than was available earlier. ATLAS sees a signal with significance 4.1 sigma, CMS at 3.4 sigma. These results are consistent with the SM, and rule out some SUSY alternatives in which the Higgs would behave differently. The Register headlines this Exotic physics takes an arrow to the knee.
- Not CERN related, but the last month or so has seen other new results ruling out some SUSY and other SM-alternatives. A good place to follow this is at Resonaances, where Jester discusses the LUX result on dark matter, and the new limits on the electron EDM.
- Plans are being made for long-term preservation of LHC data, keeping it in a usable form for the future. Nature has a story here, this this presentation has more detail.
- Meanwhile, CMS has a pilot project going to make some data available publicly in a form that can be accessed by high-school students.
- CERN DG Heuer has this announcement about activities of the FCC (Future Circular Colliders) study group looking into prospects for a large lepton collider (TLEP) as well as a higher energy hadron collider post-LHC.
- The CERN-sponsored SCOAP^3 open access publishing initiative will start operation next month. From their web-site, it appears the idea is to spend up to 10 million euros/year, mostly going to commercial publishers to finance their journals that publish HEP papers. In return the papers (almost all of which were already accessible on the arXiv) will be "open access". The publishers will get paid a per-article charge, so will have a serious incentive to publish as many articles as they can. I don't see a document explaining exactly how the money will be spent, but for some idea of where it will go, see this list. It indicates that the two big recipients will be Elsevier (with 1300 or so papers/year in Physics Letters B and Nuclear Physics B, at around $2000 per paper) and some combination of Springer and SISSA where about 1650 JHEP papers will cost 1200 Euros each. I gather that in return for this the journals will reduce or eliminate subscription charges, but don't know the details.

Comments

1. **PhysGrad**
   December 5, 2013

   The Resonaances link you posted appears to discuss only the electron EDM, not neutron. As far as I'm aware, there hasn't been an update to the experimental neutron EDM value recently, though there are several experiments that are either in planning or ongoing to push the upper limit of the nEDM closer to the SM prediction (as well as various BSM predictions which could show up at several orders of magnitude higher than the expected SM value).

2. **Peter Woit**
   December 5, 2013

   PhysGrad,
   Fixed. Thanks!

3. **Bernhard**
   December 6, 2013

   "at 13 GeV total energy Jan. 2015" –> "at 13 TeV total energy Jan. 2015"

4. **Peter Woit**
   December 6, 2013

   Thanks Bernhard, fixed.
   I seem to make this mistake a lot, maybe it has something to do with early experiences where this was the right scale for a collider energy…

5. **Narad**
   December 7, 2013

   > I don't see a document explaining exactly how the money will be spent

   Indeed, this would be quite interesting. It's become standard practice to eschew copyediting altogether or to provide a simulacrum obtained at rates that guarantee inadequacy. A quick look at Nucl. Phys. B. and JHEP reveals predictably amateurish "typesetting" of the LaTeX-is-a-magic-incantation variety (when you manage to accomplish poor spacing on wide measure, you're simply *bad at the job*). What's left? Driving everybody up the wall with an awful peer-review "management system"? Dealing with the occasional MS Word document? A little bit of thoughtless art processing? Adding pointless internal links that may not even work right? (JHEP's figure links are putting the end of the figure legend at the top of the page.) Serving proofs and not bungling the corrections? Spitting out some sort of shockingly ugly HTML and delivering it on a nightmarishly crufty platform à la Elsevier?

   Perhaps the name should be changed from "processing charge" to something more transparent, because I've yet to find anything resembling $2000 worth of actual work on any given paper. In fact, in the case of JHEP, I'm not finding anything resembling anybody's even having looked at *anything* in the first place: "$p_{\rm T}$ -cut", with the space, is in both the published version and nucl-ex/1307.1249.

Peter Higgs: "Today I wouldn't get an academic job. It's as simple as that"

December 7, 2013
Categories: Uncategorized

The Guardian has an interesting piece about Peter Higgs, evidently their reporter talked to him on his way to the Nobel Prize ceremonies this week in Stockholm. Higgs will be speaking tomorrow (Sunday), and I'm curious to hear what he will have to say. His talk will be available live at the Nobel Prize website.

Higgs points out that the kind of work he was awarded the prize for was done in an environment that no longer exists:

> He doubts a similar breakthrough could be achieved in today's academic culture, because of the expectations on academics to collaborate and keep churning out papers. He said: "It's difficult to imagine how I would ever have enough peace and quiet in the present sort of climate to do what I did in 1964."

By the time he retired in 1996, he was glad to be out of academia:

> After I retired it was quite a long time before I went back to my department. I thought I was well out of it. It wasn't my way of doing things any more. Today I wouldn't get an academic job. It's as simple as that. I don't think I would be regarded as productive enough.

Higgs has definitely not been a careerist sort, turning down a knighthood in 1999:

> I'm rather cynical about the way the honours system is used, frankly. A whole lot of the honours system is used for political purposes by the government in power.

He thinks he likely would have been fired by his university back in the 1980s if there hadn't been a prospect of him getting a Nobel.

The work Higgs did in 1964 was on a rather unpopular topic. At the time the reigning ideology was "S-matrix theory", which argued that local quantum field theory was a hopeless subject, so one should be working on formulating basic physics just in terms of S-matrix amplitudes, using their holomorphicity properties (this idea has had somewhat of a comeback in recent years). The 1960s however was a time of a great expansion in the number of university positions, so people like Higgs could make a career despite working on unpopular topics.

Progress in particle theory slowed dramatically after the early 1970s. One reason for this of course has been the huge success of the Standard Model, as well as the inherent difficulties involved in getting experimental access to higher energy scales. One wonders though whether the post-1970 collapse of the HEP theory job market and very different environment that ensued might have had something to do with this. As Higgs himself is well-aware, if he had come along 10 years later, he would not have found a job in the field.

In the UK today, things seem to be getting even worse, with strong pressures from the government to only fund work likely to have an immediate economic payoff. For more about this, see this commentary at Physicsfocus by Philip Moriarty on The Spirit-Crushing Impact of Impact. The UK has just announced the founding of a new Higgs Centre for Innovation, to be built in Edinburgh and opened in 2016. It will be devoted though not to the kind of research Higgs had success with, but to "big data" and "space", considered by the government to be among the most promising technologies for the future. It's rather ironic that Higgs is the sort of scientist who would not be employable by the Higgs Centre.

Update: For the acceptance speech by Higgs, see here, and see here for an official interview. For a different point of view, from one of the experimenters who made the award to Higgs possible, see here.

   I think this is a bit strange characterization of Higgs. Actually, Higgs worked on quantum gravity in his early years. See for example this paper:
   http://prl.aps.org/abstract/PRL/v1/i10/p373_1

   The site: http://www.edition-open-access.de/sources/5/3/index.html notes that: Peter Higgs too had been part of Hermann Bondi's Relativity and Gravitation group at King's College, London, since 1956. It was Pirani who urged him to take more interest in quantum gravity, prompting him to take up the position at the IOFP. Though invited to the institute to study gravitation, Peter Higgs ruefully admits that he spent his time there working on symmetry breaking in quantum field theory.15 Higgs first encountered Bryce DeWitt in 1959, in Royamont France. This was the second GRG conference16, and it was shortly after that the International Committee on General Relativity and Gravitation was formed (see Kragh [11], p. 362). He met him again at the GRG3 conference in Warsaw, in 1962. After 1956, following Pirani's advice, Higgs began looking at quantum gravity – at the time he was working with Abdus Salam at Imperial College. Here he wrote on the constraints in general relativity. This led, in 1964, to DeWitt's invitation to Higgs to spend a year at the institute, which he did, arriving in September 1965, after a year's postponement. Bahnson died tragically in an airplane crash the year prior on June 3, 1964 – a chair was established at UNC in his honour, to be occupied by Bryce DeWitt.

2. **Benni**
   December 7, 2013

   It is perhaps for the above reason, that Higgs has to say the following on the Higgs center, according to your link: "Prof Higgs, 84, said: "This support from the Treasury and the STFC will create an environment in which future generations of scientists from around the world can share and develop ideas in theoretical physics."

   Surely, Higgs would not promote the Higgs center with that words, if it did something that Higgs does not approve of. It is generally consensus that astrophysics, general relativity, quantum gravity and mathematical physics are the fields where physics can still make some advance. Higgs hat a professorship for mathematical physics in Edinburgh. Unfortunately, the number of chairs with that topic, in europe is almost zero. The few chairs that exist are highly competitive and someone like Higgs, who contributes very deep but also very few papers would have almost no chance.

3. **Florin Moldoveanu**
   December 7, 2013

   I certainly understand where Prof. Higgs is coming from. I published my first paper in my last undergraduate year and then I joined a small and prolific group which was publishing a paper every month. Then I came to US to get my PhD and I began questioning the value doing this incremental busy work which kept me from thinking on really deep problems. After graduation I left academia and started working in the industry where I have a successful career. In the meantime I kept thinking on hard problems and the effort payed off. Then I tried to come back thinking that if I had a very promising domain and nice results everyone would appreciate them, but surprise, surprise, there is a large background crackpot noise you need to break through. Basically you need to accumulate credibility, play the game, and (re)build your network and reputation.

It was lucky for Professor Higgs to make his discovery while in academia, because nobody would have taken him seriously if he was on the outside. On the outside the silence is deafening.

4. **Peter Woit**
December 7, 2013

Benni,

It's hard to tell without more detail, but the "space" research to be supported by the Higgs Innovation Centre appears to be space technology with commercial applications, not quantum gravity research. In any case, while Higgs supports this and lends his name to it, that doesn't mean they're any more likely to hire him than academia would be, and he makes clear his view about his chances there.

5. **Chris W.**
December 7, 2013

Compare with Kenneth Wilson.

6. **MathPhys**
December 8, 2013

"After I retired it was quite a long time before I went back to my department. I thought I was well out of it."

ha ha ha that was really funny. I think that's how many of us will feel as well.

PS I met Peter Higgs in 1985 went I attended a summer school in Edinburgh. A quiet, mild-mannered man. It was the first time that many of the students at the school, and probably even some of the lecturers, realized that there is actually a man behind the name that we all learnt in class and went for a handshake and chat with him. He was very kind, approachable, unassuming and obliged us all. He didn't patronize us. There was no posturing.

Meeting Francois Englert was also very good but in a different way that I'd rather not get into here.

7. **Gordon**
December 9, 2013

There are lots of us older academics that wouldn't have got a job today- or maybe more likely we would have played today's game. What is unfortunate is that Higgs' point about "productivity" is valid and can be a major barrier to some forms of research unless hidden in a fog of salami publication (and mixed metaphors).

8. **Steven Chan**
December 9, 2013

While all folks in academia do need to publish something, but the number of publiciations should not be the single most important benchmark. Writing good paper take months, and I think one first-authored paper every year or every other year should be considered enough.

You said I should avoid politics, but short-termism isn't just a science problem. It is a political and financial disease that infected science. We are just being affected by a much wider-scale problem.

9. **Eric**
December 9, 2013

Higgs may also have the lowest h-index of any Nobel winner. He was right topic, right time…and very lucky.

The other five credited with the theory seemed to have done well in academia.

10. **Eric**
December 9, 2013

@MathPhys

This sounds very interesting…do tell.

"Meeting Francois Englert was also very good but in a different way that I'd rather not get into here"

11. **Ike**
December 9, 2013

Here's what the reality looks like; Currently if you are a postdoc in the US seeking for a faculty position and have less number of publications compared to most of your colleagues, you cannot go forward!. The naked and widely known fact is that when you apply for a faculty position with less than 15 -20 papers, you cannot even pass the first stage and will be eliminated automatically. If you want to get a life and a permanent position, publish more often, if necessary divide one project into as many sub-publication as you can, publish even more, so they'd look nice on you CV or on google scholar website…

12. **S. Molnar**
December 10, 2013

Perhaps slightly off-topic in a narrow sense, but another Nobel prizewinner makes a related complaint against the big science journals, also reported in the Grauniad: http://www.theguardian.com/science/2013/dec/09/nobel-winner-boycott-science-journals.

13. **MH**
December 11, 2013

Higgs: ‘because of the expectations on academics to collaborate’

Reminds me of what Dijkstra (Turing award 1972) said in 1994:

In the wake of the Cultural Revolution and now of the recession I observe a mounting pressure to co-operate and to promote “teamwork”. For its anti-individualistic streak, such a drive is of course highly suspect; some people may not be so sensitive to it, but having seen the Hitlerjugend in action suffices for the rest of your life to be very wary of “team spirit”. Very. (http://en.wikiquote.org/wiki/Dijkstra)

I wish I knew this before going to graduate school….

15. **steve**
December 17, 2013

“He was very kind, approachable, unassuming and obliged us all. He didn’t patronize us. There was no posturing”. That’s very much the Higgs I remember, being a student at Edinburgh in the 80s. I’m surprised to learn though that the university considered firing him at one point since I always though he had a depth that no-one else quite had. It came across when he lectured with frequent side applications or subtle points that showed he really knew the stuff. His elegant solutions to homework problem got straight to the heart of the matter and that’s what his famous paper did too. It is good to see him speak out now about modern academia which seems to work against lone researchers. It’s a bit like the 1976 movie ‘Rollerball’ whereby “…the game was designed to show the futility of individual effort…” And yes, it is ironic that he would not get hired now by the institute to be named after him. Others like a young K. Wilson probably wouldn’t be hired now either, and if Von Neumann was alive today he would probably be a hedge fund manager:)

16. **anon**
January 1, 2014

Here are some questions that I would ask Dr. Woit and others.

(1) Would all of you agree that the prospects for future graduate students in mathematics or physics to pursue research in their fields is poor? Do any of you foresee this situation to improve in the future, or to further deteriorate?

(2) If you met a student who is thinking of pursuing graduate studies in mathematics or physics, would you consider discouraging him/her from doing so, and maybe instead direct them to more “applied” fields (e.g. engineering, medicine, statistics, computer science, etc.)?

(2)

17. **Peter Woit**
January 2, 2014

anon,
The situation in math is much better than physics. Even in math, getting a permanent position at a research insitution is difficult, but it’s much easier than in theoretical physics. I don’t have any problem encouraging students to get a Ph.D. in math, since there are some reasonable academic job prospects. Theoretical physics is a different story, there students do need to be made aware of how awful the job situation is (and will be for the forseeable future).

As for applied subjects, I would guess job prospects depend a lot on the exact field, but I’m not well-informed about what is happening in different fields. People should be aware that claims of an “STEM shortage” are nonsense, so if they go into some applied STEM field expecting jobs to be plentiful they probably will be disappointed.

What's Next?

December 9, 2013
Categories: Multiverse Mania

Last week's public lecture at the Institute for Advanced Study by Nati Seiberg is now available online. He was speaking with the title *What's Next?* and promoting a story about where particle physics is and where it is going pretty much identical with that coming from his IAS colleagues. Despite the overwhelming failure of string theory unification and the dramatic evidence from the LHC ruling out popular ideas about SUSY, there was no admission of any discouragement about string theory or SUSY.

String theory was described as the best candidate for a fundamental theory, one that has been making "enormous and exciting progress with amazing new insights" and "all signs are that we will continue to make progress." For more details Seiberg points to talks given by Witten such as this one. According to Seiberg, string theory has not problems and failures, but "challenges". One challenge is that "we do not understand the principles" of string theory. Another is that "we need experimental confirmation", which makes it sound like the problem is one of experiments not done yet, rather than the real problem, which is a "theory" that predicts nothing.

The hierarchy problem is emphasized as the central problem for particle theory, with almost exactly the same point of view as that of Nima Arkani-Hamed, which I've discussed here many times (see for example here and here). We're told not to think of the LHC results as providing evidence against SUSY, but to interpret LHC results as choosing between two possibilities:

- SUSY exists at LHC scales and arguments about SUSY solving the hierarchy problem are vindicated. Things don't look good for this so far, but hope is held out for the next run, with an admission that if it doesn't turn up then, that's it for SUSY as a solution to this problem.
- No SUSY at LHC scales just means it is at higher scales, and the multiverse is now brought in to deal with the hierarchy problem. In a recent Science Weekly podcast, Arkani-Hamed says he's still willing to bet several years salary that SUSY exists, but now he thinks maybe it only shows up at higher energies than he'll see in his lifetime. He's willing to bet that SUSY will show up at the next LHC run, but just $50.

Since even enthusiasts who have devoted their career to the cause are now only willing to put up $50 in favor of SUSY at 13 TeV, it's pretty clear that hardly anyone is now expecting to see this. We're already in the era of trying to understand the implications of no SUSY at the LHC, with the multiverse the main argument now being deployed in favor of not giving up on cherished speculation about SUSY and strings, no matter what experiments say.

Seiberg does give a different historical analogy for the hierarchy problem, likening it to a fine-tuning problem that Newton was worried about, that of the stability of planetary orbits. Why does a small perturbation of such an orbit not lead to exponentially large changes, destabilizing the orbit? Seiberg lists three possible solutions to such fine-tuning problems:

- There really is no problem if you understood the theory well-enough.
- You need to invoke new physics as a stabilizing mechanism.
- The answer is "environmental": the orbits are generically unstable, we just happen to live in an unusual place where they are stable.

The odd thing about his use of this historical analogy is that the lesson to be drawn is that of course the answer is the first alternative, but he quickly passes that one by as not worth talking about. I doubt the last alternative ever occured to Newton as anything other than a joke, and don't know of any evidence that he tried to come up with models of things like new unseen planets to solve this supposed problem. Newton surely realized there was plenty that he didn't understand about what Newtonian mechanics had to say about celestial mechanics. It's just as clear that our best model of the Higgs, with its large number of undetermined parameters, is such that we just don't fully understand where the Higgs potential and Yukawas come from.

The Seiberg talk seems to be one of a series (others listed here) of talks associated with the Milner Fundamental Physics Prize. IAS director Dijkgraaf introduced Seiberg as one of the four IAS winners of the $3 million Milner prize, with this leading his list of honors awarded to Seiberg. The talk was a public one of a sort that has for the IAS not just an educational role, but also a fund-raising one. Something is being sold here, the idea that SUSY and string theory are great successes, with the IAS faculty well-deserving the multi-million-dollar checks awarded to them for their work on these topics. Later this week they'll be getting together in San Francisco to decide how to split up $3.6 million in new checks among five other string theorists (the announcement of the winner of the 2014 prize will be made Thursday). All of this I fear has something to do with why we're not hearing from those at the IAS a truer picture of what no SUSY at the LHC means: the collapse of ideas that don't work and evidence that we don't yet have any viable conceptual framework for going beyond the Standard Model. This summer the IAS will host its usual PiTP program to train grad students and postdocs in what they need to know to face the future. The topic? String theory.

   December 9, 2013

   Peter, something OT but relevant to particle physics
   I am the 50th anniversary of the texas symposium and Steve Weinberg (in his talk)
   was discussing many papers by Shaposhnikov and others which proposed
   a 126 Gev mass of Higgs boson based on asymptotic safety. (He also discussed
   implications for models of inflation based on these asymptotic safety scenarios)

2. **Yatima**
   December 9, 2013

   It is interesting to take the stability of planetary motion as example.

   The only planetary motion that we knew about up until 10 years ago is solar system's. The problem of the stability of the solar system remains, as far as I know, unsolved. Numerical integration shows that small perturbations of orbits and masses will indeed lead to exponentially large changes over *fractions* of the lifetime of the solar system and the current configuration has no à priori reason to be stable.

   However, Earth did indeed stay reasonable habitable over the lifetime of the solar system.

   So the answer could be any of the three ones proposed, or a mix of them: We are at a local minimum in phase space that we don't understand yet (possible); there is some new physics at large scales we haven't found yet (not at all impossible) or it's environmental – we just happen to live in a solar system that happens not to have seen major excursions from a configuration in which Earth stays habitable over > 4 * 10^9 years (quite possible if the weak anthropic principle is applied, but I don't like it).

   December 10, 2013

When I was a science student it was my dream and the dream of my colleagues to be at IAS. I find this very disheartening, the mix of big money and buying shelf space in the education Big Box store.

4. **JohnB**
December 10, 2013

Much like economics has a 'heterodox' crowd for challenging the (by now embarrassingly false) mainstream, physics probably needs a similar break, and (like economics) it's unlikely to come in an academia partially captured by interests that promote string theory.

That seems to make it a slightly politically dominated topic (far less so than economics mind) – so probably going to need to attract a large source of funding, for creating institutes that lobby against string theory as a field of study, and instead both promotes and directly funds large projects that study/develop alternatives.

It's unfortunate how much scientific study seems to be corrupted by politics and good old cognitive bias, as pretty much any other area of human interaction.

December 10, 2013

When I was younger I was so lucky to have a few conversations with Dr. Dijkgraaf, back when he was teaching at the Amsterdam University, here in The Netherlands. I love how this professor seems to give a romantic twist to the the profession, not afraid of asking the big questions: Is there a certain system driving the world? Are we the only ones in the universe? Is the youth getting smarter? even asking if we are living in a matrix of created by a computer program. It's typical for Dijkgraaf to grab the opportunity to give a second role to such a great event as the IAS, always thinking outside the box. A great and charismatic man, which the world can learn a lot of, and not just in hard science.

6. **Michael Schmitt**
December 10, 2013

Like Yatima, I appreciate the analogy with Newton's Laws and planetary motion. And I agree with Peter's reaction – the first scenario is the best one and perhaps the most likely one.

7. **Anon**
December 10, 2013

Dear Peter, you once wrote a paper together with N. Seiberg:

http://inspirehep.net/record/191060

How was your impression back then?

8. **Tom Andersen**
December 10, 2013

The previous story on Peter's blog, 'Peter Higgs: "Today I wouldn't get an academic job. It's as simple as that"' is very related to this post.

What is happening in physics in recent decades is something I call the **Paradigm Mountain**. As the last 10 decades have rolled by, the speed of communication has increased by about three orders of magnitude. This of course will have consequences – **mostly good.**

The bad: even though many scientists have read and understood Khun's thesis about scientific revolution, its still hard not to trivialize new theories as wrong because they don't explain 'result X' or 'effect Y'. With instant communication comes instant critique (often even instant ridicule).

In other words, the internet has made the 'paradigm mountain' of the Standard Model very hard to penetrate. To quote Peter Higgs *"It's difficult to imagine how I would ever have enough peace and quiet in the present sort of climate to do what I did in 1964."*

9. **Mathematician**
December 10, 2013

I wonder if, in the long run, this will damage the IAS "brand".

10. **Peter Woit**
December 10, 2013

Anon,

This is in no way intended to be personally critical of Nati Seiberg (who I did work with happily way back when, but haven't talked to in a long time).

As a general comment (not about Seiberg particularly) about the four IAS Milner prize winners and new director Dijkgraaf, are all quite good, hard-working physicists. They do though share a certain style that I've never found congenial (common among hep theorists, much less so among mathematicians), that of liking to work on the latest, hottest new idea appearing from within the dominant paradigm being followed by the most influential people in the field. I think this has gotten them into trouble as this paradigm has worked its way far down a blind alley. Unfortunately the Milner money has had the effect of painting this blind alley as some sort of success story, making the problem worse.

11. **Umesh**
December 11, 2013

The first option you seem to 'interpret' from the talk, which is:

There really is no problem if you understood the theory well-enough.

was not what Seiberg said. He argued that Newton's dilemma was shown to be unfounded as it was shown that the solar system is chaotic. But the analogous situation in the case of the standard model leads only to the conclusion that one's logic is totally wrong. This, though a possibility, would be a vacuous and an uninteresting conclusion, therefore it won't be pursued.

12. **Peter Woit**
December 11, 2013

Umesh,

I did understand that Seiberg was justifying not discussing the first option (however you want to exactly interpret it) as "not interesting", but this is where I fundamentally disagree with him. If you find that your argument leads to two possibilities, one ruled out by experiment, and the other saying you should give up on conventional science, it seems to me that this means you have learned there is something wrong with your argument. It's not at all the case that the "hierarchy argument" is just a piece of logic, but rather it's various possible sequences of assumptions. My take on the current situation is that the LHC has just told us that a certain popular speculative argument doesn't work. Instead of standing up before the public and repeating this argument vigorously, making it sound much solider than it is, why not give a talk saying "here are the components of this argument that has been killed by the LHC, it's exciting that we've learned one of them is wrong". An example of where you go from there is the Weinberg talk Shantanu pointed out, which deals with one possible way around the hierarchy argument.

13. **Anon**
December 12, 2013

Dear Peter, thank you very much for your thoughtful comments.

14. **Umesh**
December 12, 2013

Sorry, I couldn't understand you. Are you saying that the hierarchy problem is not a problem? Just looking at the SM parameters show such a huge span of numbers, and isn't it a valid question to ask why are the numbers distributed over the range they are? Secondly, if one can't think of any 'natural' way (by which I mean some vague, qualitative principle at least, which may be made precise later) which makes sense of the span of the numbers, we're left with the three possibilities which Prof. Seiberg spoke of. Now, unless you tell me some way (vague, qualitative would do, details may be worked out later) to understand your statement, which is:

"understand the theory (SM) well enough"

and we are sure we understand QFT well enough to say that such numbers can't possibly arise unless delicate cancellations occur, we are forced to conclude that there is possibly no creative avenue analogous to the theory of classical chaos which may lead to 'better understanding' of the SM. The stability of these numbers is a very fragile issue as you know, because quantum corrections drag every (classical to begin with) number to the scale of the problem involved, and no one knows of a way to prevent it, apart from symmetry principles, which is why SUSY is such an attractive avenue. In the scenario that SUSY is not seen at LHC, what Prof. Seiberg says is that one would be forced to give up the notion that the SM as a gauge theory is special; it will herald another revolution analogous to the Copernican one. I fail to see why you call this giving up 'conventional science' any more that you'd say the same thing to people who were forced to give up the idea that the earth was the center of the universe. This time, it's the SM and the rest of our models, which are defined by parameters that aren't special, that's all.

To conclude, a word about the asymptotic safety scenarios you point me to. They're inherently perturbative in nature and any treatment of gravity based on such field-theoretic scenarios will eventually run into the fact that classical gravity has black hole states, which can't be reproduced by any known local QFT, hence the dictum 'gravity is not a QFT'.

15. **Peter Woit**
December 12, 2013

Umesh,
The question of the SM parameters of course is perhaps the biggest question around, and we have no idea why they take the values they do, over the large range that they do. That's not at all though what is commonly called the "hierarchy problem", which usually refers to the quadratic sensitivity of the Higgs mass to the cut-off scale. The fact that SUSY theories (with SUSY-breaking scale at the weak scale) don't have this feature has been one of the main arguments for SUSY, but it's not at all an air-tight convincing argument.

One problem with what Seiberg does in his talk is that he doesn't clarify what the "hierarchy" or "naturalness" or "fine-tuning" problem is, and that's the interesting question now that the LHC has shown that the SUSY "solution" to it doesn't work.

I describe the multiverse "solution" to the "hierarchy problem" as "giving up on science" because it's completely untestable. It's just an empty pseudo-scientific excuse for not understanding something. In fundamental physics, for anything we don't understand, someone can always say "that's something that's different at different places in the multiverse, so what we see about it can't be predicted". Sure, this could be true, we could live in a Matrix, etc., etc. but such things are not science.

The argument that we should give up the idea that the SM is "special" because of LHC results is absurd: the LHC just dramatically confirmed a whole new sector of that theory, and the whole thing over a large new energy range. The LHC is telling us emphatically that the SM is "special".

As for quantum gravity, we have zero evidence for it, zero evidence for what happens at the Planck scale, and only highly speculative and likely wrong ideas. Using this to argue for a multiverse or anything else isn't a solid argument at all.

16. **Umesh**
December 12, 2013

Of course the LHC has not only verified the SM, but probably is also hinting that there's nothing beyond the SM. But very sound counter arguments show that there HAS to be physics beyond the SM. Just because the LHC confirms the SM doesn't itself mean it's special. It may be a **SPECIAL** feature of this particular phase or 'vacuum' of the relevant high energy completion of SM and gravity. You haven't yet shown one serious flaw in the arguments, such as an invalid extrapolation or the failure of using EFT techniques or some such thing.

"As for quantum gravity, we have zero evidence for it,.."

I fail to understand this statement. Does it mean that you think quantum gravity doesn't somehow make sense? What more 'evidence' can one need other than the fact that both quantum mechanics and gravity operate in one and the same universe, and thus when the two regimes meet, as they surely would at the Planck scale, one would need such a theory?

Next, no one is remotely suggesting the following:

"The argument that we should give up the idea that the SM is "special" because of LHC results is absurd:.."

Indeed that no one is immediately giving up on the idea of the SM being 'special'; one would like to find the 'special' solution to the equations of the correct high energy theory once the task of unifying gravity and QM is completed. Sure, sounds awesome and it's the dream of many physicists – Prof. Seiberg himself said he'd be reluctant to give up the idea that the solution that we currently observe isn't somehow uniquely determined (in other words, 'special') – but unfortunately, if one doesn't find a mechanism by which the apparent 'specialty' can somehow make sense, by which I mean that the parameters stay put where they are instead of getting dragged here and there by quantum corrections, what is one supposed to do? Keep sticking to the 'prejudice' of the SM being 'special' in the face of all evidence? Just like geocentric people who didn't wanna give up the 'special' place of the earth in the universe?

You write:

“One problem with what Seiberg does in his talk is that he doesn’t clarify what the “hierarchy” or “naturalness” or “fine-tuning” problem is, and that’s the interesting question now that the LHC has shown that the SUSY “solution” to it doesn’t work.”

Prof. Seiberg very clearly elucidates (in my opinion in a beautiful way) what the ‘hierarchy’ or ‘naturalness’ or ‘fine-tuning’ problem is. It is the question of the stability of the numbers (the parameters) of the SM, and yes, the Higgs mass is one of them, particularly affected by the quadratic divergences you mention. Some parameters, like the fermion masses and mixing angles could have explanation in the physics at extremely high energy – he mentions the neutrino mass as an example – and some don’t. When they don’t – like the theta angle of QCD – one *HAS** to look for a mechanism which solves the problem at the energy scale in question. And, yes, SUSY was useful precisely for this reason and the expectation was that it would be seen at the LHC. It didn’t. So, back to the question: what keeps the numbers stable? SUSY hasn’t solved this set of issues, so what gives? The conclusion that SUSY doesn’t work has the important caveat – that it doesn’t work at the scales probed by the LHC.

Indeed the multiverse can’t be ‘tested’ in the sense that in case there are causally disconnected regions, no signal can ever reach us. But that such cases can occur have been around in the theory of inflation as well. What one does is then try and understand ‘our neck of the woods’ as Prof. Seiberg says. I still don’t see what issues you have with these (straightforward) argument.

17. **Peter Woit**
December 12, 2013

Umesh,

We just don’t have any evidence one way or another about some completely different theory at high energies, with the SM only an effective theory (and thus “not special”). What we have learned in recent years is that those who argued that since the SM is just an effective theory, we should see new physics at the TeV scale were wrong.

Re quantum gravity, if you would read the rest of the sentence and not delete it, my meaning would be clear.

I’ve endlessly discussed the hierarchy problem here, don’t see much point in repeating myself. One basic point to keep in mind though is that there’s something highly speculative about any argument based on relating energy scales we have no access to or information about and the electroweak scale, as in “it’s a huge problem that small changes in physics at the Planck scale have enormous effect on physics at the electroweak scale”.

About predictivity and the multiverse, see
http://www.math.columbia.edu/~woit/wordpress/?wp_super_faq=whats-wrong-with-having-a-multiverse-doesnt-inflation-imply-one

18. **Umesh**
December 12, 2013

We surely do have evidence for a completely different theory at high energies, and most certainly at the Planck energy. Are you contesting the point the the very structure of QFT breaks down at (Planck) such energies? Even if the SM is (and surely it is not) the story all the way up the Planck scale, we surely need a **NEW** theory at the Planck scale. As for new physics (at the TeV scale), it was expected based on plenty of evidence, not empty speculation. The evidence, apart from numbers that can’t be explained at the level of the SM itself (numbers like neutrino masses etc) included numerous other observations. I am free to discuss what these ‘numerous other observations’ are in case you’re willing to indulge me.
The very fact that no new physics was seen is forcing a rethink of the whole paradigm, beginning with the ‘most flimsy’ so to speak – which may/may not include naturalness.
Of course I read your statement about quantum gravity fully, and understand it to mean that you think all ideas about it are not only highly speculative, but most likely wrong. This is wrong. What we DO NOT have is a complete theory of quantum gravity, but we do have a very good idea of what the high energy (trans-Planckian, if you wish) physics qualitatively looks like. Just to give you an idea, it’s certainly true that at very high energies, say energies exceeding the Planck scale, the states are dominated by large black holes. This is just one among very many concrete statements about physics at the Planck scale, which you seem to just ‘brush under the carpet’ as ‘speculative’ or ‘most likely worng’. Please feel free to indulge me in case you wanna know more.

“One basic point to keep in mind though is that there’s something highly speculative about any argument based on relating energy scales we have no access to or information about and the electroweak scale, as in “it’s a huge problem that small changes in physics at the Planck scale have enormous effect on physics at the electroweak scale”.”

Unless you tell me what you mean by ‘..there’s something highly speculative..’ I have to reply to the above paragraph with “..there is nothing speculative..”. This is because no one is ‘relating energy scales’ – at least in the arbitrary manner you seem to imply. It is a very sound procedure which is based on solid knowledge we know about the current energy scales, what the renormalization group has taught us, and so on. Again, feel free to indulge me in case you want to know, though I suspect that you already know what I’m on about.

19. **Umesh**
December 12, 2013

In fact, I can also tell you about a very well known quantum theory of gravity, but the requirements of staying on topic prevent me from going into it. I have just read the FAQ you linked me to above, and what you write there is wrong. Let me explain. You say:

“The issue is not whether there’s more than the observable universe out there. That may very well be, and maybe someday we’ll even understand inflation well enough to have a good model of what that might be. The point though is that there is zero evidence that whatever else there is has different physical laws than ours, and that is what is needed to make the whole anthropic business work. In simple models of inflation, whatever else is out there will have the same laws as ours, so yes, you can get a multiverse, but a pretty boring one. You can use string theory or something else to come up with much more complicated models that give you pretty much any physics you want in different parts of the multiverse, but there’s no evidence for these, they are untestable and explain nothing.”

Sorry for copy-pasting the whole paragraph, I don’t want to be accused of ‘deleting’ sentences again. Whether or not the other universes have ‘different physical laws than ours’ is a question that involves detailed knowledge of the correct dynamics of the high energy theory, which includes knowledge of the fact that which numbers are of fundamental importance and which are not (i.e., which ‘laws’ are to be the same and which ‘laws’ can be/have to be/may be different), and such knowledge is beyond reach even in calculable models of quantum gravity, the ones of the kind which I mentioned at the beginning of my comment. Thus, it’s impossible to a priori say which ‘model’ of inflation wold be chosen, and consequently what the nature of the vacuum would be. Once this can be achieved, one may ask why is it that we happen to ‘live’ in this neck of the woods and not in others. Whether or not inflation may require the ‘laws’ in other bubbles to be same or not is irrelevant here, because full information about the high energy theory (to the point of having detailed knowledge of vacuum selection) would render any statement made on the basis of inflation (which surely you’d agree would probably naturally arise as a requirement of the detailed laws) redundant, and it’s yet to be seen which features survive to be considered ‘laws’ – i.e., which won’t change throughout the multiverse – this number may be zero such statements, and which may be just be reduced to mere environmental numbers – a la the radii of the orbits of the planets of the solar system, as Prof. Seiberg beautifully explained.
As for whether the anthropic argument ‘to work’ or ‘not to work’ once the main task of understanding the high energy dynamics of gravity is well understood, we may be in a position to argue which parts of the argument stand and which don’t, as I’ve already explained above.

20. **Umesh**
December 12, 2013

"– i.e., which won't change throughout the multiverse – this number may be zero such statements, and which may be just be reduced to mere environmental numbers – a la the radii of the orbits of the planets of the solar system, as Prof. Seiberg beautifully explained."

Please excuse the sloppy editing of the above paragraph. I meant:

"– i.e., which won't change throughout the multiverse – this number may be zero- and which may be just be reduced to mere environmental numbers – a la the radii of the orbits of the planets of the solar system, as Prof. Seiberg beautifully explained."

21. **Igor Khavkine**
December 12, 2013

Dear Umesh, these wonderful arguments that you are referring to and that supposedly tell us so much reliable information about how Planck scale physics and quantum gravity are supposed to behave certainly exist. Not only do they exist, they are quite well known to anyone who has spent enough time interacting with high energy physicists. And that most likely includes Peter as well.

However, now you must realize that it is possible for two reasonable people to be exposed to these same arguments, yet not be equally convinced by them. And that's not because of lack of familiarity. So rehashing these arguments here is unlikely to help anyone. What make the difference are different standards of evidence. Once one adopts somewhat stricter standards of evidence than those that are common in the very mathematically adventurous high energy physics community, it becomes evident rather quickly that the state of the art of our knowledge about the non-perturbative and Planck scale behavior of QFTs (including gravity) is full of open problems. What all these well known wonderful arguments (and quite a few less well known ones) provide are conjectures (sometimes contradictory ones) about how these open problems could eventually be resolved.

So before making bold claims of certainty about how quantum gravity is supposed to behave in non-perturbative Planckian regimes, lets wait until a similar yet easier problem is solved and the Yang-Mills Clay Millennium prize is actually awarded to someone. Such a conservative position is not just hot air. If it were never adopted by anyone, we would still be quibbling about which model of aether is the right one, since an aether substrate is so absolutely mathematically necessary to explain the wave nature of electromagnetism.

22. **Umesh**
December 12, 2013

Sorry Igor, but it's not the 'standard' of evidence which is under question here. In case you, or anyone else for that matter can point out what 'exactly' reduces the 'standard' of the evidence presented above, it would be much better. It must be emphasized that the statements above (what you call rehashes) are not mere 'high adventure' maths, but arguments which are based on solid, well tested theories – general relativity for example. The Clay prize for the YM gap problem is one of proving in great detail the existence of the mass gap, which has nothing to whatsoever to do with the problems under discussion here. In case you really wanna know, we can discuss, but the blog owner would cry foul. I'm sure you're'nt suggesting that until the Clay prize is awarded, one sit idle about other important conceptual questions. In case it gets solved and tells us something useful about QFT, great, but in the meanwhile we need to address other (more important) conceptual questions – and be sure they have nothing to with QFT – like the behavior or high energy gravity. Unless you can tell me – based on the best current theory of gravity – why are the arguments wrong – and these don't include statements such as 'we have to solve other easier problems' etc etc – it is hard to essentially stop thinking about the quantum nature of gravity. Please feel free to point out (even vague would do) what you find invalid about the arguments which I presented above. You may choose any. There has to be some reason (mathematical reason) to believe that unless the YM mass gap is proved as required by the Clay committee, one mustn't think about quantum gravity, and I'm sure there's no such logical, physical or mathematical reason, except personal prejudice.

23. **Peter Woit**
December 12, 2013

Umesh,

I'm sorry, but we seem to have fundamentally different views on how science works. My reading of the history of physics is that it is full of theorists who were convinced that something or other was "certainly true", until someone did an experiment and showed it wasn't, or some other theorist who better understood the matter showed that it wasn't. Given this history, some humility and careful distinction between what one has experimental evidence for and what one doesn't seem like a very good idea. People should study highly speculative topics like transplanckian physics and may learn something this way, but, personally I'm not about to take seriously their claims that they know what is "certainly true" about this.

Somewhat similarly, about the multiverse, when you have a solid theory with some evidence for it that determines what our possible laws of physics are, then I'm willing to discuss the question of what this means about what things are predictable and what are environmental. At the moment, from everything I've seen (and I've spent a lot of time looking), the people trying to sell this have nothing at all, just a bunch of conjectures about how to construct a theoretical framework designed to evade any confrontation with experiment. To me, this does not count as science.

24. **Umesh**
December 12, 2013

Fair enough, then I think you wouldn't believe any statement made about the nature of the interplay between quantum mechanics and gravity. But I would still like to know what you consider 'highly speculative' about the standard extrapolations made from known theories. Even for starters, the Planck scale is very well out of reach of any conceivable experiment to get 'directly tested'. Going by your view, it's a totally futile endeavor to even think about this. But unfortunately, it's not about the scale, it's about the concepts – both of which work too well – and it must be possible, with or without experiment, to formulate the correct unification. It's not anybody's fault that the scale (in our vacuum) at which the two effects come together is totally untestable. You still have to come up with a valid argument (by which I mean something like RG, some semi-quantitative argument) as to why this whole enterprise, by your judgement is totally doomed from the start. That experiments could be performed for every conceivable scale so far in history is because of the ready possibility. And it would be extremely foolish to completely ignore the issues posed by quantum gravity as futile just because there can be no experiment performed, even though that's what is dictated by history.

25. **Peter Woit**
December 12, 2013

Umesh,
I don't believe thinking about how to quantize gravity is futile (I've spent some time doing so myself, and if I thought I had a good idea, would spend a lot more), I just believe those that do so have to keep in mind how large the uncertainties in such arguments are. In the question at hand (electro-weak scale physics and the hierarchy argument that the Planck scale has something to do with this) I'd argue that the uncertainties are large indeed.

26. **Igor Khavkine**
December 12, 2013

Dear Umesh, of course, thinking about conceptual issues in quantum gravity is important. And I would actually be out of a job if it weren't allowed. What I'm objecting to is claiming extreme certainty in what one comes up with along the way. Let me illustrate by closing a gap in my previous comments.

The reason I brought up the YM Millenium prize before has nothing to do with the specific question of the mass gap. My general understanding of the logic behind its formulation is that the mass gap is only a particular example of a non-perturbative property of a QFT. The main outcome of a solution is expected to be a proof that **shows the existence** of a non-perturbatively defined QFT and verifies that it has some particular property, like a mass gap. The mass gap could really be substituted with any other equally or more interesting property.

So, here's a specific problem with all these wonderful arguments that you are very ready to 'rehash'. In order to be really convincing, they need to include the following steps. Formulate a precise conclusion, **construct** a relevant non-perturbative QFT model (or your favorite QFT alternative), verify that the conclusion holds. Surprise! All of them are missing the step highlighted in bold. The main reason to pay attention to the YM Millenium prize is that, in case you are not following the literature on this subject, it acts as a helpful barometer for the completion of the construction step. So until then…

There is an alternative, though. Forget about all this mathematical stuff. Forget about all these wonderful arguments. Just take their conclusions as scientific hypotheses and test them! Then trust the ones that work. But in the case of quantum gravity I'm not holding my breath.

27. **Georges Melki**
December 13, 2013

Wolfgang Pauli didn't only say :"Nicht einmal falsch"! He also said:"Man muss nicht so viel reden "! I wish all concerned would heed the latter…

28. **Umesh**
December 13, 2013

Very well, since we agree that thinking about quantum gravity is an important problem, we may proceed. Igor, the problem with the Clay prize problem is about 'constructing' in a mathematically rigorous manner a non-perturbatively complete QFT. But this has nothing to do with the physics per se. All asymptotically free theories are non-perturbatively consistent (as far as physics is concerned, and one can even show such consistency in controlled situations), because they behave more and more like free field theories in the UV. I don't understand what a more rigorous construction of the said QFT can do for questions in other areas.

But, coming back to topic, we were discussing the hierarchies of the SM and allied problems. I haven't still understood the nature of the 'uncertainties' you spoke about in your comments. What are they? How is the argument that the Higgs mass (which is related to the EW scale), which is quadratically divergent (in case you disagree with this statement, please explain) gets corrections from all particles all the way upto scales which lie much higher than it (namely, the Planck scale, or whatever scale you want to insert in b/w) possibly an argument that has **UNCERTAINTIES**? I ask again, what exactly is the nature of these uncertainties?

Are you claiming that the demand that parameters like the Higgs mass (which aren't protected by symmetry) are unstable is somehow WRONG? This may be because you know something that others don't; it would be nice to see what this argument is, which doesn't need to invoke other high energy scales and somehow solves the problem at the EW scale itself. Please be sure that you can't postpone this problem to higher energies and you HAVE to solve it at the relevant enrgy scale (in this case the TeV scale) itself. In case you can show a loophole or a flaw in this argument, you're welcome, but I can't see any. In the absence of such an argument, Wilson's argument that scalar masses get corrections all the way upto higher energy scales stands, and nothing can be done about it. And given the fact that this 'naturalness expectation' is clearly false, i.e., the Higgs mass is really low compared to the Planck scale (this has been confirmed by the LHC) and looks quite stable, one is forced to conclude that the said parameter, namely the Higgs mass is UNNATURAL. Thus, there is no conceivable 'computation' one can do that doesn't involve UNNATURAL cancellations that would give you the desired answer. In case you feel this is wrong, please feel free to point it out.

Please note that I have cherry picked the Higgs mass for the above argument just because it's the easiest to demonstrate arguments/counter arguments about naturalness. In fact, I think that you want a NATURAL explanation for the Higgs mass (and consequently the EW scale) too, at least from your stance on the problem.

29. **Peter Woit**
December 13, 2013

Umesh,
I'm afraid we're just on different planets here. As far as I'm concerned, absolutely everything about physics at the Planck scale and how the SM we see at low energies is related to it is uncertain.

Since you invoke Wilson about the hierarchy argument, you might want to read what he had to say about it at
http://arxiv.org/pdf/hep-lat/0412043v2.pdf
(he called it a "blunder").

30. **Umesh**
December 13, 2013

Precisely why is it blunder? I am yet to read the 17 page paper you've linked to, but even for a moment forgetting the Planck scale, what is wrong, according to you, about the fact that scalar masses are subject to quantum corrections? In case you opine that this claim is wrong, I would like know.

31. **Peter Woit**
December 13, 2013

Umesh,
As I've written before, yes, in perturbation theory, scalar fields are quadratically sensitive to the cutoff. The question is what to make of that technical issue. Wilson, who was the one who first raised the issue, says the "naturalness" argument here is a blunder. You don't need to read the whole 17 pages, just look for Section 5 on "Blunders", and the second half of page 10 and first half of page 11. Then you can explain to my why Wilson is wrong and doesn't know what he's talking about.

32. **Umesh**
December 13, 2013

OK, I looked up the relevant portion of the paper linked above. I quote Wilson here:

"The final blunder was a claim that scalar
elementary particles were unlikely to occur in
elementary particle physics at currently measurable
energies unless they were associated with some kind
of broken symmetry [reference #23].The claim was that,
otherwise, their masses were likely to be far higher
than could be detected. The claim was that it would

be unnatural for such particles to have masses small
enough to be detectable soon."

I don't see how this contradicts with what has been mentioned before; Wilson just says that the expectation that small scalar masses aren't possible is the **BLUNDER**. He says that this expectation was based on 'natural expectations' (in other words, naturalness, because quantum corrections drag the mass up to the relevant scales), and it is indeed possible that small scalar masses may occur (and this has been confirmed by the LHC). What he goes on to say is that not every measurable number has to follow the NATURAL expectations, and goes on to provide the example of the nearest star to the sun as an example (a beautiful example, if I may be so bold). He explains how people during Copernicus's time said that such huge distances were 'unnatural' and couldn't occur; but today we indeed know that this is true. This in fact makes the case for 'unnatural' (or, environmental) characteristics of certain numbers even more robust, not weaker, as you claim.
In fact, what Prof. Seiberg says is precisely the above, though in a much more crisp and clear form; he said that the currently measured mass of the Higgs is uncomfortably low for technicolor schemes (to be natural) and uncomfortably high for SUSY schemes (to be natural). Thus, if there is nothing seen at the LHC that may provide some evidence for the above schemes, there might be no other choice left other than to say that unnatural numbers indeed occur in nature, and the Higgs mass is one of them.
Please tell me where you disagree.

33. **Peter Woit**
December 13, 2013

Umesh,
I think you're misreading Wilson, who is not making an anthropic or "environmental" argument. He is making an argument against doing what you are doing: extrapolating one's assumptions into regimes where you have no evidence and don't understand things as well as you assume. Read the first part of page 11, where he explains that the problem was that people in the days of Copernicus had no way to measure the distances to stars, and no understanding of Newton's first law of motion, and this is what led them to wrong reasoning. He then goes on to discuss quarks and the arguments against them, which were wrong, including an extremely relevant point for this discussion about non-perturbative qft having different behavior than expected.

34. **Umesh**
December 13, 2013

Sorry, but I have read the parts you have suggested, and find nothing that contradicts the 'environmental' argument. Of course that Wilson hasn't used the word 'environmental', but the example of the distance to the nearest star is surely environmental, do you disagree? He says, very clearly:

"There have been a number of cases where
numbers arose that were unexpectedly small or large.
An early example was the very large distance to the
nearest star as compared to the distance to the Sun,
as needed by Copernicus, because otherwise the
nearest stars would have exhibited measurable
parallax as the Earth moved around the Sun. Within
elementary particle physics, one has unexpectedly
large ratios of masses, such as the large ratio of the
muon mass to the electron mass. There is also the
very small value of the weak coupling constant. In
the time since my paper was written, another set of
unexpectedly small masses was discovered: the
neutrino masses. There is also the riddle of dark
energy in cosmology, with its implication of possibly
an extremely small value for the cosmological
constant in Einstein's theory of general relativity."

Clearly, in the above paragraph, isn't it clear that he means numbers too large or too small indeed occur in nature, just like the distance of the nearest star to the sun? And isn't he clearly likening this number to the (unexpected by today's naturalness arguments) small scalar masses? What am I missing here?
He gives that example as a warning that one mustn't 'take numbers obtained from 'naturalness' arguments' too seriously, as people in Copernicus's time thought that distances which were far enough for the heliocentric model to be true couldn't be 'natural'. And how does non-perturbative QFT have anything relevant to the discussion about scalar masses?

35. **Peter Woit**
December 13, 2013

Umesh,

He's explaining that people were making assumptions about distance scales that were wrong, wrong because they had no experimental evidence, and their extrapolations based on their best current theories were wrong.

Non-perturbative QFT is relevant, because we don't completely understand it, and our fundamental theory needs to be understood outside of perturbation theory. During the 1960s people were quite certain that a qft of quarks made no sense, based on extrapolating perturbative behavior. They found out they were wrong, when they better understood what can happen in qft. I think it's quite likely we will sooner or later learn yet more unexpected things about qft, and such things might change radically what the "hierarchy problem" looks like.

36. **Umesh**
December 13, 2013

The statement

"..sooner or later learn yet more unexpected things about qft, and such things might change radically what the "hierarchy problem" looks like."

is so vague, and you don't even point out what this might be makes it hard to take seriously. It looks more like a 'hope' or some sort of 'non-perturbative QFT saves the day' kind of emotion which really doesn't tell one about what to and what not to expect. On the other hand, we know and have measured all the couplings of the SM, and it is clear the Higgs seen at the LHC is WEAKLY coupled, and it's totally unclear to me as to how some claimed 'non-perturbative QFT' might come to the rescue of the quantum corrections that plague such scalar masses. In case you have some concrete 'non-perturbative' avenue that somehow might affect the Higgs sector, it's futile to talk about help from 'non-perturbative QFT'. All those lessons from history are sure nice to keep in mind, but you don't seem to be indicating how to make progress.

37. **Peter Woit**
December 13, 2013

Umesh,

The Higgs potential is very much a non-perturbative phenomenon (the mexican hat is not a paraboloid). All I'm saying is that the quantum dynamics of the Higgs field is not something we understand so well that we are sure we're not missing something here (and I think this is also Wilson's argument). This is an issue that people have certainly studied over the years, but it seems quite conceivable that something is missing. Quite likely actually that something is missing if you want to bring gravity into the picture. No, I don't know what it is, if I did I'd be writing a paper and not wasting time arguing with you…

38. **Umesh**
December 13, 2013

Indeed the Mexican hat is a paraboloid (can be approximated by) near the minimum, where the field rests, and one can perfectly use perturbation theory around this minimum. How is it that the quantum dynamics is 'not understood' in this simple enough regime? And all signs are that this perturbation theory works perfectly well. If there is something 'not well understood' as you claim, where is the proof of this? Any calculation or paper or something telling us this is so? Of course what you say is not Wilson's argument. 'Missing something here' etc etc are simply words, whereas the perturbation theory performed assumming a weakly coupled Higgs gives perfectly satisfactory results. I don't understand what you're talking about.

39. **Peter Woit**
December 13, 2013

Umesh,
This is going nowhere, and I really can't understand why you find it so difficult to see the simple argument Wilson is making (which is the same one I am).

First of all, no, even near the minimum the Mexican hat is not a paraboloid, the potential is degenerate so things are more complicated than that. There are many subtleties in the quantization of a non-abelian gauge field coupled chirally to fermions and to a scalar with a vacuum state in a Higgs phase. Even before you add the scalar field into this, there are serious problems with defining the theory outside of perturbation theory (have you ever looked at lattice gauge theory with chiral fermion couplings?). Adding a scalar field with degenerate minima at non-trivial values and Yukawas (including a Yukawa coupling of almost exactly 1 to the top, 1 is not a number much less than 1…) add more tricky issues. Yes, there is a standard assumption that despite all this, the usual terms in the perturbation expansion capture everything. Maybe it's right, but pretending to people that this is an open and shut case where we understand exactly what is going on and have full control of the approximations being made is just not true.

I don't think these issues can be fully discussed in a blog post though, but I do think you need to answer the question of why you disagree with Wilson (who was someone who I'm sure understood these issues much better than either of us) about this.

40. **Umesh**
December 13, 2013

Whether I disagree with Wilson or your interpretation of Wilson is something we can discuss over a whole new thread, but in my interpretation which I have given above, there is nothing that contradicts what I think about the hierarchy of scalar masses and what Wilson says in his paper you've pointed to. And be sure that many more people, which include people like Seiberg etc (who surely have understood these issues as well as Wilson did, and surely do understand the issues better than either of us) have exactly the same interpretation of the issue with the scalar masses which I have been discussing above. In case you want me to feel threatened by pointing me to some 'QFT giant' who knows much more (indeed he does), and are asking me to submit to some false understanding you want to promote, feel free to, but it doesn't help matters, just like it wouldn't help matters if I point to many of the aforementioned people (equally giants in their own right) and stake my claim to be right. At any rate, physics is not about who thought what, it's about what works and indeed the perturbation theory works and gives correct answers. Your claim about the potential being degenerate doesn't disprove anything; once we pick a minimum and shift the vev we can surely do perturbation theory assuming the potential being parabolic (near the minimum), there's nothing conceptually wrong or invalid about it. All the talk about the subtleties of gauge fields coupled to chiral fermions, the degenerate minima scalar lead nowhere contradict the claim that small scalar masses are unnatural. I think you're using all these words like 'subtleties', 'lattice gauge theory with etc etc' just to deviate from the main issue of is there or isn't there a hierarchy. I am forced to ask you again: do you agree or disagree that small scalar masses are unnatural, and the SM Higgs faces this 'hierarchy problem'?

41. **Peter Woit**
December 13, 2013

If you don't think there are any subtleties about the quantization of the electroweak part of the SM, that all there is to it is the story about how to construct Feynman diagrams that we teach beginning graduate students, fine. I don't see any hope of waking you from your dogmatic slumber.

For about the 100th time: to have a serious, non-speculative hierarchy problem caused by two widely separated scales, you need two widely separated scales where you understand exactly the physics. Right now, we have one: the electroweak scale. Whatever is going on at some conjectural much higher scale we now know exactly as much about as the people in Copernicus's day knew about the stars other than our sun. This is Wilson's point, and mine. Your "hierarchy problem" is based on a speculative picture of what is going on at some scale we know nothing about.

42. **Peter Orland**
December 13, 2013

Umesh,

Maybe I can say this in simple English, without using historical analogies or invoking any sacred names (for or against your point of view).

The "problem" with the Higgs is not a technical problem, but an esthetic one. It is a fine-tuning issue (at energy scales which are experimentally inaccessible). Some people would say, "alright, so we'll tune very finely at some very-high-energy scale. No problem."

Even if you don't like this viewpoint (and I have to admit I'm uneasy with it), it isn't self-evident that it has to be wrong. Experiment is king, not esthetics.

43. **Umesh**
December 13, 2013

I never denied any of your subtleties, I just said indeed they're there, but don't have any effect on the issue at hand, the scalar masses.

"..to have a serious, non-speculative hierarchy problem caused by two widely separated scales, you need two widely separated scales where you understand exactly the physics. Right now, we have one: the electroweak scale. Whatever is going on at some conjectural much higher scale we now know exactly as much about as the people in Copernicus's day knew about the stars other than our sun."

I'm sorry but this statement is wrong. I don't understand why should one understand the **EXACT** physics at the higher energy scale to even talk about it? There's no assumption about the detailed dynamics at that scale at all, please note that the very existence of that scale is enough for quantum corrections to drag observables up to that scale. In fact it happens all the time with quantities that aren't somehow protected by symmetry. If you claim that one needs exact knowledge of the dynamics of the higher scale, you have to show me a calculation or some such, whereas, on the other hand, there are plenty of examples in all sorts of QFTs where one may calculate continuously renormalizable quantities which get receive corrections. In fact, the fundamental lesson of RG is that the high energy effects decouple and cannot affect any of the low energy physics, but surely the quantum effects at a given low energy drag the unprotected quantities to any other relevant scale where new physics must appear. In this case it's the Planck scale, but it could be any other high energy scale in b/w, like the GUT scale. How are you claiming, without at the same time contradicting RG, that one needs detailed knowledge of the high energy scale to say something about the nature of quantum corrections to observables computed at a given energy?

44. **Peter Orland**
December 13, 2013

Perhaps I should amend my straw-man quotation to be, "alright, so Nature tunes very finely at some very-high-energy scale. No problem."

45. **Umesh**
December 13, 2013

Indeed, fine tuning is uneasy. Even if one somehow accepts some amount of fine tuning as OK, how can one say OK to fine tuning to one part in 10^32? Surely you're not advocating that this is possible? Or are you saying that you believe that such things may happen, but for that one needs to know the detailed physics at the highest energy scales? If you're saying that, then I'm willing to fundamentally disagree, because I feel that such impossible cancellations cannot occur. Indeed aesthetics have something to do with it, but it's more than that. I think to ask cancellations of that order requires miracles, which cannot be expected from random integrals. But if you insist, I would be happy to disagree.

46. **Peter Orland**
December 13, 2013

"Even if one somehow accepts some amount of fine tuning as OK, how can one say OK to fine tuning to one part in 10^32? Surely you're not advocating that this is possible?"

Of course it's possible. Just because you don't like it (and I don't like it much either) does not rule it out. Nature doesn't care about our likes or dislikes.

47. **Peter Woit**
December 13, 2013

Hi Peter O.,
That's right, but I also think there's another point, which is what Wilson was getting at, and which theorists typically ignore. Until you have a specific theory at your very-high-energy scale, you don't know what exactly you mean by "tune the theory very finely". Looking at the history of physics, theorist's attempts to extrapolate to energy scales many orders of magnitude beyond what is experimentally accessible have often if not always turned out to be wrong.

Umesh,

You think you don't need anything beyond what is in your textbook to understand what is going on at distance scales many orders of magnitude beyond what we can measure, I think those are great mysteries about which we will someday learn surprising things. Good luck with the multiverse….

48. **Peter Orland**
December 13, 2013

Peter said,

"That's right, but I also think there's another point, which is what Wilson was getting at, and which theorists typically ignore. Until you have a specific theory at your very-high-energy scale, you don't know what exactly you mean by "tune the theory very finely"."

Hi Peter. You are right. We don't really know what we are fine tuning, because we don't know the theory at the high-energy scale. I guess I am just trying to say that without access to this scale, we shouldn't take "solutions" to the fine-tuning "problem" seriously, without something compelling (like experiment). Maybe there is no solution (though I don't advocate this).

I am not arguing against esthetic criteria in science. We need esthetics to lead us to try different models of Nature. I just think esthetics is not a substitute for real information.

49. **Umesh**
December 13, 2013

Indeed one needs much more than what's written in text books. But what you don't tell me is why is it that it's imperative to understand the full physics at the higher energies fully (indeed it would be fabulous to know it, but even without it we can make reliable statements about low energy, and this is why QFT works) even to make some qualitative statement about parameters at low energy. This is textbook stuff for sure, but a very valid and possibly the most important lesson about textbook QFT. Again, I fail to see why one needs detailed knowledge about the high energy theory just to make some statement about stuff at low energies.

50. **Peter Orland**
December 13, 2013

" Again, I fail to see why one needs detailed knowledge about the high energy theory just to make some statement about stuff at low energies."

Not any statement, Umesh. Your statement.

51. **Umesh**
December 13, 2013

You mean the statement about the Higgs mass? It's just another low energy parameter in the SM, and one may make qualitative statements about it just like one can about other loq energy parameters. What's wrong with that?

52. **Peter Orland**
December 13, 2013

The statement about fine tuning.

53. **Umesh**

December 13, 2013

I can't assume that you're speaking for Mr. Woit. At any rate, as I've already stated, I fundamentally disagree if that is what he's proposing. That such impossible cancellations do occur, we must keep our mind open about it, and indeed, to know whether such cancellations do occur one needs detailed knowledge of the high energy theory, which, mind, receives contributions from all scales. Thank you very much for your patience.

54. **Peter Orland**
December 13, 2013

I don't have a blog, so Peter W. doesn't need me to speak for him.

I think the blog post (which I did not write and would not claim to quote from memory) was about the use of historical and esthetic arguments in describing Nature.

It's very hard to be a theoretical physicist without remembering history. It's even harder to study models, without esthetic guidelines. But let's not take this too far. Nature does not care about human affairs, so historical precedent and esthetic arguments must never be accepted as dogma. Only experiment is the final arbiter of fact.

55. **Umesh**
December 13, 2013

As I have already explained, the need for cancellations is more than just aesthetic. It's mathematical, which has no reason to hold. The quantum effects are integrals, and no one would just readily believe that such integrals should produce numbers which cancel to one part in 10^32. And I have also added that I disagree with you (or anyone) who wants to believe in such a miracle. There's nothing more to be said about this. Just in case this is what Mr. Woit means (I don't know for sure until he responds) when he insists on requiring detailed knowledge about the high energy theory, he should've made it clear at the very outset that he prefers cancellations coming from detailed high energy behavior, and thus views the issues about the Higgs mass as 'speculation'. This is not the impression I got from the exchange. In case he disagrees with this, then we're back to the question: why must I have detailed knowledge of the high energy theory to talk about low energy parameters, of which the Higgs mass is but just one?

56. **Peter Orland**
December 13, 2013

Umesh,

Just because you dislike fine tuning doesn't make it a miracle. You're making an esthetic argument, not a technical one.

I'm getting tired of repeating myself. Good-bye and good luck.

Latest on Amplitudes

December 10, 2013
Categories: Uncategorized

This week the Simons Center is hosting a workshop on "The Geometry and Physics of Scattering Amplitudes", talks are available here. Last week they (and the YITP) held a one-day symposium on Trees, loops and precision QCD, based around the work of Zvi Bern, Lance Dixon and David Kosower that was recently awarded the 2014 Sakurai Prize . For more about this, see Dixon's guest post here, or his talk at the symposium.

Bern, Dixon and Kosower started working on amplitudes more than twenty years ago, at a time that it was becoming clear that string theory was not working out as a theory of everything. Calculations in string theory did though lead to interesting new ideas about how to evaluate scattering amplitudes in gauge theory (I see from Dixon's list of publications that in 1994 he wrote something for the SLAC Beam Line on "Whatever happened to the theory of everything?", presumably about this, but now too deep in the past to be available on-line). The three Sakurai Prize winners have been steadily working at the problems of amplitudes in gauge theory and quantum gravity, for many years without getting much attention for their work. About ten years ago, things changed when Witten wrote a paper about getting amplitudes from the "twistor string", a topological string theory in twistor space (the use of twistor space was originated by Penrose back in the late 1960s, and was applied by V.P. Nair to gauge theory amplitudes back in 1988 while he was here at Columbia).

About six years ago Nima Arkani-Hamed entered the subject, where he has had a dramatic effect as an impresario, arguing that this is a route to revolutionary ideas about physics, overthrowing conventional notions of space and time, locality and unitarity, and doing away with the notion that gauge invariance is important. This was partly responsible for his $3 million Milner prize.

For the latest along these lines, a paper with Trnka about "The Amplituhedron" has just appeared, a topic which got wide play in the press earlier this year as Physicists Discover Geometry Underlying Particle Physics, drawing a parody from Scott Aaronson about his own work on the "Unitarihedron" and "Diaperhedron". Arkani-Hamed's talk at the Symposium covers both the ideas of Bern, Dixon and Kosower and his recent work with Trnka. It includes many appreciative remarks about their work, including some interesting commentary on how theoretical physics is done. For instance, on the likely reason for people ignoring their early work:

> It's a natural reaction among theoretical physicists, right? At any given time there's all sorts of interesting things going on, things that other people are doing and things that you are doing and especially if someone else is coming along with something that looks really exciting, in order to justify not dropping everything you have and working on it you have to sort of start inventing these reasons why what they are doing is irrelevant or crap, right? It's a very human thing, a very human thing, a very natural thing. I think everyone does it to some extent, and really good people eventually will realize that they are fooling themselves and start changing their tune if it's appropriate. Really bad people, well, we won't talk about them. It was not at all obvious that this was the tip of a huge iceberg…

There's also:

> Often fields, other fields, have what you might call prophets and there's I think usually an excessive amount of reverence for these prophets, because the prophets tend to have the property that they say some sort of vague things, I won't name any names but you can probably figure out the sort of collection of people I'm talking about. They say some sort of vague things about what might happen with physics in the future, and then twenty years later when other people have done all the hard work and really figured out what is going on and how it works in detail and why it works that way and not another way, if it vaguely looks like something they did, they say "see, I said so all along!" They have a fair amount of attraction, I think it's because a lot of physicists have father-figure issues. But anyway, Zvi and Lance and David were very much not like that, they weren't just vague prophets saying something was going on, they were extremely specific: there was something going on in this area with these kind of computations in this arena and they knew it. And it took a decade or more for many other people in the field to catch up.

(Personally, I have no idea which "prophets" he's thinking of.)

Finally, there were some personal comments contrasting Bern, Dixon and Kosower's low-key style and use of a variety of techniques with his own high-powered hype-driven sales-job of specific ideas to himself and others. Probably a good idea to read this in conjunction with the "Outlook" section of the new paper….

> I must say, and I'm really not just saying this to say it, I'm VERY envious of this, because I AM an ideologue. In my defense at least I can say that I'm a serial ideologue, in the sense that I'll take totally different ideologies and drop the last one without thinking about it, but it's very important for me personally to be an ideologue when I'm working on something and I think, and I'm saying this in all honesty, the difference is talent. If you're really good, you don't have to be an ideologue. You take this, you take that, you're solving for things left and right, you don't care where things come from. If you're not as good, there are 15 million things going on, you're holding on for dear life in the stiff wind of all the crazy stuff going on in the subject. So you have to have a strong point of view about something, you have to have a strong point of view to sort of pursue a particular direction, otherwise you'll get beaten around all the time and get nowhere.
>
> So, usually I'll get up when I talk about scattering amplitudes and give a long introduction about how spacetime is doomed, we have to find some way of thinking about quantum field theory without local evolution in space time and maybe even without a Hilbert space and blah-blah-blah. This is all very high-falutin stuff, this is stuff that Lance wouldn't be get caught dead saying. I think none of these guys would ever say something that sounds so pretentious, but I have to say it, you know I have to say it, because this is the only way I can get up in the morning, and like "I suck again, OK, here we go, I'm doing it because spacetime is doomed, I swear to God, right". But, quite seriously, the best people in the subject have this feature, they don't need to be ideologues, they take the most interesting ideas from every direction they can to make progress, so I really am quite envious.

Comments

1. **Kavanna**
   December 10, 2013

   The amplitude work is very elegant and deep stuff. It had immediate application to QCD amplitudes. But it also has surprising relevance to electroweak amplitudes, once you properly incorporate symmetry breaking. Divergences and leading parts still respect the symmetry and obey the patterns discovered by Bern, Kosower, and Dixon. The pieces that break the symmetry are nonetheless related to each other in a deep way dictated both by the symmetry and by how it's broken (by which non-singlet irreducible representation the vacuum is).

   The amplitude stuff does not in any way overthrow gauge symmetry. It does show that gauge symmetry in amplitudes is a "projection" or shadow of something geometric. It's remarkable that this work has survived the Age of Cliques and Hype.

2. **anonymous coward**
   December 10, 2013

   Did you REALLY not know which physicists he might be talking about, or are you just playing the consummate professional?

Also, is it possible to make your “I am not a spammer” thing a little more noticeable? It’s about two shades darker than the stark white background, and I like to wear sunglasses indoors at night.

3. **Peter Woit**
December 10, 2013

anonymous coward,

Honestly, don’t know who he’s thinking of. I’m aware of people who make vague, grandiose claims they can’t back up, but in my experience while people like this may think of themselves as prophets, they have few followers.

Have at least temporarily disabled that anti-spam gizmo to see what happens. Not clear if it was still effective, we’ll see…

4. **Igor Khavkine**
December 11, 2013

The last quote seems to be an exceptionally honest and genuinely self-reflective moment from Arkani-Hamed. I hope it will be appreciated.

5. **Peter Woit**
December 11, 2013

Igor Khavkine,

I do think the last quote from Arkani-Hamed is quite interesting, but I think there’s a lot of false modesty there: I don’t think he really believes that Bern, Dixon and Kosower are more talented than he is. I also don’t think his distinction of them as using a variety of ideas and techniques in their work is a significant one, since he and most theorists will happily use whatever tools they can get their hands on.

What is really interesting though is his self-reflective description of himself as an “ideologue” and his explanation of why he is that way. This kind of answers a question that has often come up in my mind when I hear one of his talks: “how can a smart guy like that engage in such vigorous hype, with crude arguments avoiding acknowledging obvious problems?” He provides a good answer here: this is what he needs to do to justify to himself continuing every day to do difficult and often unrewarding work. This I think is very honest, much more so than usual platitudes from scientists about how much they enjoy the process of discovery.

6. **Igor Khavkine**
December 11, 2013

Peter, we’re on the same page here!

7. **JohnB**
December 11, 2013

That is a very interesting (and honest) comment from him alright, regarding why he is an ideologue – I’d say it carries much weight with what I said regarding economists in my comment on the previous post (except I’d say economists academic careers depend upon never admitting such a personal fault).

I’d say agnotology among the physics community (and scientific community in general), would make for an interesting study.

It makes sense that people have to let themselves dream/hype a bit, in order to generate the enthusiasm/motivation they need for their work/study in theoretical fields like this, and it’s a good sign that people can openly admit/acknowledge that – having a safe atmosphere for such disclosure, would be important I’d say, in allowing room for reform.

8. **Bernhard**
December 11, 2013

“About ten years ago, things changed when Witten wrote a paper about getting amplitudes from the “twistor string”,”

It is hard to distinguish if this is genuine or sociological effect. Well, probably a combination of the two. I mean, would it have changed if it someone else, and not Witten, had written the paper? But then again, could someone else have done it? Not an expert on any of this, just speculating.

9. **Peter Woit**
December 11, 2013

Bernhard,

If you look at Dixon’s blog post I linked to, he describes what happened after Witten’s paper as:
“Smart young physicists like Ruth Britto, Freddy Cachazo, Bo Feng, Radu Roiban, Mark Spradlin and Anastasia Volovich flooded what had been a mostly deserted “amplitudes” landscape. ”
I don’t think that this would have gotten anywhere near the same attention at that time if the “twistor string” idea hadn’t been coming from Witten. Having Witten point out a field where few people were working, there were interesting calculations to do, and some kind of connection to string theory, got a lot of attention at a time when not much else was happening and people were looking for something to do.

In the end, I don’t think the “twistor string” part of the idea itself turned out to be that useful, but it led to various new ideas about amplitudes that were important, including the papers http://arxiv.org/abs/hep-th/0412308 and http://arxiv.org/abs/hep-th/0501052 (“BCFW recursion relations”).

10. **MathPhys**
December 13, 2013

I have learnt the very hard way that any subject that Witten works on must be (at least) mathematically interesting, and that any subject that he stays away from is possibly worthless.

11. **Cosmonut**
December 14, 2013

I guess Stephen Hawking would top the list of “vague prophet” making incredibly grandiose general claims which have all fallen flat.

While string theorists get a lot of flak for hyping their field, it must be remembered that Hawking started the trend of announcing the imminent arrival of a “Theory of

Everything” which would enable us to “know the Mind of God” and so on….

In fact, he claims that the “grand theory” has already arrived in the form of M-Theory – though I don’t think anyone takes him seriously anymore.

2014 Milner Prizes

December 11, 2013
Categories: Uncategorized

Last March an Oscar-style ceremony hosted by Morgan Freeman was held in Geneva (see here) to award the 2013 $3 million Milner Prize to Princeton string theorist Alexander Polyakov. Tomorrow an even more lavish ceremony designed to turn "Oscars of Science" into instant multi-millionaires will be held in Mountain View, California (see here). It will feature Kevin Spacey, Conan O'Brien and Glenn Close, one of whom will presumably award the 2014 $3 million Milner string theory Prize to either Polchinski, Green/Schwarz, or Strominger/Vafa.

If I had to bet I'd go for Polchinski, purely because if they don't give it to him, that will be two years in a row he walks away with a $300,000 consolation prize, and having to have him a third time up next year before getting his $3 million would be a bit silly. On the other hand, John Preskill is predicting Green/Schwarz, and he may be right. If you're going to have a prize devoted to the idea that string theory = fundamental physics since it's our hope for a TOE, then one really has to give it to Green/Schwarz for originating the whole superstring = TOE business.

On Friday, there will be a day-long symposium at Stanford sponsored by the Milner prize people (see here), with the $3 million man (or men) speaking at 5:30pm, introduced by Lenny Susskind.

Physics will actually be a relatively small part of this awards ceremony, since it will also include the award of six $3 million awards in the Life Sciences. These are being jointly funded by Milner and a group of other prominent internet entrepreneurs.

Update: News is that the awards ceremony will be broadcast by the Science Channel:

> Hosted by actor Kevin Spacey, the awards will be presented by the Prize sponsors and by celebrities including Conan O'Brien, Glenn Close, Rob Lowe and Michael C. Hall. The event was produced and directed by Don Mischer, the producer and director of The Academy Awards among other television and live events. The world premiere special 2014 BREAKTHOUGH PRIZES will premiere on Science Channel on Monday, January 27 at 9 PM ET/PT.

According to the press release, Polchinski, Green/Schwarz or Strominger/Vafa will get $3 million for being "psychics":

> The 2014 Breakthrough Prizes are awarded to those who make major breakthroughs and contributions that represent significant advances in our fundamental knowledge of the world. At the ceremony, seven prizes (six for life sciences and one for psychics) of $3 million each will be awarded for a total of $21 million.

Update: As John Preskill predicted, the $3 million string theory prize went to Green and Schwarz. Polchinski gets a second $300,000 consolation prize and another chance next year.

Update: Vanity Fair covers the event as Hollywood Stars Gather in Silicon Valley for 2014 Breakthrough Prizes in Physics and Life Sciences.

   Will the winner "give us tongue"?

2. **M**
   December 12, 2013

   Opening the possibility of imagining D-branes here and there has been an important factor in convincing that string theory has no predictive power. This key achievement deserves more that just a few millions

3. **Thomas Larsson**
   December 12, 2013

   Whatever the lasting value of Sasha Polyakov's contributions to string theory, the application of CFT to 2D phase transitions is experimentally confirmed and definitely prize-worthy. I have long thought that BPZ should receive a Nobel for this.

4. **Bernhard**
   December 12, 2013

   An unserious ceremony for an unserious prize. Fair enough…

5. **Hack**
   December 12, 2013

   What an utter circus! So now physicists want prizes given to them by Hollywood celebrities? Fantastic, hopefully next year the prize can be given out by Miley Cyrus who can recreate her MTV dance with the prize recipient! That or perhaps Kim-Yay (thats Kim Kardashian and Kanye for those of you living under rocks) could clear their busy schedules and to it. I don't know that is a real toss up…

6. **tt**
   December 12, 2013

   twerk = force x distance

7. **P**
   December 12, 2013

   M,

   What you say makes no sense. Imagining a D-brane "here" or "there" is really just the statement that there are typically D-brane moduli spaces. In many cases these are, via duality, dual to the moduli spaces having to do with sets of closed string modes.

So even if I granted your naive notions about difficulties of string theory — which themselves have issues — your argument re: D-branes making things worse is clearly wrong.

Cheers,
P

8. **M**
December 12, 2013

dear P,
before 1995 the attempts of connecting physics with strings were restricted to heterotic strings compactified on some Calabi Yau. D branes expanded the (already too large) list of possible constructions. This gives new ways to search a string model that reproduces all observed physics. But, more importantly, it makes the issue irrelevant: for any observed physics there are ≈ 10^300 string models that reproduce it.

I advise Milner to offer a prize of 10^-300 dollars for any "theory of everything".

9. **harryb**
December 12, 2013

And I quote from Edward O Wilson's new book, Letters to a Young Scientist (he being a great Life Scientist at Harvard):

"If a subject is already receiving a great deal of attention..if its practitioners are prizewinners who receive large grants, stay away from that subject….in making your own long-term plans, be aware it is already crowded with talented people. You would be a newcomer, a private amid bemedaled first sergeants and generals. Take a subject instead that interests you, and looks promising, and where established experts are not yet conspicuously competing with one another, where few if any prizes and academy memberships have been given, and where the annals of research are not yet layered with superfluous data and mathematical models. "

Lets hope some look at these prizes as an end of time for ST, and aim for other paths, make their mark in other ways.

10. **P**
December 12, 2013

Hi M,

Dualities between theories with branes and the heterotic string were precisely the ambiguity I was talking about.

Two more corrections: string model is ambiguous, you should call them string vacua. Second of all — and this is what I was taking issue with — is that the large number of vacua isn't from the D-brane moduli space (i.e. the ability to put a brane "here" or "there" as you say), it's from the Ramond Ramond background flux utilized in moduli stabilization. So, again, the 10^large is *not* from the D-branes.

Cheers,
P

11. **Mitchell Porter**
December 12, 2013

M says

"for any observed physics there are ≈ 10^300 string models that reproduce it"

In our present state of knowledge, an estimate like that above, is simply a guess – a guess which could be completely wrong.

In principle, once you choose a particular string vacuum, all the low-energy parameters become calculable. In practice, the ability to calculate such quantities is still very limited – e.g. see the opening paragraphs of [this report](#) from "String Phenomenology 2012".

12. **Peter Woit**
December 12, 2013

P, M, M-P,
Sorry, but this particular discussion is neither very interesting nor on-topic. About M-P's claim that all the low energy parameters of physics in a string vacuum (as opposed to some very specially chosen vacuum) are in principle calculable, with a link supposedly proving this, the link in question actually has

"in many string models, we don't actually have enough control to calculate physical coupling constants; often an overall proportionality factor is missing, and simply assumed to be 'of order one' (i.e. of magnitude between about .1 and 10). I think this is a very important point; 'string phenomenology' as it stands is a bit of a misnomer, because as far as I know, nobody has yet been able to do an honest calculation of all quantities like masses and coupling constants in a realistic string model."

which reads to me more like saying things are not calculable. But, anyone who wants to argue this one way or the other will have to do it somewhere else. Mercifully, even those string enthusiasts in charge of choosing Milner prize winners don't seem to think it's a good idea to give them for string phenomenology.

13. **chris**
December 13, 2013

it is astounding what people will do for money.

14. **Zhiming Wang**
December 13, 2013

The prize went to Green/Schwarz after all. *The Guardian*.

15. **martibal**
December 13, 2013

Now they will do it for maths as well…. Is that great or frightening ?

"The prize is one of a string of annual awards set up by Milner and other Silicon Valley stars to raise the profile of scientists and put them on a par – in some sense, at least

– with film and sports celebrities.” That is frightening, no ?

16. **Simple biologist**
December 13, 2013

Looking at life science winners is depressing as well. With the exception of Alexander Varshavsky, it’s all biomedical or biotech stuff. Their definition of life science break trough appears to be application of basic research to medical or biotech uses.

Basically they are awarding just the kind of research that Nobel prizes already cover, without the Hollywood celebs of course. Not sure why they waste all that money to compete with Nobel prizes. They could have used it to award biological fields outside the narrow scope that the chemistry and medicine Nobel prizes allow, evolutionary biology, ecology and so forth. Then again, maybe it’s better not to have this ridiculous hype.

17. **Low Math, Meekly Interacting**
December 13, 2013

I would like to thank tt for something to laugh about. The rest is pretty depressing.

18. **jd**
December 14, 2013

I find all these discussions about prizes, awards, and such very depressing. This severe sickness in the sciences and in our society does need to be discussed but I usually leave that to others. But today I do have a couple of thoughts. An APS Fellow I know, once pointed out to me that to become a fellow, or receive a prize, or award, or honor does not mean that you received it for your talent, skill, accomplishments. It means a good campaign was waged. This is true for science, the Academy Awards, the US presidential race, and the list goes on. Notice that after someone wins the presidency the analyses are not about whether the best person won but is on how the winner had the best campaign. In this blog before the Nobels were announced this year it was mention that campaigns were in progress, not necessarily by the candidates but by their supporters. I know of one Nobel prize winner who went around Europe and somehow got various national legislative bodies to pass do nothing bills in support of him for the prize. This was years ago. He got the prize in spite of the letters written by a number of prominent people in his field urging that the bills be ignored. I know of a US institution of international reputation that wanted to hire a certain researcher and promised that, if he came, they and their professors would throw their weight behind him for the Nobel. It is debatable that his work was of that caliber, but he did get the prize. This all is embarrassing, depressing, and in the long run hurts science and society. The argument has been made that maybe the money, the “honor,” may encourage bright young people to go into science. I ask whether that would have made a difference to any of you? If it does, then obviously you made a mistake. I personally knew, in years past, of young people, some bright, that dropped out of physics after their PhD’s because they felt that the field had changed and no longer could offer them that solid, interesting, career in teaching and research. Most of them went into medicine, law, and finance where, if money is your motivation, that is where the real money is. As for myself, so you know, I have not received any honors of any import. Years ago I had a superior and a coworker each separately offer to put me up for fellow. I thanked them and told them no, that the offer was enough honor. I looked over the current fellows and did not want to be associated with most of them. It really was not an honor. I am not at all comparing myself with Perelman, he is far, far beyond me. But I do admire his integrity with respect to prizes, at least as far as I have read in articles. And for those that take his decisions as a slam against them, so be it. Maybe they should look within themselves.

19. **Noah Smith**
December 19, 2013

Milner prize = most lavish consolation prize ever

I hope Terence Tao win Milner prize 2014

Milner-Zuckerberg Prizes for Mathematics

December 13, 2013
Categories: Uncategorized

At the Hollywood-style awards ceremony last night for $3 million string theory and biomedical research prizes, it was announced that Yuri Milner and Mark Zuckerberg will now start funding something similar in mathematics, called the Breakthrough Prize in Mathematics. According to the New York Times:

> Yuri Milner, the Russian entrepreneur, philanthropist and self-described “failed physicist” who made a splash two years ago when he began handing out lavish cash awards to scientists, announced Thursday that he was expanding the universe of his largess again: This time, he will begin handing out $3 million awards to mathematicians…
>
> For the new math award, Mr. Milner and Mr. Zuckerberg, the co-sponsor of the math prize, will decide who gets the money, in consultation with experts. Mr. Milner declined to say how many mathematicians would be chosen, but there could be quite a number of windfalls in store: for the physics price, there were nine inaugural winners, and for the life sciences prize, there were 11.

I’ve written extensively about the “Fundamental Physics Prize” and what I see as the worst problem with it (heavily rewarding and propping up a failed research program). While many physicists are privately unhappy about this prize and its effects, few prominent ones are willing to speak publicly with their name attached, since this kind of mouthing-off could turn out to be personally extremely expensive. Ian Sample at the Guardian has a story today, which quotes a “prominent physicist who did not wish to be named”:

> One prominent physicist who did not wish to be named said the huge sums of money could be used better: “The great philanthropists of the 19th and 20th centuries, like the Rockefellers and the Carnegies, did not create prizes – they created universities and research institutes that have enabled thousands of scientists to make great breakthroughs over the succeeding decades.
>
> “By contrast, giving a prize has a negligible effect on the progress of science. A few already well-recognised people get enriched, but there is little value added in terms of the progress of science compared to the multiplier effect of creating new institutions for scientific research.”

The Guardian does quote one critic by name, but it’s just the usual one.

The physics prize has turned out to be extremely narrowly targeted at one particular subfield of physics, and from what little I know of the life sciences, the prizes in that area seem to be also narrowly targeted (US biomedical research aimed at curing diseases that most afflict those in the developed world). I’m highly ignorant about life sciences research, but it seems striking that the 6 $3 million winners in this field were all men.

I have no idea how Milner and Zuckerberg will go about choosing the $3 million winners in mathematics, and whether this new prize will end up being narrowly targeted to a certain sort of mathematics research. If so, it may have very significant effects on what kinds of mathematics get done. Based on the other prizes, it seems likely that the winners will be mostly prominent US academics, people already well-rewarded by the current academic star system. I don’t see any reason to believe that these kinds of financial awards will allow such mathematicians to do work they wouldn’t otherwise do, so the main argument for the prizes is that the money (and Academy Awards-style ceremonies) will help make them celebrities, and that this is a good thing. One can predict that public criticism from prominent US academics may be rather muted once the checks start coming.

Even if the Milner-Zuckerberg prize does end up focused on the best mathematics research, I still think the whole concept is problematic. The US today is increasingly dominated by a grotesque winner-take-all culture that values wealth and celebrity above all else. While mathematics research, like the rest of academia, has been affected as a star system has become increasingly part of the picture, this field has been somewhat immune to celebrity culture. While people typically think that what mathematicians do is perfectly respectable, they don’t understand much about it and aren’t especially interested. Milner and Zuckerberg want to change this by turning mathematicians into celebrities, but I don’t see any reason to believe this is going to lead to better mathematics.

Update: Here’s the statement from Milner about the planned mathematics prize:

> Yuri Milner said: “Einstein said, Pure mathematics is the poetry of logical ideas. It is in this spirit that Mark and myself are announcing a new Breakthrough Prize in Mathematics. The work that the Prize recognizes could be the foundation for genetic engineering, quantum computing or Artificial Intelligence; but above all, for human knowledge itself.”

Comments

1. **Hack**
   December 13, 2013

   Great! It is not enough to add difficulties to theoretical physics research alone, now these prizes will cause problems in the life sciences and mathematics fields. Scientists need to grow up and put a stop to this, but we all now that will not happen. What ego-driven hard working researcher would turn down $3 million or the chance of $3 million, despite the fact that these prizes are going to hurt their respective fields in the long run. This is incredibly disappointing.

   By the way Peter, your right, it is rather amazing that no women were awarded the $3 million dollar prize in the life sciences. I am probably more familiar with that field than most of your readers and there are many brilliant and successful women researchers. One would think somebody on the prize committee would have been smart enough to think that not awarding any women the prize might lead people to believe their chauvinistic…

2. **John McAllison**
   December 13, 2013

   Who on earth came up with this clueless idea that physicists and mathematicians should be patronized by Vanity Fair magazine and presided over by actors such as Kevin Spacey at an awards ceremony?

   Let the awards be given out by those mathematicians and scientists their peers look up to, or perhaps a representative from the awarding organization itself.

   This is just adding further to the negative status of science and mathematics relative to the entertainment industry.

3. **BCnrd**
   December 13, 2013

   Jim Simons has taken a more productive/thoughtful approach in his philanthropy for mathematics: some serious long-term prizes without Hollywood distractions (with the requirement that they be used in a substantial way to support research activities), and a substantial grant program to help working mathematicians (not just super-stars) in constructive ways via summer support, sabbatical support, conference support, etc. It is quite a contrast with the approach chosen by Milner and Zuckerberg (whom I am sure have good intentions, and hopefully can be convinced to modify their plans so as to have a greater benefit to mathematics; the big prizes seem unlikely to encourage increased government support for research mathematics).

4. **Peter Woit**
   December 13, 2013

   BCnrd,

   Thanks, I very much agree. Simons has provided an excellent model of carefully thought out plans to use some of his wealth to further mathematics research. It would be great if Milner and Zuckerberg would take their inspiration from his model.

   This is likely a pipe-dream, but it really would be wonderful if the mathematicians Milner and Zuckerberg consult with about this as they start their process of choosing prize winners would politely tell them something like "we appreciate the thought, but we wish you wouldn't do this, and would find some other better way to support mathematicians and their research. You might want to talk to Jim Simons…"

5. **kashyap vasavada**
   December 13, 2013

   I think criticisms of Milner-Zuckerberg awards are unwarranted. On the one hand we complain that society awards big money to sports figures, entertainment celebrities, CEOs and hedge fund managers and ignores talented scientists and mathematicians. Then when some visionaries like Milner and Zuckerberg put large sums of their own money, we complain that it is not going to be good for science and mathematics! We cannot have it both ways! I agree people may have different opinions about which sub field deserves prizes. But there are differences of opinions about Nobel Prize also. Admittedly Nobel Prize is given for some successful previous scientific research. But I do not see any problem in awarding promising scientists and mathematicians. Also we don't tell CEOs of hospitals and pharmaceutical companies that their salaries could be used for cheaper health care!! So better use of money is also not a particularly great argument.

6. **peter**
   December 13, 2013

   I prefer Simon's effort to Milner's. But maybe we should not blame Milner. The point is why those fpp winners not spend their prizes in supporting more other young people. Since they have not made it, this means this prizes are at least important for their personal lives.

7. **Peter Woit**
   December 13, 2013

   kashyap,

   Actually, if I could get any of them to listen to me, I'd very happily "tell CEOs of hospitals and pharmaceutical companies that their salaries could be used for cheaper health care."

8. **DaDa**
   December 13, 2013

   Peter you are too cynical.

9. **Peter Woit**
   December 13, 2013

   DaDa,
   Actually I think the standard criticism of someone like me who objects to the influence of large sums of money is that I'm too idealistic, not that I'm too cynical…

10. **Simple biologist**
    December 13, 2013

    @Hack
    You're absolutely right about the gender issue.

    To add, if I needed to name the one field of science that has the best level of funding, enjoys already the highest support from the general public, is by far the most over hyped field, and was in the least need of big bags of cash & PR from eccentric billionaires…it would biomedical research into first world diseases.

    (I know it's off topic for the site and I already wrote about it in the earlier Milner topic. Sorry Peter)

11. **Hank Damage**
    December 13, 2013

    kashyap vasavada:

    We don't "complain that society awards big money to sports figures, entertainment celebrities, CEOs and hedge fund managers" at all. We complain that the money is distributed unevenly or at least not according to merit among the respective groups, which is exactly what's happening with these M-prizes again.

    Another thought/hypothesis: Convincing Milner to do the funding in a reasonable manner is impossible. Because despite claiming, that the prizes are there to promote "human knowledge itself", it is much more likely that this failed – yet obviously ambitious – physicist was trying to convert the currency he had into social currency aka said fame. Successfully too, just telling by the numbers of mentions he got in this respectable blog.

    DaDa, it's either cynicism or somatic bliss. People choose whatever keeps them going.

    Well, none of this was new, but thanks for listening.

12. **Sam Lewallen**
    December 13, 2013

    I had a thought like Peter's: especially if there are multiple inaugural math prizes, maybe there would be some way that all the winners could be convinced to pool their prize money and fund something beneficial to mathematics, such as a research center. It seems a long shot, but I'd think math would be the field most able to pull this off. I think this would generate a really interesting media response as well, and maybe send a message to Milner et al.

Maybe Jim Simons could make an open offer to the award recipients, that he would match their donations to fund a new research center somewhere (his foundation could lend their expertise in making this happen)? That would really be a neat situation. Anyone think something like this is even conceivable? Could we start a petition?

13. **Allan Rosenberg**
December 13, 2013

Certainly Edward Witten, Maxim Kontsevich, and Nima Harkani-Amed (for Amplitudhedrons or whatever they're called) should be on the short list for the Math prize. Is this one going to be awarded via Facebook?

14. **Bee**
December 14, 2013

I'm not prominent but for what it's worth I've stated my disapproval about the Milner prize here http://backreaction.blogspot.de/2013/01/private-funding-for-science-good-idea.html

15. **Navneeth**
December 14, 2013

String math, Quantum Computing, Number Theory and Cryptography. Those topics have the most visibility in popular literature, right?

16. **Zwirko**
December 14, 2013

I hope layman questions are welcome here?

Do these cash prizes come with terms and conditions? That is, are they to be used for research purposes? Fund students or buy materials and equipment? Or can the recipient use the money to buy a Ferrari or two? Are there any stories of what people have spent the money on?

I'd feel very uncomfortable if I won several million for my research and decided to keep it for myself. I think my conscience would force me to either share it with colleagues or donate to the lab.

17. **other**
December 14, 2013

This is nothing to worry about. Start being concerned when a subject develops a "priesthood" and canon of knowledge …

18. **Peter Woit**
December 14, 2013

Zwirko,

The prizes have no restrictions, people can use them for whatever they want. I know nothing about what the biomedical research people have done with the money so far, they generally have large labs that could use the money.

Among the physicists, most of the experimentalists seem to have publicly announced they are giving the money away, to various projects to support young people, teachers, etc. In these cases, the recipients were mostly spokespersons for their experiment, so it was kind of odd for them to be getting money personally. The research of the theorists is already very well supported by grants, so I don't think there's a viable way for them to spend any significant amount of the money on their own research. On the whole, there has been little news from the theorists about what they are doing with the money. If they're giving it away they're doing so privately.

19. **CU Phil**
December 14, 2013

I think Witten gave a significant portion of his to J Street, if I remember correctly.

20. **Deane Yang**
December 14, 2013

Peter et al, I think the Milner Prizes *do* benefit mathematics and mathematicians but in a very different way than what Simons does and in a similar way to the Nobel Prizes.

The Milner Prize, like the Nobel Prizes, does little directly to benefit scientific research. Both are given to prominent established scientists unconditionally, often after their best work has already been done. In that sense they are both relatively useless, and that's the focus of much criticism.

But for me the huge value they add is the attention it attracts to the great things done by mathematicians and scientists. Most media attention is devoted to the most "sexy" advances, which usually sound better than they are and draw attention to people who don't necessarily deserve it. "Cold fusion" is the one that comes immediately to my mind. Although we can all criticize the choices made by the prize committees, there is no question in my mind that these prizes draw attention to at least some of the best in their respective fields and their accomplishments.

I know you're frustrated by the Milner Prize being awarded to string theorists, but no matter what we think of the theory itself, there's no question that these are, for better or worse, the best and brightest in physics today.

21. **Jesper**
December 14, 2013

@ Deane Yang

"there's no question that these are, for better or worse, the best and brightest in physics today."

By what measure? If they all work on the wrong theory (which, of course, remains to be determined), then I don't think they deserve this distinction. Until we know what is up and what is down I certainly think there is a question.

22. **Peter Woit**
December 14, 2013

CUPhil,
While Witten was quoted as saying he would donate some money to JStreet, I'm not sure about how "significant" this is. He got the prize in mid 2012, in the JStreet 2012 report he's listed as a $10,000 donor, but not a $25,000 donor. If he did give the whole $3 million to JStreet, he would quite significantly change the organization, roughly tripling its assets.

23. **Peter Woit**
December 14, 2013

Deane,
At this point I don't think we have any way of knowing one way or another how the Facebook prize (I think I'll refer to it that way because that's where most of the money is coming from) will affect mathematics. It's quite possible that even Milner and Zuckerberg haven't figured out how they are going to make these awards.

Based on the history so far though, I think there is plenty of good reason for the math community to be worried. In both the physics and life sciences cases, the awards are targeted at a narrow part of the subject, one that already gets the most attention. Mathematicians may wake up one morning a few months from now to find that some narrow, already well-funded and hyped sub-field of mathematics has been identified as the one that's relevant to what really matters ("genetic engineering, quantum computing or Artificial Intelligence", according to Milner), and from that day forward, that's going to be the sub-field that gets attention and resources. Yes some mathematicians will become wealthy, maybe even celebrities, and get to hang out with Kevin Spacey, Conan O'Brien, etc. but will this really have a positive effect on mathematics?

Part of my reason for skepticism about whether bringing celebrity culture into science or mathematics is a good idea is based on seeing what it has done in theoretical physics, where, personally I think it has had a strongly negative effect. This has partly to do with independent problems of the subject, but I just don't see much evidence of the supposedly positive things happening. One standard argument is that this encourages young people to go into STEM careers, but I just don't believe that too few people interested in such careers is the problem. Rather the problem is more people than jobs of this kind, and celebrity culture may just change the mix of reasons why people go into these fields. Will we really be better off if fewer people become mathematicians because they deeply love mathematics and more do it because they want to meet Conan O'Brien?

24. **Peter Woit**
December 14, 2013

Deane and Jesper,

I'd change Deane's "the best and brightest" to "some of the best and brightest". Again, Milner's prize is aimed at a narrow slice of theoretical physics. Witten is definitely about "the best and brightest" around by most measures. On the whole though, the rest of the Milner prize winners, while talented and accomplished, are not significantly more so than many others in the field. As an example, consider the quote I posted here recently from Milner prize winner Arkani-Hamed about Bern, Dixon, Kosower, where he describes them as much more talented than himself. One might want to discount that as false modesty, but I do believe they're equally talented, accomplished and hard-working. Unlike Arkani-Hamed, they chose to work on less popular topics, and not to hype the significance of their work. They may of course in the future get on the Milner prize list, especially since Arkani-Hamed has been on a hype campaign for a few years now for their subfield.

An interesting example is this year's winners, Green and Schwarz. Back in the late seventies/early eighties, they were very admirably working on a quite unpopular topic (superstrings). Schwarz back in 1984 was a 43 year old research associate, without a permanent job (or even a tenure-track one). Post-1984 (Green-Schwarz anomaly cancellation and the ensuing "First Superstring Revolution) he and Green became highly-rewarded celebrities of the field. From the vantage point of 30 years later, it now is clear that the great hopes of 1984 were misguided, this is an idea about unification that hasn't worked (and likely never will). So, yes, they're good theorists who 30-40 years ago did good work on an unpopular idea, one that turned out to be misguided once it became popular and much better understood. Other than the fact that their ideas ended up getting overhyped, there's nothing else to distinguish them from a fairly large group of theorists active during the late seventies and eighties who worked on various ideas which either never worked out, or never got enough attention for anyone to know whether they might work out.

25. **Bernhard**
December 14, 2013

"Among the physicists, most of the experimentalists seem to have publicly announced they are giving the money away"

The experimentalists might have publicly announced giving the money away, but as far as I know, so far only two out of seven (Virdee and Incandela) actually did what they said.

26. **Bob Jones**
December 14, 2013

"If they all work on the wrong theory (which, of course, remains to be determined), then I don't think they deserve this distinction. Until we know what is up and what is down I certainly think there is a question."

You act as if we're all awaiting the results of some big experiment that will tell us whether these theories have any value. What you don't seem to understand is that these ideas are already known to be important. The ideas that these scientists are working on are all very coherent physical ideas which have taught us a lot about how nature works. They have remarkably rich mathematical structure and, in some cases, strong support from experiment. There's really no question that these are the right ideas to be looking at, and every one of these scientists is certainly among the best and brightest in the world.

27. **Peter Woit**
December 14, 2013

Bob Jones,
"There's really no question that these are the right ideas to be looking at"
You're doing a good job of illustrating the what's wrong with the Milner prize for physics, but, another round of string theory rules/string theory sucks is both off topic and a complete waste of time. Enough on both sides, will delete any more.

28. **Bob Jones**
December 14, 2013

Peter,

I thought you made a very good point in your earlier post when you said that the amplitudes people deserve more recognition. My reference to the "right ideas" was not meant to exclude this sort of work, which is exactly the sort of mainstream research that might one day be recognized with a Milner prize.

29. **martibal**
December 14, 2013

Peter,

maybe a thing that may “save” mathematics for being corrupted by prices is that, at the end, one needs a proof. One can have millions of dollars, hang out with K. Spacey, at the end what will convince the community is your ability to prove theorem. Hyping has no real meaning in maths, unlike what may happen in physics. Nobody can claim that “his approach to Riemann hypothesis is the only worth pursuing”, like B. Jones roughly said about string theory. Either you prove it (and this does not mean that your proof is the best one can imagine), or you do not prove it. People like Perelman or Wiles are good examples of “anti-hype” mathematicians, I would say 🙂

30. **martibal**
December 14, 2013

Schwarz back in 1984 was a 43 year old research associate, without a permanent job (or even a tenure-track one).

The best piece of news I have read for long time. So there is still some hope 🙂

31. **Jon Tyson**
December 15, 2013

All the people upset about how the billionaires give away their money should get their own philanthropic organization. Public complaints, some of which will certainly get back to the donors, can only be described as obnoxious.

32. **Marcel van Velzen**
December 15, 2013

It must feel really good to get a fundamental physics prize from a “failed physicist”.

33. **Anonyrat**
December 15, 2013

Twenty years ago, I heard a talk by Bern. I thought Bern was on the right track, and today if I was a physicist I would want to be someone like him, who has done more to elucidate the world we actually live in, not the world we might live in, than some big name physicists.

34. **Peter Woit**
December 15, 2013

Jon Tyson,
Billionaires can do what they want with the billions (within the law), but non-billionaires, who can’t do the same thing, have every right to obnoxiously criticize. That this criticism of their plans might get back to them doesn’t seem to me like a problem.

35. **Jay**
December 15, 2013

Congrats to the winners.

Peter, I understand some your concerns (physics almost equated with research on string theory, biology almost equated with research on cancer), but I still don’t understand how negative is your view about these prices.

Or, more precisely, I don’t understand how your rant should not apply to the prices that were setted by another nouveau riche, M Nobel. The main difference I can see is the Nobel price is in practice restricted to the oldest of our peers (but as you know we can’t blame Nobel -it’s clearly against its will), whereas Milner’s prices are given to active researchers, who are moreover free to do whatever they want with the cash. This is a freedom we hardly see anywhere else.

All in all, your main concern seems that it may drive students toward the wrong directions, even when these directions have clearly failed. Seriously? Were you yourself influenced by the Nobel price when you were to choose your carreer path? Do you know anyone in this case?

36. **Peter Woit**
December 15, 2013

Jay,
At least as far as the physics Milner prizes go I don’t see much difference in age distribution with the Nobel. The last few winners (Polyakov, Green, Schwarz) are all around retirement age. It seems that Milner in some sense wants to compete with the Nobel, awarding Nobel-type prestige to those ineligible because their ideas cannot be experimentally tested (or have been tested and failed).

About the proposed math prize, it’s unknown how it will work, but I just don’t see anything positive for math research coming out of it, and serious potential for negative effects.

Yes, the Nobel prize did affect me, and I think it affects most people’s view of a scientific field. Not by making me want to be a physicist so that I could get a prize, but by identifying certain people and their ideas as the most distinguished and most worth paying attention to. When one is trying to understand a subject, one has to make decisions about what to pay attention to, and the Nobel prize is a marker identifying a scientific consensus about the best work and most important ideas. The Milner prize is intended to play that role, indicating that string theory and other ideas it rewards are the best and most important ideas about fundamental physics. Whatever Milner and Zuckerberg decide is the most important part of mathematics will be destined for the same treatment.

37. **jonah**
December 15, 2013

It might be more of an applied math prize rewarding stuff out of scope for a Fields Medal or Abel prize. Statistics, signal processing, data mining… That would be welcome IMHO, there are several SIAM prizes already but something with more public visibility isn’t a bad idea on paper. Let’s see how this enfolds…

38. **Bob Jones**
December 15, 2013

“awarding Nobel-type prestige to those ineligible because their ideas cannot be experimentally tested”

Do you really think it’s fair to say that someone like Kontsevich is doing untestable work? Sure, his ideas will never be tested in an experiment, but that doesn’t make them any less important. These are formal ideas that aren’t even subject to testing. When you use this kind of language, you’re just misleading the public and stigmatizing some of the world's top scholars.

39. **Peter Woit**
December 15, 2013

Bob Jones,
Kontsevich is kind of a special case, the only mathematician to get a Milner prize. Yes, the test of good mathematics is not experimental testability.

I'll stand by the statement you quote, it's accurate and not misleading in the least (unlike the vast hype campaign of the past 30 years that has now achieved huge success by getting a billionaire to provide $3 million awards for failed ideas like Green-Schwarz's work on string theory unification).

40. **Jay**
December 15, 2013

>Yes, the Nobel prize did affect me, and I think it affects most people's view of a scientific field.

Well, let's agree we don't have the same perception of what affect most scientists. But realistically, what kind of decision did you take that was influenced by this? If this is not too personal, I'm really curious!

41. **Bob Jones**
December 15, 2013

Okay, so you agree with me about Kontsevich. How about Maldacena? Or Witten? Or Seiberg? Does it really make sense to say that they're doing untestable work?

42. **Bob Jones**
December 15, 2013

In fact, I'm pretty sure my comments apply to everyone who's won this prize… Can you point to a single person whose work is untestable but not formal?

43. **Peter Woit**
December 15, 2013

Jay,
All I mean is that when I was first learning about quantum mechanics and particle theory, and thus first learning names like Heisenberg, Dirac, Feynman, Gell-Mann, the fact that these were Nobel Prize winners did make an impression. This made me want to learn more about them and their work, so was one of many factors determined what book I read and what subjects I tried to learn more about. It's not that they had won a million dollars, but that the physics community had identified them as the individuals who had made the most important advances.
I think this is pretty common. Popular science articles often identify people as Nobel Prize winners I think exactly for this reason: it's a way of saying "this person is not just anybody, but someone who the scientific community has identified as responsible for one of the most important advances in the subject".

44. **Peter Woit**
December 15, 2013

Bob Jones,

Characterizing the work of these people as "untestable", that that's why they get a Milner prize, not a Nobel, is accurate. If it's math, that's not a bad thing, it's not supposed to be testable, and they're not supposed to get Nobel prizes. If it's supposed to be physics, it can be a bad thing and is, intentionally, a serious criticism of their work. I'm not going to review the long list of things all the Milner prize winners have worked on, and what significance they have. But I think the characterization of "untestable" is actually too kind in many cases. Arkani-Hamed's work on extra dimensions and SUSY has been experimentally tested, and is just wrong. He's a case of a $3 million award for not just untestable, but wrong ideas. The latest award (Green-Schwarz) is another example: string theory unification is now clearly not just an experimentally untestable idea with current technology, but one that predicts nothing, so is both vacuous and wrong as an idea about science.

45. **Bob Jones**
December 15, 2013

Green and Schwarz demonstrated that superstring theories have certain formal properties. These theories describe strings in ten-dimensional spacetime, so they have nothing to do with the real world a priori. In order to talk about testing these theories experimentally, you first have to specify a particular phenomenological model. Otherwise you might as well be complaining that mathematics is untestable…

46. **Igor**
December 15, 2013

I think the point of such prize is to have more researchers with rock star status. Terence Tao is such example in math.
Prize money could be used to promote breakthrough that has been achieved.

47. **gs**
December 15, 2013

IMHO first-class work should also be recognized when it invalidates a widely held theory, even if a correct replacement for the theory is not immediately at hand. The Michelson-Morley experiment was recognized via the Nobel Prize; maybe there should be a major award for such contributions. I'm thinking not only of experiments, but e.g. of the claim that 10^lots string-theory parametrizations are compatible with currently foreseeable experiments. In mathematics, counterexamples could be recognized.

Roughly speaking, if demonstrating A would win something like the Nobel or the Fields, then demonstrating not-A should qualify for the proposed award(s). Such prizes perhaps should not be awarded on a regular schedule.

It would be hard to persuade people of means to fund such an award. If a wealthy short seller wants to perpetuate their name. that might be a possibility.

48. **Muri Yilner**
December 15, 2013

And then more "Perelmans" would continue to decline awards…

49. **Peter Shor**
December 15, 2013

@gs: there are lots and lots of experiments looking for stuff that would probably be given the Nobel if they found it. There's LIGO looking for gravity waves, many experiments looking for dark matter, SETI looking for alien civilizations, experiments looking for an electron dipole moment, cold fusion, …We can't give all of them prizes.

50. **gs**
December 15, 2013

Peter Shor: Without having thought through the criteria for a "Naked Emperor Prize", I suspect that, vis–à–vis the "regular" prizes, deserving candidates would be relatively sparse.

51. **Jay**
December 15, 2013

Peter W,

All I mean is I find hard to believe that "bad prizes could pervert the youth" is the reason of your sour opposition. Of course when younger we were impressed by Heisenberg, Dirac and Feynman, all Nobel Prize winners. Of course we were also impressed by Minsky, Penrose, Shannon, Turing, Von Neumann, all without any Nobel Prize (but I had to verify!). If you're right that the subfield Milner choose to acknowledge goes in the wrong direction, we will forgot these laureates the same way so many Nobel Prize laureates are unknown (at least to me -I checked the list to verify the age distributions were differents for the two prizes). BTW, thx for the exchange of view.

52. **Jesper**
December 15, 2013

I'm a little late on this, but I want to respond to the "best and the brightest in physics today" (Deane, Bob Jones, Jay…).

I think that declaring someone the best and brightest a field can only be done in retrospect. With the Nobel there is a requirement of experimental verification and with Math prices of proof, and thats great.

I can imagine that before Copernicus there were some very "best and brightest" people around computing epicycles to astounding precision – but seen from a modern perspective they were people on the wrong track. They were wrong. It may be that string theory turns out to be a great and wonderful theory of "it all" and in that case these people deserve a mountain of praise – but if not, then they were not the best and brightest in physics at our time – because they were wrong (they may be praised for other things, math perhaps, or PR talent).

This is what is wrong with the Milner Price. It may give praise to someone who is completely lost in the forest.

53. **Peter Woit**
December 15, 2013

Jay,
I'm actually rather unconcerned about the youth, I was just addressing the main argument I always hear that more publicity for science is always good, even when it's for bad ideas, because it will get young people interested in science. The reason for my "sour opposition" is quite simple, and the quote from me in the Guardian got it right. I just don't think huge financial awards to people for over-hyped ideas that don't work are a good idea. The Green-Schwarz award is a perfect example of the problem. Superstring unification really is a failed idea, so why reward it? Is that good for science?

54. **Jesper**
December 15, 2013

@ Jay

"If you're right that the subfield Milner choose to acknowledge goes in the wrong direction, we will forgot these laureates the same way so many Nobel Prize laureates are unknown"

Difference: the Nobel laureates may be unknown, but they were right. I think its naive to think that such a big prize as Milners will not twist the research field(s) in some way – and since it is deliberately detached from experimental verification it may very well – judged in restrospect – twist the field(s) in a very negative way. Yes, we'll just forget the Milner prize winners if they turn out to be wrong – but a lot of time and effort may be wasted before we or our grand^many -children are in a position to make the final judgement.

55. **Jon Orloff**
December 16, 2013

Is it possible that a key reason for these prizes and the way they are handed out is to promote the names of Mlner and Zuckerberg – to make a connection of their names to esoteric areas of science? Sort of like self-promoting groupies.

56. **Kavanna**
December 16, 2013

Peter is right. Prizes like this just concentrate attention and fame on dubious exemplars. Better is supporting institutions and rediscovering real standards of scientific progress.

And science prizes, if we must have them, should either concentrate on ideas tested and proven in retrospect (like the Nobels); or just be given out in small amounts in a semi-random fashion, as proposed by Smolin and Essex.

57. **Sebastian Thaler**
December 16, 2013

Peter,

You're featured in Business Insider–as a "famous math professor":
http://www.businessinsider.com/math-professor-pans-zuckerberg-3m-prize-2013-12

58. **Peter Woit**
December 16, 2013

Thanks Sebastian,
Well at least so far the Milner-Zuckerberg math prizes have made one person “famous” in the media, that’s what they want, right?

59. **Chris Oakley**
December 17, 2013

Peter,

I thought that ‐ at least according to Jacques Distler’s definition ‐ you are not an active researcher, and therefore raising your profile in the media is not what Milner and Zuckerberg intend. Still, it is some kind of compliment being passed over in a prize funded by someone famous for stealing someone else’s idea in a ceremony hosted by people who pretend to be somebody else for a living.

60. **Edwin Pell**
December 17, 2013

Thank you Peter. You are right America is being feed the ubermensch view of the world. That is a few rich powerful people make it all happen everybody else is useless and unneeded. Let’s remember Hubbell started as the janitor went on to do fundamental work and was never was rich or famous.

61. **Curious Wavefunction**
December 17, 2013

I wonder why Anderson has not openly spoken out against the prize.

62. **Peter Woit**
December 17, 2013

Curious Wavefunction,

I suspect that at 90 years old, Anderson might feel he has better things to do with his time and energy than take up causes that will intensely annoy his colleagues (like criticizing the $15 million bounty they have personally collected in the past year or so).

63. **Nathalie**
December 20, 2013

The most important difference between Nobel Prizes in sciences and many other prizes is due to the process of evaluation of the nominees. In the case of Nobel Prizes the work of a potential candidate is scrutinized by several referees, a process which can take many years. Moreover, the Prize is not given to speculations, irrespectively of how spectacular they may be. Indeed, some speculations in the field of physics may turn out to be correct but most of them do end up in the “physical wastepaper basket” and don’t deserve the Prize. Better late than wrong!

Some Physics Laureates may be unknown to us simply because their contributions fall outside our field of expertise.

64. **littlestar**
December 20, 2013

Hi , I have a suggestion for the Milner prizes:
Experimental verification and empirical proof are fundamental things in physics , so the fundamental physics prize should be given primarily to physicists with innovative physics theories that have been experimentally verified and/or for important discoveries in physics , and a smaller prize could be given to work done in theoretical and mathematical physics , and string theorists (among others) would be included in this smaller prize.
A (Breakthrough) Prize in Mathematics could be useful if created , but it ought to be given for new creative proven and coherent work or theories in mathematics , and it would be good of these theories have applications in the rest of the exact sciences.

A Bubble-Universe at Stanford

December 19, 2013
Categories: Multiverse Mania

Video from last weekend's [Fundamental Physics Prize scientific meeting at Stanford]() is now available, in unedited form, [here]().

The first video there is a discussion moderated by Yuri Milner, who does a good job of asking Strominger, Polchinski, Green, Schwarz and Vafa questions, although getting pretty much exactly what you'd expect out of them (the hot topic is firewalls).

After skimming through the rest of several hours of video, what struck me is that Milner has managed to all by himself implement the bubble-universe picture of reality that has been propounded at Stanford for many years by Linde, Susskind and others. By smashing tens of millions of dollars into a small target (some prominent academics), he has created a new bubble-universe, with new laws of physics and a new conception of science. In this particular bubble-universe, problems with string theory unification have magically vanished and don't need to be mentioned. Whether a scientific theory can predict anything or not is irrelevant, since you just know what has to be true (the idea with the big money attached to it). The embarrassing fact of no SUSY at the LHC does get fleeting mention, but John Schwarz assures everyone that in his view, there is no question that superpartners exist, whether or not the LHC ever sees them. The multiverse is seen as the answer to all problems, although Cumrun Vafa does warn that maybe one should also look for other answers. Polyakov says that he has nothing against this kind of "Anthropology", except that it is very boring. That's an accurate characterization of the science of the new bubble-universe at Stanford.

Most remarkable is the last video, where things truly become causally disconnected from the universe outside Stanford. After a long introduction from Susskind, Michael Green takes the stage with a talk recapitulating the entire history of science, with string theory the successful culmination of this history. He and Schwarz then settle in to accept congratulations from the audience for their great discovery that has made the bubble-universe possible.

   Thanks Steve, I stopped reading at "Parallel Worlds exist and will soon be testable" but I'm sure the rest is really interesting.

5. **John**
   January 1, 2014

   > The embarrassing fact of no SUSY at the LHC does get fleeting mention, but John Schwarz assures everyone that in his view, there is no question that superpartners exist, whether or not the LHC ever sees them.

   Well that's falsifiability thrown out of the window and religious belief entering by the door.

Latest on abc

December 19, 2013
Categories: abc Conjecture

In case you haven't been following this story, "abc" refers to a famous conjecture in number theory, for which Shin Mochizuki claimed last year (see here) to have found a proof. His argument for abc involves a new set of ideas he has developed that he calls "Inter-Universal Teichmuller Theory" (IUTeich). These are explained in a set of four papers with a total length over 500 pages. The papers are available here, and he has written a 45 page overview here. One can characterize the reaction to date of most experts to these papers as bafflement: what Mochizuki is doing is just so far removed from what is known and understood by the experts that they have no way of evaluating whether or not he has a new idea that solves the abc problem.

In principle one should just be able to go line by line through the four papers and check the arguments, but if one tries this, one runs into the problem that they depend on a long list of "preparatory papers", which run to yet another set of more than 500 pages. So, one is faced with an intricate argument of over 1000 pages, involving all sorts of unfamiliar material. That people have thrown up their hands after struggling with this for a while, deciding that it would take years to figure out, is not surprising.

Mochizuki has just released a new document "concerning activities devoted to the verification of IUTeich". It explains the state of his efforts to get other mathematicians to check his work, a project that has been going on since last year, leading to many ongoing updates to the papers making up the proof. He explains that he submitted the four IUTeich papers to a journal last August, but will not have anything to say about the journal or the state of the submission process. This is the way mathematics is supposed to work: the papers should be refereed by experts who have agreed to go through and check them carefully (and confidentially). Given the unusual character of the series of papers, finding willing and able referees may be very difficult. It would of course be most satisfying if such referees can be found and can either identify holes in his argument, or vouch for correctness of the whole thing.

In the meantime, he has been working since October 2012 with Go Yamashita, who has carefully gone through the papers and is now writing a 200-300 page survey of what is in them. Yamashita may also give a course on the topic at Kyushu University sometime after next April. As part of this process, three other mathematicians participated in a seminar in which Yamashita lectured on the papers.

Another mathematician working on this is Mohamed Saïdi, who devoted about six months to studying the papers, then spent three months visiting Kyoto and discussing them with Mochizuki. According to Mochizuki, he has said that he believes the theory to be correct. Mochizuki summarizes the current situation as

> the issue of whether or not one should regard the verification of IUTeich as being, for all practical purposes, complete, i.e., as a result of the activities of Yamashita and Saïdi, is by no means clear, and any sort of "final conclusion" on this topic must be regarded as a matter that lies beyond the scope of the present report.

Mochizuki goes on to claim that, based on what he has heard from Yamashita and Saïdi, researchers trying to read his papers should find it possible to understand the theory if they work on it for roughly half a year. He warns that they do need to be aware though that an attempt to make sense of what he is doing by expecting "a similar pattern of argument to existing mathematical theories is likely to end in failure." They also need to keep in mind that he's not particularly focused on proving abc, that for him it is the IUTeich theory itself that is the object of interest.

This is a remarkable story, with little precedent. After more than a year, I haven't heard anyone willing to bet either way on how it will turn out. Mochizuki is a talented mathematician and maybe he has a proof. Or maybe he has a complicated set of ideas which don't do what he hopes. Perhaps someday one of these alternatives will start to emerge, but it doesn't now look like this will be anytime soon.

2. **Kent**
   December 19, 2013

   Putting aside for a moment the question of whether or not the supposed proof of abc is valid, does anyone have any indication that IUTeich will be useful for obtaining other results? In other words, is there a reason, other than wanting to verify the abc proof, for someone to study IUTeich? Or is this a case where if the abc proof turns out to have a flaw, any time spent on IUTeich would be a waste?

3. **David Appell**
   December 20, 2013

   Perhaps IUTeich is a part of 22nd-century mathematics that has fallen by chance into the 21st century.

4. **anon**
   December 20, 2013

   Has Faltings (his Ph.D. supervisor) come out and said anything? I heard some rumors going around.

5. **Mitchell Porter**
   December 20, 2013

   "is there a reason, other than wanting to verify the abc proof, for someone to study IUTeich?"

   You could just be curious to know what these new ideas are about, and how they relate to known math.

6. **chorasimilarity**
December 20, 2013

This looks to me as a social problem, not a mathematical one. On one side, there are no “experts” in Mochizuki field, because he made it all. On the other side, the idiotic pressure to publish, which is imposed in academia (the legacy publishers being only opportunistic parasites, in my opinion), makes people not willing to spend time to understand, even if Mochizuki past achievements would imply that there might be worthy to do this.
To conclude, is a social problem, even an anthropological one, like a foreign ape which shows to the local tribe how to design a pulley system, not at all believable to spend time on this. Or it is just nonsense, who knows without trying to understand?

7. **Peter Shor**
December 20, 2013

If this proof is accepted (with something between a line-by-line verification and complete understanding), but nobody else ever learns the theory well enough to do anything with it, should it be considered a success or a failure?

On a more positive note, I expect that once people are more convinced that it’s correct, more of them will be willing to invest the amount of time need to understand what’s going on.

8. **OMF**
December 20, 2013

> This looks to me as a social problem, not a mathematical one.

The problem is one of culture. Modern Mathematics has become so fragmented, so disconnected, that it is in fact possible for someone to write 1000+ pages on a completely new theory working in complete isolation and moreover to have the prospect of this work actually taken seriously by the wider mathematical community because of the way that minor field specialization has become the norm.

Another problem is what I like to call “simplicity-free mathematics”. Theorem’s are proved by a small wall of text peppered with multiple references to, at best, previous lemmas of theorems in the text, more usually not so well known theorems from increasingly obscure branch of mathematics in question, and at worst, references to outright conjectures that neither the author nor anyone else has yet proved(This last style goes back to Galois). Simple elements and frequently actual numbers are usually completely absent.

My gut feeling for mathematics is that you’ve either got a formula/algorithm, or you’ve gotten lost. Obviously this doesn’t apply to absolutely everything, but the lack of such hard results has real consequences in the form of the increasing obscurity of various fields, and the lack of feedback from these into the core discipline.

But, aside from that perspective; At the end of the day if you require 1000 pages of specalised argument to prove your result I think it is reasonable to conclude that you don’t really understand your results and neither will anyone else. Regarding such works as proved, and worse, as a foundation for future material is what has lead us to our present state of affairs, and it shouldn’t be tolerated.

9. **Peter Woit**
December 20, 2013

OMF/chorasimilarity,

For some great wisdom on this topic, I urge everyone who hasn’t done so to read Bill Thurston’s “On proof and progress in mathematics”
http://arxiv.org/abs/math/9404236
For Mochizuki’s proof to be accepted, other members of the community are going to have to understand his ideas, see how they are supposed to work and get convinced that they do work. This is how mathematics makes progress, not just by one person writing an insight down, but by this insight getting communicated to others who can then use it. Right now, this process is just starting a bit, with the best bet for it to move along whatever Yamashita is writing. It would be best if Mochizuki himself could better communicate his ideas (telling people they just need to sit down and devote six months of time to trying to puzzle out 1000 pages of disparate material is not especially helpful), but it’s sometimes the case that the originator of ideas is not the right person to explain them to others.

10. **Mr Monopole**
December 20, 2013

>>>*It would be best if Mochizuki himself could better communicate his ideas*
–
In preface to ‘Three – Dimensional Geometry and Topology’ W. Thurston wrote:
“The notes were originally aimed for an audience of fairly mature mathematicians…
Some of the feedback from seminars and individuals convinced me that it would be
worth filling in considerably more detail and background; there were several places
where people tended to get stuck, sometimes for weeks…”
–
Last chapter of this book covers Teichmuller space (BTW: Mochizuki likely did not read the preface).

11. **Michael Schmitt**
December 20, 2013

I recently gave a course on the responsible conduct of research, and one of the main messages of the course is the necessity of publishing one’s results and methods so that others can verify them. To underscore the point, we looked at infamous cases of scientific misconduct in which proponents of great discoveries failed to share the details of their work, thereby making it impossible for others to reproduce and confirm their results. I emphasized that scientific research must be shared with the scientific community, else it (almost) isn’t science. Review and criticism by peers is a major part of the process of moving forward.

————————————

From reading the comments above, one almost has the impression that mathematicians put less value on publishing and verification from peers than scientists do. Is it OK to be right but impossible to understand? Is it OK to have a great insight but not to record it and have it approved by the community? Are individual insights more important than widespread comprehension?

————————————-

Probably I am reading too much into some of the comments people have written…

12. **Allan Rosenberg**

December 20, 2013

This sounds like a problem for Nicolas Bourbaki's group.

13. **Peter Woit**
December 20, 2013

Michael,

Actually I think mathematicians put more value on publication and the refereeing process than other scientists do. It's very important to them to know which results have been checked and are reliable, in order to use them to build reliable proofs of something else.

It is true however that mathematics research can be very specialized, very abstract, and so intensely demanding in terms of anyone being able to follow and check it. For typical work, often only a handful of people in the world have the right background to quickly understand a certain new piece of work and evaluate the arguments. The Mochizuki case is quite unusual: as usual there really are only a small number of experts in the field, but he has gone off by himself in his own direction a great distance, then reappeared to claim to have made a major discovery. The experts are faced with the problem of how to figure out whether he is right. Do they invest the six months he is asking from them? Do they tell him: forget it, you need to write this down in a more comprehensible form that won't take us 6 months or more to understand? Do they wait and see if someone (like Yamashita) who has invested a lot of time in following this will report back with a more comprehensible explanation of what is going on?

14. **Peter Woit**
December 20, 2013

Allan,
Except for the problem that they're no longer active…
One of the motivations for Bourbaki was to produce a careful and complete set of arguments for the standard results used in different parts of mathematics, so that these could carefully be checked for reliability and be used to go further.

15. **srp**
December 20, 2013

At least in math each investigator has pretty compatible (with overall progress) incentives in deciding whether to spend his time reading something obscure. If you figure out how to make better sense out of something that's already been proven the community gives you some credit.

Across the whole span of disciplines I suspect that we reward writing (original stuff) too much and reading too little.

16. **AndreasK**
December 21, 2013

..first of all, the main problem in the reception of Mochizuki's work IS indeed a cultural one, but obviously not quite in the sense it is discussed here; from a 'western' perspective, Mochizuki is perceived as the 'great other' and the 'otherness' of his work comes with a mutually-amplifying 'otherness' of his culture and 'race', if he would be white and/or (at least) western his work would be considered not as 'scientific misconduct' but as a 'great and visionary' cultural achievement, his teachers would be hailed, his descendants would be famous and he would be ubiquously present at various life-time-achievement-awards still in 30 years. But the 'otherness' of his work is probably on the other hand exactly the result of being perceived as the 'other' on a sociological basis, which can mean exclusion, but also freedom, a certain space for creativity. In any case, all this exactly transcends western norms of 'workforce', his papers are more meditation than results and given this, they are among the most inspiring pieces of work I have read in the last ten years (and I know only a tiny piece of them).

Also from another, more substantial perspective: from my point of view, the discourse which is reflected here is wrong in essential aspects, that his, his contribution to a possible proof of the abc-conjecture is certainly LESS, not more important than his general insights, in this sense, it is excactly not important whether his announced proof turns out to be true in a line by line-evaluation, not of course from a 'factual' point of view, but from a 'philosophical' one. 'Millenium problems' are catalysts for theory-builders, often not so quite interesting in itself (again, from my perspective). As I already mentioned in a related discussion, his theory of 'étale theta functions' seems to reflect a deep aspect of the latter: these functions form a bridge between 'purely arithmetic and topological data' of a given object, or in his terms between 'Frobenius-like' and 'étale-like' structures and in this sense his 'etale theta functions' have for instance great similarities to 'flux mappings' in symplectic topology. The 'etale-like structures' have 'the ability to 'penetrate walls' (cf. his survey paper on p. 32), all these are eminently deep and important observations; the correspondence of certain rigidity structures. From my personal point of view, very similar constructions should be possible in diff. geometry and should for instance allow to relate rigidity of 'classical Hodge structures' and symplectic rigidity, again using certain theta-like structures. The existence of a 'Galois-theoretic Kodaira spencer morphism': from my point of view this is neither esoteric nor completely 'out of the blue', it HAS to exist. One should consider that mathematics can be a very lonesome and 'individual' endeavour, Mochizuki possibly represents a certain, very special 'type' of mathematician, who is as important as those types of mathematicians who will eventually evaluate and re-work his ideas.

17. **mo**
December 21, 2013

This is not the first case when mathematical and social issues have been raised and similar sentiments were voiced. The first one was the classification of finite simple groups. The only difference is that many (over 100) mathematicians worked on it rather than one, but still the mathematical community was skeptical. Since the complete proof takes over 10,000 pages it is fair to assume that no one understands it in its entirety.
mo

18. **Peter Woit**
December 21, 2013

AndreasK,
It's just not true that Mochizuki is "other" to Western mathematicians. He grew up in the US, went to Princeton, his advisor was Faltings (who is "hailed"). He's someone personally known to most experts in his field, and they met him at pinnacles of the US establishment like Princeton and Harvard. The idea that he's not taken seriously because he's not white is absurd. No one thinks he is engaging in "scientific misconduct", and everyone agrees his ideas are potentially interesting, possibly revolutionary and of great significance. Whether they can prove the abc conjecture, which our current best ideas don't seem to be able to prove is a measure of the depth of these ideas, whether they tell us something new, or just repackage things we already know.

19. **CPV**
December 21, 2013

Is this a good candidate for computer verification of the proof?

20. **Peter Woit**

December 21, 2013

CPV,
No, I don't think Mochizuki's argument is written in anything like a form that can be made ready for computer verification. Also, in general, if experts can't understand the overall structure of an argument and which of its parts are the new and tricky ones which need to be carefully checked, I don't believe a computer program exists that can do this for people.

21. **Michael Schmitt**
December 21, 2013

Peter, I appreciate a lot these posts about mathematics and mathematicians. They help me, an experimental physicist, gain some notion of the wonderful world of mathematics (or at least the experiences of mathematicians). The article you referred to by William P. Thurston is extremely interesting and stimulating, although it concludes on a rather odd note. There is even something in Section 3 about the near-impossibility of teaching students mathematics (or physics). Thurston's commentary shows that mathematicians are very caught up in the issue of communicating their results – indeed, publication is only one of several important modes of communication. My earlier comment was indeed very naive!

22. **Edward**
December 21, 2013

I am wondering if Mochizuki can provide a "appetizer", i.e. an important result, but perhaps not as significant as abc, whose proof is relatively "quick".

In Perelman's case, the appetizer is the noncollapsing theorem, whose proof people verified and accepted in weeks. This built up huge confidence in Perelman's other arguments.

23. **Armin Nikkhah Shirazi**
December 22, 2013

This seems like the kind of problem which would lend itself well to the polymath approach, except that instead of discovering new results it would involve checking results (presumably) already obtained. That (apart from the scarcity of experts in the relevant field) may be enough for that kind of collaborative effort to become unlikely. Personally, I think that if someone claims that that he or she has made a major discovery, the responsibility for explaining the work to the rest of the world in a manner that it can follow rests squarely with the claimant. Also, it may even happen that when one makes a concerted effort to explain an idea intelligibly to others one will find ways in which the idea simplifies, points to new connections or becomes clearer in one's oen mind. Thus, even the original claimant may benefit from such efforts.

24. **srp**
December 23, 2013

Let me second the motion on the value of the Thurston article you linked. It is a model of introspection, social observation, and writing clarity.

25. **AndreasK**
December 24, 2013

Peter, the words 'scientific misconduct' were taken from this very thread, even if they were not aimed 'openly' at him. Also, the subtext which I attacked was also taken mainly fom this very thread. In the mathematical community, things don't lie 'out in the open', the acceptance of proofs is a sociologically and psychologically (apart from any mathematical question) not completely understood process and is intertwined with power discourses that without ANY doubt part south from north, white from non-white, established from non-established. I am not accusing here anyone personally, but it seems that certain processes or mechanisms might be not completely conscious to many people involved in certain discourses. My text above was meant as a polemic, I thought this would be sufficiently clear. Still, there are many odd questions in the reception of Mochizuki's work, most of his ideas evolved since 10 to 15 years and obviously they are only interesting SINCE he claimed to have proven the abc-conjecture, and, in between of many other questions, one could ask why this is the case. Why do experts expect to understand ideas which were obviously to a certain degree ignored for 15 years should lead to a line of argumentation understandable to anyone in time scales of some weeks? Can anyone here answer this simple question? Grothendieck's ideas were famous long before Weil's conjectures were finally settled. But again this simple fact: the discrimination of non-white mathematicians, of women in mathematics will not vanish just because one claims there wouldn't be 'proofs' for it, and that to have grown up in the US is no guarantee not to be 'othered' in which (white, western) context ever is unfortunately one of these not 'provable' facts.

26. **Peter Woit**
December 24, 2013

AndreasK,
Enough of this. You're just trying to put this story into an ideological framework where it doesn't fit. Mochizuki is as "Western" a mathematician as anyone, and no, he's not a woman or black. The idea that the people having trouble figuring out what Mochizuki has done are having this problem because he's racially East Asian is just ridiculous. As for the comparison to the reception of Grothendieck's ideas, just look at the history. Grothendieck developed his ideas in active collaboration with others (they were often written up by other people he was working with).

27. **milkshaken**
December 24, 2013

If I remember correctly, when Andrew Wiles gave the expose of the first version (the one that turned out to be flawed) of his famous proof, he disguised it as an advanced class and asked his colleagues – who were checking the proof – to sit on it, over the course of a semester. Maybe this would be the right method here as well/

28. **Simon Pepin Lehalleur**
December 24, 2013

@AndreasK:

This way of interpreting the story does not sound very plausible for me either. The field of algebraic/arithmetic geometry is full of brillant Japanese mathematicians, with a long tradition going back at least to Shimura and Taniyama. The staff of Mochizuki's home institution RIMS includes (among others) Morihiko Saito, Shigefumi Mori, Shigeru Mukai, Takuro Mochizuki, Masaki Kashiwara. Each of them has produced deep mathematical work, spawning whole new field, e.g. Saito's mixed Hodge modules, the Mori (minimal model) program, Fourier-Mukai transforms, Mochizuki's irregular Riemann-Hilbert correspondance, Kashiwara's crystal bases.

All of them have interacted productively with the "Western" mathematical community. Because of this tradition, quite a few arithmetic geometers are familiar to various degrees with Japanese culture, have learned some Japanese, etc.

I fully agree that it is a pity that few other mathematicians (including Japanese/Asian ones !) tried to keep in contact with Mochizuki's ideas over the years.

29. **Peter Woit**
    December 24, 2013

    milkshaken,
    As far as I know, there was only one person (Nick Katz) in on the fact that the material being discussed in that class was a crucial part of a proof of Fermat. The case of the Wiles proof is a good comparison to the Mochizuki one. Wiles did work for many years alone and developed new ideas, but once he made his proof public experts very quickly were able to understand his ideas, then dig in and check things carefully. The problem was found (I believe by Katz) as part of the conventional refereeing process for the paper.

    This story makes clear that for this kind of proof, even when an extremely careful mathematician like Wiles has checked things thoroughly with another expert, there can still be a flaw in the proof. The community is not going to accept that Mochizuki's proof is valid until it has undergone a similar level of scrutiny. The problem now is that people seem stuck at an early stage of the process, that of understanding the structure of the proof and the techniques used well enough to be able to start checking carefully for subtle flaws.

30. **Hahn**
    December 25, 2013

    I'am not qualified to talk about the correctness of these papers.

    However I am suspicious. If I have to, I will bet there are unfixable problems.
    * people don't mix proof in number theory with ZFC axiomatic set theory.
    * people don't put out 5 papers in a series and revise all of them for others to check out.
    * people don't say "Go Yamashita gave a course, Mohamed Saïdi said he believes the papers to be correct"

31. **preda**
    January 7, 2014

    "Wiles did work for many years alone and developed new ideas, but once he made his proof public experts very quickly were able to understand his ideas, then dig in and check things carefully. The problem was found (I believe by Katz) as part of the conventional refereeing process for the paper."

    To my information, none of these is totally right. First, Wiles is purported to have completed the Cambridge lectures with the words "I think this completes the proof of Fermat". Next, Nick Katz – together with P. Sarnak, if I remember well – looked for it that a team of 8-12 mathematicians got involved in understanding Wiles`s proof. This was not part of the refereeing process yet; the material was distributed in pieces, and this is how the gap was found relatively fast. It is not easy to believe that the material of Mochizuki can be split in parts, since there are fundamental new ideas that everyone must understand, who wants to verify even a small part of the work.

    The more I read about the issue, the more I gather the feeling that there is hardly anything that Mochizuki could have actively done in order to facilitate the verification process, and which he did not do – or even "refuse to do", as one sometimes reads. We have at present two people who studied the material over a longer period of time, and had long discussions with him. It is to be hoped that this example will spread.

32. **Peter Woit**
    January 7, 2014

    preda,
    I don't think there is anything at all inaccurate in what I wrote. See for instance Mozzocchi's "The Fermat Diary", page 19. He describes what happened with the Wiles proof was that Wiles gave it to Mazur, who was an editor of Inventiones. Mazur chose six referees and assigned each one of them a section of the paper. Katz was assigned section six, began work on it (with help from Illusie) and was the one to find the problem.

Trust the math? An Update

December 21, 2013
Categories: Uncategorized

Back in September, I wrote here about the news that Snowden's revelations that confirmed suspicions that back in 2005-6 NSA mathematicians had compromised an NIST standard for elliptic-curve cryptography. The new standard was promoted as an improvement using sophisticated mathematical techniques, when these had really just been used to introduce a backdoor allowing the NSA to break encryption using this standard. There still does not seem to have been much discussion in the math community of the responsibility of mathematicians for this (although the AMS this month is running this opinion piece).

After my blog post, some nice detailed descriptions of how this was done and the mathematics involved appeared. See for instance The Many Flaws of Dual_EC_DRBG by Matthew Green, and The NSA back door to NIST by Thomas Hales. The Hales piece will appear soon in the AMS Notices. Hales also has a more recent piece, Formalizing NIST Standards, which argues for the use of formal verification methods to check such standards. Also appearing after my blog post was the news that RSA Security was now advising people not to use one of its products in default mode, the BSAFE toolkit.

One mystery that remained was why the NIST had promulgated a defective standard, knowing full well that experts were suspicious of it. Also unclear was why RSA Security would include a suspicious standard in their products. Back in September they told people that (see here) they had done this because:

> The hope was that elliptic curve techniques—based as they are on number theory—would not suffer many of the same weaknesses as other techniques

and issued a statement saying:

> RSA always acts in the best interest of its customers and under no circumstances does RSA design or enable any backdoors in our products. Decisions about the features and functionality of RSA products are our own.

Today there are new revelations about this (it's unclear from what source), which explain what helped make RSA swallow the bogus mathematics: a payment from the NSA of \$10 million. I guess there's a lesson in this: when you can't figure out why someone went along with a bad mathematical argument, maybe it's because someone else gave them \$10 million…

Update: For another explanation of the math behind this, see videos here and here featuring Edward Frenkel.

Update: There's a response to the Reuters story from RSA here. As I read it, it says

- They do have a secret contract with the NSA that they cannot discuss
- They used the NSA back-doored algorithm in their product because they trust the NSA
- They didn't remove it when it became known because they really are incompetent, not because the NSA was paying them to act incompetent

It's hard to see why anyone would now trust their products.

   Both bitcoin and PGP use elliptic curve cryptograpy. Lately, the exchange rate for bitcoin has been soaring. Do you have an opinion on whether or not it is really secure?

2. **S. Molnar**
   December 22, 2013

   $10 million is the corporate rate; it looks like $3 million may be the individual rate.

3. **Yatima**
   December 22, 2013

   Note that in this case we are talking about

   Dual Elliptic Curve Deterministic Random Bit Generator

   which are less random than thought. It is recommended to get random bits, including pseudorandom bits, from elsewhere.

   Elliptic Curve Cryptography is something else.

   And Bitcoin uses Hashcash, based on SHA-256, not Elliptic Curve Cryptography.

   See also: How the Bitcoin protocol actually works

4. **Peter Woit**
   December 22, 2013

   Tinos,
   Anyone looking for info on what cryptography to trust should be looking elsewhere than this blog, since I'm no expert. While trying to figure out what and who to trust, I'm just pointing out that now you have to realize that part of the math community and the main US standards organization have been actively trying to deceive you. And the main commercial cryptography company has been bought off to also try and deceive you. People in general, and mathematicians in particular, might want to think about whether something should be done…

5. **anon**
   December 23, 2013

   The RSA response is certainly ridiculous but now that I think about it actually, I don't see anything necessarily wrong about mathematicians working on military projects of this sort. (And the behaviour of the NSA should not be unexpected; this is, after all, what they usually do.) Mathematicians have a long history of working in the defence industry. If I remember correctly, even Euler translated a treatise on ballistics. And of course, in more recent times, Ulam was involved in the design of the hydrogen bomb and nuclear pulse propulsion.

6. **Peter Woit**
December 23, 2013

   anon,
   One can reasonably argue that mathematicians at the NSA who came up with this were just following orders, and that any at RSA who were encouraged to play dumb were also just following the policy of their employers. One can also argue that all of this is perfectly legal (although the fact that courts have been thwarted from ruling on whether these things violate the Bill of Rights may mean the legality issue is still up in the air).

   There remains the question though of what people in general should do in response to the NSA revelations, and of what the mathematics community in particular should do in response to the fact that mathematics and mathematicians have played a role in this. "Nothing" is one defensible position, as is Beilinson's "treat the NSA the way mathematicians treated the KGB in the former Soviet Union". In any case, I think there's a strong argument for publicizing what is known about exactly what happened here so that people can make up their own minds about what they think about it.

   > Mathematicians have a long history of working in the defence industry. If I remember correctly, even Euler translated a treatise on ballistics.

   No. The situation that Mathematics finds itself in is completely unprecedented.

   The NSA is probably the world's single largest employer of pure mathematicians. At ~1000 or so. Since there are about ~100,000 mathematicians in the world, this is a sizable enough fraction ~1% of the world's quotient, to say nothing of the research funding and recruitment operations of the NSA outside of those in its direct employment. Within the US itself, the influence of the organisation is obviously even stronger.

   This bears many similarities towards the move in physics towards "Big Science" in the post war period, but also several key differences.

   Firstly, unlike big science, the developments at the NSA have been almost exclusively negative, socially, politically and scientifically. The mathematics employed there is being turned into a tool of oppression in a way that few scientific developments have even been so directly employed. Secondly, a large body of mathematicians are now engaged in research — and now we know in publishing research — that is deliberately incomplete and even deceitful. This second development is on a scale previously unheard of in this discipline.

   Finally, we may likely see a large political split developing in the mathematics community, centered around the cooperation of mathematicians with the NSA. Elements of this can be seen in the December issue of the AMS notices — Alexander Beilinson's letter calling for the AMS to sever its NSA ties along with the conspicuous absence of the monthly NSA recruitment advertisement. Politics — real politics — has entered the mathematical community for the first time, the US community in particular, in a very direct and unavoidable way.

   Even in the Soviet Union, mathematics was in general an apolitical activity, and mathematicians were given considerable autonomy. However the recent NSA scandal has brought mathematics and its activities directly into the political spotlight, and these activities into question. The world may be facing a situation where certain types of mathematical research becomes restricted, or taboo, or boycotted. This would be an unprecedented development. From ancient times, mathematics has always been an international, collegial activity; outside the temporal and certainly the political sphere; No longer?

   The greatest irony in all of this is that the branch of mathematics involved — number theory — was only 50 years ago regarded as the most "pure", abstract, and austere expression of the subject. The "Queen of Mathematics" in Gauss' words. Now the Queen seems to have fallen in with a bad sort, and the scandal threatens to rock the entire Kingdom to its foundations.

8. **anon**
December 23, 2013

   OMF,
   I completely disagree. We are entering a brave new world and we (including mathematicians) must embrace it or be left behind. It's not only the NSA by the way, but also the IDA in Princeton and many other agencies. In any case, no one is forcing anyone to do research they are uncomfortable with, or that is "so harmful for the fabric of human society," as Beilinson would put it. I seem to recall that one or two decades ago there was a controversy when it was discovered that some mathematicians were receiving military funding and an attempt was made to expose them. Even W. Browder, whose father I think was chairman of the Community Party of America, called it a witchhunt.

9. **anon**
December 23, 2013

   I mean *Communist* Party of America.

10. **Peter Woit**
December 23, 2013

    anon,
    I agree with you that we are entering a brave new world (Snowden did a lot to show how far we have gotten into this world already), but personally I don't believe we should embrace it, quite the opposite.

11. **Michael Gogins**
December 23, 2013

    In my view, mathematicians should accept the vocation of developing protocols that are transparent, open to independent scrutiny, verifiable, and capable of replacing the protocols used by institutions that have shown they cannot be trusted.

    These should be developed for currency, telecommunications, networking, data storage, and voting.

    If such developments succeeded, they might replace existing protocols or, perhaps, keep them honest.

    If such developments do not succeed, there is an obvious danger that we will end up living in 1984 with no way out.

    Preliminary signposts for such protocols: PGP, Bitcoin, Tor.

12. **Wayne**

December 23, 2013

I'm afraid I'm unable to discern the correspondence between your latest update's summary bullets about RSA, or any inference that can be drawn from their summary of 22 December, which supports the conclusions you draw. RSA states that their reliance was on the NIST, which aside from sharing two letters in its acronym has nothing in particular do with the NSA.

Many — perhaps along with RSA itself — now wish something more than RSA's trust in the NIST had been their guiding force in 2007. But if I am reading your latest addition correctly, I simply don't follow the logic suggesting such a wish provides evidence of incompetence and a (company-denied) secret contract with the NSA?

Wayne

13. **Jim Akerlund**
December 23, 2013

I am having a problem with separating the mathematicians involvement with the NSA and the NSA's use of spycraft. It looks like this RSA story is the NSA's use of spycraft. Reading Google's and Yahoo's interserver transmissions is more spycraft. True, mathematicians did create the eliptic curve pseudo random number generator, but where the problem seems to be occurring is the adoption of this number generator industry wide, which is out of the hands of mathematicians. I guess I am looking for the smoking gun that is in the mathematicians hands in this NSA mess.

14. **Peter Woit**
December 23, 2013

Wayne,
The problems with this elliptic curves algorithm were publicized back in 2007, the question is why RSA kept this as the default in this particular product after that time. Their argument that they didn't do this because they were paid off really only leaves true incompetence as an explanation (they were unaware of the claimed problem despite it being publicized, so incompetent at knowing their own field, or were aware of the claimed problem, but made the incompetent judgment that the claims were wrong).
Their statement acknowledges their relationship to NSA, says they never "divulge details of customer engagements". To me their denial seems carefully worded not to deny a contract with the NSA whose details they cannot divulge, just to deny a specific accusation about exactly what is in the contract.

It's quite true that the details of how the NSA corrupted the NIST approval process have still not been revealed. I don't understand why this is the case if the NIST wants to regain any credibility for its cryptography standards.

15. **Peter Woit**
December 23, 2013

Jim Akerlund,
I'm not well-informed about this, but I would assume there are mathematicians involved in the NIST standards approval process for a cryptographic standard based on this kind of mathematics. Similarly I would assume RSA Security employs mathematicians to evaluate such cryptographic algorithms. If neither organization uses mathematicians to make such evaluations, but just decides "oh, an NSA mathematician says everything is fine", that would explain how this happened, but I'm finding it hard to believe these organizations operate in such an unprofessional manner.

16. **NotSuper**
December 24, 2013

Off topic, sorry, but this may be of interest for this blog:

17. **milkshaken**
December 24, 2013

based on the Reuters article, by the time the 10million deal went down RSA was not doing any crypto research in house anymore (because their reorganized their research group out of existence) so they were eager to grab the NSA-supplied goodness, just to stay at the technology edge – They might have done it even without the cash… So this was not failure of math, just corporate culture as usual. More interesting would be to read about the NIST part of the story

18. **maqroll**
December 24, 2013

Trust the mathematicians (who work for the NSA)?
" requested removal of an NSA employee from an IETF group co-chairmanship"
http://www.ietf.org/mail-archive/web/cfrg/current/msg03554.html
(by way of Bruce Schneier's blog https://www.schneier.com/blog/archives/2013/12/nsa_spying_who.html)
I'm not a mathematician or cryptographer. I do not know whether or how/how much the particular algorithm/standard is important. Maybe not at all, maybe a lot. But the question is whether we can trust even mathematicians. Distrust of science & scientists is widespread – in many contexts (e.g., pharmaceuticals) scientists are seen as shills for the corporations that employ them. Naively, one might have thought mathematicians were immune to this sort of suspicion – after all they have to provide "proofs" don't they?
How should mathematicians who work (worked) for the NSA be treated? Ban them from at least positions of power on cryptographic standards bodies? Trust them, which becomes impossible in light of Snowden's disclosures?

19. **Abraham Sternlieb**
December 25, 2013

Peter
After reading all the above,it is not unreasonable to speculate that Milner Prizes represent a sofisticated endeavor by some unfriendly party to sabotage the USA physics community,by means of encouraging the brightest minds to go into unreasonably wasteful directions such as String Theory,thus diverting them from generating meaningful and useful science for the nation

20. **Falcon**
December 25, 2013

IMHO the amount of panic Snowden's revelations have generated is becoming pathological. I find especially amusing comparisons with the USSR/KGB, not to mention Orwell's Oceania. It is remarkable how before Snowden the unbearable involvement of the government in our personal lives went completely unnoticed. As someone originating from the USSR I assure you that we did not have the privilege of this blissful ignorance.

What I find even more ridiculous is making the mathematicians employed by the NSA into some sort of villains, as if they are in any way responsible for the abuse or at least knowingly followed obviously foul orders. I don't think that if the NSA and other defense related organizations consisted exclusively of Snowdens the nation would be better off.

21. **milkshaken**
December 25, 2013

    the sad part is that what must have been a top management betrayal is going to affect all current and former RSA employees; it's something bound to come up every time they apply for a job.

22. **paddy**
December 25, 2013

    A somewhat on-topic news item: Crown Finally Pardons Alan Turing.

23. **paddy**
December 25, 2013

24. **milkshaken**
December 29, 2013

    Matthew Green fills in new background info on the NIST involvement (on his blog – a post written yesterday). Turns out, at least some cryptographers on the committee that helped to set the new standard knew about the backdoor right from the beginning – since January of 2005 – and they went along with it and kept quiet…

25. **werner**
January 5, 2014

    It seems like it took less than two years for a couple of guys at MS to identify the weaknesses of this algorithm and warn against its use. The warnings were public and I suppose that anyone whose life or livelihood really depends on crypto would have learned of them quickly. If their trick couldn't go unnoticed for two years, maybe all those NSA mathematicians aren't THAT good after all…

26. **Peter Woit**
January 5, 2014

    werner,
    Perhaps the point of this story is that the NSA mathematicians don't need to be very good when others are being paid to look the other way.

Trespassing on Einstein's Lawn

December 29, 2013
Categories: Book Reviews

Amanda Gefter, a science writer who has often covered theoretical physics topics for New Scientist, has a new book coming out soon, Trespassing on Einstein's Lawn. On one level it's a memoir, telling a story that begins with her father getting her interested in fundamental questions about physics. This led to a career interviewing well-known physicists and writing about these topics, and now, a book. Self-reflexivity is a major theme of the book, with one aspect of this the way it tells in detail the story of its own genesis and creation.

In many ways, it's comparable to last year's book by Jim Holt, Why Does the World Exist?, with both books motivated by versions of the question "Why is there something rather than nothing?" In both books, there's a memoir aspect, with the author front and center in a search for answers that involves meetings and discussions with great thinkers. For Holt, these were mostly philosophers with a few physicists thrown in, while for Gefter they're mostly physicists, with a few philosophers making an appearance. These are lively, entertaining writers with wonderful material about deep questions, and I greatly enjoyed both books. Gefter is the funnier of the two, and I had trouble putting the book down after it arrived in my mail a couple days ago.

For those familiar with the topics she covers, the descriptions of her encounters with famous physicists is what will most likely provide something new. A few examples:

- She somehow managed to get to moderate a private debate between Lenny Susskind and David Gross, mainly on the topic of the multiverse. Much of the result is familiar to anyone following the topic over the last ten years (Gross detests the multiverse, Susskind is madly in love with it), but one interesting aspect is Gross's comparison of Susskind's behavior to his own back in 1984-5:

  > What I'm saying… is that some of the reaction is exactly like the reaction I got for exuberance in 1984, when we believed the answer was around the corner and we got carried away with that position. And, Lenny, you are carried away with this position. The stakes are damn big. So you are open to severe criticism.

  So, it seems that Gross is accusing Susskind of engaging in hype deleterious to physics, while acknowledging that he did much the same thing to get string theory unification off the ground and widely accepted.

- Several string theorists pointed out that strings themselves have pretty much disappeared from the story. The emphasis is now on the holographic principle and the hope for some unknown M-theory that embodies it. About M-theory, Polchinski has this to say:

  > It's remarkable to know so much about many limits and yet have no good idea of what they are limits of! Holography is clearly part of the answer. The fundamental variables are probably very nonlocal, with local objects emerging dynamically.

  Witten tells Gefter that the "M" in "M-theory" really was intended to refer to membranes. He doesn't see much happening though as far as new ideas about understanding it:

  > …in the mid-eighties and mid-nineties, before the second revolution happened, there were kind of hints that something was going to happen – I didn't know what, of course. I don't have that feeling now, but perhaps other people do… If I had my druthers I'd like to go deeper into what's behind the dualities, but that's really hard.

- John Wheeler plays a large role in Gefter's story, which starts with her asking him a question at this conference in 2002. She has a fascinating description of Wheeler's journals, which have been preserved in Philadelphia, where she and her father spent quite a lot of time looking through them.

The list of interviewees includes also Kip Thorne, Raphael Bousso, Tom Banks, and Carlo Rovelli.

Gefter makes it clear that she started out with essentially no background in physics or math, other than enthusiasm shared with her father for speculation about "nothingness" and the like. She studied not physics, but philosophy of science at the London School of Economics. Despite this lack of technical training, she does a good job of accurately characterizing what the physicists she talked to had to say. Towards the end the book does suffer a bit as she moves away from reporting what others are telling her to expounding her own interpretation of what it all means.

While I liked the book, at the same time I found the whole project deeply problematic, and would have reservations about recommending it to many people, especially to the impressionable young. The part of physics that fascinates Gefter is the part that has gone way beyond anything bound by the conventional understanding of science. This is really and truly "post-modern physics", completely unmoored from any connection to experiment (the discovery of the Higgs in the middle of the period she is writing about just gets a short footnote). The questions being discussed and answers proposed are woolly in the extreme, focused on issues at the intersection of cosmology and quantum mechanics, suffering from among other things our lack of a convincing quantum theory of gravity. Gefter seems to be sure that the problem of quantum gravity is an interpretational one of how to talk about a quantum cosmology where observers are part of the system. The very different, much more technical issue of how to consistently quantize metric degrees of freedom in a unified way with the Standard Model fields is ignored, perhaps with the idea that this has been solved by string theory.

Not recognizing that this post-modern way of doing science is deeply problematic and leading the field into serious trouble isn't so much Gefter's fault as that of the experts she speaks to (David Gross is an exception). Those taking the field down this path are dominating public coverage of the subject, and often finding themselves richly rewarded for engaging not in sober science but in outrageous hype of dubious and poorly-understood ideas. Only the future will tell whether the significance of this book will end up being that of an entertaining tale of some excesses from a period when fundamental physics temporarily lost its way, or a sad document of how a great science came to an end.

Comments

1. **CIP**
   December 30, 2013

   I have the feeling that we are going to need to discover some new physics before philosophical speculations about its new foundations will be very rewarding. I'm an old geezer, but I will probably read the book just for the interviews.

2. **Stacy McGaugh**
   December 30, 2013

   Fascinating. It was (in part) Gross's excessive enthusiasm for string theory in the mid-80s that drove me (as an impressionable grad student at Princeton) away from theoretical physics (and into astronomy). String theory may have been a beautiful idea, but it made no predictions that could be tested experimentally in the then-foreseeable future. That's not science.

   A quarter century later and the theoretical physics community has yet to wake up and realize that there is new physics right under their noses – just not the new physics they've been expecting (GUTs, strings, membranes, etc.). Galaxy dynamics are consistent with a single, universal force law, but this unexpected behavior has largely been ignored because it doesn't fit with particle theorists' dreams of super symmetric dark matter particles. That we do not understand the observed behavior makes it *more* interesting than the "expected" (but unobserved) new physics: who ordered this?

If we are witnessing "a great science come to an end" then a large share of the blame can be laid on our arrogance in putting theoretical ideas ahead of empirical facts.

3. **imho**
December 30, 2013

Great science will not come to an end in a technologically driven society like ours. Resources will likely be shifted to more economically productive areas, but that's a different issue and in my opinion… probably healthy. Society could benefit with more smart people thinking about plasma physics, fusion, quantum computing, computational algorithms, etc and fewer people worrying about the Planck scale. There's nothing wrong with wild speculation at the frontiers of knowledge. It's only a problem if it starts to consume a disproportionate share of the available resources.

Hi Stacy, MOND (if that's what you're talking about) has been ignored because physics is not really about unmotivated empirical curve fits. Don't get me wrong, classical forces where great stuff back in the Maxwell / Newton eras, but we're not there anymore. When MOND can also explain time dilation and space time curvature all while admitting a cosmological constant… maybe we'll pay more attention. Moreover, the bullet cluster data even breaks the curve fit.

4. **Peter Woit**
December 30, 2013

All,
From what I remember, there's not a word about MOND in the book (and definitely not in my posting). Those who want to argue about MOND or other dark matter models will have to do this elsewhere.

January 1, 2014

Wembrane?

9. **Peter Woit**
January 2, 2014

Yatima,
Best to leave discussion of TED to another time. They do all sorts of things, some more dubious than others (I did get involved once, see http://www.math.columbia.edu/~woit/wordpress/?p=3985 and that invitation came from a TEDx person who explicitly wanted something different than the silliness about physics they often have).

Related to this book though, I think people often make the mistake of blaming science popularizers for the multiverse and similar outlandish speculative stuff. I see this differently, with the main source of the problem leading figures in the physics community. There always has been and always will be nonsense in the popular media about fundamental physics, but the new and dangerous thing going on is that it is now being driven by leading academics. The TED talks about the multiverse are not the ones being given by Deepak Chopra….

10. **Kavanna**
January 2, 2014

Stacy: Nice to hear that someone was driven away from string theory so early. Those of us remaining in theoretical physics had to contend with this cult until we couldn't stand it any more.

The Wacker posting (Quora) on integrity in science was heartening to read. It's good to know that being a "senior scientist" full of one's own half-baked ideas isn't enough to steamroller the basic checks that authors are supposed to do. Sadly, the string cult is an example of a once-thriving area of physics dominated by senior figures who went around the bend 30 years ago, taking a generation of impressionable students with them.

The sociology of a (former?) science dominated by senior figures off their rockers is an important theme in Lee Smolin's The Trouble With Physics.

11. **Chris W.**
January 5, 2014

See this essay by Amanda Gefter at Edge.org, which presents what I'd guess to be an important underlying theme of the book—including its problematic aspects.

Acknowledgments

December 30, 2013
Categories: Uncategorized

Two of the prominent string theorists working on ideas about holography and cosmology featured in Amanda Gefter's new book are Tom Banks and Willy Fischler, who have a new paper out on the subject, entitled Holographic Space-time and Newton's Law. Besides the usual sort of thing, this paper contains a rather unusual acknowledgments section (hat-tip, the Angry Physics blog):

> The work of T.B. was supported in part by the Department of Energy. The work of W.F. was supported *in part* by the TCC and by the NSF under Grant PHY-0969020. However, the authors *do not* thank either of these agencies, nor their masters, for the caps placed on their summer salaries, nor for the lack of support of basic research in general.

It seems that while debating philosophical issues concerning holography and cosmology can put one at the upper end of the current academic star system pay scale, it doesn't stop one from getting embittered that it's not enough. The authors did revise this text a few days later to remove the complaints.

For those who don't know what this is all about, prominent theoretical physicists (and mathematicians) in the US generally have research grants that pay them not only research expenses, but "summer salary". Historically, the reasoning behind this was that academics needed to teach during the summer to make ends meet, so agencies like the NSF would get them more time to do research by paying them to not teach. That was long ago, in a distant era. At this point the typical sums universities pay for summer courses are so much smaller than the academic-year salaries of successful senior academics that few would consider dramatically increasing their teaching load this way to make a little extra money.

Taking the NSF as an example, the standard computation is that an academic's salary is considered just pay for nine months, with the NSF allowing grants to pay for up to two months of summer salary. In other words, grant applications can include a request for 2/9ths of a person's salary, to be paid as additional compensation in return for not teaching summer school. As the salaries of star academics (who are the ones most likely to get grants) have moved north of 200K/year, these additional salary amounts have gotten larger and larger, crowding out the other things grants pay for (post-doc salaries and grad-student support are the big items).

Several years ago the mathematics part of the NSF instituted a "salary cap" on these payments, limiting them to about \$25K/year. This year, in response to declining budgets, such a cap was put on payments to theoretical physicists, at \$15K/month. So, any theorist with an academic year salary of over $135K/year saw a reduction in their additional compensation (although as far as I know only two were so outraged by this that they complained in the acknowledgments sections of their papers). The report of this year's panel on the future of particle theory in the US includes the language:

> This past year, the DOE instituted caps on summer salaries, and the NSF is following suit. We agree that this is preferable to further cuts in student and postdoctoral support, but it should be noted that still lower caps will have implications for research productivity, particularly if they reach the level of junior faculty (assistant or associate professor salaries). Many researchers may have to supplement their income with further teaching or other responsibilities in the summers.

Since Banks and Fischler work at public universities, one can check for oneself that they are seriously impacted by the new caps. Fischler is at the University of Texas, Banks has positions at UC Santa Cruz and Rutgers (I have no idea how the two institutions split his salary). Some of the grant information is also publicly available, for instance the NSF grant referred to in the acknowledgment is this one. It expires soon, but was supposed to provide \$690K over three years, presumably including summer salary for Fischler, Weinberg and three others. One anomaly here is Weinberg, who at over $500K/year is likely the highest paid theorist in the US. The same people have a new grant recently awarded, for \$220K.

Comments

1. **Seyda Ipek**
   December 30, 2013

   They have a newer version of the paper, which leaves the last bit of the acknowledgements out.

2. **CIP**
   December 30, 2013

   Research physicists need Porches too…

3. **lun**
   December 30, 2013

   Does the AdS/CFT correspondence put a quantum limit on how small can a violin be?

4. **Jeff M**
   December 30, 2013

   Uh, do Banks and Fisher have some sort of special deal? UT Austin pays full profs 144K and UC Santa Cruz 128K, according to the AAUP, so the effect of this on either of them would be either very small or nonexistent. Of course UTA pays Weinberg who knows how much, so maybe both have some special deal. In any case it's honestly gross, I mean if they wanted money they could have worked in industry, or become lawyers, or worked on Wall Street.

5. **Peter Woit**
   December 30, 2013

   Jeff M,
   I don't know what those AAUP numbers mean. The Texas state info I linked to has a range of about \$90-240K for tenured faculty in the UT physics department, with Weinberg way off scale at \$536K (Fischler is at \$192K).

   Banks was one of the four string theorists brought in by Rutgers in 1989 with a very special deal (I wrote about Dan Friedan's description of how it happened in my book…). At the time he would have been one of the highest paid theorists in the country and this is probably still the case (UCSC lists him at $243K, Rutgers at \$235K, but I think those are full-time salaries and he's not full-time at both places).

   In any case, the amounts lost to the salary cap should be quite significant for both of them.

6. **A.J.**

December 30, 2013

Questions for anyone angry that some theorists might be paid well:

1) Does it worry you that our society rewards a lifetime of Nobel-quality academic work less richly than a few years playing for the Yankees?

2) Would we really be better off if Weinberg had gotten a JD instead of a PhD?

3) How does our culture benefit if the only way to make significant contributions to science is to sacrifice some or (quite possibly) _most_ of your potential future earnings?

4) Who exactly are we selecting to be our scientists if we insist that a scientific career necessarily involves a monastic lifestyle?

5) Is there any evidence that limiting the pool of scientists in this fashion produces better science?

6) Are we better off as a society if we take care to pay scientists poorly enough that they are underrepresented among the politically influential social classes?

7. **Peter Woit**
December 30, 2013

A.J.,

The “summer salary” issue is a different one than that of whether theorists are paid well. Weinberg’s \$536K/year from UT should be compared to the fact that their football coach is getting $5.266 million/year (although he doesn’t have tenure and the team is not doing well…), so you can easily make the case that Weinberg is a bargain for UT. But would it really make sense for the NSF to pay him an additional 2/9ths of this (about \$120K), taking this money away from hiring postdocs and funding grad students, with the excuse that otherwise he wouldn’t have time for research because he would have to teach summer school? Or, maybe there should be a salary cap of some kind?

Of course I have no idea what Weinberg’s actual “summer salary” arrangement is, and he’s not known to have complained about it getting capped.

8. **A.J.**
December 30, 2013

Peter,

I don’t think CIP or Jeff M were talking about summer salaries. In any case, I think it’s worth keeping in mind that we’re talking about a system with a power law distribution of rewards where the most highly compensated are barely on the bottom rung of the top percentile.

9. **Peter Woit**
December 30, 2013

A.J.,
Yes, top string theorists in the US are “barely on the bottom rung” of the top income percentile. Or put differently, have a great job, perfect job security, and are making about six times as much as the average citizen. Lots of ways to look at this, but you don’t have to be an Occupier to think that people in such a situation probably shouldn’t expect sympathy when they complain about their sort, or that scarce NSF funds shouldn’t be given to them proportionately to how far up they manage to climb in that top income percentile.

10. **A.J.**
December 30, 2013

The string theory salaries discussed here don’t get you to that bottom rung. I was talking about Weinberg.

11. **Peter Woit**
December 30, 2013

A.J.,
I don’t know where you’re getting your data. I was looking at
http://politicalcalculations.blogspot.com/2013/09/what-is-your-us-income-percentile.html
where, if I put in \$210,000, I get 99.0% for income percentile ranking “among all U.S. individuals with incomes”.

Household income is something different, there it looks like \$310,000 gets you to 99.0%. From what I remember, Weinberg’s wife is or was a lawyer, so likely to contribute significantly to their household income. I have no idea what the average spousal income is for top string theorists, but it could very well be at least \$100K, putting them in the top 1% for household income also.

12. **A.J.**
December 30, 2013

Let’s grant that you’re right about the percent cutoff. (Although iirc wikipedia puts the cutoff at about $350K for household income, which could be slightly above the sum you’re discussing.) It doesn’t change my point: These guys may look a bit silly for griping about summer salary in particular, but the big problem here isn’t that one of them might be well off enough to afford an expensive car. It’s that we’re massively underfunding scientific research.

My original comment was an attempt to get people to realize that there’s some tension in thinking that we don’t pay scientists well enough and being angry that some of them are quite well paid. You can try to level compensation within science, but a) I suspect this doesn’t really work without at least massive changes in the grant system, and b) I think the message it sends to the rest of society — namely, that we put a limit on the value of scientific research — is a bad one.

13. **Peter Woit**
December 30, 2013

A.J.,

I just don’t agree that “we don’t pay scientists well enough”, especially when you’re talking about star-academics. I don’t have time to go get precise numbers, but typical salaries for tenured faculty have for many years more than kept pace with inflation, and outpaced typical salaries for the average person. Yes, people in a few other fields (finance, professional basketball, university administration) have done even better, but I don’t see how that’s an argument for higher academic salaries, any more than it’s an argument for paying everyone in society more.

What has changed since the 60s in the academic pay scale is an increased income spread, including a huge growth in the number of very poorly paid adjuncts, with stars at the top doing better and better. I don't see how taking limited NSF resources away from those at the bottom of the research hierarchy (grad students, post-docs) to make sure that those at the top keep climbing into the top 1 percent sends a good message to the rest of society. And academic 1 percenters whining about a summer salary cap doesn't help the image of science either, it definitely won't convince the average US citizen that they need to support better science funding.

To the extent it's true the US is underfunding scientific research, it's not because it's not writing large enough checks to successful academics for additional compensation. It's because it's not doing things like spending the $10-20 billion it would take to build a higher energy collider. That's not spending that would go to the 1 percenters of science, but spending that would go to building things and employing lots of more modestly paid people.

Sorry that this is becoming a bit of a rant, A.J. You're welcome to respond, but other than that, from now on I'll do my best to restrain myself and others and try and stick to the summer salary issue rather than larger issues of inequality in US society.

14. **Jeff M**
December 30, 2013

Well I should probably stay out of this, but I'm with Peter on this one. Academics (with tenure, at good schools, a quickly shrinking group) do quite well in relation to almost anyone else. They have of course worked very hard for that, but plenty of people work very hard, and many of them make very little money. Try teaching little kids sometime. And the adjunct issue is quickly becoming a major problem, which most of us with tenure unfortunately just ignore. Imagine spending years getting a doctorate, and then ending up teaching 6 classes at three different schools each semester, and earning (if you're lucky) 40K for the year. My brother in law, who has tenure at a very small school, where he doesn't make much, sometimes ends up teaching an extra class if he was worried something wouldn't run because enrollment would be low (and keep in mind he teaches a 4-4 load). When this happens, he just gets paid adjunct rates for the class. I think nowadays it's about 2K per class. There is no way I would ever do that, but I'm lucky, I have tenure at a pretty good state school.

15. **paddy**
December 30, 2013

Just saw PW's last response and as a result have painfully swallowed the diatribe I was writing…suffice it to say I agree with PW (after decades of experience in academia, industry, and government).

16. **A.J.**
December 30, 2013

Not much to add. I've already belabored my point, I don't have any easy fixes for the 80-20 problem, and I'm happy to see the conversation turn from "why are these few guys getting tens of thousands of dollars?" to "why aren't all these folks getting collectively billions?".

17. **Zathras**
December 30, 2013

" From what I remember, Weinberg's wife is or was a lawyer, so likely to contribute significantly to their household income. "

She's a professor at the UT Law School, so her income (at least what she gets from UT) is readily available: $229,949.
http://www.texastribune.org/library/data/government-employee-salaries/the-university-of-texas-at-austin/louise-weinberg/252999/

18. **CIP**
December 31, 2013

I wouldn't mind a world in which top physicists get paid better than football coaches, but given the choices that DOE and NSF had (cutting faculty summer salary or student support) its pretty tawdry for pretty well off guys like Banks to whine in their acknowledgments – the whines might be better appreciated in the science faculty lounge – and they might not get hella sympathy from humanities types either.

19. **Russ Whirton**
December 31, 2013

A tenured academic making \$200k is dramatically better off than a professional making \$200k: The academic has much greater flexibility, and is typically required to work only about twelve hours per week (most work much more, but some don't, and none lose their job for working the bare minimum). The academic can spend a significant period of each year at conferences of his choosing, which are often just a quasi-holidays. Every few years, the academic gets an even bigger holiday in the form of a sabbatical. As the academic ages into his 50's, 60's and 70's, he continues to receive his full salary – there is no concern about losing his income after being ousted by smarter, harder working youngsters, and no real concern about losing his job to layoffs or corporate bankruptcy.

Many academics in their 20's and 30's do work extremely hard. But they know that at any time after tenure, they can reduce this workload to whatever level they desire, and preserve their same income stream into their 80's. For a hard working professional to aspire to the same cushy lifestyle and high degree of security, the only means is to stuff a lot of cash into the bank during their young productive years. I would therefore argue that an academic salary of \$200k is actually equivalent to a professional's salary of around \$600k.

Don't get me wrong – I'd certainly like lawyers and athletes to be paid a lot less. But I do feel academics tend to miss the big picture of financial life in the real world.

20. **kashyap vasavada**
January 1, 2014

Very interesting discussion. I think, the whole grant system for research has corrupted American universities beyond any reasonable limit. While it is true that one needs grants to buy equipment, to pay graduate students and to get release time from teaching to do research and poor students should not pay for that, it has become excessive capitalist enterprise for universities. Administrators like it because they get free overhead money without doing anything. In turn they pay professors who get large grants large sums of money. Usually even promotion and tenure are also related to how much money you bring in. As it is well known, for faculty at small universities, it has become extremely hard to get grants in basic physics. The success rate for a proposal is usually less than 10%. In India, it is certainly not like that. I wonder how it is in Europe. Most likely they have a different system.

21. **OMF**
January 1, 2014

Paying someone on a salary for only 9/10 months of the year is a ridiculous practice. Either they are a full time employee or else they are on wages. And if they are on wages, institutions should reduce their expectations of work output as a result.

Discussion of tenure do not enter into this. Employers cannot be allowed to operate with such bizarre practices while still claiming to employ people full time.

22. **Peter Woit**
January 1, 2014

OMF,
The “9 months” salary scheme at US universities is a bit of a fiction, there for the convenience of the faculty. People are almost always paid this “9 months” salary in 12 equal installments monthly. The reason for the 9 month business is to allow people to claim not to be paid during the summer, so eligible for “summer salary” for up to three months. In some fields there probably are ways for faculty to make significant sums working at something else over the summer. Among most of the mathematicians and physicists I know though, the only viable summer job is teaching, and that doesn’t pay enough to make it worthwhile except sometimes for the most junior people. So, in practice they’re collecting the 9 month salary just like a 12 month salary, with some hopes of additional compensation of up to 2/9ths of their yearly salary via the grant system.

23. **Pawl**
January 1, 2014

These are important points (which may be coming at a particularly awkward time, for academic funding in general). I’d like to know more about the issue of overheads, raised by Kashyap Vasavada. What is the argument for universities just getting a fixed percentage overhead on all (standard) grants? Do they have to account for the money?

24. **Peter Woit**
January 2, 2014

Pawl,
As far as I know, universities have an overhead rate they have negotiated with the granting agency, and rules as to what things the overhead rate applies to. Summer salary is something that they get overhead on, so it’s not just individuals benefiting from the summer salary arrangement, but their institutions also.

The standard argument for overhead is that the university is providing facilities used by the faculty member to carry out their research (office, staff, lights, library, computer network, etc. etc.) so they should get part of the grant money to pay for this.

25. **Jeff M**
January 2, 2014

Pawl

In my experience (as a department chair) overhead money goes to the department to use as they see fit. Some will let the PI choose what to do with it, some just put it in the general department fund. I assume there are schools where the money never gets to the department.

26. **Pawl**
January 2, 2014

Peter, Jeff, thanks for your replies.

I had heard the arguments about offices, lights, etc., before, but it is not obvious how they are justified at a quantitative level (and there are reasons I can think of for being skeptical about the whole idea). Does anyone know what is involved in universities’ negotiations with grant agencies in setting the overhead, and in simply taking it to be a percentage of the grant?

27. **Peter Woit**
January 2, 2014

Pawl,

For a recent news story about this, see
http://www.bostonglobe.com/news/nation/2013/03/17/harvard-mit-and-other-research-schools-thwart-obama-administration-effort-cap-overhead-payments/Nk5PT0Mc8MQZihFVNs5gNK/story.html
which has
“Overhead rates are calculated based on a complex formula that takes into account an institution’s historical costs for construction, maintenance, utilities, and administration.”
Critics point out that this formula is leading to the wealthiest institutions (e.g. Harvard) getting the highest rates since they have the most expensive construction and the highest paid administrators.

There was a scandal about this back in the early 1990s, see
http://en.wikibooks.org/wiki/Professionalism/Stanford_Research_Scandal
when it became known that the president of Stanford was charging personal expenses (yacht, wedding ceremony, flowers) as “research expenses”. I haven’t heard much about this though in the past 15-20 years.

28. **Peter Shor**
January 2, 2014

After the Stanford scandal, universities have become much, much more careful about charging inappropriate expenses to research grants. I don’t think we’ll see something like that again any time soon.

29. **Kuas**
January 2, 2014

Does it make any sense to lash out at the NSF for the inadequate overall levels of research spending? I’m sure the NSF would be happy to dole out as much funding as congress would give them.

Anyhow, if you happen to be working in string theory in the US, you should also factor in to your compensation calculations the significant probability your turn will eventually come up for the $3M Milner payoff.

30. **Pawl**
January 2, 2014

Peter, thanks once more. (There’s an NSF page.) A couple things come out of this:

(a) Indirect Costs are **not** readily identifiable with the research project (they are not the costs of keeping the researcher's lights on, etc.) but are part of the general cost of keeping the organization running.

(b) Indirect Costs are negotiated (or set by the granting agency). I have not (so far) seen any "complicated formula" which determines what they are.

It is completely unclear from this why Indirect Costs should be a percentage of the grants. The whole thing seems to be a general way of subsidizing organizations (mainly universities) which produce research, but without really specific objectives.

The questions of what exactly is being rewarded, and what effects these incentives have, really deserve some attention.

31. **Peter Woit**
January 2, 2014

Pawl,

If you take a look at
http://www.nsf.gov/bfa/dias/caar/docs/idcsubmissions.pdf
especially Attachment IIIa, you can see a sample computation of an indirect rate.

32. **Bernhard**
January 7, 2014

kashyap vasavada,

"I wonder how it is in Europe. Most likely they have a different system."

Not really. In some universities in Europe getting an important grant (like ERC) is sometimes the ONLY way to get a tenure-track position. Furthermore when positions are open "demonstrated ability to acquire external funding for research projects" is one of the first things people look at here. Mind that some universities don't even pay full salary, they simply expect you to get grants. And I'm not talking about the " "9 months" salary in 12 equal installments monthly." that Peter was mentioning. You need to get a grant at some point otherwise you risk getting fired.

Short Items

January 2, 2014
Categories: Uncategorized

- Harvard has announced that the Chinese firm Evergrande Group will be supporting various activities at Harvard, including a new Center for Mathematical Sciences and Applications, with S.-T. Yau as director. No details of what the center will do other than "serve as a fusion point for mathematics, statistics, physics, and related sciences." The company has its own announcement here (they might want to check on the name of Harvard's President…).
- The new Physics Today has an article Paul Ehrenfest's final years, a sad bit of physics history I'd never seen the details of.
- Last month in Moscow there was a conference for Boris Feigin's 60th birthday. Videos of the talks are now available here.
- Dick Gross's wonderful lecture series here at Columbia on *Representation theory and number theory* has been available on video since he gave the lectures. Now Chao Li at Harvard has produced a transcription of the talks, so a high-quality written version of the material of the lectures is now available. This is one of the best sources around to learn about the local Langlands conjectures. His website contains a lot of other interesting expository material.
- Phenomenologist Jay Wacker has a blog at Quora, called Particle Physics Digressions. The latest entry is an odd tale of something I would have thought was rather unusual, but Wacker says it's not exceptional, happens everyday.

Comments

1. **Peter Donnelly**
   January 3, 2014

   Ehrenfast article sounds interesting, but not $30 interesting.

2. **Thelonious**
   January 3, 2014

   I have to agree that paying 30$ is a little hard to swallow, do you know if there is a good summary somewhere ?

   Do you know if there is going to be an Eilenberg lecture this coming semester (Gross's lectures are amazing !!) ?

3. **Thelonious**
   January 3, 2014

   I should add that Chao li's lectures have been around for at least a year I think. On the other hand he just wrote, this semester, lecture notes from a course by Jack Thorne (http://www.math.harvard.edu/~chaoli/doc/AutomorphicForm.html) which, as far as I can tell, are one of the best ressource for learning thoroughly about the important objects in the number theoretic Langlands program (it isn't just a broad overview, he actually proves stuff).

4. **Peter Woit**
   January 3, 2014

   Thelonious,
   No Eilenberg lectures this spring, Joe Harris just finished his lecture series a couple weeks ago. I second the recommendation of the Thorne lecture notes.
   If anyone knows of a another source for the material about Ehrenfest, let me know. The policy of Physics Today to charge $30 to look at an article seems to have no point other than to ensure that no one does it.

5. **David Brown**
   January 3, 2014

   http://books.google.com/books?id=qsodmIGD0fMC&pg=PA232 excerpt from bio of Dirac by Farmelo

6. **claudius**
   January 3, 2014

   If even you think that $30 is too much to pay to look at an article,
   why did you even bother to link to it?

7. **Martin**
   January 3, 2014

   http://www-history.mcs.st-and.ac.uk/Biographies/Ehrenfest-Afanassjewa.html

   "Paul Ehrenfest through his life had suffered from low self esteem, but now began to suffer from depression. He was also greatly saddened by his youngest son Vassily who suffered from Down's syndrome and had severe problems both physically and mentally. On 25 September 1933 Ehrenfest shot Vassily in the waiting room of the Professor Watering Institute in Amsterdam where Vassily was being treated. Then he shot himself. The Dutch papers only reported his sudden death and gave lengthy accounts of his achievements. Ehrenfest-Afanassjewa returned to Leiden where she remained for the rest of her life. Not only did she lose her husband and youngest son in such a tragic way, but a few years later, in 1939, her eldest son Paul was killed by an avalanche while skiing in the French Alps."

8. **Peter Woit**
   January 3, 2014

   claudius,
   From my office at Columbia (as well as probably at many other places with an institutional subscription), Physics Today articles are freely available. I didn't realize they were charging $30 to non-subscribers (actually I'm wondering if that's new, hadn't seen that before).

9. **kashyap vasavada**
   January 3, 2014

   If you have an account at the campus computer center (most state univ. in U.S. will allow this for state residents) they will let you download physics today articles or even journal papers free. I am not sure about private univ.

10. **gs**
January 3, 2014

This first: A hat tip to Evergrande and Hui Ka Yan for their generosity. Hopefully it augurs constructive relations, not enmity, between the USA and China.

Nevertheless, it is surprising that a Chinese real estate company is underwriting mathematics and immunology at Harvard. (The Green Buildings initiative is more understandable.) The details would seem to warrant journalistic looking into, not in a spirit of suspicion but of due diligence. That said, I do not imply impropriety, and repeat my appreciation of Evergrande's action.

11. **Isidore Seveille**
January 3, 2014

IMHO, the donation from Evergrande is good PR work for Chinese companies given that some of those Chinese companies are placed under suspicion by the Congress and the media.

On a related note, Huawei, a Chinese telecom company, has been supporting mathematics and theoretical physics research in IHES, according to [this report](#) .

12. **Peter Donnelly**
January 4, 2014

OMG that was sad.

13. **Thomas Larsson**
January 4, 2014

I was excited to find that the Feigen conference was dedicated to, among other things, double affine and toroidal algebras. Unfortunately, none of the talks seems to be about this subject.

In my own work, I preferred to use the terms multi-dimensional affine and Virasoro algebras, rather than double (triple, quadruple, …) affine algebras, because the restriction to tori is not fundamental. Note that triple affine algebras are not related to gauge anomalies in QFT in 3+1 dimensions, since the extension is proportional to the second Casimir rather than to the third. The algebra pertaining to QFT gauge anomalies is called the Mickelsson-Faddeev algebra, and is something completely different.

14. **lcs**
January 5, 2014

12 issues of Physics Today costs $69, yet they charge $30 for a single article? Talk about not even wrong. Even if they charged $30 to download an entire issue it would be grossly out of proportion. Someone needs to upbraid these silly AIP publishers, who must be pompous beyond imagination to think their content merits this pay scale.

15. **Jeff Murugan**
January 6, 2014

There's a related story on the sad story of Ehrenfest's last few days in Graham Farmelo's "The Strangest Man"

16. **harryb**
January 6, 2014

Added a comment to the Ehrenfest article site on Physics Today noting the sentiments of frustration on this blog. Would have been preferable to have been able to comment on the content. Their choice.

17. **Paul Guinnessy**
January 7, 2014

We've made the Physics Today article free so that its easier for people to access. We do offer a $4 rental free to view the article, but we're still ironing out some quirks in our new publishing system. Hence I apologize that this option was not available at first.

The magazine is a benefit of membership in ten science societies. If you've previously registered with Physics Today, just click on the "sign in" option on the right hand side and you'll be able to access everything, including our entire back archive, no matter whether you're on campus or not.

18. **Peter Woit**
January 7, 2014

Paul,

Many thanks for arranging access to the article about Ehrenfest!

19. **harryb**
January 8, 2014

Good response from Physics Today – thanks.

January 8, 2014

Thank you, Physics Today.

Scientists Find a Practical Test for String Theory

January 6, 2014
Categories: This Week's Hype

This sort of thing seemed to be dying down (2013 required a record low number of "This Week's Hype" postings), but 2014 is starting off with the usual promotion by physicists of nonsense about how they have "found a test for string theory". This time the news that [Scientists find a practical test for string theory] comes from a group at Towson University, who are basing their claims on [this paper], published [here]. I'm not sure where phys.org got this, but it reads like a university press release, and they credit "Provided by Towson University".

What's actually in the paper is a proposal for a test (and not a very good one, as far as I can tell…) of the equivalence principle. The claim is then that a violation of the equivalence principle would be evidence for string theory. I've written about this kind of claim before (see [here]), pointing out that string theorists sometimes argue that the equivalence principle is a prediction of string theory. So, string theory can be tested, and the test is even "practical", but since the prediction is that either the equivalence principle will be violated or not, it's pretty likely to pass the test.

Update: Another source for the press release is [here].

Update: Matt Strassler [weighs in], a week later:

> Baloney. Hogwash. Garbage.

Comments

1. **CIP**
   January 6, 2014

   If I understand correctly, the question here is really the validity of the so-called "strong" or Einstein Equivalence Principle (EEP), which insists that fields that couple directly to matter (like gravitation), couple through the metric. Brans-Dicke and other fifth force variants don't.

   The same may be true of the dilaton and some other string theoretic fields, but that doesn't seem to be iron clad. Still, any fifth force type effects seen would seem to give string theorists and other alternative gravity people something to work with.

2. **Jim Akerlund**
   January 6, 2014

   Peter,

   Here is a different test for equivalence principle, but no mention of String Theory.

3. **Peter Woit**
   January 6, 2014

   CIP,
   One thing that I don't doubt is that the day after evidence for a fifth force shows up, the headlines will be "Evidence found for string theory!"….

4. **Jim Akerlund**
   January 6, 2014

   Here is the missing link. Sorry.

   [Three Star Test]

5. **David**
   January 6, 2014

   How do they know that there isn't a fourth component in the system, too dark to see, but with enough mass to cause deviations from the computed 3-body solution?

6. **Allan Rosenberg**
   January 6, 2014

   You have to give them credit for honesty. How many people proposing this sort of test have the cojones to say that "[s]tring theory is infamous as an eloquent theoretical framework to understand all forces in the universe…."

7. **Paul**
   January 7, 2014

   One of the studies authors had this to say:

   "Hi, I'm one of the authors of the paper. It's crazy to see my undergraduate research on Reddit!
   Basically, some versions of string theory propose that elements will "fall" at different rates (i.e. violate the equivalence principle). Well, planets are "falling" around the Sun, along with asteroids in the same orbit. Moons are falling around planets as well.
   We have a pretty good idea of exactly where everything is supposed to be. When we calculate these things, we assume that everything falls at exactly the same rate (that is to say, inertial mass is the same as gravitational mass). And within margins of error, they ARE right where we expect them to be.
   So, if these versions of string theory that say things can fall at different rates are true, we should see some kind of discrepancy between the models and what we really observe. We don't see these discrepancies. This places limits on the parameters of those versions of string theory (and other "beyond the standard model" theories that don't technically involve strings).
   Of course, we don't know where everything is to an infinite number of decimal places. Perhaps Jupiter is 0.00001 arcseconds away from where we claim it is. We can't measure that precisely. So if there is an effect due to something from string theory, it would have to be hiding in that uncertainty. In our paper, we take the limits of that uncertainty and turn it into limits on how much something can violate the equivalence principle. From there, if you had a string theory model, you could calculate how much it would violate the equivalence principle, and if it was bigger than our numbers, you might want to be skeptical about your model (especially since our numbers are

quite conservative and aren't even as strong as other methods).
Hope that helps."

Interested to hear your response as I am not nearly smart enough 🙂

8. **Bee**
January 7, 2014

They propose to test for some kind of dilaton coupling. I actually read the paper last year. You only have to look at the first page to see that they are not actually claiming that they test string theory. They propose to look for generic violations of the equivalence principle that could hint at physics beyond the standard model. I think it's a reasonable proposal, but the phys.org headline is more than just misleading. It is a) wrong and b) most likely deliberately so.

9. **Bee**
January 7, 2014

PS: I said reasonable – I don't think it's terribly exciting because I can see no good reason the effect should appear in the parameter range that the experiments are sensitive to. That isn't to say one shouldn't look though.

10. **Zhiming Wang**
January 7, 2014

Wow, I like that "Three Star Test" referenced by @Jim Akerlund. A great example of how to spice up some regular scientific discovery/progress so that it sounds revolutionary.

11. **Shantanu**
January 7, 2014

I asked matt strassler about whether string theory violates equivalence principle
or not (since as Peter mentioned I have heard conflicting claims on this issue) and his reply was
http://profmattstrassler.com/2012/08/15/from-string-theory-to-the-large-hadron-collider/
(although you will have to sift through lots of comments to see his reply inline)

Regarding the actual paper, it doesn't cite the limits from binary pulsar(pulsar/white
dwarf systems) which I think they are equally stringent compared to solar system limits.

12. **Peter Woit**
January 7, 2014

For a serious discussion of the physics here, see Thibault Damour's recent
http://arxiv.org/pdf/1202.6311.pdf
especially page 12. I think a fair reading of Damour is that "the current string landscape prediction is no equivalence principle violation, but if equivalence principle violation is found, that just means string theorists need to look at other currently less popular string theory models".

So, usual story for string theory "predictions".

13. **chris**
January 7, 2014

if a violation of the strong equivalence principle would indeed be found, the one theory that raises in popularity would probably be MOND.

14. **Curious Wavefunction**
January 7, 2014

That's a little weird and it almost sounds like a tautology. It would be like claiming that the existence of friction is evidence for string theory (since string theory is supposed to be true).

15. **BobDastro**
January 7, 2014

> What's actually in the paper is a proposal for a test (and not a very good one, as far as I can tell…) of the equivalence principle

The authors are not proposing a test of the equivalence principle. Rather, they actually determine new (and significantly improved) upper limits to deviations from the equivalence of inertial and gravitational mass based on existing Solar System observations.

I would also say the paper makes no real claims about testing string theory *per se*. The authors cite in passing one speculative stringy model, but it is mentioned as only one example among several other classes of theoretical proposals that allow for composition-based differences between inertial and gravitationally-derived masses. IMHO this is a clearly written paper that is well worth reading for those of us interested in observational data that bear on the fundamental properties of gravitation.

16. **Eli Rabett**
January 7, 2014

Wife's comment on seeing the press release about a test for string theory: Oh, they found the Big Ball

17. **MathPhys**
January 8, 2014

From a quick reading of the paper, I agree with BobDastro's comment above. It's a paper on theoretical astronomy that basically says *"If you observe this, then that means that"*, which (assuming it's technically correct) is fine and educational.

Now if someone has decided to blow the string-theory-can-be-tested trumpet to attract attention, that's a different (and sad) issue.

18. **Peter Woit**
January 8, 2014

BobDastro/MathPhys,

This is following the usual pattern: published article includes only minor references to string theory, since no referee would allow the author to claim that this was a “test of string theory” (since it isn’t). On publication of the article, the author has their university press office issue a press release about how they have discovered a “test of string theory” (I don’t believe in claims that university press offices issue press releases about their faculty’s work without the faculty member’s agreement). The press release then gets spread through various media outlets, often with the outrageousness of the claims increasing as it spreads. Finally, you end up with lots of news stories like
http://www.huffingtonpost.co.uk/2014/01/07/string-theory-experiment-announced_n_4552931.html

There are by now dozens of examples of this. You can argue about who is responsible for the public getting misled here, my vote would be for the physicists who allow or encourage such press releases to go out (together with their colleagues who raise no objection or sometimes provide supporting quotes for the stories).

19. **Zathras**
January 8, 2014

It seems to be almost a contradiction in terms to have universities put out non-peer-reviewed press releases on peer-reviewed results. Maybe these press releases should be peer reviewed as well?

20. **chris**
January 8, 2014

the peers of university press people are other universities press staff, right? that would be a nice peer review.

21. **DaveC**
January 8, 2014

My university has put out press releases on our work (in condensed matter; not at our suggestion but at the journal’s). Our press guys take great pains to represent faithfully what we talk about in the interviews and incorporate all our own proof edits. I find it hard to believe this is the exception rather than the rule.

22. **Chris W.**
January 8, 2014

Press release = Marketing blurb

Is that too strong? There is an incentive for both the researcher and the institution to claim too much. (And yes, universities are operating more and more like for-profit entities.) Unless there are clear negative consequences in terms that truly matter to them, this stuff will tend to become standard practice.

23. **Olivier Minazzoli**
January 9, 2014

> I think a fair reading of Damour is that “the current string landscape prediction is no equivalence principle violation, but if equivalence principle violation is found, that just means string theorists need to look at other currently less popular string theory models

I don’t think so. As far as I understand, Damour says that EP violation is a generic prediction of string theory, but a widespread assumption is to say that there might be a mechanism that protects the EP. Though, it is just a “convenient” assumption that is used by “model builders” . In general, Damour’s work (originally with Polyakov [1]) shows that even a massless dilaton (which has a long range dynamic that should imply a long range violation of the EP) can lead to a very small EP violation only, because the dilaton field’s cosmological equation can have an attractor at late cosmic times (hence leading to a very small violation of the EP at current epoch, that would thus be compatible with current experiments). (Note that it is said that they “can” and not that they “would”, see also [2]).

In any case, although string theory generically predicts EP violation, observing one of its various representations is indeed not a test of string theory since string theory is not the unique theory to propose EP violation anyway. But it would certainly be a small argument in favor of string theory. Also, this “prediction” is qualitative only, which is not quite the standard of “checkability” in modern science…

Otherwise, as far as I understand, there might be a way to put a quantitative constraint on the string theory effective action. Indeed, the full loop effective action of string theory in the gravitational sector should predict a unique specific coupling between the dilaton field and material fields. But it has recently been shown that depending on the such a coupling, the so-called post-Newtonian parameter gamma can be either more than one or less than one [3] (or even equal to one for a very specific coupling [4]). Hence, as explained here, the sign of 1-gamma (if measured) may put a strong constraint on the non-perturbative effective action of string theory, if someone is able to compute it, of course…..

24. **Peter Woit**
January 9, 2014

Olivier,
You’re ignoring the “string landscape” issue completely. What “string vacuum” are you planning to use to evaluate the effective action of string theory? Damour explains clearly on page 12 that the standard string landscape scenario implies a prediction of no observable EP violations:
“Though such a mechanism might entail observable short-range modifications of
gravity [30], it predicts the absence of any long-range EP violations.”
This same argument has often been given by Douglas in recent years as a response to those like me who say string theory predicts nothing. According to him, the string theory landscape does make a prediction: no observable EP violations (because un-fixed moduli will contribute to the CC). According to you, string theory predicts EP violations.

I do think you’re both right: string theory predicts anything you want, either EP violation or no EP violation.

25. **Olivier Minazzoli**
January 9, 2014

Dear Peter, Damour also says p.12 (a little after your quote)

“This family likeness between the dilaton ϕ(x) and the metric g_{μν}(x) (which entails a correlated likeness, say in heterotic string theory, between g_{μν}(x) and the gauge couplings g^2_a(x), as well as the string-frame gravitational coupling G(x)) suggests that there might exist consistent string vacua where some of the moduli fields are not stabilized, but retain their long-range, spacetime-dependent character. As recalled above, such a situation would entail long-range violations of the EP. How come such violations have not yet been observed, given the exquisite accuracy of current tests of the universality of free fall (at the 10^{-13}level [26]) and of current tests of the variability of coupling constants [32]? A possible mechanism for reconciling a long-range, spacetime varying dilaton (or, more generally, moduli) field ϕ(x) with the strong current constraints on the time or space variability of coupling constants is the cosmological attractor mechanism [33, 17,34]”.

As far as I understand, it says that one can expect some moduli fields to be long-range, just as the metric is, and in particular the dilaton field. In that case, one should expect an EP violation, at least form the dilaton field.

Hence, although a violation of the EP wouldn't prove string theory of course (nor would it be a striking evidence that string theory might be correct), it still seems to me that it would be a **small** argument in favor, since one should expect such a violation from string theory.

Otherwise, in the last part of my last comment, I assumed that the dilaton-matter coupling in the effective action does not depend on the string vacuum considered (for instance, at tree level, the dilaton coupling is universal no-matter what). But I'd love to have a comment from an actual string theorist on this issue.

26. **Peter Woit**
January 9, 2014

Olivier,
It still seems to me that Douglas's argument is that no unstabilized moduli is the generic expectation in the landscape picture, and thus no EP violation. Damour is saying it is worth thinking about alternatives and "suggests that there might exist" ones that violate the EP. This is different than your "one can expect some moduli fields to be long-range".

I don't disagree at all that one can find string theory models with or without long-range moduli and thus EP violation. The question is which alternative to expect, with Douglas saying he expects no EP violation from string theory, you saying you expect some. String theory here has no predictive power. Put differently, if we see EP violation, Douglas's claims implies this is evidence against string theory, while you and the authors of this press release want to claim it would be evidence for string theory.

27. **Olivier Minazzoli**
January 9, 2014

Dear Peter,

it is not because several people claim opposite things that it means that the theory actually allow opposite things to exist within its paradigm. It could simply be that one of the two arguments is wrong. Only a formal proof would tell which argument is correct, but as far as I can tell, formal proofs are rather difficult to get in string theory. I don't know Douglas's argument that you are refereeing to. Could you send me a link please? I guess you have my email address. Thanks a lot 🙂

Otherwise, if the effective dilaton-matter coupling(s) in the effective 4D action is(are) indeed string vacuum independent, if the dilaton field is proven to be massless (or light), and if one can compute the full loop effective dilaton-matter coupling(s), then a measurement of the value of 1-gamma could be a strong constraint on string theory, because its sign depends on such a coupling [1]. That's a lot of ifs, but it's better than nothing…

28. **Jeff M**
January 9, 2014

What, physicists do formal proofs, really 🙂

29. **Peter Woit**
January 9, 2014

Olivier,
For a paper by Douglas relevant to this, see
http://arxiv.org/abs/hep-ph/0112059
But the reason I refered to the Damour paper is that he makes the basic argument explicitly (end of page 11 to page 12). For another similar Damour claims, see
http://pagesperso.ihes.fr/~damour/Conferences/Onera19sept2011.pdf
where on page 8 he writes "EP tests are important because they test an assumption commonly made in string theory, and could refute it."
I don't see any reason why dilaton matter couplings should be string vacuum independent.

In any case, Damour clearly is claiming that an assumption commonly made in string theory implies no EP violation. This is inconsistent with any claim that string theory generically will imply EP violation.

30. **Olivier Minazzoli**
January 10, 2014

Dear Peter,

thank you very much for the links.

Still, the way I understand Damour is rather that: in general, string theory predicts EP violation. However, one can use an assumption that forces string vacua to respect the (long-range) EP in order to get specific models one can play with. May it be widely used or not, as far as I understand, it is still only an assumption. Not a prediction.

Regarding Banks, Dine and Douglas paper, as far as I understand, it only argues that it *wouldn't seem natural* to have a variation of the dimensionless couplings, according to our current understanding of QFT. Though it probably shows the state of the art regarding the QFT's point of view on the problem of the variation of the dimensionless constant, I'm not quite sure one can deduce that it means that string theory predicts no EP violation, as you seem to argue. But maybe have you linked the wrong paper? Or maybe have I missed something?

Thanks.

31. **Peter Woit**
January 10, 2014

Olivier,
I've heard the argument a couple times directly from Douglas that string theory predicts no variation in moduli. For an example in print
http://arxiv.org/pdf/hep-th/0610102v3.pdf
page 18
"This is perhaps the simplest testable prediction of string/M theory for which contrary evidence has ever been reported"
(referring to claimed observations of variation of the fine structure constant). Here he refers to the Banks/Dine/Douglas paper. You're right though that I don't think it's just a naturalness argument, what I remember hearing from Douglas was an argument that variation of moduli would imply a huge variation in the vacuum energy, but I don't immediately know of a source where that appeared.

Of course the occurrence of large number of moduli fields in string theory means that generically you have lots of different sizable long-range forces, so that is some sort of "generic" (and completely wrong) prediction of string theory. The question is whether some such things survive the standard landscape picture. My reading of both Damour and Douglas is that this is not supposed to happen in this picture. Douglas is quite definite about there being a "prediction of string theory" here, and it's the opposite of a prediction of observable moduli.

32. **Rafael**
January 10, 2014

Dear Peter, do you believe it is true http://bnews.kz/en/news/post/180213/ ?

33. **Peter Woit**
January 11, 2014

Rafael,
Seems unlikely to be true (solution to Millenium problem), but I know little about this subject.

34. **Bernhard**
January 11, 2014

And it will be quite hard to verify it since the guy decided to publish the solution in a Kazakh journal.

35. **Olivier Minazzoli**
January 11, 2014

Dear Peter,

thanks again for this new link! 🙂

Thus, as far as I understand, according to the reference to Banks/Dine/Douglas paper in Douglas/Kachru paper, no EP violation is a "prediction" of QFT alone, not string theory in particular. (It seems to me that it is actually not a prediction, but more an expectation based on our current understanding of QFT). Therefore, it appears to me that Douglas's claim that no EP violation is a prediction of string theory is exaggerated (if not wrong), unless I have missed something.

If the EP is to be expected from QFT, as Banks/Dine/Douglas paper seems to tell, then it would mean that any theory with (measurable) EP violations would be "unnatural" from the QFT point of view, may this theory be one of the vacua of string theory with no EP violation or anything else.

It is very interesting. However, one should remain cautious with QFT's predictions since, as far as I know, QFT is still far from being completely understood, not to mention the possible loopholes that may hide behind Banks/Dine/Douglas argumentation.

Anyway, thanks for the discussion 🙂

36. **vmarko**
January 11, 2014

Olivier,

"no EP violation is a "prediction" of QFT alone, not string theory in particular"

The equivalence principle is a statement describing how gravity couples to matter. As such, it cannot be predicted by any theory which does not incorporate gravity at some deeper level. String theory notwithstanding, there are no standard QFT's out there that contain gravity in any shape or form, and therefore no ordinary QFT can ever predict the EP.

In order to seriously discuss the theoretical prediction/violation of EP, you need a theory of quantum gravity. And today it is common wisdom that QG cannot be described with the formalism of QFT (except in some very unusual hypotetical constructions involving the existence of a nonperturbative fixed point etc.).

So QFT in general has nothing to say about EP.

HTH, 🙂
Marko

37. **Peter Woit**
January 11, 2014

Olivier,
So, according to you, Douglas/Kachru are just completely wrong to in their claim about a "prediction" of the string theory landscape. Fine, I'm definitely not going to be the one to spend time defending string theorist's claims for their "predictions"….

38. **David Brown**
January 11, 2014

http://www.math.kz/images/journal/2013-4/Otelbaev_N-S_21_12_2013.pdf Otelbaev's publication in Russian with English abstract at the end

39. **Olivier Minazzoli**
January 12, 2014

Marko,

It might be a matter of nomenclature. By QFT, I mean a set of tools one applies on actual theories originally defined classically in order to get their quantum behavior. Now, as far as I understand, Banks/Dine/Douglas suggest that a coupling of the form "scalar times Lagrangian of material field (=\Phi L_m)" would be "unnatural" from the QFT point of view for a light scalar field (actually they restrict their attention to L_m=F^2). Such a type of coupling could indeed come from string theory but from many thing else as well. For instance, one can simply postulate such a coupling to begin with, without invoking string theory. I don't quite see how Banks/Dine/Douglas argumentation can be transformed into a "no Ep violation is a prediction of string theory". As far as I can see, it has nothing to do with string theory, but depends on QFT arguments alone.

Peter,

at least from what I read, I don't understand how such a claim can be made. But I could easily miss something. However, as far as I know, the string dilaton is massless at first loops and its coupling is of the form of the one considered by Banks/Dine/Douglas (see (2.1) and (2.2) in [Damour and Polyakov]). Besides, Damour/Piazza/Veneziano say

> A striking prediction of all string theory models is the existence of a scalar partner of the spin 2 graviton: the dilaton ϕ, whose vacuum expectation value (VEV) determines the string coupling constant g_s=e^{ϕ/2} [1]. At tree level, the dilaton is massless and has gravitational-strength couplings to matter which violate the equivalence principle [2]. This is in violent conflict with present experimental tests of general relativity. It is generally **assumed** that this conflict is avoided because, after supersymmetry breaking, the dilaton might acquire a (large enough) mass.

That would be nice to have Douglas explaining from where the claim that "EP satisfaction" is a prediction of string theory is coming from because, as far as I understand, the reference Douglas/Kachru use in their paper doesn't seem to say so. But I am certainly not the best person to talk about that.

40. **vmarko**
January 12, 2014

Olivier,

"By QFT, I mean a set of tools one applies on actual theories originally defined classically in order to get their quantum behavior."

Correct. And if your classical theory contains gravity (say GR), the QFT formalism breaks down (loses predictive power) since the theory is nonrenormalizable.

"scalar times Lagrangian of material field (=\Phi L_m)"

In the context of string theory, the "scalar" is the dilaton, which (one could argue) is a part of gravitational sector. The above coupling then violates the EP, unless one breaks supersymmetry high enough etc.

Outside of the context of string theory, there is absolutely no justification to claim that the "scalar" is part of the gravitational sector. From the point of view of QFT, it is just another matter field, and the above coupling has nothing to do with EP. You could also argue, for example, that this scalar is the piece of the Dicke-Brans-Jordan gravity (the scalar-tensor theory), but in that case there should also be the curvature term in the theory, again rendering it nonrenormalizable. Consequently, QFT breaks down and can make no statements about EP.

Don't get me wrong — I agree that the formalism of QFT is made use of in discussing the EP violation. But this can be done only if that QFT is considered to be an effective low-energy limit of string theory. The argumentation about EP violation simply does not hold outside the context of string theory, because you don't know if that scalar field is part of "gravity" or "matter".

HTH, 🙂
Marko

41. **Olivier Minazzoli**
January 12, 2014

Marko,

The low-energy effective action of string theory **is** a scalar-tensor theory (Brans-Dicke-like) with a non-minimal scalar-matter coupling (see (2.1) in Gasperini/Piazza/Veneziano. Therefore, I don't quite understand when you seem to argue that with a scalar-tensor theory with non-minimal scalar-matter coupling, one cannot make statements about EP; while one could(?) with string theory. Please specify what you have in mind.

Otherwise, you don't need string theory to postulate this kind of coupling in an otherwise usual scalar-tensor theory. I.e. you don't need string theory to postulate the action (2.1) of Gasperini/Piazza/Veneziano. Other principles than the string theory ones can lead to such an action.

42. **vmarko**
January 12, 2014

Olivier,

"Therefore, I don't quite understand when you seem to argue that with a scalar-tensor theory with non-minimal scalar-matter coupling, one cannot make statements about EP; while one could(?) with string theory."

Ok, suppose that you have the scalar-tensor theory with nonminimal coupling to matter fields as your classical theory, without any mention of string theory. If you try to quantize this classical action (which you must if it is to be fundamental), you will find that it is nonrenormalizable — you cannot eliminate divergences consistently, and thus the corresponding QFT is not well-defined. Consequently, that QFT does not have any predictions at all, and in particular no predictions regarding the EP.

Now consider that same action as a low-energy effective action of the string theory. The effective action (by its nature) is not something that needs to be quantized, and consequently there are no renormalization issues. This is because string theory has some form of UV completion (which makes it perturbatively finite), and because your effective action is valid only at low energies — at higher scales it will receive nontrivial correction terms from string-UV-completion, and these terms are supposed to cure any and all divergences. But at low energies those corrections are supposed to be small, and the effective action should be approximately correct. Consequently, you can analyse its form and find out that EP is violated, unless the dilaton gets a large mass from supersymmetry breaking (in which case EP is not violated), etc.

It goes without saying that the string theory has its own share of problems regarding the prediction of EP violation. Peter's argument is basically that due to all those problems (essentially lack of uniqueness of the formulation of M-theory), string theory also doesn't make any predictions regarding the status of EP, but for different reasons and despite the knowledge of the low-energy effective action.

So it's the same action, but in two different contexts — one where you don't have a well-defined UV completion (and consequently you don't have any theory to speak of), and one where string theory does attempt to give you a UV completion (and if successful, you consequently do have a well-defined effective theory, which can be studied).

The general moral of the story: QG =/= QFT. 😉

HTH, 🙂
Marko

43. **Olivier Minazzoli**
January 14, 2014

Marko,

are you saying that the somehow very general argumentation in Banks/Dine/Douglas paper is actually restricted to string theory because the discussion wouldn't make sense otherwise? Am I correct to assume that it is what you are saying?

Also, as far as I can tell, Banks/Dine/Douglas paper is about the violation of the Eintein equivalence principle, while you seem to talk about the weak equivalence principle. Indeed, they are interested in the variation of the fine structure constant only. But a variation of the fine structure constant is a violation of the Einstein (and the strong) equivalence principle — and in that case, the scalar-field (ϕ) that couples to the material sector (eg. ϕ F^2) is not necessarily part of the gravitational sector: it could be any moduli field. On the contrary, if the scalar-field is part of the gravitational sector as in your exemple, and as it is for the dilaton for instance, then indeed it would lead to a violation of the weak equivalence principle in addition to the strong and Einstein EPs. But Banks/Dine/Douglas don't seem to consider this situation in particular.

44. **vmarko**
January 14, 2014

Olivier,

"are you saying that the somehow very general argumentation in Banks/Dine/Douglas paper is actually restricted to string theory because the discussion wouldn't make sense otherwise?"

Essentially yes, that's right, with a caveat that their argumentation could be also restricted to some other, non-string theory of QG. So yes, outside of a context of some theory of QG, their argument wouldn't make sense. Moreover, the authors actually say that themselves in the first sentence of the second paragraph of their paper:

"Within both the contexts of effective field theory and M-theory, it is natural to
model the change of the fine structure constant by coupling a dynamical scalar field ϕ to the photon kinetic term in the low energy effective action."

Note the phrases "M-theory", "effective field theory" and "low energy effective action". Without M-theory (or some other theory of QG), the latter two phrases don't actually have any meaning. One can discuss them only in a QG context, never in the QFT context alone. As I said earlier, QG has proven to be extremely hard (if at all possible) to construct within just the QFT framework.

"Banks/Dine/Douglas paper is about the violation of the Eintein equivalence principle, while you seem to talk about the weak equivalence principle."

The various flavors and formulations of the EP basically depend on how you make a split of all relevant fields into "gravity" and "matter" sectors. One version of the (strong) EP which is particularly suitable says that the coupling between gravity and matter is such that when one writes down the laws of matter fields in a locally-inertial coordinate frame, they reduce to the form that they would have if the gravity sector was "turned off" completely (i.e. laws of physics would then take the so-called "special-relativistic" form). The enforcement of the EP dictates the "minimal coupling" between gravity and matter.

So if the scalar field in the BDD paper is considered to be a "matter" field, then their analysis says absolutely nothing about the EP (any flavor). If, OTOH, the scalar is considered to be a part of "gravity", then its coupling to EM-field clearly violates the EP. But considering the scalar field to be part of gravity can be done only in the context of some QG theory, never in QFT alone, because no QFT can describe QG.

Note also that the BDD paper is all about estimating a cutoff scale to fix the upper limit on the variation of the fine structure constant. The very presence of a cutoff scale is an indication of the fact that they work in some (unspecified) QG context, where above that cutoff QFT fails to be a valid description of nature. IOW, the violation of EP (as embodied in the variation of the fine structure constant) depends on the scale where QFT doesn't work anymore. This is precisely inside the domain of QG and outside the domain of QFT. That is just the same statement formulated in different language — QFT alone cannot say anything about the EP.

Btw, we are getting sort of off-topic here, and it seems that I am repeating the same statement in four posts already…

Best, 🙂
Marko

45. **Olivier Minazzoli**
January 15, 2014

Marko,

"with a caveat that their argumentation could be also restricted to some other, non-string theory of QG."

Well, the caveat here changes everything on whether EP is a string theory prediction, as claimed in Douglas/Kachru (mentioning Banks/Dine/Douglas), or a generic prediction that comes from QFT arguments only — which was my original point — not mentioning that it is actually not a prediction but rather an expectation.

Of course the argumentation is restricted to a theory that might have a chance to be proven well defined down to the quantum level. The point if that, as far as I know, we currently **do not** have the nonperturbative tools in order to (even simply) know whether **or not** a theory might be correct down to the quantum level.

"So if the scalar field in the BDD paper is considered to be a "matter" field, then their analysis says absolutely nothing about the EP (any flavor)."

As far as I can tell, this is not correct. If the fine structure "constant" is a function of any non-gravitational scalar field, then it violates the local position invariance and therefore Einstein EP. Indeed, then *the outcome of a local non-gravitational experiment in a freely falling laboratory is **NOT** independent of its location in spacetime* (see Will's Living review). Anyways, Banks/Dine/Douglas actually don't even mention the equivalence principle but only argue about the possibility of a variation of the fine structure constant 😛

So the question here really is: does Banks/Dine/Douglas paper show that string theory in particular predicts the invariance of the fine structure constant? or rather that QFT seems to put a strong constraint on string theory (among other theories)?

Otherwise, I don't think we are off-topic here. But maybe Peter would indeed prefer if we were continuing our discussion privately. Peter?

Best 🙂

Olivier

46. **Peter Woit**
January 15, 2014

Olivier,
I don’t think you’re off-topic, but I do think this has gotten to the point where it would be better if the two of you continue the discussion privately. If either of you needs help figuring out how to contact the other, let me know.

What Scientific Idea is Ready for Retirement?

January 14, 2014
Categories: Multiverse Mania

Every year John Brockman's Edge web-site hosts responses to a different question. This year the question was What scientific idea is ready for retirement?. It shouldn't be too hard to guess what I chose to write about, with results available here.

Every year Brockman manages to attract more responses, so this is now getting to be a statistically significant sampling drawn from the population of people who write about science for the general public. Before trying to divine some general trends among the physics responses, I'll first mention a few of them that stand out as unusual.

First, there's one from Paul Steinhardt that I very much agree with. He's had it with the multiverse and thinks it needs to go. I'm very glad to see someone else making many of the points that I endless repeat on this blog in a tiresome way. So, go read what he has to say, which ends with this challenge to the theoretical physics community:

> I think a priority for theorists today is to determine if inflation and string theory can be saved from devolving into a Theory of Anything and, if not, seek new ideas to replace them. Because an unfalsifiable Theory of Anything creates unfair competition for real scientific theories, leaders in the field can play an important role by speaking out—making it clear that Anything is not acceptable—to encourage talented young scientists to rise up and meet the challenge.

It would be great to see someone other than him and David Gross start publicly speaking out.

A second outlier is Gordon Kane, who uses this as an opportunity to claim that he had predicted the Higgs mass using string theory. I don't know of anyone other than him who takes this seriously. He doesn't mention his other string theory based predictions, which include the prediction that the LHC should already have seen gluinos.

Another odd one is from Max Tegmark, who argues that we have to get rid of equations in physics that aren't just based on finite and discrete quantities. The only positive argument I can see from him for this is that it would help get rid of the "measure problem" of the multiverse, but listening to Steinhardt and dumping the multiverse itself seems to me a much better idea. Tegmark has a new book out, I'll write more about this here in a few days.

Maria Spiropulu is with me on the need to retire naturalness, also wants space-time to go. Getting rid of space-time has multiple proponents, including also Steve Giddings and Carlo Rovelli.

Another theme is people starting to sound like John Horgan, announcing we're reaching the limits of science. Martin Rees thinks that some scientific problems may never yield to our understanding: "The human intellect may hit the buffers". Ed Regis thinks the cost of a next generation collider is just not worth it for what it is likely to tell us.

A variant of this is the argument that we've reached the end of the road for unification and simplicity in our basic physical laws. Here the argument often seems to be that since SUSY/GUTs/string theory were such beautiful elegant ideas, their failure means the whole elegance thing is misguided. Another point of view (which I think someone wrote a book about) would be that these always were heavily oversold as "elegant", since if you looked into them they were rather complicated and didn't explain much. Writing in the anti-elegance vein are experimentalist Sarah Demers:

> It is time for us to admit that some of the models we have been chasing from our brilliant theory colleagues might actually be (gorgeous) Hail Mary passes to the universe.

along with Marcelo Gleiser and Gregory Benford. At this particular time in intellectual history, it seems that hardly anyone has anything good to say about mathematical elegance as a powerful principle behind deep ideas about physics.

Finally, the biggest contingent are the multiverse maniacs. There's Andrei Linde, who deals with the problem of evidence for his ideas by:

> A pessimist would argue that since we do not see other parts of the universe, we cannot prove that this picture is correct. An optimist, on the other hand, may counter that we can never disprove this picture either, because its main assumption is that other "universes" are far away from us.

He's joined by Sean Carroll, who wants to do away with the Popperazi and their inconvenient demands for falsifiable predictions. Also writing in support of the idea of a multiverse of different physical laws, implying we'll have to give up on the idea of understanding more about the ones we see are Lawrence Krauss and Seth Lloyd.

Update: A couple more late additions that I missed. Eric Weinstein is with me in going after "string theory is the only game in town" as something that should have been retired long ago. Alan Guth uses this venue to promote some recent speculative work on the arrow of time with Sean Carroll (no paper yet, so hard to tell what it really is).

Update: Sean Carroll has a blog posting up about his argument for getting rid of falsifiability. He seems to not be getting a lot of support, either in his comment section (see for instance here), or places like here. I don't think the skeptic community is ready to disarm itself intellectually in arguments against religious believers by ditching the conventional scientific method.

Update: Scott Aaronson writes here about the falsifiability issue, pointing out about string theory/multiverse research that

> I wouldn't know how to answer a layperson who asked why that wasn't exactly the sort of thing Sir Karl was worried about, and for good reason.

Sean Carroll responds that the problem here is

> somber pronouncements about non-falsifiability from fuddy-duddies.

Comments

1. **tulpoeid**
   January 14, 2014

   Half of the answers you cover make me wish that the public will one day demand to end public funding of theoretical physics. It'll definitely be more beneficial to science compared to the present state.
   If the public can achieve the end of private funding as well we're even more on the correct path. And while we're there, can the public also make it quick? :p

2. **Tim Howells**
   January 14, 2014

   I'm puzzled by Prof. Steinhardt. See this video from April 2011:
   http://www.youtube.com/watch?v=IcxptIJS7kQ

In this talk he describes string theory (starts at 44:40 mark) as a very elegant theory that unifies many observations and has great explanatory power, and which is the only game in town anyway etc etc. He cautiously criticizes cosmic inflationary theory but only because he wants to propose a new theory in which "Brane-Worlds" existing in 11 dimensional space bounce off each other eternally, with each bounce creating an effect that is almost indistinguishable from the big-bang, but possibly with different settings for the natural laws etc etc.

By contrast his Edge paper sounds very coherent and sensible, and quite inconsistent with the talk at least in terms of string theory.

Disclaimer: I am not a physicist or a mathematician! I would be interested in comments on this by more knowledgeable people.

3. **imho**
January 14, 2014

First a general statement, from a cond matt theorist perspective. It seems to me that you guys are 1.5 good papers away from deriving gravity from the thermodynamics of entanglement, yet I keep hearing about the multiverse and string theory… I guess old habits die hard? Thank god for the faction of the new generation that seems to have a wonderful ability to completely ignore the old guard and chart their own path. I will enjoy watching this all play out.

tulpoeid:

Don't worry, other scientists (even Physicists) have already started the process of "redirected" funding. No one thinks it's a good idea to end public funding, but it's probably a good idea to reduce the number of young people in certain fields.

4. **Shantanu**
January 14, 2014

Peter: one more thing which Maria has mentioned is possible death of particle dark matter
which I too would have pointed out if I had a chance.
PS: I presume the deadline for writing something is over?

5. **Peter Woit**
January 14, 2014

Tim Howells,
Steinhardt's objections aren't really to string theory itself, but to the "string landscape" idea and its version of inflationary cosmology. For more about his objections to this, see his Scientific American article, available here
http://www.physics.princeton.edu/~steinh/0411036.pdf

6. **Peter Woit**
January 14, 2014

Shantanu,
The way this works is that Brockman sends out invitations asking people to write something in December, deadline to send something to him was a week or so ago. He then does some minor editing. Those writing can see the responses as they are posted, with the order I guess inverse chronological in terms of time received.

7. **Curious Wavefunction**
January 14, 2014

I agree that string theory has not made any predictions, but isn't it a little extreme to ask that we completely "retire" the whole framework? If nothing else, isn't there some useful mathematics that has come out of it?

8. **Jesper**
January 14, 2014

I find the contribution from Sean Carroll quite weird/extreme/confused/self-contradictory. He wants to get rid of falsifiability, and yet he ends with "… but nature is the ultimate guide." To me that doesn't make any sense – I guess my point of view is quite mainstream and much repeated here…

9. **Jesper**
January 14, 2014

Just one more sentence on Sean Carroll. If 'Nature' has zero way of saying "you are wrong" – which is falsifiability – then how can it be the ultimate guide? To me it sounds more like having a Teddybear to hold your hand …

10. **Peter Woit**
January 14, 2014

Curious Wavefunction,
What I wrote was specifically about string theory unification, the idea of getting a unified TOE using strings in 10d (or M-theory in 11d). These days "string theory" often is used to refer to all sorts of things that have little or nothing to do with this, and little or nothing to do with quantized strings. One can't sensibly argue against all of "string theory" in this larger sense, partly because it does include valuable ideas, partly because it's unclear exactly what one would be arguing against…

Jesper,
I certainly agree. One of things I find most incomprehensible about Sean Carroll (as well as Max Tegmark and some others) is the way he simultaneously devotes his life to going to war with religion, taking up the banner of the scientific method, while at the same time announcing that his research shows that the conventional scientific method has to go. Of course he's right that the scientific method is more complicated than sometimes portrayed, with much more to it than "falsifiability". But the kind of theoretical work he favors (e.g. his multiverse explanation of the arrow of time) come with no convincing ideas about how to test it, with or without "falsifiability". The "nature is the ultimate guide" sloganeering does then seem very empty.

11. **Pawl**
January 14, 2014

If you search the abstracts from December's Texas Symposium on Relativistic Astrophysics, you will find no mention of "multiverse" and only two (in contributed talks) for string theory. Much of the Symposium was about cosmology, although admittedly much of that was given over to observation.

12. **Low Math, Meekly Interacting**
January 14, 2014

I sometimes think a blog post devoted to an updated view of on how one could even hope to define "(Super)String Theory/M Theory" would be a valuable endeavor, if it's not a huge inconvenience. I'm vaguely aware of the complexity from an outsider standpoint, and I think Matt Strassler, to give one example, has done a phenomenal job of helping to clarify some of these exceedingly complex issues. As a biologist I'm used to sloppy nomenclature, but in the field of HEP, "String Theory" seems to almost anything you want it to be, and different, quite well-informed HEP theorists might not even agree that what a particular investigator is doing amounts to "string theory" research. It's appears to be quite hard to even define basic criteria like "success" and "failure". Sure, maybe the ST landscape is without predictive power and many now seem to agree that this represents a failure of sorts. At least, it's a major disappointment when juxtaposed with the late-20th-century enthusiasm for the idea of a vacuum selection principle falling out of "M Theory" that would yield the Standard Model and GR as a low-energy limit. That whole notion appears to be as dead as dead can be, and has apparently been pining for the fjords for well over a decade.

But what of the rest? Lots and lots of legitimate debate about that, I think. A tool for learning more about quantum field theories? Seems like there's at least a case to be made. Its role in this new amplitude business (along with twistors and all kinds of other things I could barely comprehend)? Does anyone even aspire to know with any level of certainty? Insights into strongly-coupled condensed matter systems? Much more debatable, perhaps, but maybe not as hopeless as the anthropic principle.

I'm truly not attempting to do anything like advocate, just hoping to gain some additional clarity about it all in the public discourse, if such a thing is attainable.

Thanks!

13. **Peter Woit**
January 14, 2014

LMMI,
The complexity of some of these issues is one of the main reasons I wrote a book, and I think what's in the book holds up very well, with not that much changed in the past ten years since the book was written. For some of the more recent topics that have gotten a lot of attention as advances in "string theory", typically again there's a very complex story, which would require a book-length treatment to do justice to (but I'm not going to write that one…). For example, there are now probably close to 10,000 papers referencing the original AdS/CFT paper, and I'm not going to do justice to what they cover in one, or many blog posts. Strassler's series of several blog posts does try to do this a bit, although he ends up writing a sizable chunk of a book, just to get at one small piece of that story.

The other problem here is that I don't have the expertise to evaluate the significance of some heavily promoted supposed applications of string theory. For applications of AdS/CFT to heavy ion physics, you need a heavy ion physicist, although Sabine Hossenfelder has had some good blog entries about this. For AdS/CMT, you need a good condensed matter theorist, not me. The story about amplitudes and twistors is an incredibly complex one, I've tried to say something here about the parts I understand, link elsewhere for what appear to be the best sources of info about things I don't understand. To be honest though, I find this often a discouraging business, with sometimes a lot of people more interested in muddying the waters and making dubious claims ("string theory explains high temperature superconductivity") than in really explaining what is going on. I certainly encourage anyone who understands these issues to write clear and honest explanations of them, and I link to such things when I see them, but my willingness to devote lots of time to that thankless task is pretty limited.

14. **CFT**
January 14, 2014

I actually liked Max Tegmark's paper. He has a logically valid point, Infinity is not measureable, and thus putting anything into any kind of measureable (finite) ratio with it is ridiculous, and not logically sound. I understand the concepts of big and little just fine, and how they are relational, and how things can be measured and compared in a ratio of known sizes. I reject the premise you can put anything into a logical relationship that is truly infinite, unless you are using the term euphemistically. If you don't know how big (or small) something truly is, 'infinite' is not the correct answer. Just say, " I have no idea how big it is, or how far it goes, I have no way to measure it…my data has limits and I admit it" and you are on the road to making rational arguments that are scientifically accurate and honest about the limitations of your data. Infinity is an abstract concept. Concepts or ideas can be infinite, because they are a product of your imagination, not limited to measureable data, and not bound by physical limitations or time. Reality is by comparison, far more stringent logically, and utterly bound by the limitations of measurable (finite) data, time, and space.
*
As for Sean Carroll,
I ditched his blog a long time ago when I realized he talks out of both sides of his mouth about the scientific method, treats the definitions of words like taffy when it is convenient. Sean has openly shown contempt for anyone who does not share his political views and has great difficulty discerning science from open political advocacy. I do understand his methodology however, if you eliminate falsifiability from the criteria of logical scientific reasoning, you can make any fanciful claim whatsoever and never be wrong or 'not even wrong' since you can always claim it is true somewhere else or 'in another universe'. IMHO: Sean would not seem to have internalized the burden of proof or evidence in THIS universe.

15. **hopffiber**
January 14, 2014

Low Math, Meekly Interacting,
there is a lot of work indeed that on the surface only seems vaguely related to string theory, like the whole amplitude business, integrability, entanglement entropy and so on. These are interesting on their own, and I hope that (even) Woit will agree that they contain many valuable ideas. However, most of these ideas comes from string theory in one way or another, mostly through AdS/CFT. And as AdS/CFT shows us, a string theory can be precisely equivalent to a quantum field theory, so the two things are really closely related, even if it might seem distant at a glance. One can do a lot of quantum field theory using string and M-theory.

And I think that talking about the landscape, sure it is disappointing and the hope of a unique theory of everything seems far gone, but really, it's the same as in quantum field theory. In QFT, we have an infinite landscape of possible models, and there is no selection mechanism at all, so one could state that QFT is very non-predictive and indicative of a multiverse. We need experimental data to select a specific QFT model, namely the standard model, and then this model in turn is highly predictive and can be tested against new experiments. This is the same that we seem to have in string theory, it's just that the we don't understand the string theory vacua as well as we understand different QFT models, and that the experimental data is a lot harder to get (since the energy scale of quantum gravity is very high). But once you select a specific string vacua, the model is in principle just as predictive as say the standard model.

16. **SA**
January 14, 2014

Not even wrong: http://arxiv.org/abs/1401.1219

17. **Peter Woit**
January 14, 2014

hopffiber,
What you write is pretty much pure hype, exactly the sort of thing that makes attempts to have a serious discussion about complicated issues pointless and unrewarding. For the last part of it, see
http://www.math.columbia.edu/~woit/wordpress/?wp_super_faq=isnt-string-theory-just-as-predictive-as-quantum-field-theory

All,

Sorry, but if it's not directly about the material in this posting, I'm deleting it as off-topic.

CFT,
"Infinity" is a perfectly well defined concept (not finite), as well as an extremely useful one. I don't see what the value is in abandoning it, other than requiring much more complicated ways of saying true things. There are some very specific cases in physics where it appears in an abuse of language, with multiverse maniacs the main offenders. But I don't see what conclusion can be drawn from this other than that they shouldn't do it.
As for political views of bloggers and others, I'm not going to allow debate about that here. However dumb such expressions can be, the arguments about them in comment sections are even stupider.

18. **Anonyrat**
January 14, 2014

The best line in Sean Carroll's piece is "Fortunately, science marches on, largely heedless of amateur philosophizing." Indeed!

19. **Anonyrat**
January 14, 2014

Even if we accept Sean Carroll's criteria of good scientific theories — they are definite and they are empirical — in place of Popper's falsifiability, his two examples are no good.

* Particles as strings is definite, but not empirical.

* The multiverse may be empirical (if you accept Carroll's reasoning) but it is not definite.

20. **Neil**
January 14, 2014

The Edge website might need to be retired. I've been trying to get on it all day without any luck.

It seems to me, though, that the very question suggests that something is wrong with physics today. It used to be that a scientific idea was retired because it was inconsistent with observation, such as the plum pudding model of the atom or the steady state theory of the universe. Now it seems to be a matter of fashion and exhaustion.

21. **Justin**
January 14, 2014

Woit, would you be optimistic if the top theorists began working on new ideas? I have this bad feeling that even if the greatest theorists were working on non-string related ideas, that they still would go nowhere. My feeling is that there's nothing left for a physics student to dream about.

22. **Low Math, Meekly Interacting**
January 14, 2014

Hi, Peter,

Oh well. I still think an "updated skeptic's survey" would be a wonderful read, but I thank you for the attention you gave my thoughts anyhow.

23. **Peter Woit**
January 14, 2014

Justin,
It's not really a matter of "new" vs. "old" ideas. It's entirely possible that progress could be made by re-examining old ideas. And, while people are trying to market the multiverse as a "new" idea, it's one that has been around forever and is now past its sell-by date.
The problem with the whole multiverse business is that it's a desperate attempt by some people to avoid admitting that certain ideas have failed. If their ideas haven't worked out, they could go do something else with their lives, or try different ideas. Instead they go on a campaign to convince people that no one can ever understand the things they've failed to understand, not exactly inspirational to physics students everywhere.

Quantum field theory is an example of a topic we still understand very poorly. Anyone who studies it will find a lifetime's worth of things to ponder. Just ignore the multiverse maniacs, wait for them to retire, and for journalists to lose interest as it becomes clear how old and tired their ideas are. Physics and math are full of fascinating, poorly understood things to think about.

24. **harryb**
January 14, 2014

Peter,

I am most of the way through Max Tegmark's new book you refrence – (Our Mathematical Universe). Its a strange brew. The first five chapters, as he admits, are mainstream, and seem perfectly lucid standard model material. Then comes the Multiverse in its various Levels.
It is interesting to see this up close – the detail of the earlier chapters and quite interesting perspectives on particle physics suddenly dissolves to leave personal statements and increasing use of exclamation marks. As his own biography unfolds in the book, you see a personality prone to hype and headlines gradually grab the Multiverse as the next great misunderstood Relativity Theory.
Tegmark's switch mid-book from lucid guide to particle physics, to wild-eyed evangelist of outre science, particularly the Multiverse, is very sobering. The two "books" sit uncomfortably – one grounded in deep theory, the other a very personal journey into extreme beliefs, which he associates with Newton, Einstein and, to Tegmark, Everett.
Physics succumbs to attribution error, and availability heuristics.
Many many wild theories were also shown wrong Mark!, one shouts at the book, but those are conveniently overlooked.

25. **Peter Woit**
January 14, 2014

harryb,
Thanks. There's a lot to say about this, both about Tegmark as scientist and about the scientific claims of the book. I'll write a lot more in a separate posting in a few days, hope to have an interesting discussion on this topic then.

26. **Patrick**

January 14, 2014

Neil: I think it's a lot easier to ditch a theory when there's a clearly better one on hand; and that's not really the case in BSM physics. Hence the cliched defence that string theory is "the only game in town." And in any case, I think it's unfair to characterise "physics" on the behaviour of this sub-field's practitioners.

27. **Chris W.**
January 14, 2014

Edward Fredkin and Stephen Wolfram should sue Tegmark for copyright infringement. Fredkin gets first dibs on the award. 🙂

28. **MR**
January 15, 2014

What is surprising to me is the idea of withdrawing the notion/concept of space and time. Even the quantic human observer is deeply attached to its own space and time, which is a mixture of the macro and micro realms. If the goal is to reduce space to the quantum space and time to the quantic time, ¿what do we mean by quantic space-time? We know little of black holes, superluminal effects, dark matter and dark energy, very little indeed to say that space-time should be deleted, seems like a bizarre idea.

29. **JR**
January 15, 2014

The more common proposal is not that space-time should be "deleted", just that space-time is emergent from something else. We have encountered numerous emergent phenomena in other areas of physics. See http://vimeo.com/65880636 for examples.

30. **Neil**
January 15, 2014

Patrick: We do not disagree. Now that I've finally accessed the Edge website, I see that most of the entries are about assumptions, organizing principles or world views that should be retired, rather than precise theories or models.

31. **Hack**
January 15, 2014

Physicists are too polite, people like Sean Carroll should be laughed right out of physics and science. In fact it is a shame Edge published his response. I will refrain from name calling, but this is utter foolishness and the sooner physicists put an end to this nonsense the better. Many years ago I thought physics was one of the last bastions of 'truth' well that is obviously no longer the case.

And yes, I know the argument, but so and so is brilliant and has made valuable contributions in others fields. Well if brilliant so and so is leading the charge into the wilderness and foolishness, maybe he's not as brilliant as everyone thinks.

32. **Peter Woit**
January 15, 2014

Hack,
Sean Carroll's point of view is unfortunately not an unusual one, but a relatively mainstream one these days. If you want to kick him out of science, you'd have to do the same thing for a bunch of prominent physicists, including various $3 million prize winners (did you read Andrei Linde's piece?). Carroll I think sees himself as Mr. Science, a voice of the physics establishment. The problem is what is going on with the physics establishment, not him (and this is the point Steinhardt was making).

33. **Jeff**
January 15, 2014

The link for Sarah Demers's statement is pointing to Ed Regis's.

34. **Peter Woit**
January 15, 2014

Jeff,
Thanks, fixed.

35. **ScentOfViolets**
January 15, 2014

I think you're letting Sean off too easy, Peter. The problem is that he is determined to present his opinions to the public as *the* voice of mainstream science on this particular subject when the reality is that he represents a minority viewpoint, in fact, I would say an extreme minority. I've seen him become quite irritated more than once when this misrepresentation is pointed out to him and he needs a public smack down by his peers on this one. Let me emphasize that I have no problems with him presenting his ideas in a book to the lay public despite the fact they are (imho) wrong-headed at best. I just have problems with him misrepresenting those views to the lay public as mainstream thinking. That sort of thing has got to stop – and won't until there is some sort of visible policing by his fellows.

36. **Kavanna**
January 15, 2014

Hail Mary pass, indeed. Is it the fourth quarter, last down?

To get back to basics: naturalness, elegance, and unification are sound approaches to modern physics. They have more than proven their worth. However, the technical avenues that we have now for implementing these ideas have been, for the moment, exhausted. And anyone who knows this history — starting with Maxwell's unification of electricity, magnetism, and light, and his prediction of the displacement current — knows that this program has worked only when it remained close to experiment and stimulated the technology needed to expand what could be tested, when adequate technology was not previously available.

These days, if you want to expand our fundamental understanding of the universe, you need to be doing astrophysics and cosmology. High-precision laboratory experiments are also worthwhile. Accelerator-based fundamental physics is dead.

Carroll is a fine popularizer of science. But his arguments about falsifiability are incoherent nonsense. It's amazing that these same people object to, say, creationism or astrology as being anti-science or non-science. The truth is that they're poseurs, riding on the historical prestige of science to perpetrate something that clearly isn't science. It may only seem so to the layperson, and even lay people, these days, are getting wise to this hoax. Steinhardt's statement about "unfair competition" is right: it's Gresham's Law applied to science: bad ideas driving out even the possibility of good ones.

Reduction of funding for theoretical physics is an idea whose time was already here a decade ago. (I mean string theory-like mania, not astrophysics or cosmology, or whatever's rooted in experimental and laboratory science.) The problem is that the people administering such reductions are almost certainly going to be the same "string/multiverse" maniacs.

37. **Bernhard**
January 15, 2014

I just read Sean Carrol's response. I don't feel like reading anything he has to say ever again. It is a barely crackpot point of view defended with academic eloquence. HEP, once feared and admired, is becoming the laughing stock of science because of these guys.

38. **Peter Woit**
January 15, 2014

ScentofViolets,
I still think that Sean Carroll is not the problem. If you know anything about academia, you know that the people with significant influence are those holding tenured full professorships at the major physics research departments. Sean is not in this category (he's an astronomy Ph.D. who didn't get tenure and is now a research associate, not even on a tenure-track line). The problem is people like Linde, Susskind, Polchinski and all too many others like them. They are the ones in leadership positions of the field, the ones claiming multiverse mania as mainstream physics, and they are the ones responsible for the problem. The day they abandon this or get a public smackdown from their peers and lose credibility will be the day Sean changes his tune. He's a symptom of the problem, not its source.

39. **emile**
January 15, 2014

Kavanna and Bernhard,

I think we probably agree on the definition of science but you two have to be careful…

Kavanna: "accelerator-based fundamental physics is dead". Really? We just found a new particle in 2012. In 2013, it was called "a" Higgs boson by CERN based on the results of the 2012 run. That's pretty fresh… Now, do you disagree with Sarah Demers who says that we should "measure the hell" out of that particle? Do you already know the answer? The LHC is re-starting at higher energy. Do you already know what will be found or not found? Should the thousands of physicists bother looking at the data at all? Nobody knows what will be found. We need to experimentally check that there is nothing else at those energies. If after running at higher energy the LHC finds nothing and the Higgs that was found looks even more Standard Model-like, then we can talk about what the future of accelerators should be. It may be a likely scenario for you and me but as scientists, we absolutely have to check.

Bernhard: you write "HEP, once feared and admired, is becoming the laughing stock of science…". First of all, for every Linde, there are a dozen theorists (phenomenologists), doing calculations that make predictions that can be tested and are tested by the 6000 LHC experimentalists. This is normal science and it is doing great. The problem comes from a minority (though high-profile) people who want to redefine science. Hundreds of -scientific- papers are coming out of the LHC , comparing predictions made by theoretical physicists with observations made by experimentalists. So the results show that the SM explains everything up to now. This still needs to be demonstrated experimentally. If that is Nature's choice, then so be it. Don't denigrate all this *scientific* work.

In general, I get annoyed with the notion that "physics is in trouble". Physics is doing just fine. I am part of a big physics dept. and the research done by my colleagues in various fields, both experimentalists and theorists, is very interesting and exciting. I wish I could live longer and work in other branches of physics. Even in HEP, science is getting done by 98% of the HEP physicists… We need to fight back when high profile physicists want to redefine the meaning of science but we should not say that physics is in trouble. We should say that these guys are not doing physics.

40. **george ellis**
January 15, 2014

What emile says is exactly right. The entire group that Peter complains about are not what most present day physics is about, see for example http://iopscience.iop.org/1367-2630/page/Focus%20on%20series. They are a very small albeit very vocal group on the fringe of mainstream physics. And they are in fact advocating, implicitly or sometimes explicitly (as in the case of Susskind and Carroll), abandoning the core feature of testability that has led to the rise of modern science. If you abandon that core, astrology is Ok too. But they do not represent mainstream physics nor even mainstream high energy physics. And in terms of philosophy, they are real amateurs.

As to Tegmark's comments on infinity: I think he's absolutely right. David Hilbert said the same thing: infinity is needed in mathematics but it never occurs in real physics. If you claim it does, then give me an experiment that will demonstrate that any physical entity whatever is infinite (number of galaxies in the universe, number of *physical* points between my fingers when I hold them 10cm apart, anything you like where it is claimed that a physical infinity of something exists). You can't. There is no such experiment. You should rather refer to the large but finite number that is relevant to physical observations and testability. Nothing is continuous on a small enough scale if spacetime is quantised, as seems to be very plausible. It just looks continuous when coarse-grained to experimentally relevant levels.

41. **Anonyrat**
January 16, 2014

Which scientific idea is ready for retirement?

It seems some of the ideas of some of theoretical physics' most elite researchers are overdue for retirement.

We know that in America, the elite retire only with golden parachutes. It seems to me the Milner prizes could serve that purpose. The elite, having received their golden parachutes, can retire along with their prize-winning ideas, keeping their dignity intact. Perhaps one (secret) condition of the prize should be that the recipient should not publish in a scientific journal again.

42. **imho**
January 16, 2014

Hi Peter,
Regarding your comments about who is influential and who isn't… I couldn't disagree more. It's not like scientific culture exists in some impregnable bubble, completely immune to the normal rules of human interaction. Of course those with the biggest microphones get heard, of course they have influence. The specific detail of their official title, while important, is not the only significant term. I would argue that young up and coming graduate students are just as interested in Sean, Peter, and Lubos as they are Linde, Susskind, and Polchinski. I would also argue that funding agencies are just as exposed to former as the latter. Your own experience is a glaring confirmation of this. The only thing special about Sean is that the ideas he's been selling for the past decade are pretty widely agreed upon to be nonsense.

43. **Peter Woit**
January 16, 2014

George Ellis,
Yes, you can formulate physics questions in ways that avoid using "infinity", but what I object to are claims that this actually solves your problem (which is what Tegmark is claiming). An example would be the "infinities" of quantum field theory, where, yes, it is often a good idea to think about the problem in terms of a finite cut-off theory. In non-renormalizable theories though, this doesn't do away with your problem, it just makes it clear that the problem is that you don't understand what is happening at the cut-off scale, and this matters when you try and calculate some physical quantities.

Similarly, the "measure problem" of multiverse theories is not one that can be removed by announcing that everything is finite. The problem isn't infinity, but that you don't really have a theory: "anything goes" is going to be an empty statement, whether things are finite or infinite.

44. **Peter Woit**
January 16, 2014

imho,
I'm sure blogs do have an influence, with for instance Lubos doing a great job of convincing graduate students to avoid string theory, and physics departments not to hire string theorists (if he starts arguing for the multiverse, that will be very helpful…). In the long term though, it's the tenured people at certain institutions who train the next generations of theorists and either succeed or don't at helping them make careers in the subject (as well as convincing their colleagues who to hire to ultimately replace them). The subtext of a lot of this debate is a battle over whether major research institutions will hire those doing multiverse research, and whether the NSF/DOE will fund grants to them. Susskind and allies often behave as if they have won this battle, but I think it's still on-going (Steinhardt's piece is an important salvo). When the whole business started more than ten years ago I thought it was so ridiculous that it would go nowhere, but I was very wrong about that, and have no prediction now for where things will end up.

45. **notagain001**
January 16, 2014

Peter what do you think of Ed Witten's argument for string theory?
He's a true believer

http://scgp.stonybrook.edu/archives/996
ed witten's take on string theory

You claim that string theory is the only theory that incorporates quantum gravity. Some physicists make the same claim about a different theory: loop quantum gravity, which unlike string theory does not require any extra dimensions. This has generated some controversy in the literature. What is your take about this?

Instead of taking your question literally and giving a negative answer, I'd prefer to answer anotherquestion. One really can only expect string theory to be related to areas of mathematics and physicsthat have real substance. And indeed, it has fascinating links with numerous areas of science. A list would be too long to offer here, but would have to include the theory of strongly interacting gauge theories, heavy ion physics, the theory of quantum critical points, topological field theory, topological insulators, noncommutative geometry, twistor theory, and on and on.

46. **Peter Woit**
January 16, 2014

notagain001,
This really is off-topic, and discussed ad nauseam on this blog. The best answer to the question of where I disagree with Witten about string theory is that I wrote a whole book about this ten years ago, and I don't think much has changed since then (except for SUSY not appearing as Witten and other string theorists had hoped…)

47. **Bernhard**
January 16, 2014

emile,

I used "HEP" without much care. I agree with you first paragraph, after all I am myself part of the effort. I used HEP because people talking about this sort of baloney (and I also agree we should not even say this guys are doing physics) are in majority connect to HEP. Considering they are very outspoken and powerful this tend to affect people doing real HEP.

About physics being in trouble, well that is certainly not my feeling working with it and also not the feeling I have when I go to conferences. But it is definitely my feeling when I read a lot of current outreach material, which is read by everybody (hence my laughing stock comment).

Perhaps after these guys are gone people will just forget about all this multiverse business. What worries me is that people defending this crap are very influential and how much they will infect the youngsters is still to be seen.

48. **Hack**
January 16, 2014

emile and george ellis,

What you say may be true, physics is not in trouble, it's just a few over hyped physicists. The problem than is that these over hyped physicists are the face of physics, supposedly the best and the brightest! I teach a conceptual physics course, what do the vast majority of my students ask me about? String theory. Because of these over hyped physicists, many students have asked about and believe that string theory is correct and is a valid old fashioned scientific theory. In fact I have a had a hard time convincing them to just look at it as an unproven, untestable theory. Meanwhile, very few students know about things such as dark matter, dark energy, super conduction etc. Now we can blame educators or publishers or journalists. But in the end this 'policing' resides with the physics community, they are the only ones that can put a stop to this nonsense (or if some how funding dried up). If the statement 'physics is in trouble' bothers you I understand, a lot real testable physics research is being done. But than it seems to me you need to get rid of the people who hype their foolish theories or at least get them to shut up. As I said before, physicists are too polite. Oh, which reminds me, students also ask me a lot about the multiverse, lucky me.

49. **srp**
January 16, 2014

Hack, dark matter and dark energy get tons of media play. Admittedly, much of this is redundant or badly explained, but as mysterious "we don't know what's going on" stuff they are naturally appealing to lay audiences.

It's an interesting fact that lay audiences are usually a lot more curious about what is unknown than in what is pretty well known–a naive view would suggest that people would want to get "the good stuff," high-quality tested and articulated knowledge. But I think the notion of a mystery, a story whose ending is unknown, is intriguing, while something worked out is more threatening and mentally confining to the lay audience.

50. **george ellis**
January 16, 2014

I agree more needs to be done on the public relations side for solid physics. Here are a few of the books that do so:

1. Stuff Matters by Mark Miodownik
http://www.theguardian.com/books/2013/jul/03/stuff-matters-strange-miodownik

2. The first half of Jim Baggotts' book Farewell to Reality, see

http://www.math.columbia.edu/~woit/wordpress/?p=6002

3. The Theory of Almost Everything: The Standard Model, the Unsung Triumph of Modern Physics by Robert Oerter

http://www.goodreads.com/review/show/388743664

4. The Wave Watcher's Companion: Ocean Waves, Stadium Waves, and All the Rest of Life's Undulations Gavin Pretor-Pinney

http://books.google.co.za/books?id=5YRUDDDwxNgC&dq=The+wave+watchers+guide&hl=en&sa=X&ei=g7HYUtDoOYGM7QbNkoGgBg&ved=0CDIQ6AEwAA

and of course

5. QED: The strange theory of light and matter by Richard Feynman

http://books.google.co.za/books?id=Uv-uxB0sRKEC&printsec=frontcover&dq=qed+feynman&hl=en&sa=X&ei=6LHYUviTM6Wq7QbR6oDgCQ&ved=0CC8Q6AEwAA#v=onepage&q=qed%20feynman&f=fa

and a host of astronomy books such ss

6. Gravity's Fatal Attraction: Black Holes in the Universe by Mitchell Begelman and Martin Rees

http://www.amazon.com/Gravitys-Fatal-Attraction-Black-Universe/dp/0521717930

Why do they not make as much impact as the far out stuff? Maybe because they are not written in such a polemical way. And we are not served well by theoretical physicists who look down on other branches of physics as inferior and say so publicly. Nor for that matter by physicists who look down on other branches of science like chemistry and biology.

51. **Dom**
January 17, 2014

Does Carroll have an eye on The Templeton Prize?
I'm sure they would love the implications for claiming any belief is as strong as any other regardless of falsifiability.

52. **philh**
January 17, 2014

I used to think falsifiability was the be and end all. However I am not so sure, maybe someone can bring me back, although I certainly don't think it should be retired.
To me the hypothesis that life has existed on another planet is a) not falsifiable and b) is a scientifically plausible hypothesis.
There are scientific reasons to believe this hypothesis is true, and there has been scientific progress to making us more confident in its truth. The more we discover organisms that live in harsher and harsher environments there higher our confidence becomes in the hypothesis. Of course until we actually find life on another planet we should not be certain. But the way I see it we can never falsify the idea that there is no life on other planets. . Even if we visited every planet in the galaxy, life could have arisen on some of them in the time it took us to visit them, or maybe it went extinct before we got there. , or maybe it only arises on average in 1 in a million galaxies.
To me science is a mix of theory and experiment, but with experiment being the supreme judge. A hypothesis that is falsifiable if far more preferable than one that is not. However in the real world it seems things are messier than just the issue of falsifiability.
How could you falsify the idea that a human being could not survive a trip the centre of a black hole? But do you think such a statement has nothing to do with science? So whilst falsifiability is ideal, there seems to me to be other considerations. Is a hypothesis consistent with established physics? Is it implied by established physics? Can it ever be verified by data? These may not be as good a criteria as falsifiability, but i don't think such consideration should be equivalent to religious fantasy.

53. **philh**
January 17, 2014

Sorry obviously the above should read you cannot falsify the idea that there is or has been life on other planets.

54. **Michael Schmitt**
January 17, 2014

I fully support emile's statement about the quality of most scientific research in HEP and other fields of physics and astronomy. We do not need to obsess about the hype and we should not forget that much of scientific progress is incremental and unglamorous. The people who work hard for a modest advance should not be swept aside while we go after those who would occupy center stage. As George Ellis pointed out, there are serious and successful attempts to describe real progress in physics. What does it matter if uneducated undergraduates have heard more in the news about string theory than about the baryon asymmetry? Galileo, Newton, Maxwell, Lagrange, Heisenberg, Einstein, Zwicky and many others certainly did not worry about the hype of their days nor about what students were attracted to. There were plenty of charlatans in the past but physics and mathematic marched on. I hope it will continue to do so, despite some of the anti-science ideas expressed by notable, influential people.

55. **Peter Woit**
January 17, 2014

philh,
Falsifiability is definitely not the be all and end all of distinguishing science from non-science. Besides the example you give, there are plenty of others where one can see that this is a very tricky question. In situations where you don't have falsifiable predictions you need to carefully think about what the nature of the evidence is for your scientific claims. The danger with arguing for "retiring falsifiability" is that you need to say what you intend to replace it with, and ensure that you don't start adopting

justifications for your ideas that are pseudo-scientific, applying equally well to religion, for instance. Some of Sean's commenters are pointing out to him precisely this problem, that his argument for what is a scientific claim applies equally well to claims about the existence of a deity.

In the case of multiverse theories, without falsifiability, you need to check to see what exactly is being used to justify them. Sean's argument for the multiverse has often been that "String theory predicts it", changing the problem to what the justification for believing in string theory is. Then you run into the argument that "we can't test string theory because it predicts a multiverse, and we could be anywhere in this". The problem here is that you have hit circularity.

56. **Low Math, Meekly Interacting**
January 17, 2014

philh

I like to use "testable" as a criterion, if "falsifiable" is too strict or otherwise unworkable. I'm not well-versed enough in statistics to claim to be a "frequentist" or a "bayesian", but the data we have on known life that you mention leads me (and many others) to conclude that testing exobiological hypotheses is an eminently reasonable goal. It is entirely plausible that technology will advance enough even in my lifetime to directly image thousands of exoplanets in our galaxy, and spectroscopic and other data derived from those observations is likely to be informative, perhaps even definitive on an individual basis. We can adjust our exobiological expectations based on those data. We'll never be able to image all the planets around all the stars in all the observable universe, but we could reasonably hope to observe a fairly representative sampling. Surely we could make some very informed deductions once we have those data.

Can we aspire to anything remotely like this example as we explore the hypothetical anthropic landscape, especially if it says nothing sufficiently specific about our vacuum to assess plausibility, and the remaining (effectively) infinite vacua are forever beyond our horizon?

57. **Chris W.**
January 17, 2014

The importance of some sort of falsifiability can be reduced to a simple question one can ask about any idea: "If this idea was wrong, how would I know it?" Whether observations and experimental results in the physical world are relevant to answering this question depends on what the idea is about, i.e., on what problem it was proposed to address or solve.

Some people appear to conclude that not having an answer to this question justifies accepting the idea on faith, or according to one's taste. Of course, one doesn't have to fully accept an idea to investigate it and develop it to see where it leads, but the endgame in science is finding a way to meaningfully check it against observation.

I should emphasize the asymmetry that Popper wrote about frequently. Having a way to check an idea of universal scope—as physical theories are—in no way allows one to prove that the idea is correct. At most, it allows one to establish that idea has value, insofar as it has passed many tests and has (perhaps) been effective in applications.

58. **Dom**
January 17, 2014

Excuse me if I have this wrong but if we negate the idea that Life exists or has existed on other planets don't we falsify it by finding evidence that it does or has? Isn't the framing of the original position the problem here?
Using appropriate language we can easily create apparent problems with logic e.g. "This statement is false"

59. **JR**
January 17, 2014

I am with Dom on this. "life has existed on another planet" is not falsifiable, but the converse: "life has never existed on another planet" is definitely falsifiable. So we can, in principle and in practice, make progress. Compare this to "The multiverse exists" and its converse "the multiverse does not exist". As far as we know right now, neither of these is falsifiable, either in principle or in practice, so they are outside the scope of science.

60. **imho**
January 17, 2014

philh said:
To me the hypothesis that life has existed on another planet is a) not falsifiable and b) is a scientifically plausible hypothesis.

I don't think this makes any sense. Using your logic, physics couldn't make the statement "all electrons have mass X", or "Every action has an equal and opposite reaction". In this universe, there is no such thing as "absolute falsifiability" as you seem to be suggesting. I have no idea about all this Popperian pontificating, but the operational real-world criterion for scientific acceptability is: overwhelming evidence in-support-of with no know counter evidence against. For example, we can never measure the mass of every electron in the universe (even in principal), but in the 100,000 experiments that have been performed that could detect such a thing, we have never seen a deviation from the accepted quantity. Also, the idea that all electrons have the same mass fits perfectly into the currently accepted wider Physics framework. This discussion needs less philosophical nonsense and more "shut up an calculate".

61. **Peter Woit**
January 17, 2014

Maybe that's enough about falsifiability for now. I don't think it's a topic that lends itself to this kind of unfocused discussion.

62. **Simple biologist**
January 17, 2014

Reading the Edge pieces by theoretical physicist on Edge is doing wonders on getting rid of whatever residual physics envy I had left.

Thanks for Carrol et al. for that.

63. **theoreticalminimum**
January 18, 2014

I would like to react to Tegmark's response. When I was an undergraduate, it really struck me when I learnt that Nature realises the (regularised) infinite sum 1+2+3+… = -1/12 in the Casimir effect; one computes the Casimir force as being proportional to this sum, and the result is exactly what one measures in the lab. Wouldn't this stand as a counterargument to Tegmark's comment about retiring the idea of infinity? Without the series being infinite (but regularised), we cannot compute the Casimir force.

64. **Chris W.**
January 18, 2014

> This discussion needs less philosophical nonsense and more “shut up and calculate”.

Don’t forget “shut up and do some experiments” and “shut up and *think*”. These days there is plenty of calculating going on, but not necessarily with much point to it.

65. **Shantanu**
January 19, 2014

Peter, something OT to this post, but not OT to the blog.
video to a seminar by Paul Langacker at PI which gives an idea
of where particle physics/string theory is going.
http://pirsa.org/13010116/

66. **Peter Woit**
January 19, 2014

Shantanu,
Thanks. Looks like the story is still going to be “string theory very promising”, no matter how clear it becomes that it predicts nothing and the LHC sees nothing even vaguely encouraging.

67. **philh**
January 20, 2014

Hello Peter, thanks for your for your reply. I’m glad you agree that falsifiability is not the “be all and end all” of science.
I also agree that it should not retired in favor of a theory of anything,
One difficulty I have is to class all multiverse theories in the same set.
Like you, I’m unimpressed with the string theory landscape, string theory has not had any empirical data to back it up, as you point out there has no super symmetry, extra dimensions or black holes found at the LHC. I’m also unimpressed with the many worlds interpretation of QM; there are too many interpretations and no data to choose between them.
However I find it had to put the inflationary multiverse in the same bracket. The reason is just as experimentalists have failed to find anything like what strong theorists hoped for at the LHC, experimentalists have said the data favors inflation. Wmap and Planck team said this.
At the same time the source you quoted as the one you agreed with (Paul Steinhardt) said
Inflation leads to eternal inflation. Guth said the same thing..
I’m not qualified to say if Guth and Steinhardt’s statements are true or not. But If I see theorists telling me inflation is generically eternal and experimentalists telling me the data is favorable to inflation then I have to say the inflationary multiverse does not appear to be in the same boat as other multiverse proposals like the string theory landscape. Steinhardt also said it would be possible to falsify inflation by detecting a blue tilted gravity wave spectrum.
So whilst the generic idea of a mulitverse may not be falsifiable , the specific idea of an inflaitonary multiverse could it seems be falsified simply by falsifying inflation in the way the Steinhardt has suggested.

Perhaps the problem is for people to decide if a scientific hypothesis is true or false or science or not science. Why can’t each of these be a continuum? With some things obviously false and obviously pseudo science, other things being a plausible scientific hypothesis, and of course, yet others being confirmed solid science.
So If Sean Carroll tells us there’s a multiverse because of the string theory landscape I think he’s on vary shaky ground, but if says it on the back of the inflationary multiverse then it seems to me to be a little bit more solid. Have I gone wrong here Peter, if so where?

68. **philh**
January 20, 2014

Hellow IMho, your discussion of electrons is interesting. But there is a big difference between saying the electrons has mass x and answering the question, is there life on other planets?
The difference is staring you in the face, we have electrons and we can measure their mass. It’s not the same with exo planets. We cannot answer the question of life on other worlds with “shut up and calculate”. How are you going to do that?
Dom and Chris please note my discussion of multiverse above.
Low math I agree testable is better than falsifiable. However whilst I agree the tech will get better to characterise exo planets. If we find nothing, that wont falsifies the idea of life on other planets. Under the falsifiable framework people looking for exo planets aren’t doing science, but under the testable framework they are. That’s why I prefer the testable framework as better. Although a theory that is falsifiable will be always be more compelling than one that is not. Again I’m calling for a continuum here rather than black or white criteria.

69. **Kavanna**
January 20, 2014

String theory doesn’t predict the multiverse. String theory predicts nothing.

The multiverse idea was cooked up precisely to *prevent* string theory from predicting something, something clearly wrong, and thus be disproved. The multiverse idea gained ground to keep the string party going. Attempts to get rid of falsifiability are motivated by the same motive. It’s a racket.

70. **Low Math, Meekly Interacting**
January 21, 2014

philh,

I think we’re largely in agreement. Most of the arguments against “falsifiability” are straw-man nonsense anyhow, but occasionally one has enough nuance to worry about. Absolutists aren’t helpful in any case, which is where the “probabilistic” moderation I think is helpful. I doubt Popper himself would have argued otherwise. You’re right: falsifiability is always highly desirable. But if I can never falsify the prediction that “some day the Sun will rise in the West”, I can make a pretty compelling case for summarily dismissing such foolishness on time scales any mortal ought to be worrying about.

Our Mathematical Universe

January 17, 2014
Categories: Book Reviews, Multiverse Mania

Max Tegmark has a new book out, entitled Our Mathematical Universe, which is getting a lot of attention. I've written a review of the book for the Wall Street Journal, which is now available (although now behind a paywall, if not a subscriber, you can try here). There's also an old blog posting here about the same ideas.

Tegmark's career is a rather unusual story, mixing reputable science with an increasingly strong taste for grandiose nonsense. In this book he indulges his inner crank, describing in detail an uttery empty vision of the "ultimate nature of reality." What's perhaps most remarkable about the book is the respectful reception it seems to be getting, see reviews here, here, here and here. The Financial Times review credits Tegmark as the "academic celebrity" behind the turn of physics to the multiverse:

> As recently as the 1990s, most scientists regarded the idea of multiple universes as wild speculation too far out on the fringe to be worth serious discussion. Indeed, in 1998, Max Tegmark, then an up-and-coming young cosmologist at Princeton, received an email from a senior colleague warning him off multiverse research: "Your crackpot papers are not helping you," it said.
>
> Needless to say, Tegmark persisted in exploring the multiverse as a window on "the ultimate nature of reality", while making sure also to work on subjects in mainstream cosmology as camouflage for his real enthusiasm. Today multiple universes are scientifically respectable, thanks to the work of Tegmark as much as anyone. Now a physics professor at Massachusetts Institute of Technology, he presents his multiverse work to the public in *Our Mathematical Universe*.

The New Scientist is the comparative voice of reason, with the review there noting that "there does seem to be something a little questionable with this vast multiplication of multiverses".

The book explains Tegmark's categorization of multiverse scenarios in terms of "Level", with Level I just lots of unobservable extensions of what we see, with the same physics, an uncontroversial notion. Level III is the "many-worlds" interpretation of quantum mechanics, which again sticks to our known laws of physics. Level II is where conventional notions of science get left behind, with different physics in other unobservable parts of the universe. This is what has become quite popular the past dozen years, as an excuse for the failure of string theory unification, and it's what I rant about all too often here.

Tegmark's innovation is to postulate a new, even more extravagant, "Level IV" multiverse. With the string landscape, you explain any observed physical law as a random solution of the equations of M-theory (whatever they might be…). Tegmark's idea is to take the same non-explanation explanation, and apply it to explain the equations of M-theory. According to him, all mathematical structures exist, and the equations of M-theory or whatever else governs Level II are just some random mathematical structure, complicated enough to provide something for us to live in. Yes, this really is as spectacularly empty an idea as it seems. Tegmark likes to claim that it has the virtue of no free parameters.

In any multiverse-promoting book, one should look for the part where the author explains what their scenario implies about physics. At Level II, Susskind's book The Cosmic Landscape could come up with only one bit of information in terms of predictions (the sign of the spatial curvature), and Steve Hsu soon argued that even that one bit isn't there.

There's only small part of Tegmark's book that deals with the testability issue, the end of Chapter 12. His summary of Chapter 12 claims that he has shown:

> The Mathematical Universe Hypothesis is in principle testable and falsifiable.

His claim about falsifiability seems to be based on last page of the chapter, about "The Mathematical Regularity Prediction" which is that:

> physics research will uncover further mathematical regularities in nature.

This is a prediction not of the Level IV multiverse, but a "prediction" of the idea that our physical laws are based on mathematics. I suppose it's conceivable that the LHC will discover that at scales above 1 TeV, the only way to understand what we find is not through laws described by mathematics, but, say, by the emotional states of the experimenters. In any case, this isn't a prediction of Level IV.

On page 354 there is a paragraph explaining not a Level IV prediction, but the possibility of a Level IV prediction. The idea seems to be that if your Level II theory turns out to have the right properties, you might be able to claim that what you see is not just fine-tuned in the parameters of the Level II theory, but also fine-tuned in the space of all mathematical structures. I think an accurate way of characterizing this is that Tegmark is assuming something that has no reason to be true, then invoking something nonsensical (a measure on the space of all mathematical structures). He ends the argument and the paragraph though with:

> In other words, while we currently lack direct observational support for the Level IV multiverse, it's possible that we may get some in the future.

This is pretty much absurd, but in any case, note the standard linguistic trick here: what we're missing is only "direct" observational support, implying that there's plenty of "indirect" observational support for the Level IV multiverse.

The interesting question is why anyone would possibly take this seriously. Tegmark first came up with this in 1997, putting on the arXiv this preprint. In this interview, Tegmark explains how three journals rejected the paper, but with John Wheeler's intervention he managed to get it published in a fourth (Annals of Physics, just before the period it published the (in)famous Bogdanov paper). He also explains that he was careful to do this just after he got a new postdoc (at the IAS), figuring that by the time he had to apply for another job, it would not be in prominent position on his CV.

One answer to the question is Tegmark's talent as an impresario of physics and devotion to making a splash. Before publishing his first paper, he changed his name from Shapiro to Tegmark (his mother's name), figuring that there were too many Shapiros in physics for him to get attention with that name, whereas "Tegmark" was much more unusual. In his book he describes his method for posting preprints on the arXiv, before he has finished writing them, with the timing set to get pole position on the day's listing. Unfortunately there's very little in the book about his biggest success in this area, getting the Templeton Foundation to give him and Anthony Aguirre nearly $9 million for a "Foundational Questions Institute" (FQXi). Having cash to distribute on this scale has something to do with why Tegmark's multiverse ideas have gotten so much attention, and why some physicists are respectfully reviewing the book.

A very odd aspect of this whole story is that while Tegmark's big claim is that Math=Physics, he seems to have little actual interest in mathematics and what it really is as an intellectual subject. There are no mathematicians among those thanked in the acknowledgements, and while "mathematical structures" are invoked in the book as the basis of everything, there's little to no discussion of the mathematical structures that modern mathematicians find interesting (although the idea of "symmetries" gets a mention). A figure on page 320 gives a graph of mathematical structures which a commenter on mathoverflow calls "truly bizarre" (see here). Perhaps the explanation of all this is somehow Freudian, since Tegmark's father is the mathematician Harold Shapiro.

The book ends with a plea for scientists to get organized to fight things like

> fringe religious groups concerned that questioning their pseudo-scientific claims would erode their power.

and his proposal is that

To teach people what a scientific concept is and how a scientific lifestyle will improve their lives, we need to go about it scientifically: we need new science-advocacy organizations that use all the same scientific marketing and fund-raising tools as the anti-scientific coalition employ. We'll need to use many of the tools that make scientists cringe, from ads and lobbying to focus groups that identify the most effective sound bites.

There's an obvious problem here, since Tegmark's idea of "what a scientific concept is" appears to be rather different than the one I think most scientists have, but he's going to be the one leading the media campaign. As for the "scientific lifestyle", this may be unfair, but while I was reading this section of the book my twitter feed was full of pictures from an FQXi-sponsored conference discussing Boltzmann brains and the like on a private resort beach on an island off Puerto Rico. Is that the "scientific lifestyle" Tegmark is referring to? Who really is the fringe group making pseudo-scientific claims here?

Multiverse mania goes way back, with Barrow and Tipler writing *The Anthropic Cosmological Principle* nearly 30 years ago. The string theory landscape has led to an explosion of promotional multiverse books over the past decade, for instance

- *Parallel Worlds*, Kaku 2004
- *The cosmic landscape*, Susskind, 2005
- *Many worlds in one*, Vilenkin, 2006
- *The Goldilocks enigma*, Davies, 2006
- *In search of the Multiverse*, Gribbin, 2009
- *From eternity to here*, Carroll, 2010
- *The grand design*, Hawking, 2010
- *The hidden reality*, Greene, 2011
- *Edge of the universe*, Halpern, 2012

Watching these come out, I've always wondered: where do they go from here? Tegmark is one sort of answer to that. Later this month, Columbia University Press will publish Worlds Without End: The Many Lives of the Multiverse, which at least is written by someone with the proper training for this (a theologian, Mary-Jane Rubenstein).

I'm still though left without an answer to the question of why the scientific community tolerates if not encourages all this. Why does Nature review this kind of thing favorably? Why does this book come with a blurb from Edward Witten? I'm mystified. One ray of hope is philosopher Massimo Pigliucci, whose blog entry about this is Mathematical Universe? I Ain't Convinced.

For more from Tegmark, see this excerpt at Scientific American, an excerpt at Discover, and this video, this article and interview at Nautilus. There's also this at Huffington Post , and a Facebook page.

After the Level IV multiverse, it's hard to see where Tegmark can go next. Maybe the answer is his very new Consciousness as a State of Matter, discussed here. Taking a quick look at it, the math looks quite straightforward, his claims it has something to do with consciousness much less so. Based on my time spent with "Our Mathematical Universe", I'll leave this to others to look into…

Update: Scott Aaronson has a short comment here.

   if you search for the WSJ review on Google (eg 'Our Mathematical Universe' by Max Tegmark book review Peter Woit), you will be able to read the article for free from the Google search link – at least here in the US and hopefully anywhere else

   I actually read Max Tegmark arXiv paper mentioned here some years ago as I found it very interesting from a science fictional point of view and as a basis of sf world building like for example in several recent acclaimed sf novels like Anathem by N. Stephenson and the Orthogonal series by Greg Egan (Riemannian universe with metric ds^2 = dx^2 + dy^2 + dz^2 + dt^2 and lots of cool implications including speculations on what intelligent beings would look like and what the arrow of time would mean)

   Taking it seriously as applying to the universe we are living in is obviously a different issue, but I would not really be worried that much about this happening as the scientific method is still alive and well.

2. **DLB**
January 17, 2014

   He seems to confuse reality with representations of reality and forget that mathematics is a language. Though it provides rigorous objective representations and a means of standardization, mathematics remains a language and any language can be used to express lies as much as truths. Saying the reality is mathematics is like saying that language is reality.

   Just a heads up for the 'you can try here' link.

   Worked for me and I'm an European with no subscription.

4. **Max Tegmark**
January 17, 2014

   Thanks Peter for taking the time to write the thought-provoking and (I thought) eloquent WSJ review, which I found significantly more nuanced than your post above! It's not clear to me whether our views actually differ on any matters of physics as opposed to matters of speculation: what we're guessing might be ultimately turn out to be fruitful for physicists to research. Would you agree with me that parallel universe are not a theory, merely predictions of certain theories, and that some of these theories may themselves be testable by other means? For example, would you agree that inflationary cosmology is a scientific theory that can be further tested by searching for B-modes with CMB experiments, etc., and that if we choose to take inflation seriously, then it's not unreasonable for scientists to take seriously all of its predictions, even the untestable ones?

   I feel that our job as scientists is not to tell our cosmos how to be based on our emotional preconceptions (that there must be a multiverse, that a multiverse is impossible, etc.) I therefore dislike being told not to explore certain ideas. For example, I decided to meet with someone from the Templeton Foundation may years ago precisely because a famous professor told me *not* to talk with them. A key goal of the Foundational Questions Institute is to encourage people to challenge prevailing dogmas in physics, like you have yourself courageously done. I think it would be awesome if you'd join our discussions – would be be interested in attending one of our future conferences?

/Max

5. **Max Tegmark**
January 17, 2014

Thanks DLB for raising this interesting point about mathematics as a language, which ties in with the age-old debate about whether mathematics is invented or discovered. Personally, I think that it's crucial not to confuse the *language* of mathematics (which we humans clearly invent) from the *structure* of mathematics, which many mathematicians feel that they discover. For example, any civilization interested in regular 3D polyhedra would discover that there are precisely 5 of them (the tetrahedron, cube, octahedron, dodecahedron and icosahedron). Whereas they're free to invent whatever names they want for them, they're *not* free to invent a 6th one – it simply doesn't exist. The same applies to the mathematical structures that are popular in modern physics, from 3+1-dimensional pseudo-Riemannian manifolds to Hilbert spaces. Once we've classified all irreducible representations of the Poincare group, we're not free to invent new ones!
My $0.02,
Max

January 17, 2014

is the multiverse landscape of string theory limited to only those w/ 3 large spatial dimensions and 1 time dimension and 6–7 curled dimensions?

is there any reason the landscape could not also include any combination of large, curled and time dimensions that adds up to 11? i.e 6 large spatial dimensions, 2 curled spatial and 2 time dimensions? also why do the curled dimensions have to be spatial? why couldn't they be curled closed time like dimensions? i.e 3 large spatial dimensions 1 large time dimension 6 closed timelike dimensions

7. **Pat**
January 17, 2014

This past summer, Tegmark was one of the featured lecturers at TASI and his entire effort would best be described as a sales pitch. He was supposed to have a few lectures on cosmology, but what he actually did was just rip some basic slides and pretty pictures from his public lecture. It's well understood that the point of lectures at these schools is not to gain a complete understanding of the topics (especially something as fundamental, to high energy theory students at least, as cosmology), but to fill in some gaps and get somewhat comfortable with the cutting edge. Tegmark was more interested in using the grad student audience as a warm-up for his featured public lecture (there are a couple given every year at the school).

As another MIT professor (a respectable QCD guy) was one of the directors of the school, there were probably a half dozen MIT grads present. I don't think any of them attended his public lecture because they had seen this show before. When I asked why some of them why they were not interested in going, the best response was because a running joke around Cambridge is that Tegmark is more like a "used car salesman" than a physicist when promoting some of these ridiculous ideas. After going to the public lecture, me and every last student who attended could not agree more. The local organizers (who have been running these awesome schools every summer in Boulder for the last decade, at least; note to NSF and DOE, KEEP IT FUNDED) seemed embarrassed as almost every physicist in the room cringed whenever some of the sillier aspects of Our Mathematical Universe came up. What bothered me the most was the way he would try and legitimize some of his ideas by appearing to connect them to basic principles of cosmology, while any expert (or almost any grad student) knew he was blowing smoke. For instance, he would say something like "… the universe is math, it's all around us. We were just discussing this in Cosmology lecture today …" I really don't mind that he makes a buck selling this drivel, I just don't like being used as implicit endorsement of his ideas.

As for the ideas themselves, I think empty is the best way to describe them. While I'm not a huge proponent of the multiverse and I haven't read the book, I just remembered thinking that he was not really saying anything when he talked about the book. Beyond issues of predictability, postulating that Math=Physics=Everything seems more like a metaphysical statement than anything that even resembles a testable theory. No to digress, but to it's more like trying to prove that people rode around on dinosaurs by building these creation museums. In issues of faith, scientific evidence is beyond the point, so why even try? The fact that such a prominent physicist can seriously promote science fiction with the encouragement of other prominent physicists amazes me. More serious people in the community can mostly just ignore these claims, but large sums of money seem to be diverted towards such useless pursuits. I admire Tegmark's contributions to cosmology (SDSS and WMAP efforts in particular), and I'm sure other TASI students do as well, but he will forever be the butt of our jokes when we reminisce about that summer.

8. **Max Tegmark**
January 17, 2014

Thanks Pat for sharing your views on the TASI school. I take teaching very seriously and therefore welcome criticism of my lectures. I was very happy to hear the many positive comments I got from students afterwards, so I don't think it's 100% accurate to suggest that you're speaking for everyone. Just to clarify: what do you mean by "just rip some basic slides and pretty pictures from his public lecture", when I in fact spent most of my lectures deriving equations on the blackboard, and the long and fun student discussion sessions we held involved no slides whatsoever? You're referring to the school of 2013, right?
/Max

9. **Pat**
January 17, 2014

Max,

On second thought, I may have been too harsh in comments about your Cosmology lectures. To me they just seemed very basic, but half of the students worked on QCD, not BSM physics or cosmology. I don't envy the task of trying to make cosmology material interesting while still having to start from scratch over only 3 or 4 lectures. And at some level what's basic material for physics grad students will overlap with basic material in a public lecture. I thought the lectures were fun and I find The Mathematical Universe interesting and, obviously, provocative. My issue is mainly blurring the lines of science, reality and philosophy. Maybe a having such a different perspective is the point, but larger ideas are typically beyond my pay grade as a BSM phenomenology grad student.

10. **Anonyrat**
January 17, 2014

Isn't it a matter of human psychology more than anything else that there are only 5 regular 3D polyhedra is a surprise, seems like a discovery, while 2+1=3 does not?

11. **Florin Moldoveanu**
January 17, 2014

I acknowledge that Tegmark's position is not popular and smells of being crackpot, and also that Tegmark has sharp political skills, but solely on the scientific value of the idea, it has real merit and I want to defend it.

If reality is not mathematics what is reality based on? Now we have two choices: (1) the question is not well defined (2) reality is based on "something". For option (2) the obvious question is who created that "something"? This may lead us to the idea of "God", but this is not necessarily true. If the idea of ontology is enlarged (like in "the mathematical universe“), software programs, even cartoon characters may be considered ontological and who is to judge that one ontology is better over another? For a software program, it is not “God” who created the program, but a software engineer, who belongs to another ontological level, and so there could be valid levels of recursions in defining reality. The recursion will either end or not (does God of the gaps ring a bell?). A natural termination criterion for this hierarchy is “reality is ultimately mathematics”.

So “the mathematical universe” idea has at least some handwaving arguments going for it, unless choice (1) is true, or maybe the ontological layers go on forever. So the question is not in the least settled. To convince the skeptics, what is needed is to derive mathematical consequences from it. For example, we know that space time is 4 dimensional, we know that nature is quantum mechanical at core, we know the gauge symmetries of the Standard Model. Can we derive this from “the mathematical universe” idea? In effect this means solving Hilbert’s sixth problem of physics axiomatization. Now this I believe it is possible in principle. But to do it, you need to turn Tegmark’s approach upside down: it is not important how reality and mathematics are similar (you are a mathematical theorem says Tegmark), but how they are different. This generates physical principles which distinguish (select) particular mathematical structures from the infinite world of mathematics. Every mathematical structure is unique, but very few are distinguished by nature. As a side note, this bypasses the Gödel’s incompleteness theorem roadblock because the final selected mathematical structures do not have to be in a closed form of a monster meta-structure. If the physical principles are correctly chosen, we should pick precisely the mathematical structures which are used by nature, nothing more nothing less. And this approach actually started to produce results. In particular I am able to derive quantum mechanics in the c*-algebra formalism! (I had submitted preliminary results for publications to serious journals).

So what about being a mathematical theorem? Am I a mathematical theorem? This is malarkey as Joe Biden would say. Mathematical structures are the ultimately building blocks of reality, but they arrange in such a way to avoid contradictions. I think we will be ultimately able to show that this leads to the concept of time, but this is a separate story. As “ugly bags of mostly water”(https://www.youtube.com/watch?v=paH97dYR6Lg) we are “entropy and information parasites” and our existence is not a mathematical necessity.

In conclusion, I think mathematical structures are the ultimate building blocks of reality, but demanding reality to be a mathematical theorem is too constraining and incorrect. But don’t take my word for it and be skeptical. In a year’s time I hope to pass peer review scrutiny in deriving quantum mechanics and win over the skeptics with valid mathematical proofs.

12. **Yatima**
January 17, 2014

In a sense. “Surprise” means there is high informational content. The default assumption of a primate brain would probably be “there is an infinite series of regular 3D polyhedra”, something which evidently can be checked by going into the street and ask people (one should do this!). This has less to do with psychology than with the fact that brains are not generators of theorems about the world of 3D geometry. Misjudgements of such an ethereal kind are luckily not deleterious to one’s capacity to procreate.

On the other hand, while 2+1=3 is indeed a theorem it is also a statement about the result of a program so simple that most people manage to implement it in their heads.

13. **Laymammal**
January 17, 2014

So let us look for a non-mathematical structure out there in reality to falsify this theory. What would that be? An impossible object. Even if it showed up, how would we be able to grasp it? Or we’d end up creating mathematics to accommodate it, which would make it a mathematical structure(like how we handle infinity). Looks like Tegmark’s theory is pretty secure.

14. **srp**
January 17, 2014

ISTM that the Level I multiverse is the most challenging because it simply extrapolates the consequences of well-known and tested theories to produce a hard-to-believe result. This extrapolation from the known to the unknown (and bizarre) is at the heart of Tegmark’s rhetorical question in the thread above about believing the untestable implications of testable (and non-falsified) theories. (I would like to know if most physicists and cosmologists accept the combinatorial arguments for the Level I multiverse; if so, why this highly “woo-woo” conclusion hasn’t been taken up by the popularizers and if not what is the flaw in the argument.)

But when people are skeptical of the foundation “theory” (e.g. M-theory) his rhetorical extrapolation point is much weaker–it’s easier to say that the bizarre consequences are just another reason to reject the foundational claim. In that case, his only real argument is a radically Platonist twist on Occam’s razor, i.e. that a theory with fewer asymmetries and free parameters is preferable even if it multiplies unobservable entities without measure. I suspect most people, however, find a theory with a small number of unobservable entities, even with many free but observable parameters, to be far superior to one with no free parameters and an unstructuredly infinite number of unobservable entities.

15. **vmarko**
January 17, 2014

Max (and others),

I think you are misinterpreting math to be a far too unique body of knowledge. Let me explain what I mean:

“I think that it’s crucial not to confuse the *language* of mathematics (which we humans clearly invent) from the *structure* of mathematics, which many mathematicians feel that they discover.”

I’ll be bold to say that those many mathematicians are deluding themselves in thinking so. Any mathematical statement consists of assumptions, conclusions and the rules of inference (the “A”, the “B” and the “=>” in a statement A=>B, respectively). The point is that *all* of them are arbitrary, most notably the rules of inference. The fact that most mathematicians are using ordinary first-order predicate logic as a “commonly accepted” set of inference rules, it is by no means unique or better than other, different logic systems. So saying that people *discover* math structures, based on axioms they *invented* and rules of inference that they also *invented*, is simply misleading. Math is completely a *language*, an *invented* thing, together with axioms and the ways we perform proofs of theorems based on those axioms. The fact that the first order predicate logic is commonly accepted as “the truth” is a consequence of the way our brains evolved, rather than that it is any “truth” per se. It’s just another (useful) language, nothing more. People who are doing research in mathematical logic know this for a few centuries already (so these are not just my wild opinions).

“For example, any civilization interested in regular 3D polyhedra would discover that there are precisely 5 of them (the tetrahedron, cube, octahedron, dodecahedron and icosahedron). Whereas they’re free to invent whatever names they want for them, they’re *not* free to invent a 6th one – it simply doesn’t exist.”

I disagree. If you build a 3D Euclidean vector space over a field of rational numbers as scalars, then you can prove (assuming standard logic) that none of those solids exist. Namely, an equilateral triangle doesn’t exist in such a space, given that its area is an irrational number. Imagine a civilization which didn’t invent the concept of real numbers — they could say that your “discovery of 5 solids” is plain false. This has actually already happened in our own history — Pythagoreans had problems with the diagonal of the square… And if you don’t like rational numbers, you can close them up in one of the p-adic fields, as opposed to reals. And if you don’t like modus ponens rule of inference, just choose some other logical system (oh yes, there indeed are logical systems where modus ponens does not hold).

Math is a language all the way, from “A” over “=>” to “B”. Plato’s world of ideas, that is being “discovered” in math, exists only for people who choose to use the same language for “A” and “=>”. There is no “existence” in math beyond the common language assumptions. Plato of course couldn’t have known this, since “other” logical systems have been shown to be possible only in 19th and 20th century. But today, nobody has an excuse for not studying and understanding mathematical logic…

And don’t even get me started on set theory (actually, theories), axiom of choice, Banach-Tarski paradox, etc. 😉

Best, 🙂
Marko

16. **Florin Moldoveanu**
January 17, 2014

@Marko

I highly recommend this essay by Alain Connes on mathematics: http://www.alainconnes.org/docs/maths.pdf

To this I would only have to add that mathematics is about abstract relationships and as a nice example consider the history of imaginary numbers. People did not accept them (and the very name imaginary echos its history) for more than 200 years until someone discovered a well defined matrix representation. Those abstract relationships (and physical laws) existed well before someone discovered and named them. E=mc^2 was valid during dinosaur time too.

Mathematicians are exploring a timeless landscape of abstract relationships. Which part of this landscape is explored, the order of the exploration, and the name of various part of the landscape are historical accidents.

Set theory is not necessarily the foundation of math. Category theory is a viable option. Godel incompleteness theorem is a serious roadblock but it can be avoided.

17. **vmarko**
January 17, 2014

Florin,

Maybe you misunderstood my post. I don’t have a problem with irrational numbers. I have a problem with the uniqueness of rules we claim to be valid when we prove theorems in math. Things like rules of inference, laws of excluded middle, concepts of “true” and “false”, etc. The complete body of mathematics resides on these rules, and my point is that those rules are completely arbitrary and nonunique. There are no absolute truths in math, only the ones that pertain to the language you use.

“Mathematicians are exploring a timeless landscape of abstract relationships.”

No, they are *inventing* that landscape (typically unintentionally). If you apply a different logical system to a given set of axioms, you will reach different conclusions. One could also say that mathematicians are “exploring” some landscape using tools that actually construct that landscape. Using a different set of tools would give different landscapes.

I suggest that you take a glance at the Wikipedia article about non-classical logics, there are many of them:

http://en.wikipedia.org/wiki/Non-classical_logic

The whole math ultimately boils down to a definition of a language we accept to use. There are no mathematical “objects”, or even statements, whose existence is independent of the choice of that language, which is itself quite arbitrary.

Best, 🙂
Marko

18. **S**
January 17, 2014

Leaving aside the (very important and forceful) questions about testability, etc., it’s always seemed to me that Tegmark’s “everything in math” stuff would run into some very strange consequences for our own universe, right now.

If “all mathematical structures” exist, then I guess that means (maybe?) that *every* set is somehow instantiated in reality, *every* topological space is a “spacetime” somewhere (whatever that means), and so on. But the thing is, most mathematical objects aren’t very nice. There are far more discontinuous functions than continuous ones (in a reasonable topology); there are far more non-Hausdorff topologies than Hausdorff ones; and so on.

If every mathematical object exists, then why shouldn’t our universe be one of the ones that stops being nice tomorrow? It’s basically just David Hume’s induction-skeptical argument, of course, but it seems to me that it gets very awkward for physics once you actually assert that, yes, you believe in all these universes, and that for every spacetime that acts in a nice regular way like ours up to today, and then keeps doing so tomorrow, there’s an uncountable infinity of them that acts nice and regular up to today, and then lapses into awful, unmeasurable incoherence tomorrow.

What would be the rationale for believing that *our* spacetime is one of the structures that’s nice globally?

Again, these are questions that *every* physicist and every person has to address (at least in theory), since Hume; but Tegmark, it seems to me, has given a negative answer, without drawing attention to it: we can’t. We’re probably in a universe where the laws of physics stop working tomorrow. End of story.

That seems like a big problem with the theory. But possibly I’m missing something.

19. **S**
January 17, 2014

“everything in math” should read “everything is math.” *sigh* Sorry.

20. **Florin Moldoveanu**
January 18, 2014

Marko,

You state: “There are no absolute truths in math, only the ones that pertain to the language you use.” I completely agree.

"If you apply a different logical system to a given set of axioms, you will reach different conclusions." agree again.

"One could also say that mathematicians are "exploring" some landscape using tools that actually construct that landscape. Using a different set of tools would give different landscapes." this becomes repetitive. I agree 100%

"There are no mathematical "objects", or even statements, whose existence is independent of the choice of that language, which is itself quite arbitrary." ditto

So how can I agree on all this end yet hang on the "math landscape"? I think we differ on the semantics of "existence" (As Bill Clinton put it, "It depends upon what the meaning of the word 'is' is."). Let me repeat my prior observation: math is about abstract relationships with the emphasis on abstract. The same abstract mathematical structure can have very different and distinct concrete realization. In math the notion of truth is not definable inside an axiomatic system (Tarski theorem) and there is no "context independent" notion of truth. In nature any two observers agree on an event and the notion of truth is context independent. That is why physics is an experimental science and we settle disputes between competing theories (e.g. classical vs. quantum mechanics) by experimental evidence. In physics true means agreement with nature.

When I say that nature is ultimately made out of mathematical relationships I mean there is nothing unexplained which cannot be described as a mathematical relationship (here I agree with Tegmark). This is a restatement of Wigner's position: "unreasonable effectiveness of mathematics". Where I don't agree is that reality is one giant mathematical theorem/structure. This is because nature and reality is not abstract and in nature truth is context independent. One funny way to state this is: sticks and stones may break my bones, but when was the last time you read in the news that someone was hurt by Pythagoras theorem?

Let me present an analogy (to be taken with a grain of salt like any analogy). Suppose that you want to understand ice and water, you don't know any chemistry, but a friend of yours who is a chemist tells you that ice and water are made out of the same building blocks, H2O. You are very familiar with ice but never seen liquid water before (ok this is far fetched, but please play along). What would you do? Trusting your friend would you look at the similarities, or at the differences to understand liquid water? If when you have a hammer, everything looks like a nail, you will pick the similarities and pretty soon you will run into great difficulties. If you look at the differences, you can learn something new. In this analogy the water molecules are like the abstract mathematical structures. The ice corresponds to the concrete realizations of the abstract mathematical structures into what you object that are historical accidents: set theory, groups, a specific type of logic, etc. Just like ice, those mathematical structures are immutable or "frozen". Liquid water corresponds to nature and another way to have a realization of the abstract mathematical structures: arranged in such a way to give rise to a context independent notion of truth. You don't need to agree with me on this, but from looking at the differences I can derive hamiltonian mechanics (both classical and quantum mechanics) and I am in the process of publishing this. What differences gives you turn out to be very useful physical principles. Here is a key new physical principle which I am using: the laws of nature are invariant to how we partition in our mind a physical system into subsystems. This is trivial but unbelievably powerful because the laws of nature must be invariant to tensor composition and there are only 3 possible ways this can be achieved (one of which is quantum mechanics).

Back to the math landscape. The fact that in flat 2D space the sum of the angles in a triangle is 180 is a "timeless" statement true in its context. It is the very existence of the abstract math landscape which makes proofs possible.

When we talk math which describes nature we are talking about an infinitesimal small amount of mathematical structures which are selected by nature. For example, why nature prefers SO(3,1) for example? Why not SO(p,q) with p and q arbitrarily large? Why is SO(3,1) distinguished from the infinite number of possibilities? The standard way of physics is to look at the experimental evidence and state: with so and so precision, in its domain of validity, this or that theory/mathematical structure describes nature. "Why" is not a scientific question, but a nebulous philosophical blabbering for crackpots or Nobel prize winners gone soft. What I do want to show is that this question "why" is actually very scientific and falsifiable in Popperian sense, and moreover the answer can be given in the most rigorous mathematical way. On key ingredient however is that reality is ultimately made out of mathematical relationships. To the approach of Tegmark, I have to say: show me the money. What can you derive from this hypothesis?

21. **Peter Woit**
January 18, 2014

Hi Max,
Thanks for writing in here, and graciously dealing with a rather hostile crowd.

I think you're right that we likely agree on what's physics and what's speculation. But we also I think disagree on how to handle different sorts of speculation. In my book I used the Bob Dylan line "But to live outside the law you must be honest" to try and make the point that if you're going to make yourself immune from being kept honest by experimental data, you need to take great care to not fool yourself.

Sure, inflationary cosmology is a theory (in lots of versions…) that you can extract predictions from. Like any theory, if you figure out how to test distinctive parts of it and it passes those tests, you can have some confidence that other, untestable parts of it correspond to reality. I really don't have a simplistic view of testability: for instance, I'm happy to agree that a theory can be so beautiful and mathematically compelling that I'd have confidence in it given only minimal experimental evidence. What I have no confidence in is the combination of a very complicated, uncompelling mathematical structure with no experimental evidence (I'm thinking M-theory…).

I also don't have a simplistic attitude about Templeton, and honestly would have loved to hear more in your book about the story of them and how FQXi happened. Templeton has an agenda of a peculiar kind that people should be aware of, but all money comes with some sort of agenda. I've attended one Templeton-sponsored workshop, and that was interesting. As for FQXi events, often the topics seem to be things I'm not particularly interested in (for instance your latest on information), but for some topics I'd be happy to join your discussions. As a general rule, I do think you and many other physicists would probably benefit from more interaction with mathematicians who work on core research mathematics. Math is a subject that takes on different aspects when you start to see what the structures are that the best research mathematicians are now struggling with.

Thanks again for writing in!

22. **Peter Woit**
January 18, 2014

Florin and Marko,
Enough, I don't see this going anywhere or having much at all to do with Tegmark.

23. **Orin**
January 18, 2014

S,

Yes you are missing something. If the MUH suggests that we are probably in a universe where the laws of physics stop working tomorrow (and it's not at all clear to me that it does), then it also suggests that there is a universe where the laws of physics *start* working tomorrow. From an anthropic standpoint no conscious observer would ever take notice of their "swapping" between such universes. This kind of logic can be extended to arbitrarily small time slices, of universes jumping in and out of existence, and I think ultimately leads to the conclusion that conscious observers should exist, blissfully unaware of their nature, in even the most chaotic and unseemly of mathematical soups. This is one form of the Bolzmann brain paradox, which I do think needs to be better addressed in "multiverse-aware" physics, although it is a really difficult problem of defining a suitable probability measure. And that's the rub of it. It may be that (for example due to some morphisms between/onto some mathematical structures being far more common than others in the set of all mathematical structures) that simpler , "nicer," more contiguous universes are far more probable than those ugly ones that give you pause.

Orin

24. **S**
January 18, 2014

Thanks, Orin, but I don't think I find that convincing. I see no reason why the concious observer would happen to jump into a spacetime where the laws were about to start working tomorrow (or jump into another spacetime at all, for that matter). It's one thing if we're talking about the past, at which point that might be an explanation for why we haven't noticed such a thing (though none is needed); but, given an a-priori belief in a level-IV multiverse, it completely fails to give any reason to believe that, in the FUTURE (i.e., even tomorrow), we will still find ourselves in an ordered universe.

In fact, I don't even know what "tomorrow" means in another spacetime. We're only in a single spacetime, and "tomorrow" is a point only in ours — if there's another universe, then none of the points of time in it can rightly be called "tomorrow" by us, here, now. My point is just that there's good reason to believe that, of all the mathematical structures whose "initial part" (i.e., that part which we've already experienced or can observe) is consistent with our universe so far, very, very few of them stay good for us for another day.

Of course, these questions would be easier to discuss if the theory in question were better defined, and Peter's point is perhaps therefore the most relevant; but I do think that it's already well enough defined to raise this fairly serious concern; unless, of course, I am missing something (else).

25. **S**
January 18, 2014

Orin,

As I think more, I suppose you are saying simply that somebody else will begin who happens to remember what the past was of the person in the doomed universe that went crazy. That would make sense as far as it went, except that I think far too much is assumed in applying the anthropic principle in such a way.

If every mathematical structure exists as a spacetime, then there will also be those where YOU exist, but everything ELSE goes crazy; and I would argue again that, of those, we should expect that in almost all of them, everything else will stop working tomorrow. (This argument of course cannot be made rigorous beyond the level of analogy to simpler mathematical contexts, but I find the analogies quite powerful).

As you say, this is getting close to a Boltzmann brain paradox, except that the concern instead is with the persistence of physics, beyond the observer, into the future. And yes, finding suitable probability measure is a problem, but the best analogies we have suggest that the answer won't look very good. I think I fail to see the motivation for adopting a theory that asserts the existence of such problems (At the very best, on a level-IV multiverse, we would have to say we have no reason in the world to believe that the laws of physics WILL persist outside us for another day), when there is rather little argument for the theory in the first place. Science, after all, is based (isn't it?) on the search for regularities, for laws. What is the motive or justification for adopting a theory that implies their probable nonexistence?

26. **Jesper**
January 18, 2014

First: Peter, thank you so much for your persistency. I truly enjoy following what might appear – but I think, is not – a work of Sisyphus.

Second: I have always wondered about what to me appears as a complete shift in the attitude of theoretical physics. Before string theory I think that the history of science and physics has a clear arrow towards simplicity. Maxwells equations, Einsteins Relativity, Quantum Mechanics … – even the Standard Model. To me, it all seems to point, perhaps not in a completely straight line, towards something very simple.

And then comes string theory and claims that its all an "accident", and the multiverse stuff, which seems to be infinitely worse. I never understood this.

I can't help mentioning Alain Connes here. His approach to the Standard Model is, in my reading, a natural continuation of the quest for simplicity. In his formulation he sees the Standard Model as unique. As a "has to be" theory. This kind of thinking appeals to me infinitely more than all this "lets just give up on science before we give up on our own ideas".

Also, about this Tegmark book: I haven't read it, but my immediate thought was – as you also points out – that he appears to need some kind of measure over the space of mathematical structures. Such a measure must, I guess, also be some kind of mathematical structure (which, of course, is completely absurd) and thus the idea appears to be self-contradictory – but perhaps I just haven't got the right attitude? Vibes …

27. **Jesper**
January 18, 2014

One more comment:

Max Tegmark writes: "…I therefore dislike being told not to explore certain ideas. For example, I decided to meet with someone from the Templeton Foundation may years ago precisely because a famous professor told me *not* to talk with them. "

I think its great to be a rebel and in a way I think its a problem for theoretical physics that we don't have enough of them – especially among young people (perhaps the rebels just don't survive, in our system today). But I think the real challenge is to be a scientific rebel. To come up with sci-fi ideas, such as "the universe is an atom in some huge being" is great while smoking pot, its easy – but to come up with truly new bold ideas is much harder – and that, I believe, does take a certain measure of 'rebelness'.

28. **Philip Thrift**
January 18, 2014

Seth Lloyd has a post on edge.org [http://www.edge.org/response-detail/25449] that relates to this "mathematical universe" idea that makes sense to me:

"Suppose that everything that could exist, does exist. The multiverse is not a bug, but a feature. We have to be careful: the set of everything that could exist belongs to the realm of metaphysics rather than of physics. Tegmark and I have shown that with a minor restriction, however, we can pull back from the metaphysical edge. Suppose that the physical universe contains all things that are locally finite, in the sense that any finite piece of the thing can be described by a finite amount of information. The set of locally finite things is mathematically well-defined: it consists of things whose behavior can be simulated on a computer (more specifically, on a quantum computer). Because they are locally finite, the universe that we observe and the various multiverses are all contained within this computational universe."

29. **Georg Mayer**
January 18, 2014

I don't think that is far off to be astonished about how well math fits reality – and especially how some areas of math evolved without any real-world triggers into something, that later on did perfectly fit to empirical phenomena. What is fascinating to me is that math can be thought and developed independently from the natural world and later on the two still fit together.

Therefore I think it is highly simplified to say that we use math only as a language to talk about the natural world. If so, it is at least a very (very very) well designed language, as it works surprisingly fine, even if we only use the language on its own. And I do not regard math as a language – using that term makes the subject too blurry.

From that perspective, the relation between math and reality are interesting. And they are not esoteric, as some of the most important natural sciences use math as a given and could not work without it. It seems to me therefore not far off or funny, if this relationship is examined a bit more – and that people come up with theories.

I also find it strange, that Max Tegmarks background (financing, name, family) is used (besides other, more reasonable arguments) to criticize his theory. It's to me not even wrong to talk about money and family when discussing scientific theories.

Seems like some people think of Max Tegmarks ideas as metaphysical and therefore throw the old stones, which are used since 2500 years in this fight. Natural science needs people who strive in the area which is currently thought of as metaphysics, in order to move scientific knowledge deeper into this realm, to find certainty where so far we only had mystery.

And no, I am not subscribing to multiverses or mathematical structures being the real reality – I agree that this sounds too easy (although it does not sound too empty to me). But I subscribe to respect and the diversity of ideas – out of that we get discussions and real scientific progress.

30. **Peter Woit**
January 18, 2014

Georg Mayer,
Tegmark's father, FQXi, his name change, etc. are all topics he discusses himself in the book. A major topic of the book (which I think is interesting and relevant) is the issue of how he has gone about working on and getting attention for things like the "Level IV multiverse".

31. **Joe Riley**
January 18, 2014

Since Dr. Tegmark is reading this blog (and his willingness to reply is most appreciated) perhaps he will clarify his comments that lead up to the statement (location 5796 in the Kindle version) that "The way I see it, inflation has logically self-destructed."

That would seem to have implications….

32. **Sandro**
January 18, 2014

> I'm still though left without an answer to the question of why the scientific community tolerates if not encourages all this.

Because some people are Platonists, though you likely are not. If you're already convinced of mathematical realism, then Tegmark argues for some rather natural implications of this view; for instance, it explains why even the strong anthropic principle is true, which is pretty compelling.

If you're already unconvinced of mathematical realism, then you're not likely to find anything in Tegmark' work to change your mind, but arguing the philosophy of mathematics wasn't his goal.

33. **Peter Woit**
January 18, 2014

Sandro,
Actually I am a Platonist, have no problem at all with the idea that physical reality is in some sense "mathematical". What I don't believe is that this statement by itself gives you any new useful insight beyond the already obvious fact that mathematics is our best and very powerful way of describing fundamental physics. In particular I don't believe it means Tegmark's "all mathematical structures exist" is anything other than a completely empty statement.

34. **Apostolos Syropoulos (@asyropoulos)**
January 18, 2014

The idea of a mathematical universe is similar to the idea that the universe is a enormous computer that computes its next state. In fact, Fotini Markopoulou has published a paper where she "proves" that the universe is a quantum computer! More generally, Seth Lloyd has already "showed" in Programming the Universe that the universe is a computer. And of course this goes back to Konrad Zuse who, to the best of my knowledge, was the first who put forth this "idea". Thus, in a sense, Max Tegmark is not saying something new but he repeats, maybe in a different way, an old idea. Personally, I think this idea is pure mysticism and has nothing to do with computing and mathematics.

35. **Sandro**
January 18, 2014

> What I don't believe is that this statement by itself gives you any new useful insight beyond the already obvious fact that mathematics is our best and very powerful way of describing fundamental physics.

If you believe that mathematical objects exist, then that implies that a mathematical object that completely describes our universe also exists. Why then would you insist that *our* physics/reality is not exactly this mathematical structure?

Furthermore, this implies that mathematics isn't our "best" tool, it's the *only* tool in the end. It also explains why the anthropic principles scientists often appeal to in order to explain existence are *necessarily* valid, as I previously said.

Tegmark's position addresses a number of outstanding metaphysical and epistemic questions in philosophy and science. While this perhaps doesn't provide much mathematical insight, at least, not the kind of mathematics that interests you, that's not the only kind of insight of interest.

> In particular I don't believe it means Tegmark's "all mathematical structures exist" is anything other than a completely empty statement.

Tegmark is saying that all *finite* mathematical structures exist. That's not an empty statement, and is a restriction on unbounded Platonism which is meaningful given what we now know from computer science.

36. **Orin**

January 18, 2014

S,

When you say “but the best analogies we have suggest that the answer won’t look very good.” What analogies are those? For analogies my mind first wanders to Feynman’s path integral formalism of quantum mechanics. One could look at these many crazy paths that far outnumber the classical ones, and ask how is it possible that all of these contribute, and yet we find ourselves in a classical-seeming trajectory? So I think there is precedent. And I think that it is logical that we try to extend good/successful ideas to their absolute limits.

I do not see how you jump to the conclusion that the MUH predicts lawlessness. That is far from clear. It may be that once a good measure is found that simpler laws are far more common. In a similar vein to the MUH there are various arguments in algorithmic information theory (I don’t know, see here for example) that indicate that lawful algorithms are far more common than unlawful ones in the set of all algorithms. This may be at first counter-intuitive but that doesn’t mean it is wrong!

Speaking to your point about motivation: for me the motivation is ultimately philosophical. Putting aside the argument about intrusion of philosophy into physics, philosophy for its own sake is not such a tragic endeavor. I personally will never be satisfied with a TOE unless it answers every last “why” question. Ideas like the MUH seem to come closest to actually being able to do that in a satisfying way (and as a class of ideas seem to be pleasantly unique in this regard). But of course to each his or her own.

37. **Peter Woit**
January 18, 2014

Sandro,
I still just don’t see Tegmark’s “MUH” as telling me something non-empty about physics (or math), and adding “finite” as a modifier doesn’t change this.
He may have something non-empty to say about philosophy, but, honestly, instead of paying attention to his philosophical views I think my time and other people’s would be better spent paying attention to good philosophers who have thought deeply about the subject and are working within a long tradition of others doing this. In other words, I just don’t have time for amateur philosophers, life is too short.

All,
Please, don’t use this as an excuse to post comments on what you think about general issues of math, physics and philosophy. If it’s not about Tegmark’s specific views or book, it doesn’t belong here. I can’t moderate a general philosophical discussion on these topics, and an unmoderated one rapidly becomes unreadable.

38. **Sandro**
January 18, 2014

This will be my last post on the philosophical aspect of this, as per Peter’s request above.

> I still just don’t see Tegmark’s “MUH” as telling me something non-empty about physics (or math), and adding “finite” as a modifier doesn’t change this.

Does de Broglie-Bohm and Many Worlds tell you something non-empty about quantum mechanics? Tegmark’s work is in the same vein. Perhaps you don’t find it compelling, but that puts you in the Copenhagen camp that dismissed the utility of such alternate interpretations for years, ie. “shut up and calculate!”. Alternate interpretations don’t say anything interesting if you’re only interested in empirical data or calculated predictions, since all interpretations are formally equivalent. They do have significant explanatory power though, a power that Copenhagen completely lacks.

I also think you are too dismissive of scientists doing philosophy. Philosophers aren’t as well versed in science and mathematics as you seem to imply, so their views aren’t necessarily so well-informed as you think. Furthermore, “long tradition” doesn’t count for a damn in selecting a scientific theory, or relativity and QM would never have been adopted, and it’s not a meaningful metric in philosophy either. What matters is its axiomatic parsinomy and the set of resolved and unresolved questions it answers.

If you’re not interested in what Tegmark’s work addresses in the philosophical domain, that’s fair enough, but that shouldn’t be taken as a value judgment of the work across all domains. Physicists often unknowingly do metaphysics, like the aforementioned work on interpretations of QM, and while this sometimes seems to have questionable value at the time, plenty of abstract reasoning has led to breakthroughs before.

> Sandro, […] what exactly do you mean by “exist”? Until such a statement is substantiated into something that can in principle be measured, I think it is pretty close to being empty.

This seems like a category error. Measurements are defined within universes, not across them. The MUH as a whole will forever be unobservable. You might as well ask whether the people in Sim City could ascertain that you exist.

At best, the MUH might eventually predict some interesting properties about our theories, on an epistemic or ontological level. Its real utility at the moment is in its explanatory power via its unification of computation, mathematics and physics.

39. **lun**
January 18, 2014

Max Tegmark, the statement “there are 5 and only polyhedra” is true given the assumptions of 3D flast space geometry (which isn’t even physically correct), and a given a formal definition of polyhedron.
Given different assumptions, the statement will not be true. Further more, as Godel taught us, our ability to follow from assumptions to conclusions is limited in principle, and (perhaps even more importantly), as Tarski taught us, even our ability to define things formally is limited.
Of course there are sensible and nonsensical mathematical structures, but, as your collegue Chomsky taught us, there are also levels of grammatical consistency, with a continuum of grammatically consistent sentences that make no sense.
So, to be perfectly honest, your distinction between language and structure might not be so clear. And if Mathematics is more of a language, saying “the universe is mathematical” is a vacuus statement, in principle and not just in practice.

40. **Abraham**
January 18, 2014

Prof. Tegmark’s book is clearly not a physics ,or a mathematics or a philosophy ,or a theology textbook.
Still,the book provides good and highly needed scientific entertainment which is so rare today

41. **Tom**
January 18, 2014

I am reminded of Stephen Wolfram’s book “A New Kind of Science”, wherein he also posits the “universe=math”, or more specifically, the universe is just a bunch of ‘cellular automata’ working to simple “rules”. Long time since I attempted to read book, so I could be mis-remembering.

Anyway, Wolfram's book was impenetrable and ultimately seemed little more than navel-gazing. I'm not aware of a single illuminating explanation, prediction, or retrodiction that ever arose from thinking of the "universe = cellular automata" in Wolframs book

I am very skeptical — no, disbelieving — of any attempt to claim the material, physical universe literally *is* "math structures" , unless one is twisting the conventional meaning of words the way Humpty Dumpty did.

42. **paddy**
January 18, 2014

How about this: with all respect (ahem) and as a "child" of the 70s and a still practicing physicist. my opinion is that what Tegmark "preaches" is nonsense. Such nonsense used to be confined to the "crackpot sessions" of the APS meetings.

43. **S**
January 19, 2014

(I think this comment is about the MUH in a sufficiently direct way not to run afoul of your above request, Peter — I apologize if not).

Orin,

An example that would leap quickly to mind to suggest that, in an MUH, most spacetimes might not be very nice, would be the space of all continuous functions on R^k with its canonical topology: the space of functions that are ANYWHERE differentiable is meager in this space, and prior differentiability (for example, differentiability for t < t_0) doesn't buy you any more than your hypothesis.

Another example would actually be algorithmic information theory, which you bring up: overwhelmingly most computable bit strings are not computable by short programs, and as the length n goes to infinity, the ratio goes sharply to zero if "short" means anything close to strong.

You raise the example of Feynman's sum over paths; but that sum has a measure with a great deal of content, the action. Where would one find such a measure in the space of all mathematical structures, since it is itself just another mathematical structure and another one could be supplied? You say you want every "why" question answered. Well, if the MUH does work only because one chooses a particular measure on it, doesn't that just mean that it has completely failed to answer the biggest question of all? How that is any better than simply looking for the laws that describe our own universe, I can't imagine.

I did skim with interest the paper that you linked, but it had a lot of very strong (I thought) hypotheses, none of which would apply to a space as big as the space of all mathematical structures. (Indeed, I am reminded of the NFL theorems, which again are relevant by close analogy if not directly).

At the end of the day, this perhaps comes down to taste — what is a convincing analogy, what is a strong assumption, what is an exceedingly non-parsimonious explanation relative to the phenoma it explains, etc. Perhaps we can both agree in the hope that such a structure as the Level-IV multiverse/MUH, should it ever gain currency, will be supported somehow by actual experimental evidence or devastating argument that simply defeats skepticism, and not by mere taste?

44. **Maurice Carid**
January 19, 2014

A question to those who have read Max' book: does it contain any major new insight by him that is not already contained in a Scientific American article he published more than a decade ago (http://arxiv.org/abs/astro-ph/0302131)?
Or is the book just an inflated write-up of that article?

45. **Peter Woit**
January 19, 2014

Maurice Carid,
In terms of the multiverse levels, and Math=Physics claims, the book is basically an extended version for a popular audience of the same material you can find in Tegmark's articles and other material (some linked here, more on the arXiv and available from his website). The book does cover other topics, for instance some of it is a memoir of his career, and at the end he writes about a variety of topics with no connection to math/physics issues.

All,
Please, no more comments that are not directly and specifically about Tegmark's work, and no more attempts to use this to promote your own ideas that have nothing much at all to do with Tegmark.

46. **Orin**
January 19, 2014

S,

I wrote you what I thought was a thoughtful reply, but apparently Peter removes only the one-side of a discussion that does not support his own opinion, even when the two sides are engaged in discussing the same thing (namely Max Tegmark's work).

47. **Peter Woit**
January 19, 2014

Orin,
I'm cutting off your discussion with S just as I've cut off a bunch of others. This has nothing to do with agreeing with S vs. you. My writing about Tegmark's empty claims does not mean I'm willing to host empty general discussions about math and physics inspired by him here.

This topic has become a crank magnet (I've deleted 2-3 times the number of comments you see here), making it even more clear to me the danger Tegmark's efforts pose (that of turning a once great subject into crank city). As I point out in the posting, I think the only interesting question his work raises is why it is getting attention from usually serious quarters of the community, and what can be done about the problems this raises.

48. **Neil**
January 19, 2014

Personally, I think it is useful to have brilliant thinkers like Tegmark proposing highly speculative ideas. The problem is when highly speculative ideas absorb a large fraction of researchers in the discipline, particularly younger researchers.

49. **Peter Woit**

January 19, 2014

Neil,
“Highly speculative” is one thing, “meaningless” is another…

50. **Max Tegmark**
January 19, 2014

Thanks Peter for answering some of my questions! Please help me make sure I’m understanding you correctly and not misinterpreting anything.

> Sure, inflationary cosmology is a theory (in lots of versions…) that you can extract
> predictions from. Like any theory, if you > figure out how to test distinctive parts
> of it and it passes those tests, you can have some confidence that other, untestable
> parts of it correspond to reality. I really don’t have a simplistic view of testability:
> for instance, I’m happy to agree that a theory can be so beautiful and
> mathematically compelling that I’d have confidence in it given only minimal
> experimental evidence.

So is it fair to say that you agree with me that what I call the Level I multiverse (the existence of at least some spatial regions the size of our observable universe that unobservable because light from them hasn’t yet had time to reach us) is a prediction from some inflation models that you in turn consider to be within the purview of science (testable scienfic theories/models)? Is it fair to say that you therefore view the Level I multiverse as a topic appropriate for scientific (as opposed to merely philosophical) discussion?
Please note that I’m not asking you the corresponding question about the Level II multiverse, since you’ve made your misgivings about the string theory landscape quite clear.

On a personal note, I’d also appreciate if you could explain the striking discrepancy between your blog post above and your review of my book in the WSJ: the latter struck me as quite balanced, with no mention of “grandiose nonsense”, “inner crank” or non-scientific speculation related to my family, name, funding, motivation, etc.
/Max

51. **Bernhard**
January 20, 2014

Max Tegmark,

One problem I see with the multiverse (and I understand that also includes your Level I) as just another prediction of a theory is that it can be used to justify virtually anything. Suppose another intelligent race (in this universe…) don’t yet know Mawwell’s theory, hit a intellectually wall and are trying to explain the value of the speed of light, which they can measure precisely. A multiverse “theory” can well be used to “explain” it (they happen to live in the the universe where the speed of light is correct). In this sense I am not sure how much the multiverse is really a “prediction” of inflation or a symptom of its weakness in a certain domain. While scientific valuable, the theory most likely cannot be extrapolated to explain, say, the cosmological constant, at least not in a non-environmental way.

PS: I really don’t want to prolong this already confusing discussion. If Max is willing to answer, it would be interesting to read what he thinks – if not, for the rest, please just ignore my comment.

52. **Bernhard**
January 20, 2014

sorry,

* doesn’t yet know Mawwell’s theory, hit an intellectual wall*

53. **Peter Woit**
January 20, 2014

Max,
Sure, a “Level I” multiverse can be an implication of an inflationary theory that you can test, and if you can get enough evidence for that theory you would have evidence for that sort of multiverse. I’m a bit skeptical that you really can get enough info about the inflaton, but sure, this is science.

About the difference between the review and the blog posting. The blog posting was aimed a very different audience, people who regularly read this blog. The aim of the review was to give an accurate picture of what’s in your book, provide some context, explain the main claim you are making, and also explain why it’s empty. I don’t think anyone reading it will miss my argument that this is a book making grandiose but empty claims.

In the blog entry, there’s a part devoted to discussing in detail your claims about testability, there because it wouldn’t fit in the review. Besides that though, the blog entry is really about a different question than the review: why is an even emptier argument than the string theory landscape getting positive attention from the public and some scientists, part of an effective campaign that has already created a highly disturbing situation in theoretical physics? The background for this I’ve written about here ad nauseam, and that context should make it clear to my readers why I’m choosing to begin with a simple and blunt characterization rather than a more polite and indirect one. I don’t think you can really disagree that claims to have figured out the ultimate nature of reality are “grandiose”, and such claims with nothing solid behind them are the province of the crank (note that I think most every theorist feels the allure of this kind of thing, we all have our own inner crank…).

The non-scientific material is there because it’s in your book, and it’s relevant to the main topic of the blog posting, which is non-scientific: why is something that traditionally would be considered crackpot science now making inroads into conventional science? How is that being done? You’re unusual among talented, successful scientists in also having a great talent for getting public attention. You’ve had significant influence in getting people to take seriously highly dubious material about the multiverse. I’m fascinated by how that has happened, although of course my main concern is how to make it stop…

54. **Bernhard**
January 20, 2014

Max Tegmark,

I realize my argument does not really hold for Level I, but then you also lose the ability to “explain” things the cosmological constant. In any case, would be interesting to read your thoughts.

55. **Igor Khavkine**
January 20, 2014

I’m puzzled by the need to invoke inflation to give an example of a theory where there exist regions of a universe inaccessible to certain observers. That can only muddy the waters by the fact that many theoretical as well as observational aspects of inflation are yet to be fully fledged out. On the other hand, already in special relativity, for any single observer (meaning an event on a worldline, or even the whole half of the worldline leading up to an event), there exist spacelike separated regions. In fact, the same thing happens in any theory with a bounded speed of propagation of disturbances (information, or whatever one might call it). All other phenomena like event horizons, Cauchy horizons, cosmological horizons are extensions of this basic property. So, it seems to me that whatever philosophical difficulties are raised by inflation have already been raised by special relativity.

56. **Joel Rice**
January 20, 2014

I would be more inclined to look at what the Standard Model does not explain, namely why there are 3 generations of fermions, rather than indulging in rampant 'modal realism' or Platonism on steroids. Perhaps getting an answer to that would point to one mathematical structure 'all the way down' – to define, rather than merely describe.

57. **Max Tegmark**
January 20, 2014

Thanks Peter for these helpful clarifications!
I've long viewed you as someone who courageously stands up for a controversial view because you feel that it is correct, even thought you get a lot of flack from the physics community for it. This is something I have very much identified with over the years, since as you know, many of my views on physics have been just as controversial as yours, and as a result, both you and I have been called crackpots.

I hope you don't find this offensive, but I must confess that I find your recent postings disturbingly unscientific. You're asking the interesting question
"Why is something that traditionally would be considered crackpot science now making inroads into conventional science?",
so why aren't you considering all logically possible answers, including the possibility that they're making inroads because the supporting arguments are actually correct and new supporting evidence has come to light? After all, many currently accepted theories (e.g. relativity theory) were also considered crackpot science by some contemporary pundits. How can you be so certain that it's a good idea to "work to stop this" if you're not willing to even consider this possibility? Instead, you appear to dismiss this possibility from the get-go and focus only on other explanations such as the science community having become dysfunctional, me personally having dubious motives, etc.

I also find your posting style disturbingly unscientific, and can't help feel that you're applying a double-standard: you keep writing interesting, respectful and carefully balanced replies to me personally about how the Level I multiverse is a valid scientific discussion topic, etc., while at the same time writing pithy sound-bites to others suggesting that everything multiverse-related is unscientific nonsense. To me, one of the core principles of scientific integrity is to only say things that you're willing to stand by. For example, when I write an anonymous referee report, I like to pretend that I'm going to sign my name under it.

My main goal in this interesting conversation with you is to identify what our common ground is (a lot, it seems!) and where we disagree. My point of view is that we don't know whether any parallel universes exist or not, but that it's interesting to explore the possibilities. In contrast, you appear to feel that this is uninteresting, and I totally respect that viewpoint – so far, so good.
Moving on to scientific claims, I make several implication claims in the book of the form "if physics theory X is correct, then multiverse level Y exists". You still haven't told me about any physics claims of mine that you feel are incorrect, so unless you tell me otherwise, I'm going to assume you agree with these too. Please let me know if this is a fair characterization of your current views:

* Level I: you agree that it's a legitimate scientific topic

* Level II: you reject it because of your misgivings about the string landscape

* Level III: we haven't yet discussed this. Do you agree that unitary (collapse-free) quantum mechanics is a (possibly incorrect) scientific theory that implies Level III?

* Level IV: you find this meaningless, but haven't identified which of my arguments you consider fallacious.

Unless I've misunderstood you (and please correct me if I have!), this means that out of the 13 chapters in my book (http://mathematicaluniverse.org – CONTENTS tab), only four (6, 10-12) contain ideas that you feel are a waste of physicists' time, and your critique of them boils down to mainly to a lack of interest, not to me making incorrect statements in them.
I'm very much looking forward to hearing what you think!
🙂

58. **Peter Woit**
January 20, 2014

Max,

First about the questions about my views. Sure Level I multiverse theories can be part of legitimate science. In practice though, they are endlessly being abused by people who invoke evidence for them to argue for the string landscape. As Igor Khavkine points out above, the idea that the universe extends indefinitely to unobservable regions, with the same physics, isn't anything by itself new or revolutionary. My views on Level II are well-known.

About interpretations of QM in general, my view is that the basic laws of QM reflect a very deep mathematical insight into the way the universe works. At a fundamental level, I think that what we still don't understand very well is how classical mechanics emerges from this (with things like "quantum Darwinism" relevant ideas). "Many worlds" seems to me one legitimate way to characterize the overall picture one is trying to understand. It doesn't though seem very helpful in getting at what we don't understand. About the claims in your book relating Level I and Level III, I've made no comment, simply because I don't understand them, and the whole idea just seems too implausible to take seriously. I am committed to only commenting about that which I understand well enough to trust my arguments. An important aspect which I value of the culture of mathematics is an insistence on keeping straight what you understand and what you don't and always knowing where that boundary is.

On Level IV, yes, I think the arguments you're making often involve meaningless, ill-defined words and sentences, so one can't find a "fallacy". The only way to pin down such arguments is to look for non-trivial implications of them. I tried to be careful in the blog entry to identify the parts of your book that claimed such implications and to explain why I thought they were not justified.

On the other issues you raise, let me make it clear that I don't think your motives are "dubious". I'm sure you believe what you are arguing for and people have the right to do what they can to make the most effective arguments for what they believe in. On the other hand, yes I do think parts of the theoretical physics community have become dysfunctional, and my arguments about this are not based on dismissing thoughtlessly the reasons people are doing what they are doing, but upon paying close attention to the issues. By the way, at this point I don't think the claim that the string theory landscape is dysfunctional science is a controversial minority view of mine, but I'd guess that it's the majority view in the physics community (maybe even within the "string theory" community, depending how you define that).

As for the claim that I often make crude sound-bite arguments about these issues, I'll just say that I do the best I can to make accurate statements about what I'm well aware are complicated issues, given the constraints imposed by the format I'm writing in. I was happy with how the WSJ thing came out, partly because I ended up with enough space to make a serious argument and important distinctions. The first draft of that piece was 900 words, which only allowed a serious argument at the cost of so little background that readers got lost. The editor decided to allow a longer (1300 words) piece, which was enough to both give the bare bones of an argument and provide some background. I'm often though in the position of writing something much more constrained by limits of space (or my time), trying to say something in much less than 900 words. This is never going to capture all aspects of the question at hand.

About your book in general, sure, large parts of it are perfectly reasonable discussions of a variety of topics. The problem though is that from the title on, it is structured as an argument for a point of view that I think is seriously misguided, one that is not just a "waste of time", but is likely to further promote the most problematic trends in this subject. I've tried to make clear exactly what my arguments against this point of view are.

As an author of a book myself, I'm well aware that it's frustrating when people discuss only one aspect of it, ignoring all sorts of things one put into it. It's true that I'm just ignoring a lot of what's in the book, just because I have nothing very interesting to say about it. To give one example, when I first saw that you were going to discuss the "singularity", my knee-jerk reaction was "Oh no, another Kurzweilian technological optimist…", but when I read that part of the book I saw that I was wrong, you have a much more interesting take on that subject. So, you see, sometimes I can say something positive…

59. **Roger**
January 20, 2014

The analogy to relativity is weak. Relativity always had solid experimental support, with Michelson-Morley 1887 and relativistic mass experiments starting in 1902. There is no experimental support for the string landscape, many-worlds, or the math multiverse, nor is there likely to be any in the foreseeable future.

Max, you have labeled your chapters as being "mainstream" or "controversial". You should not be surprised that the criticism of your book has been centered on the chapters that you labeled controversial.

60. **srp**
January 20, 2014

Since Peter has stated that the Level I multiverse seems methodologically OK and even agreed that it follows from special relativity, do we then have to assent to the argument that there must be a huge number of slightly different copies of ourselves out there, etc.? In other words, is the Borgesian stuff a straightforward logical deduction from the existence of the Level I multiverse or not? And if it is, should we just shrug it off on the basis of its direct unobservability?

61. **Peter Woit**
January 20, 2014

srp,
I don't think we have significant evidence for an infinitely extended universe (or significant evidence against it), just agree that this is a question one can sensibly hope to address by studying various cosmological models and comparing them to experiment. Personally, I've never been too interested in the paradoxes that come up when you assume infinite extension, but can see why some people are. To each his or her own…

62. **jd**
January 21, 2014

Mr. Tegmark

Since I and many of my colleagues have studied and arrived at many positions similar to those of Mr. Woit, then the conclusion is that you consider our views "controversial" and that some in the community would believe us to be "crackpots." Perhaps even you? You do not help your cause Sir with such a stand. And in truth you cannot support your position from what is being discussed in the community; I know many in the field of HEP, I have many contacts, I am at a large national lab. Also, I know what is being written. I further resent the insult you make to my intelligence by assuming that I am so naive as to swallow your illogical statements. And your weak attempt to equate yourself with Einstein is obvious when you also characterized general relativity as crackpot to some. After all Hilbert also published the field equations and I sincerely doubt that any reputable scientist would consider the both of them crackpots. Some here have said you are a nice guy. I have never met you and I wonder what motivates you. There is more that could be said. For example "why aren't you considering all logically possible answers?" To the best of my ability I am considering all my own answers and those I see in the literature. Given what supporting evidence there is, I find some answers to be nonsense and I will not waste my career on them. Life is too short and there is good work to be done. Enough already.

63. **Peter Woit**
January 21, 2014

jd,
I think Max is correct to claim there are some in the physics community who think my views on string theory are "crackpot". Lubos Motl is the most prominent exponent of this view….

64. **George Ellis**
January 21, 2014

Peter,

"why is something that traditionally would be considered crackpot science now making inroads into conventional science? "

See "Physics on the Fringe: Smoke Rings, Circlons, and Alternative Theories of Everything" by Margaret Wertheim (Walker, 2011) [http://physicsonthefringe.com/] for an account of a quantum cosmology meeting at Santa Barbara where conventional scientific constraints on theories were thrown to the wind. The discussions were very similar in atmosphere to those at crank science meetings.

65. **ScentOfViolets**
January 21, 2014

There is very little — if anything — new in Tegmark's noodlings. Greg Egan famously used the 'dust hypothesis' in his *Permutation City*, and in the linked FAQ, Egan points out that his dust is almost identical to Moravec's *Simulation, Consciousness, Existence* paper.

The bottom line? 'Math is everything' is fun as a science fictional device, but there's very little 'there' there. This will continue to be the case until there's some way to tell theories of this type are wrong . . . and you can can get an experimentalist to test for what happens in the requisite setup. Sorry, Max, but science is, above all, a very practical sort of enterprise. Metaphysics need not apply.

66. **Mathematician**
January 22, 2014

MUH? Meh!

67. **OMF**
January 22, 2014

I'd just like to say that it's a little annoying to find that I have to rupture my hump making sure my calculations and research are rigorously fit enough to publish while others can actually make an entire career out of this stuff.

tl;dr bitter-vet is bitter.

68. **C Wright**
January 22, 2014

"The Universe is made of Math"

How might one begin to investigate such a claim?
Let's assume this "new" hypothesis is true and ponder a boundary condition for quick insight. One reasonable boundary condition might be at the onset of the "Big bang." We have T = 0, E >>0, and I suspect, more than a few other initial condition parameters (please feel free to mentally provide). What's the status of mathematics at this conjecture? If mathematics is non existent at this point in time, but comes into being only after T=0, then it cannot be our hypothetical constructor. Therefore, let's assume some mathematics exists at or before T=0. How much mathematics? We surely need enough to define all the universe's initial conditions. This will take more than a little mathematics – certainly more than all that is known today. Restating then, at the beginning of the universe when T=0, a lot of mathematics (maybe all of it) exists. And where does mathematics exist/reside? Don't tell me, there is no place in the universe just yet, so let's define an arbitrary place for it. Will you go for the "Great Omnipotent Depository?" (Something sounds a bit familiar with this concept.) With all this mathematics existing before the universe began, and since the "universe is made of math," I see we can also conclude that a virtual universe also exists at T=0. WTF, from our original hypothesis, we can conclude that the universe virtually existed before the universe began.

Hmm, I'm sensing more salesmanship than science. Thank you, but I'll likely pass on this book.

69. **Max Tegmark**
January 22, 2014

Dear Peter: although I'm grateful for you answering more of my questions, I'm surprised that you didn't answer the main one!
I'm sorry if I didn't ask it clearly enough – please let me ask it more explicitly. You're asking the interesting question
"Why is something that traditionally would be considered crackpot science now making inroads into conventional science?".
There are of course many possible explanations, including
1) The physics community is becoming increasingly dysfunctional,
2) A "crank" and "impresario" named Max Tegmark with a "taste for grandiose nonsense" is corrupting the physics community,
3) Money from the John Templeton Foundation is corrupting the physics community,
4) They're making inroads because the supporting arguments are correct and new supporting evidence has come to light.

Your posts above explore options 1), 2) and 3), but isn't the scientific approach to explore all possibilities, including 4)?
When I talk to physicists other than you, on both sides of the multiverse debate, they routinely mention three explanations in category 4:

a) Observations of the cosmic microwave background by the Planck satellite etc. have make some scientists take cosmological inflation more seriously, and inflation in turn generically predicts (according to the work of Vilenkin, Linde and others) a Level I multiverse.

b) Steven Weinberg's use of the Level II multiverse to predict dark energy with roughly the correct density before it was observed and awarded the Nobel prize has made some scientists take Level II more seriously.

c) Experimental demonstration that the collapse-free Schrödinger equation applies to ever larger quantum systems appears to have made some scientists take the Level III multiverse more seriously.

Is it really completely obvious that these people are all deluded and that none of these three developments have any bearing on your question?
I can't help feeling disturbed by similarities between your posts and the recent hate-mail I've been receiving from a Young-Earth Creationist: you both seem to start by assuming that your conclusion is true ("Earth is 6000 years old"/"Multiverse ideas are nonsense"), and simply avoid mentioning any evidence to the contrary. If I stop posting on your blog, it will be because your approach is too unscientific for my taste.

70. **Tom**
January 22, 2014

Paul Steinhardt has quite a distaste for the "anything goes" multiverse, eg read here:
http://www.edge.org/response-detail/25405

Does Steinhardt's "Cyclic" hypothesis, an alternative to "conventional" inflationary Big Bang theory, somehow dispense with the Level 1 and other multiverses being discussed here?

71. **Peter Woit**
January 22, 2014

Max,

About the 3 strongest examples of "experimental evidence" for the multiverse you mention.

First "c". This is kind of ridiculous. I've never heard of anyone expecting QM to fail for such larger systems, so the evidence that it doesn't can't possibly have surprised anyone or changed their mind about anything. If it did fail, that would be a huge surprise and would change people's attitudes dramatically. This is also irrelevant to any of my arguments since I don't have anything in particular against many-worlds interpretations (although I also don't think they get at the interesting questions). On the other hand, if you have any evidence for your cosmological interpretation of QM that would be different, but I saw none in your book.

About "a". Again, I'm not arguing against Level I multiverses. On the question of eternal inflation, from what I can tell we still have little to no relevant experimental evidence, although I freely admit to not being an expert on this. Since you are one, here's a question: later this year Planck will release B-mode polarization results. What does eternal inflation say about this? If Planck sees nothing, will that be evidence against inflation and people will start having less faith in an eternal inflation scenario and thus such a multiverse? If this is a subject with real connection to experiment, what's the prediction here?

About "b". Obviously I'm well aware of the Weinberg argument about the CC (it's basically the only one anyone ever brings up for a Level II multiverse). Sure, I agree that that argument and the observed value of the CC have had an influence. I don't happen to think it's particularly strong evidence, but, sure, it's at least something. No, I don't argue that anyone interested in Level II multiverse theories is a fool with no reason to be thinking about this.

As for the three explanations you have me making for interest in the Level II multiverse (as opposed to your fourth claimed correct one that it is due to increased support from experiment and better theoretical understanding), first of all, you're ignoring the main one I am making: people who have a lot invested in string theory refusing to admit their theory has turned out to be an empty failure. Do you honestly claim this is not a major contributor to interest in the Level II multiverse?

Of the three explanations you do assign to me, about Templeton I do think their money has had some effect, I don't know how much. Maybe increased interest in the multiverse in the last ten years was not affected at all by things they financed, like the 2003 "Universe or Multiverse" Stanford conference and the book that came of it. I suspect they think their money has an effect or they wouldn't have kept spending it. I don't think it's deniable that, at least in 2003, the NSF was not about to finance such a conference. In an alternate part of the multiverse where John Templeton died a pauper, I think it's fair to suspect there might be slightly less interest in the multiverse.

About your influence, again I'd find it hard to quantify, but it's non-zero. Recall that no less a source than the Financial Times tells us "Today multiple universes are scientifically respectable, thanks to the work of Tegmark as much as anyone." As for terminology, applying "impresario" to your FQXi activities and others seems to me rather accurate. To be accurate, I referred to you not as a "crank", but as a scientist who, with this book and the Level IV business in general, was "indulging his inner crank". Do you honestly have no idea what your colleagues think about this kind of thing? How many do you think believe the Level IV business is anything other than empty grandiose nonsense of a characteristically crank or crackpot sort?

As for the comparison of me to a Young-Earth creationist spewing hate-mail, get a grip.

72. **Neil**
January 23, 2014

Thank you Peter and Max for an enlightening exchange.

One comment on Templeton and the multiverse, if I may. As I understand it, maybe I am wrong, Templeton is interested in financing research that links science to god, or as they say in their mission statement, the "spiritual dimension." The multiverse is used by materialists to explain fine tuning and other existential "mysteries" as an alternative to god. I don't think Templeton has any great interest in promoting the multiverse.

73. **Jusnem**
January 23, 2014

This has been a very spirited and interesting debate. I would like to propose a compromise which I believe both sides can agree on. The mathematical universe hypothesis is a religious principle.
–
There seem to be two options to explain the existence of our universe in light of the fine tuning required for us to be here: (1) God made it that way, or (2) all mathematically possible structures exist. If there is a third option, then Mr Woit should be able to identify a specific flaw in Mr. Tegmark's reasoning. So far, I haven't seen one.
–
Mr. Tegmark's proposal provides a logical foundation for the religion of atheism. For any physicist with faith in determinism (and how can we have physics without that faith?) Mr. Tegmark's conclusion is unavoidable. With that said, I personally can't imagine any scenario where this hypothesis would be falsifiable. Of course, that should not detract from its value for inspiration and clear thinking.
–
Mr. Woit's criticism is based not on a critique of Mr. Tegmark's logic, but rather on a religious belief in God, free will, or a more traditional notion of our world. I don't see how this opposition can be reconciled with the basic assumptions that external reality exists and that physics can describe it, but it too is based on sound religious notions.
–
Of course, if this debate is really about who should get funding for what then these comments don't really add anything to the debate so feel free to ignore them.

74. **Dom**
January 23, 2014

Max – to be fair as much as I don't like the Lubos Motl type of language e.g. "crank", I was clear that Peter was referring to particular ideas rather than you as a person. I don't personally see the harm in putting forward any idea however outlandish as long as we do not give the lay person (or even the reasonably well-informed person) the idea that what we are saying is experimentally confirmed fact.
I have found what you have to say very interesting and as someone elsewhere said, you are at your most impressive when you ignore the stuff other people would take personally (hard to do, easy to admire).

75. **Peter Woit**
January 23, 2014

Neil,
Templeton's agenda is more interesting and subtle than just linking science and religion, and promoting religion (although they do plenty of that). If you look at what they don't support, they're explicit about not supporting experiment, and they pretty much avoid serious mathematics. One could say they like to support "philosophy", and their "philosophy of cosmology" initiative is part of this. I don't think they have a side pro or con on the multiverse, but it definitely is a topic they like to support discussions of. All in all, they like to support ideas and work that the scientific community doesn't normally support because it seems rather empty and unlikely to be fruitful. Some of this ends up supporting actually interesting work, some is just a waste of time, and, yes, going on about religion and science fits nicely into this.

One way of describing the effect they're going for (and to some extent achieving) is to move topics like "universe or multiverse" from the category where the consensus is "empty waste of time, best ignored" to "controversial" (i.e. worthy of debate).

76. **Lee Smolin**
January 23, 2014

Dear Peter and Max,

I was going to stay out of this debate, having in print already two books that explain why anthropic multiverse cosmologies cannot possibly yield falsifiable predictions. These books, Life of the Cosmos and Time Reborn, also put forth also an alternative program for cosmology that does yield falsifiable predictions, based on the hypothesis that laws evolve in time.

But I don't want to let pass Max's claim that Weinberg's prediction of the order of magnitude of the dark energy provides evidence for a multiverse. Weinberg's prediction happened to turn out roughly right but the argument that that provides evidence for the multiverse is based on fallacious reasoning. I explained why on page 136 of Time Reborn, from which I quote:

"One problem with that conclusion is that the critical value referred to is the one above which galaxies would not form if the cosmological constant were the only parameter that varied. But theories of the early universe have other parameters that can vary. If we vary some of those while we vary the cosmological constant, the argument loses its force.

Let's look at one case, in which we vary the size of the density fluctuations, which, as we discussed earlier in this chapter, determine how evenly the matter in the early universe was distributed. These are relevant because if they were bigger, the cosmological constant could be far above the critical value and galaxies would still form in the very dense regions created by the fluctuations. There is still a critical value for the cosmological constant, but it goes up as the size of the density fluctuations goes up.

So you can rerun the argument, letting the cosmological constant and the fluctuation size both vary over the population of universes. Now you pull two numbers out of the hat for each universe, one for the cosmological constant, the second for the size of the density fluctuations. We choose these numbers randomly, within the range in which galaxies form. It turns out that the probability of randomly getting both numbers to be as small as they are observed to be is now down from 1 chance in 20 to a few parts in 100,000.

The problem is that because we don't observe any other universes, it is impossible to know which constants vary over the hypothetical multiverse. If we assume that the right story is that only the cosmolog- ical constant can vary over the multiverse, Weinberg's argument does well. If we assume that the right story is instead that both the cosmological constant and the fluctuation size vary, the argument does less
well. In the absence of any independent evidence as to which, if any, of these hypotheses are true, the argument leads to no conclusion.

So the claim that Weinberg's argument correctly predicted the rough value of the cosmological constant fails, because of a subtler fallacy than the one discussed above. This fallacy, which is known to specialists in probability theory, arises whenever you take advantage of the freedom to arbitrarily choose a probability distribution that describes unobservable entities and so cannot be checked independently. Weinberg's original argument has no logical force, because you could reach a different conclusion by making a different assumption about unobservable entities."

(there are citations to the scientific literature in the text.)

Max, do you have a response to this or do you agree that Weinberg's argument offers no evidence for a multiverse?

Thanks,

Lee

77. **Peter Woit**
January 23, 2014

Thanks Lee,
It did occur to me after writing that comment about this that referring to your arguments about this would have been a good idea.

Another thing I could have added was the following simple point I often tried to make in arguments about this way back when. The Level II Multiverse theory of the CC is effectively the same as my own personal theory of the CC, which is that I have absolutely no idea what is responsible for its value. So, hey, no reason to think any particular value is more or less likely. I think the implications of the Level II Multiverse theory and my theory of the CC thus should be the same: from nothing you get nothing.

78. **Bernhard**
January 23, 2014

"But theories of the early universe have other parameters that can vary."

I was under the impression that in these multiverse theories one was allowed to do anything. In the book "Universe of Multiverse" ()http://books.google.se/books?id=U_Jm2DT_AVAC&printsec=frontcover#v=onepage&q&f=false on part II, when Craig J. Hogan enters with particle physics he is talking about changes in the Yukawa couplings – which by itself, could give you almost anything given enough creativity. I suppose the multiverse should even make SUSY irrelevant since it can also solve the hierarchy problem.

79. **Daniel Miller**
January 23, 2014

Hi Peter, Max and Lee,

First, I have read both Our Mathematical Universe and Time Reborn and enjoyed them both very much. I view them as popular novels appealing to a wider audience that presents both non-controversial as well as controversial ideas. I see no problem with presenting or even pushing controversial ideas provided there is no attempt to deceive. Neither book was deceptive, so there is no issue. Furthermore, these controversial ideas are often exciting and effective in attracting a wider and uninitiated audience to the subject.

Second, I appreciate the obvious importance in questioning the falsifiability of theories, as long as this process itself is carried out scientifically – lest you become a hypocrite. What I see absolutely no value in is attacking and dismissing admittedly controversial ideas outright simply because you find them exceedingly peculiar or fear their potential effects on the direction of the field, provided of course that they have some merit – which is for the field to decide. Indeed, I can easily imagine negative effects resulting from these kinds of (unscientific) attacks being much more plausible than some critical number of students being misled into studying "empty" theories and this resulting in some crisis of the field – this would require severe misjudgment on a large scale in a manner that is not compatible with the typical student of physics. In short, it's a needless concern and appears to me to be a cop-out for more legitimate forms of dismissal.

Third, radical theories, both good and bad, must often be "sold" if they are to find wide-spread acceptance – it just follows logically from the nature of revolutionary ideas and is supported by the history of physics.

Finally, being a PhD student in physics I can tell you that it wasn't very-well founded, falsifiable ideas that got me interested in physics. It was reading Thorne's "Black holes and time warps" and Kaku's "Hyperspace" as a child, which then led to Bertrand Russell's "ABC of Relativity" and more "non-controversial" material.

Finally, finally – REAL crises do exist such as global warming and nuclear proliferation that scientists are going to need to get comfortable speaking about with some emotion and zeal that they are not characteristically known for – hell, it would even be great if we had a few "academic celebrities" – because if we don't sell these issues to the public then there won't be any meaningful landscape left to falsify.

80. **Peter Woit**
January 23, 2014

Daniel Miller,

The "Mathematical Universe Hypothesis" and Level IV multiverse of Tegmark's book is not "controversial". As far as I can tell, no serious scientist other than him thinks these are non-empty ideas. There is a controversy over the string theory landscape, but none here. These ideas are also not "radical", they are content-free.

You refer to Tegmark's book as a "novel", and then you expect it to inspire young people about science, and convince the public to take scientist's warnings about global warming seriously. This makes no sense. What will inspire smart young people to be scientists is good science, not obviously empty claims. I don't think this book helps the credibility of scientists with the public one bit, quite the opposite. Yes, scientists sometimes need to sell their work to the public. But to do this, they have to have something of value to sell.

81. **Tim May**
January 23, 2014

I was at Max Tegmark's talk last night in Santa Cruz.

I made a joke to him about our weather vs. East Coast weather during the setting-up period, but had no chance to talk to him during the now-obligatory book-signing period, which appeared to be about 30-50 people long. (I bought the book via Amazon and it arrive on the day of official pub, the 17th).

He said little about multiple universes. I thought his talk was very good at what I'll call the "George Gamow, One, Two, Three Infinity" level. Understand, this was a book that mightily influenced me in the 60s when I was about 12.

(To my left in the crowd was a woman with a young boy. Tegmark spoke directly to a few of the young kids (boys) in the audience. This boy said he was 9. Tegmark asked him about his interests. "Chemistry" was not terribly surprising. But he also asked about some sums, and the kid responded correctly. And he sat during the presentation paying rapt attention, apparently. (One has to be careful about observing others, the Heisenberg Pedophelia Principle.)

So, Tegmark did a nice prevention about the frontiers of astronomy (the Hubble Deep-Field), some mentions of some stuff possibly beyond, but he did not discuss the controversial aspects of his MUH theory.

(As we were dispersing, I hear one very famous UCSC professor saying "Well, it was good that there were no questions about alternate universes." I overheard him and quipped "Don't worry, in 10 to the 700 other universes they asked questions.")

My feeling is that Tegmark's lecture, and his book, which I have skimmed since receiving it last week, are not terrible things for people to read.

I grew up on reading Gamow, Asimov, etc. on popular science, plus the then-excellent Scientific American. The weird stuff about monopoles, tachyons, etc. was out there, but one developed a good idea of what was plausible and what was longer-term, somewhat implausible.

As a long-time reader of Peter Woit's blog, and his book, but as someone who also reads Lubo Motl's blog, I think Tegmark's books is a fairly good popularization of some background in physics and cosmology and and an introduction to the more outré aspects.

(Sorry to be personal, but string theory never grabbed me. But the recent EPR = ER stuff really, really grabs be. Doesn't make it right. But it sure is suggestive.)

–Tim May

82. **Daniel Miller**
January 24, 2014

Hi Peter,

Thanks for responding – this comment thread got blown up! Aside from addressing the validity of an idea, which is clearly totally worthwhile and necessary, I was trying to speak to other separate issues which I will try to be a bit more clear about.

1) The concern that MUH will lead the field astray and waste time that could be better spent elsewhere: I was trying to say that I think this is unlikely. A similar argument has been made about string theory and the landscape, yet physics appears to not have imploded yet nor does it appear to be approaching a crisis. I'm not saying that MUH has the legitimacy or establishment that string theory has found, nor am I saying it is without merit. Nor had Max even remotely tried to claim this is an accepted mainstream idea. And this will all be clear to anyone serious about physics. So this entire concern is unwarranted.

2) Young people may be inspired toward science by ideas that stir their curiosity and which they find intellectually fascinating. This can be "good science", science fiction, or anything in between. But above all it must be interesting. What will make them "good scientists" is the entire formal process required to become a scientist. I have more than a few friends who were originally inspired to pursue science from Star Wars.

3) There is nothing inherently wrong with "grandiose" ideas, being an "academic celebrity" or selling one's ideas. In fact, these qualities are currently needed more among scientists to appeal to the public about pressing social issues. This was a statement about the virtue of these traits alone, which were mentioned somewhat derogatorily in previous posts, and not with respect to the book or the books role in promoting awareness about global warming. And, unfortunately, it is not the credibility of scientists that pushes part of the population toward climate change denial – it's the loudness, visibility and grandiosity of (totally incredible) pundits.

The overall point being that both Max and his more fun ideas have a net positive effect on both science and the world we live in.

Have a goodnight,

Dan

83. **Peter Lynds**
January 24, 2014

Hi Lee,

I can't help but question why you felt the need to mention about your own work and its ability to make falsifiable predictions. I think this is maybe a little bit rich, considering that charges of empty content and the rest could easily be pointed in your direction with regards to your recent book and arguments and claims concerning the reality of time. That is, time and the empirical don't, and will never, go together.

Peter

84. **Lee Smolin**
January 24, 2014

Dear Peter Lynds,

My logic, as was carefully explained in Time Reborn (TR), takes three steps, which in outline are:

1) The various arguments which have been given that time is an illusion, i.e. emergent from a more fundamental timeless level of description, depends on an assumption, which is the immutability of the laws of physics. This is one of the conclusions of Part I of TR.

2) Specific hypotheses about how the laws evolved are testible by real,doable experiments and observations, a few are even falsifiable.

3) Therefor, if a hypothesis that laws evolve were confirmed by evidence, the laws cannot be immutable, therefor the arguments that have convinced physicists that time is unreal would have no force.

So there is a relationship between the view of time and empiricaly testible hypotheses.

Furthermore, the hypothesis of cosmological natural selection, published in 1992, made two falsifiable predictions which continue to stand up to empirical test. It also remains the only proposed explanation for the fine tunings of the standard model that makes falsifiable predictions.

Thanks,

Lee

85. **Marcus**
January 24, 2014

IMO that 3 step argument must surely be the most interesting thing that has appeared in this thread and contains what could be the REAL reason that the natural world appears mathematical.
Since Max T. seems to like mathematical regularities/patterns, this argument, I suspect, is what the second half of his MUH book should actually have been about:

Leibniz principle of sufficient reason (for the manifest regularity Wigner referred to) implies TIME = a process by which regularities emerge and become "laws"

Thermodynamics of physical law. The universe becomes more predictable as time goes on. More "mathematical" more patterned, more regulated, more repetitive. Paradoxically beautiful and from another perspective boring: more expected and less surprising.
Like a Shannon channel whose information capacity is gradually diminishing until the listener at the other end hears nothing, or nothing he didn't already know.

So this three step argument shows us the real MUH. And there is only ONE universe in this MUH. It is unnecessary, old-fashioned, and ridiculous to imagine more than one.

Leibniz+Wigner –>time, and time is "testable" in the sense that we might someday witness the emergence of an unprecedented regular pattern.

Extremely farfetched, but still nice.

The first half of Tegmark's book, from what I have sampled, is pedagogically excellent. It reminds me of Timothy Ferris' *Coming of Age in the Milky Way*, really A-plus. Maybe it is such a good front end that it should have a different back end. :0)

86. **Peter Woit**
January 24, 2014

All,
This is turning into a discussion of another book…

Please, comments should be about the Tegmark book, and at this point coming up with something new about that might not be easy.

I promise a couple new postings soon.

87. **Peter Lynds**
January 24, 2014

Hi Lee,

Thanks. There is more I'd like to say than this, but I agree that it would be off topic. If I can, though, I would like to quickly mention that, unless one is very selective, arguments for time's non existence don't depend on the assumption that the laws of physics are immutable (I can think of plenty that aren't, including simply that time is unobservable). The thesis that the laws of physics should be mutable and internal to the universe (I don't think there can be any doubt that the latter is correct) also obviously isn't dependent on time existing.

While I disagree with his ideas, I think Max deserves credit for participating in this discussion. Hopefully he'll come back. If he does, I think some sensitivity to his position (maybe a bit like an English soccer supporter walking into a rival team's local bar) wouldn't go amiss.

Peter

88. **Roger**
January 24, 2014

I was also at that Santa Cruz bookstore lecture. I was surprised that he peppered his talk with arguments that we are not spending enough money and effort trying to reduce risk of future disasters. His math multiverse implies that time is an illusion, that we have no free will, and that all future scenarios happen, regardless of what we might try to prevent.

89. **Max Tegmark**
January 26, 2014

Thanks Lee for bringing up this important point!

> Max, do you have a response to this or do you agree that Weinberg's argument offers
> no evidence for a multiverse?
I fully agree with the mathematics in your analysis. In fact, I reached a similar conclusion in http://arxiv.org/pdf/astro-ph/0410281v2.pdf (see around 81), and so does Alex Vilenkin. The bottom line is that galaxy formation efficiency depends not on the dark energy density alone, but on what we might call the dimensionless "Weinberg" parameter W=rhoL/Q^3 xi^4, where Q ~ 2e-5 is the CMB fluctuation level, rhoL ~1e-123 is the dark energy density and xi~2e-28 is the dark matter density per photon, all

in Planck units. What Weinberg's argument gives is then a prediction for the parameter W, no more and no less. Vilenkin has emphatically argued that Weinberg's prediction for W is impressive because it predated its measurement (by observations of CMB, supernovae, etc).

On a separate note, since you too got picked on above for making controversial statements, I want to add that I find your work extremely valuable, particularly because your conclusions are so different from mine. Whenever we face a science question to which we don't yet know the answer, I find it valuable when the community carefully explores the full range of logical possibilities. On some issues related to the roles of time and mathematics in physics, your work and mine in a sense explores the opposite extremes of the spectrum of possibilities.
In contrast, I find conformist pressures to lampoon and dismiss certain scientific topics to be against the spirit of science. Indeed, it's been disturbing to see that the loudest cheerleading for this particular blog thread has been in the Intelligent Design community:
http://www.uncommondescent.com/intelligent-design/mathematician-wonders-about-the-respectful-reception-new-multiverse-book-is-getting/?utm_source=feedburner&utm_medium=feed&utm_campaign=Feed%3A+uncommondescent%2FJCWn+(Uncommon+Descent)

90. **Peter Woit**
January 26, 2014

Max,
There is no "controversy" about your MUH and Level IV arguments, just a consensus that they are empty, and that's what you need to address.

I notice that you have decided to stop answering any of the arguments I raise, in favor of a sleazy tactic of slandering me as a creationist. Up to you how to behave, I don't think you'll find this helps you or your case.

91. **John**
January 26, 2014

Don't you think that little bit of insinuation is beneath you Max? After all, what the hell does the opinion of the Intelligent Design community have to do with this.

92. **Orin**
January 26, 2014

Peter, it's not fair to ask Max (or anyone) to address a claim that the MUH is "empty" if you don't define what that means. Do you mean only that you think it is unfalsifiable? Or do you believe that it is "empty" philosophically as well? You keep saying it over and over, but nowhere in this thread or in your original post do you present an argument for anyone to rebut. One might say your criticism is "empty." Some in this thread have presented examples of how the MUH may turn out to be predictive. You completely ignore these arguments (sometimes removing them from the comment section) and just keep shouting "empty!" without addressing their points. Even your reaction to the recent discussion of the Weinberg argument ("I don't happen to think it's particularly strong evidence, but, sure, it's at least something.") is perplexing in the context of your statement that the MUH is "completely empty". Completely? You just admitted that the L2 multiverse has perhaps some weak predictive content! So you really need to be clear about exactly what you mean by "completely empty" before asking others to defend against an attack that is itself "completely empty" in its current form.

93. **Max Tegmark**
January 26, 2014

Hi John: Peter Woit's latest accusation that I'm somehow claiming that he's a creationist is so silly that it hardly warrants a reply. Please let me repeat and expand on what I wrote above, in the hope that it won't be further misunderstood.

I wrote that I couldn't help feeling disturbed by similarities in argumentation style between Peter's posts and the recent hate-mail I've been receiving from a Young-Earth Creationist: both seem to start by assuming that their conclusion is true ("Earth is 6000 years old"/"Multiverse ideas are nonsense"), and they then proceed to simply avoid mentioning any evidence to the contrary. I gave a detailed example of how Peter did this in my January 22, 2014 at 6:44 pm post above, by avoiding any examination of option 4. To me, this is an unscientific approach. As far as I can tell, the posters on that creationist site I linked to appear to dislike my book because they feel it represents a naturalistic world view. Again, they don't appear interested in examining all logically possible options (in particular, the logically possible option that modern cosmology is correct), instead dismissing this with pithy quotes about "nonsense", "crank" etc. that they've borrowed from Peter Woit. If we scientists are to have any claim to the moral high ground in scientific debates, I feel that we need to practice what we preach and conduct our debates at a higher level of civility and rigor!

94. **Peter Woit**
January 26, 2014

Max,
While pointing to your January 22 comment, you studiously ignore my response to it, following up your attack on me as similar to a hate-mail-sending Creationist with a sleazy comment about my supposed connection to a "disturbing" ID blog. You then end with "I feel that we need to practice what we preach and conduct our debates at a higher level of civility and rigor!". Impressive.

By the way, I just noticed that you're featured in an upcoming film, The Principle. Have you seen it, and if so do you think you do a good job of representing the scientific viewpoint in this film?

95. **Peter Woit**
January 26, 2014

Orin,

In this context, "empty" = "implies nothing about the real world"

I devoted a fair amount of time to carefully reading the Tegmark book and looking for where he discussed the implications for physics. In the blog entry above I discussed those carefully and completely, giving an argument (that no one has contradicted) that Tegmark was unable to derive and real implications of his MUH or Level IV multiverse for physics. This has nothing to do with the argument about Level II predictions.

96. **Orin**
January 26, 2014

Peter, then I suggest you add the adverb "currently" before your use of the word "empty." Even more fair would be "currently not predictive." There is a big difference between being vacuous (which is what "empty" may imply) , and simply being a theory that may or may not yield testable predictions at this time. The argument you need to be making then, is why you are so sure that this theory has no possibility whatsoever of ever yielding testable predictions. I have not seen this argument from you, and I think it is an argument that needs to be made if you really believe that the MUH is not worthy of further study. I have a hard time believing that you could really hold such a hard line, when it is so obvious (from arguments like Weinberg's discussed above) that there really can be no possibility of predictive consequences of such a theory (the Level II apropos of Winberg is not level IV, but in theory the logic is no different).

97. **Peter Woit**
January 26, 2014

Orin,
The problem is not one of "currently untestable", but one of "in principle untestable". Tegmark is the one who wrote scientific papers and a book about this, he's the one responsible for explaining why the ideas are not vacuous, by giving a plausible explanation for how his ideas could be tested, at least in principle. The burden of proof is not on me, but on him. I've argued above carefully above that he hasn't met this burden (although he claims in his book that he has).

If you follow the discussion between us in these comments, I think you'll see that the point at which he starts going on about hate-filled creationists is the point where he no longer has an argument. That's what people do…

98. **Orin**
January 26, 2014

Peter, you well know that an idea exists independently of a promoter of that idea. To insist that you will only accept an argument from Max and only Max is a bizarre form of straw man. There have been examples given in this thread of how the MUH is not necessarily vacuous. You have ignored them.

99. **Peter Woit**
January 26, 2014

Orin,
You seem to find it plausible that Tegmark wrote a whole book about his "hypothesis", but didn't bother to include in the book an explanation of how his "hypothesis" could be tested. Now, before I can argue that he doesn't have anything, it's my job to prove that there's no way for anyone to come up with tests for his "hypothesis". Right? Sorry, we disagree, I think my job is to read the book, assume he has put his best arguments in there, and see if these arguments are convincing, or if they don't hold water. I think any scientist who reads the book will see that the latter is what is going on here.

By the way, have you read the book? On which page did you see a convincing argument from him that his "hypothesis" was testable?

100. **Orin**
January 26, 2014

Peter, I'm afraid I haven't had the time to read the book yet, but I'm familiar with the material I expect to be in it. Hopefully I'll get to it next week. I will admit that if what you say is correct then I am puzzled that Max would not include in his book the interesting ways in which the MUH can lead to physical predictions. Of course I know well from your past opinions that you don't take kindly to some of the tools that would be brought to bare, such as anthropic reasoning(*). Nonetheless such reasoning is not vacuous, it exists independently of whether or not Max puts it in his book, and you are surely aware of it, so it seems disingenuous to take such a hard line as "vacuous" with regard to these ideas. It would be refreshing if you admitted that in principle these ideas could yield fruit. Could they not?

(*) I should note that this is by no means the only reasoning; it may not even be necessary if a sensible measure is found to be predictive.

101. **Chris W.**
January 27, 2014

In this context it might be a good idea to read (or re-read) Peter Medawar's review of *The Phenomenon of Man*.

102. **CJ**
January 27, 2014

Dear Max, it is your behavior that is having the chilling effects not only on this blog, but throughout the entire physics community.

It is quite remarkable that while you are the one with millions upon millions of dollars at your disposal, a professional publicity machine, MIT's PR department, and legions of Ph.D.-free pop-sci-fanboys, you accuse Peter of being a "creationist" bully for merely reading your book and reflecting on its empty content as a lone individual. To pile irony upon irony, it is also remarkable that while your book does little more than promote a faith-based initiative, which is not testable science, you then have the gall to accuse scientists and objective writers of behaving like religious fanatics.

Max Tegmark's biggest defender Orin writes, "Peter, I'm afraid I haven't had the time to read the book yet, but I'm familiar with the material I expect to be in it."

Max, you do realize that your career is built more on laymen who have not read your book, than on scientists who have?

103. **Orin**
January 27, 2014

Well Peter, this "Ph.D.-free pop-sci-fanboy" has given your blog a fair shake. Specimens in irony like the above only do you a disservice by lending credence to Max's comparison. Enjoy your echo chamber.

104. **Peter Woit**
January 27, 2014

Orin,
I hope once you do get around to reading the book under discussion, if you find a non-vacuous argument in it for the MUH or the Level IV multiverse, you return to let me know.

105. **Shantanu**
January 27, 2014

Max (or anyone else an expert on inflation)
Is there a lower limit on r from inflation? It seems that there are so many models of inflation (for example this ~ 400 page paper on all models of inflation http://arxiv.org/abs/1303.3787)
that given any observations (or non-observations) one can always construct any model of inflation.

106. **Pete**
January 27, 2014

Regardless of whether or not the MUH is true or not, I was wondering about your view regarding the idea of platonism/mathematical realism in general Pete. I know that a vast majority of mathematicians and a good deal of physicists would adopt a view that mathematical structures and truths are independent of human beings and that mathematical propositions are objectively true/false.

I must admit I think this view is very plausible, considering the history of mathematics and the sciences (especially fundamental physics) and the influence both disciplines have had on each other. This is not to try and bring in mysticism at all, as I am a naturalist and a physicalist, thought the second part gets increasingly harder to penetrate as you decompose "matter" into a collection of atoms that are 99.999% empty space with particles in a nucleus that decompose into further elemental particles represented as mathematical points or "vibrating strands of energy" in String Theory, whatever the hell that would even mean physically.

I mean, when modern physics points to fact that solid, physical matter is in fact vast amount of empty space linked together by interactions of profoundly small particles than seem to have an ephemeral existence all their own, is Platonism or realism about abstract structures and mathematical relations underlying the physical world really so outlandish? I agree it could probably never be tested, making it more philosophical than empirical, but do you think it a reasonable view?

By the way Frenkel's book, Love and Math, is brilliant so far and its clear from the reading that he, along with a long list of other mathematicians, wholeheartedly embraces the Platonic view without the slightest bit of crackpot "mysticism."

107. **Peter Woit**
January 27, 2014

Pete,
I myself favor some form of "Platonism" or realism about mathematics (see a following posting, which has a link to something about the "Putnam-Quine indispensability thesis" and I think Quine had some of the most to the point things to say about how to think about what is "real"). The problem is the claim that this tells you anything you didn't already know about physics, in particular Tegmark's claim that it implies that we should think of ourselves as living in a Level IV multiverse, with no particular physical theory=mathematical structure more fundamental than any other. It is this sort of thing that I claim is empty, implying nothing about physics. It's only use is the ideological one of promoting untestable claims about the "multiverse".

108. **DrDave**
January 27, 2014

Dear Mr. Tegmark,
Like many, I feel that dragging creationism into a scientific debate is both surprising and alarming, or to use your word "disturbing." I don't think there is any excuse for this, and, frankly, I think it sets a bad example for observers to see how a scientific debate should be handled. In addition, bringing in an irrelevant buzzword to the debate simply highlights a lack of a clear counterpoint to the argument.

109. **Lee Smolin**
January 28, 2014

Dear Max,

Many thanks for replying and for your kind words. I was unaware of your version of the argument you make, but I did comment on Garriga and Velinken's version in a footnote in Time Reborn. To quote again from there, p 284,

"23. Jaume Garigga and Alex Vilenkin have pointed out, in "Anthropic Prediction for Lambda and the Q Catastrophe," arXiv:hep-th/0508005v1 (2005), that a particular combination of the two constants does better when applied to Weinberg's argument: It happens to be the cosmological constant divided by the fluctuation size cubed. But this leaves two issues: First, what sets the size of the fluctuations? Second, we already knew that the argument did all right when only the cosmological constant was considered. There are many combinations of the two constants that could be tried; the fact that one combination does better than the others is not surprising and, even if there is an argument for it, this does not constitute evidence for the hypothesis that our universe is one world of a vast multiverse."

I would think that this would also apply to your W which depends also on the dark matter density per photon. Should we be surprised that there is a combination of powers of three constants that is extremized in nature? Given that there are many hypotheses and scenarios and many combinations of constants that could be tried, how strong of a case does this make for the hypothesis that our universe is not unique?

Also, Weinberg's paper did predate the measurement, but yours and Garriga and Vilenkin's did not. Even if we accept that your argument is a better version of Weinberg's, it was made after the observation and, in any case, you agree that Weinberg's logic was wrong.

Raphael Sorkin also published a paper before the observation of dark energy, predicting correctly the magnitude that was observed. He did this on the basis of causal set theory, an approach to quantum gravity. No one disagrees with his logic or prediction. It seems that the case here is stronger than for Weinberg as the argument did not have to be improved after the observation. So if you are being logical, and responding to the evidence, shouldn't you be writing a book promoting causal set theory rather than the multiverse? Instead, Sorkin's correct prediction is almost never mentioned, except by specialists in quantum gravity.

Thanks,

Lee

110. **Pete**
January 29, 2014

Thanks for the response Pete. I'm pretty much in total agreement with you as far as that's concerned. And by the way I'm hoping that Frenkel/Holt debate you mentioned in that recent post continues as well. Always good getting some philosophy of mathematics out there in the open.

111. **chris**
January 30, 2014

Does Tegmark talk about issues like inverted spectra and Mary in her black and white room? I know these are usually presented as problems for physicalism, but it seems to me they also present a problem for the idea that "everything is maths".

112. **Shantanu**
January 30, 2014

Lee or anyone else,
could you point me to Sorkin's paper where he predicted the value of cosmological constant using causal set theory.
Many thanks

113. **Lee Smolin**
January 31, 2014

Shantanu,

R.D. Sorkin, “Spacetime and Causal Sets”, in J.C. D’Olivo, E. Nahmad-Achar, M. Rosenbaum, M.P. Ryan, L.F. Urrutia and F. Zertuche (eds.), Relativity and Gravitation: Classical and Quantum (Proceedings of the SILARG VII Conference, held Cocoyoc, Mexico, December, 1990), pages 150-173 (World Scientific, Singapore, 1991);

114. **D R Lunsford**
January 31, 2014

Tegmark should address Peter’s most important point, which is that he doesn’t really have any inner understanding of mathematics as a discipline in itself.

-drl

115. **Orin**
February 9, 2014

Hi Peter,

I read the book (I thought it was delightful), and I have to say I’m left even more perplexed than before at your characterization of the MUH as “empty”. Max says (Chapter 12):

“If the theory that the Level IV multiverse is correct, then since it has no free parameters whatsoever, all properties of all parallel universes (including the subjective perceptions of self-aware substructures in them) could in principle be derived by an infinitely intelligent mathematician.”

Of course this is fleshed out in the book, but I think it is fairly self-evident. Examples of the kind of strategy for falsifiability begin as early as Chapter 6, where he writes:

“If we’re living in a random habitable universe, the numbers should still look random, but with a probability distribution that favors habitability. By combining predictions about how the numbers vary across the multiverse with the relevant physics of galaxy formation and so on, we can make statistical predictions for what we should actually observe.”

So I continue to not understand why you insist on using the word “empty.” I think Max makes a very persuasive case in the book for the potential of the MUH to be predictive, and even falsifiable (he discusses this extensively in Chapter 11, giving examples of falsification using naive measures, ultimately concluding that the major hurdle to be overcome is a solution to the measure problem).

116. **Peter Woit**
February 9, 2014

Orin,

Sure, all properties of all universes could be “derived”, just look at “all properties of all mathematical structures”. Fine, but this predicts nothing at all about any particular property of our particular universe.

The part you quote from the book is referring to the sort of “Level II” multiverse of the anthropic string theory landscape: there’s some specific fundamental physical law that determines the probability distribution he invokes. There are plenty of problems with this, but it’s not what I’m referring to as empty, the Level IV business of the title of his book.

I’ve gone over here carefully what is in his book that claims to be a prediction of Level IV, and I’ve explicitly challenged him here and at the Scientific American site where he wrote a response to this, asking him for a falsifiable prediction of “Level IV”. The best he could come up with is “if we find a physical phenomenon not describable mathematically” that would do it. See
http://www.math.columbia.edu/~woit/wordpress/?p=6669
and the Scientific American site
http://blogs.scientificamerican.com/guest-blog/2014/02/04/are-parallel-universes-unscientific-nonsense-insider-tips-for-criticizing-the-multiverse/
for my comments about why this is empty. If there are all sorts of great examples of how to falsify Level IV in the book that I missed, how come Tegmark is not invoking them when asked about this issue?

You could argue that all you have to do is “put a measure” on the space of mathematical structures, but this is again an empty statement until you give some indication of what such a measure should look like. The only thing he discusses in the book is some sort of counting measure, but obviously you get more and more examples of mathematical structures as you increase complexity, so this sort of thing, besides the “measure problem” due to infinity, has the obvious problem that it predicts your mathematical structure will be as complicated as possible, whereas we know that fundamental physical laws are based on remarkably simple mathematical structures.

On a related note, Tegmark likes to claim that he just has a “measure problem”, not knowing how to relatively count things, when he has something much worse: he doesn’t know how to characterize the space he is trying to put a measure on (the people trying to use string theory at Level II have a much simpler version of this problem: not only do they not know how to compute relative weights of string vacua, they don’t know what the set of string vacua is).

117. **Orin**
February 9, 2014

Peter, you seem to be setting the mark for what is not empty just high enough to fit your definition. I think Max has outlined the beginnings of a theory that is clearly not empty in principle. You point out that it is currently empty in practice. That is fine (if you make it clear what you mean), but obviously theories have periods of gestation before predictions are made, and I don’t think it is fair to be quite so dismissive of the fact that they are not yet mature. There is a Chicken/Egg problem here; you won’t be satisfied until the theory is predictive in practice, yet the theory won’t have an honest shot of being predictive in practice until more people work on it.

On your point about the measure problem (second-to-last paragraph) and the apparent simplicity of physical laws, I think your argument is not as strong as you think it is. For one, your measure must be “anthropic aware”, a feature Max harps on quite a bit (although I don’t think he uses that wording), and it is not at all clear to me that the “pruning” afforded by such a measure would not alone be a sufficient counter-argument. But additionally (and this is a point Max does not make in the book, but nonetheless his ideas should be discussed independently of this particular book written for lay-audiences), a strong case can be made that as you go up the latter of increasing complexity, there are correspondingly increasing numbers of approximate equivalences between structures of greater and lesser complexity. There are also fairly strong counter-arguments in algorithmic complexity theory (I linked to one example earlier in this thread) that clearly indicate to me that your intuition is off. So no, I don't think the measure situation is nearly as dire as you think it is.

118. **Peter Woit**
February 9, 2014

Orin,
I'm not talking about "in practice", but "in principle". All the arguments I've given about the emptiness of "Level IV" are arguments of principle. To show it is non-empty you need to produce a non-empty prediction, even if it is only "in principle". Tegmark hasn't been able to do this (and you don't seem to either). And you can't hide behind every crackpot's favorite excuse "OK, I haven't been able to get anything out of my wonderful theory of everything, but if only lots of people would work on it, maybe they would find something".

It's not possible that "my intuition is off" about "all mathematical structures", because I have no intuition at all about what that even means. As far as I can tell it's a concept every bit as empty as saying "all sets" or some such. There's no there there. The counting measure I was quoting was Tegmark's intuition, not mine. Again, I don't think his problem is a measure problem, his problem is that he doesn't know anything non-trivial about the space he wants to put a measure on.

From your comments, you seem to have your own Tegmarkian theory, since you're making claims not in his book. If you've written it down anywhere, and you have non-trivial implications of such a theory that he doesn't have, let us know what they are. So far, neither you nor he are able to point to anything in his book that gives, in principle, an implication of this MUH that is not on its face empty.

119. **Orin**
February 9, 2014

Peter, the quote I provided from Max's book is exactly such an example, even including the words "in principle." Apparently you need a specific "in principle" prediction (this seems like an oxymoron; I'm not positive what you mean) rather than a general one. Fine, but the fact that the theory can in principle make specific predictions is the reason I am pestering you about your use of the word "empty." The theory is not empty. It clearly can in principle make specific predictions, and the practical reasons why it currently cannot are made as plain as day in Max's book.

120. **Peter Woit**
February 9, 2014

Orin,
This has now become a waste of time, you're just ignoring whatever I write here. I'll just cut and paste the relevant part.

"Sure, all properties of all universes could be "derived", just look at "all properties of all mathematical structures". Fine, but this predicts nothing at all about any particular property of our particular universe.

121. **Orin**
February 9, 2014

Peter you are playing dumb. Obviously that is not the only implication of what Max wrote when he discusses the prediction of "the subjective perceptions of self-aware substructures" in a multiverse in which he has already established that in principle there are "probability distributions that favor habitability," with which one can use to falsify the theory. He is not just saying one can in principle derive the properties of all mathematical structures. He is clearly saying that if a reasonable measure is found then one can in principle derive the probability for us to live in a universe with an effective Standard Model lagrangian and General Relativity with a finely tuned cosmological constant, etc, and that if this probability is found to be small then the theory is falsified.

122. **Peter Woit**
February 9, 2014

Orin,
Now we're back to "all I have to do is find the right measure on the space of all mathematical structures", and the problem that "all mathematical structures" is an empty concept. From nothing you get nothing. Tegmark gets nowhere with this in his book because it's inherently empty and can't go anywhere. If you point to anything other than absurd wishful thinking about explaining everything from nothing, please do so, but so far you're just wasting your and my time.

123. **billandturk**
February 11, 2014

Suppose some relatively slightly more advanced alien civilization living in Omega Centauri has already solved, for instance, their metabolic syndrome and counteraffects of ageing, integrated successfully with their quantum computing power, essentially have achieved a form of immortality. There's probably a Hollywood movie playing this out, or at least there should be.
What gives when an alien from this civilization visits you, Peter (after all, they originate in our own galaxy) and tells you Everettian postulates about decoherence, many worlds, and ultimately MUH are all true? As a matter of fact, the alien even takes the time to demonstrate to you on his quantum hand-held device how he has uploaded his "essence" innumerable times into his planet's hosted quantum supercomputer, and in fact is himself living out "many lives" … any and all of which can and do seem no more or less "real" to him.
Theoretical emptiness, perhaps.
Impossible or improbable?

124. **Peter Woit**
February 11, 2014

billandturk,
If a space alien or a guy with gold tablets appears magically in front of me, and explains to me about how string theory really is the TOE, the multiverse works, the space of all mathematical structures carries a natural measure that explains everything, etc. I am happily going to agree that yes, these ideas are testable science and have been tested.

However, if this possibility is the argument from proponents about why their ideas really are non-empty and scientific, I think they have a problem….

125. **billandturk**
February 11, 2014

Thank you Peter taking the time replying.

I am young, dumb, and novice with this subject matter and even more “rookie” with the math underpinning it all; however, your response to my post actually helps me better contextualize and appreciate your points.
I like the saying: There are known unknowns – things we know we know; There are known unknowns – things we know we don’t know; and There are unknown unknowns – things we don’t know we don’t know.
After having just finished Tegmark’s book, I was inclined to believe his ideas fell into that middle category. I see where you’re coming from, and it also makes sense to me now, that perhaps (not trying to suggest my words are coming out of your mouth and hopefully not to be taken offensively), these ideas are more the latter, “unknown unknowns”, and the fundamental flaw with this category is presuming you can articulate “science” attributes upon it?
Oh well, genuinely thanks again!

Not Giving Up

January 23, 2014
Categories: Uncategorized

One question I've been wondering about for the last 20 years or so has been what SUSY proponents would do when the LHC finally gathered data and found no SUSY. Would they finally admit this was an idea that hadn't worked out, or would they never give up, no matter what the data said? The answer is now in. John Ellis was a co-organizer of a Royal Society conference earlier this week, and a report from the conference has the following:

> "I think that the physics case for supersymmetry has, if anything, improved with the LHC's first run, in the sense that, for example, supersymmetry predicted that the Higgs should weigh less than 130 gigaelectronvolts, and it does," Ellis said.
>
> "Of course, we haven't seen any direct signs of supersymmetric particles, which is disappointing, but it's not tragic," Ellis added. "The LHC will shortly almost double its energy — we're expecting eventually to get maybe a thousand times more collisions than have been recorded so far. So we should wait and see what happens at least with the next run of the LHC."
>
> And if the LHC's next run does fail to reveal any sparticles, there is still no reason to give up on looking for them, he said. In that case, new colliders with even higher energies should be built, for collisions at energies as high as 100 TeV.
>
> "I'm not giving up on supersymmetry," Ellis told LiveScience. "Individual physicists have to make their own choices, but I am not giving up."

So, Ellis has made his position clear: no giving up, no matter what the LHC data from the next run says.

Comments

1. **Thomas Larsson**
   January 23, 2014

   Is it even theoretically possible that susy will be found at the LHC?

   My impression is that the SM is so constrained by high-precision data, that a direct discovery of sparticles at 14TeV is very unlikely. What could rather be found is some anomaly in the high-precision data, which could herald a discovery at yet higher energy. Or something else.

2. **Neil**
   January 24, 2014

   Wow. You'd think ACME's zero dipole moment measurement for the electron would give the SUSY crowd some cause to doubt that there is an exotic particle zoo out there.

3. **CIP**
   January 24, 2014

   Reasons not to give up on SUSY include the fact that there aren't many promising alternatives. The two biggest mysteries in physics are dark matter and dark energy, and SUSY can at least hint at solutions. What else can? Nor are there many promising alternatives for quantum gravity.

   Physics will move on if something more promising comes up.

4. **Friedwardt Winterberg**
   January 24, 2014

   It is ironic that the Ptolomaic system failed because it was stuck with the more symmetric circular motion against the less symmetric but observed elliptical motion, while the more symmetric supersymmetry leads to a less symmetric nonspherical electron with a non-observed electric dipole moment. I once had told Edward Witten that supersymmetry can exist without superstring theory but not the other way around. His answer was that you can say this about almost any theory. But without supersymmetry can there be a superstring theory? And how about Juan Maldacena's anti de Sitter (ADS/CFT) conjecture in face of our more de Sitter (not anti) observed universe? Shall we rally believe in the 10^500 universes? In an e-mail exchange I once had with Lubos Motl, this good man had the following slogan on all of his e-mails: "String/M theory is the language in which God wrote his world". In a reply I wrote him: "Lubos, this is not science but religion in the guise of science".

   January 24, 2014

   CIP and s.vik.
   To give one example : asymptotic safety.

6. **GoletaBeach**
   January 24, 2014

   Well, the light Higgs is interesting. I think Ellis has a point there. Of course the confirmation of the precision electroweak analyses is the biggest news. But something or other keeps the Higgs light, and that is definitely interesting. Maybe it is SUSY. Maybe not. Not really Black & White to me that no direct SUSY particles is a complete SUSY rejection. Many searches for free quarks came up empty.

7. **Peter Woit**
   January 24, 2014

   GoletaBeach,
   Not just many, but all searches for free quarks came up empty, because there are no free quarks. Any theory of the strong interactions with free quarks is a wrong theory.

   Similarly, it's now pretty clear that superpartners aren't going to show up, and any theory like the SUSY extensions of the SM that have been studied for 40 years is a wrong theory. Time to look for something quite different if you want to get anything out of SUSY. What's odd is that Ellis is not talking about that, but about just looking for the same thing at higher energies.

8. **Alex Sander**
January 24, 2014

Woit,

I think you are beeing too simplistic. Notice that among other good things SUSY has gave us is that its also a good “signal generator” in the sense that has trigered interesring searches for physics (and will keep doing so) that may ultimately let to discoveries (sparticles or other physics cases).

9. **Curious Wavefunction**
January 24, 2014

Sorry, but I have to admit that thinking of this kind reminds me of a classic feature of conspiracy theories: When evidence arguing against your theory emerges, you simply expand your ‘circle of belief’ to accommodate that evidence.

10. **Noah Smith**
January 24, 2014

OK, but here is the obvious question: What group of humans on this planet is going to shell out the billions of dollars needed for a next-generation collider just to look for SUSY?

If the answer is “no one”, what do the SUSY researchers do?

11. **Low Math, Meekly Interacting**
January 24, 2014

What’s most puzzling is how obvious it is that SUSY is a belief system, and how little that seems to concern its proponents. “SUSY”, in all its myriad permutations, could appear over a vast range of energy scales. “Look at higher energies” is an argument that could hold theoretically no matter how much negative data are produced. It is, after all, exactly what’s been said every time SUSY has lurked just beyond the reach of the current accelerator, yet astonishingly failed to appear. The rationalizations being made today so closely echo those made after the Tevatron shut down, after the LEP shut down…”Well, those expectations were silly, naive, oversold, and clearly the Not-Quite-As-Minimal-As-The-Last-Supersymmetric-Standard-Model tells us the parameter space…” Does it take a genius to get seriously worried about some of these dearly-held beliefs regarding a particular perception of “beauty”? We know what the past has tought us. What can we predict about the future, not only about Nature, but about how human nature impacts our study of Her? From what I can see, this could go on forever. Some even appear to think that’s one of the theory’s key virtues! Is this not all frightening?

12. **tt**
January 24, 2014

“If the answer is “no one”, what do the SUSY researchers do?”

Economics?

13. **DrDave**
January 24, 2014

In the absolute worst case scenario, where no evidence ever turns up, one could certainly claim that an LHC in another universe could detect something, and that ripples from this event could be seen in yet another universe, just not ours.

14. **S. Chan**
January 24, 2014

This post is one of the few occasions when the following seems genuinely appropriate: “Never Gonna Give You Up …“

15. **Low Math, Meekly Interacting**
January 24, 2014

I should say again that I, at least, when I voice my concerns in my own insignificant way, never do so with a sneer. I see these individuals, with very few exceptions, as brilliant, honest, devoted scientists working at the pinnacle of human intellectual achievement. It was their professional ancestors who made “science” what it is. They seem always to be at the forefront of whatever science is evolving into. So the truly worrisome question is, what is science evolving into?

16. **Jesper**
January 24, 2014

@ CIP. To use “there aren’t many promising alternatives” as an argument for continuing down the susy (string) path seems to be a never-ending loop. If everyone reasons like this an alternative will indeed never be found.

17. **Andreas**
January 24, 2014

It’s well known that from epistemology that theories do not disappear from one moment to another. They disappear with the scientists who developed them. Then they get old and retire, eventually their theories – which are not supported by data – will retire aswell.

Obviously one can understand psychologically why people like Ellis do not give up. They based decades of their scientific career on this topic. Would you be able to admit that all you have done was wrong? 😮

I think everything goes its predicable way…

18. **SUSY**
January 24, 2014

Woit, what do you think reasonable scientists in HEP and QG should pursue in the event of no-SUSY in LHC and other experiments? What is a scientifically responsible and reasonable course for HEP/QG after non-SUSY LHC 2016?

19. **David Folsom**
January 24, 2014

Andreas:
Quote:"Obviously one can understand psychologically why people like Ellis do not give up. They based decades of their scientific career on this topic. Would you be able to admit that all you have done was wrong?"
.
There is a saying I like to use for situations like this: Do you want to be wrong today, or do you want to be wrong forever?

All due credit to anyone who invented it before me.

20. **Noah Smith**
January 24, 2014

"Economics?"

Oh, God. That's what I was afraid of.

FUND THE COLLIDER AT ALL COSTS

21. **PlanckConstant**
January 25, 2014

A new scientific truth does not triumph by convincing its opponents and making them see the light, but rather because its opponents eventually die, and a new generation grows up that is familiar with it

22. **emile**
January 25, 2014

PlanckConstant: a new scientific truth does not triumph by convincing people and making them see the light or by a generation of proponents or opponents dying. It triumphs with experimental evidence.

23. **Tommaso**
January 25, 2014

Hello Peter,

a bit off topic, but I would like to point out that Ellis' quote contains a misconception that I think does not belong there, not even if the target of his text are laymen.

I have always believed that in order to explain hard concepts to outsiders
one has to simplify things to the point of making slightly incorrect statements.
But I don't think that saying "we're expecting eventually to get maybe a thousand times more collisions than have been recorded so far" falls in that category.

What Ellis forgets is that the rate of event recording is not going to improve by x1000,
but maybe by x2 or x4. CMS and ATLAS have recorded in total less than 10B events, and in the future they won't go above some tens of billions; that's because the increase of luminosity is not matched by a multiplication of data acquisition power – and it would not be meaningful of course. A better way to explain what is in store is to say "we are expecting to produce a thousand times more collisions", retaining the overall meaning.

Cheers,
T.

24. **lun**
January 25, 2014

On a semi-related topic, did you attend this:
http://physics.columbia.edu/amplituhedron
and do you think thespeaker's approach of studying carefully a world with many SUSYs
as toy model can revolutionize our understanding of our world with, perhaps, not even one?

25. **Peter Woit**
January 25, 2014

lun,
Yes, I was there, will write about this soon. As far as the topic of this posting goes, there was almost nothing in the talk about SUSY, at least in the first two hours…

26. **Peter Woit**
January 25, 2014

SUSY,
Fo theorists, the set of reasonable things to work on post no LHC SUSY is about the same as the set of reasonable things to work on pre no LHC SUSY, since there never was a good reason to expect LHC SUSY, and it was a subject that had been studied to death for years.

27. **Peter Woit**
January 25, 2014

Thanks Tommaso,
That's interesting, I hadn't thought much about that distinction. I guess it's not too important if you're discussing very rare events and some ideal triggering scenario, but clearly there are measurements where the high luminosity is not going to help for the reason you give.

28. **GoletaBeach**
January 25, 2014

"GoletaBeach,
Not just many, but all searches for free quarks came up empty, because there are no free quarks. Any theory of the strong interactions with free quarks is a wrong theory."

Not quite all, but those that had positive results (Fairbanks, 1980 or so, for example) were (rightfully) discredited. But people kept looking for a long, long time, nice review…

http://www.annualreviews.org/doi/pdf/10.1146/annurev-nucl-121908-122035

I differ with you, Peter… the issue cannot ever be settled by theory, only by experiment. What we know is that in normal matter the free fractional charge abundance is <10-23 per nucleon or so. I think whether QCD has peculiar and rare states that somehow preserve fractional charge is still an open question, although one that is unpopular.

"Similarly, it's now pretty clear that superpartners aren't going to show up, and any theory like the SUSY extensions of the SM that have been studied for 40 years is a wrong theory. Time to look for something quite different if you want to get anything out of SUSY. What's odd is that Ellis is not talking about that, but about just looking for the same thing at higher energies."

`Pretty clear' is not the same as doing the experiment and checking. It was `pretty clear' at SPEAR in 1973 that no narrow resonances were present… their scan had skipped over the J/Psi. So in 1974 they found it.

Experimentalists are quite different than theorists. You theorists seem to think you are in a chess match where checkmate means something. Experimentalists find you all a bit ego-driven and narrow, and overly certain (one way, favoring certainty, or another way, rejoicing in rejection).

Experimentalists usually (not always) are much more diffident at heart. I think many experimentalists never caught the SUSY wave but solidly support going to the highest energies technologically possible to look for surprises. Conversely, trash-talking the 14 TeV run because SUSY won't likely be there seems similarly wrong-headed.

You go to the highest energies and look for new phenomena. You keep looking for free fractional charge with whatever clever trick you can find. You look for electric dipole moments, mu-e, dark matter, neutrino mass, etc, etc, and view theorists as an odd opinionated tribe. An odd tribe that was initially quite hostile to, for example, the observation of the tau lepton, to parity violation, to fission… the list is interesting and long.

29. **jd**
    January 25, 2014

    Well, good luck on getting a machine for higher energies. The well is running dry.

30. **theon**
    January 26, 2014

    Having studied in the then "world gauge center", Utrecht University with Veltman and 't Hooft, I learned about the standard model but got appalled by SUSY. Seeing its near defeat decades later, does not feel as a victory. Too much damage has been done, first by SUSYers, then by SUGRAvers and the blow by (Super)Stringers. It seems fair to conclude that physics reached the end of the Gauge Principle. How to continue? Why not look at the basis of quantum mechanics? Its measurement problem has been solved recently, leading towards its statistical or ensemble interpretation akin to classical ensemble theory, doing away with many worlds, many minds and so on. But if we do *one* experiment and get *one* outcome, one may ask the question: what goes on in the apparatus to generate this outcome? We do not have a theory for this down-to-earth question! So my bets are on a sub-quantum theory, more classical than quantum theory itself. Integration with gravity should be done at that level. Not surprisingly, the possibility of a sub-quantum theory kept Einstein and 't Hooft busy for decades.
    This answer the what-to-do question: Turn around and start again.

31. **Nathalie**
    January 26, 2014

    theon

    You write that the measurement problem in quantum mechanics has been solved recently …

    This is a very important statement. Please give the relevant references. Thanks.

32. **chewbachelor**
    January 26, 2014

    There is something I find a bit incredible. In the past, 1. the theorists were making predictions, 2. if the predictions were correct, the theorist received recognition, 3. if they were not verified, the theorists were not recognized. Now, it seems that none of these considerations matter.

    E.g., nobody asks a SUSY theorist to make predictions, only moral suasion; if the predictions are wrong, the theorist can simply change them; finally, the recognition is for granted, once the theorist is paid by a prestigious place and if he/she can publish empty but successful papers.

    Instead, when I hear a talk of a theorist, I immediately ask: What are his/her achievements in physics? This simplifies a lot the assessment and allow me to save a lot of time.

33. **Peter Woit**
    January 26, 2014

    theon,
    I strongly disagree with your conclusion that the failures of SUSY/SUGRA/Superstring theory mean the "end of the gauge principle". A better conclusion would be that they indicate something went awry in the "SUSY" extension, not with gauge symmetry (where the recent discovery of the Higgs vindicates the gauge theory point of view).

    All,
    Sorry, but measurement theory in QM, while a wonderful topic, is off-topic here.

34. **Peter Woit**
    January 26, 2014

    GoletaBeach,
    I don't really disagree with you. By all means, experimentalists should do whatever they can to look for new phenomena. To the extent though that they have to make choices and decide to get some guidance from theory, best to work with a clear-eyed view about what theory does say and what it doesn't. By all means, look for fractionally-charged objects, but realize that the ones theorists saw as most likely in 1964 (u,d,s quarks) now look quite unlikely, so better to search widely and not assume anything about, for instance, which fractional charges to look for. Similarly, of course the higher energy LHC run is important and searches should be done there for anything and everything that might show up. When designing triggers, etc., though, it would be a good idea to make sure things are not narrowly tuned to looking for specific superpartners heavily advertised in the past by theorists, since such theories now look quite unconvincing.

35. **srp**
January 26, 2014

GoletaBeach makes an interesting point. Scientific American has a cover story this month about how two valid methods of measuring the radius of the proton give two very different answers. The CERN briefing book says that the spin of the proton can't come close to being derived from the measured spins of its component parts. Transverse polarized proton beam collisions either violate the QCD prediction massively or nobody knows how to compute the correct prediction. Are protons too "composite" to interest high-energy theorists these days? It's hard for a layman to understand the apparent lack of interest in such fundamental matters (no play on words intended). I'm very fond of the protons that give me most of my mass while kindly refraining from decay, even if it turns out that their components have no superpartners.

36. **GoletaBeach**
January 27, 2014

We're on the same wavelength, Peter. Leptons and missing energy and jets remain the fundamental things to look at, and will always be done. What is really hard to guarantee is that there won't be another `scanned over the J/psi' , that is, missing something by not considering all the possibilities type of oversight in the 14 TeV.

srp, oddly enough, the size of the proton is not considered by most particle physicists as particularly sensitive to interesting new physics. We could be wrong, in fact, I hope we are wrong. My guess is that the two different measurement techniques (electron scattering and muon atoms) might have slightly different corrections needed to back out the fundamental thing, that is the size of the proton. And maybe nobody has spent sufficient time doing those corrections accurately to the few in a 100 level.

Topcites 2013

January 25, 2014
Categories: Uncategorized

The people at SLAC for a long time have been compiling "Topcites" data which includes various lists of the most heavily-cited papers in HEP. From 1997-2003 Mike Peskin each year would write something about the significance of the lists. I first wrote a blog post about one of these lists nearly 10 years ago, about the 2003 list (see here). The 2013 list has just appeared, with a blog entry here, and the lists available here.

I haven't written much about these lists for the past few years, since there didn't seem to be much new to say. By the 2005 list it was becoming clear that there was so little new happening in hep-th that the list was dominated by pre-2000 papers, specifically the early AdS/CFT papers, as well as papers about speculative large extra dimension scenarios. This pattern has continued to this day. If you think citations mean something, this data shows a collapse of HEP theory having taken place sometime around mid-1999. The last two theory papers that appear in the overall heavily-cited paper list are a Randall-Sundrum paper from June 1999 and Seiberg-Witten's String theory and non-commutative geometry (which I suspect makes the cut because "non-commutative geometry" is in the title, so this gets referenced by lots people doing something with non-commutative geometry, even if it has little to do with this paper).

The dominance of this list and of hep-th by AdS/CFT papers is hard to exaggerate, with Maldacena's paper long ago leaving behind every other theory paper ever written, on track to hit 10,000 citations sometime later this year. Just as "string theory" has become ill-defined, now "AdS/CFT" is starting to become ill-defined, with these 10,000 papers covering a huge variety of different things. In addition there's a great deal of hype and ideology surrounding this subject, with an ex-Harvard faculty member and now world's most prominent string theory blogger yesterday calling for the murder of anyone caught "talking about the AdS/CFT correspondence's not being dependent on string/M-theory". More positively, Matt Strassler has been writing a very long series of blog posts that appear to be aimed at sooner or later getting to AdS/CFT. He's at number 8, but I fear at least a hundred or so would be needed to cover the subject. By the way, people who like carrying on a tedious rear-guard action in the string wars by arguing about string theory and AdS/CFT should do it at another blog.

To get more fine-grained information about what recent work is getting cited, see listings here by arXiv category. The listing here of papers cited by hep-th papers during 2013 is dominated by the old AdS/CFT papers, but more recent things that occur in the top 10 are ABJM from 2008 (3d version of AdS/CFT), a 2006 paper on entanglement entropy from AdS/CFT (now a hot topic), and a review paper on AdS/CMT.

Comments

1. **Bob**
   January 25, 2014

   This is depressing. More useful would be a list of the most promising hep-th papers from the past few years.

2. **CU Phil**
   January 25, 2014

   I'm surprised that nothing on amplitudes made the list.

3. **Peter Woit**
   January 25, 2014

   CUPhil,
   It looks like the highest cited amplitudes paper appears as number 63 on the list of papers cited this past year (with 69 citations). One reason for this I think is that the amplitudes business is still rather small, with a limited number of people working in it. It's a complicated story, involving a lot of technology, so a high barrier to entry. And I think lots of people are still not convinced there's anything that will come out of this except maybe some modest progress on doing complicated amplitudes calculations. For more about this, see the next posting…

4. **S**
   January 27, 2014

   You don't talk about AdS/CFT much yourself, Peter; does it fall under the string tent for you, and receive the same opinion?

5. **Peter Woit**
   January 28, 2014

   S,
   Various topics about AdS/CFT have been discussed in detail here over the years. As I note above though, at this point the name refers to such a wide variety of things it's hard to say something sensible about 10,000 papers. As for its relation to string theory, that argument has gone on ad nauseam, and pretty much immediately turns into religious warfare if the topic comes up. The only new recent development I've seen is the call for the killing of anyone who suggests string theory is not fundamentally responsible for AdS/CFT.

The Amplituhedron and Twistors

January 25, 2014
Categories: Uncategorized

Yesterday Nima Arkani-Hamed was here at Columbia, giving a theory seminar on the topic of the Amplituhedron, which is a characterization of the integration region in a calculation of scattering amplitudes by integrating over regions in the so-called positive Grassmannian. This is a modest advance in mathematical physics, one that for some reason a few months ago garnered a lot of hype (see here for more about this).

As seems to often be the case, the Arkani-Hamed talk was a bit bizarre as an event. Scheduled to start at noon, people soon settled in with the sandwiches provided by this seminar, and he started talking about 12:15. About an hour and a half into the talk, people were reminded that he doesn't mind if they leave while he's speaking. Two hours into the talk, soon after he said he was only a quarter of the way through his material, I had to leave in order to do some other things. I don't know how long the talk actually went on. It's too bad I didn't get a chance to stay until the end, since he promised to then explain what the current state of progress on these calculations is.

What is being calculated are scattering amplitudes in a conformally invariant theory, with the simplest example the planar limit of tree-level amplitudes of N=4 super Yang-Mills. One wants to extend these methods to loops, to higher order terms in 1/(number of colors), and to non-conformally invariant theories like ordinary Yang-Mills (at the tree level, ordinary and N=4 super YM give the same results).

As usual, Arkani-Hamed was a clear and very engaging speaker. Also as usual though, it's unclear why he thinks it's a good idea to not bother trying to fit his talk into a conventional length, but just keep talking. One reason for the length was the extensive motivation section at the beginning, which had basically no connection at all to the topic of the talk. There was a lot about quantum gravity of an extremely vague sort. In a recent talk I wrote about here, he explains one reason why he does this, that he's describing the motivation he needs to keep doing this kind of mathematical physics. I suspect another related reason is that this kind of vague argument about quantum gravity and getting rid of space-time is all the rage, so if you're not working on the firewall paradox, you have to justify that somehow.

Once he got beyond the motivational stuff (and a complaint about BRST: "almost anytime you hear BRST, there is something formal and complicated going on") the talk was worthwhile and I learned a fair amount. The main thing that struck me was just how much the whole story has to do with Penrose's twistor program. Penrose developed twistors also with a quantum gravity motivation: they provide a very different set of basic variables, with usual space-time points not the fundamental objects. Of course I was aware of some of the twistor part of the amplitudes story (see for instance here), but I was unaware of the important role played by Andrew Hodges, of Penrose's twistor group at Oxford, in these recent developments. Hodges, besides writing a fantastic biography of Alan Turing, has worked on twistor theory for about forty years, and some of his innovations have been crucial for the recent advances on gauge theory amplitudes. One example is his "twistor diagrams", and for more about this and how other work of his has contributed to the emerging story, see his up-to-date Twistor Diagrams website. Hodges is a wonderful story of someone who didn't follow fashion, but stuck to pursuing something truly worthwhile, it's great that he has now been getting attention for this, as his work has become useful for more popular research programs.

For those who keep asking about interesting, promising ideas about fundamental physics to work on, twistors are something they definitely should look into. The recent amplitudes work is one specific application of thinking in twistor variables, but the whole question of how to do quantum field theory in twistor space seems to me to still be wide open. Twistor theory involves some wonderfully different ways of thinking about four-dimensional geometry, and these seem far more likely to play some role in future advances in the direction of unification than any of the tired ones (GUTs, SUSY, string theory) that have dominated the field for so long.

Comments

1. **OMF**
   January 26, 2014

   > Hodges is a wonderful story of someone who didn't follow fashion, but stuck to pursuing something truly worthwhile…

   Are you implying that a lot of what is fashionable is not very worthwhile? (I am asking a very serious question here.)

2. **J.S.**
   January 26, 2014

   I find peculiar that according to you what Hodges does is awesome but not so what Nima does, after explaining how related both things are.

3. **Peter Woit**
   January 26, 2014

   J.S.,
   I was writing here about what I learned from Arkani-Hamed's talk. He was the one who credited Hodges with coming up with the important ideas he was discussing (with three examples "twistor diagrams", dual conformal symmetry, and the idea that the amplitude was a volume of a polytope). For more details of who did what, see this page at Hodges's web-site
   http://www.twistordiagrams.org.uk/papers/index.html
   which tells the story in a way quite consistent with Arkani-Hamed's version in his talk.

   So, if you want to simplify this to "what Hodges does is awesome", you can, but that's not "according to me", it's a report of the story according to Arkani-Hamed.

   OMF,
   Yes, a lot of what is fashionable is not worthwhile. This is true to some extent in all subjects, certainly is true in theoretical physics. One can get into an argument about what of such currently fashionable ideas are the ones that are not worthwhile, but if you want an example, I've made it very clear what I think of the multiverse. No matter what your views on that, I think if one goes back and looks at the topics fashionable at any given moment in HEP theory, most of the time you'll find that some of the fashionable topics didn't turn out to be worthwhile, while people doing some very unfashionable things in obscurity turned out to be doing something much more worthwhile. Hodges is a good example of this.

4. **Peter Woit**
   January 26, 2014

   Thinking about both this talk and the Tegmark story, an odd parallel occurred to me. Tegmark early in his career downplayed the multiverse part of his interests, in order to make sure people took him seriously as a scientist. These days, it's somewhat the reverse, with Arkani-Hamed using, if not the multiverse, quantum gravity research at the boundaries of science, in order to get people to take seriously his work on what they otherwise might decide was just an obscure corner of mathematical physics.

5. **J.S.**
   January 26, 2014

To say that the multiverse mania is fashionable you have to provide evidence: what fraction of the vacua contain string theorists? and in what fraction of those are they actively discussing the multiverse?

Platonism CageMatch at MoMath

January 25, 2014
Categories: Uncategorized

After spending two hours in the middle of the day hearing about unexpected uses of twistors to study particle scattering amplitudes, yesterday I went down to Manhattan's relatively new Museum of Mathematics, which had scheduled a "Family Friday" event, featuring Edward Frenkel and Jim Holt. The event began with Frenkel giving a presentation about math, kind of an introduction to his wonderful new book Love and Math. Everyone in the audience hoped that the kids in attendance didn't catch his comment about a typo in reference to the LHC (given Frenkel's film experience, some had suggested that a joint event with the neighboring Museum of Sex would have been a good idea).

Things really got exciting though when Jim Holt joined him on the stage, for a no-holds-barred discussion of Platonism and mathematics in front of a standing-room-only crowd. Holt ripped into Frenkel as engaging in "mysticism" by claiming that mathematical objects are "real" and "exist". He quoted from Bertrand Russell, who early in life took Platonist positions, but in his old age renounced them. Frenkel countered, dismissing Russell's later quotes as those of someone who had gone soft in the head. He went on to quote arch-Platonist Kurt Gödel, with the response from Holt a low blow: he told the story of how Gödel had died a paranoid, starving himself to death. Holt continued the attack in the same vein, telling about Georg Cantor, and his end in the loony-bin. The implication was that Platonists are not just mystics but nuts.

Frenkel then decided to try taking the high road, invoking W.V.O. Quine and Hilary Putnam (distinguished non-nuts Harvard professors I took courses from) and their Indispensability Argument. The basic idea there is that the best choice of what "exists" is those entities that are an indispensable part of our best theory of the material world. Not sure yet whether twistors count, but if they become part of the new unified theory of gravity and the Standard Model, then they surely exist as much as anything does. Holt parried with Hartry Field's Science Without Numbers: A Defence of Nominalism which supposedly shows you can do Newtonian physics without math. Frenkel (together with much of the rest of the audience) scoffed at this, making the obvious riposte: what about GR?

This was finally brought to an end with a few questions from the audience, a sizable contingent of which was underage. They seemed to be having a great time, far more entertained by this sort of thing than by the usual flashy trinkets people use to try and get them interested in math (but which seem to work better on the pre-verbal baby crowd). All in all, a highly edifying experience, I hope the Frenkel/Holt show gets taken on the road.

For a picture of the action, see here.

Comments

1. **Shecky R**
   January 25, 2014

   sounds like a very entertaining evening… don't s'pose you know if there will be a video-upload to YouTube or elsewhere?

2. **CIP**
   January 26, 2014

   Of course what they were really arguing about was what one means by "exists". It's not easy for me to believe that arguments about the meanings of words mean much.

3. **S. Molnar**
   January 26, 2014

   A logician who spent time at the Institute in the 1950s told the story of how Gödel looked up something in a book in the Institute library that he had consulted some years before. Finding that it did not say what he remembered, Gödel concluded that there are demons that go around changing things in books. This, along with his later paranoid belief that people were trying to poison him, suggests a sort of mad hyper-Platonism that strikes me as being a reasonable disqualification when it comes to the more mundane question of mathematical Platonism.

4. **CIP**
   January 26, 2014

   Given the number of great mathematicians who wind up nuts, maybe it's not a talent one should wish for.

5. **Chris Kennedy**
   January 26, 2014

   Peter,
   With regard to the typo, I wasn't there but I've often wondered if all sorts of trouble could have been avoided the past few years by referring to the LHC as the Baryon Collider instead? Speaking of which (slightly off topic) do you plan on reviewing Moffat's "Cracking the Particle Code of the Universe" book containing his very detailed take on the Higgs discovery?

6. **Peter Woit**
   January 26, 2014

   CIP,

   I agree that bald questions like "Do mathematical objects exist?" can be a waste of time, just an uninteresting argument about the meaning of words. The argument over "Platonism" that Frenkel and Holt were having I think is more interesting (besides being kind of fun), since it gets at the question of what to make of "the unreasonable effectiveness of mathematics". Different takes on this question aren't necessarily "right" or "wrong", but lead one to value and take interest in different aspects of mathematics and physics. To the extent that there really are philosophical issues with substance, to me this one of how mathematics, physics and our relationship to reality fit together is a great one.

   As for the great mathematicians = lunatics idea, that's just not my experience at all. There's nothing much to the idea that mental illness corresponds to mathematical talent and achievement. While there have been great mathematicians with mental health issues, generally they did great work while healthy, not so much while sick.

7. **Peter Woit**
   January 26, 2014

   Chris Kennedy,

Probably you're right that CERN should have gone for LBC instead of LHC to stay away from trouble…

I briefly skimmed through the Moffat book in the bookstore, don't think I'll carefully read it or write about it here. His take on the Higgs discovery is an unusual one, since he was prominently arguing for theories with no Higgs. Those who want to know everything about the subject may find some interesting new things in the book (and what I read looks accurate), but in general his personal skepticism about the Higgs so far just seems to have been a wrong direction, making his take on the story not of wide interest.

8. **Peter Woit**
January 26, 2014

S. Molnar,
The story about Gödel that you mention doesn't sound like "hyper-Platonism" so much as the all-too-common symptoms of some varieties of mental illness.

9. **S. Molnar**
January 26, 2014

Peter Woit: Yes, I agree that it was a product (or aspect) of mental illness, but merely wanted to point out that a mind that does not distinguish well between imagination and reality in general is not necessarily a reliable authority on Platonism.

I also doubt that madness exists at a rate among the best mathematicians that is greater than that of top people in other creative fields, but I'm not so sure about logicians in particular. Was it not George E. P. Box who said "All model theorists are mad, but some are useful"?

10. **Chris W.**
January 26, 2014

Speaking of logicians, life did not end well for C. S. Peirce, either. (Granted, "logician" is too narrow a characterization of Peirce.)

11. **srp**
January 26, 2014

Anyone managing socks coming out of the dryer has at least a little sympathy for Godel's position re: book demons.

12. **David Edwards**
January 27, 2014

I think you might find the following sociological facts interesting:

Every time I've made the following statement to mathematicians, they've responded with a broad grin and total agreement!

Even if God hadn't created the Universe, still there would be an infinite number of primes.

Recently, I followed the above with the following:

Even if God hadn't created the Universe, still there would be the category of categories.

I was amazed to discover that young (~30) mathematicians also totally agree with the second statement modulo logical qualms!!

13. **Kavanna**
January 28, 2014

You know, just because you're paranoid, doesn't mean you don't have enemies — or haven't lost some socks in the laundry.

But seriously: while a ga-ga sort of Platonism is congruent with certain kinds of mental illness, the two are not the same, and one doesn't require the other. You're keeping your sanity when you regard nonsensory (but not nonsensical) entities as hypothetical or contingent. You just have to avoid the ga-ga part, thinking that you're perceiving some definitely existent nonsensory, "higher" reality through pure thought, as Descartes and Plato dreamed of.

Ask instead for some proof of relationship to sensory reality. Then you're using your reasoning power soundly, to understand a reality that is beyond our limited senses, but somehow connected with them. Hold on to your senses, as Aristotle said, and accept form as always related to matter and matter to form.

14. **Hardy Hulley**
January 28, 2014

It always interests me that most mathematicians and physicists "behave" as though they were Platonists, even when they are not. By this I mean that the language they use to describe the mathematical concepts used in their work is inherently Platonic. It is only when you press them on the issue that some of them reluctantly admit that mathematical Platonism is problematic philosophically. The point is that mathematicians and physicists "perceive" mathematical objects as though they were real, and this illusion is very compelling.

Curiously, we also "perceive" moral principles as though they were real, even though moral realism exhibits similar deficiencies as mathematical realism (unless you are willing to invoke religion). This is why I think debates about mathematical realism are important – I think that an adequate account of our perception of mathematical "truth" might shed important light on our perception of moral "truth."

15. **nasren**
January 28, 2014

The ad hominem arguments from Jim Holt are a disgrace. If he has a convincing argument for Nominalism then he should give it; and if he doesn't then he should lay off the personal attacks. Cantor was driven into a depression from the attacks of Kroenecker. Gödel was denied full professor status for many years due to the personal vindictiveness of one leading figure in the IAS. If both were paranoid it was also true that both had some reason to be. If personal attacks are allowed then how about we start assembling data on the marital failures of Nominalists, or their alcoholic intake, or what have you.

Some days the slide of academia into idiocy is too much to bear.

16. **Peter Woit**
January 28, 2014

nasren,
I was exaggerating a bit the combative nature of the argument for effect, since I found novel and amusing the phenomenon of a lively, entertaining, high level discussion in front of a general audience of all ages of the philosophy of mathematics. Normally this sort of thing is done in a way that puts all but the most devoted to sleep. Yes, there were some low blows, but everyone knew they were low blows intended for entertainment purposes. Why do you think I described this by the term used for professional wrestling? Do you think that professional wrestlers are trying to hurt each other?

17. **nasren**
January 28, 2014

Hi Peter — yes, I understood your intention, but as a sometime contributor to this debate I can tell you that low blows are not at all uncommon. Platonism is not so much refuted as routinely abused. And this irrationalism has increased markedly in the last twenty years. The idea that Platonism is just a whacky, space-cadet view is becoming completely standard. It seems to me that post-modernism (abuse, rhetoric-as-argument, ad hominem attacks, hero worship of celebrity "thinkers") has become the norm across all areas, including much of theoretical physics. So far only mathematics has been exempt from this corrosion. So far…

18. **Peter Woit**
January 28, 2014

nasren,
I guess my perspective is different. Working in a math department, I don't hear anyone arguing against Platonism, just see lots of people working happily with things that they consider very much real. Those who want to argue against Platonism, from this point of view, are not a threat but a welcome opportunity to think about the deep questions of how math, physics and reality are related.

19. **nasren**
January 28, 2014

Yes, it's outside of the maths department that the war is being lost, in the general culture. I have to say I'm very much on Frenkel's side in this. As long as people see maths as a mere game — as Formalists are won't to do — it will be very much harder to bring people into maths in the future. So my concerns are not just about maths at the College level, but how it is perceived in high schools and junior schools. But my frustrations at what is happening at these early levels is beyond worries about abstract ontology.

20. **Jim Holt**
January 29, 2014

To Nasren:
My ad hominem remarks about Gödel and Cantor were meant to be in a jocular vein. (You had to be there.) The serious argument against mathematical platonism is the "epistemic" one: if mathematical entities transcend spacetime and are causally inert, then how do we, as physically embodied beings, come to have knowledge of them? Platonists like Penrose, Gödel, Connes et al. respond to this point by waving their hands and saying consciousness "breaks through" (Penrose) to platonic reality or that we apprehend it in some extrasensory way. One practical issue here is whether (given Gödel-incompletess) we can somehow refer to a platonically unique "intended model" of Peano arithmetic–whether, that is, we have an absolute notion of finitude.
Cordially, Jim Holt

21. **Prof. David Edwards**
January 29, 2014

You might find it interesting that

Platonism Is the Law of the Land, David A. Edwards
http://www.math.uga.edu/%7Edavide/Platonism_is_the_Law_of_the_Land.pdf

22. **anon**
January 29, 2014

Well, Quine and Putnam may not be nuts, but then again neither is Atiyah, and he does not claim to be a Platonist (see, for example, Created or discovered?, Did we invent number theory?, and the first part of The Nature of Space). I generally find it more profitable to listen to the opinions of mathematicians themselves rather than philosophers of mathematics.

I was a Platonist as an undergraduate (it is often said that all mathematicians are when they are young) but I later realized that formalism (which, by the way, is really a term of abuse; Hilbert himself never used it, it was what his critics called him) is the more sophisticated and the better view. I agree with Jim Holt.

23. **Peter Woit**
January 29, 2014

anon,
Thanks for the links to Atiyah, who always has wonderfully insightful things to say. Listening to these though, I'd personally describe his point of view as basically Platonist, while also taking into account some of the subtleties of the question. He describes mathematics as having a "background", "there waiting to be discovered". For him mathematicians do not invent mathematics, what they do is discover it in a certain way, a way that does depend on human beings and their history. His main image is of mathematical research as searching in the darkness for objects to discover. The names given to mathematical objects come from mathematicians, as does the path of the discovery. The way we think about a field of mathematics definitely depends upon its history, what was discovered and named first, what vision the discoverers had of how things fit together when they made their discoveries (as well as what parts of it remain now dark, still to be discovered). But I think the way he talks about this, the picture is primarily Platonist, one of objects out there to be discovered, while acknowledging that the order and way discoveries are made matters (he should know, having discovered more things himself than most people…).

24. **anon**
January 29, 2014

Peter,

I certainly agree that Atiyah takes a more nuanced, middle-of-the-road approach. I would personally say, however, that his position, at least as it seems to me, tends to lean toward the formalist side.

The traditional Platonist view, as I understand it, is that mathematical objects truly exist as Platonic forms and that mathematicians are somehow able to discover them. Atiyah makes the observation that the sense in which they exist is really quite trivial. What we call mathematics is simply an expression of how mathematicians, as human beings, *perceive* the physical world. If mathematicians did not exist, mathematics would not exist. So the way I see it, and this is how I interpret Atiyah's position, mathematics exists as mathematical *language* in the brain of the mathematician. It is, of course, inspired by our experience of the physical world, but to say that mathematics exactly *is* the external world is a jump that is not philosophically justified. One can certainly say that mathematics represents or reflects the physical world, but only in a rather limited sense.

I think many Platonists have the impression that formalists see mathematics as a purely logical exercise in symbolic manipulation that is not connected to the physical world, but that perception is not true. Even Hilbert, of course, loved mathematical physics.

Atiyah himself makes the comparison to metaphysics, in which Kant synthesizes the views of Plato with those of Hume, who denied the existence of the external world and affirmed only our perceptions of it. In this interview, for example, Quine stubbornly insists on holding on to his materialist views, whereas it seems to the interviewer, as well as myself, that idealism is the better view (it is very probable that the powers of our faculties of perception are limited and therefore the true nature of the existence of things is forever beyond our reach – that is the Kantian prohibition, something I think the multiverse theorists should become more familiar with).

25. **nasren**
January 29, 2014

Jim — duly noted. The internet could be defined as chloroform for humour. I am guessing the tone made intentions clear.

My own view on the epistemology question (regarding mathematical Platonism) is that philosophers have screwed that question up for some eighty years or so. Epistemic access does not require causal access, and if it did a lot of non-mathematical knowledge would be in trouble as well. (Like our knowledge that we will die someday: we obviously don't have causal signals being sent backwards from our deaths.) Philosophers have just been dumb about this.

On the Atiyah question I agree with Peter: I don't see how one can listen to that first video "Created or Discovered" and not realise that he is espousing Platonism. The second video does not much modify it. He is and always has been a nuanced Platonist. He doesn't believe in some super-magical ability to contact a spirit realm in which the number two exists but that idea is the nasty caricature of nominalsts — "Plato's Heaven" said in sarcastic tones.

26. **srp**
January 31, 2014

If you would like a science-fictional elaboration of the Platonist/anti-Platonist debate where the consequences really matter, I recommend Neal Stephenson's Anathem. It's also pretty funny in spots.

27. **Bill**
February 15, 2014

Frenkel's article on NYT: http://www.nytimes.com/2014/02/16/opinion/sunday/is-the-universe-a-simulation.html

28. **Anonyrat**
February 16, 2014

While manifolds may exist in nature – we are said to living in one – the open sets, the sets of coordinate patches we use to define describe them are not manifestly visible. In fact, if I understand correctly, the mathematics of manifolds is supposed to be about what independent of these methods of description. Which leads me to two questions –

1. Should it possible to do all of our familiar mathematics without the artifacts such as coordinate systems?

2. If we have to invoke things that do not exist (arbitrary constructions such as coordinate systems) in order to do mathematics, why is it so far-fetched that we have to invoke things that do not exist in nature (mathematics) in order to do physics? That is, just as coordinate patches are artifacts we need to do useful work with manifolds, which are conceived as existing independent of any particular atlas of coordinate patches; mathematics is the artifact we need to do useful work with Nature?

I am not now and never have been a creationist

January 26, 2014
Categories: Uncategorized

Max Tegmark seems to have decided that my criticism here of the emptiness of ideas in his recent book is "similar to hate-mail I've been receiving from a Young-Earth Creationist". Also, the fact that I have fans at a certain Intelligent Design blog shows that I'm "against the spirit of science". Given this, I guess I need to formally make the statement that

> I am not now and never have been a creationist.

More specifically, everything I've seen about Intelligent Design indicates to me it is nonsense, and I've done my best to ignore those who promote such nonsense, whether they link to my blog or not. Sometimes you'll see trackbacks on my blog coming from such links, basically because while sometimes I delete them, other days I think ignoring these people means really not wasting any time at all on them (and I've had my own problems with people censoring trackbacks…). On the larger issue of how to deal with evolution-deniers, one reason I live in New York is because it's easy to ignore such people here, they're not much of a problem. For those living in other parts of the world where they're more of a problem, you have my sympathy and concern. I admire and congratulate people like Lawrence Krauss for their efforts to deal with the problems caused by such deniers. For most of us, I think the best tactic is to ignore them, on the grounds that not doing so will just lead to getting more attention for them and their arguments. As part of this, any comments arguing pro or con about evolution posted here will be immediately deleted.

While I'm not joining Krauss and others in their admirable efforts, I do think there is one way I can contribute to dealing with the threat from this kind of nonsense. If physicists like Tegmark succeed in publicizing and getting accepted as legitimate mainstream science their favorite completely empty, untestable "theory", this threatens science in a very real way. IDers like the bloggers mentioned above now can point to mainstream physics to justify their own untestable "theory", Intelligent Design, or whatever other nonsense they find attractive because they like having a deity around. Yes, physicists need to fight pseudo-science coming from quarters like the IDers, but they at the same time need to fight pseudo-science coming from within their own community, which in the end may be even more dangerous.

Update: It took about 5 minutes for this posting to attract dumb arguments about religion and they're now flooding in. Sorry, comments closed.

The Principle

January 26, 2014
Categories: Film Reviews

I just found out about a new film coming out this spring, which appears to exemplify exactly the dangers I was pointing to in my last posting. It's entitled The Principle, and features physicists Michio Kaku, Lawrence Krauss and Max Tegmark, with Kate Mulgrew (aka Captain Janeway) as narrator.

You can take a look at the trailer, this blog, or this interview to start to get some idea of what's going on. The person behind this is Robert Sungenis, a bizarre figure with extreme religious views. He holds a Ph.D from an institution located in Vanuatu, and is an advocate of the idea of "geocentrism", the idea that the Catholic church was right, and scientists since Galileo have got it all wrong (see his web-site Galileo Was Wrong). For another Youtube video explaining what this is all about, see here.

As near as I can tell from all this, without having yet seen the full film, it appears that what probably happened is the following. Sungenis decided that the anthropic principle business in cosmology supported his views, so he went and got physicists like Kaku, Krauss and Tegmark to say silly things on camera, then edited this to suit his case. Maybe the trailer is misleading, and these people actually make a cogent case against Sungenis's nonsense and for solid science, we'll see…

Update: For a different point of view on this, from someone worried that geocentrists will discredit the Catholic Church, see here.

Comments

1. **Shooter**
   January 26, 2014

   I think the whole Galileo affair is misunderstood. The Church already knew of Kepler's view of planetary motions and whatnot, and every cosmologist read his work. As for Galileo, he engaged in scientific misconduct, insulted the Pope, and a lot of other crimes. It is strange that Sungenis isn't aware of these facts.

2. **Chris W.**
   January 26, 2014

   In its underhandedness and general level of intellectual dishonesty this film sounds like a reprise of *What the Bleep Do We Know!?* (released nearly 10 years ago).

3. **David**
   January 26, 2014

   Shooter, that's a mischaracterization of history. The church did not examine whether Galileo had engaged in "scientific misconduct," which of course is a concept that did not exist at the time. The church did indeed know about heliocentrism before Galileo published his book, and in fact Pope Urban asked GG to write about it, with a warning to not endorse heliocentrism. The insult to the pope is that GG wrote a character into the *Dialog* who used the pope's own words – the character was named Simplicio and the pope's words supporting heliocentrism were shown in the book to be foolish. Maybe GG brought it on himself by speaking forthrightly, but nonetheless, his conviction was for promoting heresy (that the earth moved, in contradiction to the bible). The church has, sort-of, apologized for GG's mistreatment, but never actually said, in writing, that he was right and they wrong.

4. **srp**
   January 26, 2014

   Geocentrism? Really? I sure hope they mean that in some metaphorical way or else peoples' neurons will actually die watching this film.

   Of course, by appropriate choice of coordinate system I've been able to define the srp-centric universe which is very convenient for me, but I don't think that's what they have in mind…

5. **Peter Woit**
   January 26, 2014

   Chris W.,
   Yes, this does look like the cosmology version of What the Bleep? (actually, maybe quite a bit loonier than that). I wrote about that film long ago here
   http://www.math.columbia.edu/~woit/wordpress/?p=83

6. **Rick DeLano**
   January 26, 2014

   I am the producer and writer of "The Principle".

   The film is an examination of the Copernican Principle.

   As its title is intended to suggest.

   The precognitive reviewers are of course welcome to try their hands.

   The film will disappoint them, once it is not what they have channeled it to be.

7. **Yatima**
   January 27, 2014

   Meanwhile, the popular press on the popular topic of Hawking on the hot topic of firewalls.

8. **Dom**
   January 27, 2014

   Rick
   Thanks for your reply, one question though . . . What do your last three oddly-phrased sentences mean ?

9. **Peter Woit**

January 27, 2014

Dom,
He's just obviously referring to the fact that people are discussing the film only having seen the trailer.

It's true that until the whole film is available, it will be unclear what role the physicists play in it. There seems however to be a huge difference between the point of view of the physicists and that of the filmmakers, so, I at least am curious to see how that plays out., with one obvious guess that the views of the physicists get misrepresented…

10. **Neil**
January 27, 2014

The contrast between the Copernican principle and the Anthropic principle is interesting. Is our observational vantage point privileged [A], or is it mediocre [C]? It depends. Obviously the most plentiful location in the universe is the intergalactic void, not a planet in the habital zone of a stable star, so the earth is no doubt a privileged vantage point. It is hardly profound to understand why we have it, and if that is the anthropic principle then it is trivial. But asserting a multiverse is something else. We know the intergalactic void exists, we do not know other universes exist.

11. **Rick DeLano**
January 27, 2014

Peter:

Thanks for correctly characterizing your guess as a guess.

I am not guessing.

Your guess is wrong.

"The Principle" is noteworthy, first and foremost, not because of the exceptionally high quality of its interviewees.

You can see most of these guys on the Discovery Channel any night of the week.

"The Principle" is noteworthy, first and foremost, because it is, so far as I can tell, the first film focused on the Copernican Principle itself.

It is interesting that this foundational *assumption* of the modern world should never have presented itself to anyone else as a worthy subject of a documentary film.

Sometimes one has to look at the world differently, in order to see what the consensus doesn't.

I do not expect you to approach my film as you would any other; you will pre- cognitively review it.

That is fine.

You are wrong, and when the film is released you will see just how wrong.

12. **Peter Woit**
January 27, 2014

Rick,
OK, looking forward to seeing how the obvious difference between the point of view of these physicists and that of the filmmakers plays out…

13. **Rick DeLano**
January 27, 2014

Thanks, Peter.

It plays out, as any good drama should, in a wonderful intellectual slugfest that includes excellent punches from all sides.

I know it is hard for some to believe, but I am interested in making an excellent film.

I know it is harder for some to believe, but the Copernican Principle is very seriously challenged by observations…….

and always has been.

14. **CJ**
January 27, 2014

Dear Rick,

You write, "I know it is harder for some to believe, but the Copernican Principle is very seriously challenged by observations."

Where can we read about these observations? Or do we have to wait for the film? Do Michio Kaku and Max Tegmark reveal the Kaku/Tegmark observational satellite in the film, alongside the new data found in a parallel universe?

That alone would be worth the price of popcorn these days. 🙂

15. **Bill**
January 27, 2014

Any publicity is good publicity. Ok, the post about MUH was necessary but, Peter, why not use your connections and the popularity of your blog more often to give visibility to interesting things going on in physics and mathematics instead?

16. **CJ**
January 27, 2014

Dear Bill,

Peter *does* use this blog to regularly report on cool things going on in science and math! Have you read the last several posts?

What Peter also does, which too few folks/"science" reporters do, is call out all the modern-day hokem, hype, and snake oil, sold as science.

Also Bill, when certain folks are using multi-million-dollar war-chests to promote personal, faith-based, science-free initiatives as "science," Peter provides an invaluable service in pointing this out, as such faith-based initiatives both displace and disgrace professional physics and physicists.

17. **Peter Woit**
January 27, 2014

CJ,
If you look at the long interview linked to in the posting, at one point there's a segment from the film featuring Max Tegmark. He's explaining about the "axis of evil", and I gather the film makers see that as evidence against the Copernican principle (although others claim it as evidence for the multiverse and thus for a larger "Copernican principle").

Bill,
The two postings this weekend about twistors and about the debate over Platonism were I thought exactly what you are asking for. Debates over philosophy of mathematics are not to everyone's taste, and I guess there's no form of that debate you can watch, but there was a bit of content in my post amidst the silliness. About twistors, I'll undoubtedly write more sometime, but I highly recommend the Andrew Hodges web-site I linked to. It gives a lot of detail about this story, with excellent references to follow up. It does a far better job than I ever could of writing about the technical aspects of this story.

18. **CJ**
January 27, 2014

Dear Rick,

In addition to including scientific luminaries such as Max Tegmark and Michio Kaku, does your film also include Einstein?

Albert Einstein stated, "Once it was recognised that the earth was not the center of the world, but only one of the smaller planets, the illusion of the central significance of man himself became untenable. Hence, Nicolaus Copernicus, through his work and the greatness of his personality, taught man to be honest." (Albert Einstein, Message on the 410th Anniversary of the Death of Copernicus, 1953)

It seems that many are not content to only attempt to undo the scientific work of Einstein and Copernicus, but they also must undo the spiritual work of Einstein and Copernicus, and "teach men to be dishonest."

19. **Bill**
January 27, 2014

Peter, yes, I did enjoy your post about amplituhedron, and I went to Andrew Hodges website and read his story, which was fun. That post would be even more interesting to me if it had nothing to do with Nima. As for stories involving Edward Frenkel (another common character), instead, I would prefer more updates about mathematics, like recent work of Vincent Lafforgue. In any case, I shouldn't have sounded so critical, since I do enjoy your blog.

20. **Peter Woit**
January 27, 2014

Thanks Bill,
I'd also like an update on the Vincent Lafforgue stuff, unfortunately I don't think I can provide it due to lack of expertise. Every so often I try and ask my colleague Herve Jacquet about it since he is an expert. If I ever understand his answer I'll try and write something here…

21. **Rick DeLano**
January 27, 2014

CJ:

It is difficult, for me, to reconcile Einstein's comment concerning how Copernicus "taught men to be honest" (they were dishonest before Copernicus??), with his own view of reality, expressed below:

"I have come to believe that the motion of the Earth cannot be detected by any optical experiment."

"…to the question whether or not the motion of the Earth in space can be made perceptible in terrestrial experiments. We have already remarked…that all attempts of this nature led to a negative result. Before the theory of relativity was put forward, it was difficult to become reconciled to this negative result."

22. **CJ**
January 27, 2014

Dear Rick,

Firstoff, are you and your film stating that the earth does not move, like the pre-Copernicuns?

As Einstein never stated thusly. Instead, in 1922 he stated, ""I have come to believe that the motion of the Earth cannot be detected by any optical experiment." - http://physicslink.ucsd.edu/students/courses/winter2011/physics2d/einsteinonrelativity.pdf

This has nothing to do with a geocentric universe, and everything to do with the fact that the laws of physics are the same in all inertial frames–a famous postulate of relativity.

Throughout your film, do you just pull quotes at random, take them out of context, and reassemble them at will, having Michio Kaku and Max Tegmark mouth them? While not science, perhaps your film is postmodern performance art?

At any rate, good job on the publicity. I love comedies and am very much looking forward to it on Netflix.

23. **Rick DeLano**
January 27, 2014

CJ:

We do agree that Einstein believed the motion of the Earth could not be detected by any optical experiment.

We apparently differ on whether that fact is of interest, in a documentary about the Copernican Principle.

I understand you to be quite opposed to the idea of a film made by those who view the evidence differently than you do.

Oh well.

On the other hand, the filmmakers consider it important not to impose a particular conclusion on the audience.

You might not like that either.

Oh well.

Thanks, by the way, for your compliment about the publicity.

We have made an interesting film, on a subject that has a great deal of interest, clearly for the public.

24. **Andrew Foland**
January 27, 2014

Anyone interested in observational evidence of motion through the solar system should read about calibration of the WMAP experiment, for instance, at http://oberon.roma1.infn.it/lezioni/laboratorio_specialistico_astrofisica/pdf/lezione12.PDF .

Motion of the earth around the sun shows up as an easily-detected 300 uK annual modulation in the CMB dipole data.

25. **CJ**
January 27, 2014

Dear Rick,

You write, "We do agree that Einstein believed the motion of the Earth could not be detected by any optical experiment. We apparently differ on whether that fact is of interest, in a documentary about the Copernican Principle."

Yes, every physicist knows that Einstein's statement that "the motion of the Earth could not be detected by any optical experiment" has nothing to do with the Copernicun Principle, and everything to do with Einstein's Theory of Relativity.

And yes, I almost agree with your second statement, but there's a typo. You meant to write, "We apparently differ on whether that fact is of interest, in a comedy about the Copernican Principle, starring Max Tegmark and Michio Kaku."

If one's goal is to make a bit of money by taking Einstein's words out of context and leveraging the general public's (& general science reporters' and even some famous professors') lack of knowledge regarding science, Copernicus, and relativity, then I imagine you are quite pleased with your creation.

I mean, after all, what the bleep do we scientists know?

26. **Rick DeLano**
January 27, 2014

CJ:

Pre-cognitive reviews are always interesting, I will certainly add yours to my collection.

The film will be released this spring, and then we will publish all the pre-cognitive reviews.

Thanks!

27. **Rick DeLano**
January 27, 2014

@Andrew Foland:

Thanks for the interesting link.

Our film examines the Copernican Principle, and the question of the motion of the Earth is a crucial part of the history of the development of that principle.

What the evidence shows is that there is a relative motion between Earth and CMB.

This is interpreted in your link as a motion of the Earth wrt the CMB.

I would be curious to know whether any other possible explanation might exist, because if not, then we have established Einstein to have been in error when he stated that no optical experiment could detect the motion of the Earth.

Is it your understanding that Einstein is proven wrong in this assumption by the data presented at your link?

28. **CJ**
January 27, 2014

Dear Rick,

My words are not a pre-cog review.

Rather, my words are pointing out not only your complete lack of understanding of the Principle of Relativity and one of its Postulates, but your lack of character and honor in actually creating an entire film based off faulty science to both mislead the general public and make money off them.

You are the one stating that your film conflates Einstein's Postulates of Relativity with a stationary earth in a geocentric universe which denies the noble work of Copernicus and countless others.

You are telling us that this is the central premise of your film, and we are merely pointing out the fallacy of the central thesis which you claim underlies your film.

Thus our words are not a pre-cog review of your film, but rather they are a post-cog review of you, your misguided words, and your unscientific thought process.

Posting your extremely severe misunderstandings here a few years ago could have saves a lot of time and trouble. 🙂 But as your film will help Michio Kaku and Max Tegmark sell more sci-fi books, all is not lost. 🙂

29. **Danny**
January 27, 2014

It would be a tremendous disappointment, and a minor betrayal of our ethical commitment to society, but perhaps there should be a discussion in the community about closing ranks — and not saying anything stupid, at all — until such time as the current flock of hypothetical ideas are either experimentally verified or put on a solid theoretical foundation? As it is, idiots like Mr Delano and poor media coverage are causing too much damage to the long-term health and reputability of our field.

30. **Rick DeLano**
January 27, 2014

CJ:

I must say you are approaching hysteria in your pre-cognitive reviews.

What is it that has you so profoundly disturbed by a film which recounts the history of how we view our place in the cosmos?

One that you have not seen?

One which you insist you understand better than I do, when I wrote and produced it?

One of the interesting aspects of "The Principle" is the truly remarkable degree of passion it seems to stir up.

I think this is going to be an important part of the story.

31. **Rick DeLano**
January 27, 2014

@Danny:

The ranks do not seem closeable to me.

There is a growing sense of unease, in the minds of the best theorists, about the foundations upon which our cosmology rests.

This is understandable.

96% of the universe's mass/energy must exist in undetected forms, in order for the consensus cosmology to stand.

We haven't found the easier form, dark matter, despite 50 odd years of exquisitely sophisticated attempts.

I don;t think the ranks are closeable at this point.

I think we live at one of those remarkable times when real change is in the air.

I hope so.

32. **Jesper**
January 27, 2014

Reading comments from Rick DeLano sounds an awful lot like climate-change deniers and creationists, now going for Copernicus – this is one that I didn't see coming.

33. **Michael Moyer**
January 27, 2014

In the January issue of Scientific American we published a feature story titled "The Case Against Copernicus," which detailed the excellent (as of the 17th century) scientific arguments against the heliocentric universe. The story is online here, although it's behind our subscriber paywall:

http://www.scientificamerican.com/article/the-case-against-copernicus/

(If you are at an institution that subscribes to Nature you can also get it via the Nature site.)

Here's the story in brief: In a heliocentric universe, we should observe annual parallax as Earth goes around the sun. Astronomers of the 17th century could not detect parallax, implying that the stars were unimaginably distant. Since each star has a finite apparent width, this width and their distance implied that the stars should be unaccountably large–many orders of magnitude larger than the sun. This argument, along with a few others, kept heliocentrism from being adopted more widely. (Also, Tycho Brahe had come up with a hybrid model of the universe—geo-heliocentrism—which was the preferred alternative until the 18th century.)

Of course, the star size problem was illusory. The apparent width of stars was due to diffraction. Parallax was eventually observed. And Newtonian gravity provided an explanation of how a heavy, solid like Earth could move in an ellipse through space.

Now, why anyone in the 21st century would doubt heliocentrism is beyond me. I agree—this documentary sounds a lot like What the bleep do we know? But then again, I admit that I am "pre-cognitive."

34. **CJ**
January 27, 2014

Dear Rick,

I understand the panic that is now setting in as you are becoming aware that the entire thesis of your film, which you shared with us, is based on a gross misunderstanding, whence you mistakenly conflated Einstein's Principle of Relativity with a geocentric, pre-Copernicun universe.

Rick–the great thing about science is that there is no shame in admitting you were wrong, correcting your mistakes, and moving forward.

As there is plenty of time before your film is released, you have plenty of time to add a disclaimer at the beginning, stating:

"Shortly after completing this film, it was brought to my attention that when Einstein stated that "the motion of the Earth could not be detected by any optical experiment," in a 1922 lecture on the origins of Relativity, he was not opposing the Copernicun view nor stipulating that the earth was stationary nor at the center of the universe, but rather, he was restating one of the postulates of relativity that states that 'The Laws of Physics are the same for All Inertial Observers.'"

Then, Rick, before you cut to Max Tegmark mimicking an explosion or the big bang, you could present the audience with another piece of information you just became aware of today:

Albert Einstein stated, "Once it was recognised that the earth was not the center of the world, but only one of the smaller planets, the illusion of the central significance of man himself became untenable. Hence, Nicolaus Copernicus, through his work and the greatness of his personality, taught man to be honest." (Albert Einstein, Message on the 410th Anniversary of the Death of Copernicus, 1953)

Dear Rick, please feel free to use this invaluable science freely. I need no reference nor payment for it. All I ask is that, in the spirit of science, you share it freely with your audience in your film, as I shared it with you.

Best,

CJ

35. **Jesper**
January 27, 2014

This is probably hugely off-topic (and just off in many other ways), but since you've come to discuss the more colorful "science films" I thought I'd mention the movie "Hortons hears a who". I watch the movie as a funny and cute analogy to the string theory landscape and all the multiverse stuff. Especially viewable is the 59th minute, where there is a fantastic view of the entire landscape (zillions of universes, all pink!), and also the fantastic Katie line ("In my world , everyone eats rainbows and poops butterflies") at the 29th minute. Seriously, its a must watch for any serious physicist.

Sorry – couldn't help it 🙂

36. **Rick DeLano**
January 27, 2014

@CJ:

I am increasingly amused by your observations concerning my film, but it seriously appears to me that "panic" is something more appropriately describing you here.

But we do seem to be talking past each other at this point.

I assure you, no such disclaimer as you propose would be necessary, or even appropriate, given the development of Relativity in the historical context of the failure of all experiments to detect the universally-assumed motion of Earth around Sun.

That historical context is what is present in "The Principle", and absent in your panic-stricken attempts to tell us what it is pre-cognitively.

37. **Dom**
January 27, 2014

I am reminded of one of Tom Tomorrow's excellent cartoons regarding a similar subject
[Sphericated v Flaticular]

38. **Rick DeLano**
January 27, 2014

@Michael Moyer:

Certainly very few things have ever been as plausible as the Copernican notion of heliocentrism, as developed successively by Kepler and Newton.

Remarkably, the only nail that never could get hammered down was the direct measurement of that universally-assumed motion of Earth around Sun.

Everything was perfectly plausible.

But the motion was never measured by any experiment.

This seemingly minor detail destroyed Newton's absolute space, and required us to either (a) admit the Earth was not orbiting the Sun, or (b) insist that absolute motion was a fiction, and that physics could account for parallax, for example, no matter whether the Earth was taken to be fixed, or the Earth was taken to be moving.

Einstein makes this point here:

"The struggle, so violent in the early days of science, between the views of Ptolemy and Copernicus would then be quite meaningless. Either CS [coordinate system] could be used with equal justification. The two sentences, 'the sun is at rest and the earth moves', or 'the sun moves and the earth is at rest', would simply mean two different conventions concerning two different CS [coordinate systems]."

Certainly Einstein does not agree with you, that parallax constitutes that "optical experiment" which detects the motion of the Earth.

Einstein came to believe no such experimental demonstration was possible.

Do you disagree with him?

39. **CJ**
January 27, 2014

Dear Rick,

Yes, "are talking past each other," as I am quoting Einstein on Relativity and Copernicus, while you are warping words to merely build hype for a film based on a primal, embarrassing misunderstanding and misconception–a true rookie mistake that any freshman physics student would have quickly realized, and corrected their erroneous ways.

However, the horse has left the barn so there is little use in shutting the door, and with the luminary cast of Tegmark/Kaku et al., the film should bring you a modestly handsome monetary profit, and an even greater sense of accomplishment along your bizarre crusade against science, philosophy, honor, physics, and reason. 🙂

40. **CJ**
January 27, 2014

Dear Rick,

Are you really

1) insisting that the Earth Does Not Move.
And that 2) Einstein actually stated that there is no proof that the earth moves?

Because Einstein never said thusly, and too, the Earth Moves.

Rick, your vast and resounding errors and misunderstandings have been shown, but now you are treading on new ground, in not only being wrong, but exacerbating your dire, desperate situation by peddling and promoting a film which knowingly misleads and misinforms the public, all for private profit. Is it legal to profit off of fraud?

41. **Rick DeLano**
January 27, 2014

CJ: "I am quoting Einstein on Relativity and Copernicus"

Einstein on Copernicus: "The struggle, so violent in the early days of science, between the views of Ptolemy and Copernicus would then be quite meaningless. Either CS [coordinate system] could be used with equal justification. The two sentences, 'the sun is at rest and the earth moves', or 'the sun moves and the earth is at rest', would simply mean two different conventions concerning two different CS [coordinate systems]."

42. **Rick DeLano**
January 27, 2014

CJ:

It is illegal to profit off of fraud.

You could, if you wish, allege it in court.

We would certainly be prepared to respond.

But, should you ever wish to seriously (in court) allege our film to be fraudulent, may I suggest you watch it first, before filing your claim.

Just sayin'…..

43. **CJ**
January 27, 2014

Dear Rick,

When you write,

"Einstein on Copernicus: "The struggle, so violent in the early days of science, between the views of Ptolemy and Copernicus would then be quite meaningless. Either CS [coordinate system] could be used with equal justification. The two sentences, 'the sun is at rest and the earth moves', or 'the sun moves and the earth is at rest', would simply mean two different conventions concerning two different CS [coordinate systems].""

You are merely restating Einstein's Postulate of Relativity that the Laws of Physics are the Same in all Inertial Frames.

Then, you are misinterpreting, mis-extrapolating, and misappropriating the quote to teach blatant falsehoods as truth, denying that the earth moves, while stating that Copernicus was wrong.

Dear Rick, do you also claim that the earth is flat after you drive down a straight road with Max Tegmark for a half hour in your film? Also, do you set up a camera at the beach whiel sunning with Michio Kaku to record the rising and setting sun, to show that really the sun is moving, while the Earth is stationary? 🙂

What was the budget on your foundationally fallacious film? & who funded it? Certainly not physicists!

44. **Rick DeLano**
January 27, 2014

CJ asks if I am "1) insisting that the Earth Does Not Move."

>> Einstein insists no experiment can *detect* any such motion. I insist that is a very interesting thing to know, in the context of a film about how we have come to view our place in the cosmos.

"And that 2) Einstein actually stated that there is no proof that the earth moves?"

>> Here is what Einstein actually stated. I know you have a hard time believing him, but that is your problem, not mine:

“I have come to believe that the motion of the Earth cannot be detected by any optical experiment.”— Albert Einstein

45. **Anonyrat**
January 27, 2014

Mr DeLano, on Google Books, there is a book from 2005 “Physics Before and After Einstein” edited by Marco Mamone Capria. A passage in there seems specially addressed to you (see section 14 of chapter 5), titled “Was the Copernican Controversy a Pseudo-Problem?”
http://books.google.com/books?id=SdLLsj-0rqIC

Since this was written years before your film was a gleam in your eye, you can hardly claim “pre-cog review”. And it specifically addresses the Einstein-on-Copernicus quote that you are hawking.

The key quote is: “Coming back to the main physical issue which was at stake in the Copernican controversy, does general relativity make any difference to the distinction between locally inertial and non-inertial (e.g., rotating) systems? Not much. As two Italian physicists pointed out in 1929, in general relativity a locally rotating system, for instance, is as easily distinguishable from a locally inertial system as it is in classical mechanics. In other words, inertial effects exist also in general relativity! If this was not the case, general relativity would simply contradict ordinary empirical evidence.”

46. **Anonyrat**
January 27, 2014

If that was not clear enough, even more explicitly “Our conclusion is that, though repeatedly and authoritatively endorsed, the claim that general relativity finally ‘solved’ the Copernican controversy by showing that Copernicus and Ptolemy were ‘both right’ is based on several mistakes, concerning both the gist of their disagreement and the scope of ‘general covariance’. However such a claim was probably decisive in winning for Einstein’s theory a cultural and philosophical place second to no other physical theory of his time.”

47. **Anonyrat**
January 27, 2014

Regarding Einstein’s “no optical experiment can detect the motion of the earth” – he could not have meant that in general, because he himself gave an explanation in special relativity of stellar aberration. See the Wiki article:
http://en.wikipedia.org/wiki/Aberration_of_light

48. **Peter Woit**
January 27, 2014

CJ/Rick,
Enough, you really need to find another topic to argue about.

To say one thing in favor of these filmmakers, I don’t think this is going to make them rich, seems unlikely they’re doing it for the money…

49. **kashyap vasavada**
January 27, 2014

@ Rick DeLano: I am reading very interesting debate between you and other readers of this blog. I do not know about your scientific literacy, but it seems that you did not take physics even in high school. Correct me if I am wrong. Any way let me point out something which surprisingly other people have not mentioned. Do you believe that earth is very small compared to the sun and there are stars which are millions of time bigger than sun? Even if we ignore all scientific theories, is it possible that everything in the entire big universe revolves around the tiny little earth? This would totally defy common sense.

50. **Bill**
January 27, 2014

It’s interesting that for some people geo-centric movement of the solar system looks just as natural as the helio-centric movement.

51. **Anonym**
January 27, 2014

Rick, it does not follow that the earth is stationary, even if we cannot because of the equivalence principle prove that it moves. A moving earth or a non moving earth are both valid view points, but neither one is true in any absolute sense.

The claim that “Galileo was wrong — the church was right” found on your web page is thus false, since the church claimed that the earth stationary. (You have to claim either that “Galileo and the church were wrong” or that “Galileo and the church were right” to make sense, if you appeal to the equivalence principle.)

So your own wise ass appeal to the equivalence principle thus turns against your case for “geocentrism”.

52. **Yatima**
January 27, 2014

“I am increasingly amused by your observations concerning my film, but it seriously appears to me that “panic” is something more appropriately describing you here.”

I am getting flashbacks to the deepest infernos of alt.science.alternative, complete with fund drives for zero-point energy devices.

53. **max**
January 27, 2014

While you are no doubt correct about the dubious motivations behind this project, the scientific and philosophical stance is an interesting one from the point of view of quantum gravity. If one allows that local observers (on the earth) are a key feature of the quantum theory, and that one must understand how this fits into a human cosmology (not necessarily a stupid stringy multiverse), then there is a real sense in which the earth is special (for us). After all, classical spacetime is supposed to emerge from other data.

Moreover, in Galileo’s trial, which was actually easy for him because he was quite friendly with the church, it was clear that he did not yet understand his relativity. He actually insisted that the earth moved. So he was wrong, no matter how you look at it.

54. **Roger**
January 27, 2014

Scientists and others have been using Copernicus, Galileo, and Einstein as examples to show various points for a long time. Usually the facts and the science get distorted so badly that the lesson is hopelessly confused. My hunch is that this movie will also get the story confused. But maybe we just defer judgment, just in case the movie gets it right.

55. **Rick DeLano**
January 27, 2014

@Anonyrat: Interesting quotes. The same forces arise, regardless of whether the Earth or the cosmos is taken as rotating. Einstein:

"One need not view the existence of such centrifugal forces as originating from the motion of K' [e.g.-the Earth]; one could just as well account for them as resulting from the average rotational effect of distant, detectable masses as evidenced in the vicinity of K', whereby K' is treated as being at rest."

@ Peter: You are quite right. We never in our wildest dreams expected the film to generate the kind of interest it has, even at this extremely early stage. No car crashes, no love scenes.

@kashyap: Yes, I decided to let the physicists speak in the film since, as you correctly note, I doubt anyone would much care about what I might have to say, although I have enjoyed thinking about these matters over the last several years.

You ask a very interesting question: "Even if we ignore all scientific theories, is it possible that everything in the entire big universe revolves around the tiny little earth? This would totally defy common sense."

I think it is very safe to say that consensus cosmology totally defies common sense.

Relativity certainly defies common sense.

Quantum physics might be the death of common sense.

The idea that the Earth is at the center of the Universe and not moving made perfect common sense to almost every person who ever lived….until Copernicus.

The idea that the Earth is at the center of the universe and not moving now defies common sense.

That alone is a very interesting thing to think about, since the change was clearly not the result of any experimental detection of the motion.

It is a very interesting story.

I think we do a very good job of presenting it to the general audience in "The Principle".

56. **Anonyrat**
January 27, 2014

Mr DeLano, read the whole chapter. Macy's Principle is not borne out by General Relativity.

57. **Peter Woit**
January 27, 2014

Since I allowed Yatima earlier to introduce a link to a story about Hawking's recent ideas on black holes (which I understand not at all and have nothing to say about…), I suppose I should provide this link, from the Borowitz report

http://www.newyorker.com/online/blogs/borowitzreport/2014/01/stephen-hawkings-blunder-on-black-holes-shows-danger-of-listening-to-scientists-says-bachmann.html

There are rumors it is satire, but these days in this subject, figuring out what is satire and what isn't can be tricky…

58. **abbyyorker**
January 27, 2014

Of the three scientists in the trailer, we right away stopped mentioning Krauss. Then Kaku vanished in half the posts. So in the end, Tegmark alone is tarred with the "Rick" brush.
Despite his crimes, I don't think this is especially classy.

59. **paddy**
January 27, 2014

I think that Peter is teaching himself and us by proxy that one cannot engage these folks in legitimately conversation. Although one's mind does come up with eloquently stated logical flaws in their arguments…it will do no one any good. They answer to a higher truth than truth.

60. **Peter Woit**
January 27, 2014

abbyyorker,

I tried to be even-handed…
It looks like Kaku gets top-billing. My reference to Tegmark's segment was just because someone was asking what the "evidence" against the Copernican principle was, and that was the one thing I had seen.

I have no idea why these three physicists got involved in this, I doubt they knew what it was when they went on camera. It was pretty odd though to run into this right after Tegmark was giving me grief for links to my blog from IDers…

61. **Paulo Guerra**
January 27, 2014

When Einstein said:

"I have come to believe that the motion of the Earth cannot be detected by any optical experiment."

he was refering to the motion relative to the ether, the hypothetical medium in which electromagnetic waves were thought to propagate. Since no such motion could be detected, the ether was not needed.

62. **Chris W.**
January 27, 2014

Peter: You mean rumors that Hawking's recent statements are satire?

Andy Borowitz is a humorist, of course. I think everything he writes for the New Yorker is a gag, not that Michele Bachmann can't keep us supplied with unintentional howlers all by herself.

63. **Chris W.**
January 27, 2014

By the way, what the hell is up with this odd use of the term *precognitive*? I detect the faint odor of Scientology…

64. **Fred Page**
January 28, 2014

@Rick DeLano-

While I agree that I can't comment on a movie I haven't seen, I can comment on your comments here. It's no longer 1922. We presently have multiple probes – including one around Mars, one around Saturn, two around the Sun, and one in interstellar space all of which need to know where the Earth is at any given point so that they can communicate back with the Earth. As they succeed (otherwise we wouldn't get information back from them), our current models are giving us useful answers.

I think On the Revolutions of the Celestial Spheres has sufficient arguments in and of itself. That said, constructing a model with an Earth-centric universe would require rejecting:
1) Newton's theory of gravity
2) Einstein's theories of Special and General Relativity.
3) All our Earth-based gravity-mapping data.

It may be an interesting philosophical and/or mathematical exercise to discard the theory of Gravity, and attempt to create mathematics consistent with all our observations – but with a geo-centric universe. However, scientifically, you aren't going to end up with a useful model in this manner; the GOCE data alone would seem to be an insurmountable obstacle.

65. **Mike Sharples**
January 28, 2014

I am baffled at the complexity of the arguments here.

Rick Delano's central argument is:
"There is no way Geocentricism can be disproved."

Without even wasting breath questioning the validity of that statement simply consider:
In what way does that argument prove Geocentricism? In what way does that argument disprove Heliocentrisism?

The whole is based on a logical fallacy. There is no need for Science to rouse itself at this time.

66. **Rick DeLano**
January 28, 2014

I have really enjoyed this thread.

The degree of mutual (and self) contradiction among the participants is hilarious (we believe Einstein but we know he was wrong when he said it was equally valid to take the Earth as stationary and the Sun as moving- we know Einstein said no optical experiment could prove the motion of the earth but he didn't really mean *no* optical experiment, just whatever optical experiment we think he meant, etc etc etc).

I appreciate all the wisdom, but I must say it is not me you need to persuade.

I personally think you guys are completely lost.

You have no idea how to make the universe obey your theory of gravity.

You are completely certain your theory of gravity must be right- after all it has worked so well for so long.

I can appreciate this. We have seen it before.

Newton, compared to the present consensus, was so much more persuasive, logical, and consistent……

Newton was wrong.

So are you guys.

I hope you enjoy the film.

If not, make your own.

May the best film win.

67. **Mike Sharples**
January 28, 2014

Dear Mr DeLano.

If you cannot prove something is true it does not mean that you have proved it is false. Please apply basic logic before advancing any scientific argument.

68. **GoletaBeach**
January 28, 2014

Einstein certainly must have understood the aberration of starlight. His statement about optical motion was most likely embedded in some sort of context that has now been omitted in this blog.

In any case, science at its core is not a cult of personality. Einstein was no pope or Mormon prophet that was infallible.

My 2 year-old daughter also thinks she is the center of the Universe. Who knows, maybe she is. I don't have the funds to make a popular movie about it, but maybe the Coen brothers will make a comedy about one of their kids who thinks the same thing, I bet they could make a lot more money than this film. I might even go see it.

Once European nobility thought they were god's chosen ones by heredity. Well, if you've assassinated your way to the top, I guess you need some special clemency from god.

Once white people thought they were superior. Once some Aryans thought they were superior. Didn't turn out well (skirting Godwin here!).

At the vary least, anyone claiming that the Earth is special must deal openly and adequately with the possibility that they are fooling themselves in the same manner as those groups. Probably it is impossible to do so.

69. **Dom**
January 28, 2014

Rick
Something I see too often in science-based internet fora is someone who appears, does a Gish Gallop and departs claiming triumph. Usually they claim to be overturning scientific reality but oddly you never hear about them picking up their Nobel Prize.

70. **Katy**
January 28, 2014

See, I have a huge problem with Bill Nye going to the Creation Museum to "debate" evolution. There is no debate. There are no "two sides" to this story. If people are seriously pushing creationism and geocentrism on religious grounds, then they are not doing so because they are misinformed. They've been perfectly informed many times over. You may think you're being altruistic on behalf of science by enlightening these people but you aren't. You are making them think the point is arguable. We should simply condemn people who promote bunk loudly, but not communicate with them directly.

71. **Laymammal**
January 28, 2014

A. If the Earth revolves around the sun, then the sun has greater mass than the Earth. B. If the sun revolves around the earth, then the earth has greater mass than the sun. This has nothing to do with the relativity of motion in different reference frames. It is an either/or.(period)

Accept B, and you contradict so many theories in so many fields from chemistry, nuclear physics, particle physics, astronomy, and others(like Relativity)that you will need a new library of theories to try and overcome all the inconsistencies that appear. You could ignore mathematics and logic if you like as well.

72. **Kavanna**
January 28, 2014

Thanks, Peter, for taking on the Tegmark et al. nonsense. Many of us have been worried for a long time about the lasting damage that string theory and related manias (like the multiverse) would do to the seriousness and credibility of science. We saw it in the 1990s with academic anti-science post-modernism. Creationism and other para-scientific and anti-scientific movements were only a matter of time.

(IDT never seemed like nonsense so much as circular and empty: if true, trivial; if not, no way to know. It has that in common with Tegmark.)

About Galileo: (1) he didn't fully understand the principle of inertia or of relativity — he had it in a half-formulated state; (2) he wasn't exactly friendly with the Church, but did have powerful protectors amongst the secular powers, like his sponsors, the Medici. That protection did him some good. The Church barely noticed Copernicus' book. But it was not in good humor in the early 1600s, with the Reformation, Counter-Reformation, and wars of religion in full swing and various people claiming the right to interpret scripture as they saw fit. Galileo, without fully realizing it, got caught in this showdown.

All part of that drama of the "two swords" in modern Western history, the divided sovereignty of religious and secular authorities that gave birth to modern science and freedom of thought, without either side intending it.

73. **max**
January 28, 2014

Wow, that wikipedia entry on Sungenis is scary. So he understands the dogmatism of sola fide and sola scriptura, but is he free from Catholic dogmatism? Does he think its right to treat women as subhumans by upholding the strict doctrine of the eucharist? Which, by the way, is related to the dogmatic interpretation of trinity supposedly beneath the true reasons for Galileo's home detention. This film could be interesting.

74. **Dave Miller in Sacramento**
January 28, 2014

Peter,

Part of the problem here is that Americans are just not taught in school what the evidence is for the Copernican model. I have been running a little experiment for several years asking non-scientists what the evidence is against geocentrism. Only one guy (a Swedish fellow, who said he did not learn it in school) mentioned stellar parallax. No one has mentioned the fact that Copernicus was able to explain why a number of the Ptolemaic circles just happened to have a period of 365 ¼ days – i.e. there is really only just one such circle, the earth's orbit around the sun,

Of course, most Americans will ignore the geocentrists for the same reason they ignore atheists, Communists, libertarians, and anyone else outside the "mainstream" – they have been told by authority that geocentrism is wrong, and they have learned to accept authority. But, it would be nice if our fellow citizens had learned the evidence, instead of just accepting the diktats of authorities.

I trust your recent comments on this and on the IDers mean that your next book will be a wide-ranging discussion of the sociology of science and pseudo-science? You are certainly gathering lots of material!

Dave

75. **Peter Woit**
January 28, 2014

Dave Miller,

I'm more sanguine about the wisdom of the average person than you I think. They'll ignore "The Principle" for lots of good reasons, from what they've been taught in school and understood, to just being able to recognize flakiness and people pushing religious agendas. I'm much more worried about what the effect is of people seeing prominent, respected scientists pushing pseudo-science. What does a high school science teacher say to students who come to them with some of the latest nonsense about the multiverse?

My favored policy about IDers and all the other varieties of pseudo-science has always been to ignore it, not write books about it. I'd like to see multiverse mania die down to the point where it can be safely ignored, hope we'll see that someday.

76. **srp**
January 28, 2014

I wouldn't worry about the public being converted to geocentrism by this film. There's a bizarre quality to the geocentrism idea given a) our ability to see so much of our galaxy and other galaxies and even detect planets around other stars and b) our records of having landed probes on other bodies in our solar system. Sure, you could plot the whole shebang into some Rube Goldbergian series of motions around a stationary Earth, but even a layman can see how kooky that is given a). As for b), if our feeling of motionlessness on Earth is "real" then what does it mean that people and probes on the surface of the Moon and Mars also feel motionless?

What seemed like intuitive "common sense" before we knew there were other solar systems and before we had visited other bodies in the solar system no longer seems intuitive to average Joe. Out-of-context quotes from physicists aren't going to budge that intuition.

77. **Chris W.**
January 28, 2014

What the Bleep Do We Know!? was a low-budget independent film that ended grossing over $10 million. That's the key to this little scam; it will generate some controversy and publicity, and get a fair number of people to see the film, netting a nice financial return for the producers. That's the way a lot of our economy works; promote some provocative BS and make a tidy little bundle. This film certainly won't be a blockbuster, but it cost a hell of a lot less to make.

78. **Peter Woit**
January 28, 2014

Chris W.,
What the Bleep had as message the idea that quantum mechanics implies anything you want to happen will, an idea easy to get people interested in. This film looks like it's going to be trying to get people interested in the idea that the Copernican Principle is wrong, a much harder sell. Honestly, I suspect the only audience interested enough will be all the outraged physicists. While I'll buy a ticket and go see it if it comes to New York, to see how outrageous the outrage is, I doubt the theater will be full…

79. **paddy**
January 28, 2014

I must admit to learning something in this discussion..thank you Dom for the "Gish Gallop" reference.

80. **Chris W.**
January 28, 2014

You may well be right, Peter. Then again, "Springtime for Hitler" (in *The Producers*) was supposed to be a flop. 🙂

(Actually, this film deserves a comparison to *Battlefield Earth*. On that basis, it will almost certainly be a flop.)

81. **Neil**
January 28, 2014

To me, the case against geocentrism, as if there were any need for one, is the annual seasons. The geocentric theory requires the sun move north and south each year as it orbits the earth, by some unknown reversible force. Surely earth's tilted axis is far more convincing.

82. **zathras**
January 28, 2014

Yatima: "I am getting flashbacks to the deepest infernos of alt.science.alternative, complete with fund drives for zero-point energy devices."

Exactly my thought. I'm expecting Ludwig Plutonium to jump into the discussion any minute now.

83. **Rick DeLano**
January 29, 2014

Geocentrism is quite easy to falsify.

Just measure the absolute motion of Earth.

Of course this creates a problem.

This his supposed to be impossible under General Relativity.

Or it's perfectly possible.

It is and isn't, depending upon which comment you read.

I think you guys are lost.

I don’t think you understand the implications of your own theory, and hence advance contradictions which you ignore, or else do not recognize.

I have asked twice, I ask again:

Is there an experiment that measures an absolute motion of Earth wrt to some rest frame?

If so, Einstein was wrong.

If not, then geocentrism must be assessed on other grounds.

84. **Krzysztof**
January 29, 2014

To me, this Geocentrism hype is a perfect match (or response?) to the multiverse mania. They are worth each other in many ways.

85. **David Bailey**
January 29, 2014

Surely the point is that the earth is not in uniform motion, it is accelerating doe to the gravitational attraction of the sun and indeed the galaxy! Therefore regardless of the equivalence principle, Rick could not be right except for one instant in time!

86. **Rick DeLano**
January 29, 2014

@Kryz: Then falsify both. Experimental evidence please. Oh, you can’t? Then you are opposed on metaphysical/religious grounds. That’s fine. Geocentrism is a profoundly superior metaphysical thesis, vis a vis the multiverse, simply because if we accept the multiverse, then all cosmology becomes geocentric in order to tell us *anything* useful.

The only important *fact* of physics in a multiverse is our location (address, if you like) in it.

@David:

Surely, Einstein already thought of that? Surely, Einstein recognized that centrifugal forces do not allow us to establish absolute motion?

Motion is relative, David, for Einstein.

He has told you so several times on this thread.

Was he wrong?

87. **Manyoso**
January 29, 2014

Hi Rick,

I’ll answer your question!

“Is there an experiment that measures an absolute motion of Earth wrt to some rest frame?”

No!

Now, can you answer a question for me? Is there an experiment that measures an absolute motion of Mars wrt to some rest frame?

If not, it would seem geocentrism has some competition from Mars centrism, no?

Cheers,
Adam

88. **Manyoso**
January 29, 2014

One more question Rick! Can you iterate over that question substituting in turn every celestial body in the heavens? If the answer I each of these questions is similarly “No!”, then what do you think this applies for the theory of geocentrism?

Thanks!
Adam

89. **Manyoso**
January 29, 2014

Err, s/applies/implies/

90. **Bernhard**
January 29, 2014

This may be of interest to people discussing this thread:

http://blogs.discovermagazine.com/badastronomy/2010/09/14/geocentrism-seriously/#.Uuj0bLQo-pp

91. **GoletaBeach**
January 29, 2014

Delano writes… “Geocentrism is quite easy to falsify.

Just measure the absolute motion of Earth.”

I suggest that rather than spending money on a movie, the advocates of geocentrism would do better to fund their own experiments toward this end and publish them in reviewed journals.

“I think you guys are lost.”

Not at all. All data we have in consistent with no preferred frame of reference. Einstein certainly knew that the relative motion of the earth relative to the stars was measured by the aberration of starlight, day in day out by people with simple telescopes.

We’ve measured the relative motion of the sun w/r to the cosmic microwave background radiation. The empirical data is very supportive of no preferred frames of reference.

“If so, Einstein was wrong.”

Einstein was wrong so many times there is no motivation here. His son was a professor at Berkeley and boy you couldn’t talk to him without finding out how wrong Einstein could be.

92. **Rick DeLano**
January 29, 2014

@Manyoso:

No!

Therefore let us repeat MMX on the Space Station. That is all you need to shut me and the geocentrists up.

We have requested this experiment to be done many times.

It has not been done, and so the ball is in your court.

It is not hard to falsify geocentrism.

It simply has not been done.

@ Goleta:

Thanks for refuting Andrew above.

93. **Rick DeLano**
January 29, 2014

@Manyosio:

If Relativity is true, then absolute motion is a question beyond the competence of physics.

If Relativity is false, then experimental tests of absolute motion are possible.;

Which is it, do you think, Manyioso?

94. **Manyoso**
January 29, 2014

Relativity is true and has been demonstrate so by every experiment to date. There have been incredibly precise experiments showing just how successful since Einstein formulated it.

Again, please answer my questions as I answered yours.

If you rely upon relativity to assert geocentrism, how do you account for Mars centrism?

Thanks,
Adam

95. **JG**
January 29, 2014

I don’t have the educational background that most of you have, but I find the argument here interesting sort of as an extreme outlier of quasi-religious pseudo-science positions. Meaning if you go from ID to Creationism to Young Earth Creationism to Geocentrism, you have, I think, finally reached the bottom of the barrel.

Lastly, I understand that you can select a frame of reference, and then play with the mathematics to make geocentrism “work” after a fashion, but can you explain annual stellar parallax with it? Hard to see how that would be done.

96. **Jesper**
January 29, 2014

@ Rick DeLano

I’m wondering, are you fairly familiar with General Relativity? It appears to me that you’re good a quoting Einstein, but are you also familiar with the mathematics?

I’m just curious, because if the answer is no, then how can you oppose something, which you do not understand?

Reading the above (very entertaining and also bizarre) debate, it seems to me that you do not really understand what general covariance actually means.

(Personally, I find Manyoso’s Mars-centrism much more interesting than geo-centrism…)

97. **Jesper**
January 29, 2014

@ JG – yes, you'd think that this is the bottom, but who knows. That anyone would argue for geocentrism at the present moment, where our knowledge of the universe (based on GR) is expanding at such a rapid rate, is really bizarre. But why not go for flat-earth?

98. **emile**
January 29, 2014

This is so bizarre that it has to be some practical joke.

I mean, who in 2014, can possibly doubt mars-centrism?

99. **harryb**
January 29, 2014

A moment's googling of The Principle and its Producer takes you into a rather strange world that honest science ought to quickly walk past, collars up.

Multiverse thinking, and its ilk, is clearly co-opted into this sad cause. Shame on it.

Geocentrism, or whatever awful notion du jour in these worlds, is a dead-end.

The syntax of denial is short cadence it seems.

We can all use abrupt sentences to sound authoritative.

Science is much harder than this – dogma is easy.

Must do better.

You and your guys seem very very lost.

Tennis with the net down.

And so on … ad absurdium.

100. **Jesper**
January 29, 2014

I find this debate interesting – not because of its substance, since it has none – but because it reminds me so much of other debates within science, for instance evolution and climate change. On the one hand there are people familiar with the subject, and on the other hand cranks who talk nonsense – and in the middle are lay people who can't tell who's who.

I always thoughts that if the debate of climate change somehow depended on GR, then "GR-deniers" would quickly emerge and convince the public that there is much doubt and need for further research etc.

101. **Rick DeLano**
January 29, 2014

So.

No experiment can detect any absolute motion of Earth.

Interesting, then, that so many commenters above- including, presumably, at least one contributor to Scientific American- allege the contrary.

"The Principle" will be an excellent remedy for this contributor, along with the one who supplied a link to the CMB data.

"How on earth can anyone believe in this day and age" is not scientific argument.

It is not, even, an argument from personal incredulity, really.

It is, instead a dunderhead's appeal to the peanut gallery.

102. **Manyoso**
January 29, 2014

Jesper,

Glad to see another Mars-centrism recruit!

Still waiting for Rick to answer the simple question I asked him in return for answering his simple question.

Cheers,
Adam

PS: I find it odd for Rick to use relativity as an argument for geocentrism and then to deny relativity when it comes to Mars-centrism…

Here is hoping Rick will give equal time to Mars-centric spokespeople and not let the geocentric folks hog all the time in the movie.

103. **Rick DeLano**
January 29, 2014

Manyoso:

Your question is so simple-minded I assumed it was rhetorical in nature.

Since you apparently think it is instead relevant, I now answer it.

If Relativity is true, then Mars, or Earth, or the tip of Manyoso's nose, are each and all equally justified in being taken as the center of the universe.

Some consider this to be prima facie evidence that Relativity is an absurd theory.

Others consider it to be necessary, if absurd, since in the absence opt Relativity the experimental evidence supports geocentrism.

"The Principle" is a very important film, since the historical context of the adoption of Relativity is apparently virtually forgotten among pop science combox warriors.

104. **srp**
January 29, 2014

Oops.

"If Relativity is true, then Mars, or Earth, or the tip of Manyoso's nose, are each and all equally justified in being taken as the center of the universe.

Some consider this to be prima facie evidence that Relativity is an absurd theory."

Game over. The whole point of the Copernican principle is that there is no center of the universe so every point has an equal right to be called the center. Now the geocentrist's only response is to beg the question–it's "absurd" to say that there's no universal center! But he has conceded the empirical point that Mars-centrism would be equally valid to Earth-centrism using the available data.

These guys are not as good as the IDers at this sort of exercise, although admittedly they've set themselves a much more obviously erroneous position to defend.

105. **Manyoso**
January 29, 2014

Hi Rick,

Thanks for answering my question. I assure you it was not rhetorical.

Since you agree that Einstein's relativity gives no room for the Earth to be regarded as the center of the Universe I wonder why you were quoting Einstein to seemingly bolster the idea of geocentrism. This puzzles me.

To clear up my confusion, can you answer another simple – non-rhetorical – question?

Do you believe that relativity is correct?

Thanks!
Adam

106. **Rick DeLano**
January 29, 2014

Adam:

I am certain that it is not correct.

On metaphysical grounds.

I believe we will- possibly already have- obtained evidence that a preferred frame exists, and that it will be- perhaps already is- possible to establish absolute motion with respect to some preferred frame.

Perhaps that frame will turn out to be the CMB.

Otherwise, it will turn out to be Earth.

But a preferred direction certainly exists in the CMB, and that preferred direction is pointing at us.

107. **Manyoso**
January 29, 2014

Hi Rick,

Ok, well thanks for clearly answering although I am still puzzled as to why you kept quoting Einstein earlier in this thread in support of geocentrism. I could be wrong, but I always thought of Einstein as a big proponent of relativity. Have you unearthed some previously unknown historical data showing that Einstein actually thought the whole relativity thing a bunch of hooey?

I mean you did find it hard to believe Einstein supported the Copernican revolution given the oft cited quote in this thread about not being able to detect the absolute motion of the earth…

I mean you weren't knowingly quoting Einstein out of context to support a theory of geocentrism that Einstein's own theory of relativity disproves were you??!!

Cheers,
Adam

108. **Manyoso**
January 29, 2014

Hi Rick,

One more thing… You say above that you think it might be possible that you'd give up on geocentrism in favor of – forgive me – CMB'ism?

This intrigues me. Can you please direct me to where in the sky this CMB is with respect to the earth so that I might look up the possible center of the universe?

Thanks,

Adam

109. **Rick DeLano**
January 29, 2014

@Manyoso:

Nope. Never misrepresented Einstein in any way.

I left that to the folks on the thread who ignored my direct citations of his work 😉

The CMB is purported to occupy the entire observable universe.

Some have proposed that it might constitute a rest frame; that is, they suppose that there might be a frame where the CMB would present no dipole, and that this frame might be possible to employ as a rest frame to measure absolute motion.

There are a number of serious problems with that, by the way, among the biggest being the remarkable recent papers showing that the CMB dipole cannot be exclusively due to a supposed motion of the local group, but that's another issue.

Of course, if the CMB dipole is confirmed to be an intrinsic anisotropy in the CMB, then all of consensus cosmology is wrong, and the placement of Earth in the cosmos becomes a matter of the worst nightmare of the Relativist coming true.

The CMB would neatly divide the cosmos, along the equinox plane.

The quadrupole and octopoles would, just to prove God has a real sense of humor, point out the ecliptic plane.

Anybody smart enough to measure the CMB and perform a spherical harmonic analysis would find themselves directed to us, from anywhere in the cosmos they might happen to be looking.

Yes, I think "The Principle" is going to be a very interesting film indeed, for the folks who actually *pay* for this remarkable science.

110. **Manyoso**
January 29, 2014

Hi Rick,

"We do agree that Einstein believed the motion of the Earth could not be detected by any optical experiment.

We apparently differ on whether that fact is of interest, in a documentary about the Copernican Principle."

Since you now concede that relativity – and hence Einstein – refuted geocentrism, then why do you think his quote – about relativity – is of interest for geocentrism?

Rick, I am concerned it is starting to look like you took his quote out of context in order to bolster a point that you new was unsupported. I am afraid I can no longer assume good faith on your part which is sad because you came into this thread promising that you did not take Krauss, Tegmark, and Kaku out of context in your film.

Given your behavior in this thread it doesn't bode well for your movie. I hope you did better not taking these scientists interviews out of context than you did Einstein in this very thread.

That's it for me. Have fun with your earth centered universe while I dream of Mars.

Cheers,
Adam

111. **max**
January 29, 2014

DeLano: Of course, if the CMB dipole is confirmed to be an intrinsic anisotropy in the CMB, then all of consensus cosmology is wrong.

OK, now I really am interested, as a proponent of such a CMB picture … with the caveat that we observe Our universe and NOT the one unique universe given to all observers. How long until the film comes out?

112. **max**
January 30, 2014

The Catholic Church might be worried about a successful CMB geocentric cosmology, but on the other hand nobody seems much interested in actually solving serious problems in cosmology.

113. **Patrick Harris**
January 30, 2014

Dr. Woit,

I apologize to add to this already lengthy thread, but I found your recent comments regarding the possible greater danger of recent popularity with untestable theories in fundamental physics, over other attacks on science such as ID'ers, to be noteworthy. Do you think the recent rise in popularity of pseudoscientific concepts such as 'quantum consciousness' and, now, geocentrism is indicative of the issues you've raised regarding recent trends in physics? Or do you think there's still a stronghold within at least the physics community safeguarding the necessary rigor the scientific method?

I'm a bit new to the blog, so I apologize to add any noise that you've already addressed. But I appreciate, as someone who isn't an expert by any means but is nevertheless intensely interested in the subject, a place where I can read about those sharing my concern over recent trends.

Anyway, great blog, thanks for fighting the good fight!

114. **KMS**
January 30, 2014

As is well known, thermal equilibrium states in relativistic theories, like e.g. the CMB, do single out a preferred rest-frame. So in the setup of a relativistic theory (i.e. a theory _agreeing_ with relativity theory) on can indeed in some states single out one frame of reference as a "preferred" one – by referring to a special state. And of course this is nothing special to relativistic physics: Also assuming just the Galilean relativity principle there are many situations where one can single out a reference system by referring to specific objects; examples are the reference system at rest relative to earth or the system at rest relative to mars.

However this is _not_ what the discussion of geocentric vs heliocentric system is about: Of course one is free to choose a reference frame where the sun is moving and the earth is at rest (this is a purely kinematical question).
The question is about dynamics and accelerations: What conventional physics tells us ("the Heliocentric system") is that the sun experiences small accelerations (mainly due to Jupiter) while being orbited by planets experiencing much larger accelerations
("pure" Heliocentrism would be for an infinitely heavy sun experiencing no accelerations at all).
Acceleration however is something absolute also in Einstein's theory of relativity: The magnitude of the acceleration experienced by an observer moving along a worldline (e.g. worldline of the sun or the earth) can not be changed by changing reference frames! And even though the quote by Einstein – given without context – might suggest otherwise: Of course one can measure accelerations – in contrast to uniform motions! – using optical experiments, an example is the Sagnac effect.

115. **Alex**
January 30, 2014

Rick,

when, by a future satellite, the expected v_Earth/c ~ 10^-4 seasonal doppler variations of the CMB dipole frequencies are detected, will you concede that you are wrong? 😀

116. **Alex**
January 30, 2014

erm, that was supposed to read:

"of the CMB frequencies"

117. **kashyap vasavada**
January 30, 2014

@ Rick DeLano: By now it is well known from observations by Kepler satellite that there may be billions of earthlike planets where life could exist. Why wouldn't life exist on these? Would you insist on geocentric idea even if we find life on such planets?

118. **Rick DeLano**
January 30, 2014

@max: We are presently negotiating a (very limited, at least initially) theatrical release. If all goes well, we should launch either the first or second week in May.

@max: I agree with your observations, especially concerning the fear and loathing which recent CMB observations apparently elicit from a certain type of "enlightened and modern" Catholic, which type is frankly unhinged by any evidence which might suggest-horrors!- that the Church actually had the better of the argument with Galileo after all.

@KMS: "Acceleration however is something absolute also in Einstein's theory of relativity"……"absolute" with respect to *what*?

@Alex: Why would such a seasonal signal indicate a motion of the Earth, rather than a motion of the cosmos?

@kashap: Strictly speaking, the existence or non-existence of life elsewhere does not directly bear on the location of the Earth wrt large scale structure.

However, the much more interesting metaphysical question certainly arises:

Given all these billions and billions of planets, perfectly adequate for life, in our own galaxy, some of which would be billions of years older than Earth under consensus cosmology assumptions…………..

Where is everybody?

119. **Peter Woit**
January 30, 2014

Patrick Harris,
I see zero danger that geocentrism and "quantum consciousness" will take over mainstream physics. And I don't think these are more popular now than in the past (the number of followers of "geocentrism" I believe is and always will be minuscule).

120. **Jesper**
January 30, 2014

@ Rick. You write "@KMS: "Acceleration however is something absolute also in Einstein's theory of relativity"……"absolute" with respect to *what*?"

That brings me back to my previous question (which you did not answer): are you familiar with the mathematics of GR? It certainly sounds from your comments that you are not.

121. **Peter Woit**
January 30, 2014

All,
Enough comments that no one in their right mind would want to read. If your comment is not specifically about the film, please don't post it here.

122. **jaco**
February 1, 2014

Peter,
Have you gone off the rails? I am totally shocked you would even mention such a travesty as this film much less lend credence to it on your blog. A little dust up with Max couldn't have changed your focus that much could it?

What's next, alien autopsy?
Sorry. Keep up the (otherwise) good work.
Cheers

123. **Peter Woit**
February 1, 2014

jaco,
You don't seem to have noticed that mentioning travesties is one of the specialties of this blog.
And, this has nothing to do with Tegmark. The idea of a film promoting geocentrism featuring prominent physicists is pretty darn amusing, no matter who they might be. And that trailer is a hoot, I really do hope the thing comes to New York…

124. **Rick DeLano**
February 5, 2014

"The idea of a film promoting geocentrism featuring prominent physicists is pretty darn amusing, no matter who they might be."

The idea of a film about the Copernican Principle *not* involving an examination of geocentrism is pretty darn amusing, no matter how shocking it might be to find that no experimental falsification of the theory has ever been obtained.

125. **Anonyrat**
February 6, 2014

"….no matter how shocking it might be to find that no experimental falsification of the theory has ever been obtained."

Let's ask the question this way: Mr. Rick DeLano, please describe what would constitute acceptable (to you) experimental falsification of geocentrism?

126. **Rick DeLano**
February 6, 2014

Establishment by direct measurement of a motion of the Earth with respect to some absolute frame would do nicely.

127. **Mike Sharples**
February 7, 2014

And because there is no absolute frame, geocentrism cannot be disproved.

And because geocentrism is not disproved it is proved.

(You could easily substitute heliocentrism in those two statements but hey-ho)

I suggest it is time to stop feeding Mr DeLano on this thread. He refuses to engage on viable rules of logic.

128. **Martin**
February 7, 2014

See the great book by Arthur Koestler:

https://archive.org/details/ArthurKoestler-TheSleepwalkers-AHistoryOfMansChangingVisionOfThe

Free download.

The problem with the Ptolemean system (Earth fixed) is that the planets, viewed from Earth, perform weird motions such as retrograde motion. No creationist has ever come up with dynamical laws that would induce such retrograde motion (the planets seem to change their mind; lets go in the opposite direction for a while). The big advantage of the Copernican system is that the motions become much simpler: the planets simply track their courses in the same direction all the time. Later, with Kepler's laws it became even more evident, and then Newton, of course. Several weeks ago I saw the trailer of The Principle; it starts with a lady saying that according to Copernicus the earth does not have a "special" place in the Universe. It's all about Earth and the people on it (not the poor animals, they have not been created in the image of God) HAVING to be "special", which is not such a current idea anymore since Darwin. It is not about rules of logic or about science, it is about feeling.

129. **Rick DeLano**
February 7, 2014

@Martin: see Tycho Brahe.

@Mike: "there is no absolute frame"– please describe what would constitute acceptable (to you) experimental falsification of this assertion.

130. **Anonyrat**
February 8, 2014

@Rick DeLano – define experimentally an absolute frame of reference.

Do you know what an inertial frame of reference is? If not, please see Wiki:
http://en.wikipedia.org/wiki/Inertial_frame_of_reference

Now, neither earth-centric frames of reference nor sun-centric frames of reference are inertial frames of reference. I think the accuracy of our long-term computations of solar system mechanics is in part limited by our limitations in the observational establishment of a suitable frame of reference (so there are small residual non-inertial forces that we fail to account for).

Having said that, for a given size of acceptable error, a sun-centric frame works better as an inertial frame for a much larger volume of space and length of time than does an earth-centric frame.

131. **Anonyrat**
February 8, 2014

@Rick DeLano: here for instance is something about the Radio Optical Reference Frame, constructed using the positions of some 400 extra-galactic objects. http://rorf.usno.navy.mil/

We are told elsewhere (http://www.erikdeman.de/html/sail040r.htm) that the Radio Optical Reference Frame is "stable to at least 0.020 arcseconds per century", and is improving with increased time of observations. In contrast, two previous reference frames, using nearby stars, called FK4 and FK5, drift apart at about 0.085 arcseconds per century.

It is in this sense that I mean that a sun-centric frame is a better approximation to an inertial frame of reference than an earth-centric one; just as a reference frame centered on extra-galactic objects is better than one centered on stars in our galaxy. This is, I think, the modern meaning of the old Copernicus/Ptolemy, etc., debate.

132. **Rick DeLano**
February 9, 2014

@Anonyrat:

It is well known that various frames can be chosen on grounds of ease of calculation or metaphysical preference.

The frame you mention is centered upon an object which is, variously, determined to be traveling at somewhere between 365,000 km/sec and 1,600,000 km/sec.

Clearly, this motion is calculated with respect to some other frame, which is alleged to not be moving at 365,000 to 1,600,000 km/sec.

So, either your inertial frame is a mathematical fiction, very much like the ECI frame for GPS, or else you are telling us that the Sun is not moving at 365,000 to 1,600,000 km/sec.

Which is it?

133. **Anonyrat**
February 12, 2014

@deLay, choice of reference frame is not a metaphysical preference. To correctly account for all forces, real and inertial, one needs to know whether the reference frame is inertial, or exactly how it departs from being inertial. For instance one or both of FK4 and FK5 depart from being inertial (though rotating at a rate of fractions of an arc-second per century).

134. **Rick DeLano**
February 13, 2014

@Rat:

"choice of reference frame is not a metaphysical preference."

>> It certainly is. One must assume a metaphysics in order to choose one's reference frame, if, as Einstein says:

"The struggle, so violent in the early days of science, between the views of Ptolemy and Copernicus would then be quite meaningless. Either CS [coordinate system] could be used with equal justification. The two sentences, 'the sun is at rest and the earth moves', or 'the sun moves and the earth is at rest', would simply mean two different conventions concerning two different CS [coordinate systems]."

" To correctly account for all forces, real and inertial, one needs to know whether the reference frame is inertial, or exactly how it departs from being inertial."

>> Since we are not in a position to account for all forces, real and inertial, involving quasars and radio sources, then we cannot satisfy your demand above absent metaphysical assumptions.

"For instance one or both of FK4 and FK5 depart from being inertial (though rotating at a rate of fractions of an arc-second per century)."

>> The frame you propose is a useful mathematical fiction, very such like the Earth Centered Inertial frame in GPS.

135. **John A**
February 19, 2014

Wait. The website, Gallileo Was Wrong is NOT satire?!?

136. **Makka**
February 21, 2014

Krauss has been quoted as saying the CMB from wmap data could indicate we are att he centre of the universe, due to the alignment with the ecliptic.

While i find it interesting, surely the CMB as shown by planck satellite confirm this axis this is worrying for the current theories out there.

Does anyone have any information what krauss is currently saying regarding the planck satellite findings?

Scientific Bookstores, RIP

January 29, 2014
Categories: Uncategorized

A few days ago I tried to stop by the Barnes and Noble store here in New York at Fifth Ave. and 18th St., just to find that it had closed earlier this month. This was the first book store I had access to as a high school student that had a serious collection of math, physics and astronomy books, and I've been buying such books there for about 40 years. The huge 18th St. store dates back to 1932, and by the early 1970s was the only Barnes and Noble store, at the time that the company was revived and started its huge expansion.

With the closing of this store, there now are no longer any bookstores that I'm aware of in New York City that have a large collection of technical math and physics books. Other Barnes and Nobles like the Columbia bookstore have a smattering of such books, and the Strand has a large collection of used and remaindered books, but that's about it (maybe a reader will tell me about a place I don't know). At one point in a long-ago golden age there were several bookstores here devoted to scientific and technical books, including Book Scientific and the McGraw-Hill book store.

The same phenomenon is taking place around the country. Cody's in Berkeley is gone, and if there's a good technical book store in the Bay area now, I don't know about it (but haven't spent much time there in quite a while). Among the places in the US I regularly travel, the only bookstore I can think of that still carries quite a few math and physics books is the Harvard Coop (also some at the MIT outpost). Other countries may be doing somewhat better, with several such bookstores surviving in Paris at least (Gibert Joseph and Eyrolles for instance).

Of course the reason for this is the internet, more specifically Amazon and the online Barnes and Noble. These do have their virtues, and allow fairly quick access to a much more vast array of technical books than any physical bookstore ever could. But the loss of the experience of being able to spend an hour or so browsing through books, with the serendipity of finding something unexpected (something that Amazon's finely tuned algorithms wouldn't ever present to you) is a very real one.

RIP New York technical bookstores, I must find a way to get to Paris more often…

Comments

1. **Douglas J. Keenan**
   January 29, 2014

   I am sorry to hear about the NYC Barnes and Noble and the McGraw-Hill Book Store. In London, the main Foyles store still has a decent, though not great, math section.

   About being able to browse serendipitously, I agree that is valuable, and it is infeasible with the current Amazon. This could be argued, though, to be just a weakness in the construction of Amazon's site. They should have a "serendipitously browse in related books" button. Maybe if enough people suggest it to them, they will add it.

2. **A.J.**
   January 29, 2014

   Black Oak Books on San Pablo Ave in Berkeley has a pretty good collection of math books.

3. **Zathras**
   January 29, 2014

   Back in the 90s Borders (and to a somewhat lesser extent Barnes & Noble) had really solid technical sections. Physics and Math sections could have hundreds of technical books. By 2000 these were much less, and by 2005 these were mostly gone, aside from the odd book (Misner Thorne Wheeler always seemed to be in stock). I really miss browsing these.

4. **Zathras**
   January 29, 2014

   "But the loss of the experience of being able to spend an hour or so browsing through books, with the serendipity of finding something unexpected (something that Amazon's finely tuned algorithms wouldn't ever present to you) is a very real one."

   In artificial intelligence the distinction is made between supervised and unsupervised learning. The distinction between Amazon's algorithms and browsing on your own is a direct parallel to this distinction.

5. **Jamshid**
   January 29, 2014

   I live in the Bay Area, and as for physics and math books, I can't think of any good ones. But go down south to silicon valley, and of course you will still find a great technology bookstore (programming books….). Check out DigitalGuru in Sunnyvale. I think it even had a few math/CS books on one wall.

6. **Bobito**
   January 29, 2014

   If it weren't for pirates from east of the Rhein, many of us would have no access to scientific books at all.

7. **Adam J Calhoun (neuroecology)**
   January 29, 2014

   There is always Powell's. If you don't make it up to Portland enough, then you should start finding your way there more often!

8. **Kartik Prabhu**
   January 29, 2014

   What about NY Public Library? Do they not carry technical books on math and physics?
   This was pointed out to me by [@craigmod](#) *on Twitter* [*here*.](#)

9. **AcademicLurker**
   January 29, 2014

Back when I was a grad student, the first Borders in the Baltimore area opened and they had an excellent math/science section. In fact, a better selection of technical books than the university bookstore.

The OP is right that, these days, visiting the Harvard coop when you happen to be in Boston is about the best you can do.

10. **Peter Woit**
January 29, 2014

Kartik Prabhu,
What's happening to research libraries and their technical book collections is another, much more complicated story, which I don't want to even try and get into here. In any case, few such libraries have ever been well set up for browsing recent technical books, which is what has been lost by the loss of these bookstores.

11. **Heinz Lackner**
January 29, 2014

I do not understand their business model but at Science Books Online you can download pretty much everything ever published for free. There is no way that Cody's, I miss it too, could compete with online sources like that. My last time at Cody's was when Brian Greene was peddling his book about The Elegant (stringy) Universe.

12. **Kevin**
January 29, 2014

When my dad used to live near Columbia on 114th St. I would go to Papyrus bookstore, which Yelp says is still there. I recall them having lots of science books. Maybe I'm just hallucinating though…

13. **Peter Woit**
January 29, 2014

Kevin,
That store is now called Book Culture. It's a good book store with an academic bent, but these days only a small collection of technical math books (and just about none in physics or other sciences).

14. **John McVirgo**
January 29, 2014

I see myself and others partly responsible for this.

In the past, I'd go into a good academic place like Blackwells, browse the books, and then buy it quite a bit cheaper from Amazon. Nowadays, I'll deliberately order a more expensive book from the place, out of appreciation and concern for the people that work there that make real world browsing possible.

15. **Greg Lee**
January 29, 2014

Price is the obvious cause for the demise of technical bookstores, but just as important is a reduction of their role in discovery. The specialty buyers employed by bookstores acted as scouts for the customers, leading to the serendipity and pleasures of browsing. Today I rely on blogs such as our host's, and I'm probably as well informed about new and interesting books as the specialty buyers once were at Cody's, Printer's Inc, and Stacey's—Bay-area bookstores that once had killer math and computer book sections.

16. **BobDastro**
January 29, 2014

I am dating myself here but…
When I was a Physics grad student at Columbia in the 1970s, the University Bookstore was not the best place to browse for books. For browsing, I used to patronize a scientific bookstore somewhere in the East Village not too far from NYU (on Christopher St., maybe?). They had an enormous selection, and one of the pleasures of those days was impulsively buying physics and mathematics texts that were not required for my courses but which were considered important standard references. I acquired quite a hardcover library, including Dirac's *Principles of Quantum Mechanics*, most of the volumes in Landau and Lifschitz's *Course in Theoretical Physics* library, and other similar works.
Even factoring in inflation, these books were remarkably inexpensive (L&L's *Nonrelativistic Quantum Mechanics* was $15, according to the flyleaf on my copy). Alas, these affordable prices did not survive the inflationary spikes of the mid-70s. One reason specialized bookstores are becoming so rare may be that the impulsive acquisition of academic books has become very challenging from a purely financial standpoint.

17. **Shantanu**
January 29, 2014

Peter, just to clarify : are all B &N bookstores in NYC (and elsewhere in USA) closed down or just the one on 5th and 18th street?
There used to be a nice B & N book store
near BU which had a great collection of technical books were I used to sit for hours.
Hope its still there.
Anyhow you are still lucky than those of us based in germany (and other non-english countries except probably Paris) where its very hard to find any decent bookstore (with English language technical books) to do the sort of browsing.

18. **Peter Woit**
January 29, 2014

Shantanu,
It's just the 5th Ave and 18th St. one that has recently closed. This was an unusual one, besides being historically the oldest, it also was the main one that historically had textbooks for lots of NYC colleges. I think part of the reason they closed is that the textbook business is collapsing, as students get their course books on-line.

In recent years a couple of other Barnes and Nobles in the city have closed, but most are still in operation. It's definitely a different environment though than twenty years ago, when they were opening up new ones everywhere all the time.

19. **Richard Séguin**
January 29, 2014

University Bookstore in Madison WI used to carry a large number of math and physics books and I spent a lot of time there browsing, sometimes discovering interesting books that probably would not otherwise have come to my attention by other means. They also had annual Springer sales. Over the years, the math section shrank to a joke, and finally completely expired. I occasionally found something interesting in Borders, but that large building is now office space. Barnes and Noble carries nothing interesting. Paul's used bookstore has an odd assortment of mostly older books. Sad.

20. **Pavel Krapivsky**
January 29, 2014

There is a nice B & N book store near BU (right at the exit from the Kenmore station) which still has a good collection of technical books. Perhaps less rich collection than the one at Harvard coop and the one at Gibert Joseph in Paris (on boulevard Saint Michel), but good enough to spend an hour. Overall, there are of course less and less of such bookstores. I remember a wonderful specialized little bookstore Quantum Books here in Boston (more precisely, in Cambridge), but it is gone…

21. **Patrick**
January 29, 2014

Raven Used Books in Boston has a great selection of math/science books. There's one in Harvard Square about a block from the COOP and there's one on Newbury St. in Boston proper. Most of the technical books are Dover or university press; lots of monographs too. Not quite as extensive as the COOP, but still a really good selection that's often cheaper than Amazon. Also usually has some interesting obscure texts. Almost always serendipitously find something unexpected when I go. The Barnes & Noble in the Prudential Center is also still around.

22. **OMF**
January 29, 2014

The instinctual urge here is to blame the internet and the likes of Amazon.

Personally I think people just aren't buying books anymore.

23. **Don Jennings**
January 29, 2014

I used to think I loved books. My office bookshelf is indulgently stacked with about $20k worth of maths & physics titles. Now I realize I hate them. They're overpriced, heavy, unsearchable, fragile, don't stay open properly, and don't backup or synchronize with anything. I'd happily trade all mine for the corresponding pdf's, if only IP lawyers would get out of the way.
It's the ideas in books that I like, not their physical manifestations.
Yes, browsing in traditional bookstores is a nice idle luxury for us affluent urbanite first world academics with relatively mainstream interests and strong backs and bank accounts, but overall I think the world will be better off when they're gone.

24. **Sebastian Thaler**
January 29, 2014

Peter,

I had the exact same experience last Friday evening–went down to Fifth & 18th after work and found that B&N closed. Very surreal and sad; it was also my favorite B&N in NYC for its huge science and philosophy sections (luckily, Book Culture is excellent for the latter). Especially infuriating was that the Union Square North store nearby–which I've never especially liked–did not have the new Rubenstein book on multiverses in stock, despite it being available on both Amazon and B&N…

BobDastro,

I wonder if you're thinking of National Book Stores (yes, plural), located on Astor Place just west of Cooper Square. First bookstore I ever browsed that had the complete collection of Dover science paperbacks. On its last legs in 1986 and closed soon afterward. It's now a Starbucks, naturally…

25. **Michael Gogins**
January 29, 2014

The problem with publishing, and this goes for music scores, books, fine art prints, and music recordings, is that there is a serious competition underway between two legal and business models of publishing.

In the older model, authors produced works that agents peddled, editors or A&R people bought, publishers published, critics reviewed, stores stocked, and people browsed and bought. In the newer model, anything that can be scarfed up for free is put online as a vehicle for advertising. In the newer model, the publications are instantly available, either free or very cheap, and of lower average quality.

In both cases all original works are copyrighted because simply producing something entitles you to its copyright, but in the second model, the payment to the author is fame, more than it is money.

With respect to scientific publishing, this is of course not the whole story, because academic publishing has a variation on the older model described above, in which a captive audience is charged a premium for works that they mostly produce themselves. But the fame compensation, in a general and honorable sense, is also the main driver for authors in the scientific publishing model.

There are two things that frighten me about the new model.

The first one is that the good stuff will be lost in the shuffle. Whenever I try to look for works of quality online in self-publication (I'm not talking about the arXiv here), for example original visual art photographs, music recordings, online essays and poetry and especially science fiction, I find myself just swamped. Every month Amazon hosts literally thousands of self-published works of science fiction, while the commercial publishers put out a few dozen, with a few dozen more republications of classics. I can easily and quickly evaluate the few dozen commercially published books, but it takes hours to trawl through the self-published things. I have found just one self-published book (Hugh Howey's Wool) that I would have bought if it were commercially published. I'm sure there are more like Wool, but damn are they hard to find.

The second thing I fear is that the ability to carry ads will infest self-published works and warp their direction and quality. Obviously part of Amazon's motive for hosting self-published works is to attract customers. These books are ads as much as they are anything else, at a minimum they bring the author and his or her friends to Amazon to browse a bit.

About scientific publishing, peer review that is both open and critical is, well, critical. A purely online scientific publishing system run by the scientists themselves and reviewed (blindly) by themselves would seem to be an attractive way out of the mess, so why hasn't it caught on? The arXiv doesn't fit this description, either.

26. **Joel Rice**
January 29, 2014

That is awful. I got Kernighan and Ritchie at the BN on 18th st, and used to go to the McGraw Hill store every week – then to the 40th st Science library. One you did not mention was the National Bookstore near Cooper Union – great place to browse, until they shrink wrapped all the books (long ago). They had a big Dover section – got Weyl on Group Theory for $3.50 !! But about The Strand – there was a character who got there every thursday and scapped up all the good stuff before anyone could even look at it, though I did find Cartan's Lectures on Spinors – in French.

27. **Shecky R**
January 29, 2014

I too lament the disappearance of brick-and-mortar bookstores. I understand the appeal for fiction-lovers of downloading dozens of novels onto their Kindles etc., but have never understood how readers of math and science (and some other non-fiction) could find tablets satisfying. And as a member of Barnes&N., with the additional coupons they offer, I essentially get most of my books at their store for the same price I would pay Amazon by the time shipping& handling is added on.
First, the big box stores came along and put the local mom-and-pops out of business, and now the Web is putting the big boxers out of business… sad to see the landscape changing (guess I'm just an old fogie!).

28. **Visitor**
January 29, 2014

Kartik Prabhu mentioned the NY Public Library. Their http://nypl.org website has an interesting feature – if you look up a book in their on-line catalog, you will have the option to "browse the shelf". (I've never used it though, so I can not say how well it works.)

I recall when Broadway in the area of the Strand was lined with second-hand bookstores. But except for the Strand, there is not a single one left. And the Barnes & Noble Annex, across the street from the main B&N store on 18th & 5th, which was probably the second-largest used bookstore in the city (after the Strand), closed down some time in the mid-90's if I correctly remember.

29. **srp**
January 29, 2014

The Internet has been a complement rather than a substitute for used books; the ability to do online sales has increased the "velocity" of the stock of books, with people more easily able to buy and sell them. So in L.A., where on the westside there is nary a new bookstore, there are many used book stores, some of which carry idiosyncratic and varying inventories of technical books.

Long before B&N and Borders started shutting down their stores, L.A. lost its Technical Bookstore, which used to be a fantastic browsing spot. Their actual business seemed to depend very heavily on selling medical books to aspiring nurses, paramedics, physicians, etc., but they carried an amazing variety of stuff, especially in engineering and computer science areas that I would never have even known existed. Their new arrivals display was a great way to see what was going on in different fields. They moved online, I think.

Just found another L.A. technical bookstore that says it will be closing on February 14: http://opamp.com/

30. **Jim Akerlund**
January 29, 2014

Adam J. Calhoun,
I used to live in Portland and frequented Powell's Technical. This past September I passed through Portland and decided to visit Powell's Technical. They moved it. What was once a large store has now been reduced to the size of a 7-11 and now sits across the street from Powell's main store.

31. **Tim May**
January 29, 2014

I've lived in the greater Bay Area (counting the Monterey Bay Area) since 1974, minus 1980–82 when I lived near Portland, OR.).

As of the 1980s, the South Bay (Silicon Valley) was remarkably rich in technical bookstores. Computer Literacy opened in Sunnyvale in around 1983 and later opened a couple of other branches. They closed sometime around 10 years later. Also, Stacey's in Palo Alto, on University, had a very large collection of math, physics, and CS titles.

Even Printer's Inc., part coffee house, part bookstore, had a large selection. And Stanford Bookstore, both the campus store and the University Ave. store, had large selections.

(I bought many books at these places. Some I expensed to my employer at the time, Intel, some I bought on my own.)

First to go was the vaunted, famed Computer Literacy. Then Staceys went. (The store on University turned into a Pottery Barn…this will perhaps figure into the history of the decline.) Printer's Inc. reverted to just a coffee house (with some sort of art gallery attached, last I looked, 5-8 years ago. It may be gone now.).

Borders vanished. A small outlet of Brentano's at a regional mall also vanished (perhaps years earlier).

There may still be a Barnes and Noble in Santa Clara/San Jose. Last I was there, it was infested with after school kids occupying all chairs and coffee house seats doing homework.

(This is also what happened to my local Borders in Santa Cruz. Every available seat was filled with kids with laptops. I think this figures centrally in why Borders failed.)

In my town, Bookshop Santa Cruz is still thriving. It was always in the ranks of Kepler's in Menlo Park and Cody's in Berkeley (though never with the technical coverage of Cody's, but at least the equal of Kepler's in its heyday). BSC seems to be thriving, and is quite crowded on many days. It may survive the current ice age.

Fortunately, Amazon long ago became a better place to find interesting books. If the high retail prices are a problem, the used copies are generally excellent. I've probably bought 80% of my math and physics books in the past 10 years via the best used deal. Rarely have I been disappointed. (Authors and publishers may scream that buying used books is depriving them of their profits from a $149.95 academic text.)

And then there's the East of the Rhine site someone mentioned. Google for it. Many of the paper books I already own I have "checked out" from this library in PDF or EPUB form. Ever so much much handier on my 64 GB iPad. Always there, never misplaced, easily searchable. 30,000 books can fit on this iPad, and bigger ones are coming.

Hint: LibGen, or Library Genesis.

–Tim May

32. **Mayer A. Landau**
January 30, 2014

Back in the 80's, when I lived in NYC, I used to go a lot to Book Scientific. The store was at 18 East 16th street in Manhattan. They would give you a standard 10% discount. Some books had a 30-50% discount because they were second hand.

Then, sometime in the late 90's, they went out of business. I went to the going out-of-business sale. There were huge discounts on the books that remained on the shelves. I asked the owner why she was going out of business, and she said they could not compete with online retailers. The problem became that book prices on technical books kept going up, up, and up. So, while in the 80's, you could put $30-$40 down on a book, by the late 90's many books were heading to over a $100. At that point, casual buying stopped for me. If I needed, or otherwise wanted, a book, I would go online to Amazon and see if anyone was selling the book second hand for a lot less. Or, I would xerox it at the University library.

Then, in the last few years, a lot of foreign internet websites popped up in Russia, China, and the Ukraine with free electronic copies. At that point it became simply a matter of going to Google translate, finding the book you wanted and downloading. You can't beat that! I have not bought a book now for four years.

Now, does an electronic book beat holding a paper book in the hand and reading it while lying on the couch? No, but with the price of books what they are, it is far cheaper to print out the book and read your printed copy on the couch. Furthermore, most of the books I bought were for reference mostly, not full throttled cover to cover reading. For that electronic is preferable, for two reasons. You can search a pdf and you can carry your whole library with you on a thumb drive.
Finally, as LaTex and microsoft word spread through the land, it became easier and easier for professors to write a book. With ease of writing came poorer quality. Many technical books out there right now are not worth the paper they are written on, and certainly not $100.

In the end, the technical bookstore became an anachronism, whose demise was speeded up by the unabashed greed of the book publishers, and maybe the rushed poor quality writing of the authors.

33. **chiz**
January 30, 2014

Peter Woit:

> In any case, few such libraries have ever been well set up for browsing recent technical books

I find the New Book Displays in local libraries useful for this purpose. Do the libraries you use not do this or is there some other problem?

34. **Youngun**
January 30, 2014

What I don't think has been stated is that there is a vast array of material on the internet which is legal and free.

Lecture notes, full textbooks, lecture videos, videos by leading maths figures, and not lest places like wikipedia and ncatlab and simple google searches.

I also observe that it is common practice to maintain a personal pdf library, sourced from the internet.

35. **karthik**
January 30, 2014

Citylights in SFO has a good section on popular math and science books.

36. **Michael Gogins**
January 30, 2014

Youngun or whoever you are (I add "whoever you are" to everyone who uses a handle online), one of the main problems many of us are having is, sure there is a great deal of great stuff available online, and nobody wants to turn back the clock on that, but a library, a bookstore, an edited journal, provide an extremely useful filtering and selecting mechanism. This pre-selection saved us a lot of time and presented us with a wonderful smorgasbord of high-quality eats.

There probably is actually more high-quality stuff in total on the internet nowadays, but there's no selection. There are, literally, hundreds or even thousands of mediocre or outright incompetent items for every one that would have been selected by an editor or librarian in the old days. I don't have time to wade through this crap, and believe me I have tried.

What do you do about that?

Regards,
Mike

37. **Charles G Waldman**
January 30, 2014

I share your sentiment of sadness in the decline of scientific bookstores, but I'm happy to note that the Seminary Co-op Bookstore in Chicago has a large math/physics section, and is still going strong.

38. **Curious Wavefunction**
January 30, 2014

Sometimes I feel like relocating to Portland solely for the pleasure of being able to visit and buy from Powell's Bookstore (they have both a general and a separate technical store). I still remember how I found a second edition of Dirac's quantum mechanics book there.

39. **Benni**
January 30, 2014

In Munich, it was the same.
Next to Ludwig-Maximilians-University, which has, since the early days of Sommerfeld and Heisenberg, a world renowned Physics department, there was a book store which had, nothing else but math and physics books. The owners were old. Their children did not want to run the shop, because it was not lucrative enough. Its profit decreased astonishingly year for year, since amazon expanded in germany. So the shop finally closed. Now there is no shop in munich, where one can look into specialized physics and math books before buying them. The other shops only have few undergraduate books when it comes to physics.

40. **Bob The Programmer**
January 30, 2014

I remember the old Kroch's and Brentano's in Chicago, huge math and science section at all levels.

And the days when university bookstores had serious STEM sections also.

Somehow Amazon and smaller competitors don't seem to be a complete substitute.

41. **TomD**
January 31, 2014

Peter,
Remember in the 80's the U-store at Princeton was great.. It used to be that one of my greatest treats was to spend a few hours in there or at the Harvard Coop. I think the loss of good technical bookstores is terrible. For one thing, I have a hard time reading electronic versions when one has to flip back and forth to see previous equations, figures, etc.

It's good to hear from other posters that there are a few places left. UT Austin used to be good, but now just has shirts. Stanford bookstore declined tremendously.

Of course, every time I move I promise myself to never buy another book!

42. **Bobito**
January 31, 2014

With respect to what Michael Gogins says, one might add that browsing online is not the same as browsing physically. In the old days one went to the library or bookstore and found the book one was looking for and rapidly could see that it was useless, but the book next to it turned out to be just what one needed. That doesn't happen as easily now, and no one seems to have found a good substitute for it. Summary: now there is more available, but the filters are less functional, and search process less efficient.

The flip side is that when one works in a less-well-financed-than-the-USA country, there weren't any libraries/bookstores worth a damn anyway, so the current situation is an improvement.

43. **BooBooks**
January 31, 2014

Important comments and discussion, Peter!
In Berkeley there was not only Cody's, which had the best math collection, but also Moe's, Shakespeare and Co (used) and North Side Bookstore. Are they all gone now?

In Paris the other wonderful Shakespeare must still be thriving, having been passed on recently to the next generation, but it has never had any math or science to speak of.

Random notes: in Urbana Illinois, the Illini Union Bookstore is a shadow of its former wonderful self, all ipods and ipads and t-shirts and sweatshirts. Brazil has always been bad for book-lovers; the culture there is going out or TV rather than reading, but there is a vicious circle as books are way too expensive, imported ones even more so. One good bookstore on Pedroso de Morais- 4 stories of books 15 years ago- was taken over by the French chain FNAC which added cds, dvds, tvs, cameras and computers. That meant there were 2 floors of books left, then one, most recently only 1/3 of a floor, divided with cds and dvds, as ipods and flat screens have taken over the rest of the 4 stories.

Yes, pdfs are wonderful as a portable library, but only for reference, not for reading,
not for studying. I learned so much from my old wonderful texts which I still have crowding my too-small apartment. What are today's students supposed to do? Library copies, pdfs or xerox copies are a poor substitute. And Amazon is great but the deals I so often found browsing at used stores were much better.

Maybe the new mac Retina screens help somewhat with the eyestrain, or the Kindle reflected light screen; but does the latter accept pdfs?

While we are lamenting the decline of literacy, I have recently heard that many US kids are no longer learning cursive writing (or reading). I was shocked to learn this; kids will be sent out into the world partially handicapped. What, "mastering" the mouse, or Excel or Power Point is supposed to compensate for that? This dumbing-down of the populace is apparently one more legacy of the over-testing mandated by Bush's inappropriately named "No Child Left Behind" program.

44. **Simple biologist**
January 31, 2014

Interesting topic and also the one that has finally made me feel like a luddite. I'm only (only?) in my late thirties, but I have l've been using computers for over 30 years. Got my mom to thank for that. It's really the ebooks and on-line book stores that have become the first technological advancement- in my life time- that have made me firmly to say no.

For me there's no replacement for the smell of ink, the texture of paper and browsing through (physical) books in a book store. No online store or digital book will ever be the same for me. Oh and quality book stores are dying in northern europe as well.

Just screw the tablets and get of my lawn!

45. **Peter Woit**
January 31, 2014

Some recent experiences in bookstores reminded me of some of the reasons I've found them so valuable, providing something I can't get on Amazon:

1. As some others mentioned, what makes a good bookstore is not having everything, but having a well-chosen selection of things. On Amazon, you have millions of books, and a computer algorithm that tries to figure you out. In a good bookstore, someone has done the work for you of sorting through a huge number of possiblities, picking out the most interesting and worthwhile ones. If they've done this well, this is an extremely valuable and high-level service.

2. If I find a book in a bookstore, the fact that I can look at any part of it (unlike Amazon, where you just get blurbs, and maybe access to the table of contents and a few pages) means that I can make a well-informed decision about whether the book is worth my time and money. For a book that looks interesting, I can quickly flip through and find the parts most likely to be of interest. I can then see whether there's really not much there, so buying the book would be a mistake, or, more happily, that there's a lot of interesting material, making the book purchase a good idea. With the high price of technical books, even for those in wealthy countries with dedicated funds from their institution for books, one can't afford to buy everything that initially looks interesting.

46. **August Penn**

January 31, 2014

Hey Peter,
The West Towne Mall in Madison, Wisconsin has a fairly good math and science section, probably not as good as the B&N in New York at Fifth Ave. and 18th St. had though. I feel for you.

47. **Tim May**
February 1, 2014

I'm happy with the current situation, as compared to, say, 1970.

Back then, there was a good scientific bookstore in downtown Washington, D.C., but it was quite a trek for me (just finishing high school, just starting college). The local bookstores were helpless…a Waldenbooks several miles away, a Brentano's about 15 miles away. I could special order a book, like Lawden's "Tensor" book (which I recall ordering), but it took a few weeks to arrive.

I experienced the heyday of technical books in the Bay Area. That is, the 1980s. I had five or six bookstores within 10 miles of me: Computer Literacy (3 locations), Printer's Inc. in Mountain View, Stacey's in Palo Alto (and they even opened a second one in Cupertino), Kepler's in Menlo Park, and two very well-stocked Stanford Bookstore shops. (The main campus one was huge, the University Avenue Annex was also pretty well-stocked, on three levels.) And I may be forgetting a couple of others.

But times change. Books shot up in price, from fairly reasonable $15 prices to nosebleed prices of $150 or more (for math and physics non-popular books). Binding quality also went down, from sewn binding that would withstand years of use to glued binding that never laid flat and that, at worst, had pages literally falling out.

(I bought a Springer Verlag copy of Mac Lane and Mjordiik's "Sheaves" and the pages literally began to fall out as soon as I opened the book. First a few, then more. I contacted an office of S-V in Virginia, listed as the printer, and they said "Tough luck." I eventually removed all of the pages, punched holes in them, and put them into a small 3-ring binder. This was what book publishing came to.)

Today, I have access to tens of thousands of PDFs and EPUBs, readable on my Mac Book Pro Retina (no eye strain) or my iPad Retina (no eye strain).

I don't lose them, misplace them, or lend them out.

And, they mix easily with the vast number of Archive and other PDF papers I have.

I don't miss the past.

–Tim May

48. **Richard Séguin**
February 1, 2014

Tim,

Badly bound books is not a new problem. In the 1970s I bought a copy of Rotman's The Theory of Groups and the pages began falling out almost immediately. You're right about the hugely inflated price of books though. The Rotman book cost only $14.50 at that time. Now, I cringe thinking of ordering an $80+ book from Amazon without being able to "look inside."

49. **David Derbes**
February 1, 2014

I've bought technical books for nearly fifty years. The beginning of the end of good technical bookstores was the capitulation of nearly every university bookstore to Barnes and Noble (including the celebrated Harvard Coop.) In my salad days I bought books at HK Lewis, Gower Street, London (gone); Dillons, London (gone, or more accurately, transformed to a Blackwells, I think), Princeton's U-Store, MIT Coop, Heffer's in Cambridge UK, Blackwells in Oxford (Weinberg's "Gravitation and Cosmology", nine pounds in 1974, about $18 US), James Thin in Edinburgh (gone), Reiter's in Washington, DC, and many another store now gone. The original Blackwells, Broad Street Oxford had a wonderful collection in the '70's, when I was a grad student in Edinburgh, but the last time I was there it was really disappointing.

So, without further ado, the best technical bookstore I now know of still extant: The Seminary Co-Op, Woodlawn Avenue, Hyde Park, Chicago, 60615. Tremendous math section, much better than average physics. This is, in my opinion, the finest scholarly bookstore in North America. Last time I was there the bookstore at the University of Illinois at Urbana-Champaign also had a great selections in math, physics and computer science. We also have in Hyde Park the original Powell's, second-hand only. Incidentally they are selling a great number of Chandrasekhar's personal books. When Mike Powell finally tired of the perpetual winter, he lit out for Portland.

I don't know why they've all folded. Part of it is the unbelievable greed of many textbook publishers (I bought the great Purcell "Electricity and Magnetism" for $6.95 from the U-Store in 1970; when McGraw-Hill last offered it, it listed for north of $210. Not bad for a book originally published in 1964, whose author was dead for twenty years. Happily, Cambridge sells it, and hurray! a third edition in MKS units with a gazillion new problems by David Morin, for a reasonable sum ($80, I think.)
The other part is that I guess kids don't buy books any more. I find this unbearably sad.

50. **Jeff m**
February 1, 2014

Sorry to hear about b&n closing, loved that place as a teenager. Got some great physics and math books, plus some amazing other stuff like a comic book version of Chaucer's The Millers Tale done by the fabulous furry freak brothers. Also sorry to hear about book scientific, spent a lot of time there when I was at the GC

51. **Mayer A. Landau**
February 1, 2014

David Derbes,
$80 for a textbook published in 1964 is not a reasonable price.
"Kids" don't buy books anymore because they now have alternatives to being gouged by the publishers. That's a good thing. Not sad at all.

52. **Dave Bacon**
February 2, 2014

If you're ever in Seattle check out Ada Technical Books. I do miss Cody's 🙁

53. **book sci**

February 2, 2014

In February of 1996 Book Scientific moved to 10 West 19th Street # 3B (though it kept their phone number according to my handy black book from when I was a graduate student, (212) 206-1310). I'm not sure what happened after that.

54. **Peter Woit**
February 2, 2014

book sci,
Book Scientific was on 19th st at that 3rd floor location for several years, then finally closed for good. Oddly, before the move it was across the street from Revolution books, then Revolution books also moved to 19th st, across the street. Now Revolution books is on 26th st, I suppose I should try looking for a revived Book Scientific across the street somewhere…

55. **chris**
February 3, 2014

It's not just NYC. Here in Germany they are also dying at a fast pace, with the surviving bookstores shifting their emphasis to toys and gifts.

The real tragedy though is that the online bookstores – which would technically be extremely well equipped to offer you browsing through a vast variety of books, much better than any real book store – can't do this because of the screwed up publication system still in place. With the 20th century bookstores dying off, I hope the 20th century business model of publishers will die soon, too.

56. **Richard Haas**
February 27, 2014

I am late to this discussion. I worked in Manhattan for twenty years and I want to mention a couple of other bookstores: There was Viktor Kamkin Importers on 21st and 5th ave which had a fine science and math selection, all Mir Publishers Moscow, mainly in English, some in Spanish. It also had such curiosities as the complete collection of Oz books bound in silver by "Lyman F. Baum" and albums including "The Soviet Choir Sings Negro Spirituals".

On Warren Street was Warren Street books. The collection was so random in might have been a cover for something else; however, on weekends Warren Street Books would set up at computer shows in NJ and sell Springer Verlag, North Holland, Birkhauser, etc. When a book was several volumes they were never displayed together.

There was also in the late '80s and early '90s a father and son team that supplied street vendors (mostly Indian) with recently published books that they would sell on the streets of Manhattan from folding tables. They had 15,000 feet of wharehouse space in South Williamsburg and asked me if I could come up with a way of cataloging what they had with a bar-code scanner and a database, somehow. I had just quit a job on Wall Street and was not interested in going back to work. The new books were in large boxes on skids and there was no logic to how they were grouped. They did not tell me how they came by them.

What books the Strand had could be "bursty". One burst occurred when Louis V. Gerstner, Jr. closed IBM plants and offices. Their libraries ended up at the Strand.

In Paramus, NJ there was for a couple of years a Barnes and Noble across Route 17 from a Barnes and Noble. And, actually, there used to be a Barnes and Noble Annex across from the 18th St. Barnes and Noble that sold old books.

There is this about the Viktor Kamkin Store in Maryland: http://ww2.gazette.net/stories/021706/businew180145_31958.shtml
The article says, "Thousands of books, all in Russian and some still in plastic packaging, were taken to the trash transfer station at Shady Grove to be recycled." In fact there was a large selection in English. Amazon does not do a very could job with these, see, eg: http://www.amazon.com/Aksel-Berg-Century-Outstanding-Scientists/dp/0828532575/ref=sr_1_fkmr1_1?ie=UTF8&qid=1393512351&sr=8-1-fkmr1&keywords=aksel+berg+radar

Quick Links

February 1, 2014
Categories: Multiverse Mania

- I've always thought more philosophers of science should be weighing in on the debate over "falsifiability" and the "demarcation problem" surrounding string theory and the multiverse (i.e. are these really science?). This is a complex and tricky subject that they have a long tradition of exploring, and it would be great to have this inform some of the debate instead of the often very naive arguments that dominate the discussion. Massimo Pigliucci does a nice job here, responding to Sean Carroll's attack on falsifiability (see here, more discussion here). Pigliucci's posting is great, giving a concise explanation of the way philosophers of science have found to think about these issues. It does though show that much of what needs to be examined are technical scientific issues (what exactly does "string theory" say or not say? What exactly are the conceivable things one could expect to measure and compare to theoretical predictions? What exactly is the state of efforts by string theorists to make predictions: how deadly are the obstructions they have run into?). In any case, here's Pigliucci's conclusion:

  > But at some point the fundamental physics community might want to ask itself whether it has crossed into territory that begins to look a lot more like metaphysics than physics. And this comes from someone who doesn't think metaphysics is a dirty word…

- This evening at ASU there will be a program on Parallel Realities: Probing Fundamental Physics, you may be able to watch it live here. With David Gross there, at least it won't be the usual "Isn't the Multiverse cool?"-fest that this sort of thing recently often has turned into. Yesterday on Science Friday, Krauss, Wilczek and Brian Schmidt discussed Could There be a Crisis in Physics?
- In case you're wondering why there's been no discussion here of Hawking's recent claims about black holes, the reason is that I'm in agreement with Wilczek's wise characterization of this on the Science Friday program:

  > I think the kind thing to do is to pass this over in silence.

  If you really need some Hawking material, there's The Top 10 Science Jokes, As Told by Stephen Hawking. Warning: safe for work, but not very funny…

- Quite a bit funnier (although some might say, also kind of tired and sad..) is this "debate" between Bousso and Rovelli at the latest FQXi conference: String theory vs. loop quantum gravity.

Update: Video of the ASU talks can be found here. Wilczek is still sticking with SUSY, but says "no more excuses… these particles have to materialize ". According to Twitter, this really was a rock-star event, with the local ladies "getting dolled up" and ready "to throw our panties onstage."

Comments

   http://www.ustream.tv/recorded/43354237

   Unfortunately, the Q&A is missing

6. **Martin**
   February 2, 2014

   Science does not work only via falsification. The logical positivists referred to verification: a statement is true if you can verify it. Popper retaliated by referring to statements that can be falsified but not verified. This is old ideological stuff from the 1930's.

   In science we want to estimate the credibility of a statement or hypothesis. Seeing the Higgs boson is a verification. Not seeing SUSY is a falsification. Both, verification and falsification depend on empirical data: from these we can judge whether a theory works well or not. This is in general not possible with metaphysics, which generates statements that could perhaps be true or not without there being any way of judging this on the basis of empirics (seeing, measuring, etc). The problem with string theory is that it is experimentally irrelevant. The problem with mathematical physics is that its afficionados do not care about experiments. Thus they talk about Hawking radiation and multiverses etc. without being bothered about whether there is any experimentally supported reason for taking these subjects seriously. This is a clear symptom of decadence. I do read QFT because it is experimentally relevant, even when it is only an effective theory. I cannot get interested in string theory, though.

7. **Tom**
February 2, 2014

Matt Strassler has a more “nuanced” (I dislike that word!) view of the Hawking/Black Hole Kerfuffle & attributes a lot of it to “Media absurdity”.

Read:
http://profmattstrassler.com/2014/01/30/did-hawking-say-there-are-no-black-holes

8. **Peter Woit**
February 2, 2014

Tom,
I assume that you’re making fun of Strassler here, whatever he’s up to, it’s not “nuanced” (dramatic accusations against journalists in red type with multiple exclamation points????). I did write a comment there, which it looks like he didn’t really understand. His claim that when Hawking write a paper saying there are no event horizons and explicitly writes “there are no black holes” the media should not quote this doesn’t make any sense to me. The media coverage I’ve seen has been pretty accurate about Hawking’s claims.

The one criticism I have is that it would be better if the media provided some context, that this was just one of a lot of rather incoherent stabs at the black hole information paradox, in the backwash of the “firewall” realization that just invoking holography doesn’t solve the problem. I think the media is accurately portraying the claims of a small group of prominent physicists. If other prominent physicists were willing to go on the record (kudos to Wilczek) saying that this, and Hawking in particular, is best ignored, we’d be much better off. This is a (minor) physics community problem, not a media problem.

Personally I don’t see any reason to waste time on this. The media is doing a reasonable job. A celebrity physicist is getting too much attention, some physicists are hyping their work, while most of the physics community is ignoring them. All is normal. It’s not like the multiverse or string theory story….

9. **Thomas**
February 2, 2014

The exact quote is:

“The absence of event horizons mean that there are no black holes – in the sense of regimes from which light can’t escape to in□finity. There are however apparent horizons which persist for a period of time. This suggests that black holes should be rede□fined as metastable bound states of the gravitational □field.”

http://arxiv.org/pdf/1401.5761v1.pdf

For decades, physicists and their huge egos have been roaming the earth claiming to whoever would listen that black holes are places where the density of matter produces such extreme spacetime curvatures that, to cite what has to be the most tired cliché ever, “nothing, not even light, can escape.”

Hawking’s quote above is a direct repudiation of this definition, period. Both him and the press have recognized it and there is nothing wrong with that. It remains to be seen whether the new definition has content or not. Let’s not hope too much, but if via Hawking’s paper the firewall craziness could actually help physicists to retire their nauseatingly obligatory “nothing, not even light, can escape” phrase, and to try and seek words of their own when they talk to the public, then it will have been worth something.

10. **DrDave**
February 2, 2014

Fave quote from Pigliucci on the fine tuning problem: “I actually think that people who seriously maintain that this universe is friendly to life haven’t gotten around much in our galactic neighborhood.”

11. **Art**
February 3, 2014

Actually, I much prefer your one-sentence assessment above (“just one of a lot …”) to the smug, snide (and disrespectful) put-down by Wilczek that you applaud. People are interested in this stuff, and are looking to experts for informed guidance, but not to just be told “ignore it” with no back-up. Kudos to Motl for engaging with the argument.

12. **Peter Woit**
February 3, 2014

Art,
You’re right that people are interested, and looking to experts for informed guidance. I think Wilczek is providing exactly that: telling you that this is getting much more attention than it deserves and your time is better spent elsewhere. I actually think he’s trying to be polite by not giving more detail about why he thinks this (as well as trying to avoid wasting his own time). If you really want to ignore wise counsel from a Nobel Prize winner and join Lubos and others in studying this, go right ahead, but I don’t think you should be criticizing Wilczek for providing something the field sorely needs. Far too few like him are doing what should be part of their job: giving an expert opinion about what is overhyped and best ignored.

13. **Sesh**
February 3, 2014

I don’t agree with one aspect of Pigliucci’s argument: the cosmological constant problem is not simply one of “fine-tuning”, and certainly if the minimalist version of the anthropic argument proposed by Weinberg actually correctly predicted the value of the cosmological constant, this would be a very good reason to take the multiverse seriously.

However, in light of modern observational data Weinberg’s argument does not give the right value of the cosmological constant. It is off by about three orders of magnitude, which is pretty much the limit at which Weinberg’s original paper stated we should conclude the anthropic argument did *not* work. Which is not a fact that is often mentioned.

What’s worse is that, as Lee Smolin was pointing out in the comments on a previous post here, the stringy multiverse actually does not satisfy one of the key assumptions necessary for Weinberg’s argument (namely that the bubble universes differ *only* in the values of Lambda). Once you allow other variables to vary there is no longer any model-independent prediction for Lambda and therefore no way that the multiverse hypothesis can be tested by any observed value of the cosmological constant.

So ultimately I agree with Pigliucci’s conclusion, though not with the reasoning. The details of this argument are of course pretty well known, but for completeness I have also written them up explicitly here.

14. **Art**
    February 3, 2014

    Fair enuf, but these days “proof by reputation” doesn’t cut it. (Did it ever?). The thing is, it wouldn’t have required much more effort to make the contextual eval you did above, and then reputation can legitimately come into play, since it’s clear that there’s some basis for the opinion. Love your blog …

15. **Peter Woit**
    February 3, 2014

    Sesh,
    I commented on your blog also about this, but for here also, could you provide a reference to the best current numbers for this kind of “prediction of Lambda”?

    Thanks!

16. **Sesh**
    February 3, 2014

    Peter,

    I’m afraid I’m not enough of an expert on this to give you the “best current numbers”. However, I think the point is somewhat moot in any case. Weinberg’s original argument was attractive because it didn’t depend on the details of the measure problem. But that argument gives the wrong value.

    To get the right value (even assuming that only Lambda varies) one must tackle the measure problem, and since there is consensus on the correct way to do this, it becomes a question of retro-fitting the measure to get the correct Lambda. Note that even the Martel et al paper you linked to on my blog does this, because it was already clear by 1997 that Lambda was too small for the original argument to work.

17. **Sesh**
    February 3, 2014

    Sorry, I meant *no* consensus in the comment above.

The Perfect Theory

Cosmologist Pedro Ferreira has a new book about to come out, entitled The Perfect Theory. The author accurately describes the book as a "biography of general relativity", and it's quite a good one, of the short and breezy variety (as opposed to the detailed and exhaustive sort).

The theory's parentage (Einstein), conception and birth are covered, in particular the way in which mathematics played a crucial role, with Einstein getting important help on this from his friend Marcel Grossman, as well as David Hilbert, who found the right dynamical equations at the same time. This material goes by fairly quickly though compared to many other sources for this history, in order to get to the main topic: the life story of the theory so far, nearly 100 years on. After the birth of the theory, it soon started to get wide acceptance, with Eddington helping to provide both the experimental confirmation in 1919 of the theory's distinctive prediction about deflection of light by the sun, as well as ensuing publicity.

Some implications of GR were found immediately (e.g. the Schwarzschild solution in 1916), and the 1920s saw early work on applying the theory to cosmology (de Sitter, Friedmann, Lemaitre). By 1929 Hubble's observations of an expanding universe had shown the way forward in this area. Ferreira goes on to follow several different strands of how the theory has developed. These include: black holes (Oppenheimer, Wheeler, singularity theorems from Penrose, Hawking, the information paradox), cosmology (Hoyle and steady state models, the CMB, Peebles and the now standard model, with dark matter and dark energy), relation to quantum theory (DeWitt, supergravity), gravitational waves (Weber, LIGO, proposals like LISA), and quite a few others. A wealth of different topics and interesting pieces of the history of the subject are covered, although none in great detail. The emphasis is on this history, along with the present state and prospects of the subject, with not much attempt to try and explain the intricacies of the physics (which would take a much longer book).

On the hot-button issues of string theory and the multiverse, Ferreira does a good job of giving an even-handed description of the arguments. For instance, he counsels reader to pay attention to George Ellis as well as multiverse proponents.

For more about the book, there's a very good review by Graham Farmelo here. Oddly though, just like with his excellent biography of Dirac, which ended with a weird attempt to claim Dirac as a string theorist, here Farmelo ends by trying to enlist Ferreira and GR in the cause of string theory:

> 50 years later, the mathematical aesthetic of relativity has been enhanced by the beautiful demonstrations of its veracity that Ferreira describes. These would probably have made Born ponder why he and his peers did not spend more time developing a deeper appreciation of the theory soon after Einstein first presented it. Maybe there's a lesson here for some of today's string-theory sceptics?

I've never seen anyone else try and claim that the history of GR is analogous to the history of string theory. As Ferreira's book explains, unlike string theory, GR is a classic example of a testable scientific theory, coming with one impressive post-diction (precession of the perihelion of Mercury) and followed up by an impressive test of a distinctive prediction (bending of light at the 1919 eclipse). As for mathematical aesthetics, GR uses beautiful mathematics (Riemannian geometry) and its dynamics is determined by the simplest possible Lagrangian density (the scalar curvature and nothing else). Whatever the equations of string theory might be, they remain unknown. Rather than a lesson for string theory sceptics, this book provides some good lessons about what a successful fundamental theory looks like, ones that string theory proponents would be well-advised to ponder.

"The Perfect Theory" is a good title for the book, with GR remaining our best example of a beautiful, powerful fundamental physical theory, based on the deepest mathematical ideas, with almost no free parameters. Ferreira does a great job of leading readers through the story so far of this amazing theory.

Update: For another review of the book, see Ashutosh Jogalekar at The Curious Wavefunction.

Update: Nature now has a podcast with an interview of Ferreira.

   February 3, 2014

   I didn't find the book by Graham Farmelo excellent at all. What Richard Dalitz used to tell about Dirac was far more interesting. Dalitz had known Dirac personally, but unfortunately didn't write a book about him.

5. **Bernhard**
   February 3, 2014

   "Maybe there's a lesson here for some of today's string-theory sceptics?"

   It doesn't matter how empty an argument is, you can always count with someone comparing it to Einstein and relativity. That's a rule that works both with cranks and people with reputation.

9. **Giotis**
February 3, 2014

We should not mislead people. GR is far from perfect; in fact it’s another effective filed theory with the Einstein-Hilbert term being just the first term in an infinity series of irrelevant terms.

The correct view is that GR is the effective filed theory of massless spin 2 particles which is valid only up to certain scale. Beyond that scale you need new degrees of freedom to describe the theory.

10. **Peter Woit**
February 3, 2014

Giotis,
Given that we don’t know what the theory is that GR is supposed to be an effective field theory for, I don’t think “the correct view” is the right terminology.

Of course, GR is a classical theory, presumably the classical limit of something we don’t understand. That given, please, that’s no excuse for another tedious ideological argument about quantum gravity.

11. **Art**
February 3, 2014

Does it include refs to the literature?

12. **Peter Woit**
February 3, 2014

Art,
Yes, the book has extensive references to the literature. Since he’s interested in history, these are mostly to primary sources, the original papers, rather than later expository materials.

For example, for the “string wars” he recommends looking at blog entries from that period from this blog and from a couple others…

13. **Art**
February 3, 2014

Cool. Thx!

14. **Neil**
February 3, 2014

There are indeed some parallels between GR and string theory. Many experimentalist physicists considered GR a waste of time, as experimentalists do today with string theory. Some were quite prominent (and not nazis)–Millikan, Essen, Rutherford to name a few. Rutherford called it rubbish I believe. And although GR did make the deflection prediction and precession retrodiction you mentioned, most of its predictions and the ability to test them were decades in the future.

Another interesting parallel. Einstein’s “happiest thought” was that he could transform away gravity by moving to the accelerated frame. The string theorist’s happiest thought is that he can transform away gravity by moving to the AdS boundary.

15. **Chris W.**
February 3, 2014

Somewhat later in the 20th century, Percy Bridgman was another contemporary of Einstein who regarded general relativity with considerable skepticism as I recall. (I made a brief attempt to locate a decent online reference for this, without success.)

Bridgman was also primarily an experimentalist, whose writings on the philosophy of science were influential, but arguably more strongly in psychology than physics. There is a certain parallel with Ernst Mach here. Indeed, Mach himself lived to see the advent of general relativity, but did not receive it well.

16. **Peter Woit**
February 3, 2014

Chris W.,
I’ve never heard of anything about “considerable skepticism” towards general relativity from Bridgman. His interest in the philosophy of science and “operationalism” made the question of how to think about special and general relativity a major concern for him, but that’s quite different.

Mach died at the age of 78 three months after Einstein and Hilbert published the field equations, long before the 1919 experimental confirmation, so I don’t think one can reasonably try and sell him as an example of a skeptic about GR.

17. **nige cook**
February 4, 2014

Mach in 1913 (after Einstein’s nascent and incorrect pre-GR paper of 1911, which predicted only half the correct deflection of light by gravity) was apparently skeptical:

"I can accept the theory of relativity as little as I can accept the existence of atoms and other such dogmas." – E. Mach, 1913.
http://www.maths.bris.ac.uk/~macpd/gen_rel/

18. **Bernhard**
February 4, 2014

Neil,

The history of science is full of examples of correct theories that found skepticism from from contemporaries, that parallel would not be exclusive of GR. More importantly though, is that history of science is also full of examples of incorrect theories that were correctly dealt with skepticism from contemporaries, and this is most likely the right parallel to be applied to string theory, given that the theory, unlike GR, was unable to provide predictions up to now.

I agree that testing all predictions from GR is not easy and this is actually still work in progress (e.g. direct observation of gravitational waves). But in any case the deflection of light by the Sun prediction found almost immediate confirmation. Even if you consider the 1919 result to be biased you can still use the 1922 confirmation by the Lick Observatory. It is a joke to compare string theory to this.

Furthermore, the examples you give are not all correct. I did not go to the trouble of checking your claims about Millikan and Essen but at least Rutherford I know changed his mind about it. On December 1919 Rutherford co-authored a Nature paper called "Radioactivity and Gravitation" (see "Studies in the History of General Relativity" by J.M. Sanchez-Ron), where he reported results on experiments to test whether the rate of radioactive substances is affected by subjecting them to high-centrifugal acceleration (given the equivalence principle). This is not coming from someone who thinks the theory is rubbish.

Your ""happiest thought" parallel is not really worth a comment.

19. **Neil**
February 4, 2014

Bernhard,

Yes, I agree that GR has proven itself capable of generating testable hypotheses, including frame dragging and gravitational lensing, in a way that string theory has not to date, and may never will. Reading the history of GR, however, it was certainly the case that GR was considered controversial and young physicists were counseled to avoid it as a dead-end. It is significant, I think, that Einstein's 1921 Nobel citation expressly stated that his "services to Theoretical Physics" was not a reference to his relativity work.

I thought my "happiest thought" comment is at least worthy as an amusing joke, as it was intended.

20. **Anonyrat**
February 4, 2014

Regarding Millikan, this is what Wiki says:

> Since Millikan's work formed some of the basis for modern particle physics, it is ironic that he was rather conservative in his opinions about 20th century developments in physics, as in the case of the photon theory. Another example is that his textbook, as late as the 1927 version, unambiguously states the existence of the ether, and mentions Einstein's theory of relativity only in a noncommittal note at the end of the caption under Einstein's portrait, stating as the last in a list of accomplishments that he was "author of the special theory of relativity in 1905 and of the general theory of relativity in 1914, both of which have had great success in explaining otherwise unexplained phenomena and in predicting new ones."

So Millikan acknowledged that relativity had a tie to phenomena.

The Perfect Wave

February 4, 2014
Categories: Book Reviews, Multiverse Mania

Sometimes when I have come across claims of exotic phenomena at the far-out edge of the field of BSM physics based on branes and string theory (like time travel, or brane-world explanations of the bad OPERA result), my initial reaction has been "Are these people on drugs?" A new book out from Harvard University Press, The Perfect Wave, by theorist Heinrich Päs explains that yes, some of this particle theory activity has its intellectual roots in psychedelic drug consumption.

The book opens with a short chapter about surfing in Hawaii, but then turns to a long chapter about LSD, the author's experience with magic mushrooms, and the cult of Eleusis in ancient Greece. Supposedly this cult revolved around consumption of a psychedelic brew called "kykeon", and we're told that this was of great influence on Plato. The discovery of atoms is also attributed to a drug trip:

> Moreover, the perception of smallest details during a drug trip may have affected the atomism of Democritus, who first assumed that the world should be built up of indivisible elements.

The next chapter goes on to discuss quantum mechanics from this point of view. Starting with Heisenberg's claims of inspiration from Plato's *Timaeus*, Päs moves on to Heisenberg's student von Weizsäcker and his ideas about quantum mechanics and Plato's *Parmenides*:

> In summary, Weizsäcker arrives at an amazing conclusion, that the notion of complementarity has its source in ancient Greece: "We find … the foundation of complementarity already foretold in Plato's Parmenides." We actually can recover the feel of what the ancient Greeks experienced in their mystery cults in modern twentieth-century physics!

From there the book moves to the multiverse and Everett's many-worlds interpretation of QM, telling us that:

> It is actually possible to recognize the multiverse — the collection of all of Everett's parallel universes — directly as Parmenides's primeval One: the unity of the world the ancient Greeks felt thay had lost in the charted modern world, and for whose reunification with the individualized ego they looked in the ecstasy of their mystery cults, in their Dionysian arts, or in the flush induced by psychedelic drugs.

The main part of the book then begins with chapter four, which starts out:

> Physics is like surfing. Or like an LSD trip.

The final chapter closes with an invocation of Nietzsche and a return to the multiverse of the many-worlds interpretation, with this now providing the Dionysian vision of science that he desired:

> For Nietzsche, science thus was the original cause for the ancient Greek's suffering from the separation of subject and object. And for modern humanity being torn from the integral unity of nature.
>
> Only if science were reconciled with the Dionysian tragedy, with art and music, only if Socrates would start to *make music*, only then could science grant humanity with a deep metaphysical benefit, could establish a true meaning of life.
>
> In view of this, it is probably most amazing that science itself, with the many-worlds interpretation of quantum mechanics, leaves some room for an entire multiverse of alternative realities beyond our immediate experience — a multiverse mirroring the unity of Parmenides's philosophy, as well as the egolessness of Aldous Huxley under the influence of psychoactive drugs, and a Dionysian creative moment bursting open all boundaries.

In betwen the first few chapters and the last one, there's a short 200 page book about neutrinos. This is the field of the author's expertise, where he started out as a theory student working with the Heidelberg-Moscow double beta decay experiment. Claims from this group that they see a signal have been challenged by recent (too recent to be in the book) results from GERDA. The GERDA results are here, Heidelberg-Moscow's response here. Neutrino physics is a complicated and fascinating subject, and one can certainly make a good argument that it's now the part of HEP where there are things we don't understand and promising avenues to explore using existing technologies (you don't need TeV-scale accelerators).

Unfortunately what most interests Päs is the far-out part of the subject, specifically ideas like using neutrinos to travel in time by hopping between branes. In the foreword to the book he does give a warning:

> Warning up front! The book deals with established scientific insights and with wild speculations… I highly recommend that the reader be alert to this difference.

and then briefly notes which topics he will cover are extremely speculative, but then ends with an inspirational quote from Glashow:

> The wild ideas of yesterday quickly become today's dogma.

These warnings are quickly left behind, and it requires a careful and well-informed reader to sort through which of the material on neutrinos has some sort of relation to reality, and which is just baseless and wild speculation.

When I bought this recently released book in the local bookstore (Book Culture, if you're interested…), at the same time I acquired another very recently released book, which I'll write more about here soon. The odd thing is that both of these books come from Ivy League university presses, and both end with a stirring and enthusiastic invocation of the multiverse as providing a Neitzschean answer to rationalistic Western science. There's definitely a trend here… For the Päs book in particular, I'm rather mystified why Harvard University Press decided this was something they should publish.

In the next to last chapter, Päs shows some awareness of why rationalistic science is so important:

> But useful application is not the point of neutrino physics. Rather it is a quest for a better basic understanding of the universe, thereby ultimately contributing to a solid foundation for the an incorruptible, rational world view. At times when intolerance, religious fanaticism, gut instincts, and irrational esotericism are flourishing, this is an effort whose importance should not be underestimated.

I'm not sure that "irrational esotericism" is any more of a widespread problem in the culture at large now than it has ever been. If it is though, I don't see how promoting over-the-top groundless speculation, the multiverse, and the idea (attractive as it may be) that fundamental physics should be a Dionysian activity based on psychedelic drug consumption is really going to help…

Update: Heinrich Päs sent me the following. It addresses a few things in the review that could easily be misunderstood, providing very helpful clarifications and some of his point of view.

Dear Peter,

thanks for your extensive review of my book. If you allow, I would like to comment on a few points though which might be misunderstood:

Your review may give the impression that the wild speculations in this book are not clearly identified. However, the preface you are citing identifies GUTs, supersymmetry and cosmic inflation as speculations which nevertheless represent "the present hopes… of most of the scientists working actively in these fields", marks string theory and extra dimensions as "wilder" speculations, admits that shortcuts in extra dimensions are "speculations squared" and that time travel in extra dimensions may be considered as "speculation to the power of 1,000". Also later on in the book I put some effort into saying clearly when I talk about textbook science and when I discuss scientific (and other) speculations, and I always motivate these speculations. For example, I mention your very own criticism of string theory as being "not even wrong" and I actually agree with you that scientific theories should make testable predictions. Of course this is one important difference of science and religion (or esotericism). However – and I hope you didn't take that personal – I continue by arguing that it is more useful and pragmatic to try to find out whether some ideas of string theory could actually lead to testable predictions – what people like Antoniadis, Arkani-Hamed, Dvali, Dimopoulos, Randall and Sundrum have started – than to condemn it.
And this is another important difference of science and religion: textbook theories can be questioned. Without speculation there would be no relativity and quantum mechanics, there would actually be no science at all.

You also mention the controversial result of the Heidelberg-Moscow group and the wrong OPERA result. Let me clarify that I'm not an author or advocate of the Heidelberg-Moscow result, and that I always have emphasized that the OPERA result is most probably due to a mistake in the experiment. The results are mentioned in the book as what they are: controversial and wrong, respectively. And while the GERDA result is not in the book, the somewhat earlier result by EXO which also challenged the Heidelberg-Moscow result with a comparable sensitivity is discussed.

Having said this, I actually like your review. It transmits the correct idea that this book takes you on the wild trip through neutrino physics, and may some of your more intellectually adventurous readers actually motivate to buy it.

Kind regards, Heinrich

   "Are these people on drugs?"

   They might be. Carl Sagan certainly was. (I am going to presume that you are aware of that being a factual statement.)

2. **Low Math, Meekly Interacting**
   February 4, 2014

   Kary Mullis claims frequent use of LSD helped him conceive of polymerase chain reaction (for which he won a Nobel), so there you go. My own brief period of experimentation with psychedelics leave me somewhat skeptical of that assertion. Dropping acid is way more fun than doing PCR, for one thing. If brane-world cosmology is a closer rival, I now wish I could do high-level maths more than ever.

3. **RalphB**
   February 4, 2014

   I'm retired from an industrial lab and was driving home last night after teaching my community college physics course. One of my usual FM stations was cutting in and out with others, but suddenly a woman was talking about the "mind-blowing reality of quantum physics" with its "infinite number of universes." I was told that every decision she makes leads to a splitting of the universe. This splitting also happens when she dreams. And it also happens when her cat makes decisions.
   I teach respiratory therapy students, some psychology majors, some very bright high school students. I was tired last night. And feeling like I am now swimming upstream against the current.

4. **Michael Gogins**
   February 4, 2014

   I have not read this new book of Rubenstein's but I have read a few of her presentations and papers. The most relevant is this one: http://works.bepress.com/cgi/viewcontent.cgi?article=1008&context=mary_jane_rubenstein.

   Rubenstein is a learned, articulate, and evidently very intelligent author. What I read was extremely interesting and I learned a great deal (try her lecture on Heidegger, http://works.bepress.com/mary_jane_rubenstein/31). At the same time, she left me a bit uneasy. I feel she has multiple agendas, perhaps not always on the surface. I wonder if she is interested in natural science for its own sake, or only as an instrument in her various theological and scholarly discourses.

   In the paper I cite, Rubenstein's core argument is that "creation from nothingness" is an idea born of ecclesiastical political dialectic, which cannot obscure the fact that founding documents of Western religion discuss no such thing and leave the "primordial waters" (not God as pure "spirit and truth") firmly in place as the actual fount of physical being. (This is not MY argument!) And she equates these "primordial waters" with the quantum fluctuations of eternal inflation. Then, by virtue of the anthropic principle, WE appear as the conscious face of those waters.

   I don't think Rubenstein actually "gets" science in spite of her competent and very insightful recaps of recent physics and cosmology. She is suspicious of the drive to "oneness" that motivates science, and sees it as a political (I read: patriarchal) move that ends up sucking the life out of actual existence.

   My own view is that, be that as it may, the undeniable progress of science lends considerable weight to the philosophical presuppositions (rarely discussed as such) of science. It may be that those presuppositions are not coherent. If so, some work is needed to make intelligible that undeniable progress.

   It would be great if you could engage Professor Rubenstein directly in your review.

5. **Luca Ambrogioni**
   February 4, 2014

   What is your opinion about many world interpretation Peter? I have the feeling that once you open that door there is a lot of pseudoscience that can enter. Ok maybe it is coherent with the mathematical structure of quantum mechanics (but I do not see any sign of "splitting" in the quantum formalism, for me it replaces the collapse with something equally mysterious), but it is still a wild extrapolation. Besides what is your opinion about the relational interpretation? I think that it takes the good parts of the many-world interpretation without accepting its metaphysical burden.

6. **Peter Woit**
   February 4, 2014

   Michael Gogins,
   Thanks, before commenting more about the Rubenstein book I need to actually read it. It's clear though she's not a scientist, and coming at this with an agenda and set of interests which don't have to do with the science.

   Luca Ambrogioni,
   I don't want to get into a serious discussion of QM interpretations here, since that's a very complex subject, one I'm not expert in, and the context is not conducive to an intelligent discussion of this. One thing to say about many-worlds though is that in its simplest form it's just the unsurprising statement that you can apply the standard QM formalism to arbitrarily large systems, including the entire experiment including the observer. The difficult questions then are how classical behavior emerges, the role of decoherence, and a host of other thorny issues. These are quite interesting, but very difficult and poorly understood topics. I don't see how going on about your cat causing splitting of worlds, or the joys of psychedelic drugs helps understand anything here.

7. **CIP**
   February 4, 2014

   @Luca –

   I personally am of two – or actually, of infinitely many – minds on the many worlds interpretation. I am pretty sure they aren't interfering constructively.

8. **Nex**
   February 4, 2014

   People are easily carried away by the eureka-euphoria of making dubious connections in their minds.

   "The first principle is that you must not fool yourself — and you are the easiest person to fool." -RPF

9. **Dave Miller in Sacramento**
   February 4, 2014

   Luca,

   The two main technical problems with many-worlds are often referred to as the "preferred-basis problem" and the "measure problem": The first refers to why the multiverse is sliced up into worlds in which you have definite experiences rather than superpositions of experiences. The second refers to how you get probabilities out of an infinite number of branches of the quantum multiverse. From time to time, someone (e.g.,, David Deutsch) convinces a few people he has solved these problems. Then people look more carefully and decide not. And so it goes, for decades now.

   If you want to look into the technical details of decoherence (i.e., not philosophical mumbo-jumbo), see Schlosshauer's *Decoherence and the Quantum-to-Classical Transition*. In my judgment, these technical details in the decoherence program are very informative in understanding quantum phenomena, but I am doubtful that decoherence resolves the longstanding philosophical issues.

   You'll note that neither Peter nor I have told you whether or not we think "many-worlds" or any other approach is right. At least in my case, that is because I do not know (and I frankly doubt anyone does).

   Dave

10. **Mark Thomas**
    February 4, 2014

    There is a similar claim of the influence of psychedelia on the information age, Silicon Valley and its creative revolution. However, their claims don't go back to the ancient Greeks but the newly invented chaotic psychedelic light/music shows fostered by Syd Barrett in Cambridge and down the road with the Beatles in 1967 with Sgt. Pepper. Lots of borders were crossed.

11. **Peter Woit**
    February 4, 2014

    Thanks Dave,
    I second the Schlosshauer recommendation. But also still want to discourage discussion here of QM interpretational issues. Maybe someday a good new book on that topic will come out…

12. **John R**
    February 4, 2014

    Peter, when you ask, "why Harvard University Press decided this was something they should publish," the answer doesn't hinge on the veracity of the many-worlds hypothesis. The answer is grounded in this here and now. The profit-potential from a book like this enables the publication of some really good books that cost more than they make. It may just boil down to the bottom line.

13. **Fredf**
    February 5, 2014

    The use of psychedelics goes back forever. And it is typical of users to claim enhanced creativity as a result of their use.
    Most studies, however, suggest that the creativity is more assumed that realized…that is to say that in reality there isn't much creativity to come out of drug use, whatever may be the impression of the user.
    Whatever its import for physics is, it's not as a basis for new theory!

14. **Dom**
    February 5, 2014

    Nice update from the author and he is correct, I may well buy it now.

15. **JohnB**
    February 5, 2014

Speaking of Carl Sagan and Plato: There's an incredibly good section from one of his documentaries here, outlining how Plato and the Pythagorians, snuffed out science in favour of gibberish – analogous to the topic at hand:
https://www.youtube.com/watch?v=z_966RzTF6k&t=260

A quote (which I believe is from this) on Wikipedia (doesn't do the few minutes of the video justice mind):
"Science and mathematics were to be removed from the hands of the merchants and the artisans. This tendency found its most effective advocate in a follower of Pythagoras named Plato." and "He (Plato) believed that ideas were far more real than the natural world. He advised the astronomers not to waste their time observing the stars and planets. It was better, he believed, just to think about them. Plato expressed hostility to observation and experiment. He taught contempt for the real world and disdain for the practical application of scientific knowledge. Plato's followers succeeded in extinguishing the light of science and experiment that had been kindled by Democritus and the other Ionians."
https://en.wikipedia.org/wiki/Carl_Sagan#Scientific_advocacy

When physicists fail to ground their theories with observation and evidence, preferring just to play with their ideas and presently-inapplicable (in the sense of being applied to experiment) mathematical abstractions instead, how long can this go on – crowding out resources from other areas of research – before they become much like Plato and the Pythagorians?

16. **JohnB**
February 5, 2014

Note: That I apply that comment mainly to string theorists, not to physicists in general.

17. **Prof. David Edwards**
February 5, 2014

Nietzsche introduced the idea of perspectivism: in the final analysis, all we really have is a manifold of interlocking perspectives. For example, consider the following toy model. If humans are small finite, represent each possible human perspective by a small non-empty subset of {1,…,n} where n is a large natural number. Then, there are minimal perspectives, but no maximal human perspective. Still, there is an ideal finite perspective which sees everything! If n=infinity, then there is still an ideal infinite perspective which sees everything! (God's eye-view!) If one accepts the standard quantum logic then one has a manifold of perspectives which cannot-by Gleason's Theorem-be embedded into any single perspective! There are now maximal perspectives, but no universal perspective! (Theologically, this requires accepting polytheism!! Alternatively: Even God suffers from cognitive dissonance!!)

18. **Tim May**
February 5, 2014

Thanks, Peter, for the review and/or calling out of the book. I just ordered a copy.

I've never used recreational drugs, save for alcohol, and never noticed any of my physics colleagues or Intel colleagues (I was there from 1974-86) influenced by drugs, but I've read a lot of Nietzsche, Heidegger, etc. Not as it relates to physics or math, but in general. (And some of the pre-Socratic stuff from Heraclitus et. al. has resonances with "process" over "object," and perhaps thus to the operator/transformation or category theory point of view.)

I got exposed to the "many worlds" thing through Bryce DeWitt's book, circa 1971, and of course through the fiction of Borges, Niven, et. al., but I didn't let it warp my hard science career. As you point out, there are a bunch of aspects of QM which are interesting….I won't add my two cents here.

— Tim May

19. **M. Anderson**
February 5, 2014

Literally every sentence of the Wikipedia quote above concerning Plato (the second quoted section, beginning 'He (Plato)') is either flat inaccurate, sloppily worded (so sloppy as to be misleading), or grossly exaggerated.
The Mysteries at Eleusis did not "revolve" around the ingestion of a drug, and though Plato was indeed fascinated by, and perhaps even influenced by, the Mysteries, there is no evidence that he had any interest in or experience with psychedelics (maybe he did, but there is no evidence either in the dialogues or the ancient testimony).
There is also no evidence of this in the case of Democritus.
This all reads very much like the sloppy use many humanists make of half-digested, and thus misunderstood, science–only in reverse.

20. **M. Anderson**
February 5, 2014

Nietzsche later rejected the version of Dionysianism developed in The Birth of Tragedy (in which appears the notion of "humanity being torn from the integral unity of nature"); his "science" (Wissenschaft) means "scholarship" (as in his own early discipline of philology) as much or more than it means science in our sense; of course he did not believe in a "true meaning of life," probably not even in BT; and there is simply no way to tell what he would think of the multiverese; his idea of the music making Socrates and notion that science will eventually develop into a new need for myth (also in BT) stesses a different sort of art than the "art" of evidence-free theories of physics.
Again, sloppy interpretations, wild leaps of association, lack of concern with evidence–is there a trend here.

21. **Mozibur Ullah**
February 9, 2014

I'm fascinated by the beginnings of philosophy and physics in classical times. Does Heinrich provide any solid evidence for his claims about Democritus & Plato being on 'drugs'?

I don't think it being entirely outside the bounds of possibility that hallucinations – drug-induced or otherwise might give some impetus to thinking about the realness of reality. But, most people have these without having to take drugs – they're called dreams.

And we have solid evidence in the 20C for artists have used dreams & hallucinations as a subject for their work – I'm thinking of surrealism here. But this doesn't mean of course that technique can be dispensed with. Dali was a very good painter in the classical western tradition.

Of course, art is not science. But one gathers that the boundaries between what counted as religion, science, art & philosophy in Antiquity would be more fluid than is the case now.

Wasn't Kekule inspired by a dream of a snake eating its tail – which actually is a mythological motif – to think of structure of Benzene? Or is that also a myth?

Possibly one might consider the wilder speculative moves in cosmology and physics – multiverses, firewalls, landscapes, as part of that same mode of thinking in the 20C – as a kind of esoteric science, to be considered in conjunction with and apart from exoteric science – science that is properly evidence based in the classical sense.

22. **Peter Woit**
February 9, 2014

Mozibur Ullah,
No, not much detail about drugs and Democritus or Plato.

Yes, lots of the multiverse stuff fits in well with traditional "esoteric science". Another name for "esoteric science" among physicists of course is "crackpot science"…

23. **nasren**
February 14, 2014

I second M. Anderson's comment about Plato. Not only Wikipedia but also the Carl Sagan quote are full of inaccuracies about Plato, the Pythagoreans and Greek science in general. I'm particularly tired of hearing that the discovery of incommensurability "wrecked" the Pythagorean philosophy and that they killed the man who discovered it. Complete rubbish, but repeated ad nauseam in popular accounts. Also the idea that any Greek philosophers or scientists had any acquaintance with psychedelic drugs is pure invention: there isn't a single mention anywhere.

What we seem to have in these books is the eternal recurrence of Fritjof Capra — it keeps repeating like indigestion.

More Links, Interesting and Tedious

February 5, 2014
Categories: Multiverse Mania, Uncategorized

First some links to interesting things:

- There's a fascinating interview with Deligne in the latest AMS Notices.
- Alexandre Grothendieck: A Mathematical Portrait includes some great expository pieces about the mathematics developed by Grothendieck. There's also available Grothendieck's own Esquisse Thématique, giving his description of his major mathematical achievements.

In the category of things that have gotten tedious, first there's the ongoing hullabaloo about "firewalls" and Hawking (with the bottom line as far as I can tell just that, yes, there is an information paradox, might have something to do with the fact that we don't understand quantum gravity…). If this interests you, you can take a look at

- Matt Strassler, here, here and here, with creative writing here.
- New Scientist has Fiery black hole debate creates cosmological Wild West.
- Michael Lemonick here sensibly asks whether people really should be paying this kind of attention to Hawking at this point.

In the multiverse-mania category, I'm forcing myself to read the Rubenstein book I've mentioned, will report on this when done, in the meantime there's

- In the London Review of Books, David Kaiser has a review of Lee Smolin's book from last year Time Reborn. The review is mostly about the string theory landscape case for the multiverse, a bit about Smolin's take on it.
- Tom Banks has a new paper out surveying the issue of Supersymmetry Breaking and the Cosmological Constant. He surveys the anthropic string theory landscape argument and concludes that

> It is therefore fair to say, that much of the standard model, and certainly the peculiar values of many of the parameters in the standard model, cannot have an anthropic explanation. In string theory, extra generations of matter correspond to more tuning of moduli, small parameters do not appear to arise without a symmetry explanation, and symmetries are rare on moduli space.
>
> One cannot escape the implication that, on the basis of current theoretical knowledge, the String Landscape is ruled out by experiment.

Besides being experimentally ruled out, the whole Landscape thing doesn't work anyway

> My personal conclusion from all of this analysis, is that the theory of CDL tunneling provides no positive support for, and lots of negative evidence against, the proposal of a String Landscape…
>
> When combined with the phenomenological challenges I presented in Section 2, I conclude that the String Landscape is an hypothesis of dubious validity.

This is a subject in which solid predictions are hard to come by, but I'll make one here: string theory partisans will just ignore this, with the "String Landscape" now an hypothesis which has achieved some sort of new extra-scientific status. It's an ideology you sign up for to justify not giving up on string theory (or as a foundation for your multiverse-mania), and as such, arguments like those from Banks are irrelevant.

- Also in the category of serious scientific arguments against the anthropic landscape that will just be ignored, see Sesh Nadathur who explains why Weinberg's original argument for the CC implies one that is 10^3 times too big. This is part of some arguments with Shaun Hotchkiss you might want to have a look at, see other blog postings here and here.
- Finally, Max Tegmark is on tour promoting multiverse-mania and his Level IV version of it. The latest from him is here at Scientific American, where he's claiming that his Level IV multiverse is science because it could be falsified by finding "some physical phenomenon that has no mathematical description." I've tried arguing the absurdity of this with him in the comment section, so far no luck getting anything other than a dismissal of me as "emotional".

I was interested to see that his perception of what has been going on for the past decade as endless popular books promoting the multiverse have appeared is that

> whenever a physicist writes a book about them , the Web erupts with claims that they are unscientific nonsense.

Curious to know what part of "the Web" he is referring to other than my blog…

Comments

1. **Chris W.**
   February 5, 2014

   Max Tegmark has jumped the shark.

   There, I said it…

   (It's hardly worth saying anything more on the subject.)

2. **Ahab**
   February 5, 2014

   1-

   > Michael Lemonick here sensibly asks whether people really should be paying this kind of attention to Hawking at this point.

   Actually, he does no such thing. The article is about the media hype that has surrounded Hawking for much of his career, and it includes a mention of how Hawking himself has opposed it. The article at some points was a bit too hostile and unfair, but the relevant point is that it admits the fact that Hawking was and *still* is "one of the world's leading physicists".

   2-

   > Curious to know what part of "the Web" he is referring to other than my blog…

You quoted from the 1st paragraph. If you look at paragraph immediately after it you'll find that Tegmark says:

> My new book "Our Mathematical Universe" proved to be no exception. "Is this still science?" the biologist Mark Buchanan wondered on the pages of New Scientist, "Or has inflationary cosmology veered towards something akin to religion?" The physicist Peter Woit dismissed it as "grandiose nonsense".

3. **Amos**
February 5, 2014

The black hole information paradox and firewall paradox have jumped the shark. I think I'm going to try to stop paying attention to this until somebody comes up with a theory that makes an actual prediction.

4. **Peter Woit**
February 5, 2014

Ahab,
1, Actually, he calls him a "pretty-great" physicist…

2. I did read that. And actually I linked to the New Scientist Buchanan review in my blog posting here
http://www.math.columbia.edu/~woit/wordpress/?p=6551
The parts Tegmark quotes are questions, not statements, with Buchanan only saying about them "some scientists wonder". As close as Buchanan gets to criticism is ""there does seem to be something a little questionable with this vast multiplication of multiverses". As far as I can tell, of the dozen or so reviews out there, only Buchanan's and mine contain any criticism of the sort Tegmark is claiming "erupt all over the web". Of the other many multiverse books, I can't at the moment think of any reviews (certainly not in New Scientist) or a significant other number of blog postings (besides mine) criticizing these books. Tegmark seems awfully thin-skinned about criticism for someone who poses as "Mad Max" the revolutionary with controversial ideas…

5. **Navneeth**
February 6, 2014

> "Curious to know what part of "the Web" he is referring to other than my blog…

There are parts of the Web (a multiweb, really) that you cannot possibly access, now or in the future.

6. **theoreticalminimum**
February 6, 2014

Thanks for the link to the Schneps' page on "Alexandre Grothendieck: A Mathematical Portrait", Peter. Do you by any chance know if this will get published in a book/ebook format?

I wish you had more links like that than depressing ones to articles/books/blogposts tirelessly rehashing the same thing about multiverses :-\

7. **Bernhard**
February 6, 2014

" … for someone who poses as "Mad Max" "

Some kids will just never accept they will never become Einstein when they grow up…

8. **Roger**
February 6, 2014

I have attacked the level II, III, and IV multiverses on my blog also. Tegmark admits that many of the multiverse ideas are untestable, but says that we should take them seriously anyway because they can be formulated as parts of theories that have testable implications for our universe.

9. **Shaun Hotchkiss**
February 6, 2014

Hi Peter,

Thanks for linking to my discussions with Sesh.

Whereas I agree with Sesh that the anthropic prediction for Lambda is off by 10^3, that was still a *prediction* that got closer to the correct value than any other prediction of its time. That alone makes it compelling enough to me that, whereas I'm glad that I don't have to work on it myself, I have no qualms if other people do want to explore it. I certainly don't view a multiverse as even close to established fact, but as a speculative idea it *does* have its *scientific* merits.

On this side of the Atlantic I rarely encounter anything I would label multiverse mania. And even string theory in general, although certainly part of the mainstream in Europe, is far from dominant (arguably it is on decline). My perception of the U.S. is that things are a little different (at least from theory postdoc job advertisements over the last five years, which *typically* are either dealing with data/the lattice, or string-inspired-something-or-other – with some notable exceptions, e.g. in/near Chicago).

I think both sides (the hypers and the naysayers) need to take a longer term view of things. No, the multiverse is not established fact, and the hypers shouldn't be saying it is just to score media points, but neither is it unfalsifiable, in the long term.

10. **Shaun Hotchkiss**
February 6, 2014

Sorry, I can't edit the above post, but I should stress, that whenever I mention "multiverse" (here, or elsewhere) I am referring solely to the eternal inflation with multiple possible vacua one (Tegmark Type II, I guess), and definitely not Tegmark's III and IV.

11. **Luca Ambrogioni**
February 6, 2014

But all in all is the Tegmark's level IV multiverse very different from what Lawrence Krauss is continuously repeating about a supposed origin of the laws of physics from nothing (whatever that means)? I think he went on that direction several times.
Anyway I currently think that the main problem is that physicists are starting to feel authorized to try to answer questions that would have been considered outside physics just few years ago.

I pretty much agree with the Platonist philosophy of Penrose (much less with his view about physics) but I think he never confused philosophy with physics. It seems to me that the main attitude is becoming "any sensible question is a physical question". Of course I strongly disagree.

12. **Manyoso**
February 6, 2014

Anyway I currently think that the main problem is that physicists are starting to feel authorized to try to answer questions that would have been considered outside physics just few years ago.
I pretty much agree with the Platonist philosophy of Penrose (much less with his view about physics) but I think he never confused philosophy with physics. It seems to me that the main attitude is becoming "any sensible question is a physical question". Of course I strongly disagree.

This in triplicate. What's worse is that we are learning that very bright scientists nonetheless can produce very naive/shoddy philosophical thinking.

13. **Dr. Shrevinsky**
February 6, 2014

Yes Manyoso, "What's worse is that we are learning that very bright scientists nonetheless can produce very naive/shoddy philosophical thinking."

And also that not very bright scientists nonetheless can produce very naive/shoddy philosophical thinking.

14. **Jeff McGowan**
February 6, 2014

OK, as a mathematician I'm really curious how Tegmark thinks you might go about proving that "some physical phenomenon has no mathematical description." I guess it depends on what you mean by "mathematical description," I mean naively everything has a mathematical description in that one can take a description (e.g. the visual description, but it could be anything) and use math to encode that. I assume Tegmark is talking about a predictive description of some sort, though perhaps not given the current state of theoretical physics. Even with a limited meaning for mathematical description I can't see how one would go about proving it didn't exist for some phenomenon.

15. **Manyoso**
February 6, 2014

Jeff McGowan,

Indeed, I remember in freshman calculus the "Spherical Cow" and wonder if Tegmark believes that because one can – crudely – mathematically model a cow as a sphere, if he believes there is some universe of spherical cows 🙂

Cheers,
Adam

16. **Peter Woit**
February 6, 2014

Shaun,
Thanks for your comments. I think though that the multiverse (specifically the anthropic string theory multiverse) is unfalsifiable, in the long term. I know of no current or planned, or even conceivable experiment that could falsify this picture, since it makes virtually nothing in the way of significant predictions. For the one it is claimed to make (Weinberg's), failure of the prediction (off by a factor of a thousand is pretty bad…) is explained away, either by an unknown measure factor, or by the "at least it's not off by 10^120" argument.

In the paper I linked to, Banks gives good arguments that if you look at other things than the CC, and apply the anthropic string landscape argument logic, you get massive failures, so the whole thing should be experimentally ruled out. Arguments like his are just ignored, what is going on here is not the usual sort of science.

Of the things we're likely to experimentally learn in the future, the most obvious case is the Planck polarization data, I hear due this summer. I'm no expert, but it seems there are "predictions" of a measureable effect, as well as "predictions" of no measureable effect. No matter what Planck reports, I see no possibility that it can count as evidence against the string landscape picture, and I'm pretty sure that it will reported as "new scientific evidence about the multiverse", with scientists X, Y, and Z explaining how it agrees exactly with their multiverse model.

As for the sociology, ten years ago when I was writing my book, the whole anthropic landscape thing seemed so unserious and with such little support that it barely seemed worth mentioning (I did write about it, without much detail). I was pretty sure, like I think most people, that this was something that would just disappear of its own accord. I was very wrong then, and this has made me much less sanguine about the future, for instance about what will happen with obvious absurdities like Tegmark's. Multiverse mania in the US dominates the popular coverage of the subject, and in physics departments from what I can tell the problem is one of "the best lack all conviction, the worst are full of passionate intensity".

Jeff,
The same though occurred to me. A problem with the idea of a physical phenomenon that can't be described mathematically, is that you can embed the English language in a mathematical structure, then any description you make in words is a mathematical description. What Tegmark needs for his falsification is some physics that can't be described, something like "the peace of God, which surpasses all understanding"…

17. **Russ Whirton**
February 6, 2014

I wish people would stop referring to "Tegmark Type II" etc. It makes him sound as though he raised some profound questions.

Which he didn't.

18. **Roger**
February 6, 2014

Jeff: Yes, our theories are mathematical, and they predict experiments well, but Tegmark wants to make an ontological argument that the physics *is* the math. If two distant electrons are entangled, then it is impossible to give a mathematical description of one electron independent of the other one. The usual way out of this paradox is to day that there is a mathematical action-at-a-distance, but not a physical one. To me, that says that the physics is *not* the math.

There are alternative explanations, such as saying that there is a physical nonlocality that is not directly observable. To me, this is unsatisfactory as it is like believing in psychic powers that can never be demonstrated in a controlled way, or believing in one of the unobservable multiverses.

19. **CU Phil**
February 6, 2014

    Peter,

    Regarding prospects for testing the multiverse (it looks like the multiverse of eternal inflation, not the string landscape, although the comment about extra spacial dimensions muddies that a bit), here's something close to home this Monday:
    http://physics.columbia.edu/colloquium-matt-kleban

20. **Peter Woit**
February 6, 2014

    CU Phil,
    Probably will try and make that, although it's just likely to lead to more tedious material appearing here…

21. **Art**
February 6, 2014

    A lot of Hawking-envy out there in physics-land… Which is strange: hands up, those who want to trade places. The point is well taken that, like the elderly Einstein, the media pay un-justified attention to his recent work. But I don't think you can change that behavior; the human-interest story is just too compelling. What you can do is to exploit that attention to educate and re-direct the curious. I suppose that's what Wilczek was attempting, like you said, but it still strikes me as a particularly clumsy attempt.

    Thanks much for the Deligne interview link. Imagine a lecturer postponing a session because an auditor was absent!

22. **Shaun Hotchkiss**
February 6, 2014

    Sorry for that Russ, I completely agree. He made the classification of course, but given that he only invented one of the classes in his classification and it is the "either he's a genius who has seen deeper than everyone else, or he's just talking nonsense" class, that doesn't really count.

    Thanks for the reply, Peter. I do think that people take heed of all the issues you've pointed out, just perhaps not the vocal people, at least not publicly. The reason why those issues aren't enough to kill off the idea is that (and this does depend on priors, I suppose) the anthropic explanation of the cosmological constant, even if that far off, is still one of the best on the table (though I guess you'd disagree). If the cosmological constant problem were to be compellingly solved with some other mechanism people would give up on an anthropic multiverse pretty quickly (though maybe that is youthful naivety).

    Also when I write "long term" I mean *long term* (i.e. potentially 100s of years) and I'm implicitly considering the possibility that the correct inflationary potential gets determined (if inflation is correct), and/or the standard model is found within the landscape and/or early collisions of inflating bubbles can get witnessed, and/or more catastrophic boundaries are discovered. The point is, any elapsed period of time during which any of the above is not achieved does "falsify" the multiverse a little, but substantial "falsification" will take this continuing to happen for many years and/or the more compelling alternative arriving.

    Or, at least, that's how I currently view things.

23. **Asnant**
February 6, 2014

    Hey Peter,

    Here's a link I'd like to get your view on:
    http://iainews.iai.tv/articles/beyond-the-universe-auid-309

    (sorry for going off topic)

    Cheers

24. **Peter Woit**
February 6, 2014

    Asnant,
    Never got around to mentioning that particular piece of multiverse mania, there just are too many… But I did write here recently about Mersini-Houghton's claims, basically the same ones she is making in that piece, see

    http://www.math.columbia.edu/~woit/wordpress/?p=5907

25. **mathematician**
February 6, 2014

    Peter,
    The speakers for ICM 2014 are announced. Any rumors for yet?

26. **Peter Woit**
February 6, 2014

    mathematician,
    Haven't heard any, just speculation about the obvious candidates (for the Fields). If I do hear any interesting rumors, will blog about it (or, if I don't, may do this anyway to try and generate some…). But, so far, I got nuthin.

27. **Yatima**
February 8, 2014

    Meanwhile, ideas for the [next european circular hadron collider at 100 TeV]() are being collected.

28. **TomH**
February 8, 2014

In his SciAm article, Tegmark writes:

" … all their arguments involve what logicians know as "modus ponens": that if X implies Y and X is true, then Y must also be true. Specifically, they argue that if some scientific theory X has enough experimental support for us to take it seriously, then we must take seriously also all its predictions Y, even if these predictions are themselves untestable (involving parallel universes, for example). "

Well, I dont see why we have to take seriously _ALL_ its predictions. Most theories are only applicable in a limited domain of energies, scales, or other simplifying assumptions. Eg, Newton's gravity theory. And who hasn't heard of the "spherical cow" simplifying assumption?

re Tegmark's comment:
" … falsify the mathematical universe hypothesis by demonstrating that there's some physical phenomenon that has no mathematical description … "

Seems to me most complex systems _don't_ have a tractable mathematical description.

Try creating a mathematical description of human consciousness & self-awareness.

Too hard?

Try to create mathematical description of the c.elegans' (a nematode worm) behaviour. It has only 109 neurons.

Still can't do it?

QED, I have falsified Level IV multiverses.

29. **Simple biologist**
February 8, 2014

@TomH
"Try creating a mathematical description of human consciousness & self-awareness.

Too hard? "
Not for Max. You must've missed his new consiousness paper.

http://arxiv.org/abs/1401.1219

30. **Peter Woit**
February 8, 2014

Tom H,
I don't have a problem with Tegmark's claim that if some parts of a theory are well-tested and we have lots of reasons to trust them, then it's reasonable to believe that other implications of these parts of the theory will work out, even if we can't test them. Of course this all assumes you are talking about a theory you understand well, so you know what its implications are, and you have serious and compelling tests of the relevant parts of the theory. The situation with Level II multiverses, which are supposed to be predictions of theories like the string theory landscape, is that we don't understand the theory at all, and to the extent we understand it have zero evidence for it (or, as Banks argues, good arguments against it). I also see no serious argument for how we are supposed to get such evidence in the future.

Tegmark's tactic here is to argue based on assumptions that are nowhere near where science is or has any hope of getting, but are close to the place he wants to end up. It's kind of like arguing with someone about the existence of God, and you start by saying "assume that an Angel with gold tablets appears in front of you…."

As for falsifying Level IV, Tegmark is certainly not discussing "tractable" mathematical descriptions. As he states his argument, to falsify his hypothesis you need to show there is no possible mathematical description of some phenomenon, not just be unable to find a tractable such description. It has been pointed out here that "no possible mathematical description" seems to be equivalent to "no possible description", since one can embed a natural language like English in a mathematical structure. Tegmark does claim "consciousness can't be described using mathematics" as a possible falsifying example, but I'm not sure what that means, unless you are a non-materialist, believing consciousness is not a physical phenomenon, in which case this has nothing to do with his hypothesis.

31. **Laymammal**
February 8, 2014

Tegmark's comment:
" … falsify the mathematical universe hypothesis by demonstrating that there's some physical phenomenon that has no mathematical description … "

I think Tegmark's statement itself is problematic. From what I can get from his work, he makes a claim of ontology not the less radical claim of description. Here he gives a falsifying example for the "uncontroversial" claim as proof that his "ontology" theory is scientific. Doesn't work. If he is only claiming description, so what? Description does not beget ontology.

32. **Jim Akerlund**
February 8, 2014

Off topic,

Peter, I see your first post for NEW was 3-17-04. Do you have anything planned for the ten year anniversary of NEW?

33. **SUSY**
February 8, 2014

One cannot escape the implication that, on the basis of current theoretical knowledge, the String Landscape is ruled out by experiment.

Besides being experimentally ruled out, the whole Landscape thing doesn't work anyway

My personal conclusion from all of this analysis, is that the theory of CDL tunneling provides no positive support for, and lots of negative evidence against, the proposal of a String Landscape…

When combined with the phenomenological challenges I presented in Section 2, I conclude that the String Landscape is an hypothesis of dubious validity.
^

if the string landscape is of dubious validity what does this mean for string/M-theory and offshoots like adS-CFT?

34. **Peter Woit**
February 8, 2014

Jim Akerlund,

Well, I'll be on a spring break vacation in Northern Italy, nothing planned yet.

SUSY,

For string/M-theory, just that even a pathetic last-ditch, pseudo-scientific effort to salvage unification via string/M-theory doesn't work. For adS/CFT, nothing at all.

35. **cthomas**
February 9, 2014

It seems to me that it would be quite easy and simple to empirically refute any version of the multiverse hypothesis, including Tegmark's approach. The test is that if we ever happen to meet an omniscient and honest being, then the being would affirm the sentence, "Tegmark's hypothesis is true" if and only if the hypothesis is true and would affirm the negation if and only if false. Now granted, we don't happen to be able to carry out this decisive experiment given current conditions, but the availability of the future possibility of this decisive test clearly shows that it is falsifiable in principle, and hence fully scientific.

36. **Susanne**
February 9, 2014

Peter,

Your blog is always an inspiration for me. Today I have one point to ask: isn't the best prediction of the cosmological constant simply that it is the zero-point energy of the box defined by the universe? This gives a prediction (1/Radius of the universe)^2 for the cosmological constant, very near to the observed value, with an error of the order 50%.

The prediction has the disadvantage that the constant would need to change with time. But the experimental data is not yet good enough to allow checking for such a decay. Is there a reason that this "prediction/postdiction" is not discussed more often?

37. **SUSY**
February 9, 2014

Peter, do you find Tom Banks reasoning sound on scientific grounds?

How would you respond to a string theorist who would argue that the moduli of the Yau-Calibi space cannot be determined on a priori grounds but only through experiment and observation, and that we do not have the technology to test this. Once this universe moduli could be thus determined string theory becomes completely predictive with only 1 parameter.

38. **Peter Woit**
February 9, 2014

Both of these are off-topic, so, please, do not try and turn this into a discussion of the CC or moduli stabilization, about which I don't think there is anything to say that hasn't been said hundreds of times here and elsewhere.

SUSY,
There are plenty of problems with string theory models, Banks is pointing out some, I've discussed others here and in my book. The standard answer from string theorists is that we don't understand string theory well enough to know how severe these problems are. If we understood string theory better, maybe they would go away, is the argument, but that seems to me just pure wishful thinking.

There are typically dozens to hundreds of Calabi-Yau moduli parameters, not 1. In addition, you need to add some physical mechanism to fix the parameters (e.g. KKLT moduli stabilization), which introduces yet more physics you don't understand, ensuring you can calculate nothing.

Susanne,
I'm not sure exactly what argument you have in mind, the distance scale of the CC I would have thought was 10^-3 eV (since it is the 4th power of this). If you do want to relate it to the size of the universe you do have the problem that it is supposed to be changing, which is presuamably testable.

39. **Cspan**
February 10, 2014

cthomas,

"if we ever happen to meet an omniscient and honest being, then the being would affirm…"
"the availability of the future possibility of this decisive test clearly shows that it is falsifiable in principle"

I don't think, to *ask someone* is what is considered a scientific experiment and even the possibility to do so is not falsifiability.

40. **CThomas**
February 10, 2014

Cspan — my bad. Failed attempt at sarcasm on my part. Not very humorous, in retrospect.

Best regards.

41. **Cosmonut**
February 10, 2014

Thanks for the article about Hawking.

IMO, Melnick is being too generous – much of Hawking's o
overblown reputation is due to his wild self promotion
rather than media hype.

For a great example, read his latest autobiography
where he claims to have created a successful
approach to quantum gravity and
explained the origin of the universe. via his No Boundary proposal

Both claims are completely false, but my dishonestly
presenting mere speculations as established scientific fact in
popular books, Hawking has created an image of having done
far more than he actually has.

Nice article in "New Scientist". From layperson's point of view, does not this remind of the ultraviolet catastrophe in the early 1900 physics that started the quantum era, only in reverse? There, classics dictated continuous spectrum where micro structure was discrete…. here, classic theory says discrete wall (event horizon) where on micro level (Planck scale?) there could be still some continuity. Look for a theory with a smudged event horizon? Would be really funny and ironic if this "little spot on the horizon" sparked a new theoretical revolution, wouldn't it? 🙂

The Multiverse, Evidence and Theology

February 11, 2014
Categories: Book Reviews, Multiverse Mania

Yes, this multiverse business is tedious, but since it is becoming mainstream physics, with colloquium talks here at Columbia devoted to it, and the Columbia University Press publishing books about it, seems to me that someone at Columbia should be commenting on these, and I don't see anyone else doing it. Will try to make this short.

Yesterday Matthew Kleban's talk here was entitled Testing the Multiverse. The only part that actually really was about testing the multiverse was the part describing work on bubble collisions with other universes. This has been heavily advertised in the press, see here, here, here, here, here and many others. Kleban described some of these ideas, but when it came to the experimental testing part, he just briefly acknowledged that all searches for these things have come up empty. The only prospect for the future mentioned was the polarization data to be released later this year by Planck, which would give some new things to look at, but he seemed unenthusiastic that this would realistically lead anywhere. So, as far as the "testing" goes, it has been done and the tests failed.
The rest of the talk was about various inflationary models, including Kleban's work on "unwinding inflation" (see here, here and here). Some of these models do have testable consequences, and many do lead to "eternal inflation", so in such models you expect to continually produce new inflated universes, although with exactly the same physics. This is being sold as "testing the multiverse", and string theory is brought in to justify lots of possible different physics in different universes, but this is not a testable part of these scenarios. What's being advertised is a grandiose picture of the string landscape, laws of physics determined environmentally, etc., etc., but if you actually look at the product that you're actually buying as "testable", you don't get any of the cool stuff. For slides of a somewhat similar recent talk by Kleban, see here.

A while back I acquired a copy of the new book Worlds Without End: the many lives of the Multiverse, started reading it and was planning on writing a detailed review. I soon got bogged down in the first half of the book, which is a detailed intellectual history of speculation about multiple universes (so lots about relevant parts of Plato, Aristotle, Lucretius, the Stoics, Augustine, Nicholas of Cusa, Giordano Bruno, Kant and others). Finally I realized I just didn't have the energy to serious read this material. People with other interests and/or more time on their hands may find this quite worthwhile.
The second half of the book is devoted to the question of current speculation about physics, so more up my alley, but again I found it hard to focus on this. I fear it is only mildly interesting to see what a theologian/philosopher of religion makes of the current multiverse mania, not enough so though to do more than skim the text. From this skimming, what's in the book is a lot of retelling (sometimes introducing misunderstandings) of the hype-laden tales of the multiverse told in dozens of books and magazine articles over the past decade or so.

Rubenstein ends the section about what physicists have to say with Tegmark, seen as having reached the final endpoint of the "Ultimate Multiverse":

> So some worlds will be linear, and some will be cyclical; some will be singular, and some will be plural; some will be infinite, and some will be finite; some will branch forward, and some will branch back. Some worlds will be manufactured, and some will be simulated; some designers will be kind and some will be cruel, some capable and some all but incompetent.
> And, presumably, some of the set of all possible world will have a creator-god who breathes over primordial waters, who separates the sea from dry land.
> How on earth did we get back here?

I take Tegmark's vision as empty, so a good thing to ignore, but Rubenstein sees this as an opening for theologians to get back into the mainstream cosmology business, and the rest of the book focuses on this. With the boundaries between science and religion now gone, all sorts of possibilities open up for theologians. The final part of the book begins by invoking (just like Henrich Päs, who comes at it from the mind-altering drug rather than theological angle) Nietzsche:

> Nietzsche concludes the *Genealogy* by expanding this vision, promising "*all* great things bring about their own destruction through an act of self-overcoming" (3.27, emphasis added). This promise then, has me wondering. If science can be regarded as the self-overcoming of a particular form of religion, might multiverse cosmologies be something like the self-overcoming of *science*? Might they mark the end of the fantasy that "science" has wrested itself free from "religion", "objectivity" free from subjectivity, and matter free from meaning? After all, we have seen each of these multiverse cosmologies open onto metaphysics and mythology not in moments of lapse or weakness, but precisely where they are scientifically most compelling.

It seems that, unlike most authors, Rubenstein actually has got the story of multiverse mania right: it's left conventional notions of science behind and entered into the realm of theology. We do, however, disagree about whether or not this is a good thing…

Update: Bogus claims about Multiverse "predictions" are now all the rage. For the latest, see the Caltech Quantum Frontiers blog, which has Yasunri Nomura writing about Making Predictions in the Multiverse. There of course are no predictions there, just mainly a discussion of the idea that many-worlds and the eternal inflation multiverse are somehow the same, an idea I continue to find unfathomable. Nomura doesn't mention that he actually did have a prediction from the Multiverse (and someone made a movie about it…). The prediction was for a Higgs mass of 140 GeV, but of course when you're in the multiverse business, wrong predictions are not a problem, they're always true somewhere.

Update: For more on the multiverse front, Edward Frenkel has a review of the Tegmark book in this Sunday's New York Times. He does a great job of explaining the problems with the way Tegmark is trying to use mathematics. John Preskill tweets in agreement (positive and negative).

Update: Nomura, when asked about experimental evidence for the multiverse, responded that the experimental situation is

> not much different from some other situations—e.g. in the big-bang theory, inflationary cosmology, and Darwinism in biology

So, the scientific evidence for the multiverse is "not much different" than the evidence for evolution? And Tegmark thinks I'm the one in league with creationists…

Comments

1. **Manyoso**
   February 11, 2014

   I take Tegmark's vision as empty, so a good thing to ignore, but Rubenstein see this as an opening for theologians to get back into the mainstream cosmology business, and the rest of the book focuses on this.

   Massimo Pigluicci's blog has a new podcast with Tegmark discussing his ideas. A lot of the answers are not very responsive as you might expect.

   One interesting thing is that Tegmark is now requesting to divorce his critique of the use of infinity in physics with his multiverse of mathematical universes hypothesis. He thinks the two should be treated as unrelated.

   It is very hard to understand his critique of infinity in mathematical physics now. He seems to be saying that because we can't find any physical process or thing that is infinite that we shouldn't use infinities in our math describing physics. I'm still trying to figure out what he means by this. Are we allowed to use pi for instance…

> I soon got bogged down in the first half of the book, which is a detailed intellectual history of speculation about multiple universes (so lots about relevant parts of Plato, Aristotle, Lucretius, the Stoics, Augustine, Nicholas of Cusa, Giordano Bruno, Kant and others).

It's amusing that the supposed thoughts of such thinkers on the "multiverse" would be considered relevant, when the extent most of what we know as the observable universe was completely unknown to them. I can see why you got bogged down.

Even the notion that we are part of one galaxy among many was only beginning to be understood (mostly as speculation with hints from observational astronomy) in the 18th century, and was a subject of active research and disagreement in the 1920s.

3. **CPV**
February 11, 2014

Throughout history humans have bundled up things they couldn't explain or understand and called that bundle 'religion'. While that bundle has gotten smaller, it still contains a fairly large payload of questions. Scientists should feel unashamed of admitting that there are questions that they can't answer, or maybe even properly formulate, at least for the time being. At some point the answers to these questions may become part of the scientific domain, but until then they can remain labeled as part of religion or pure speculation. The multiverse stuff is almost entirely like that. What will falsify the mulitverse? Nothing. What should people be working on? Better explanations for the specific form and character of physical law. That's the job.

4. **thecrud**
February 11, 2014

Well we dont have all the answers. I know back to invisible sky beings that grant wishes.

5. **Michael Gogins**
February 11, 2014

Peter Woit:

I'm very sorry to hear you're not going to give more attention to Rubenstein's book. I think that going further into this would be well worth while for everybody concerned. I am, I confess, a bit afraid of what is happening here. I have fears both for the integrity of science, and for the integrity of religion.

Rubenstein is plenty smart and pretty engaging, and if she goes astray, she may take some people with her. I think you are prescient in your concern for the empirical integrity of science.

Manyoso:

It is possible to consider that the value of pi is NOT infinite because it IS recursively enumerable. You can make as many correct digits as you like using finite means. I think some scientists are thinking this means that pi doesn't "actually" have an infinite number of digits, because there are simple rules for getting as many as you need, without limit.

However, there is another arena well known to physicists where an "actual infinity" is much harder to exorcise, and that is the randomness that seems to be built in at a basic level in quantum mechanics. It is now known, thanks to recent results, that it is possible to certify that a sequence of bits produced by quantum processes are truly, irreducibly random. It is also known that it is not possible to compute an irreducibly random sequence of indefinite length using a program of finite size. So as far as I can see, this means that the universe is not any sort of computer, because if it were it would not be possible to physically certify that a random sequence is random.

The only way that I can even begin to imagine a way out of this quandary is to suppose that the randomness of quantum events is produced by a completely deterministic process that also completely determines how and when we will measure it, so that it is statistically random to us though it is completely pre-determined. This would provide a loophole in the strong free will theorem by removing the freedom that is assumed to exist for experimenters to set up experiments any old way. There are, after all, two senses of "random" at work here, random as uncaused and random as statistically random.

CPV:

Religion has in the past provided mythological explanations for things that now are explained scientifically, but without such explanations, there is still religion.

Let's say you love your wife, and she is working on a novel. She asks you to promise that if she dies before she finishes the book, you will not publish it. And because you love her, you do promise that. And then, unfortunately, she dies before the book can be finished.

Your wife is dead and gone, but your obligation not to publish her book lives on. Physically she is dead, scientifically she is dead, but existentially she is alive, because your promise was not to any publishers and not to yourself, but to her.

Spiritually, she is eternal.

There's a lot more to say about this, but this is not the place. I'm just trying to point out that there are ways of demarcating human discourse between science and religion that do not reduce the one to the other, or the other to the one.

6. **David**
February 11, 2014

Absolutely. Theology and multiverse cosmologies are remarkably simpatico. It does require setting aside some things – "fine tuning" arguments and "first cause" arguments being among them. But the potential for interplay between classical theology and this speculative cosmology is nontrivial.

7. **Manyoso**
February 11, 2014

It is possible to consider that the value of pi is NOT infinite because it IS recursively enumerable.

Huh? Just because pi is computable doesn't mean it is not irrational. There are an infinite number of digits to pi and this has been proven for centuries. I still don't know if this means Tegmark wishes us to develop a mathematics without the reals for calculating physical processes or what…

8. **Koray**
February 11, 2014

Manyoso: there are non-standard analyses in mathematics, e.g. computable analysis. If certain concepts like infinity or transcendental reals don't make sense (or are not required) in physics, it may make sense to restrict the math used in physics to exclude them.

9. **Peter Woit**
   February 11, 2014

   Enough about infinity, please. Besides not being very interesting, that argument of Tegmark's doesn't appear in the book, or in Kleban's talk for that matter.

10. **vmarko**
    February 11, 2014

    "It seems that, unlike most authors, Rubenstein actually has got the story of multiverse mania right: it's left conventional notions of science behind and entered into the realm of theology."

    Belief in untestable conjectures is a natural realm of religion. IMO, it was just a matter of time before people picked up on the multiverse (level II) as a piece of that realm.

    In the next period, various folks will spend some time playing with the "multiverse religion". Once they get to know enough of it, they'll figure out that multiverse is a very lousy example of a religion, providing almost no answers that any respectable religion does. Once that happens, they'll throw multiverse out the window, and return to more serious religions, and serious science.

    I am only eagerly waiting to see how multiverse-loving atheists are going to handle this… 😉

    Best, 🙂
    Marko

11. **Peter Woit**
    February 11, 2014

    Marko,
    The thought did occur to me that I didn't really want to review this book, but I did want to read a review by Sean Carroll of the book…

    Also, perhaps theologians could try marketing religion as the "Level V" multiverse.

12. **Jerry Lisantti**
    February 11, 2014

    I'm not sure which audiences Rubenstein is addressing. But you are right it is following the multiverse mania. There is much attention to the work of Mersini-Houghton. I'm not sure what is purpose of this book. A review of multivariate literature?

13. **Anm**
    February 11, 2014

    In other news, Tao gave the first credible line of attack against Navier-Stockes : http://terrytao.wordpress.com/2014/02/04/finite-time-blowup-for-an-averaged-three-dimensional-navier-stokes-equation/

14. **Peter Woit**
    February 11, 2014

    Jerry Lisantti,
    It's an academic monograph, aimed mostly at an academic audience interested in the universe/multiverse debate throughout intellectual history, but also aimed at an audience with interests in philosophy of religion. It's definitely not a mass-market book, like the typical multiverse-promoting book of recent years.

    Anm,
    Thanks, but I know next to nothing about that kind of math, so comments should go to Tao's blog. I did notice this, but also noted that he says "There is a real (but remote) possibility that this sort of construction can be adapted to the true Navier-Stokes equations." and " The paper reflects my current thinking on the subject, which is that (a) proving global regularity for Navier-Stokes is a hopeless task for the foreseeable future, but (b) proving blowup for Navier-Stokes is not… But there is still quite a long way to go to actually reach a proof of blowup for Navier-Stokes."

15. **paddy**
    February 11, 2014

    Sometimes I wonder why I come here to read these comments once or more a day. As PW says some of them are tedious. Especially since I must expend some considerable effort in resisting the temptation for snarky posts (e.g., "Bless me father of Tegmark V for I have sinned…oh not you father of Tegmark X"). On the other hand one does finds jewels like Anm's Navier-Stokes/Tao reference. Thank You

16. **Patrice Ayme**
    February 11, 2014

    "Nietzsche concludes… promising "all great things bring about their own destruction through an act of self-overcoming" … This promise then, has me wondering. If science can be regarded as the self-overcoming of a particular form of religion, might multiverse cosmologies be something like the self-overcoming of science? Might they mark the end of the fantasy that "science" has wrested itself free from "religion", "objectivity" free from subjectivity, and matter free from meaning?"

    Science was never the self-overcoming of a religion. It was the triumph of common sense. Buridan made that very clear, when he discovered the Principle of Inertia and used it to propose the heliocentric system around 1320. (For 140 years after that, the Church approved of Buridan, his "impetus", and heliocentric system. His works were put on the "Index" later!)

    Nietzsche's proposal is more akin to Gödel First Incompleteness Theorem (at some point a choice appears, on esthetic grounds)

    What may simply be going on with the Will To Multiverse is much simpler. What was the first multiverse theory? Everett's Many World Interpretation of Quantum Mechanics.

    So, on the face of it, the Multiverse arose first as a self-overcoming of Quantum Mechanics. Not a self-overcoming of science, just an "overcoming" of the "collapse", "measurement", "observer" and "EPR/Elements of Reality" problem in QM. Behind the whole thing may be an anxiety about Quantum Mechanics, and, or "Cosmic

Inflation".
Unfortunately, the proffered solution, the Multiverse, has indeed jumped far out of science.

17. **Michael Gogins**
February 12, 2014

Lisantti:

Rubenstein's audience would be, for the most part, her colleagues in academic theology and the philosophy and history of religion, but also the educated public.

The purpose of the book, as nearly as I can make it out (I haven't read it [yet?]), is to take the "multiverse" as a contemporary myth of creation, a contemporary cosmogony, that can be related to ancient myths of chaos that predate the patriarchal, "create everything out of nothing" God of Christian (until the late 20th century anyway) theology.

18. **Georg Mayer**
February 12, 2014

Hi Peter,

thank you for your patience in pointing out "what comes from" certain kinds of theories, even if (some of) their creators did not intend to open the door to the dark alleys of theology, which I thought our species has roamed long enough in the past. Reading your blog (and other materials) during the last weeks, have changed my mind mainly about the intend of the multiversers and I still puzzled that this was necessary.

I was not aware how quick people are capable to jump from "new theoretical physics theory" to "mathematical platonism" to "every religious believe is just a wonderful reality in our happy infinite possibilities muliverse duckburg". But I find it even more frustrating that scientists who come up with these initial theories (which is in general a great thing) do not clearly and strictly speak up against e.g. the movie "The Principle" (thanks for linking to the trailer) or the Rubinstein book you just reviewed. This gives the whole approach of many of these theories a very bad taste – it leaves me with an impression as if people are looking for such esoteric cross-references, maybe to just get more popular (bad) or because they believe it themselves (baaad).

This not only discredits natural sciences, but also those people who try hard to understand the nature of abstract principles in e.g. mathematics or philosophy. Anything that goes into the direction of metaphysics has to be handled carefully in order to not fall into the abyss of mysticism and people coming up with wild explanations should not fort that sometimes oneself is not aware of the fact that she or he is already in the process of accelerated downfall into fairies country.

We don't know why math works so well, most of the people who see it working are startled by this fact. There are tons of philosophical books and articles about this and many of them are a better read than multiversology. Just because we do not understand something doesn't mean we should push it as the explanation itself. And just saying "as long as math works it proves that math is the thing itself" is at best strange – tomorrow linguists stand up (as they did before) and proclaim that "as long as words can describe everything, everything is language" and immediately afterwards we see the well-known folks coming up and arguing that Pegasus and unicorns are part of reality (as they are part of language).

Therefore, after looking into the mathematical universe I return to the tools of refutability, Occam's razor and at most the Quine-Putnam Indispensability argument. We have to respect the limitations of our perception and have to be very serious about them, else we are lost in speculations that do not bring us forward, but cause tragic (esoteric) deviations from the scientific strive for truth and understanding.

Thanks again – you gave my brain a good shake, now my feet stand on solid ground again.

19. **Peter Woit**
February 12, 2014

Michael Gogins,

I think you're making some unjustified assumptions, based on the idea that Rubenstein is a "feminist theologian". Her book isn't really concerned with myth, or with feminist theology and the issue of a "patriarchal" deity. It's very much about the standard Western philosophical tradition, from Plato on, together with the standard physics story about cosmology. As I mentioned, it ends up with Nietzsche as inspiration for "overcoming" science, and he's not exactly a feminist role model. The book ends by invoking the possibility of a theology
"that asks more interesting and pressing questions than whether the universe has been "designed" by an anthropomorphic, extracosmic deity" and, to the extent that she has a voiced agenda, that's it.

I'd characterize her position as much like that of the Templeton Foundation. They're very excited to support multiverse research, for much the same reason she likes the topic: it promises to erase conventional boundaries of what is science and what isn't, bringing science and religion together and giving legitimacy to people who want to mix the two. In both cases, their interest in theology is not at all in fundamentalist religion, so they are just as much interested in invoking science against that as they are in bringing science and their conception of religion together.

20. **Peter Woit**
February 12, 2014

Georg Mayer,
There are some big differences between these various topics. The world is full of people like the geocentrists promoting their outlandish alternative science ideas, and it's both wise and conventional to just ignore them (I wrote about the "Principle" here mainly because I thought it was hilarious to see physicists taken in by this, not because anyone is going to take this seriously). As for academic monographs claiming some support for their philosophical positions from speculative science, they're also normally best ignored (do you have any idea how many people read a typical book of this kind? I'm guessing they'd all fit in one room, and not a very big one…). So, the fact that physicists are ignoring geocentrism and Rubenstein isn't either surprising or a bad thing.

Tegmark is quite a different issue. He's a prominent physicist at a leading institution, a talented expositor, academic fund-raiser and politician, working very hard for his agenda, getting a lot of top-level media attention. In this case I do think it is a big mistake for influential physicists to ignore this, hoping it will just go away, which I think it what most of them are doing.

21. **John Urbanik**
February 12, 2014

Sometimes the simplest explanation is this best. Theology is about the universe being created and with that a purpose for the universe to be created. The Multiverse is the attempted explanation that there was no "creation" or purpose but instead the universe was just one out of all possibilities. It all comes down to design vs. random chance.

Both should be part of philosophical discussion and neither should be part of any scientific debate.

22. **Martin**
February 12, 2014

This multiverse business will continue as long as it is funded. In addition, theoretical physics has in common with theology that it does not cost that much. Experimental work is much more expensive. And if the public likes to read about this sort of esoteric stuff then politicians think that some tax money should go toward this subject. Panem et cercensis, it is an old practice.

23. **Jim Given**
February 12, 2014

As a devout Catholic and professional physicist, I tell you that string theory is located at the similtaneous limit of no physics and no theology.

24. **Peter Woit**
February 12, 2014

Martin,
I don't think people do multiverse stuff because they think that's what the NSF wants (I suspect that NSF panels are not very enthusiastic about multiverse research proposals). Tegmark in his book explicitly explains how he was careful to only do this as a sideline, not so much that it would hurt his career. This is mostly not being funded by taxpayer money, but often by private money (e.g. Templeton). Don't blame politicians for everything, they're mostly leaving physicists alone to make their own funding decisions.

The appeal of the multiverse physics is that it's a way to do research work which seems to engage with the deepest problems in physics, but isn't very demanding. This is appealing for reasons of personal motivation (see Arkani-Hamed's comments about what it takes to get up in the morning and go to work on a physics problem), also if you like media attention, this will get it for you, unlike more serious work. If you look at most multiverse papers, they're using minimal mathematics, and nothing very difficult in the way of calculations. Then of course, nothing you do is testable, so there's no danger of it being wrong. John Baez describes this sort of activity as "playing tennis with the net down". Some people enjoy this, others don't…

25. **Kavanna**
February 12, 2014

There are questions that science cannot answer, and it's best to admit these are not science. For a philosopher or theologian to be interested in them as forms of speculative metaphysics is fine. Just don't call it science.

26. **Eric Habegger**
February 12, 2014

I think this interest in the multiverse is fascinating as a social phenomenon. What is the attraction to science for an idea, which by most lights, cannot ever be tested and which allows for almost any solution. It is hard to see, yet the attraction is obvious in the ever increasing attention paid to it.

Maybe it's time to quit analyzing that attraction if there really is no substance to the main tenets of the idea. Maybe we should look instead for a nexus of ideas that people are uncomfortable with and dislike. Sort of like a black hole nexus of ideas that people sense peripherally that is pulling them in and from which they want to be distracted.

Throughout the dark ages something similar happened. Religion and belief in a God that attended every fallen sparrow provided comfort to individuals in an often harsh physical environment. People wanted to feel cared for when times were tough. That seems like the primary motivation for a geocentric universe that predominated then. Maybe there is something similar going on today. Of course nobody, especially a physicist, would willingly admit that they are prey to such feelings and that it influences their thinking about science. What better way to refute it than to invent a whole panoply of universes. It's the little kid in them saying to everybody "See, I'm not afraid of nothing!"

27. **SUSY**
February 12, 2014

do other BSM theories like LQG and AS predict a multiverse?

28. **Peter Woit**
February 12, 2014

SUSY,
String theory doesn't "predict" a multiverse, since it doesn't actually predict anything. You can have string theories with a single universe, or ones with a populated landscape, lots of universes. The function of the multiverse in string theory is not as a prediction, but as an excuse for not making being able to make predictions. Theories like LQG don't have anything to say about non-gravitational forces, they explicitly are not designed to make predictions about such things, so they don't need an excuse. If you wanted to make an LQG multiverse, you probably could, but there's no reason for it.

29. **Max Tegmark**
February 12, 2014

I'm amused that Peter keeps finding novel ways to criticize me on this blog. If some theologian misunderstands the multiverse predictions of inflation etc., this doesn't constitute a scientifically valid critique of inflation. I very much doubt that all theologians imagine a deity that strictly obeys mathematical equations, and can therefore equivalently be described as a purely physical entity.
I've summarized the top-8 criticisms of my book here: http://mathematicaluniverse.org

30. **Peter Woit**
February 13, 2014

Max,
The part I quoted is Rubenstein's reaction to your Level IV multiverse, which Brian Greene calls the "Ultimate Multiverse". This really has nothing at all to do with inflation.

As for whether a deity can be consistently described by a mathematical structure, I'd guess that depends on your deity. From my little knowledge of theology I'd suppose theologians have more definite ideas about what they don't know about a deity than about what exactly its properties are and whether or not they can be expressed as a mathematical structure. Maybe you've opened up a whole new area of debate in theology about this kind of question.

As for your "top 8 criticisms", the only one that is one of mine is number 6. I don't think "our cosmos has no non-mathematical properties" is a testable prediction of a conventional scientific sort.

31. **Thomas Larsson**
February 13, 2014

"Also, perhaps theologians could try marketing religion as the "Level V" multiverse."

The Level VII multiverse would be better. The seventh heaven.

32. **Georg Mayer**
February 13, 2014

To Kavanna, John Urbanik, others:

It strikes me that people say "there are questions, which science cannot answer, so leave those to theology/religion/believe".

First of all – we don't know which questions science can answer and which not. So if there is something were we cannot get further today then in my eyes (if we are really interested in the question), we should look for scientific ways to get at least close to an answer.

500 years ago some might have asked how man exactly got created. Science at that time gave no answer. So some left the question to the local preacher. After we got the answer from Darwin we saw (in the light of evolution) that our question was put a bit self-important in the first place and that the answer was not really what we expected. But now we know. It was wise to not give up and to explore further, without relying on the holy scriptures.

Furthermore, if we leave open questions to religion, mysticism and unscientific teachings, these "explanations" do not answer anything, but mutually contradict each other (Jesus says the Gluon is blue, but Buddha had a more greenish vision of it, whilst the Tao guarantees you it is black and white). So what good are these answers (if you are interested in *answers*)?

And even more, this makes it so hard to think seriously about anything that scratches the metaphysical discussion – e.g. like the nature of numbers/sets/mathematical laws. There are a lot of questions in this area, but once somebody asks such a questions you can find a whole lot of deep thought guys jump up and down and sing the "Pegasus exists, because we have a word for it" song.

Approaching questions is a difficult business and for sure not solved by just giving up on them, i.e. leaving them to non-scientific realms. The hardest thing most likely is to admit that wedon't know most of the things at the moment. But that should make us eager to to equip ourselves better (scientifically) to approach the lack of knowledge somehow.

I am also a bit shocked how easily people put theology/religion and philosophy into one pot. "Don't call it science, leave it to philosophy and theology" – but guys, philosophy IS science and many parts of it strive to find the best ways on how to do (natural) science and how we can expand our knowledge in reliable ways. (Yah, theology is also science, but based on axioms from certain books who a supposedly metaphysical being offered as the ultimate truth in the language of the neolithic age). Bacon, Leibniz, Kant, Russel, Popper are just a few who made the scientific method how we use it today possible.

33. **Jesper**
February 13, 2014

When Georg Mayer writes "We have to respect the limitations of our perception and have to be very serious about them…" then I think he's completely right.

To me, physics is about making sensible statements, and about recognizing insensible ones. For instance: the question "where is the electron, when we don't measure it" doesn't make much sense and is best left out. To me, physics is not so much about "what is" but about "what can be said (described)" – and therefore I find this whole debate about philosophy and multiverse stuff quite a bit in the wrong direction. Sure – it can be very useful to digress into pseudo-philosophical thinking, perhaps in order to find some useful metaphors and mental images – but I think one must be very careful not to take it too serious.

Without knowing the subject very well at all, I also think this is the "tone" of modern philosophy: more about limitations of perception and language, and less about "what is".

Put differently, I simply don't know what Tegmarks statement (I didn't read the book) "all mathematical structures exist" means and I suspect it means nothing.

34. **vmarko**
February 13, 2014

Georg Mayer,

"It strikes me that people say "there are questions, which science cannot answer, so leave those to theology/religion/believe"."

There are questions about facts, and there are questions about choices. The former are answerable by science, the latter are answerable by religion. And the two don't mix.

Unless you think that humans are automatons without any form of freedom of choice (a stance which can be called "cognitively unstable" as Sean Carroll likes to say), there are always these two types of questions. Sometimes (like in the case of the multiverse) it isn't very clear into which of these two categories a given question belongs, but eventually such things get cleared up.

But no serious scientist claims that science can answer *all* questions. Just like no serious theologian claims that religion can answer *all* questions. At best, they can both answer all questions from their respective domains, nothing more.

HTH, 🙂
Marko

35. **Bernhard**
February 13, 2014

Nomura did get a direct question about predictions from Jerry Lisantti (http://quantumfrontiers.com/2014/02/13/making-predictions-in-the-multiverse/comment-page-1/#comment-7636).

Would be interesting if he would answer to it at length (although Lisantti should have said "present or future data").

36. **Peter Woit**
February 13, 2014

All,
Please, enough general discussion of science and religion, this has little to do with the topic of the posting, and I doubt anyone has anything new to say about this in general.

Bernhard,
Yes, it would be interesting to try and get a response to the predictions question. From all I can tell, at this point Nomura has a prediction that failed, and a story about why predictions aren't really possible (the measure problem). Given this, why pursue the subject?

37. **George Ellis**
February 13, 2014

Yasunri Nomura states "In cosmology our space is surrounded by a cosmological horizon", and then develops ideas related to the horizons that occur in black holes. However the horizon that limits what we can see in cosmology is an *event horizon*, not a particle horizon (see Rindler's classic paper: http://adsabs.harvard.edu/full/1956MNRAS.116..662R). His further discussion then uses results that refer to black hole event horizons: but they do not apply to the particle horizons that occur in cosmology (in the actual paper, he refers to "apparent horizons", which again occur in black holes but are not the same as the visual horizon that occurs in cosmology, see http://scitation.aip.org/content/aapt/journal/ajp/61/10/10.1119/1.17400).
So not only does he have no testable predictions but his theory is based on a case of mistaken identity. The properties of event horizon and particle horizons are not the same, and are both distinct from the properties of apparent horizons, which are locally defined (event horizons are globally defined).

38. **Will Nelson**
February 14, 2014

I like your blog although I also like strings and susy quite a bit, and the multiverse too, which I feel is just a logical development of the copernican insight. It certainly could exist, logically and mathematically, so whatever consequences that has for the nature of science are kind of tough luck. The universe wasn't made to match the preconceptions of some philosopher of science.

But anyway, not to be tedious. I wish you would highlight more of whatever interesting things you think researchers *ought* to be doing, instead of bashing what various people are doing. That seems kind of tired and a better way to "win" the battle would be to help people see different and better directions to go in. For example the fact that the LHC hasn't found susy isn't great, but it hasn't found anything else either aside from the Higgs, so who's doing something interesting based on that? I don't know, maybe you do…

39. **Shantanu**
February 14, 2014

Peter, did anyone in the question ask the obvious question about prediction?

40. **Peter Woit**
February 14, 2014

Shantanu,
Kleban did in the talk explicitly make clear what actual predictions there are. For bubble collisions, certain signals are predicted, they've been looked for, they're not there. For the various inflationary models, there are some very general predictions, e.g. about the spatial curvature, that he did mention.

To me, the problem was the high level of hype, that the discussion of models for the inflaton potential, instead of seriously examining exactly what current data implies, and what prospects for future data are (this was basically not discussed) was all about eternal inflation and the multiverse. While the models and data have nothing to say about bubble universes with different physics and string theory, that was a lot of what was being sold.

At all of the many hype-filled physics talks I've been to, I've never seen anyone in the audience object to this or point out the problem, and that didn't happen here. To all appearances, the audience ate up the hype, considers this normal physics these days.

41. **CPV**
February 14, 2014

I think a topic that is relevant here is the "cult of personality". It seems that many of the physicists involved in the Multiverse type of ideas are people who clearly enjoy hearing themselves talk, and also enjoy media attention (at least, much more than most people enjoy it!). Since the conventional approach to progress has proven difficult, here's a new road with very little effort required that produces great amounts of publicity. Some of these people are complete charlatans, but some are not. The unifying similarity seems to be the idea that it's much more important to get attention of any type than to have integrity. It's really all about them at the end. They will not be ignored.

42. **Jess Riedel**
February 14, 2014

Hi Peter,

Like you, I'm baffled by this claimed equivalence between many worlds and inflating patches, and I'm likewise skeptical that any of this will lead to testable predictions. But I do want to point out that it's unfair to say that Nomura is falsely claiming to derive an observable prediction from a multiverse theory in this blog post. (Your words: "bogus claim".) Rather, he's trying to solve the measure problem, which means finding a method for extracting predictions–even mundane ones that will agree with non-multiverse theories–from a theory of eternal inflation. Like you I think he'll fail (and moreover that repeated failures of this type are evidence that this school of thought is diseased), but the effort to extract predictions and to describe his reasoning is defensible in principle so long as he does not prematurely claim success.

43. **Peter Woit**
February 14, 2014

Jess,
What struck me as bogus about Nomura's piece was his using the title "Making predictions", when the piece was really mostly about this "Multiverse= quantum many worlds" business, which as far as I can tell has nothing at all to say about how to make a prediction. Nomura says "the picture presented here does not solve all the problems in eternally inflating cosmology", but I can't see how it solves any problems at all.

Yes, he does explain the obvious measure problem, so in that sense addresses "Making predictions", but purely negatively. Entitling the piece this way when the only relevant content is about why you can't make any predictions is maybe best described as misleading, if not a "bogus claim". I could for instance write a blog entry and title it "Calculating the electron mass", then use it to tell you that my idea was just that the electron mass could be anything at all, so, not surprisingly I have a "measure problem" and can't calculate anything. That's about what he is doing here.

44. **Peter Woit**
February 14, 2014

I've deleted an exchange with "Caltech graduate student", who I'm pretty sure is not one, but someone else with a particular agenda.

45. **Chris W.**
February 14, 2014

> I like your blog although I also like strings and susy quite a bit, and the multiverse too, which I feel is just a logical development of the copernican insight. It certainly could exist, logically and mathematically, so whatever consequences that has for the nature of science are kind of tough luck. The universe wasn't made to match the preconceptions of some philosopher of science. [from **Will Nelson**]

That the multiverse could exist, logically and mathematically, is not a reason to assert that it does exist, and especially to do so without regard for "whatever consequences [it] has for the nature of science".

Theories are not epistemologically neutral. Theorizing of any kind runs a risk of undercutting the basis for any critical examination of the theory that is being proposed. The worst of such theories are nonsensical "word salad", but they can be much more insidious than that.

The Copernican insight led to a whole line of investigation with rich empirical ramifications. The multiverse ideas now being discussed have no empirical ramifications, *essentially by construction*, and that very fact is being used to argue that they could be true. This mendacious game could have been played at any time in the history of science. If it had been, and its legitimacy had been widely accepted, then the "science" at issue would have devolved into a shallow, self-justifying fraud.

I suppose the main protection against that happening now is that the results will in the end be mind-numbingly boring and vacuous, and later generations will lose interest in them. We're already pretty far down that road.

46. **Neil**
February 14, 2014

Does any multiversarian, if that is what they are called, actually assert that the multiverse exists? I thought their position is that it *could* exist and that this perspective, if that is what it is, allows us to interpret some puzzling observations, such as fine tuning, in a useful way. It can be argued, as it is in this forum, that unless we are given more reason than logical possibility for the multiverse to exist, it really provides no interpretation. The multiversarians think that the landscape or eternal inflation provides such a reason, but of course there is no evidence for either. They too are simply logical possibilities.

47. **vmarko**
February 14, 2014

Neil,

"I thought their position is that it *could* exist and that this perspective, if that is what it is, allows us to interpret some puzzling observations, such as fine tuning, in a useful way."

There is **nothing useful** about the multiverse "explanation" of fine tuning. It's actually completely **useless** in every possible sense, since it basically says that all fine-tuned parameters are such as a result of a pure accident. Saying that the SM parameters have been chosen randomly is an **absence** of explanation.

HTH, 🙂
Marko

48. **Peter Woit**
February 14, 2014

Please all, if it's not about the topics of the posting (the Kleban talk and the Rubenstein book) it's off-topic.

49. **Sebastian Thaler**
February 15, 2014

Edward Frenkel has reviewed Tegmark's book:
http://www.nytimes.com/2014/02/16/books/review/our-mathematical-universe-by-max-tegmark.html?ref=books&_r=0

50. **Simple biologist**
February 16, 2014

"not much different from some other situations—e.g. in the big-bang theory, inflationary cosmology, and Darwinism in biology"

The last bit could actually be the first evidence for multiverse. Nomura clearly lives in a different universe than I do.

In my universe, I work with evidence of evolution on (almost) daily basis.

51. **Laymammal**
February 16, 2014

"This idea of the multiverse, as we currently think, is not simply a result of random imagination by theorists, but is based on several pieces of observational and theoretical evidence." A new kind of evidence: the theoretical kind. Noumura ends the same article with the oxymoron "concrete theoretical progress."

52. **Peter Woit**
February 16, 2014

Laymammal,
I don't think this is the problem with Nomura's argument. If you did make a lot of real, specific theoretical progress, you could call it "concrete" if you wanted. It this progress showed that theories you do have strong evidence for were tightly linked to theories that produced a multiverse, you might call that "theoretical evidence" for a multiverse.

The problem is that there is no theoretical progress of the sort Nomura and others want there to be. The more we learn about the properties of a conjectural "M-theory", the more we see that just about any physics at any scale is consistent with it. We are getting "theoretical evidence" here, but it is evidence against the picture Nomura wants to sell. Similarly, "string cosmology" seems to be able to give one any inflationary model properties one wants, so again, to the extent there is "concrete theoretical progress", it is progress towards showing that these ideas just don't work, in the sense that they don't tell us anything about anything.

53. **OMF**
February 16, 2014

I guess your blog looks like it's found another post-string hype purpose on the internet.

54. **nasren**
February 16, 2014

Geore Mayer said "And even more, this makes it so hard to think seriously about anything that scratches the metaphysical discussion – e.g. like the nature of numbers/sets/mathematical laws. There are a lot of questions in this area, but once somebody asks such a questions you can find a whole lot of deep thought guys jump up and down and sing the "Pegasus exists, because we have a word for it" song."

You obviously like your straw men: no one has ever given that as an argument for mathematical realism. Try engaging with the discussion that exists — it is smarter than you are supposing.

55. **Brian Dennehy**
February 17, 2014

From Frenkel's review of Tegmark's book:

'Conceding this point, Tegmark replaces Mathematical Universe Hypothesis with Computable Universe Hypothesis: Only "computable" mathematical structures should be allowed. But this rules out all structures that contain infinity! In fact, he admits that "our current standard model (and virtually all historically successful theories) violate the C.U.H.," which does not bode well for the whole idea, to say the least.'

I thought this was quite a glib comment by Frenkel. Surely the question of whether the continuum field theories of modern physics are but approximations to more basic theories (which may themselves be 'computable') is currently unresolved.

56. **Lee Smolin**
February 17, 2014

Dear SUSY,

Just to pick up a query raised earlier in this thread, LQG does not admit a multiverse, as the spatial topology of the universe must be fixed. Either we are in the cosmological case with compact spatial sections or there is a boundary imposed, as in asymptotically flat or AdS cases. The set up of canonical quantization does not permit the spatial topology of the universe to change as indeed the action principle is only well defined with either compact or well prescribed boundary terms and conditions. In particular you cannot have non-compact critical points of an action without proper boundary conditions being satisfied.

One thing I have wondered is how this necessary technical subtlety is dealt with in eternal inflation models.

Thanks,

Lee

57. **Fellow Hampshire Alum**
February 17, 2014

Lee,

Possibly silly questions, but I'm a mathematician not a physicist. By "spatial topology" I'm assuming you mean the topology of the subspace of space-time consisting of the space dimensions? And the point is that assuming canonical quantization, the topology of the 3D (I assume) cross section at any given fixed time is always the same? The boundary would be the spatial boundary, i.e. the boundary of the observable universe?

Thanks…

58. **Jesper**
February 17, 2014

Dear Lee

when you write that the topology in LQG is fixed – is that really the case? The configuration space of generalized connections, which is the basis for the entire LQG quantization scheme, involves all possible smooth connections on a given manifold (with a given topology) as well as a all the non-smooth generalized connections (which form the 'bulk' of this space connections). Couldn't some of these (generalized) connections correspond to geometries of spaces with different topologies than the original fixed one?

For instance, assume that we start with the trivial topology (which seems natural), then I guess there would also be points in the space of generalized connections, which actually correspond to a non-trivial topology?

59. **Narad**
February 17, 2014

From Frenkel:

> This does not stop [Tegmark] from entertaining various situations involving multiple copies of "you" living in those universes, such as: "When the number of yous increases, you perceive subjective randomness. When the number of yous decreases, you perceive subjective immortality." (The real question, however, might be, What is the number of yous who can understand what this means?)

Funny, that's not quite how it worked in *The Man Who Folded Himself*.

60. **Lee Smolin**
February 17, 2014

Dear FHA, yes to all.

Dear Jesper, Even if the answer was yes, which would need to be shown, time reversibility of the dynamics suggests that if such a sector could split off it could rejoin… but I doubt Peter wants to host a technical discussion of LQG dynamics.

Lee

61. **Peter Woit**
February 17, 2014

Lee is right. I'm glad to have his comments here, but this isn't a great place to try and host a technical LQG discussion. It would be pretty much off topic, and beyond my abilities to sensibly moderate.

62. **Jesper**
February 18, 2014

Dear Lee,

yes, I think you are right and I don't mean to suggest that there is a multiverse setting within LQG. But I have never been convinced that there can't be topological non-trivialities arising in LQG.

And sorry Peter – I knew it was semi-off-topic.

US HEP Theory Funding News

February 20, 2014
Categories: Uncategorized

Laurence Yaffe has gathered some information about DOE funding of US HEP theory groups, showing sharp drops (average 23%) in such funding for groups reviewed in FY2013 and FY2014. These drops imply serious reductions in the numbers of theory graduate students supported and in the number of postdoc positions funded. To get an idea of the reaction to these numbers, the file name is calamity.pdf. Sean Carroll has a blog posting here, also with the "Calamity" title.

There's something very odd though about these numbers, with no explanation available from Carroll or Yaffe, who both interpret the situation as a sharp reduction in US government support for HEP theory. If you look at the numbers for total amount of funding, there's no evidence of the 23% drop (for sources of numbers, see references in Yaffe's document, the DOE HEP budgets here, and HEPAP presentations here). The recent Congressional agreement on a FY2014 budget puts the DOE HEP total at $798 million, significantly higher than FY2013 ($750 million) which was reduced by the sequester, and higher than FY2012 ($770 million) and FY2011 ($776 million). Of these amounts, the amount going to theory seems stable at around $50-$55 million/year (exact numbers depend on exactly what you include, Yaffe quotes FY12 and FY13 at an identical $51.3 million/year).

So, the "calamity" of collapse of government support for theory is somehow taking place despite no collapse in the amount of money budgeted for this. What is going on? I'd love to hear from someone who understands this. The only explanation I've seen is that this is a temporary phenomenon having something to do with how the budgeting process works. Note that with the way typical multi-year grants are made, the DOE is promising to provide money several years in the future, despite the current US budgeting environment, where budgets are typically set not in advance, but often very late. The current fiscal year's budget was set last month, although the fiscal year started Oct. 1. This was considered a huge success… One conjecture is that the DOE has been promising less to theory groups, partly because they only recently found out about the good FY2014 result, and partly because of a policy change to budget for future year outlays in current years. If this is the source of the calamity, it should quickly disappear as the FY2014 money comes in and the transition to new budgeting ends. Yaffe examines some other possibilities for explanations, but without anything conclusive.

The main concern raised is about the effects of a reduction in the number of US HEP theory grad students and postdocs. Perhaps more worrying than this though should be the trend of numbers of permanent research positions in the subject, which Erich Poppitz has gathered here. These numbers come from the Theoretical Particle Physics Jobs Rumor Mill, and show a constant level of 11 jobs/year for the past three years, about half the level of the years 2000-2007. The number of jobs posted this year is so far only 13, which can be compared to around 20/year in recent years. It's still early in the season, so more jobs may appear, and more may get filled than in recent years, but the trend of US institutions hiring significantly fewer permanent people in HEP theory is clear. Given this trend, there's a reasonable argument to be made that numbers of grad students and postdocs should also be reduced. There's no evidence though that some decision has been made to do this, or that this is the reason for the numbers Yaffe is looking at.

Comments from anyone well-informed about this are strongly encouraged, while comments from people who just want to make the usual arguments about government funding for science rules/sucks will be deleted.

Update: More commentary at Ted Bunn's blog. He sees this as possibly an implementation of changes at DOE designed to "decrease the effect of historical inertia", which might be moving money from historically well-funded major groups to others.

Possibly all that's going on though is just the "bridging" problem mentioned on slide 7 of this presentation. A decision was made to start grants later than in the past on April 1 (with the idea that typically it's not going to be until that deep in the fiscal year that Congress has got its act together and given DOE a budget number). This meant though that money had to be taken out of upcoming grants to cover extending current ones until April 1 when new ones might start. The number on that slide reflects a 25% charge to new grants to cover this, suspiciously close to Yaffe's 23% number.
The same slide though does point out that this is a temporary problem: "will be better in 2015". If that's all it is, and grad student/postdoc number are slated to go back up a couple years from now, maybe "calamity" isn't the right word here.

Update: For more from Yaffe, see here.

Comments

1. **AcademicLurker**
   February 20, 2014

   At the end of calamity.pdf Yaffe lists the 25 institutions from which he collected data. What % of total HEP theory research in the US do these institutions represent (honest question. I have no idea)? Maybe there's been a shift of support from a few large groups to lots of smaller ones?

2. **QM**
   February 20, 2014

   If you want more readers of the sympathetic yet amateur nature, you could expand a few acronyms, such as HEPAP (High Energy Physics Advisory Panel) and HEP (High Energy Physics).

3. **Noah Smith**
   February 20, 2014

   The hiring data doesn't look like a secular downward trend, it looks like a boom in the '00s that is now over. If hiring goes back to 90s levels, it hardly seems catastrophic…

4. **Peter Woit**
   February 20, 2014

   Noah,

   Given that there were about 80 US theory Ph.Ds/year during the 00s (best estimate I could make when I was writing my book), so about 4 times as many as jobs, I don't remember anyone back then thinking that was a "boom" in the job market. There was an awareness that things had gotten a bit better than in the 80s-90s when the job market was even worse, but one person's "boom" is another person's "return to normal level".

   More relevant would be a comparison of the HEP theory job market with other parts of physics and with other fields in academia. My purely anecdotal impression of the math job market is that (after post 2008 problems), it is getting back to something like the market of the 00s, and certainly not something like the HEP situation of half as many jobs. Again, anecdotally, I hear of places where universities are cutting back in physics as opposed to trendier sciences (buzz words here are "data science" and "personalized medicine"), and of physics departments where HEP physics is viewed as having an uncertain future.

5. **Jollick**
February 20, 2014

Peter,
Is there a summary of such anecdotes somewhere, or would you mind sharing yours? A rumor-mill of which physics depts or HEP groups might have uncertain futures would be very interesting to a lot of people. (Such as those people whose own futures depend on them, for example.)

6. **Peter Woit**
February 20, 2014

Jollick,
I don't have any very significant information of that kind. I was more referring to general comments about the perception of physics in general and HEP in particular among administrators and academics in various fields. At any given moment there are certain subfields of science getting attention as "the next big thing" in terms of advances, especially technological ones. "Data Science" is hot now, and as I mentioned, I've heard that "Personalized Medicine" is starting to get attention. In physics, the promise of quantum computation has off and on gotten this sort of attention. In the run up to the LHC start, LHC physics was a hot topic, and if you wanted to get an HEP job, there was a time when that was the thing to be doing.

So, all I meant to indicate is that I don't see HEP physics as something perceived anywhere as a "hot field", which university administrations want to expand in, so the job market is likely to remain limited for the forseeable future.

7. **Jeff M**
February 20, 2014

Peter,

As far as the math job market goes, good it's not, though of course it will never be as bad as physics. This year we're hiring, and we put our ad in late (December). We still got about 350 applications, we're a regional comprehensive state school, you're expected to do research but you also teach a pretty heavy load. Historically in math the market was quite good until 1992 (the year I got my doctorate, perfect timing 🙂 The market got worse for maybe 5 years, and then as far as I remember the VIGRE grants started up, and things got better. Problem was it was a temporary fix, once people started coming out of the VIGRE things got much worse again, and haven't really improved since then. Most math PhD's can get academic jobs of some sort, unlike in physics, but it's a tough slog and you're likely to end up with not what you were expecting.

8. **Laurence Yaffe**
February 20, 2014

Peter, according to information I just learned today, the DOE/HEP theory budget for FY14 is down about 5% from last year, despite the fact that the total DOE/HEP budget is up substantially. This presumably reflects the planned rebalancing between research and projects. I would call a 5% cut a significant reduction, but not a calamity. What turned this into a 20+% hit on renewing grants was a decision to shield from cuts (or at least, cut much less than 5%) a majority of the DOE-supported theory program, namely lab-based theory groups, and university-based groups who had undergone comparative review in earlier years. So the central concerns are not changes in total funding for high energy physics, or even total funding for high energy theory, but the allocation of funds which were available, and the resulting impacts on young researchers.

9. **Peter Woit**
February 20, 2014

Thanks Laurence,
That starts to make things clearer. A 5% cut is a significant one, and I can see how a decision to take it out of just one subclass of grants could magnify it greatly for those affected.

Does the change in priorities from "research" to "projects" inherently mean a change in favor of experiment (since only experimentalists have "projects"), or are there also theory "projects"?

10. **JoAnne Hewett**
February 21, 2014

Hi,

I am the department head of the theory group at SLAC National Accelerator Laboratory. Larry has written an interesting piece, and he has nailed a serious problem: funding for theory is decreasing, year after year, in order to divert more money to the project line. This is also true for the experimental research lines, but, in principle, they can recoup some (but not all) of the monies from the project lines.

The real problem is decreasing monies for science. The DOE theory research line was cut by ~5% in FY14, after a cut in FY13, after a cut in FY12…. This is bound to result in a decrease in postdoc and student positions, and senior faculty salaries. This decrease in funding is combined with a change in the funding process for the DOE, namely the institution of comparative reviews. A perfect storm! The comparative review process is similar to what has been done at the NSF for years. The labs have undergone comparative reviews since 2008, and the universities started in 2012. Personally, I think this is a very fair way to allocate ever decreasing funds. Rather than let historical precedence be the guide, what matters most now is what a researcher actually does. The most productive researchers are being rewarded and whatever fat there was is now out of the system. (I have to say that I come from a working class family and I was brought up to think that what I actually did is what matters, so I like the new system.)

Nonetheless, the numbers and graphs in Larry's paper are misleading. First, only some fraction of the groups responded – generally it's the folks that wish to complain that respond. Second, the DOE instituted salary caps ($15k/month) for summer salary payments and this was not factored into his graphs depicting the decrease in funding. I know of some groups whose cuts were solely from the caps. (It's worth noting that lab scientists are in general paid less than their university counterparts and few of us would hit this cap.) Third, the weak FY13 postdoc hiring cycle is a direct result of the FY12 (and not FY13) comparative reviews due to the timing of the annual hiring cycle. Fourth, the picture at the labs is not as rosy as Larry paints. Lab groups have been cut every year, in sync with the overall theory budget. After the last lab comparative review, several senior scientists with lab "tenure" were fired. Postdoc positions were reduced. At SLAC, we have graduate students from Stanford, and the number of student positions we could afford was cut in half.

Lastly, I would like to stress that the single worst thing the theory community could do is to fight amongst itself. We could divide ourselves up many different ways: lab vs university, formal vs phenomenological, old vs young, red-headed women who wear blue-jeans on Tuesdays vs everyone else….and this hurts us greatly. Divide and conquer is the famous phrase and that is appropriate here. If half of the community loses its funding, it goes to projects, not the other theory half. We must stick together and fight for appropriate funding for a world-leading theory program.

-JoAnne Hewett

11. **CPV**
February 21, 2014

It would seem like the actual theory reductions in DOE funding are being more than compensated for by private funds (FXQi, Milner, Perimeter, etc). The targeted and concentrated nature of the private money is problematic however.

12. **Gonçalo Dias**
February 21, 2014

As far as I can tell, the same is happening here in Portugal, with a tremendous transfer of funds from individual grants and money for fundamental research to the so-called projects and applications. The trend is a cutback from fundamental and theoretical research and a move to "corporate science". Unfortunately, this new trend is nothing like the olden days of, say, Bell Labs. If this is any indication at all of a wider trend in the EU, I guess the move is timed to happen at the same time on both sides of the Atlantic. This means that the old university-based research is at an end and so the future of most of fundamental research.

13. **Peter Woit**
February 21, 2014

Thanks Joanne!

What I'm now finding hardest to understand is why DOE would make such large cuts in grant amounts to some subset of the community, seemingly without providing any explanation for why this is being done. There seems to be agreement that part of the problem is a significant 5% FY14 cut to overall theory research (has there been a rationale given for this choice?) Beyond that though, it seems unclear whether the much larger cuts seen by some groups are due to: salary caps, better treatment of the labs, better treatment of groups reviewed earlier, the April 1 bridging problem, change in policy about future year commitments, rebalancing from well-funded groups to others, or something else. If the DOE does not clarify things, that will make worse the problem Joanne points out of people concluding that others are being better treated than they are for dubious reasons.

14. **Shantanu**
February 22, 2014

Peter, this maybe a controversial pov, but so far people working on beyond standard model of particle physics(whether it is supersymmetry/technicolor/extra dimensions etc) have failed to make a single successful prediction which has been verified by accelerators. So certainly I wouldn't be surprised if there is a cut in HEP theory funding. Certainly I hope more funds are allocated to new research directions.
This is something Avi Loeb has advocated in astrophysics/cosmology.
http://online.kitp.ucsb.edu/online/colloq/loeb1/
But same idea applies to HEP.

15. **Peter Woit**
February 22, 2014

Shantanu,
I just don't see any evidence for the idea that these new cuts in HEP theory are due to lack of progress in the field, or that funds are being redirected to new research directions. If anyone has real evidence for a DOE policy change of this kind, that would be interesting, but otherwise I'd rather people not speculate here based on what they would like to be true.

16. **M.Wang**
February 23, 2014

I just chatted with a bunch of Biology and Chemistry professors over the weekend on the Federal funding situation. There the money crunch does not appear as severe. NIH funding is stable; only NSF money seems threatened. One department chair has an appointment with a congressman on Monday. Instead of the overall funding level, her main concern appears to be the (over-)emphasis on applied research projects over fundamental ones.

17. **Maynard Handley**
February 23, 2014

"Given that there were about 80 US theory Ph.Ds/year during the 00s (best estimate I could make when I was writing my book), so about 4 times as many as jobs, I don't remember anyone back then thinking that was a "boom" in the job market."

What is the precise fear that people have here?
I see two very different issues which people seem to be commingling.

(a) Not "enough" support for the field, meaning not enough money to pay for what is considered a reasonable (by some sort of metric) number of profs and their assistants (at all levels, from postdocs to grads to, maybe, technicians like programmers).

(b) Not enough academic theoretical physics jobs available for academic physics PhDs.

These strike me as very different problems. In particular, (b) strikes me as very unlikely to be a real problem in any sense. The people who get theoretical physics PhDs do so because they have a compulsion they cannot control, not because of rational calculations about job opportunities. So I don't see the flow of talent into the field drying up.

On the other side, I can't see much individual tragedy happening (except insofar as there are ALWAYS going to be losers with positional games, and that's life). People who get theoretical physics PhDs are among the smartest people out there, and employers know that. You may WANT to be a prof at Harvard, and be bitterly disappointed that you cannot even be a PostDoc at State U, but you're not going to starve. Depending on your inclinations, you can get very rich in finance, you can join an internet startup and figure out new algorithms, you can join an established company (Google, Apple, FaceBook etc) and make a comfortable living as a technical programmer, you can move sideways into EE, and so on.

Maybe I'm wrong here — I'm not trying to be a dick. I'm just looking at my personal experience and the experience of my cohort. A few in finance, a number scattered over computing over all sorts, one at a government lab, one acting as a high level technical project manager for the feds, and so on.

So while concerns for the amount of money supporting the field strike me as justified (if they ARE justified by reasons why this amount of money is too low — and of course we all WANT the amount to be higher, but let's be realistic); bringing the academic jobs for PhDs issue into it strikes me as confusing the issue in a way that's completely unhelpful.

18. **Peter Woit**
February 24, 2014

Maynard Handley,

The problem Yaffe was discussing was very specifically about DOE funding of postdoctoral positions (and to some extent graduate fellowships). These positions are intended as training positions for permanent positions involving research in HEP theory, of exactly the sort (tenure-track academic positions or laboratory positions) followed by the rumor-mill. So the question of how many postdocs the DOE should fund is closely related to the question of how many positions are available for such trainees.

Again though, while the decrease in available HEP theory permanent positions would be a sensible reason for reducing the numbers of postdocs funded, I haven't seen any evidence that that's the actual reason for the recent decrease that Yaffe is concerned about.

More Quick Links

Categories: Multiverse Mania, Uncategorized

First, a couple of examples of recent progress in mathematics

- Terry Tao has some new ideas about the Navier-Stokes equation. See his blog here, a paper here, and a story by Erica Klarreich at Quanta here.
- I've been hoping to find more time to learn enough to write something intelligible about a major new advance: Peter Scholze's recent work on the p-adic geometry of Shimura varieties and results linking torsion classes and Galois representations. I'm still far from being up to that task, but Scholze's Marston Morse lectures at the IAS are a good place to start (see here, here and here). Last week MSRI hosted a very successful week-long "Hot Topics" program on this, see here.

- For more IAS talks, see "Cross-disciplinary" talks last week by Witten, Seiberg and Maldacena.
- Nature has a story about a recent discovery by Cormac O'Raifertaigh and collaborators of an unpublished manuscript by Einstein containing a "steady-state" cosmological model.
- A computer scientist has identified more than 120 papers published in supposedly peer-reviewed conference proceedings that were all randomly generated gibberish produced by the program SCIgen. No, these didn't appear in bogus "open access" publications, but in subscription publications from Spring and the IEEE. What's going on is described as a "spamming war at the heart of science".

Update: One more, for those of you not getting enough multiverse. Today's Washington post has an op-ed from Bush speech-writer Michael Gerson (at one point the ninth most influential evangelical Christian in the US, if you believe Wikipedia and Time). The title is Physics is Enjoying a Golden Age (also available here). Gerson thinks physics is in a Golden Age because he has just read Tegmark's book and is very excited that physics has now become metaphysics, with room for God again:

> The point here is not that Tegmark's theories are broadly accepted, only that such theories are no longer considered absurd. Physics has seen the return of the unseen — parallel universes, infinitesimal strings, floating and colliding branes — that are reasonably inferred without being physically observed. I can think of other creative forces in that category. Not for centuries has physics been so open to metaphysics, or more amenable to an ancient attitude: a sense of wonder about things above and within.

Comments

1. **Chris Oakley**
   February 25, 2014

   Just to record that I share Michael Gerson's sense of wonder at parallel universes, infinitesimal strings, floating and colliding branes, etc. being considered to be physics.

2. **SteveB**
   February 25, 2014

   I loved Terry Tao's description in his blog:

   (One could describe the dynamics here as being similar to the famous "lighting the beacons" scene in the Lord of the Rings movies, except that (a) as each beacon gets ignited, the previous one is extinguished, as per the energy identity; (b) the time between beacon lightings decrease exponentially; and (c) there is no soundtrack.)

   Humor in a Mathematics article is a nice touch.

3. **Tom**
   February 25, 2014

   I have no dog in this hunt, but it seems you (Peter) especially relish informing us that Gerson is a
   "Bush speech-writer …. [and] at one point the ninth most influential evangelical Christian in the US …"
   even though that's mentioned nowhere in that op-ed.

   Maybe this antipathy comes from being immersed in the prog-liberal, urban "bubble universe" that is Manhattan NYC ? After all, the geocentric cosmology model wrongly persisted for many centuries, too 😉

   Since Gerson is by all accounts a layman and has never trained as a scientist, he might be forgiven for thinking the constant onslaught of sensationalist books by Kaku, Tegmark, etc, in addition to the many breathless articles in New Scientist, Scientific American, etc, might imply those multiverse guys are taken seriously by the scientific community.

   As least, Gerson does seem to acknowledge Tegmark's so-called "theories" are not broadly accepted.

4. **Peter Woit**
   February 25, 2014

   Tom,
   There's no "antipathy" in my characterization of Gerson (which I think is accurate). I thought it was important to give some indication of who he is and what sort of agenda he is likely to have. This agenda pretty clearly includes bringing religion into science, and this is why he's excited by the pseudo-science of Tegmark and the "Golden Age" he sees it as ushering in.

   As for my agenda, I think it's obvious, but to make it explicit: I've no antipathy towards religion or religious people, I just don't think religion or metaphysics belongs in serious theoretical physics. I also think that those pushing the multiverse agenda, while at the same time holding up physics as the answer to religion, need to be made aware of what effect they are having. A good example is Sean Carroll, who seems to be half the time engaged in a public war for science against religion, the other half of the time trashing the scientific method and handing ammunition over to evangelicals like Gerson who have an opposite agenda.

   All, unless you've got something new and interesting to say about the multiverse/religion business, please stop submitting comments about it. I've already deleted a bunch, perhaps am making a mistake to answer this one, but, enough already…

5. **cormac**
   February 25, 2014

Thanks for that Peter. It's a very nice article, but I should say that Einstein's attempt at a steady-state model is motivated by the problematic age associated with evolving models, not the problem of origins, as implied by the article. One of the interesting aspects of the manuscript is that it predates the Lemaitre-Eddington debate concerning a beginning for the universe!

6. **Peter Shor**
   February 26, 2014

   I've occasionally wondered whether any physicists (possibly subconsciously) are supporting the multiverse for antireligious reasons … if you accept the multiverse, maybe you don't have to leave open the possibility that God wrote down the laws of physics and put the Big Bang into motion.

   If so, this strategy appears to be counterproductive.

7. **Peter Woit**
   February 26, 2014

   Peter Shor,
   Many multiverse proponents specifically make the case that one of its virtues is that it provides an explanation for fine-tuning that answers the argument from design for a deity. I agree that this is counter-productive: invoking untestable physical theory to try to win this particular argument means you've abandoned the fundamental distinction that separates what scientists do from what theologians do. Once you do this, you're on the same footing as Gerson and everyone else who wants to argue metaphysics without the discipline of making statements that can be tested and falsified.

8. **Geoff**
   February 26, 2014

   Reading Tao's ideas about the Navier Stokes equations reminded me of a very old sci-fi reference to a fluid mechanics computer from the movie Rollerball. The description occurs at the 3:20 mark.

   http://www.youtube.com/watch?v=qmTWhvWgST0

9. **publius**
   February 26, 2014

   Actually Terry Tao very interesting ideas remainded me of a Science Fiction piece too, Ted Chiang´s Exhalation
   http://www.nightshadebooks.com/Downloads/Exhalation%20-%20Ted%20Chiang.pdf
   Only that in Chiang´s story solid parts are required.
   It is fun to esspeculate if these fluid computations may be realized in stars or gas giant planets as some sort of "life" (though I see it as very unlikely)
   By the way

Quantum Mechanics, The Theoretical Minimum

February 25, 2014
Categories: Book Reviews

In recent years Leonard Susskind has been giving an excellent series of lectures on basic ideas of theoretical physics, under the title The Theoretical Minimum. The general idea seems to be to provide something in between the usual sort of popular book about physics (which avoids equations and tries to give "intutitive" explanations in ordinary language) and conventional undergraduate-level textbooks. Such textbooks generally assume college-level multi-variable calculus, differential equations and linear algebra, and often skip lots of detail and motivation, assuming that the book is a supplement to a standard course of lectures.

For Susskind's lectures, you mostly just need high-school level mathematics, up to some some basic differential calculus, as well as two by two matrices. Actually though, if you've never seen matrices and very simple linear algebra, this is a good place to learn some basics examples of this subject.

A year ago the first book version of some of the lectures appeared as The Theoretical Minimum, with George Hrabovsky writing up Susskind's lectures on classical mechanics. I wrote a little bit about the book here, and was quite impressed by the way it managed to give the details of the formalism of Hamiltonian mechanics, while sticking to as simple and concrete mathematics and calculational tools as possible.

Today is publication day for the next volume, Quantum Mechanics: The Theoretical Minimum, which is a joint effort this time with Art Friedman. It's even better than the first volume, taking on a much more difficult subject. About the first two-thirds of the book sticks to the simplest possible quantum system, one with a two-dimensional state space. The linear algebra needed is developed from scratch and Susskind works out at a very leisurely pace all the details of what the quantum picture of reality looks like in this simplest context. There's a lot about what "entanglement" really is, and this part ends up with an introduction to Bell's theorem.

The last third of the book is a quicker-paced trip through the usual material about wave-functions and the Schrödinger equation, ending up with the details for the harmonic oscillator potential.

"The Theoretical Minimum" phrase is a reference to Landau, but it's a good characterization of this book and the lectures in general. Susskind does a good job of boiling these subjects down to their core ideas and examples, and giving a careful exposition of these in as simple terms as possible. If you've gotten a taste for physics from popular books, this is a great place to start learning what the subject is really about.

I only noticed one mistake in the book, on its back cover, where one of the blurbs is attributed to a Professor of Mathematics at Columbia, when I know for a fact that his actual title there is "Senior Lecturer". Susskind does have a bit of history of getting this point wrong, but probably the fault here lies with the publisher.

Update: Nature has a review here.

Comments

1. **Lowell Boggs**
   February 25, 2014

   I just finished reading the Theoretical Minimum. Thank you for mentioning it in your blog or I would not have thought to read it. I particularly like the way that the book re-derived calculus and showed how the Fundamental Theorem of the Calculus could be used in physics to solve some kinds of problems.

   My degree was in Electrical Engineering in 1980, so I had taken most of the background science classes that Susskind is describing. However, I do not recall the concept of the Lagrangian being discussed in my physics or electrical engineering classes. It was at this point in the book, that I wish the author had gone into a little more detail about how Action differs from Work or at least more into the thinking process that led to Lagrange's equation. The difference between kinetic and potential energy, as I recalled, was the work. Sadly this disconnect between my recollection of my physics classes and the introduction of this new material left me a bit confused through the remainder of the book. I am however, hungry to understand Lagrangian and Hamiltonian mechanics better. Is there a another book on the subject that you might recommend?

   Thanks,
   Lowell Boggs

2. **Peter Woit**
   February 25, 2014

   Lowell Bogg,
   Sorry but this isn't material I've taught at this level, and I don't know the textbooks. When I studied the subject at an advanced undergraduate level the textbook was Goldstein's Classical Mechanics, but I found that rather dry and hard going. Presumably there are some good modern textbooks, at a bit lower level than Goldstein, maybe others can suggest a good one.

3. **Harlequin**
   February 25, 2014

   The classical dynamics text I used as an undergraduate was Thornton & Marion, Classical Dynamics of Particles and Systems, which has a chapter devoted to the Lagrangian and Hamiltonian. I don't know if anything new has come up in the decade plus since I took that class as a sophomore physics student, though. Looking at the textbook now, the introduction to the chapter seems pretty good; it does the thing I very much appreciate in physics textbooks of explaining *why* you would want to do something a particular way, not just *how* to do it that way.

4. **AcademicLurker**
   February 25, 2014

   The review of classical mechanics in chapter 2 of Shankar's quantum mechanics textbook* is quite good. It's very brief, as it starts with the principle of least action and goes through the Lagrangian and Hamiltonian formulations of mechanics in about 30 pages. Obviously, a lot is left out, but for a quick and intuitive introduction to the ideas at the undergraduate level, I found it was pretty nice.

   *R. Shankar, *Principles of Quantum Mechanics*

5. **CIP**
   February 25, 2014

I haven't read Susskind's TM books, but I have the feeling that the theoretical Universe has rolled off to decay into a considerably lower TM since L & L.

6. **AcademicLurker**
   February 25, 2014

   I haven't read Susskind's TM books, but I have the feeling that the theoretical Universe has rolled off to decay into a considerably lower TM since L & L.

   According to wikipedia, only 43 people passed the famous "theoretical minimum" exam between 1934 and 1961.

7. **George Ellis**
   February 25, 2014

   Lowell Bogg:

   when I looked up Susskind's book by following the link Peter gives above, Amazon.com in its wisdom guided me to "A Student's Guide to Lagrangians and Hamiltonians" by Patrick Hamill. From the reviews, it seems to be quite good.

8. **Sakura-chan**
   February 25, 2014

   Taylor's "Classical Mechanics" is as good as they come.

9. **Allan Rosenberg**
   February 25, 2014

   Thanks, I didn't know about the books. I went from freshman physics to the theoretical minimum by watching Susskind's lectures on classical mechanics and QM on youtube, and I can veryify from that perspective that they are excellent. I'm looking forward to the rest of his lectures and to reading the books.

   Senior lecturers in math at Columbia have done some excellent work, though I didn't know that Susskind was so happy with their reviews of his work. 🙂

10. **David Brown**
    February 25, 2014

    "… reference to Landau …"
    https://en.wikipedia.org/wiki/Kharkiv_Theoretical_Physics_School

11. **Art Brown**
    February 25, 2014

    Visually, this new book is a stinker; production values are noticeably worse than in the classical dynamics volume. I'd soon be exhausted trying to work through it.

    That aspect aside, I'd love to hear why one would be better served with this book than with volume 3 of the Feynman lectures (available free on-line). (By the way, Vol II ch. 19 includes a v nice introduction to the Lagrangian approach.)

12. **paddy**
    February 25, 2014

    I recall in ~ 1974 Wendell Furry teaching EMT based on Landau and Lifshitz's "Electodynamics of Continuous Media". It certainly was an eye opener for a young guy "raised" on Jackson. Not sure what I feel about physics students lectured from either the "dumbed down" or "scaring off" sources.

13. **Low Math, Meekly Interacting**
    February 25, 2014

    I may just give these a look. I recently took an intermediate stats class and a course in electrophysiology, and was happy to see that my math muscles, such as they are, haven't completely atrophied. I've done the calc and actually had some linear algebra in a pre-calc course (unorthodox high-school math teacher), but it's been ages. I don't know why, because I'll probably never use it professionally, but somehow dabbling in such things on the side does me a lot of good.

14. **MahPhys**
    February 26, 2014

    I personally don't think there is a textbook that competes with Goldstein's Classical Mechanics or with Jackson's Classical Electrodynamics. Probably no one thinks their time is worth the effort to come up with a better textbook.

15. **imho**
    February 26, 2014

    Fetter and Walecka is a better is better than Goldstein

16. **publius**
    February 26, 2014

    As a textbook Gregory´s Classical Mechanics chapters on actions, lagrangians and hamiltonians are both short and very clear, with plenty of good examples and exercises.
    Taylor´s and Kibble´s book are pretty good too.
    Perhaps surprisingly, the first chapters of A. Zee Eintein´s Gravity in a Nutshell contain an amusing introduction to variational calculus, actions and lagrangians.
    For the historical and metaphysical context of the action principle and its origins, Ivar Ekeland book The best of all possible worlds gives an excellent, and very readable and insightful introduction

17. **Lowell Boggs**
    February 26, 2014

    Many thanks to all who suggested ideas for further reading. I have ordered the Hamill book and have read through the Feynman lecture on the principle of least action. And "work" has nothing to do with it.

    Thanks Again!

Lowell

18. **Peter Woit**
February 26, 2014

Maybe that's enough comments about people's feelings concerning which textbooks on a completely different topic at a completely different level they like or don't like…

19. **John Anderson**
March 10, 2014

Be aware that there are older versions of Susskind's lectures at http://www.newpackettech.com/Resources/Susskind/PHY25/QuantumMechanics_Overview.htm The newer lectures are at http://theoreticalminimum.com/courses/quantum-mechanics/2012/winter
I made the mistake of watching the older ones which aren't as closely coordinated with the book that I am over halfway through.
At my age, I find the book challenging and the logic sometimes discontinuous. (Not trying to pun.) Perhaps I should have just watched the lectures.

20. **Ahish**

Consider this book Cornelius Lanczos – "Variational principles in Mechanics"

All Hail Resonaances

February 26, 2014
Categories: Uncategorized

I'm delighted to see Jester back in action, providing great material on the current state of HEP physics, with, over the past week and a half:

- A sober look at the sparse prospects for near-term (i.e. 2014) input from experiment, with the Planck CMB polarization results one of the few things for which there are significant expectations.
- An equally sober look at the problem of making the case for a 100 TeV collider, given that this will be the first time people don't have a "no-lose theorem" showing that something new has to turn up in the new energy range being explored (of course the argument that it's an unexplored new energy range remains an excellent one by itself for the exploration). About the arguments Arkani-Hamed is making, Jester has:

  > Nima's idea that we need a 100 TeV collider to prove that SUSY fine-tuning is larger than 0.01% is good. As a joke to relax the atmosphere. Certainly, the case for the new collider can be made stronger than that.Some ideas that are being bandied around are precision Higgs physics, double Higgs production, rare Higgs and top decays, non-perturbative electroweak effects, or WW scattering. These topics can be made more concrete and several more items can be added to the list.

- To give us all some hope, he has some news about a possible astrophysical X-ray spectrum signal that could conceivably be evidence for a sterile neutrino dark matter candidate. Right-handed neutrino fields fit naturally into the SM pattern of fundamental fields, but with zero SU(3)xSU(2)xU(1) charges. That such fields have something to do with dark matter looks more promising than the SUSY or axion proposals of introducing a new and different sector of fields. My knowledge of neutrino physics isn't what it should be, so I'd be curious to hear of good references about the sterile neutrino dark matter issue.

Update: For some idea of the case being made for a larger collider, one might want to take a look at talks in Beijing a few days ago, where there's a proposal for the Chinese to build it. Talks at a conference are here, and last Sunday there was a big event featuring Yau, Gross, Witten, Arkani-Hamed, 't Hooft, Maiani and Incandela, video here. On the whole people seem to be pretty much sticking to making the generic case for high energy, not promising superpartners or extra dimensions this time.

Comments

1. **Per**
   February 26, 2014

   I work in hep-th and there is nothing I'd love more than to find experimental evidence for SUSY.

   However, I still don't thinks its economically motivated to build a 100 TeV collider. There are other scientific areas which are more important, for example fusion and renewable energies. While funding in one field does not by necessity exclude funding in another, a mega project like a 100 TeV collider will cause huge deficits in other fields.

2. **nolose**
   February 26, 2014

   No lose?
   For the LHC, certainly, there were very strong indications that it would discover the Higgs boson. The Standard Model had already been vindicated in great detail while the LHC was in its design stages.

   The Tevatron was *not* "built to discover the top quark."
   The Tevatron was built to reach an energy of 1 TeV/beam, to explore what was out there. Note also that PEP, PETRA and TRISTAN were all built to discover the top quark.

   LEP was built to discover supersymmetry?
   Speak to Burton Richter about what he said to the CERN management circa 1981 about building an e+e- collider on the CERN site. CERN had built only hadron machines up to then.

   The SppS was certain to discover the W and Z bosons.
   This is a bit complicated. The SPS was a fixed target proton synchrotron. Once the masses of the W and Z had been estimated (indirectly) by other experiments, then there was a case to convert the SPS into a p-pbar collider. This was the stochastic cooling story, etc. But the SPS needed to be there first, and the SPS was not built to discover the W and Z bosons. Note also that Rubbia, Cline and Peter McIntyre proposed the stochastic cooling idea to FNAL first, to convert the Fermilab Main Ring into a collider to produce the W and Z bosons, and they were kicked out. The Tevatron came online in 1985, after CERN had already discovered the W and Z bosons, and before anyone had any firm estimate of the top quark mass. (And Rubbia *did* discover the top quark at the SppS, at a mass of 44 GeV/c^2.)

3. **Daniel Rocha**
   February 26, 2014

   These guys propose using the abandoned tunnels of SSC (45%) to build a 100TeV collider for the cheap price of ~1.5billion$

   http://arxiv.org/abs/1402.5973

   It's an interesting read.

4. **Peter Woit**
   February 26, 2014

   Daniel Rocha,
   They're talking about two colliders, a 240 Gev electron-positron machine in the SSC tunnel, and a 100 TeV hadron machine in a completely new 270 km tunnel. I don't see where you get $1.5 billion, the only cost numbers I see there are for $1.32 billion for a 270 km tunnel and $740 million or $1.9 billion just for the cost of the wire for the magnets in that tunnel.

   The order of magnitude for this scale machine is likely to be $20 billion, and I don't see how building the thing really huge with lower field strength magnets is going to dramatically reduce the cost. You then need to instrument a 270 km long experimental apparatus.

It seems within the realm of believability that CERN might be able to fund something on this scale over the next 20-30 years. The chance of this happening in the US I think is zero.

5. **Don Murphy**
February 27, 2014

Peter
Here is a post by Matt Strassler that gives some information and references on the X-ray spectrum you mentioned that may have something to do with dark matter:
http://profmattstrassler.com/2014/02/18/x-rays-from-dark-matter-a-little-hint-for-you-to-enjoy/

6. **Michael Brown**
February 28, 2014

A few references on the subject of neutrino dark matter (from my library, but I'm not an expert on this). See [1] for a set of lectures on the astronomical signatures of ~keV scale neutrino dark matter. [2] is an extensive review of the nuMSM = "neutrino minimal standard model", the absolute minimal model with sterile neutrinos and nothing else coupling to the SM below the Planck scale. [3] is a shorter presentation of the essential points by the same authors.

For a broader review of right handed neutrino pheno that is not wedded to the nuMSM or a particular dark matter scenario see [4]. See [5] for a "model builder's guide" and [6] for a feasibility study on collider experiments to explore the whole range of sterile neutrino masses below a few GeV.

Finally, I would just like to point out that Shaposhnikov, one of the authors on the nuMSM papers, correctly predicted [7] (with Wetterich) the Higgs mass on the basis of: a) no new physics coupled to the SM fields between the weak and Planck scales and b) asymptotically safe gravity. It's interesting that the idea works so well.

Surely you'll have no trouble navigating the literature, but I hope this helps a little!

Cheers

February 28, 2014

Thanks Michael!

That's very helpful.

8. **bobby3**
February 28, 2014

Regarding the new collider arguments, that debate between Strassler and Gross at the end of Strassler's recent talk (at KITP) was pretty entertaining.

9. **justin**
March 1, 2014

perhas this is off topic, but is this result indication of non-standard physics?
http://www.quantumdiaries.org/2014/02/28/b-decays-get-more-interesting/

10. **Peter Woit**
March 1, 2014

bobby3,
I noticed that, Gross seemed remarkably testy. The fact that he just spent a couple days on planes traveling to Beijing to try to help sell the Chinese on the 100 TeV accelerator idea might explain his reaction (overreaction, I think…) to some of Strassler's comments.

11. **M.Wang**
March 1, 2014

Is there a link to the Strassler/Gross debate?

12. **Peter Woit**
March 1, 2014

M.Wang,
I don't know if you could call it a debate, but the exchange was in the question section after this talk

http://online.kitp.ucsb.edu/online/joefest_c14/strassler/

13. **paddy**
March 1, 2014

The Strassler KITP talk is both informative and impressive. Thank you bobby3 and Peter Woit.

14. **Zathras**

March 3, 2014

On the 100 TeV collider post, there is a comment by someone named Andrew which is so dead-on that I am going to just copy and paste it here:

> "A 100 TeV collider would be nice. So would a pony. I would prioritize about half a dozen other investments before that, however:
>
> 1. $100-$500 million for improved computing power to do lattice QCD calculations both to make theoretical predictions that reduce the MOE (especially for discriminating between backgrounds and signals), and increase the power of existing experimental data and new searches with the same equipment, and would allow more precise extraction of Standard Model constants from existing data. We are pretty much guaranteed to be able get seven or eight loop QCD beta functions (the current research effort is devoted to five loops and each successive term gets much harder than the one before it to calculate) and with more accurate calculations, greatly increased theoretical precision, for example, simply by investing the money to get the computational power to do the job.
>
> 2. $1-2 billion for deep space satellites. The only thing we can be absolutely exists in terms of BSM physics is something to explain dark matter phenomena, either at least one new particle or at least one new force or both. The best way to narrow the dark matter parameter space is with precision astronomy observations that the atmosphere obscures, not with a 100 TeV collider. We can be vastly more efficient in our search for dark matter particles at some future experiment yet to be designed if we use astronomy observations to more tightly narrow this parameter space first. It is the difference between looking for a face in a crowd based on a photograph v. a police sketch artist's effort from an eye witness's blurry recollection. We can also, for example, much more accurately triangulate star distances with a pair of distant deep space satellites which would calibrate all other astronomy observations. And, better observations of neutron stars, pulsars, cosmic rays, etc. provides a different way of doing super high energy HEP with nature paying the electric bills for it. Also, realistically, the only application of 100 TeV+ scale phenomena is cosmology anyway. Very early universe observations from deep space also narrow the parameter space of 100 TeV scale physics and let us know what we should be looking for.
>
> 3. $2-3 billion+ for neutrino physics experiments (e.g. astronomy, reactor, neutrino beam, double beta decay). A little more investment here to pin down the last few Standard Model parameters and determine things like the Dirac v. Majorana basis of the neutrino mass has an immense impact on the parameter space of BSM physics.
>
> 4. Continued funding of B factories. There are dozens of meson resonances that we don't really understand well. This is an area of particle physics where predictions are frequently not matching up with experimental results. You don't need a 100 TeV collider to investigate, e.g., 0.5 to 2.5 GeV scalar and axial vector mesons.
>
> 5. $100-500 million or so to push the envelope on exclusions for proton decay, magnetic and electric dipole moments, non-collider based axion field searches, entanglement experiments, etc.
>
> 6. $100-$200 million on non-SUSY/non-stringy theoretical work. We have all of our eggs in one or two baskets. The LHC has cracked many of the other contenders. Like anything, there is declining marginal benefit to funding yet another SUSY theorist.
>
> If there is money left over, then by all means, lets go buy a 100 TeV collider.

15. **Peter Woit**
March 3, 2014

Zathras,
I don't see much reason for this kind of argument worrying about a 100 TeV machine crowding out funding for other worthwhile experiments. In the US, I see absolutely zero chance of any funding of a machine like this, the funding decisions for the forseeable future all involve deciding between projects like the ones mentioned in the comment.

Similarly, in Europe any prospects for building a machine like this are a long way off, with the current plan to operate the LHC until 2035. The discussion about the future and a 100 TeV machine is about what to fund 20 years from now, not what to fund now.

It's only in China that I see any conceivable possibility of someone starting to fund this kind of project in the next 10-20 years, and there the argument to the Chinese government is for special funding for this particular project. If they do decide to do it, it would not necessarily conflict with them providing some of the much lower levels of funding needed for the projects in the comment. And if they don't decide to do it, you can ask people who were around in US-HEP when the SSC was cancelled to tell you how that caused the rest of the field to flourish amidst an abundance of resources…

16. **nasren**
March 3, 2014

My take on the Strassler-Gross discussion at the end of the KITP talk.

Strassler: We need to think differently.

Gross: No, let's just keep thinking the same!

I thought Matt Strassler was just saying (pretty clearly) we should look for other ways to consider experiments for BSM physics, other than building a higher energy collider. And Gross' response seemed to be that we shouldn't do that. It seemed like a bad misunderstanding — the strange thing was that others in the audience seemed to share it. My guess is that they were miffed by a different point (and then transferred it over) which was that supersymmetry has not made an appearance so we should consider other ideas.

I thought Nima's talk was very interesting — a great pity that the discussion was cut off at just the point where the weakness was about to be exposed.

17. **Peter Woit**
March 3, 2014

nasren,

Strassler makes the case for a 100 TeV collider here in his latest blog entry
http://profmattstrassler.com/2014/03/03/a-100-tev-proton-proton-collider/

I was surprised at Gross's reaction, since I figured Strassler obviously was in favor of a higher energy machine, just arguing that there were good reasons to also look elsewhere. Looking back at the talk, I think Strassler's comment that pure SM behavior at the LHC would be circumstantial evidence against string theory (not really controversial, since SUSY at the LHC was always argued to be the most likely circumstantial evidence for string theory) was what set Gross off. He and others are tempted to try and argue that there's no major problem with the SUSY/string theory paradigm collapsing, we just need a bigger accelerator, but I don't think that's going to fly and they're starting to realize this.

18. **CU Phil**
March 4, 2014

I took Gross to be arguing something that I've heard both from people who think that all we need is a bigger accelerator, and people that think that the motivation for low-energy SUSY was weak from the word go: that, on reflection, perhaps naturalness wasn't as good an argument for SUSY as we thought. People like Gross go on to argue that the failure of naturalness doesn't mean we should give up on SUSY, since there are other arguments for it, while the other group who gives this argument concludes that we probably should have been looking elsewhere earlier, but we definitely ought to start start now. Gross seemed to place Strassler in the latter camp, even though he explicitly is not.

19. **Shantanu**
March 4, 2014

Peter, I disagree that the cancellation of SSC did not benefit other fields.
I know that when SSC was cancelled many people whow were working on SSC
switched to LIGO and also neutrino experiments (and probably other astroparticle
experiments which I am not aware of). So even though I agree that there is no evidence
that SSC cancellation increasing funding in other fields, certainly other fields
did benefit from more manpower/expertise of those who worked on SSC.

Various and Sundry

March 5, 2014
Categories: Multiverse Mania, Uncategorized

- It seems to be too early for April Fool's day, and yet the arXiv has [Dark Matter as a Trigger for Periodic Comet Impacts]() by Lisa Randall and Matt Reece, a preprint described as "Accepted by Physical Review Letters, 4 figures, no dinosaurs." The Register has a story: [Dark matter killed the dinosaurs, boffins suggest]().

  Also recently at the arXiv in a similar "too early for April 1" category is [Crossing Stocks and the Positive Grassmannian I: The Geometry behind Stock Market](), which deals with the "stockmarkethedron", also known as the [Geometrical Jewel at the Heart of Finance]().

- The president's FY2015 budget request is out, with [news for HEP]() not so good: a 6.6% cut proposed in DOE HEP funding. No details about the NSF budget, but the proposal is basically for flat funding (an overall cut of .03% in the research budget). The NSF is proposing one big increase, 13.5% for management. This is just an initial proposal from the administration, with the possibility of something different ultimately emerging from Congress.
- The particle physics documentary [Particle Fever]() opens here in New York at [Film Forum]() tonight, with appearances tonight and this weekend by the director and "physicists from the film". There's a [review]() in today's New York Times.

  I saw the film last fall at the New York Film festival and wrote about it [here](), with the summary:

  > most of it I thought was fantastically good and I really hope it finds distribution and gets widely seen. On the other hand, some of it I thought was a really bad idea.

  The film is a very inspiring inside look at the LHC experimental search for and discovery of the Higgs. My misgivings were about the theoretical framing of the story, which was the Arkani-Hamed point of view that this is all about two alternatives: SUSY or the multiverse. The NYT review shows that these misgivings were quite justified, with the reviewer's summary of what they learned about the significance of the Higgs from the film:

  > While the discovery of the Higgs may not have immediate consequences for the way we live, or applications in the world of technology and industry, its implications, according to "Particle Fever," could hardly be more profound. Through most of the film, the scientists are awaiting a specific bit of data, a single number that will either vindicate a theory of the universe known as supersymmetry or suggest the possibility of multiple universes.
  >
  > The differences between these two outcomes seem very stark. In the first case, more particles are likely to be found, contributing to a detailed and orderly picture of the nature of things. In the second, the Standard Model will be thrown into chaos, and the stability of the universe itself may be called into question. It won't be the end of the world, but for some theorists, it will feel that way.
  >
  > Mr. Kaplan is hoping for supersymmetry. His friend and sometime table tennis partner, Nima Arkani-Hamed of the Institute for Advanced Study in Princeton, is in the multiverse camp.

  Physicists often get outraged when they feel journalists badly misrepresent science to the public. Will they get equally outraged when it is physicists doing the misrepresenting?

- For some insight into the current concerns of particle theorists, you can watch some of the videos at last week's KITP conference. In particular, there's [Matt Strassler's talk](), where he got all Peter Woit and argued that "one could make the argument" that not seeing SUSY (or anything else stringy) at the LHC "would be significant circumstantial evidence against string theory as a description of nature" and that just seeing the SM at the LHC would be "circumstantial evidence against effective quantum field theory as a complete description of known particle physics". This got him an argument from Gross about his insufficient enthusiasm for a 100 TeV collider. Gross then also got all Peter Woit, arguing that the failure of the "naturalness" argument for new physics was no big deal since it wasn't a very good argument to begin with (I get all sorts of grief when I do this..).
  The conference ended with a [session of people trying to predict the future of the field 30 years hence](). This was mostly pretty discouraging, with a lot of people envisioning more of the same: endless generalities about quantum gravity, firewalls etc. Prominent by its absence was any role of mathematics in theoretical physics, with only Greg Moore speaking up for the question of the significance of now popular 6d superconformal theories, and Nati Seiberg mentioning that connections of the field to mathematics were a good thing.

  Lots of talks mentioned people's good experiences working with and interacting with Polchinski, who seems to be a very nice guy. I've never met him personally, but people have speculated to me that he had something to do with the decision of the arXiv to block links to my blog (he was unhappy about my characterization of his Scientific American article promoting the multiverse). What the truth is about that particular story I suppose I'll never know.

Update: Another [review of Particle Fever]() leads with this explanation of the main point they got from the film:

> Stakes come no higher than in Particle Fever, a dazzling, dizzying documentary about nothing less than whether we exist in a coherent universe of ordered, even beautiful laws — or whether, as Princeton physicist Nima Arkani-Hamed theorizes, our universe is one of an infinite set of other universes defined by a chaotic mash-up of unstable, inexplicable, random conditions.

Update: Reddit has a [live Q and A with physicists involved in the film](). Savas Dimopoulos (described as "considered the most likely to have a theory confirmed by the LHC") argues for the multiverse and tells questioners that "We may know about whether Nature prefers the Multiverse or the more traditional (super)symmetry path after the second run of the LHC which will start in a year." Arkani-Hamed also gives the multiverse argument, also claiming "I envy anyone who is jumping into fundamental physics as a grad student today!". No theorists in sight who might think there's more significance to the negative LHC results about SUSY than "must be the multiverse".

Update: Reddit the next day hosted a [live Q and A with Michio Kaku](). He there explains to the public that:

> The best theory comes from string theory, which states that dark matter is nothing but a higher vibration of the string. We are, in some sense, the lowest octave of a vibrating string. The next octave is dark matter….
>
> The next big accelerator might be the ILC in Japan, a linear collider which might be able to probe the boundaries of string theory…
>
> In the coming decades, I hope we find evidence of dark matter in the lab and in outer space. This would go a long way to proving the correctness of string theory, which is what I do for a living. That is my day job. So string theory is a potentially experimentally verifiable theory.

Seems that well-known theorists going on Reddit to mislead the public is now a daily phenomenon…

Comments

1. **imho**
March 5, 2014

First, what's wrong with the Randall Reece paper. Why is it absurd that dark matter can influence Fermionic matter. I haven't read the paper, but I'm sure they at least did some back of the envelope calculations to test plausibility. These aren't Brane Worlds – a fairy tale wrapped in a fairy tale – this is solid falsifiable Physics. So why the negativity?

Second, how is talk about Firewalls discouraging. This whole business of connecting entanglement to gravity seems new and exciting, and imho, smells like the beginnings of something profound. I'd put my money, and perhaps direct a little bit of funding, towards The Thermodynamics of Entanglement… it has such a nice ring 🙂

Finally, there is nothing wrong with rebalancing national research priorities. Sometimes a tweak here or there is healthy.

2. **Peter Woit**
March 5, 2014

imho,
Of course dark matter can influence other matter. And maybe what Randall-Reece are suggesting for a major solar-system effect of dark matter makes sense (I don't know enough about solar-system astronomy to have any real idea). Still, seems to me that a "dark matter killed the dinos" PRL paper sounds like an exceptionally clever April 1 stunt.

The black hole information paradox is now at least 30 years old, with debate about entanglement and gravity going back at least that far. I haven't seen any really solid insights into quantum gravity coming out of this so far, and another 30 years of the same doesn't seem like an inspiring vision to me. But others who feel differently should follow their inspiration. Given the latest trends, I'm not worried about the idea of "thermodynamics of entanglement" not getting enough attention (some days it seems hard to find a new hep-th paper on the arxiv that doesn't have "entanglement" or "entropy" in title/abstract).

3. **Giotis**
March 5, 2014

The theory Greg Moore has in mind is the interacting 6d (2,0) SCFT.
It is inherently Quantum mechanical with no classical limit and without a (known) langrangian. It is the field theory with the highest Super symmetry in the highest dimensions and a mother theory of 4d SYM and of other interesting field theories.

It is dual to M theory on AdS7xS4 and describes the dynamics of multiple coincident M5 branes. It is also known as the theory of tensionless self dual strings since as the M5 branes approach each other the self dual strings in their world volume (coming from the M2 branes stretched between them) become tensionless.

So indeed it is a remarkable theory but still mysterious. Understanding it better is crucial for M theory and QFT in general…

4. **Asnant**
March 5, 2014

http://beta.slashdot.org/story/198975

Thought you might like this link 😉

5. **Peter Woit**
March 5, 2014

Asnant,
Sure, but Slashdot is kind of behind the times, since that's pretty much from May of last year, see
http://scienceblogs.com/startswithabang/2013/05/15/the-rise-and-fall-of-supersymmetry/

6. **gs**
March 5, 2014

No details about the NSF budget, but the proposal is basically for flat funding (an overall cut of .03% in the research budget). The NSF is proposing one big increase, 13.5% for management.

But of course! Management needs more resources to navigate the tight budget.

(Back when I was in school HR, still called Personnel at the time, responded to a budget crunch by requesting additional staff to handle layoffs.)

7. **Neil**
March 5, 2014

I do find the firewall result interesting. Yes, the blackhole information paradox has been around a long time, but the firewall (possible) resolution is new. Since there appears little or no way to explore the issue experimentally, the fact that we have this logical inconsistency between QFT and GR on the event horizon offers some hope, I think, for making progress on the quantum gravity agenda (which has been stalled a long time).

8. **So**
March 6, 2014

Peter, can you argue a little about that jewel in finance ? Why is it absurd to use combinatorics in finance ? It looks fine to me, but I'm not an expert in stock market !

9. **Michael Hutchings**
March 6, 2014

So: the "crossing stocks" paper does not say anything useful about finance. It starts with the observation that if you plot several stock prices on the same graph then the curves sometimes cross either. It then uses this a launching point to start rambling about permutations and various related topics in combinatorics. I'm kind of amazed that this paper even made it onto the arxiv.

10. **So**
March 6, 2014

Michael : Do you know what a crossing of stocks means for the market? In other words can you tell how the crossing affects an investor portfolio?

11. **S. Molnar**
March 6, 2014

Almost, but not quite, amusing typo: “feel journalists badly”, not “feed journalists badly”.

12. **Dave Miller in Sacramento**
March 6, 2014

Peter,

Polchinski and I were in the same dorm for three years as undergrads and then we overlapped for a year or two at SLAC when I was finishing my doctorate and he was a young post-doc. So, I knew Joe pretty well, though I can’t claim we were close buddies, since I was a very prudent fellow and Joe was one wild-and-crazy guy (I won’t relate all of his exploits except to say that it is good that he did not fall down the nine-story air-shaft when he was climbing up the air-shaft to the roof of the Caltech library!).

I have no specific information about Joe and links to your blog at the ArXiv, but it does not sound like Joe at all: he was always a very free-wheeling, libertarian kind of guy. Of course, people change, but it would surprise me if he was involved in blocking links to your blog.

Dave

13. **Peter Woit**
March 6, 2014

S. Molnar,
Thanks, fixed.

14. **Peter Woit**
March 6, 2014

Dave Miller,
Thanks. One thing I learned during the “string wars” though was that when you publicly criticize people who are used to adulation rather than criticism, you get some very odd and unusual behavior from otherwise sensible and mild-mannered people. One strange thing is that from everything I’ve heard, what upset Polchinski here is public criticism of the multiverse, of a sort rather typical or even milder than typical opinions of his colleagues about this (they just weren’t making these publicly).

I don’t know what the true arXiv story is, but from what Polchinski wrote publicly about this on blogs, and from what I’ve heard from others about his private comments, I wouldn’t describe any of it as a libertarian defense of the rights of others to express views he didn’t like.

15. **Low Math, Meekly Interacting**
March 6, 2014

Of course, New Scientist is all over the dinosaur thing.

That said, however plausible, it’s plenty falsifiable. A theorist could do worse.

16. **Anony**
March 7, 2014

Peter wrote — No theorists in sight who might think there’s more significance to the negative LHC results about SUSY than “must be the multiverse”.

Theorists would be the losers if they do not think of alternatives other than these two — the more likely thing is that there are theorists who think of alternatives but are not necessarily projecting their work, other than publishing it in journals. Popular media and even physics blog follow the more well known and outspoken ones and do not look at on going research work.

For example there can be fine tuning in other gauge symmetry breaking scales — not just the standard model scale — and this does not bode well either with multiverse (no anthropic reason for it) or SUSY. For example any non-SUSY model with additional groups including GUTs, belongs in this category where more gauge groups potentially have the hierarchy problem….and there is lot of research with such groups.

An interesting result is at http://arxiv.org/abs/1401.5066 (Click) which obtains bounds on the scale of B-L gauge symmetry breaking in left-right symmetric models using the hierarchy problem.

17. **Casey Leedom**
March 7, 2014

Wow:

> Arkani-Hamed … also claiming “I envy anyone who is jumping into fundamental physics as a grad student today!”

He must really be bitter if he’s recommending HEP for current students. Don’t get me wrong, I’m an avid follower of physics news, etc. but it’s definitely not an easy field to be invested in these days.

18. **D R Lunsford**
March 8, 2014

Salon has praise for multiverse mania.

-drl

19. **Sterling**
March 8, 2014

Hi Peter,

I found it interesting that both Brian Greene and Michio Kaku did AMAs within 24 hours of each other on Reddit.

While I am aware both have taken roles as "popularizers" now, something that bothered me was that Kaku described himself as a "leader in the field" and a "co-founder of string there", while Greene, who is more cited so arguably more influential, did no self accreditation.

Maybe I read too much into this, but I almost feel like the two are fighting each other for supremacy as "top" popularizer.

(Here the Greene AMA in case you missed it: http://www.reddit.com/r/IAmA/comments/1zqteb/i_am_brian_greene_theoretical_physicist_cofounder/)

20. **Peter Woit**
March 8, 2014

Sterling,
I did take a quick look at Brian's Reddit AMA, and it seemed to me he was careful to avoid making unsupportable claims about the LHC/ILC and string theory, or engage in the kind of self-promotion Kaku favors. In Brian's case, his focus is on his World ScienceU project, which has just launched:
http://www.worldscienceu.com

As far as I know though, neither Brian nor Kaku seem to have ever even considered making outrageous claims that the LHC provides evidence for the multiverse, along the lines of what Arkani-Hamed and Dimopoulos are engaged in and the film promotes. The Salon piece drl links to is pretty amazing, bashing creationists by holding up Dimopoulos and his multiverse claims as a sterling example of how different scientists are. If you want to torpedo the credibility of science, this is a good way to set about it.

21. **Neil**
March 8, 2014

OMG, what is an AMA?

22. **Peter Woit**
March 8, 2014

Neil,

I learned this yesterday: AMA= "Ask Me Anything"

23. **Luigi Vampa**
March 9, 2014

Peter, do you think Kaku and others like him have committed acts of sufficient harm to the public and to science such that their tenure should be revoked?

24. **Peter Woit**
March 9, 2014

Luigi,
Tenure is designed to ensure people's freedom to express their ideas, no matter how wrong-headed. There will always be physicists getting attention by making silly and misleading claims about fundamental physics, if you want attention, it's a lot easier to do that than to get attention for something serious. To me the problem is the rest of the (tenured) physics community: one reason they have tenure is so that they can challenge nonsense put before the public by prominent colleagues. I very rarely see any of them doing it.

25. **srp**
March 9, 2014

Saw Particle Fever last night with the editor and David Kaplan present for some Q&A afterward. They had over 500 hours of footage to condense into a movie, so it occurred to me that to some extent their problem was analogous to the LHC experimentalists: How do we handle this surfeit of information, decide what to throw away, and develop a truthful and interesting story about the phenomena?

In my opinion, I would have preferred more inside stuff from Atlas about deciding on what was noise v. signal, how blinding works, debates over how to set triggers, etc. To make room, I would have cut some of the redundant theorists' agonizing over their lives' work being at risk–some of that is fine, but they almost made that the main story.

Multiverse Mania at Wikipedia

March 9, 2014
Categories: Multiverse Mania

The quality of Wikipedia entries about mathematics is often quite good, but unfortunately the same cannot be said for their entries about physics. I happened to take a look today at the Wikipedia entry for Multiverse, which is an outrageously one-sided promotional piece for pseudo-science.

It's hard to know where to start with a document like this, and I've neither the time nor the Wikipedia expertise to start trying to edit it to something sensible (at this point I'd suggest that the most sensible edit would be to remove the whole thing).

I include just a couple of random examples of problems with the entry. The "criticism" section has little actual criticism, just some mild comments from Ellis and Davies, together with positive quotes from them about the multiverse as a research program. Nothing from Gross or Steinhardt, for instance. Much of the "criticism" section is actually defense of the multiverse through claims about experimental evidence from Mersini-Houghton that I don't think anyone except her takes seriously. Other claims of experimental evidence are completely outrageous, for instance we read that "Recent research has indicated the possibility of the gravitational pull of other universes on ours." where reference is to a Planck collaboration paper which states the exact opposite ("There is no detection of bulk flow").

There's a good case to be made that I pay too much attention to popular media nonsense about the multiverse. Unfortunately Wikipedia is taken a lot more seriously by the public than magazine stories. At this very moment, hundreds of high school students may be copying material out of it for their assigments…

Update: Some people have written to tell me about the appearance of the multiverse in the new *Cosmos* program that started last night. I saw just 20 minutes of the end of the program, missed that part. Presumably Tyson will deal with this in more detail in a later episode, so I'll wait to write more about this then.

1. **Vanzetti**
   March 9, 2014

   What prevents you from editing the article?

2. **Lamont Granquist**
   March 9, 2014

   If you've ever tried to edit a wikipedia article like this you'll quickly get frustrated. Without citable evidence your edits will quickly get reverted. The fact that the opinions which made it into the article first are based on nonsense and without citations themselves (or with incorrect citations) will not matter. Just in order to get the "There is no detection of bulk flow" statement correctly inserted into the article will take finding a moderator who understands physics well enough to be able to make a judgement that you're correct, but sufficiently removed from the subject that they're considered unbiased. It is much easier to 'greenfield' nonsense into wikipedia than it is to get that nonsense corrected.

3. **Peter Woit**
   March 9, 2014

   Vanzetti,

   I tried this once, in an even more egregious case, see here

   http://www.math.columbia.edu/~woit/wordpress/?p=1657

   Based on my experience then, unless you know a lot more than I do about how to deal with the systemic problem of determined wikipedia contributors devoted to using it to spread nonsense, trying to add sensible edits is just a waste of time. This is all in addition to the fact that the whole thing is such an outrageously misleading production that editing it to something sensible would be a massive amount of work.

   If others with more knowledge of how to get sensible edits put in of nonsense like this are able to get somewhere, that would be great. My blog entries about problems with the multiverse contain a large number of links that I would hope would be useful to anyone trying to get involved in this. Personally, I'm already wasting more of my time than is sensible on this topic.

4. **vmarko**
   March 9, 2014

   My take on these cases is to edit the article by putting "citation needed" superscripts on every sentence which sounds suspicious. These placeholders are usually not removed without providing an actual reference, which in these cases may be hard to find, if at all.

   When a typical student opens the Wikipedia article and sees "citation needed" superscripts in virtually every sentence, this will be just enough alarm to refrain from trusting the article too much. 😉

   And yes, math articles are often quite well written, while physics articles vary in quality between an excellent and a complete stub.

   HTH, 🙂
   Marko

5. **Brandon Brown**
   March 9, 2014

   The Wikipedia page was brought to my attention in Sunday school (of all the places) by another reader of this blog. We both decided that Peter wouldn't like what was written and it just might ruin his weekend or a wonderful meal.

6. **bhny**
   March 9, 2014

Pointing out things on the talk page does get results. Most serious editors just want to make a good article and aren't trying to push a point of view. If there's an obvious disconnect between the text and the reference, then fixing it with an edit is the fastest way to go.

I've already fixed the "Recent research has indicated the possibility of the gravitational pull" sentence. I'll look at your other links during the week. It seems the pro-multiverse crowd have the loudest voices at the moment and so get greater representation in the article. Another fix I could do is to spread the criticism throughout the article (which is normal wikipedia style) rather than a separate section.

7. **cthulhu**
March 9, 2014

Peter, hopefully not too far off topic, but what about "Eric Weisstein's World of Physics" at http://scienceworld.wolfram.com/physics/ as an online physics resource? I generally find that *Mathworld* (http://mathworld.wolfram.com) is a reliable math resource, at least at the level I need (MS level in a fairly mathematical part of engineering, i.e., control theory). I've been not too impressed by Wikipedia in the engineering disciplines…

8. **anonymous**
March 9, 2014

Now you've got me worried that high school teachers could be asking their students to study the multiverse.

I've found Wikipedia to have calmed down over the years, even since your troubles in 2009. A small edit that adds material and includes a citation is less likely to be seen as offensive as removing other cited material because that way you won't have to get into a debate over which source is more "authoritative" than the other. There already seem to be some new edits from bhny along those lines. The multiverse article by its very nature is likely to be more of a crackpot magnet than others, sure, but notice how nobody has reverted bhny's edits yet.

You might also want to put the multiverse article into perspective among all the physics articles out there. According to the list of [popular physics pages](), the multiverse article is only 294th on the list, albeit in a mix that includes many biographical/historical/interdisciplinary topics. There are plenty of other potential crackpot magnets that are much more popular than the multiverse, e.g. [Schrödinger's cat](), [Coriolis effect](), or [LHC]() to name just a few. By far the most popular physics article is [Watt](), which only has a "C" rating. It's a topic that has real consequence for people in the real world and can be taught as early as middle school. There's an argument to be made that the thinness of the Watt article is as worrisome as the unbalanced weight of opinion in the multiverse article as measured in terms of the total number of people viewing the article who don't learn the material properly. If you're worried about some sort of personal conflict of interest but still want to help people learn physics in your spare time by editing Wikipedia, try first focusing on some of the other popular, imperfect articles on the list. Get a feel for how it's done these days and how different it is from 2009.

9. **Tom**
March 10, 2014

"caveat emptor" w.r.t to any faddish or hot-button topic at Wikipedia.

eg, Some of the most egregious, one-sided Wiki articles are about "global warming", "climate change", "climate disruption", etc.

Many of Peter's critiques on the Wiki physics & multiverse articles, are just as relevant & applicable.

10. **Jerzy Kierul**
March 10, 2014

It seems that Wikpedia on Yang-Mills theory has changed, no references to Marco Frasca now.

11. **Patrice Ayme**
March 10, 2014

I watched the new Cosmos today, with my 4 year old. Neil De Grasse Tyson replacing his mentor Carl Sagan. Some of it was excellent. However the Multiverse was presented as a fact, and part of our "address". I was shocked. Especially after the narrator had pontificated, a few minutes prior, that scientists don't make guesses.

12. **Richard**
March 10, 2014

> unfortunately the same cannot be said for their entries about physics

That's nonsense.
Not even wrong.
99.4% of Wikipedia articles about physics are tremendously good, far better than anything that anybody outside a research university had any access to a decade ago.

Keep some sense of proportion, people! Orders of magnitude, orders of magnitude.

Wikipedia is, in fact, one of the few things that makes me proud to be a human.

Ignore articles about "multiverse" just as one would articles about "Ariel Sharon" or "Barak Obama" and you'll be just fine.

Baby with the bathwater, Mr Woit.

13. **imho**
March 10, 2014

Hi Richard,

Wikipedia articles are imho not tremendously good, which I think, is part of Peter's point. Wikipedia is a great tool for lay people to learn the basics of a subject. For example I would like to find out more about the prescription I've just been prescribed or I'm interested in this Multiverse thing I just heard Neil Tyson speak about. For professionals in any field it's really only tangentially useful. From this perspective it's important that these introductory articles are giving correct information.

14. **TB**
March 10, 2014

Agreed IMHO, but as a layman's resource, that puts even more onus on it to be evenhanded at best. If Cosmos drives people online to learn more, Wikipedia will always be at the too of their search results.

15. **Peter Woit**
March 10, 2014

bhny,
Thanks. It looks like, due to your efforts and others, the Wikipedia entry has been significantly improved. It's encouraging to see that this seems to be easier to accomplish than the bad experience I had back in 2009.

imho/Richard,

To put things more positively, I should say that one thing I've found most remarkable about Wikipedia is the quality of some of the mathematics entries. Often I've run across quite good explanations of very difficult material that is understood by only a small fraction of professional mathematician.

Patrice Ayme,

I just saw about the last 20 minutes of the Cosmos show last night. No multiverse there, but I have to say I don't see what the fuss is about that program. It looked more or less identical to dozens of other inspirational science programs that fill the cable TV channels. It's not very encouraging that Tyson gives the multiverse as a main example of why Sagan's version needs updating, see
http://www.huffingtonpost.com/2014/03/04/neil-degrasse-tyson-cosmos-god-alien-life-multiverses-interview_n_4790408.html
but I'll wait to see how he handles the topic, since it appears likely he'll devote a lot of attention to it in some later episode.

16. **Jeff McGowan**
March 10, 2014

As a mathematician I can second Peter on the quality of the math entries, in general. I'll sometimes look something up I've forgotten, usually something quite specialized and very high level, and it's rare for it to be either missing or incorrect. Actually, it's usually not only correct, but quite well written. There have been a few times when I'm pretty sure I know who wrote it…

17. **Jozape**
March 10, 2014

Neil mentioned the multiverse as a possibility some scientists believe may be true, but I do not remember him stating it was a fact, nor do I remember our cosmic address including the multiverse. Actually, the multiverse barely even received a mention.

18. **TB**
March 10, 2014

Jozape
It came at the end of the portion with the cosmic address, that we're one of billions of bubble universes. I don't know if people would take it as a fact, but it was definitely an endorsement.
I would say it was presented in the context of the cosmic address, and as there was no alternative presented, most people would feel that Tyson the scientist believes that is part of the address.

19. **Peter Woit**
March 10, 2014

I see that Jennifer Ouellette's review of the show

http://www.latimes.com/entertainment/tv/showtracker/la-et-st-cosmos-20140309,0,7079191.story

emphasizes the multiverse as the 21st century improvement over Sagan:

"Tyson adds a 21st century twist by invoking the multiverse: the notion that our universe might be just a bubble among bubbles in a vast infinite sea of universes. That's the kind of notion that used to fall firmly into crackpot territory – or make for bestselling science fiction novels — but is now taken quite seriously by many cosmologists, even if it's not (yet, if ever) a testable hypothesis. "

No discussion of whether untestable hypotheses are really an improvement on Sagan.

She's also quite fond of the Giordano Bruno section, which I saw at least part of. Seemed to me cartoonish, in all senses of the word, and that's not an improvement on Sagan.

20. **Tom**
March 10, 2014

New Cosmos's mix of fact and fantasy is not easy to tell apart, by laypeople.

My non-technical family interpreted the "multiple bubble universe" segment as a more-or-less "established fact".

In future episodes, I'm uneasy whether other speculations will be passed off as "likely" or "probable" or "fact". Unless you are listening *very* carefully, Tyson's subtle qualifiers are easily overlooked.

I may be too pessimistic, but this series could end up as a "What the Bleep Do We Know" type of gibberish & nonsense.

21. **Kavanna**
March 10, 2014

Among non-scientists, the multiverse mania is creating confusion, reinforcing credulity, and discrediting credibility, all at the same time. Peter has rediscovered what many of us already know, that correcting errors in Wikipedia articles is an arduous exercise. Some of the articles should just be deleted and recreated from scratch. Many areas of Wikipedia are controlled by editing cartels.

I've heard mixed things about the new Cosmos. But one thing that remains from the original series is the pomposity, including absurd statements like "scientists don't make guesses." Of course, they do, all the time. They just develop ways to check their guesses, and, if they can't, they labels those guesses "guesses," not "facts."

The multiverse isn't even much of a guess, just hand-waving. It's shocking but not surprising that the multiverse is presented as a scientific datum, not as what it is, a speculative mania like a stock market bubble.

22. **Peter Woit**
March 10, 2014

Kavanna,
To be fair, unlike in 2009, this time some errors did get corrected in Wikipedia very quickly. I only have personal knowledge now of two data points…

23. **Mike**
March 10, 2014

Peter,

I didn't get that Ouellette's review touted the multiverse segment as an "improvement." And, she does in fact specifically say that the hypothesis my never be able to be tested. It certainly is, however, 21st century 🙂

I tend to agree with your dislike for the cartoon segments — and to top it off, they weren't even good (i.e., costly and painstakingly produced) animation!

Tom above says that he may be too pessimistic, and that this series could end up as a "What the Bleep Do We Know" type of gibberish & nonsense. I think he is too pessimistic. At least from the first show, I don't see it going that way.

While there will probably be little new in the show for readers of this blog, I do think that on balance it is a very a good thing for the American public to view. I especially thought that the relatively strong criticism of religion and mysticism was a great way to kick off the first show. On that note, perhaps a redeeming aspect of cartoon segment was the depiction of the evil church elders. 😉

And, on a sentimental note, I thought Tyson's personal link to Sagan was very good TV.

Guess I'm not as negative as some — perhaps my standards are just lower.

24. **D R Lunsford**
March 10, 2014

The original Cosmos was riddled with science errors, particularly about relativity, but more importantly with historical errors – the largest of which was the fable of Hypatia as martyr at the hands of a Christian mob. The new one goes one better, setting up Bruno as some martyr for science, perhaps the founder of modern science itself. Nothing could be further from the truth. He had neither knowledge of, nor interest in, the considerable body of medieval science, and was simply promoting his own version of Hermetism. Nor was there any official papist position on heliocentrism when the torch was lit around his ankles in 1600. He was a garden variety heretic, very probably mentally ill and strange (he thought disease was caused by demons) who had 10 years to get his act together, and failed. I look forward to Peter's review.

-drl

25. **Peter Woit**
March 10, 2014

All,
Maybe that's enough about Cosmos, unless someone has something new and interesting on the multiverse angle. I assume Tyson will deal with the more speculative areas of physics in later programs and I'll be curious to see how he does this, may write more then.
In the meantime, from the little that I saw I don't see any reason personally to pay more attention to this. On topics like Giordano Bruno, in addition I'm pretty ignorant of the real history (and felt that the Cosmos segment did nothing to change that), so best for all to find a blog moderated by someone who actually knows something about this.

26. **Bill Hunt**
March 10, 2014

> No, it wasn't. Watch again. "Multiverse" was NEVER listed as part of our Cosmic Address. Tyson simply said of the Multiverse concept, "Many of us suspect…" that it's true. Not that the Multiverse is factually proven true. I get that there are a lot of people around here who hate the idea of Supersymmetry and the Multiverse, and I appreciate the arguments against excessive flights of fancy vs. experimentally proven fact, but the point of Cosmos is to inspire a love of the wonders of science in lay people. Not be a strictly dry and 100% exactly accurate reassurance for more knowledgeable and scientifically literate viewers. I love and appreciate this blog and its comment section, but sometimes it takes on a little too much of the tone of the Lone Gunmen nitpicking the scientific accuracy of Earth 2.
>
> The great failure of science, in my opinion, is a smug assumption that everyone else is going to appreciate (or care or even pay attention to) scientific endeavor and effort as much as those working within science do, just as those same scientists tend to thumb their noses down on those of their own who attempt to communicate its wonders to the general public. It's in that very kind of environment that those who wish to distort science for political or economic reasons can get away with it. Which is a shame.
>
> To the extent that discussion of SUSY and the Multiverse in the mainstream gets people interested in science, I don't see that the harm exceeds the value of the result. When those people do take an interest and start digging a little deeper, they'll discover that theory is one thing but experiment is where the actual rubber meets the road.

27. **Geoff**
March 10, 2014

Having listened to quite a bit of George Ellis, I am of the opinion that the wikipedia snippet is by far the kindest and most generous statement about the multiverse that he's voiced. One of the better critiques I've found is the following with the multiverse discussion at the 34:00 mark. Also of possible interest is quoting your Columbia colleague David Albert at the 44:00 mark about books that have also been reviewed here.

https://www.youtube.com/watch?v=tq8-eLGpEHc

I also can't help but wonder if Ellis' opinions are drowned out partially because he's sympathetic to theistic ideas.

28. **adel sadeq (@AdelQsa)**
March 10, 2014

Dear Peter,

You seem so far to have successfully attacked just about every quantum gravity theory or fundamental physics ideas so far. So I am wondering if you have any ideas of your own on how to carry physics further(in case you see that as needed).

I don't see anything in you website or randomly checking your blog. If you think this is off topic can you tell us at least if you will address that in the future. Thanks

29. **Peter Woit**
March 10, 2014

adel sadeq,
The only ideas I've significantly criticized here are pretty much string theory, supersymmetric extensions of the Standard Model, and various versions of multiverse mania. I'm quite pleased to hear that these attacks have been successful, so I guess these subjects have now been discredited and I can stop paying attention to them.

As for what I personally find promising, I'm not one for hyping my own speculative ideas, but I've often explained here that I think there is a great deal still to be learned about how to apply ideas from representation theory to physics. For the past year or so the main way I've been working on this has been writing a book about quantum theory and representation theory. It's now about 400 pages long, the latest version is always at
http://www.math.columbia.edu/~woit/QM/qmbook.pdf
I'm hoping to finish this project this spring (probably another 40-50 pages), then get back to the ideas I never finished writing up about using Dirac cohomology instead of BRST to handle symmetries in quantum theory. Working on the book has helped me a lot to clarify in my mind what seem to me some promising questions to think about, most with some relationship to the Dirac cohomology project business. I'm looking forward to getting to work on those after there's a complete version of the book, hopefully a couple months from now. But, no, I'm not going to start a publicity campaign for my half-baked ideas.

30. **Peter Woit**
March 10, 2014

Oh, and this is quite off-topic, I'm afraid. Anyone with any helpful comments about the book manuscript is welcome to write to me. Once it's complete I'll write about it in more detail here and will be happy to discuss it extensively then. Give me a couple months…

31. **Pawl**
March 10, 2014

While I certainly applaud attempts to make Wikipedia more accurate, the most important thing for everyone — especially laypeople — is not to **assume** it's accurate. We have to bear in mind — and Wikipedia might emphasize — that the editorial process there does **not** ensure accuracy in the short run. It relies, especially for problematic subjects like the multiverse and string theory, on sources it can cite by people who've made a splash. There is no very good way within Wikipedia of disputing the logic of such courses, and no good way of explaining to Wikipedia that a lot of these views are simply not taken seriously by many experts — and almost none of those feel obligated to publish critiques. (I was at a major conference recently where cosmology was a main topic and I only heard brief, uncomplimentary comments about the multiverse.)

So: yes, try to make Wikipedia better; but also, emphasize that it does have weaknesses which seem to be structural.

32. **Don Jennings**
March 10, 2014

@AdelQsa
That seems rather unreasonable. I don't know much about Peter's work, and I'm pretty sure he's no Einstein and no Ed Witten. But nor are you, nor am I, and nor is any other living physicist. However, when I have glanced at his scientific writing it seems to be directed toward fairly difficult, plausibly promising, long-term projects, and done in a rigorous, honest fashion. I think that's all one can generally expect from non-Einsteins such as ourselves. It's certainly much much better than having non-Einsteins spout out incessant vacuous fairy-tales in an attempt to look like Einsteins. To my eye that is what Peter's attacking.

33. **Peter Woit**
March 10, 2014

Thanks Don.
But no more pro/con Peter Woit here. The ad hominem tactic for dealing with scientific criticism pretty much speaks for itself.

34. **Sam Klein**
March 10, 2014

I enjoyed this post.

Regarding math v. physics on Wikipedia: the uniform high quality of math articles is due in part to a few dozen or so prolific math grad students, and later young profs, who decided to contribute there years ago. Chemistry had a similar intentional influx; some of whom invented the article-rating scheme that the whole English Wikipedia now uses. While I'm not sure what leads some groups to take this up and others not to, there is a tipping point beyond which there are enough regulars reviewing a field (and referring to WP in their field) to make it pleasant for others on the frontier of the field to do the same.

And writing widely-read blog posts about unaddressed gaps is a popular way to influence an article, even if you don't want to edit directly. 🙂

35. **SilverDave**
March 11, 2014

Before we all get our blood pressure raised to aneurysm levels…
I think the last paragraph of this " Rational Wiki" article on "Universe " might help….
http://rationalwiki.org/wiki/Universe

While Rational Wiki probably suffers from the same citation , and editing problems as Wikipedia… this paragraph comment soothed me :

—While it is a term most commonly associated with science fiction, cosmologically speaking, the "multiverse" is the hypothetical realm which contains our universe, as well as many possible others. Some physicists do take multiverse theory kinda-sorta-seriously.
Perhaps there have been multiple universes with multiple big bangs, and each new universe receives a different roll of the cosmic dice, thus having different laws of physics. This is a philosophically satisfying interpretation of the fine-tuned universe problem.

—However, it's also completely stark-raving unfalsifiable—-

"For a start, how is the existence of the other universes to be tested? … invoking an infinity of unseen universes to explain the unusual features of the one we do see is just

as ad hoc as invoking an unseen Creator. The multiverse theory may be dressed up in scientific language, but in essence it requires the same leap of faith."
…..
Until we develop instruments which can actually see outside of the universe (which is not bloody likely), or create a universe in a jar that we can poke with scientific instruments (slightly more likely) this remains a theory to stay grounded in sci-fi. Anyone who talks about multiverse theory seriously may either be speculating wildly or trying to sell you some woo—

I felt a little better after reading that.

36. **Mitchell Porter**
March 11, 2014

On the subject of physics and the Wikipedia, there was a paper today by Stephen Adler (co-discoverer of axial anomalies), arXiv:1403.2099, where the acknowledgements include thanks to Edward Witten for helping to interpret a Wikipedia article, that Adler evidently used as a reference.

37. **DrDave**
March 11, 2014

As an occasional editor of the Wikipedia, I understand the frustration, but we still have to make the effort. Certainly "citation needed" is a start, talk page is good, but I also recommend setting up a web page with a concise, clear, short article on one or more aspects of the article, especially as a collaboration, and linking to it. You can also make a video or podcast and upload it. I suppose one can imagine a universe in which there is no multiverse article.

38. **philh**
March 11, 2014

Maybe its changed since your blog post or maybe Im missing something but I went on the link to the wiki article through your blog post and it said:
"Around 2010, scientists such as Stephen M. Feeney analyzed Wilkinson Microwave Anisotropy Probe (WMAP) data and claimed to find preliminary evidence suggesting that our universe collided with other (parallel) universes in the distant past. [23][unreliable source?][24][25][26] However, a more thorough analysis of data from the WMAP and from the Planck satellite, which has a resolution 3 times higher than WMAP, failed to find any statistically significant evidence of such a bubble universe collision.[27][28] In addition, there is no evidence of any gravitational pull of other universes on ours.[29][30]
"
It also quoted Steinhardt
"Over the entire multiverse, there are infinitely many distinct patches. Among these patches, in the words of Alan Guth, "anything that can happen will happen—and it will happen infinitely many times". Hence, I refer to this concept as a Theory of Anything. Any observation or combination of observations is consistent with a Theory of Anything. No observation or combination of observations can disprove it. Proponents seem to revel in the fact that the Theory cannot be falsified. The rest of the scientific community should be up in arms since an unfalsifiable idea lies beyond the bounds of normal science. Yet, except for a few voices, there has been surprising complacency and, in some cases, grudging acceptance of a Theory of Anything as a logical possibility. The scientific journals are full of papers treating the Theory of Anything seriously. What is going on?[6]

—Paul Steinhardt, "Theories of Anything" in Edge
That seems to me to be a fair representation , no?

39. **Peter Woit**
March 11, 2014

philh,

There have been some significant changes since my blog posting. Thanks to all responsible.

40. **Machine Elf**
March 11, 2014

re DrDave: "setting up a web page with a concise, clear, short article on one or more aspects of the article, especially as a collaboration, and linking to it."

That's not allowed, best just to edit the article and/or post to the talk page.

41. **Machine Elf**
March 11, 2014

Another good place to raise concerns: http://en.wikipedia.org/wiki/Wikipedia_talk:WikiProject_Physics

42. **Gustavo Burdman**
March 11, 2014

Colbert ended his interview of Neal De Grasse Tyson last night (10/03/14)
with this: "Yes, the idea of the Multiverse is cool. But so is the idea of the Force …".
My guess is the the show (Cosmos that is) will have to address such serious criticisms
before too long or it'll loose credibility.

43. **imnobody00**
March 12, 2014

I have tried to correct one wrong point in the criticism section of the Wikipedia page. I have done it twice. It has been reverted to the original twice.

Spring Break

March 11, 2014
Categories: Uncategorized

I'm leaving for a spring break vacation in Northern Italy tomorrow afternoon, and will shut down comments while I'm away. Back in two weeks. Some events that will occur while I'm away that might be of interest:

- The 2014 Templeton Prize will be awarded about the time I land in Milan.
- There will be a HEPAP meeting this week, likely to have discussion of US HEP funding issues discussed here recently.
- Next week will be the 10th anniversary of the blog. So far 1350 postings, 37,540 comments posted (and about 250,000 spam comments…). When I get back maybe I'll write something to mark the occasion.

No Comments

Rainy Day Posting

March 23, 2014
Categories: Uncategorized

My spring break vacation is not quite over but, after 10 days of spectacularly beautiful weather, it's now raining hard here today and I've got some time indoors to write something. First some quick links to things I've seen in my short periods of recent internet access (leaving the BICEP2 story for after I get back Tuesday …):

- I don't often link to things at Tommaso Dorigo's blog, since my advice is that you should just always follow it since it's the best HEP experiment blog to be found. His latest has news of an impressive CMS limit on the Higgs width, something that I had never realized could be done. This should get a lot more attention than it has gotten; it's a great example of experimental cleverness, getting at a seemingly impossible measurement in an indirect way.

  And, seriously, I'm not just saying this since Tommaso recently showed me around Venice…

- For another, very different, blog you should be following, there's my friend Mathbabe, who has a simultaneously amusing and disturbing take on Princeton, which addresses the question of why it produces graduates like this one.

  From what I can tell, Princeton seems to be little changed since the time I spent there more than thirty years ago, and at the time it seemed devoted to staying much like the place of thirty years before that. Something that hasn't changed is the vanishingly small number of women, with even fewer at the IAS on the other side of the golf course (and if you want to argue about why that is, please do it somewhere else).

  One thing I did enjoy about Princeton was getting to know some of my fellow students. In other HEP news, one of them, Jon Bagger, has just been appointed director at TRIUMF.

- The recent HEPAP meeting seems to have had some unusual activity from the DOE in response to Laurence Yaffe's recent complaints about large cuts to theory grants. This included a presentation specifically about HEP Theory funding, but reading it I still don't see the explanation for why, as Yaffe claimed, cuts in theory group funding seem to be much more widespread than in other areas (see page 9 of this presentation).

  The DOE/HEP presentation had a specific warning against discussion on blogs of funding problems, I'd guess specifically aimed at Yaffe:

  > Intense discussion in the community around the sociological issues can easily be mistaken by decision makers as disputes over the P5 plan, so please be careful to frame discussion points properly, especially when discussing issues we face with others outside the field.
  > – Blogging, posting on public websites are a de facto public conversation
  > …
  > 'Bickering scientists get nothing'

- Scott Aaronson has a review of Max Tegmark's Our Mathematical Universe, which argues that the main claim the book is designed to promote is empty, but everyone should read it:

  > I think everyone interested in math, science, or philosophy should buy the book and read it. And I still think the MUH is basically devoid of content, as it stands.

Comments

   Peter, tell us more about Venice. It is my favorite city in the entire world.

2. **wolfgang**
   March 23, 2014

   >> more about Venice

   Well, The Daily Mail just reported that "Venetians have voted overwhelmingly for their own sovereign state in a 'referendum' on independence from Italy".

3. **john**
   March 23, 2014

   So should the DOE statement be taken as a threat to shut up about funding cuts or loose future funding? Not an encouragement for students to enter into the field.

4. **layman**
   March 24, 2014

   It is very ironic that you have been absent from the blogosphere during the time that

   — quantum gravity was verified experimentally (yes, classical GR cannot account for the BICEP result)

   — the scale of 10^{16} GeV was probed

   — the theory of inflation, which almost cannot be without a multiverse of a sort, was indirectly verified.

   Basically, all the things you have been saying for 10 years cannot happen, are untestable, and unfalsifiable, have happened in your absence. Congratulations!

5. **Shantanu**
   March 24, 2014

   Peter something else you missed is strominger's colloquium at PI about black holes
   and also about string theory.
   I think somewhere he mentioned that ST cannot be falsified directly.
   http://pirsa.org/14030104/

Niayesh asked him about firewalls and he is not convinced by them

6. **Peter Woit**
March 24, 2014

David Appell,
No way to capture Venice in a blog comment. It's a unique and fascinating place.

Wolfgang,
Actually I saw something like the Daily Mail story and asked Tommaso about it. I can report that a lifelong Venetian says he has no idea what that story is about.

John,
The DOE presentation was explicitly claiming that any public dissent about DOE allocations of HEP funds would hurt overall HEP funding levels. No explicit threat was made about what would happen to people who did this.

Layman,
Thanks for the summary of the hype about this. I'll try and write something hype-free but it won't be for a day or two. I'm headed soon for Milan airport, will be traveling the rest of the day.

All,
I'm deleting the rest of the comments re the hype. Please, enough "BICEP2 shows the multiverse rules!" "No, the multiverse sucks!" discussion, and wait for this to be on-topic soon.

7. **M**
March 24, 2014

Notice that the Higgs width is already indirectly measured from the Higgs production rate (dominated by gg –> H) assuming safe relations such as Gamma(h –> gg) = Gamma(gg –> h)

8. **Chris Oakley**
March 24, 2014

A typical "Daily Mail" story is an account of illegal immigrants or asylum seekers exploiting the system, accompanied by a suitably hysterical xenophobic commentary. They were big supporters of the National Socialist party in Germany in the 1930s although they did at least have the decency to drop them when war broke out. Taking anything they write beyond theatre and cinema listings is generally a mistake.

9. **Ru**
March 24, 2014

Was going to say the same thing as Chris Oakley. While many non-UK folks are only familiar with the Mail Online and it's click-bait and braindead celebrity gossip, the print newspaper is an entirely reprehensible mix of hate, fear-mongering, and racism. Best not to give them click-throughs.

10. **anon**
March 24, 2014

I was a student at Princeton during the previous decade and I can attest that it has not changed.

And I've been waiting anxiously for the past several days for Peter Woit's take on Linde and BICEP2…

11. **Martibal**
March 24, 2014

As far as I know (i.e. as a non-Italian in Rome), the "referendum" was through the internet: people asked to answer on some website whether they would like Venice to be independent, as it was before the italian unification. This was organized, I guess, by some independent movement, and has no legal value whatsoever.

12. **anonymous**
March 24, 2014

Regarding the limit on the Higgs width, one should not forget that also some "dumb" theorists were involved in pointing out this possibility and showing that it is a viable at the LHC.

I am very impressed by this new result, but one should not neglect the theory input. Fortunately this is acknowledged in the CMS paper.

13. **Tommaso**
March 24, 2014

Hello Peter,

sorry to hear my influence on the weather during your vacation has expired. I guess my powers don't extend beyond 200km away.

Yes, the referendum is the work of a few nutcases. However, we must take all these manifestations of nuttiness seriously these days, as that funny old idea that national borders can be questioned if one has a strong enough army has not died out yet, apparently.

To the commenter who said that the food in Venice is the worst in Italy: I agree, with some exceptions. The main point is that it is very cost-ineffective, due to Venice being more of a tourist park than a place for Italians anymore. But mind you, we are still talking about Italian standards. I'd take an average restaurant in Venice over 95% of restaurants in Germany, for instance. Sorry for picking on Germans, just an example.

Have a safe trip back,
T.

14. **poet**
March 25, 2014

really? was princeton that way? i spent time in recent years and cathy's story doesnt sound right at all. yes, there are lots of old people from a different era, i'm sure women get condescending comments but in my experience, it is not that different from other places.

other places have superficial diversity but i find that the condescension is worse is in such places.

15. **Bill**
March 25, 2014

There is a conference next week about BICEP-2 at Perimeter: http://www.perimeterinstitute.ca/conferences/implications-bicep-2

B-mode News

March 25, 2014
Categories: Multiverse Mania

While I was away on vacation, the big news in physics was the BICEP2 result on B-modes in the CMB. Maybe it's just as well I wasn't available to blog about this, since inflation and cosmology aren't at all my field of expertise. Now that some of the dust has settled from the media blitz though, I do think it's worth while to write something here, since there are some aspects of the story where the media coverage could use some extra perspective.

First of all, there's the obligatory caveat about this result not being definitive, which most coverage by scientists has included. To my non-expert eye, looking at the main graph reproduced everywhere, if you subtract the gravitational lensing background you get something which is much larger at higher values of l than it is supposed to be if it were coming from primordial gravitational waves. But, I'm the wrong person to be evaluating this, you should read what the experts have to say, with some examination of the issue from Peter Coles here and Sesh Nadathur here and here. The great thing about this is that all you should need is a little bit of patience to see it resolved, with data coming in from Planck later this year and sooner or later from BICEP3 and other experiments as well. If this is a red-herring, we should know that within a relatively short time-frame.

Assuming that there really is a primodial gravitational wave signal, this is something that has long been predicted by inflationary models, so is a significant extra piece of evidence for some sort of inflationary scenario. I'm not the right person to try and explain the details of this, or even to point you to the best review articles, but some things you might want to look at are John Preskill's derivation of the prediction here, and many people are pointing to Daniel Baumann's lectures here. On the plane back from Italy I was looking for other reasons at an excellent introductory QFT textbook by Alvarez-Gaume and Vazquez-Mozo, which turns out to have a section (6.5) devoted to this calculation.

For the implications of this kind of confirmation of inflation, one obvious question is what it means for string theory. The standard argument from string theorists is that its testability problems arise because we can only do relatively low energy experiments, that at high enough energies, such as those of the very early universe, it would be testable (not true, since string theory is capable of giving you pretty much anything you want at any energy). The press coverage of what BICEP2 means for string theory is pretty comical , with Nature telling us:

> The BICEP2 results will also send some string theorists back to the drawing board, says Frank Wilczek, a theoretical physicist and Nobel laureate at MIT. String theory posits that elementary particles are made of tiny vibrating loops of energy. Efforts to combine string theory with cosmology have led to inflationary models that generate gravitational waves with energies much lower than the level detected by BICEP2, he says.
>
> Theoretical physicist Eva Silverstein of Stanford says she disagrees that string theory-based models of inflation are in any sort of trouble. "There is no sense in which we are forced to start over," she says. She adds that in fact a separate class of theories that involve both axions and strings now look promising.
>
> Linde agrees. "There is no need to discard string theory, it is just a normal process of learning which versions of the theory are better," he says.

New Scientist has a string theorist making the usual claim that finally, string theory is testable, showing up those bloggers who say it isn't. The idea is that the BICEP2 results don't confirm inflation, but something completely different:

> Picture the cosmos as a rolled-up piece of paper held in place with rubber bands, says Robert Brandenberger at McGill University in Montreal, Canada, who was part of a team that came up with the model in 1989.
>
> The paper is a nine-dimensional universe, and the rubber bands are vibrating strings. If two strings meet, their edges can form a single, twisted loop. That would release three dimensions of space and one of time, which can then swell to the scales we see in the universe today. This process can account for the tiny density variations seen in the CMB and strong gravitational waves – no inflation required.
>
> The BICEP2 results slightly favour this model. If Planck sees the same signal, it could be the first observational evidence for string theory. "For string theorists this is very important," says Brandenberger. "Opponents can no longer say string theory does not connect with data."

While Brandenberger argues that string theory is testable because it predicts inflation is wrong, Science has Scott Dodelson arguing that string theory is testable because it predicts various versions of inflation:

> Moreover, Dodelson says, theories of quantum gravity, such as string theory, predict modifications to the shape of the inflaton energy landscape. So if that landscape can be measured precisely, he suggests, physicists might finally put string theory—long mocked as an untestable "theory of anything"—to a concrete test.

Then of course there's Michio Kaku who at NBC News explains:

> "Inflation simply says there was a bang, and it expanded rapidly, but it doesn't say what the fuse was," Kaku said. "Nobody can say they know what the fuse is."
>
> Kaku, a string theorist, says that string theory could provide the answer … or answers. The cosmic parameters for string theory suggest that the number of possible universes could amount to around 10 to the 500th power. That's a 1 with 500 zeroes after it. Such a scenario offers so many possibilities for parallel universes that in some of them, "Elvis Presley is still alive," Kaku joked.

Besides watching the string cosmology clown-show, I've not followed at all closely the huge amount of work done by theorists in recent decades on various ways to get inflationary scenarios, so don't have anything well-informed to say about how the BICEP2 results will affect this area. One thing to watch will be a conference next week at Perimeter (thanks to a commenter here for pointing this out).

For some background on why I haven't paid much attention to this, I should explain some history. Back in 1980 when Alan Guth's work on inflation first came out, I was a graduate student and did pay close attention to what was going on. The arguments from Guth and others for inflation as an explanation for several otherwise hard to understand aspects of cosmology (the horizon problem, flatness problem) were (and are) compelling. Even better, the idea motivating Guth at the time was that the fields responsible for inflation would be those that broke the GUT symmetries, so grand unified particle physics models would explain aspects of cosmology, and cosmological observations might tell us more about GUTs. All in all, this was a very attractive idea.

Over the years though, no evidence for GUTs emerged and it became clear that GUTs didn't actually provide very much in the way of explanatory power about the Standard Model. Lots of work was done on inflationary models, but these models just typically invoked a single conjectural scalar field (the "inflaton"), with its relationship to anything known in particle physics a mystery. Earlier CMB data gave some hints of further evidence for inflation, and now the BICEP2 data provides yet more significant evidence, so there's lots of reasons to take seriously the idea of inflationary scenarios. The models getting some confirmation though seem to be very simple ones, with a single inflaton field and a very simple potential. This is great news for the general idea of inflation, but still leaves the whole subject with pretty much no convincing explanation of anything about particle physics, and with a minimal connection to quantum gravity (although one intriguing new BICEP2 paper I did notice was this one).

The sad thing about this whole subject though is how some people involved in it have reacted to its problems making connection with particle physics, by throwing in their lot with the multiverse as an explanation for the failure of string theory. The multiverse functions here as an all-purpose excuse for not being able to explain anything about particle physics, with the argument being made that particle physics is fundamentally something just random and inexplicable, different at different points of the multiverse.

The standard move of the people doing this is to point to the fact that in the simple models getting some confirmation, "eternal inflation" can give you lots of copies of our universe, all with the same physics. This is advertised as "evidence for the multiverse", with no mention of the fact that, to the extent this is true, it's evidence for what Tegmark calls a "Type I multiverse" (all the same physics), not a "Type II multiverse" (different physics in different universes, making our physics unpredictable). Several physicists in recent years have been engaged in a vigorous publicity campaign based on confusing this issue, and the BICEP2 results found them hard at work. There's Max Tegmark here and here, Sean Carroll at the New York Times, and Andrei Linde and Alan Guth everywhere (see for example here, here and here).

Luckily not all of the press coverage is dominated by this, with the better science journalists doing a good job of ignoring it and focusing on the real story (a good example is Dennis Overbye here and here).

For some other press coverage of the "BICEP2 implies Multiverse" story, there's Fox News, which has Dr. William Lane Craig explaining how this is proof the scriptures are true. Claims are also being made by The Bosnian Royal Family for having priority over Andrei Linde in this proof of the Multiverse.

Update: On Twitter, Peter Coles comments that "Perhaps there is a part of the multiverse in which the #BICEP2 results provide evidence for a multiverse, but I don't think we live there."

Comments

1. **Geoff**
   March 26, 2014

   From January 14, 2013 – "What should we be worried about?"

   Geoff: "If anyone is taking bets on where the necessary input for the way forward is going to come from, can I put my money on observational cosmology?"

   Woit: "You can put your money there, but people have been making that bet (that something learned from cosmology would tell us how to go beyond the standard model) for more than 30 years now, and so far it has been a losing one."

   I'd like to double down on observational cosmology as well as various systems that are very far from equilibrium.

2. **Shantanu**
   March 26, 2014

   Peter there was also a nice talk by Will Kinney at PI after the Bicep-2 resut and he
   mentioned that most (proposed) string theory inflation models are dead.
   http://pirsa.org/14030116/

3. **anonymous**
   March 26, 2014

   Since you've recently discussed HEP funding, I'd like you to consider for a moment the monetary implications. The LHC cost ~$10 billion. BICEP2 cost ~$20 million. (BICEP2 costs effectively more than that number because of the general costs of the US Antarctic Program, but the total for taxpayers can't reasonably exceed ~$50 million.) Think of where the future of fundamental physics ought to be, in terms of bang per buck. I actually feel kind of sorry for all the grad students and postdocs who have specialized in accelerator physics, many of whom will want/have to switch gears in the coming years while lagging behind their cosmologist peers.

4. **Sesh Nadathur**
   March 26, 2014

   Hi Peter,

   It's not true that the simplest inflationary models are the ones being confirmed by BICEP2 – in fact these models have a pretty hard time reconciling the BICEP2 data with Planck, and are therefore pretty bad fits overall. This is because such large tensor perturbations add power to the temperature power spectrum at low multipoles, where the Planck data was already marginally too low.

   One way to reconcile Planck+BICEP2 is by a very large running of the scalar spectral index, which cannot be produced by quadratic chaotic inflation or natural inflation (in spite of what Katie Freese tells the world). Another way is to introduce a blue tilt to the tensor power spectrum – something that is very definitely not consistent with inflation, but is apparently consistent with Brandenberger's model. Other possibilities within the inflationary paradigm are anticorrelated isocurvature perturbations reducing the power at large scales, something that produces a broken power-law primordial spectrum and so on.

   The data isn't yet enough, or secure enough, to provide compelling evidence in favour of any one of these alternative scenarios. But it is definitely not pointing to the simplest inflationary models.

5. **Peter Woit**
   March 26, 2014

   Thanks Sesh,

   Maybe a better way to say it is that my impression is that the data is still consistent with simplest models (I'm influenced by your latest post where you find good odds that the BICEP2 r value will come down…), and that seems remarkable. After a long career of watching HEP experiments, where pretty much all initial results that seemed to point to deviations from the simplest (Standard) model ended up going away, maybe I'm biased in favor of the expectation of that happening here.

6. **Peter Woit**
   March 26, 2014

   anonymous (and Geoff),

   The problem is that we're learning from cosmology experiments about the very early universe, but we don't seem to be learning anything new about the questions we don't understand about the Standard Model and particle physics. Yes, cosmology experiments are much cheaper than HEP experiments, but they are telling you about something different. And they require many fewer people, so a world with no LHC and just cosmology experiments would be a world with a lot fewer physicists, not the same number doing different things.

   I noticed on the Simons Foundation web-site that Jim Simons is funding some telescopes looking for B-modes https://www.simonsfoundation.org/features/foundation-news/new-telescopes-search-for-origin-of-universe/

One aspect of giving up on doing large expensive big science physics projects is that you could also give up on government support and just have hedge fund guys funding the whole business…

7. **David Nataf**
March 26, 2014

Bicep2 is a cheap experiment but it's not as though their experiment works in isolation. They require theoretical input from a large community of astronomers who have researched and detailed the properties of the gravitational lensing background; further, their result requires combination of their data with data from the Planck experiment.

Bicep2 doesn't show that we should end large experiments to only have small experiments; what it shows is that small and medium-sized experiments need to be a part of the scientific ecosystem, and that there should be a spectrum to the size distribution of experiments.

Which I'm happy to see proven. There are senior scientists who believe that everything in science should be done within the context of gigantic collaborations.

8. **Ted K.**
March 26, 2014

Dear Peter,
I read your blog site for a long time and I appreciate the information you provide about physics in general. Can you please let me know if Bosnian Crown Prince Mensur Omerbashich's claims, against Wineland And Haroche Nobel Price winning, have any merit? I know that this question is off-topic, but if they are, by any chance, true gives a bad name for some physisist and this is very unfortunate fact. Thank you.

9. **Peter Woit**
March 26, 2014

Ted K.,
By the multiverse philosophy, there are an infinite number of universes out there in which the Bosnian Crown Prince's claims are true. However, I very much doubt they are true in this one.

10. **Adam**
March 26, 2014

Hi Peter,

Nature article on the inflationary models that are winners/losers in the BICEP2 sweepstakes:

> *"But he said that the findings would agree remarkably well with 'chaotic inflation', a simple version of inflation Linde developed 30 years ago.* ***In Linde's model****, inflation never completely ends, stopping only in limited pockets of space, while continuing with its exponential expansion elsewhere.* ***Chaotic inflation would produce*** *not just our Universe but* ***a multiverse*** *containing many pocket universes,* ***each with its own laws of physics,*** *an idea that critics say would be untestable."*

This is saying that Linde's chaotic inflation model is a Type II multiverse. Is that correct? From your post it sounds like this is actually Type I, no?

Confused,
Adam

11. **Peter Woit**
March 26, 2014

Adam,
The problem is that if your inflationary model is based just on postulating a single inflaton field, with no information about what this field has to do with the fields we know about that give us the Standard Model, then it's not really going to produce bubble universes with physics different than the Standard Model. So, I'd say what Linde's theory of taking the SM + single, simple inflaton is going to do if it produces a baby universe is just produce one with the SM, so giving a "Type I" multiverse, not "Type II". Linde and others are moving from the simple model being tested here to something else without mentioning this.

12. **Douglas Natelson**
March 26, 2014

Peter, back in the dawn of time when I had Linde for graduate quantum, he did a lecture at some point at the end of the quarter about chaotic inflation. He implied through his dry sense of humor that there could be big differences between different inflated regions (e.g., "If red region fluctuates and spontaneously inflates and becomes blue region, suddenly all our protons decay and I am no longer giving you this talk."). From that remark, it seemed at the time that at the very least he was considering different values for various coupling constants and charges in the different regions. Is that considered still being within the SM?

13. **Adam**
March 26, 2014

Hi Peter,

So if I understand correctly, you are saying that Linde's simplest version of chaotic inflation does not include any reference to how the inflaton field is related to the SM. However, I see this on that [in]famous Wikipedia article about the multiverse:

> *Different bubbles may experience different spontaneous symmetry breaking resulting in different properties such as different physical constants.[10]*

Where the cited reference is to Max Tegmark apparently speaking about Linde's chaotic inflation model. Is this a direct implication of the theory or just a speculation about how the the model may be related to the SM?

14. **Peter Woit**
March 26, 2014

Adam,
This is speculation, not the simple model being used to get the B-mode prediction. It's precisely this kind of replacement of the actual model at hand being tested that one may have some evidence for by something vastly more speculative that one has no evidence for that I object to. I don't see any place though in the public discussions of

this from Tegmark, Linde, etc. where this is mentioned. What's controversial about the multiverse (and the source of complaints from "multiverse skeptics") is not the idea of lots more parts of the universe out there with the same physics that we can't see, but rather the putting forward of a speculative, completely untestable model that says you can't ever understand "why the Standard model", when there is no evidence at all for this.

There is a huge activity among theorists of coming up with specific models (for instance string models) in which the inflaton is related to the low energy SM physics in specific ways, but those aren't what is being tested here.

15. **Peter Woit**
March 26, 2014

Doug,
As I tried to explain in my posting, it's always been the idea of people doing this that the scalar field (or fields) responsible for inflation might be one of the Higgs fields responsible for breaking the symmetry of a GUT theory down to SU(3)xSU(2)xU(1). Then the behavior of inflation and the GUT would be linked, and you might get bubble universes with different symmetry breaking behavior (and, for instance, unstable protons). So, that's the vision, but it's not at all the model being tested here, where there's no known relation between the single inflaton and GUT symmetry breaking. Again, what I object to is the sleight of hand replacement of what is being tested by a speculative vision one has no evidence for.

16. **Adam**
March 26, 2014

Peter,

Thanks for the clarification. I admit to being confused by what some of these folks are saying in the popular press and wikipedia. This brings up another question for me though… this activity of generating models with some specific connection between inflation and the SM, well I'm trying to imagine a scenario where one of these models is successful in making connection with both the BICEP2+future Plank results and the SM. Is there a scenario where one of these models might also directly imply a type II multiverse?

I guess what I'm getting at is even if we know that one of these inflationary models "implies" other parts of the cosmos that are causally disconnected from our local patch we'd never be able to detect them and so how would we ever know if they contained different physics? I might be impressed with the Type II multiverse if a model that connected with all known physical experiment/observation directly predicted it, but even so we'd never be able to test and therefore this prediction would not be physical. A scenario where I would be **more than impressed** would be the existence of such a model and a long (50 years?) search that fails for a Type I model that met all observable facts. How about you?

Can you imagine any scenario where you'd be impressed or inclined to believe in a Type II multiverse?

17. **Peter Woit**
March 26, 2014

Adam,
The problem with this is that you can come up with all sorts of hypothetical models and hypothetical evidence, and what multiverse promoters like to do is to discuss those and say "AHA, you see, the multiverse IS testable". I've been through all this before with string theory, where you also can imagine all sorts of hypothetical versions of it that might be actually testable (but there's no evidence for any of them). Engaging in this just seems to me a waste of time, one that I've been forced to participate in because otherwise you get painted as some sort of fool too stupid to understand that things can be indirectly tested.

What I'd like to see from experts is an honest characterization of what the data successfully tests, and I'd be willing to spend more time to try and understand exactly what that is. It's perfectly reasonable for theorists to devote their time to studying speculative scenarios, what their implications are, whether they are ruled out, how they might be tested in the future. Absent any experimental evidence or a really beautiful convincing idea, I'm not going to spend much time though trying to follow this or engage in it myself, since there are other things I could more fruitfully be doing.

18. **Shantanu**
March 26, 2014

Peter at Stanford there was a 2 hour symposium of his which was webcast
https://www6.slac.stanford.edu/kipac-colloquium-bicep2

19. **Kavanna**
March 26, 2014

The "different physics in different bubbles" is another example of where string theorists have lifted a concept from the non-string world and use it sloppily to talk about "multiverses." The original idea was that different spontaneous symmetry breakings (and possibly different compactifications) could lead to different ground states, or vacua. Physics, in the sense of dynamics, is still the same everywhere, and there's a single connected spacetime.

The remarkable thing about the BICEP + other results is, if they all hold up, how strict the constraints are. Looking over Kinney's talk, I see a great slaughter of the theories, leaving only a few standing. But then again, that's how progress in science happens.

20. **Cormac O'Raifeartaigh**
March 26, 2014

Hi Peter,
don't forget that another impressive aspect of the hypothesis of cosmic inflation is that it gives a plausible explanation for the growth of inhomogeneities in the formation of large scale structure. As far as I know, there are few modern explanations for structure formation that don't involve some form of inflation, which is pretty impressive given that this was not part of the original motivation for the theory

21. **Peter Woit**
March 26, 2014

Kavanna,

I'm not objecting to the different ground states = different physics terminology. The problem is that you don't know what the relation is of the inflaton to the SM, so the inflaton is an independent field and you're not going to get vacua with different physics than the SM using it. When Linde says things like his comment about the proton, he's assuming some theory of the inflaton has been found in which it's part of the GUT symmetry breaking sector, but that's something he wants to be true, not something he knows how to do.

22. **Tim Fleming**

March 26, 2014

Basic Physics is out of my field. I work in an applied area, however I do try to keep track of what is going on. My question is how is this possible confirmation of inflation related to the prediction by loop quantum gravity that the universe should undergo a big bounce i.e. that there should be a period of rapid expansion (the work of Martin Bojowald and others). On the surface the bicep2 result would seem to support LQG but I am nowhere near an expert on this? Can anyone shed some light here?

23. **Jesse**
March 27, 2014

"The problem is that you don't know what the relation is of the inflaton to the SM, so the inflaton is an independent field and you're not going to get vacua with different physics than the SM using it."

At the very least, doesn't the fact that electroweak symmetry breaking is built into the Standard Model mean that in an eternal inflation theory where other causally disconnected regions undergo inflaton decay, things like the masses for the W and Z gauge bosons should vary from region to region? Or am I misunderstanding something?

24. **Sesh Nadathur**
March 27, 2014

I think Peter's right about the fact that quadratic inflation as written down doesn't give you a way to get different physics in different universes. What's more concerning is that unless you have couplings of the inflaton to the SM, you don't get a thermal bath of SM particles after inflation (the inflaton has to decay into these particles somehow). So the simplest quadratic inflation model actually doesn't give us the universe we see – there's no CMB, for instance. Of course it's possible to imagine that there are some couplings of the inflaton to the SM which facilitate reheating, but then you've got to demonstrate that they don't simultaneously change the potential during inflation, changing the model predictions (and possibly spoiling the flatness altogether). All this is made harder by the fact that the inflaton field has super-Planckian values, so using effective field theory is out but it's not clear what to use instead.

The conclusion then is that quadratic inflation is a toy model that shouldn't be taken too seriously. Or at least that's my understanding based on the situation a few years ago: if there's been any progress made in making the model more realistic, I'm happy to be corrected.

(Of course quadratic inflation is not particularly unique in this regard. As far as I am aware there is *no* complete model of inflation which simultaneously solves the problems of initial conditions, slow-roll regime predictions and reheating.)

To return to the topic of my previous comment, I think even if the Bicep result does eventually get modified down to r~0.1-0.15, the evidence still wouldn't point to the quadratic inflation in the sense that a complex model which included a running (or broken power-law etc) would still be a better fit to the data. The "simplest" models would then be disfavoured with respect to such a model at – I'm guessing – roughly the same level that, pre-Bicep, they were disfavoured relative to the Starobinsky model.

25. **Peter Woit**
March 27, 2014

Thanks Sesh, that's helpful.
Jesse,
The point is that the inflaton is not the electroweak Higgs, it doesn't couple to the W and Zs. There are models that try to use the Higgs field to do inflation, but the claim seems to be that these are not compatible with the BICEP2 result.

26. **Lee Smolin**
March 27, 2014

Dear Tim Fleming,

The effect of loop quantum gravity on models of inflation have been studied by several authors, by adding an inflaton field and potential to loop quantum cosmology models. A recent detailed study is http://arxiv.org/abs/1302.0254 by Agullo, Ashtekar and Nelson. Some of the standard picture is unaffected but there is one crucial modification to the predictions which is that the usual relationship between r and the tensor tilt is modified (see Figure 9 and eq. 5.18). This is interesting given that apparently one possible way to resolve some of the tension between the Planck and Bicep1&2 data could be to have a blue tensor tilt, which would contradict the usual inflationary prediction.

There are also implications from loop quantum gravity for parity odd effects in the tensor modes, coming from the existence of an analogue of the QCD theta parameter in the gravitational action: the Immirzi parameter. There is the exciting possibility that this parameter could be measured by observing primordial B-T and B-E correlations, which sec 8.2 of the BICEP2 paper hints may be possible. This was proposed in http://arxiv.org/abs/0806.3082 and developed in arXiv:1108.0816, arXiv:1104.1800 and http://arxiv.org/abs/1007.3732.

Thanks,

Lee Smolin

"The point is that the inflaton is not the electroweak Higgs, it doesn't couple to the W and Zs. There are models that try to use the Higgs field to do inflation, but the claim seems to be that these are not compatible with the BICEP2 result."

I guess I probably am confused about something here, from reading nontechnical accounts of spontaneous symmetry breaking I had thought that all that's required is that the energy density of the entire observable universe would have been above the scale where a given type of symmetry breaking happens, and then when the universe first drops to a sufficiently low energy, that's when the new broken-symmetry vacuum state is decided in a random way (analogous to how if an entire magnetic material starts out above the Curie temperature, then when it drops below that temperature the direction of magnetization in different domains is determined in a random way by spontaneous symmetry breaking). Are you saying it's possible that even if the energy density throughout the observable universe had been above the scale of electroweak symmetry breaking before some cosmological time T, the new broken-symmetry masses of W and Z bosons that would appear after T could have already been "baked in" before T, so that there was nothing truly random about the new vacuum state that arose after electroweak symmetry breaking?

28. **Peter Woit**
March 27, 2014

Jesse,
The problem is that you're mixing a story about the Standard Model with the story of the actual model that is being compared to BICEP2 results, and supposedly can

produce bubble universes.

I think I'm just repeating myself, but the point is simple: you can't use the model being tested here to say anything about the Standard Model, because the Standard Model doesn't appear in it. More specifically, the inflaton field being used is not one of the Standard Model fields, and you don't know how it couples to Standard Model fields.

This is the issue I was trying to point out in the posting. The idea of inflation has had some success in explaining cosmological observations, so should be taken seriously for that reason. It has not yet had any success in understanding its relation to the rest of physics: there we just have lots of speculative models, none with any compelling evidence for them.

29. **West**
March 27, 2014

@ Sesh

When you say the simplest models are disfavored, do these comparisons take into account the uncertainty in the new parameters? Or is this a likelihood ratio of the null-hypothesis vs model with best fit parameters?

30. **Sesh Nadathur**
March 28, 2014

Not quite sure I've understood your question correctly, but if you mean is the marginalized posterior probability distribution for n_run from Planck+Bicep2 data broad enough to still be consistent with the predictions from the simplest models, the answer is no.

I haven't run the fitting myself, so I am reading numbers off from tables Antony Lewis has produced. But judging from these tables I would say a zero/negligible running is excluded at roughly the 3 sigma confidence level.

31. **Chris Kennedy**
March 28, 2014

Peter,
Sorry to add overkill to your discussion with Jesse but: Is BICEP2's inflation model claiming incompatibility with Higgs because the inflation couldn't possibly be explained as a pre-Higgs field expansion in theory – or is there something more specific such as the end of the inflation period doesn't coincide timewise with the appearance of the Higgs field?

32. **Peter Woit**
March 28, 2014

Chris,
The question of whether you can use the Higgs as the inflaton is a complicated one. My vague understanding of the situation is that the simplest such model doesn't work for basic reasons (wrong shape + magnitude of the Higgs potential), but you can try and make it work by doing things like coupling the SM to gravity in a non-minimal way. This was all pre-BICEP2, and for a very general take on this, you could try

http://profmattstrassler.com/2013/03/26/cosmic-conflation-the-higgs-the-inflaton-and-spin/

That source says that such models predict r=0, so would be ruled out by the BICEP2 result if you believe it. But, a couple days after BICEP2, I recall seeing on the arXiv in quick succession two papers, one saying BICEP2 ruled out the Higgs as inflaton, another saying BICEP2 was consistent with the Higgs as inflaton.

My non-expert take on all this is that what's going on is that the simplest models of inflation are incompatible with the Higgs being the inflaton, to get compatibility you need to go to something more complicated, and that this has gotten worse post-BICEP2. But for something more specific, you need to consult an expert, not me…

33. **Bernhard**
March 28, 2014

"Linde agrees. "There is no need to discard string theory, it is just a normal process of learning which versions of the theory are better," he says."

OK Peter, now I am starting to believe you are making those things up.

Are you absolutely sure a real person (flesh and blood) said that?

I will check, be sure.

34. **West**
March 28, 2014

@ Sesh

While my question was about hypothesis testing rather than parameter estimation, thank you for your concise answer on that problem. Looking over http://arxiv.org/abs/1303.5082 (fig. 2), it's clear that even before the BICEP2 results were released there was reasonable evidence of non-zero spectral running. So your 3-sigma statement seems perfectly reasonable.

I was originally curious what the Bayes factor or evidence ratio would be when comparing the simplest models of inflation to more complicated ones. More complicated models will naturally fit the data better. That's not a surprise. I just wanted to make sure your statement about the simplest models being disfavored didn't stem from using a likelihood ratio involving best fit parameters for the two hypotheses.

Sorry about the confusion stemming from my poor wording.

35. **DrDave**
March 29, 2014

@Bernhard
Linde quote:
http://www.nature.com/news/gravitational-wave-finding-causes-spring-cleaning-in-physics-1.14910
(link is also in Peter's original post)

36. **Bernhard**
March 29, 2014

Dr Dave,

Sorry my sarcasm was not clear enough.

Bad joke on my (and Linde's) part.

37. **Krzysztof**
March 29, 2014

One thing is pretty disturbing – it seems like an established fact that the production mechanism (according to F. Wilczek for example) of the primordial gravity waves is necessarily "quantic", that is – it requires existence of gravitons. That would be a very major result, however not everyone is mentioning this aspect so strongly – including the BICEP team. Often it is even omitted. So, is that relation (between inflation and gravitons) really a compulsory part of the theoretical prediction, or not?

38. **Peter Woit**
March 29, 2014

DrDave/Bernhard,

The Linde quote does a great job of reflecting the new way of doing science embodied by "string cosmology": experiment can never show that string theory is wrong, all it will do is tell us which of the infinite variety of string theories is ruled out, with always another infinity of possibilities still in the game. I'm characterizing this behavior as a comic parody of science, but maybe it's not funny….

39. **West**
March 29, 2014

Where in the explanation of inflation is it necessary to posit the graviton as the origin of primordial B mode gravitational waves?

Inflation explains the rapid expansion of a very dense early universe prior to the hot Big Bang. So we have an anisotropic mass-energy distribution and highly dynamical spacetime curvature. Sounds like a classical GR problem to me.

40. **Oldster**
March 29, 2014

Krzysztof, I am also curious about these graviton claims. One source (I no longer have the link) appears to claim that BICEP2 proves gravity must be quantized by replacing the metric with operators, which leads to the required quantum fluctuations needed to produce the B modes, and to gravitons. I think some of the links referenced above by Lee Smolin may shed some light on this, but as I understand your question (and mine), are such models necessary, or are they merely in some sense sufficient to produce the B modes?

Another claim (again, no link) may have been trying to say that the classical Einstein equations coupled to the expectation values of stress-energy, are generally inadequate to produce the fluctuations that produce the B modes. But even that wasn't clearly stated when I saw it. Indeed, they may have been trying to talk about some WKB approximation to quantizing gravity being inadequate instead. I apologize for losing the links, and being unable to precisely quote the claims.

So I can't answer your question, but I have similar questions myself, if anyone can shed light on this. And I see West has also added a similar question above …

41. **Peter Woit**
March 29, 2014

Maybe some expert on this will help. All I can tell is that there are claims that this signal means one is seeing quantum effects, see e.g.
http://arxiv.org/abs/1309.5343
other claims that "signal no necessarily quantum", see
https://www6.slac.stanford.edu/sites/www6.slac.stanford.edu/files/B_discovery_senatore_v4.pdf

In any case, I'm more curious to know if there are any prospects to learn something non-obvious about quantum gravity. All I see in Krauss/Wilczek is standard dimensional analysis about the size of a graviton excitation if gravity is quantized

42. **paddy**
March 29, 2014

On the question of whether quantization of gravity is needed to explain BICEP2 results I have no insight just an historical note. The discussions remind me of the debate in the '70's concerning the "heuristic semi-classical" interpretation of quantum optics (fostered by Jaynes and others) about whether quantization of the EM field was unnecessary to describe any "quantum optics" phenomena. This historical analogy is only "interesting" and not "telling" since quantal absorption of energy from the EM field is and has been for 100++ years established fact whereas at least some research (links given by PW) question whether it is even physically possible to imagine a detector that can experimentally detect a graviton. If indeed, subject to time and further considerations, BICEP2 and/or other results do so indicate the necessity of gravity quantization for explanation: it is a big deal.

43. **Igor Khavkine**
March 29, 2014

I'm not an expert in the various physical effects surrounding inflation. However, based on information provided in some of the presentations of the BICEP2 results, it seems to me that the status of the B-mode signal detection as evidence of quantum gravitational effects + inflation can be put on the same footing as the status of CMB temperature fluctuations as evidence primordial quantum fluctuations of the inflaton field. Indeed, the latter seems to be fairly well accepted and the two observations are indirect in similar ways. I've based the following on information from various talks I've attended and discussions with cosmologists. It would be rather hard for me, unfortunately, to dig up specific references. Perhaps a real expert could weigh in with corrections.

In my understanding, the temperature anisotropies that we see (provided all foreground effects can be assumed to have been eliminated) tell us directly only about the photon times of flight (accounting for different amounts of red shift) from the surface of last scattering to us. These varying times of flight are then considered evidence for (classical) density fluctuations present at the time of recombination. The distribution of mode amplitudes of these fluctuations appears to be gaussian, with covariance estimated from the anisotropy 2-point function. Deviations from gaussianity have yet to be detected (as, for instance, in deviations from expected higher n-point functions).

Similarly, the observed B-modes tell us directly only the presence of (classical) gravitational waves at the time of recombination. Actually, already this point could be disputed, because the degree of directness depends on the ability to exclude other sources of B-modes. Perhaps magnetic fields could be another source, but the BICEP2 analysis team didn't seem to think that it was likely. I'm not sure about all the reasons, but lets take that for granted now. Lets also presume that the distribution of mode amplitudes of these gravitational waves was also gaussian, with covariance matrix estimated from the B-mode 2-point function. At the very least, I have not yet seen anyone bring up any evidence of non-gaussianity in the detected B-modes.

Now, the above evidence suggests the presence of classical density and gravitational wave fluctuations, with gaussian distributions, at the time of recombination. If inflation did happen, then it would leave behind this kind of signature, as amplified quantum vacuum fluctuations: (a) gaussian distribution of fluctuations connected to the gaussian shape of the quantum vacuum, (b) "large" amplitude (large enough for the fluctuations to have become classical) set by the amount of expansion during inflation, (c) a fixed relationship between gravitational and scalar amplitudes as a function of frequency (based on the similarity of the Fock-like vacua used for both the inflaton and graviton fields). The observational evidence for (c), I think, at the moment is quite weak because BICEP2 has access to only a small range of frequencies. But more concrete evidence (one way or the other) is likely to appear in short order, along with confirmations/disconfirmations by other experiments.

So, in the absence of other pre-recombination physics that would generate signals with specific signatures (a), (b) and (c), the observations of temperature anisotropies and B-modes do point toward inflation, an inflaton-driven period of rapid expansion in the early universe. And, if inflation did happen, then the detected B-modes do in fact descend from amplified graviton quantum vacuum fluctuations. A similar thing was said, and widely accepted, of temperature anisotropies long before the B-mode detection. Of course, alternatives where a signal with signatures (a), (b) and (c) is not of quantum origin might be possible, but they'd have to be subject to investigation and testing like any other hypothesis. At the moment, the inflation hypothesis seems to be doing rather well compared to its rivals.

44. **Marcus**
March 30, 2014

Peter: "This is great news for the general idea of inflation, but still leaves the whole subject with pretty much no convincing explanation of anything about particle physics, and with a minimal connection to quantum gravity (although one intriguing new BICEP2 paper I did notice was *this one*)."

this one is
http://arxiv.org/abs/1403.4226
Agravity
Alberto Salvio, Alessandro Strumia
(Submitted on 17 Mar 2014)
We explore the possibility that the fundamental theory of nature does not contain any scale. This implies a renormalizable quantum gravity theory where the graviton kinetic term has 4 derivatives, and can be reinterpreted as gravity minus an anti-graviton. We compute the super-Planckian RGE of adimensional gravity coupled to a generic matter sector. The Planck scale and a flat space can arise dynamically at quantum level provided that a quartic scalar coupling and its β function vanish at the Planck scale. This is how the Higgs boson behaves for Mh≈125 GeV at Mt≈171 GeV. Within agravity, inflation is a generic phenomenon: the slow-roll parameters are given by the β-functions of the theory, and are small if couplings are perturbative. The predictions ns≈0.967 and r≈0.13 arise if the inflaton is identified with the *Higgs of gravity*. Furthermore, quadratically divergent corrections to the Higgs mass vanish: a small weak scale is natural and can be generated by agravity quantum corrections.
24 pages
=====================
"Agravity" is short for "adimensional gravity" which is Strumish for a proposal that neatly packages fundamental physics—scale-free geometry with the Planck scale arising dynamically from a Higgs-analog field dubbed *Higgs of gravity*.
I'd like to hear comment from others.

45. **Lee Smolin**
March 30, 2014

Dear Marcus,

I took a glance at the "agravity" paper, and it is just the old Kelly Stelle theory from 1977, which has been known since that time to be non-unitary in perturbation theory, in addition the Hamiltonan is not bounded from below. It is perturbatively renormalizable and in fact asymptotically free, which in this case is bad, because there is faint hope to save the theory by going beyond perturbation theory. Many people have tried unsuccessfully to save this theory, from Terry Tomboulis and Gary Horowitz back then to the contemporary asymptotic safety people and Phillip Mannheim more recently. If I read the paper correctly, the authors admit they have nothing to add to these issues. If this was the right answer, quantum gravity would have been solved long before string theory and LQG were even invented.

Dear Peter,

Just to repeat, if these are quantum fluctuations of the gravitational field, amplified by inflation or some similar mechanism there is a great deal new to be learned about quantum gravity, starting with parity breaking effects, and continuing with non-perturbative effects modifying the relation between r and the tensor tilt.

Given the prospects for much improved precision for the observations, (quoted as r measured to 1 percent) perhaps its not crazy to say we may have confirmation of quantum gravity effects before we have direct detection of classical gravitational waves.

Thanks,

Lee

46. **Marcus**
March 30, 2014

Indeed a couple of paragraphs on page 5 of the Salvio Strumia paper refer to the 1977 Stelle work and several of the other items Lee mentioned, see their references [6] through [10]. So they confirm in some detail the negative findings that were mentioned and nevertheless seem eager to have another go at this approach.

47. **Omerbashich**
April 2, 2014

Dear Ted K. and Peter Woit,

Unfortunately for Wineland, it is in this universe that time flows only forward, so that lawyers can make their living (prove cases) based on this thing called timeline. So:

– It is in this universe that I had sent my result to Winelalnd three months before he submitted his Nature paper with the "brilliant lab technique" that took him to Stockholm.

– It is in this universe that, of all gasses, he pumped his laser exactly with Argon in order to do the praised "ingenious lab trick for abridging quantum and mechanist worlds".

– It is in this universe that Argon happens to be the only gas with the affinity ("particlequake" energy output) absolutely matching my (our universe's) gravitational resonance ratio, of 369.2, found explicitly (as an equation) in the paper I sent to him.

– It is in this universe that there exists no third physical quantity with the value of 369.2 whatsoever.

– It is in this universe that he hasn't offered a theory for his "ingenious lab technique" with which he beats to the ground: Einstein, Feynman, Dirac, Oppenheimer, Schrodinger, Mickey Mouse, et al., but nonetheless got only a share of Nobel prize – hmm, what would jury say…

– It is in this universe that Brian Josephson agreed in an email debate with me (after a few days though — perhaps after I exhausted him?): "I accept that it is a remarkable coincidence" (though Brian too had a hard time accepting how Wineland could have confused units and dimensions like no freshman would have).

Oh well, it's all "only" forensic evidence after all, isn't it. And it applies to our universe only.

HOWEVER: I was actually able to demonstrate Multiverse/Hyperverse mathematically precisely BECAUSE I lost this universe's units on G at the outset since, reasoned I, Newton had anyway attached those units to G only in order to close his own (our universe's) physics mathematically, so they have no multiversal physical meaning whatsoever! (Remember that Multiverse was the starting physical hypothesis).

So I showed that physical units aren't all that multiversal after all, meaning multiverses of Type II (or whatever pleases Max) – are real.

Meaning: whatever ratio you take (such as Argon affinity of 369.2 kJ mol–1, and compare it to G w/o its bogus units, you'll end up with SOME system of equations, some regularity, because NO UNITS ARE REAL especially when G is involved. Whatever equations you arrive at in the aforesaid way (I did it for Earth-Moon system; Wineland used that concept and did it for particles), you'll arrive at some closed mathematical form.

Now, THAT's the Hyperverse of multiverses we live in. And Wineland figured it out before Brian or anyone else did. For that alone he deserves a sole Nobel Prize — but in some other universe where plagiarizing most of someone's discovery is praised and rewarded. In this universe however, and in the USA especially, one normally ends up behind bars.

48. **Frank Borg**
April 21, 2014

BICEP2 vs quantum gravity … I also find this to be one of the more intriguing issues. It seems that some sort of QGR calculations are involved in two ways:

1. The metric is influenced by the fluctuations of the inflaton field (phi): G = < T(phi) > ; that is, one puts the quantum average of the quantum field stress energy tensor on the RHS of Einstein's field equations (semiclassical case);

2. In the linearised version of the Einstein's field equation one expands the metric in terms of creation/annihilation operators as one do in QED etc. These are then treated in a similar way as one treats the phi-operator in order to calculate gravitational wave fluctuations via quantum averages.

So no *genuine* QGR input really (not surprising since we are not there yet), but if the scalar/tensor evidence holds up it could be a tantalizing hint about gravitons (for linearized GTR); perhaps the only way we will ever get some *experimental* grip on them. Neither type of calculation is based on some consistent theoretical framework – it is basically the best one can do at present (like Bohr's pre-QM atom model) and if they pan out it will be short of a miracle …

For an authoritative account of the fundamental calculations behind the CBR stuff I recommend S Weinberg's Cosmology (2008). Another good and a wide/deep sweeping account is Peter & Uzan, Primoridal Cosomology (2009, 2013). I also looked up Kiefer's Quantum Gravity (1.ed, 2004) and he does indeed single out the CBR as one of the few possible vistas where to experimentally discover QGR effects. By the way, the idea of expecting effects of gravitational waves in the CBR goes back to a paper by Starobinsky in 1979.

A Brief History of String Theory

March 26, 2014
Categories: Book Reviews

On the long plane flight to Italy I had the chance to read the recently published A Brief History of String Theory: From Dual Models to M-theory by philosopher of science Dean Rickles. The book deals with the history of string theory, beginning with its origins in the Veneziano model of strong interactions, and ending in the mid-90s with M-theory and the "Second Superstring Revolution". It's a good serious scientific history, explaining in technical detail exactly how the theory developed, with good explanations of the high points of crucial papers, together with some of the story of how they came about. While I've spent a lot of time in the past reading about much of this history, I learned a lot from the book, about string theory as well as other topics in particle physics that interacted with it. I'm strongly of the opinion that if you want to really understand a subject, you need to understand its history, so anyone who wants to really master string theory would do well to spend some time with this book.

There is something quite unusual about this though as a work of history, since while this subject is 45 years old, it is quite unclear how to evaluate its significance as science (arguments seem to still rage about this…). I can't think of any other topic in modern science which has been the subject of such intense activity, with no one sure of how to evaluate it nearly a half century later. More succinctly, is this the history of a brilliant insight into the physical world or is it the history of a misguided failure? In the introduction Rickles worries that historians of science will find it too "Whiggish", but maybe more of a problem is not knowing what the right final end-point will be. To a large degree Rickles adopts the point of view of many prominent string theorists, that this is a success story, whatever its problems might seem to be. My own point of view is different of course, and I'd claim that in recent years the viewpoint of the physics community as a whole has shifted, with this looking less and less like a success story and more and more like something else.

I can't do justice to all that's in the book, but for personal reasons I do want to focus on one part of the story and how Rickles treats it, one where I have a significant disagreement with him, and one that points out well the basic problem faced by this kind of history. The issue is the 1984 "First Superstring Revolution", generally dated to the Green-Schwarz anomaly cancellation calculation of that summer. Rickles does a good job of explaining the background of this. He emphasizes that this didn't come out of nowhere, that the issue of the problems posed by such chiral anomalies had been identified by Witten and others as of great importance in constructing unified theories.

What should one make of the significance of the discovery by Green and Schwarz of anomaly cancellation for SO(32) in type I string theory? The story of string theory as a success is that this convinced theorists that string theory was a very promising road to unification and unleashed a revolution. But I remember this differently (I had just finished by Ph.D. at Princeton and taken up a postdoc at Stony Brook). The idea that anomaly cancellation predicted a specific gauge group and dimension was obviously attractive, but the fact that the prediction was for the wrong gauge group (SO(32)) and the wrong dimension (10 space-time dimensions) looked to me (and many others) like a deadly problem. The flurry of activity leading to the heterotic string, E8, and Calabi-Yau compactifications was an impressive use of mathematical technology, but there was no sign of the Standard Model coming out of this in any natural way. It looked all too likely that this wasn't explaining anything about particle physics, just parametrizing the choices of possible unified gauge theories in a very complicated way. Yes, there was also a theory of gravity there, but it was not obviously an attractive one.

Earlier today I was watching the video of John Schwarz's general talk about string theory at the Simons Center yesterday. Schwarz gives much the same promotional talk he and other have given many times over the last 20 years (with little change since the addition of M-theory), making claims for success of exactly the sort that inform the point of view of the Rickles book. At the end of his talk, Dusa McDuff asked about parity violation in other parts of M-theory and Schwarz explained that the original 1984 motivation from Type I anomaly cancellation has long been abandoned:

> Nowadays we have enough tricks up our sleeve that we can get parity violation out of anything.

There are now all sorts of ways of getting "string vacua" that might give a unified theory, many not using anomaly cancellation. The supposed breakthrough of 1984 is looking much more like a red herring, and the question of historical interest shifts from "how was this brilliant breakthrough accomplished?" towards "why did so many people not realize this obviously wasn't going to work?"

Rickles on page 162 explicitly takes issue with the comments in my book emphasizing the important influence of Witten at this point, mischaracterizing me (and Smolin) as claiming it was "almost as if that community had no decision-making power of its own". This is far from any thing I think or wrote (a big section of my book explained the excellent reasons why any sensible person would take Witten's opinions seriously). What I wrote was

> By itself the news that gauge anomalies cancel in a version of type I superstring theory would probably not have had so dramatic an effect on the particle theory community, but the news that Witten was now devoting all his attention to this idea spread among theorists very quickly.

and I still think that's quite accurate. Ten years ago I wrote about this in detail on the blog (see here, here and here), including a first-hand version of the story from Larry Yaffe, who was at Aspen and was the one who told Witten about the Green-Schwarz result. He reports:

> Concerning reaction to the Green-Schwarz result, my recollection is that there was relatively little immediate buzz about it at Aspen. John had a fairly diffident style of presentation, and I don't recall anyone jumping up and saying 'this will change the course of physics!'. As best as I can reconstruct my own reaction, it seemed like a technically slick calculation and a nice result but it wasn't, of course, addressing any of the conceptually hard questions about quantum gravity, and it seemed very far removed from the practical concerns of particle physics.

and

> I think the speed with which others in the particle theory community jumped into string theory had a lot to do with Ed's involvement and proselytizing, but I expect that even without his involvement, interest in string theory would have steadily grown, albeit slower.

Rickles ends his detailed history with M-theory, with the latter part of the book summarizing the recent history, again pretty much from the point of view of a string theory proponent, one on the defensive. I think he gets the multiverse issue quite wrong, characterizing the anthropic multiverse vs. search for a unique unified theory dichotomy among string theorists as:

> It is more likely that the two stances will continue in parallel, as they appear to have done for some time, defined more by the personalities of those adopting them than by the physics.

I don't think this has anything to do with personalities. The problem is that the anthropic multiverse point of view predicts nothing, and those unhappy with it are not unhappy because they have a personality that leads them to want or believe in uniqueness, but because they're aware you need to make predictions to be doing science. But, one can't expect historians to get right current events…

"Yes, there was also a theory of gravity there, but it was not obviously an attractive one."

what makes this "not obviously an attractive one" ?

2. **tt**
March 26, 2014

complicated is not attractive

3. **Philip Gibbs**
March 27, 2014

Was "attractive" an intentional pun?

4. **Aleksandar Mikovic**
March 27, 2014

Dear Peter,
I essentially agree with your opinion about the string theory history, and that Witten's involvement was very important. I was a graduate student at U. of Maryland in the period 1984-1989, and I did my PhD in string theory, with Warren Siegel, and the main reason I studied string theory was its claim that it can solve the problems of perturbative quantum gravity. This was based on the Mandelstam's work on the finiteness of the superstring theory. The fact that satisfactory string phenomenology was not materialising was not such a big concern for people who were more interested in quantum gravity, because everybody thought that string phenomenology would eventually work out, since there was a lot of compactification possibilities. But, I remember R. Mohapatra, a prominent particle phenomenologist, saying in 1988 that it was impossible for him to get Standard Model out of string theory.

The reason why many people were, and still are interested in string theory is that it is a nice paradigm for a quantum gravity theory, so that for such people the fact that string phenomenology is not still giving results, is not important. I switched from string theory to canonical quantum gravity in the early 90´s, because of string theory inability to address non-perturbative quantum gravity and the absence of a background metric. The second string revolution in mid-90´s made a progress with the problem of non-perturbative quantum gravity effects, but the absence of a background metric independent formulation of string theory is the reason I am exploring LQG and spin foam formulations of quantum gravity.

March 27, 2014

I was at Harvard from 1984-1986 and saw Schwarz speak in 1985 I think. The general mood of the older theorists at Harvard was not that positive towards string theory, but that it was probably worth looking at. Sidney Coleman said I believe that since Witten was looking at it, and the math was insanely complex, there was no point in any one else looking at it. However, the younger guys were looking for things to do and it was pretty clear that GUT and BSM model building a la Georgi was not that productive anymore. There wasn't any other really hopeful direction. Condensed matter seemed maybe more productive / interesting. People thought foundational navel gazing was a waste of time. No experimental results. Jaffe maybe had one student doing constructive field theory. Lots of theory people on sabbatical. The issues seem the same today as then, essentially. The telescopes and satellites seem like the way forward today.

6. **Peter Woit**
March 27, 2014

I don't want to start another string theory rules/sucks as a theory of QG debate. The point of my comment was about how things looked to most theorists in 1984: the idea of doing QG via string theory had been around for about ten years and was being promoted by Schwarz and a very few others. No one was buying. Like most people in the field I took a look at this and decided it wasn't worth learning more about. It seemed to be a very complicated way of getting gravity. What got people interested post-1984 was the unification angle, that this would not just give gravity, but unify it with the Standard Model.

7. **M**
March 27, 2014

A nice tradition at CERN is the annual Xmas recital of the theory division, with funny and sometimes deep jokes about latest developments. In the 2001 edition, young string theorists were represented as talibans who talked by quoting sentences from the book by Witten. Privately, young string theorists openly talked about the real situation of the their field.

8. **Kavanna**
March 31, 2014

Being a graduate student in particle theory in the 80s, it was hard to escape the impact of string theory. But unlike later, it wasn't a suffocating monopoly. Lots of other things were going on, like accelerator phenomenology and the burgeoning of astrophysics and cosmology in the Heavenly Accelerator.

The fatal blow for the field was the cancellation of the SSC in late 1993. Particle phenomenology ended, except for some specialized areas. From that point, string theory became truly the only game in town for fundamental theory, unless you were lucky enough to be working in astro/cosmo-particle physics, where real progress was and is being made.

On the West Coast, the impact of the anomaly cancellation calculation took into 1985 or even 86 to be fully felt. It was emphatically viewed as a particle/unification thing, not QG. String theory never lived up to the QG hype, of course, as it's not coordinate-independent and can't be extended beyond second order. After Kaplunovsky and others demonstrated the vacuum problem, the bottom fell out of string theory for a while. Its resurrection in the 1990s had a heavy component of marketing, through the NYTimes science section, for example. What actually happened and what was claimed were two quite different things. Theorists were constructing field theories with symmetries and other properties conjectured to arise from a conjectured "M theory." No progress was being made toward a super-unification any longer, and the claims about gravity were a shell game. It was then and after that talk of "sociology" and the tyranny of Princeton became standard, in private, of course. It took nearly another decade and a half for Peter, and Lee Smolin, to say publicly what had been obvious to many for years: string theorists had developed their own cultish version of political correctness, one that bordered on pseudoscience and drove a deep wedge between string theory and the rest of physics.

… and who is this supreme being named SUSY? What's she like? Sounds as if she's into astrology herself. I prefer SUGRA in my QF-T. (Sorry, bad theory jokes from the early 80s.)

10. **Peter Woit**
    April 4, 2014

    CU Phil,

    Thanks! I hadn't seen that. The Ellis, Kragh and Smeenk articles in particular do a very good job of explaining the problems of the "multiverse" and of "eternal inflation".

    One thing they don't much deal with (although Kragh does to some extent) is the way the anthropic string theory multiverse business emerged out of the failure of string theory. Physicists discuss this seriously, but it's very clear they wouldn't do so if the idea had emerged in some other way. Specifically, back in 1984, if Witten or any one else had promoted string theory using the anthropic multiverse justification people would treated this as pretty much crazy and obviously a waste of time. It was only after a generation of theorists had been sucked into spending decades working on this that some could be convinced to take this seriously.

11. **mathphys**
    April 9, 2014

    It was Witten's short preprint that appeared at the same time as the Green and Schwarz anomaly cancellation paper, or even right before it, and that used the words "In a stunning development" to describe the result of Green and Schwarz, that started the first superstring revolution. No doubt about that. No one had a clue what the anomaly cancellation result meant or why it was important.

    Incidentally, it was Witten's talk on string dualities at the annual string conference in 1995 that started the second revolution as well.

Sheldon Gives Up On String Theory

April 1, 2014
Categories: Uncategorized

Ten years ago I wrote here about the news that Witten had finally given up on string theory. Today I just heard a similar but even more dramatic rumor: next week's episode of *The Big Bang Theory* features string theorist Sheldon Cooper deciding to give up on string theory, realizing that he has been wasting his time working on it for 20 years. Evidently the framing of the story is that string theory has been a bad relationship for Sheldon, now he's grieving and trying to learn how to get over such a breakup.

In other April 1 news, it seems that some joker at MIT has scheduled an April Fool's Day colloquium there on Our Mathematical Universe, featuring Max Tegmark. The conceit is that Tegmark will explain how the BICEP2 results provide "smoking gun" evidence for the ideas in his book about mathematics (his Mathematical Universe Hypothesis).

Update: For more April 1 fun, Steve Landsburg has Many Many Worlds, a review of Tegmark's *Our Mathematical Universe* which describes the author as "a towering figure in intellectual history".

Update: For some reason, some people didn't believe the news yesterday in this posting. For a link with details, see here.

   April 1, 2014

   It's a nice day today. Spring has returned early to Geneva area this year; the sun, the flowers and the easy time safely away from major conferences make people at CERN feel light-hearted and good about life. Spring clothes and short sleeves are taking over, so I wonder if every t-shirt is going to come out of the wardrobes and be proudly worn by its owners.
   It's a nice and light-hearted day, and as an added bonus everything that follows is real…

   A couple of months ago a post of yours let us know that Ellis "is not giving up on supersymmetry". I wonder whether this could have been kind of an answer to the statement featuring on one of the latest t-shirts in his famous collection. The statement being, "I searched for susy for twenty years and all I got was this stupid t-shirt". (http://i61.tinypic.com/n67xc4.jpg)

   To be honest, he didn't select this one himself. It features on five t-shirts offered to five prominent members of CERN and LHC experiments. Some of them have shaped collaboration policies according to their personal favourite theory, even as Higgs was being found, others went as far as e.g. to claim that the important part about Higgs is not giving mass but constraining I'll-be-happy-to-be-reminded-what which is indirectly related to guess-which-theory.

   Offered by whom? Well, simply susy-agnostics, I guess 🙂

   It often happens that people turn to religion out of fear of death, of the unknown, or a wish of afterlife. It' understandable. In all these cases it can provide a sense of explanation and understanding of the world. Turning to the religion of the perpetually unknown, on the other hand, seems to be a privilege unique to preachers of truth-seeking.

   you must have had a big smile on your face when you deliberately posted this on April 1st; brilliant timing!

8. **frp**
   April 2, 2014

   I was at Tegmark's talk. It was an overview of inflation, there was no mention of multiverses or the MUH, other than a one sentence comment that inflation might imply more spacetime exists beyond our horizon. One interesting comment he made is that the (Hot) Big Bang should be defined as the hot state of the universe just after inflation ended. With this definition, inflation happens before the Big Bang. I wonder if this wording will catch on. To me, the Big Bang has always meant the hypothetical curvature singularity at t=0, which (if it exists) is before inflation. I think this reflects an unfortunate difference in terminology between cosmologists and general relativists.

9. **Chris Kennedy**
   April 3, 2014

   I also heard that next season Sheldon & Amy will have twins. However Any becomes upset with Sheldon because he doesn't want to recognize them as individuals or give each twin a name, rather he will only refer to them together as Cooper Pairs.

10. **S**
    April 3, 2014

    You might enjoy this article, wherein a medieval scholar's apparently-not-awful physical reasoning is coopted to suggest that, if you merely assume he understood naturality and anthropic reasoning, he discovered the multiverse!

    http://www.huffingtonpost.com/2014/04/02/multiverse-philosopher-middle-ages_n_5075959.html

11. **Kavanna**
    April 3, 2014

    Well, Sheldon throws in the brane — what do you know? String theory really has been one long bad date.

    If they're Cooper pairs, can be they canonically transformed back to an unpaired state? Will they have Primordial Soup for dinner?

    And, while we're at it, the Fermilab April Fool's Day issue is hysterical. I love the Eye of Sauron on top of the tower. Maybe that's who should be funding HE research.

    (Coming soon: some impressions of the big MIT talk tonight on BICEP2. Tegmark and Guth spoke, but there's a lot more. Doesn't look good at all for strings, BTW.)

12. **Chris Kennedy**
    April 4, 2014

    Kavanna,
    Even if the pairs transform back to an unpaired state, if one twin grows up to operate a high-speed rail and the other becomes an orchestra leader, they would still remain (in a sense) super conductors.

Quick Links

April 5, 2014
Categories: Uncategorized

Just time at the moment for some quick links. I'll start with some math news, since there hasn't been much of that here recently:

- Matt Baker has the sad news here of the death of Berkeley mathematician Robert Coleman recently, at the age of 59. Coleman was a leader in the field of p-adic geometry, and managed to continuously do important research work despite a long struggle with MS. He was both highly influential and well-loved, be sure to read the comments which contain appreciations from many different mathematicians.
- Also at Matt Baker's blog is a summary of recent work by Manjul Bhargava and collaborators on the average ranks of elliptic curves. This work shows

  > at least 20.6% of elliptic curves over **Q** have rank 0, at least 83.75% have rank at most 1, and the average rank is at most 0.885…

  and

  > at least 66.48% of elliptic curves over**Q** satisfy the (rank part of the) Birch and Swinnerton-Dyer (BSD) Conjecture (and have finite Shafarevich-Tate group)

  Conjecturally

  > 50% of elliptic curves have rank 0, 50% have rank 1, and 0% have rank bigger than 1, and thus the average rank should be 0.5. (And conjecturally, 100% of elliptic curves satisfy the BSD conjecture. :))

  Until recently

  > the best known unconditional results in this direction were that at least 0% of elliptic curves have rank 0, at least 0% have rank 1, the average rank is at most infinity, and at least 0% of curves satisfy the BSD conjecture.

  so this is dramatic progress.

- I've yet to hear any solid rumors about who will win the 2014 Fields Medals, to be announced at the ICM in August. To my mind, Bhargava is a leading candidate. Others one hears discussed are Jacob Lurie (a question is whether he has a big enough theorem, the one he's talking about here may not be finished). Often mentioned names whose work I know nothing about are Artur Avila and Maryam Mirzakhani.
- Another area of huge progress in mathematics over the past year or so has been work of Peter Scholze, who is another excellent Fields Medal candidate, but one young enough that this might get put off until 2018. I've been hoping to understand his results on torsion classes in Langlands theory well enough to say something sensible here, but I'm definitely not there yet, maybe some day in the future. In the meantime, watch his extremely clear lectures at the IAS (here, here and here) as well as the talks at this recent MSRI workshop.
- The math community award structure is for some reason prejudiced against the middle-aged, with the high-profile prizes going to the young (Fields Medals) and the old (Abel Prize). This year's Abel Prize went to Yakov Sinai, and again, I'm in no position to explain his work. However Jordan Ellenberg was, and there's video here of the prize announcement, including Ellenberg's talk about Sinai's work. In the past Timothy Gowers gave such talks, with not everyone happy about this. No news yet on whether Sowa will change his blog name to Stop Jordan Ellenberg! !!!.
- Leila Schneps is trying to raise funds for an English translation of the 3rd volume of Winfried Scharlau's German language biography of Grothendieck. Go here to contribute, I just did.

Turning to physics news:

- the recent BICEP2 data is still attracting a lot of attention. Initial news stories were often dominated by nonsense about the multiverse, more recent ones are more sensible, including Adrian Cho at Science Magazine, Clara Moskowitz at Scientific American, and a George Musser interview with Gabriele Veneziano.Yesterday Perimeter hosted a workshop on implications of BICEP2. The theory talks I looked at didn't seem to me to have much convincing in them, except that Neil Turok acknowledges that this kills off the Ekpyrotic (bouncing brane) Universe and he's paying off a $200 bet. For some reason, Nima Arkani-Hamed now seems to speak at every single fundamental physics meeting, so was also at this one. More interesting were the experimental talks, with new data soon on its way, including Planck results planned for October, possibly measuring r to +/-.01 (BICEP2 says r=.20).
- For some perspective on inflationary theory, CU Phil in recent comment section points to a new volume on the Philosophy of Cosmology. It includes some great articles putting multiverse mania in context by George Ellis and Helge Kragh, as well as an enlightening discussion of the issues surrounding inflationary theory, especially "Eternal Inflation", from Chris Smeenk.
- For the latest news about LHC results coming in from the Run 1 dataset, see this report from the Moriond conference.
- Finally, physics continues to inspire frightening movie projects, see here.

Comments

1. **katzeee**
   April 5, 2014

   "possibly measuring r to +/-0.1 (BICEP2 says r=.20)"

   does this mean r might be (if this rumor is true) 0.00+/-.01 or is this just a comment on Plancks sensitivity being +/-0.1? thx for answering.

2. **Peter Woit**
   April 5, 2014

   katzee,
   I think one of the speakers from Planck showed a plot of projected sensitivity, showing the possibility of measuring r=0.05 to +/- .o1, and I'm just assuming the accuracy number is similar for possibly larger r as claimed by BICEP2. This number does not claim to include systematics, so the likely Planck number will not be anything this accurate. It sure sounded though that if BICEP2 is right about r=.2, Planck should definitely see this.

3. **Syksy Räsänen**
   April 5, 2014

   Peter:

The official statement from the Planck team is that if the BICEP2 signal is due to inflationary gravity waves, Planck has the sensitivity to see it, but that it is not clear whether they will be able to treat the foregrounds well enough to disentangle the cosmological signal. So at the moment, Planck is not claiming that they will be able to either confirm or rule out the BICEP2 result.

4. **JG**
April 5, 2014

Skysy

If they can't then it will be highly embarrassing, for the cost of the project, to not enable a better measurement than BICEP2. Sure they're doing the whole sky and they have also focused on instensity measurements as well as polarization, but come on, their equipment is in *Space* – at very high expense.

And why has the result been so delayed – is it to prevent a Nobel award this year to the rival team? (lol) – originally Planck said polarization results would be in early 2014, now we getting quoted October and even November – will they actually publish by Christmas? I hope Planck won't be another Gravity Probe B, where publication of the results was delayed for ages and eventually not completely compelling.

5. **Shantanu**
April 5, 2014

JG gravity probe b got delayed by 40 years . When it was launched, no one really
cared one way or the other about the result.

6. **Syksy Räsänen**
April 5, 2014

JG:

The official date for releasing Planck polarisation results is October. The hard deadline is December, when there will be two conferences about the Planck results.

Planck was never optimised for polarisation, neither from the point of view of the detectors nor of the (obviously related) sky scanning strategy. Planck was designed to give the best possible measurement (within cosmic variance limits) of the temperature anisotropy of the CMB. They have delivered this, as planned.

I don't know why Planck was originally not designed with more view towards polarisation (remember that the satellite was designed as a competitor, not as a successor to WMAP), but one reason may have been that it wasn't expected that there would be anything interesting to see at this level. (Even on the website of the South Pole Telescope, which saw B-modes from lensing in July 2013, it is noted that there isn't much reason to expect inflationary B-modes with an amplitude higher than the B-modes from lensing except "in the most optimistic inflationary models".)

Also, treating the foregrounds for the full sky is a lot more difficult than for the relatively clean patch chosen by BICEP2, and this has been the main reason for the delay in the release of the polarisation data.

Note that confirming the BICEP2 data will require Planck measurements of the foregrounds in the sky patch BICEP2 looks at. The BICEP2 team notes in their paper that the main uncertainty in the foregrounds is the lack of a polarised dust map, to be delivered by Planck. (Though the foregrounds are expected to be clearly smaller than the signal they see.)

7. **Peter Woit**
April 5, 2014

Thanks Syksy,

I was going by the Douglas Scott talk at Perimeter, see
http://pirsa.org/displayFlash.php?id=14040122
At around 21 min he shows a plot of simulated data for r=.05, from some sort of semi-public not well known Planck document and that's where the +/- .o1 number comes from. He does explicitly say this is for no foreground. Maybe I'm over-interpreting, but it seems like he wouldn't be showing that plot and devoting a lot of time to it if it didn't have some relation to what they might have. If they were getting killed by the foreground, I'd expect more a talk about how difficult the foreground problem is (that wasn't something he emphasized).

8. **JG**
April 5, 2014

Thanks Syksy (sorry for mispelling your name above)

yes, I understand that one main contribution of Planck's polarization data will be an accurate dust map to enable BICEP2 (and other experiments) to improve their data analysis.

I wonder if Planck discovers a *much* more accurate value of r than BICEP2's (which is eventually confirmed) – who will take more credit historically – how far away from 0.2 will the final experimentally confirmed value have to be for BICEP2 to lose significant credit?

9. **David Nataf**
April 5, 2014

There's nothing embarrassing. The Bicep2 result actually requires Planck results in order to work, you can look up their probability contours, they say "Planck + Bicep2", not "Bicep2".

Aside from that, Planck has measured many other things. It's lowered the value of Hubble's constant and of the dark energy density, and it's giving us more precise maps of interstellar emission.

10. **Ian**
April 6, 2014

Penrose expresses skepticism, not about BICEP2 results, but about their interpretation as evidence for the Big Bang.
http://www.sciencefriday.com/segment/04/04/2014/sir-roger-penrose-cosmic-inflation-is-fantasy.html

11. **Sesh Nadathur**
April 6, 2014

My understanding is that the main problem for Planck is not foregrounds but the scanning strategy. To measure polarisation you need ideally to have two otherwise identical detectors sensitive to orthogonal polarisations pointed at the same part of the sky, or to rotate a single detector through 90 degrees and re-image. Planck attempts the second option by changing the detector angle for successive scans of the same sky region.

Unfortunately their scanning strategy is such that for some sections of the sky the scans are not performed with a full 90 degree rotation but something less than that (apparently this had something to do with this strategy optimising the rate of data transfer back to earth, which was necessary for the high-precision temperature measurements). So for those sections their ability to decompose the polarisation components is limited. Obviously this impacts their ability to extract the large-l polarisation signal, which is unfortunately where the gravitational wave signature will be.

In terms of foregrounds I would have thought Planck should actually be better placed than BICEP, because it observes the sky at so many different frequencies, and therefore is better able to determine what the actual foreground is (BICEP rely on assumptions about the foreground).

12. **Syksy Räsänen**
April 6, 2014

Peter:

I checked that part of the presentation, and I don't think there's anything there other than the official Planck position: they have the sensitivity. The Planck polarisation analysis is ongoing, showing a simulated plot like that doesn't imply that this is what they're actually seeing.

Sesh:

The scanning strategy affects the sensitivity, but according to Planck, sensitivity is not the problem. Or have I misunderstood something?

13. **JG**
April 6, 2014

Seth, that explains it very clearly.

Does anyone know if the delay in publication of the polarization map has been influenced by BICEP2, or was the delay announced previously?

Note that the original release date was stated as "early 2014" in March 2013 after the release of the temperature map, see Notes for Editors

"The next set of cosmology data will be released in early 2014"

14. **JG**
April 6, 2014

I mean Sesh 🙂

15. **David Nataf**
April 6, 2014

"Next set of cosmology data" does not necessarily imply results on all conceivable measurable parameters, does it?

It will be curious to see if their value of Hubble's constant remains 9% smaller than the value determined from standard candles.

16. **Sesh Nadathur**
April 7, 2014

Syksy:

I don't know for sure, obviously, but I was extrapolating from the fact that the reason Planck have not already released their polarization data is because they are having a hard time getting rid of systematic effects at large-l. The effect I mentioned above would affect large-l reconstructions, so I put two and two together and guessed this would be the main problem.

Since then I've looked again at this presentation which suggests again that the problems are to do with systematics at large-l. Depending on how exactly the "gain variation", "bandpass missmatch" and "calibration mismatch" arise perhaps my earlier simple explanation was wrong – but it does appear to be something to do with the scanning strategy that is causing leakage from temperature to polarization at large scales.

Note also that even BICEP have to beat down T->B leakage by a factor of ~100 before they can extract a BB signal. Since Planck have seven different frequency bands and can already remove foregrounds so well from the temperature maps it just seems unlikely to me that foreground removal is the main issue.

17. **David Nataf**
April 7, 2014

Sesh,

I doubt that foregrounds due to astronomical dust are calibrated at the most ideal precision. If it were the Planck maps would be able to use the entire sky in their analysis, instead they still need to mask parts of the Galactic plane even with their seven bandpasses. Away from the plane, the error will still be present, though smaller by a significant factor.

Further, another astrophysical foreground (background?) to worry about is weak lensing distortions. That I know much less about.

18. **Sesh Nadathur**
April 7, 2014

Sure, I understand that. But Planck sees the part of the sky that Bicep saw as well as the galactic plane and all other regions. So if the Bicep result is not due to foregrounds, foregrounds should not prevent Planck from confirming it using at least that patch of sky. Conversely, if Planck discovers foregrounds are unaccountably large even on that patch of the sky, then Bicep didn't really have a detection after all. So I still don't see how the foreground problem can be worse for Planck than Bicep.

19. **piscator**
April 7, 2014

A couple of comments.

As some members of the BICEP team are also on Planck, it seems highly unlikely that whatever the official status of published foreground maps, the BICEP team do not have some idea of what the foregrounds are going to be. And no-one I have heard from Planck has said that foregrounds are their principal worry about the BICEP result (leakage of E -> B is what I hear more commonly).

@David: Planck does not measure H_0. They measure the CMB, and by extrapolating the CMB forward here using LambdaCDM they make a prediction for the value of the Hubble constant in the local universe. But this is a model-dependent prediction, not a measurement.

For example, with an extension of rLambdaCDM to include Neff, both the Planck-BICEP tension on r and the Planck-H0 tension go away.

20. **Ben Gold**
April 7, 2014

Sesh,

Planck observes the same patch as BICEP, but they do not observe *that* patch with the same sensitivity as BICEP. Planck effectively gains sensitivity by measuring many BICEP-sized patches across the sky – but many of those are much more heavily contaminated by foregrounds.

Also, removing foregrounds from temperature maps is much easier in many ways than in polarization – the signal/foreground ratio is higher, for one. Polarization is a (pseudo)vector field, so there's more information there than in temperature maps, thus the temperature maps tend not to make very good templates, either.

21. **Kavanna**
April 7, 2014

Having seen some of these guys in the flesh at MIT's big evening public lecture last Thursday, I should briefly report on the event. Little mention of the "multiverse," BTW. The evening's MC, the MIT theorist Ed Farhi, specifically banned talk of multiverses until the question session after the last talk, which I couldn't stay for. Here's the flyer:

http://lsc.mit.edu/schedule/2014.2q/desc-physics.shtml

The speakers were Guth (inflation theory), Hughes (gravitational waves), Kovac (BICEP2 co-lead), and Tegmark (general implications). All the talks were excellent, especially Guth's. I had forgotten what a great speaker he is. He used no equations and barely any jargon beyond what undergraduate science students could understand. His only real moment of weirdness was talking about that funny inflationary equation of state, p = -rho, leading to gravitational repulsion.

Kovac's summary of the BICEP2 instrument, methods, and results was impressive and should silence most of the skeptics and critics. While some question remains open about the foreground corrections, the checks they put their experiment
through were exceptional. More to come with BICEP3, all part of the Keck program.

(This is one of those experiments where it's *foregrounds* you want to eliminate, not backgrounds.)

Tegmark gave a nice summary, including the retro-surprise of how the BICEP2 results, with the inflationary scale at 2*10^16 GeV, take us back to the original and simplest inflationary models of the early 1980s, based on GUTs. He showed in passing just how many inflation proposals are ruled out, including all known string versions. String-inspired inflation has a hard time getting the inflation/ Planck hierarchy to be 1/600 or whatever and getting "r" (tensor/scalar) to be larger than 10^(-4). Only string-inspired axion monodromy is larger, but at 10^(-3), still too small. While Tegmark didn't dwell on it, things look bad indeed for strings.

Given the quality of BICEP2's measurement, it's unlikely that they're simply wrong relative to Planck. The polarization limit inferred by the Planck team is an indirect upper limit, with some mild model dependency. For my money, I would bet that Planck's interpretation is just off. As a number of commenters here have mentioned, it's not an instrument designed for polarization measurements.

22. **Anon**
April 7, 2014

If Tegmark said that about string theory, he is incorrect.
He and others should be more careful in their claims.
Axion monodromy in string theory gives r in a range from order 10^{-2} to over .1. It does not give r of order 10^{-3}. Where do you get that?

There is on the other hand no direct connection to GUT physics, which has less evidence going for it than inflation at this point.

23. **JG**
April 7, 2014

David, that's a strange thing to say: *"Next set of cosmology data" does not necessarily imply results on all conceivable measurable parameters, does it?*

The statement is from Planck's notes for editors around the world who may not all be scientifically literate to understand "polarization map" (or be concerned with the details) – of course they meant that the polarization data was due for release "early 2014" – the interpretation of the statement is unambiguous.

Anyway I don't want to make a big deal about it, just wondered if the BICEP2 announcement came as a bit of a shock to the Planck team and caused the delay to publication of their results to October.

As for Tegmark claiming r=0.2 is bad for String Theory – well a bit strong perhaps (ask Eva Silverstein)) but we all know what the String people would be saying if BICEP2 had ruled out a high value of r – they would be no doubt be claiming another "prediction" of ST.

24. **Kavanna**
April 8, 2014

Tegmark didn't say it so strongly, just mentioning various theories in passing, that the simplest potentials, with the right hierarchy of scales, were favored and "others" were disfavored. He had a table up that I almost missed and didn't get a good look at.

The axion monodromy is the only string-based inflation model that comes close, at least that I'm aware of. The original model predicted "r" about 10^(-3), but as high as 10^(-2,-1) is possible from some more recent papers. It's stretch to get it to match the BICEP2 result.

Generally, the BICEP2 result implies a large field excursion ~few x Mplanck and vacuum energy scale ~10^(16) GeV. The latter scale is dead-on for GUTs.

25. **Kavanna**
April 8, 2014

Some more digging: watch Will Kinney's Perimeter talk from March:

http://pirsa.org/displayFlash.php?id=14030116

At about 57 min, he mentions the more recent "large r" axion monodromy, but points out that it's strongly disfavored by the combination of BICEP2 and other data. Other string-based models give much smaller "r" values, even less in agreement with BICEP2 and other data. Kinney stresses the critical empirical pressure that high "r" places on theories (and theorists). He likes the "shift symmetry" models, of which axion monodromy is one (which is why it comes close to working).

The really important thing for the next BICEP measurement is not agreement with Planck, but getting a broader range of multipoles.

26. **Cormac O'Raifeartaigh**
April 8, 2014

On a slightly different topic in your post, Peter:
The volume you mention on the philosophy of cosmology looks very interesting, lots of no-nonsense physicky papers from physicists like George Ellis. The volume is actually Issue 44 of the journal 'Studies in History and Philosophy of Science Part B: Studies in History and Philosophy of Modern Physics' . This journal generally features contributions from philosophers and historians more than physicists, as far as I'm aware, but there's some serious reading in Issue 44, thanks for that…

27. **Anonyrat**
April 8, 2014

Regarding an old post on this blog about the film "The Principle"
http://www.math.columbia.edu/~woit/wordpress/?p=6624
we now have news, that many of the participants feel that they were duped into participating in it, including Star Trek's Kate Mulgrew.
http://thinkprogress.org/culture/2014/04/08/3424505/kate-mulgrew-duped/

> Tuesday morning, Dr. Lawrence M. Krauss of Arizona State University tweeted that he had not consented to participate in the film and strongly opposed its message: "For all who asked: Some clips of me apparently were mined for movie on geocentricism. So stupid does disservice to word nonsense. Ignore it."
>
> Two other experts used in the film told ThinkProgress that they were mislead into participating. Dr. Max Tegmark of the Massachusetts Institute of Technology explained, "I was told that this would be a science documentary by independent filmmakers who wanted to increase public appreciation for science. I should clearly have asked for more details in advance! These geocentric arguments are about as unscientific as things get."
>
> Dr. George Ellis of the University of Capetown in South Africa said that the film was "not presented" as geocentrism to him. "Obviously I don't agree. Not sue how anyone can hold that view these days. Must live in a timewarp. Like Lawrence, my advice is to just ignore. There is no point whatever in responding – it just gives the film recognition and publicity."
>
> Tuesday afternoon, Mulgrew posted on Facebook that she too was duped into participation:
>
>> MULGREW: I understand there has been some controversy about my participation in a documentary called THE PRINCIPLE. Let me assure everyone that I completely agree with the eminent physicist Lawrence Krauss, who was himself misrepresented in the film, and who has written a succinct rebuttal in SLATE. I am not a geocentrist, nor am I in any way a proponent of geocentrism. More importantly, I do not subscribe to anything Robert Sungenis has written regarding science and history and, had I known of his involvement, would most certainly have avoided this documentary. ….

28. **Anonyrat**
April 8, 2014

Lawrence Krauss on Slate.com:
http://www.slate.com/blogs/future_tense/2014/04/08/lawrence_krauss_on_ending_up_in_the_geocentricism_documentary_the_principle.html

> So, the question I had to face after discovering this abuse of my words was what to do about it. I have no recollection of being interviewed for such a film, and of course had I known of its premise I would have refused. So, either the producers used clips of me that were in the public domain, or they bought them from other production companies that I may have given some rights to distribute my interviews to, or they may have interviewed me under false pretenses, in which case I probably signed some release. I simply don't know.
>
> Many people have suggested I litigate. But this approach seems to me to be completely wrong because it would elevate the profile of something that shouldn't even rise to the level of popular discussion. The best thing we can all do when faced by nonsense like that, or equivalent silliness promoted by biblical fundamentalists who claim that science supports a literal interpretation of the Bible, is to ignore it in public forums, and not shine any light on the authors of this trash. As far as this particular film is concerned, one might hope that it has high production value that cost the producers a lot of money. Then, when no one beyond the three people in the country who may somehow have missed the last 500 years of science and history during their education watches the film, we can hope that the whole misbegotten enterprise will bankrupt the production company, or at least severely cramp its style.

29. **Will McKenzie**
April 9, 2014

"These ______ arguments are about as unscientific as things get." Devil's advocate but as idiotic as geocentrism is, still more scientific than MUH. Geocentrism has a clear hypothesis. It makes predictions. It's been tested innumerable times. It's been falsified innumerable times.

30. **Peter Woit**
April 9, 2014

Please, enough about geocentrism. This was all discussed ad nauseam here
http://www.math.columbia.edu/~woit/wordpress/?p=6624
back in January.
The one mystery here is that of how physicists ended up agreeing to be filmed. This is definitely the most impressive story of physicists being taken in by filmmakers since string theorist Clifford Johnson was induced to appear on a program devoted to "How Big do Boobs Have to be to Crush a Beer Can?", see
http://www.spike.com/video-clips/9z58hb/manswers-beer-crushing-boobs

31. **Nick M.**
April 16, 2014

In regards to the BICEP2 result, did anybody else catch the article published yesterday in New Scientist titled "Star dust casts doubt on recent big bang wave result"? The cited paper (see arXiv:1404.1899), upon which the article is based, was submitted to arXiv this past April 7th. It seems that the main cause for concern is the lack of inclusion, in BICEP's foreground analysis, of the possible contamination of the polarization background produced by this dust inspired signal, and that this signal would incorrectly be attributed to primordial gravitational waves from inflation; i.e., that the patch of sky used by the BICEP2's telescope isn't quite as clean as once thought. (See, for example, the "Conclusion" section of the above paper.) Anyway, the BICEP2 team has already admitted that the contribution by dust (a foreground component) to the polarization signal is one of the main caveats to their measurement. As always, time will tell.

32. **Nick M.**
April 16, 2014

As an addendum to my post above, I just noticed that "Physics World" did an April 10th article on this very same story as well, which included a lot more info; see "Have galactic 'radio loops' been mistaken for B-mode polarization?" The story was also talked about on the blog "In The Dark"; see "Galactic Loops as Sources of Polarized Emissions". Even though it is hard to see how these "loops" wouldn't have an impact on BICEP2's result, it would probably be best to just keep an open mind, and see how this all shakes out after Planck's release later this year.

Ten Years of Not Even Wrong

April 11, 2014
Categories: Favorite Old Posts, Uncategorized

This blog was started a little bit over ten years ago, and I've been intending for a while to write something marking the occasion and commenting on what has changed over the past ten years. I've found this mostly a rather discouraging topic to think about and whatever I have to say about it is going to be pretty repetitive for anyone who regularly reads this blog, so I'll keep this fairly short.

Re-reading some of the early postings I'm struck mainly by how little has changed in ten years. Back in March 2004 I was writing about a David Gross talk promoting string theory, about whether CMB measurements would give information about GUT scale physics, about how string cosmology seemed to be an empty subject, and about new twistor-based methods for computing gauge theory amplitudes. There's been a lot of progress on the last topic since then, but little change for the others.

One big change over the past ten years is that the argument that string-theory based unification is a failed project is no longer a particularly controversial one, with most physicists now leaning to this conclusion. Last night even Sheldon of The Big Bang Theory acknowledged that this isn't working out and he needs to find something else to work on (see here). Maybe even Sheldon's real life model will soon reach this conclusion. Ten years ago the argument one often heard was that string theory was the winner in the marketplace of ideas, with skeptics just sore losers. These days, it's string theorists who are more often complaining about the unfairness of this marketplace.

One development that is just starting to have a major impact is the failure of the LHC to find any evidence of SUSY, leading to increased skepticism about SUSY extensions of the standard model. This is a developing story, with results over the next couple years from the LHC likely to make this a textbook example of what scientists do in the face of experimental disconfirmation of their most cherished ideas.

The discovery of the Higgs has been a wonderful vindication of the ideas and techniques of high energy physics, both experimental and theoretical. As we learn more about the Higgs the lesson seems to be that this sector of the Standard Model behaves in the simplest way possible. This is a significant new piece of information about nature, although a frustrating one since it doesn't provide a hint of how to improve the Standard Model.

On the whole though, I fear that thinking about changes over the last ten years mostly puts me in a not very good mood. Some of the depressing developments and trends of the last ten years are:

- One reaction to string theory's failures in the marketplace of ideas has been a Russian billionaire's decision to try and manipulate that marketplace by injecting tens of millions of dollars into it on one side. The largest financial prize in science now is devoted to each year rewarding people for work on a failed project. This is corrupting the marketplace in a significant way.
- Some of my earliest postings back in 2004 were about KKLT, the string landscape and the multiverse. At the time I was sure that if the landscape proposal being pushed by the Stanford group became widely accepted as an implication of string theory unification, that would be the end of it. Surely no sensible person would try and argue for an extremely complicated, inherently unpredictive theoretical framework. Boy, was I wrong. As I've gone on about far too often here, the current multiverse mania is a disastrous and shameful episode for fundamental theoretical physics, threatening its essential nature as a science.
- Most physics departments have reacted to the failure of string theory by at least partly blaming this failure on the over-emphasis of mathematics, instead of the fact that this was just a wrong idea about physics. An interesting document I recently ran across is this one about the connections of particle physics with other disciplines, written by my advisor Curtis Callan and Shamit Kachru. Mathematics is mentioned in a section discussing past successes in cross-fertilization with other fields, but it appears not at all in the rest of the document discussing opportunities for the future.

I'm quite surprised that I've continued to find topics worth blogging about ten years down the road, this is something I never expected when this started. Right now I'm hoping for something unexpected in coming years, that I'll be writing about something different and much more interesting ten years from now!

Comments

1. **Phoenix Woman**
   April 11, 2014

   Oh no! Hermione Granger doesn't actually exist!

   http://www.aps.org/publications/apsnews/200808/zero-gravity.cfm

2. **Michael Gogins**
   April 11, 2014

   Thank you for maintaining your blog for these past 10 years, most of which time I have been looking at it just about every day.

   I've learned at lot, but the main thing I've learned is the unsettling news that, when science gets stuck, or harder, a lot of scientists kind of give up and start doing metaphysics. Unfortunately they don't seem to want to admit that's what they're doing.

   I have nothing at all against metaphysics, quite the contrary in fact, but I would like to be able to keep my science and my philosophy separated by the criterion of empirical testing.

   I would be very interested in any suggestions about how young scientists might better be educated to avoid this trap without losing their curiosity and drive to understand.

   Regards,
   Mike Gogins

3. **Ralph**
   April 11, 2014

   The attitude that the failings of string theory are due to "too much mathematics" is just insulting to mathematicians.

   It may be that string theory was not good physics. That does not mean that the bits of string theory that pretended to be good physics, were good mathematics.

   Lets be clear : to a large extent, it is valid to see the problem of quantum gravity to be a mathematical problem.

   Giving a single theory, with a reasonable degree of mathematical rigour, that reduces to the SM and GR in appropriate limits, would be a huge advance, whether or not that theory actually turned to describe our universe.

From that point of view, testability of a theory-of-everything is actually a red-herring – the experiments have already been done: the ones that confirm GR and the ones that confirm the SM. The problem is to find any respectably rigorous ToE that gives correct calculations of the outcomes of all those experiments. Currently it appears to be mathematical rigour that is lacking.

Of course, once we have a ToE that makes mathematical sense, the questions will be "how do we test it" and "how do we experimentally distinguish it from alternatives". I am not claiming that experimental testability is unnecessary, it is just that we appear to be as far from having a real theory to test, as we are from actually probing the planck scale directly.

4. **Roger**
April 11, 2014

I was hoping for dialog like this.

Penny: What is string theory?
Sheldon: That is the idea that all mysteries can be explained by saying that everything is a string in 6 extra dimensions.
Penny: I could have told you that is a dumb idea.

5. **Bryan**
April 11, 2014

Peter, congrats on a remarkable 10 years of blogging! You've been not just the main source documenting ST irrationality, but also this blog has become a great site for all particle physics news.

6. **Richard Gaylord**
April 11, 2014

" Sheldon's real life model ". ho would that be?

7. **FCS**
April 11, 2014

Keep up the great work! I certainly enjoy reading you blog each week.

8. **JG**
April 11, 2014

Yes, thanks for the blog, it's always informative and I think you've been quite brave.

Coincidentally, we are at a quite significant moment – as many string theorists are *anxiously* awaiting to see if there will be corroboration of the BICEP2 result. Mysteriously there has not been much comment that the result r~O(0.1) *destroys* nearly all string inspired cosmology models. Yeah yeah – string gas cosmology and axion monodromy are suddenly the new stars – but there were bound to be some string inspired ideas that still survive, since the theory "predicts" almost everything!

9. **Academus**
April 11, 2014

Great past decade! I'm certain you'll be writing about interesting new physics soon…

10. **Anonyrat**
April 11, 2014

Congrats on the 10 years of blogging, and just as they yell at the political conventions "four more years, four more years", with the same spirit I write "ten more years, ten more years"!

11. **Martibal**
April 11, 2014

Peter,

"There's been a lot of progress on the last topic since then, but little change for the others."

Aren't you a bit pessimistic ? On the second topic (CMB and GUT) it seems that something rather big may have just happened. So: progress on twistor, discovery of the Higgs, and maybe indication that inflation occurs at GUT scale… this is not so bad for ten years in theoretical physics, I would say.

12. **Peter Woit**
April 11, 2014

Martibal,
Discovery of the Higgs is a great experimental triumph, unfortunately not a recent advance in theoretical physics. I don't yet see that CMB results tell us anything signficant about GUT scale physics, maybe some day, but not yet. Amplitudes are about it…

13. **hopffiber**
April 11, 2014

Why no mention of BICEP2 results here? I would argue that that changes a bit of the first points you mentions. As JG rightly points out, if the results are corroborated, it falsifies a lot of cosmological models, among them a lot of string based ones. So then clearly the assumption that string cosmology is "empty" is just wrong: the string models are just as falsifiable as the "normal" ones. And the idea that CMB observations can tell us something about quantum gravity is looking promising as well. For one thing, it gives us the energy scale of inflation, that alone is some very interesting information about GUT/BSM physics.

14. **JohnB**
April 11, 2014

Well done on the 10 years + book 🙂 Have been following the blog since the book and, even as someone with very little physics knowledge (but much interest in the general topic), this is one of the most consistently good blogs on any topic I read about.

15. **Neil**
April 11, 2014

I'd be interested to know how many real world Sheldons there are–bright young physicists wondering if they have spent their most creative and productive years on what looks like a dead end?

16. **Low Math, Meekly Interacting**
April 11, 2014

What, no mention of all the excellent rumor-mongering?

17. **Peter Woit**
April 11, 2014

hopffiber,
Yes, lots of "string cosmology models" may have been falsified, but what has not been falsified is the claim that you can get just about anything at all out of some complicated "string cosmology model", so "string cosmology" isn't science in the usual sense.

As for the CMB telling us something significant about quantum gravity and about GUT physics, that's not inconceivable but I don't think we're there yet, whatever you read in the papers…

18. **Nathalie**
April 12, 2014

We have to keep in mind that the BICEP2 results may very well turn out to be "wrong". They have no doubt measured something and have found it to be equal to 0.2 but what is it that thing? Background noise? Magnetized dust from supernovae? Following good academic traditions we have to wait before shouting hurrah.

The most striking message from LHC is that the naturalness arguments presented so far are not valid. Nature seems to have a different line of reasoning. This reminds one of the naturalness arguments for why the neutrino mass had to be zero. After all it was advocated by no less than four Nobel Laureates. Nonetheless it turned out to be wrong.

19. **Stuart**
April 12, 2014

Peter
Thank you for defending the scientific method for the past ten years!
Yes we now recognize that String theory has conceptual problems. My question is can the same be said about Loop Quantum Gravity?

20. **Jesper**
April 12, 2014

First: congratulations. I think your post plays an important role. I have always had this conviction that you can only really beat an idea by providing a better one. I think ST will eventually fade away, but it might not happen until someone gives a strong alternative. The problem is perhaps that the present setup of theoretical physics might be somewhat opaque to new ideas.

About this "over-emphasis of mathematics" on the ST side. My own experience is the complete opposite, that is, a lack of emphasis on mathematics. A couple of years ago I gave a talk with a couple of very prominent ST physicists in the audience. After my first slide I was asked – again, by a very prominent ST-guy – what a C^*-algebra is…

@ Stuart: yes, the same can be said about LQG, but of course, the problems there are of a different nature (and most likely OT).

21. **Shantanu**
April 12, 2014

Peter, there has been a lot of progress in experimental neutrino physics in last 10 years including evidence for non-0 theta_13. However its still not clear to me what exactly non-0 neutrino mass and mixing tells us about rest of particle physics and
beyond standard model theories.

22. **Bee**
April 12, 2014

Who'd have thought 10 years ago that blogs would still exist today? Your blog is one of the few that I follow, so I am looking forward to the next decades 🙂

23. **johnnythelowery**
April 12, 2014

Got the book, read the blog; not got the T-shirt yet. Congrats Peter. A lot of hard but necessary work. Anthropologists in the far future will find blogs like this a gold mine. Your predictions for the next 10 years please.

24. **Art**
April 12, 2014

Congrats on passing the 10 yr blogging milestone! Your book was an eye-opener for this layperson, and your blog is a v nice portal into today's math and physics happenings. I hope you continue…

25. **CThomas**
April 12, 2014

This seems like an appropriate entry to ask the question whether there is any sort of posting, article, or book summarizing these disputes over string theory, falsifiability, etc. appropriate for the layman. Any leads would be appreciated. (I hope I'm not overlooking an obvious answer to this posted on the site, but I didn't see it.)

CThomas

26. **hopffiber**

April 12, 2014

@Woit: sure, that claim of yours is true to some extent, but how is it different from “normal” model building, in cosmology and elsewhere? You can also get almost anything from complicated constructions using just ordinary QFT (or LQG, I suppose). String theory does add some more possibilities since its more complicated, but I don’t see any real reason besides pure anti-string bias to single out “string cosmology” as particularly empty compared to other approaches. And as long as you can test your models against new data and falsify them, isn’t precisely science in the usual sense, or how do you define “usual science”?

And as for the second part, yes, we are not there yet. But it is quite promising and could very well give us quite a bit of interesting information about the scale of GUT and inflation. So I think stating that “very little happened in 10 years” is way to pessimistic, overall.

27. **Peter Woit**
April 12, 2014

CThomas,

I’ve written a book about this (also called Not Even Wrong), and if you read that and one of the books from a string theorist (Brian Greene’s The Elegant Universe would be a good choice), you’d get both sides. Both of these books are a bit old now, but, not much has changed. Also, on this side there’s a FAQ

http://www.math.columbia.edu/~woit/wordpress/?page_id=4338

hopffiber,
http://www.math.columbia.edu/~woit/wordpress/?wp_super_faq=isnt-string-theory-just-as-predictive-as-quantum-field-theory

28. **Don**
April 12, 2014

Dear Peter

Congrats on 10 years of doing exactly what science is supposed to be: open honest debate about the current issues. Whether you are correct or not really doesn’t even matter. It is that you have provided an outstanding example of the process of refining ideas. In addition to this, your lively and slightly cynical style makes for great reading, entertainment, and the occasional “OMG, I don’t believe he said that out loud!” Political correctness is the bane of peer review, and you set a great example of how to do it the right way. Not with trivialities, but by going right to the heart of the matters and focusing on core questions.

Thanks a million and I for one look forward to many more years of your posts.

Best wishes to you, Sir,

Don

29. **Jason**
April 12, 2014

There’s simply nothing wrong with string theory. The vast majority of string theorists are mediocre and not up to the task. A tiny minority of string theorists actually do something useful and every five to ten years make significant progress. This is a ‘Theory of Everything’, after all and the only one that really works but it cannot be expected to resolve itself in the same manner as other scientific theories in the past. String theory is its own game and it has produced more losers than winners. Many were called but few were chosen. What did they expect anyway? Doesn’t nature operate this way? It’s time for the Sheldons of string theory to move on and make room for the new guard. Believe wholeheartedly in the power of young people. Somewhere, some young person is going to take the next step, bring us to a better level of understanding physics and string theory than ever before. I’m their biggest fan already.

30. **Jim Akerlund**
April 13, 2014

Got your book on 4/5/14 and finished it today. I do have a question about it. In the chapter “The only game in town” you mention the average age of tenured professors in 1970 as under 40, and that the latest figures (circa 2000 according to footnote 12) were for an average of nearly 60 for tenured professors. My question is, has that changed any since your book was published? Anyway, congradulations on ten years of good blogging.

31. **Peter Woit**
April 13, 2014

Thanks to all for the kind words and encouragement.

Jim Akerlund,
I haven’t seen more recent numbers (but haven’t looked), would be interested if anyone has any. I’d guess the average age number has stabilized (or even started to go down), as the cohort hired in the late 1960s has started to retire post-2000. Retirements by themselves should bring the number down, retirement + replacement by new hire even more so.

Jason,
That the “vast majority of string theorists” are just too stupid is an original explanation for the problems of string theory. I hadn’t heard that one before and I thought I had heard them all.

32. **Jeff M**
April 13, 2014

Jesper,

Really, a physicist didn’t know what a C* algebra is? Really? I mean I’m a mathematician, but I’m pretty sure I first learned about C* algebras when I took QM (a VERY long time ago 🙂

Did you ask him if he knew what a Hilbert space is?

33. **Jeff M**
April 13, 2014

Sorry, I assumed it was a him, my bad, there are some prominent female string theorists…

34. **Eddie Dealtry**
April 13, 2014

Peter,

Thanks for the ten years and keep up your good work.

For some of us this is the site that knocks some sense into news items and weeding out new books on physics – saving us time and disappointment with the hype.

Eddie

35. **Peter Woit**
April 13, 2014

Jeff M/Jesper,

I don't think there's anything at all remarkable about not knowing what a C* algebra is, wouldn't surprise me it most mathematicians don't know this either. You can understand QM quite deeply without the operator algebra/functional analysis perspective, and you can understand the statements relating QM and C* algebras without understanding anything significant about QM at all. So many different sorts of mathematical technologies have been tried out in string theory that surely no one understands them all.

Physicists rarely learn mathematics from the ground up, from general theory, more often from how mathematics gets used in a specific example they work with. This isn't at all a bad thing.

36. **QG**
April 13, 2014

may jason is being sarcastic. though witten et al did say to paraphrase string theory is smarter than us.

maybe string theory is the correct description of nature but humans are not intelligent enough to understand it.

37. **Peter Woit**
April 13, 2014

QG,
For any scientific idea that doesn't work out, you can try and argue that it really is fixable and will work, but we're too stupid to know how. While this could always be true, there's a good reason this is not the conventional scientific method.

38. **A**
April 13, 2014

CThomas: You might be interested in http://gilkalai.wordpress.com/2009/06/23/my-book-gina-says-adventures-in-the-blogsphere-string-war/

39. **Jeff M**
April 13, 2014

Peter,

Actually I would be much more surprised by physicists not knowing C* algebras than mathematicians, I only know about them really because I was originally a physics major. In math you would only know much about them if you work in some related field, though probably you would have seen them around. I just can't believe anyone took a real QM course where they weren't mentioned.

As for how physicists learn math, I think you're right but I do see issues with that, since it makes it much easier for them to ignore the required rigor and claim they've "proved" something when they haven't even come close. Whats the joke, "If you understand something and can prove it, publish it in a math journal, if you understand something but can't prove it publish it in a physics journal…"

40. **Goosebumps**
April 13, 2014

Hi Peter,

Congratulations on ten years of blogging! I recently came across your blog and I always find your posts entertaining. I hope to read your book someday.

I'm sorry if this is off-topic, but I thought I'd ask an expert – does the recent discovery of exotic hadrons at CERN have significant implications for HEP? I thought the reaction seemed a bit muted. Is it fully consistent with the Standard Model?

41. **Peter Woit**
April 13, 2014

Goosebumps,
Thanks!
The existence of these exotic hadrons is as far as we know consistent with QCD and the Standard Model. One of the big problems in theoretical physics is that there's a lot we don't understand about QCD, because of the lack of good calculational methods. So, we don't know exactly what the theory predicts for such states. Better understanding QCD is a problem that deserves more attention than it gets, but it's extremely difficult, and people have been working at it for about 40 years with only limited successes.

42. **Bernard Grossman**
April 13, 2014

Congratulation, Peter . I have learned alot from following your blog. But I do think there are many reasons to rejoice about progress !
I am surprised that you do not include the ADCFT correspondence and its applications in solid state, quark-gluon plasma and quantum entanglement as a remarkable area of progress . The holographic principle will most likely lead to new understanding of quantum mechanics at it deepest level. While field theorists have been accustomed to remarkable successes from the days of quantum electrodynamics, most deep problems are understood over longer periods of time with many failures. The theory of evolution is almost universally accepted,however there are in fact many ways in which its initial formulation is flawed and our understanding continues to evolve.

Evolution needs to be defended against the no-nothings who attack science, it also needs to be criticized and to be developed with our increasing understanding of ideas like epigenetics, which looks closer to the ideas of Lamarck than Darwin.
We do not know as yet whether string theory will survive as a fundamental theory, but of it does not, many of the ideas will surely survive in the transition to the next stage .

43. **TomD**
April 14, 2014

@JeffM,
I took a graduate quantum mechanics course from Ed Witten, and C^* algebras weren't mentioned…

@Peter,
Congratulations, and many thanks for the great blogging for 10 years… I read it avidly, and share lots of the posts with colleagues who are 'former QFT'ers.'

44. **Simple biologist**
April 14, 2014

@Bernard Grossman
I find the comparison to evolution to be flawed. We biologist have 150 years worth of both historic and experimental data to use for developing the evolutionary theory. If anything,at the moment biologist have exactly opposite problem, thanks to genomics/proteonomics/whatever-omics. So much emperical data and not enough tools to make proper use of it.

Things are quite different for string theorist in this regard. Apples, oranges and so on.

45. **Jesper**
April 14, 2014

About the C*-algebra stuff: perhaps I should elaborate a little. The ST-guy, who asked me what a C*-algebra is, was in the early 2000's involved in the "noncommutative geometry-meets-ST" surge. Thats actually the reason that it surprised me so much that he apparently wasn't aware of the concept of a C*-algebra. After all, he had been publishing numerous papers in a field very closely and somewhat overlapping the work of Connes (and without any doubt, had been attending conferences where Connes or someone else from NCG was speaking). Thus, for him not to know what a C*-algebra is meant to me that he hadn't bothered looking at the math so closely related to what he was doing. Since he is a leading figure in the field ST I sort of took it as an indicator.

This is just to comment on the mentioned 'over-emphasis on math' and for me, its just one illustration of something, which I have noticed over the years: that the ST people, whom I have been in contact with, certainly are not putting a lot of emphasis on math (I mean math, not computation). This may not be a bad thing (I tend to think it is) but the issue was simply the emphasis/not-emphasis.

46. **Bernard Grossman**
April 14, 2014

While the analogy between evolution and string theory is not perfect, I would say there are lessons of hope and inspiration to be learned from the comparison . The theory of evolution as a theory strictly of genetics is flawed, but survives as modified by new developments and genetics is firmly based in our thinking about biology. We do not know whether string theory is flawed or just incomplete , but our understanding of the importance of spin two field theory, gravity and the renormalization group for many areas of physics has become deeper compared to the ideas before string theory of quantum gravity as a hopelessly nonrenormalizable theory .

47. **Fredf**
April 14, 2014

Thanks for a regular dose of thoughtful blogging.

48. **JG**
April 14, 2014

Jeff M

Just like in the early days, when most physicists learnt QM from Dirac's textbook, not Von Neumann's (which wasn't even translated into english until the 1955), modern physicists are not always concerned with mathematical rigour. Any course in QM which attempts to discuss it in full mathematical rigour is pretty tedious to most tastes, and you must admit that not many breakthroughs in physics have been made by the use of mathematical rigour. It annoys me, for example, when people criticise Einstein's quite messy route to GR compared to Hilbert's apparently pristine derivation – yeah AFTER he'd got the crucial ingredients from Einstein! Or people who praise so highly Born and Jordan's rigorous rewrite of Heisenberg's crucial insights (he had not even heard of matrices at the time) – as if the mathematically rigourous formulation was the great achievement here (Dirac independently derived most of the same stuff in a few weeks, also AFTER reading about Heisenberg's crucial insight)

btw for a discussion of Dirac v Von Neumann approach see here

49. **Peter Woit**
April 14, 2014

All,
In general I'm all in favor of discussion of math and QM, but it is pretty much off-topic here, best would be to postpone this until it is on-topic. This should happen sooner or later, since I'm still working on the last chapters of the book I'm writing on this and when I finish a first draft I'll write about this here. This fall semester I'll again be teaching a course on this topic, so also likely will want to blog about this topic then.

50. **Supernaut**
April 14, 2014

Peter – Thank you for writing this blog for these ten years! Hope to read what the next ten years of NEW will bring.

51. **AcademicLurker**
April 14, 2014

I've found your blog to be very entertaining and informative, although I work in a very different area of physics and so don't appreciate many of the technical aspects of the discussions. The sociological aspects, on the other hand, have been consistently interesting.

It seems like an odd coincidence that the 10 year anniversary of *Not Even Wrong* coincided so closely with Sheldon Cooper giving up on string theory…

52. **Peter Donnelly**
April 14, 2014

Can’t tell you how much I’ve enjoyed your blog, which I’ve been tracking ever since I read your book (in old fashioned paper format.)

I chexk every day for updates, always disappointing when there isn’t one, but I guess you have a day job also :>)

Peter Donnelly

53. **Argosy**
April 15, 2014

Congratulation on 10 years of your blog, I’ve been an avid reader for the past few years, though this is my first comment. Keep up the good work!

54. **Curious Wavefunction**
April 15, 2014

Congratulations. Your blog and book have served an essential purpose and have upheld the Royal Society’s ‘Nullius in verba’ motto better than almost any other source I know. Keep up the good work.

55. **Brian Dennehy**
April 15, 2014

Just to say thanks for maintaining the blog Peter. I find it to be one of the very best sources of information for what is going in theoretical physics.

I have also always been impressed by the dignity and calmness of your writings over the years . There is a lot of `sociology’ in the theoretical physics research community and it cannot have been easy to stand up so prominently to criticise the string theory program.

In the coming years and decades I’m fascinated to see what is made of string theory as an intellectual endeavour.

56. **srp**
April 17, 2014

Can one be a dissenter without being a crackpot, a spokesman for the “silent majority” without being a commissar against the “vocal minority,” and an advocate for more rigorous mathematical foundations in physics without signing onto the most popular mathematical physics fashions? I don’t know, but you’ve making a heck of an attempt for ten years and it’s been very interesting to watch.

57. **Kavanna**
April 18, 2014

Peter,

I’ve immensely enjoyed both the book and the blog and recommend them whenever the occasion arises. The book has been read — twice, or even more times ….

Keep up the good work. Opposing the multiverse mania has been an exceptionally crucial and brave thing that you’ve done. Some days, I want to start screaming when I see some multiversal nonsense on the Web, or the new Cosmos, or wherever. Then I come here and calm down.

58. **Michael Gannotti**
April 21, 2014

I finally started watching watching the series Cosmos and 15 minutes in when I heard deGrasse Tyson mention the multiverse in the same breath as verifiable science I could not help but think of this post. Thanks for continuing to shed light on the difference between science and what is ostensible philosophy and faith dressed up and paraded as science.

59. **Edward Hessler**
April 22, 2014

As I think you know, Dr. Woit, I am not a physicist (K-12 educator) but I hope better late is better than never. This is one of my favorite blogs and I check it nearly daily. I don’t understand everything, obviously but you and commenters have helped me think about physics.mathematics more carefully as well as with (I think–so long as there isn’t an assessment of this!) greater insight.

What a service and I’m glad you do it and enjoy it.

First, Congratulations.

60. **Peter Mancini**
April 22, 2014

Love the book. Recently got it and have enjoyed reading it. The history, your central argument and your writing style are all very thought provoking and interesting. I picked it up mainly to understand how to argue against prevailing notions and I believe the book has been instructive. My field isn’t physics but the part of information science dealing with text analytics. I was a physics major as an undergrad but decided after 2 years I was more interested in computers. I’m glad people like you have stuck with it and produced such interesting results.

I enjoy your blog and I hope that new breakthroughs in physics give you good reason to unconcerned with bad theories and instead can refocus on the majesty of exploring good science.

61. **Bernhard**
April 26, 2014

I’m coming late as a was traveling, but could not miss the opportunity to congratulate you and your fantastic blog. Besides the healthy critic you always provide, this blog is still the best source of HEP news on the blogosphere. I also enjoy very much the math news which I would not have known otherwise, even though I’m generally incapable to appreciate it fully.

I second Kavanna’s comment. I, and believe many, feel the same way.

Ten more years (at least) to NEW!

62. **Jim Beyer**
April 30, 2014

Bravo!

This blog has done more to keep the pressure on String theorists to explain their (non) results than any other entity. You remind them (and us) on almost a day-to-day basis that their excuses-providing double-talk is merely cleverly worded nonsense to keep the grants rolling in.

Physics has in effect entered a mini dark age that hopefully from which it will hopefully eventually emerge. This blog is proof that at least someone kept the light of rationality on during that time.

Thanks again. Your effort in this endeavor will hopefully be recognized and appreciated by a wider audience than it is now.

Supersymmetry and the Crisis in Physics

April 15, 2014
Categories: Uncategorized

The May issue of Scientific American has a very good cover story by Joe Lykken and Maria Spiropulu, entitled Supersymmetry and the Crisis in Physics (the article is now behind their subscriber paywall, but for those with access to Nature, it will soon be here).

Here are some excerpts:

> It is not an exaggeration to say that most of the world's particle physicists believe that supersymmetry *must* be true—the theory is that compelling. These physicists' long-term hope has been that the LHC would finally discover these superpartners, providing hard evidence that supersymmetry is a real description of the universe…
>
> Indeed, results from the first run of the LHC have ruled out almost all the best-studied versions of supersymmetry. The negative results are beginning to produce if not a full-blown crisis in particle physics, then at least a widespread panic. The LHC will be starting its next run in early 2015, at the highest energies it was designed for, allowing researchers at the ATLAS and CMS experiments to uncover (or rule out) even more massive superpartners. If at the end of that run nothing new shows up, fundamental physics will face a crossroads: either abandon the work of a generation for want of evidence that nature plays by our rules, or press on and hope that an even larger collider will someday, somewhere, find evidence that we were right all along…
>
> During a talk at the Kavli Institute for Theoretical Physics at the University of California, Santa Barbara, Nima Arkani-Hamed, a physicist at the Institute for Advanced Study in Princeton, N.J., paced to and fro in front of the blackboard, addressing a packed room about the future of supersymmetry. What if supersymmetry is not found at the LHC, he asked, before answering his own question: then we will make new supersymmetry models that put the superpartners just beyond the reach of the experiments. But wouldn't that mean that we would be changing our story? That's okay; theorists don't need to be consistent—only their theories do.
>
> This unshakable fidelity to supersymmetry is widely shared. Particle theorists do admit, however, that the idea of natural supersymmetry is already in trouble and is headed for the dustbin of history unless superpartners are discovered soon…

The authors go on to describe possible responses to this crisis. One is the multiverse, which they contrast to supersymmetry as not providing an answer to why the SM parameters are what they are, although this isn't something that supersymmetry ever was able to do. Another is large extra dimensions as in Randall-Sundrum, but that's also something the LHC is not finding, with few ever thinking it would. Finally there's the "dimensional transmutation" idea about the Higgs, which I wrote about here last year. About this, the authors write:

> If this approach is to keep the useful virtual particle effects while avoiding the disastrous ones—a role otherwise played by supersymmetry—we will have to abandon popular speculations about how the laws of physics may become unified at superhigh energies. It also makes the long-sought connection between quantum mechanics and general relativity even more mysterious. Yet the approach has other advantages. Such models can generate mass for dark matter particles. They also predict that dark matter interacts with ordinary matter via a force mediated by the Higgs boson. This dramatic prediction will be tested over the next few years both at the LHC and in underground dark matter detection experiments.

It's great to see such a high-profile public discussion of the implications of the collapse of the paradigm long-dominant in some circles which sees SUSY extensions of the Standard Model as the way forward for the field. One place where I disagree with Lykken and Spiropulu is their claim that "It is not an exaggeration to say that most of the world's particle physicists believe that supersymmetry must be true." Actually I think that *is* an exaggeration, with a large group of theorists always skeptical about SUSY models. For some evidence of this, take a look at this document from 2000, which shows a majority skeptical about SUSY at the LHC. By the way, I hear those on the right side of that bet haven't yet gotten their cognac, with the bet renegotiated to wait for results from the next LHC run.

Update: I hear that the 2000 bet was revised in 2011, with a copy displayed publicly at the Niels Bohr Institute. The new bet is about whether a superpartner will be found by June 16, 2016, and the losers must come up with a bottle of good cognac. There are 22 on the yes side (including Arkani-Hamed and Quigg), and 22 on the no side (including 't Hooft, Komargodski, Bern). Also, 3 abstentions. It explicitly is an addendum to the 2000 wager, with those who lost the last one given the option of signing again, forfeiting two bottles of cognac, or accepting that "they have suffered ignominious defeat."

Update: This report from the APS spring meeting includes the following about Spiropulu's talk there:

> Supersymmetry and dark matter have become so important to particle physicists that "we have cornered ourselves experimentally," said Spiropulu. If neither is detected in the next few years, radical new ideas will be required. Spiropulu compared the situation to the era before 1905, when the concept of ether as the medium for all electromagnetic waves could not be verified.

You can watch the talk and see for yourself here.

Comments

1. **tt**
   April 15, 2014

   "renegotiating a bet" ??? where did they grow up ? i hope they have to pay with more cognac.

2. **Richard Séguin**
   April 15, 2014

   The same issue of Scientific American also has a nice article on Ken Ono (et al) and Ramanujan.

3. **Bee**
   April 16, 2014

   "Actually I think that is an exaggeration, with a large group of theorists always skeptical about SUSY models."

   There's a name for it: False-consensus effect (look it up on wikipedia). Really, once you read through a list of common cognitive biases, it's hard not to notice just how widespread they are in science, and the present susy discussion is a particularly extreme example with people trying to hang onto their hopes.

4. **Will Nelson**
April 16, 2014

Surely the models such as Lykken is describing would be at least as malleable as susy when it comes to pushing predictions out of range of existing experiments. But it would certainly be interesting to see the second of the 1990-era naturalness dogmas overturned just as lamba=0 has been…

5. **Shantanu**
April 16, 2014

Peter does this article mention the Shaposhnikov-Wetterich model on asymptotic
safety? I bet it does not.

6. **Peter Woit**
April 16, 2014

Shantanu,
The article is mostly about not finding SUSY, no details on alternatives. I quoted most of the substantive part about "dimensional transmutation", the only specific reference was "Building on seminal work by William A. Bardeen…". There was also reference to the fact that the Higgs mass is at the edge of the metastability region, but about the significance of that, just "Nature is trying to tell us something, but we don't know what."

7. **Mike**
April 16, 2014

" . . . no details on alternatives."

Peter, what alternatives do think deserve more attention? Thanks.

8. **Peter Woit**
April 16, 2014

Mike,
The problem with SUSY models has always been that they don't really solve any of the problems of the SM. So, there's no need to look for alternatives to SUSY in that sense. In the more general sense of ideas about how to improve the SM, given the huge amount of attention paid to SUSY, and the experimental disconfirmation, there's a good argument that attention would better be paid to almost anything else. One thing I don't want to do though is host and moderate here a discussion of everyone's favorite ideas on this.

9. **AS**
April 16, 2014

Nature might be trying to tell us this message: I HAVE NO MASS SCALE.

In such a case, power divergences must vanish and the naturalness problem changes. The Planck scale and the weak scale and the Dark Matter scale can all be generated dynamically.

10. **vmarko**
April 16, 2014

AS,

"Nature might be trying to tell us this message: I HAVE NO MASS SCALE."

While this is slightly off-topic, I'd have to disagree. Nature does not appear to be conformally invariant, and you cannot get nonzero mass scales out of nothing. Dimensional transmutation from conformal anomaly is a mirage, it doesn't really generate a dimensionful quantity out of dimensionless ones (when you think about it, it is mathematically impossible to do such a thing). So at least one mass scale has to exist in nature, say Planck scale, and the ratio of Higgs mass to Planck mass then turns out to be extremely small. The "hierarchy problem" is the fact that physicists find the smallness of that ratio psychologically unsettling, and try to look for an explanation.

HTH, 🙂
Marko

11. **A.J.**
April 16, 2014

"renegotiating a bet" ??? where did they grow up ?

Perhaps the no-SUSY side decided that they wanted to win on the merits rather than on a technicality?

12. **Peter Woit**
April 16, 2014

vmarko,
Pure QCD is an example where you do get non-trivial dimensionful quantities out of dimensionless ones, because of the way renormalization works. As for the significance of the Planck scale, I don't think one should assume anything about the relation of quantum gravity to the Higgs.

Another way to say this might be that the physics community has been obsessing about supersymmetry, while knowing that SUSY breaking is required to make it work and we don't have a good idea about SUSY breaking. Instead of this, it might be a good idea to spend time obsessing about conformal symmetry, while knowing that conformal symmetry breaking is required to make it work, and we don't (yet) have a good enough idea about conformal symmetry breaking.

13. **Neil**
April 16, 2014

Peter,

You once wrote an eloquent answer to an Edge question about eloquent explanations, explaining why you think symmetry is an eloquent and beautiful explanation. I am assuming what you said there is one reason why people think SUSY is compelling regardless of the results so far at LHC.

My question. Do you have a reason to believe that SUSY is less eloquent and compelling than other symmetries in physics, or is your concern solely on the lack of evidence?

14. **Peter Woit**
April 16, 2014

Neil,
The issue of supersymmetry in general is a complicated one. As a general idea, supersymmetry does have some very compelling features. One of the simplest examples of the general phenomenon is that the Klein-Gordon operator has a square root, the Dirac operator, and in some sense the Dirac operator is a generator of a supersymmetry. This is quite fundamental and one of the most beautiful and compelling ideas in the subject. The details of this are in the notes of my quantum mechanics course.

What is being tested though at the LHC is a much more complicated example of a supersymmetry, the idea that you can start with the SM, and extend it to get a SUSY theory with a super-Poincare group invariance. This is what doesn't work so well: you get theories that are much more complicated than the SM, with a new symmetry that acts trivially on the SM, telling you nothing new about it. It leads to a complicated ugly theory since you have to break the supersymmetry, and the LHC results bear out the expectation that this isn't the way to go.

I wouldn't be at all surprised if there is some deeper insight into the SM that will come from identifying some sort of "supersymmetry" of it, one that is more like the supersymmetry generated by the Dirac operator, not necessarily coming from the super-Poincare group used in SUSY extensions of the SM.

So, I think it's a promising idea that there may be an eloquent "SUSY" explanation of fundamental physics, I just don't think the version we have now qualifies, and the LHC is confirming that.

15. **vmarko**
April 16, 2014

Peter,

"Pure QCD is an example where you do get non-trivial dimensionful quantities out of dimensionless ones"

No, it isn't. When you solve the renormalization group equation for the running of the strong coupling, it becomes equal to one at a certain energy, called the "QCD scale". What people often miss to notice here is that this equation also features an arbitrary dimensionful integration constant, which needs to be experimentally determined. IOW, the whole thing is a cheap trick, since it expresses the QCD scale in terms of the "renormalization scale" at which you measure the initial value for the strong coupling constant (before you let it run up to unity). The key point here are the words "experimentally determined", because in experiment you cannot shut down quark masses. They invariably enter the process of measurement through the back door, and ultimately participate in fixing the QCD scale.

It is also easy to see this without any physics. Can you give me an example of an equation which has "1 kg" on the left-hand side, and the right-hand side built purely out of dimensionless quantities? No? Then it cannot be done in QCD either, nor in any other theory. Such an equation is not mathematically self-consistent, on "dimensional grounds", regardless of any physics.

I am actually surprised by the number of people (including some Standard Model experts!) who don't get this stuff right. It is usually explained in standard graduate courses on QCD and nonabelian gauge theories.

Best, 🙂
Marko

16. **Peter Woit**
April 16, 2014

vmarko,
I'm talking about pure QCD, no fermions, i.e. SU(3) pure-gauge theory. All parameters in the Lagrangian are dimensionless, but it has a very non-trivial spectrum of dimensionful numbers, with the scale set by what you call a "cheap trick", and I call a deep insight into nature…

17. **vmarko**
April 16, 2014

Peter,

I understood what you meant by pure QCD. But the RG equation is a first-order differential equation, and doesn't specify a single curve for the running of the coupling constant, but a family of curves. The initial condition which singles out one curve out of this family, i.e. the value of the coupling at a certain renormalization scale, cannot be predicted from the theory (not even in the elusive ab initio calculation). So it is a free parameter in the theory, and needs to be fixed by measurement.

Alas, in the real world QCD is not "pure", it is always coupled to massive fermions. So any measurement of the coupling at some renormalization scale, and subsequent running up to QCD scale, does not really apply to pure QCD. From a theory POV, the pure QCD therefore contains the renormalization scale as a free parameter of the theory, and given no way to fix it, there is no way to say that the theory really "dynamically generates" any mass scale from purely dimensionless coupling constants.

Whether this is a cheap trick or a deep insight is a matter of perspective, but the bottomline is that there is no way to express a scale in terms of scale-free quantities. The only possible thing is to express a scale in terms of another scale, renormalization or otherwise.

Best, 🙂
Marko

18. **West**
April 16, 2014

@Peter,
Are there any particular searches in LHC data that you think constitute severe tests of BSM physics, SUSY or otherwise? I don't expect there to be any silver bullet but studying some processes must probe the relevant physics better than others.

I agree with you that the "the end is just over THIS next hill, I promise" runaround from many theorists is getting quite old, but this is from someone outside of HEP. From a Bayesian perspective this near infinite flexibility when constructing models is far more a vice than a virtue. The willingness to dismiss this concern, on a scientific level, is baffling.

19. **Peter Woit**

April 16, 2014

West,
I'm not an expert on the LHC searches, and this is a really complicated subject. For each different sort of BSM model, a lot of effort has gone into finding possible signatures, and by now many have been looked for by the LHC experiments. SUSY extensions to the SM have many extra parameters, but it is these models have been most intensively studied.

One of the simplest things to look for is the gluino, the superpartner for the gluon, so it is strongly interacting and thus should in general be produced copiously. It's also something that can't be pushed up to arbitrarily high masses without ruining the standard arguments for SUSY (naturalness, coupling constant unification). From what I've seen, it now looks like gluinos pretty much have to have masses significantly over 1 TeV to have escaped notice at the LHC, and this is in strong disagreement with the expectation that superpartners should be around the electroweak scale (100 GeV).

20. **george ellis**
April 17, 2014

"it might be a good idea to spend time obsessing about conformal symmetry, while knowing that conformal symmetry breaking is required to make it work, and we don't (yet) have a good enough idea about conformal symmetry breaking."
– right on. This is a very promising direction.

21. **AS**
April 17, 2014

Dear vmarko, let me explain better.
Following Bardeen, some people impose scale or conformal symmetry in order to argue that one must select a regulator that respects them, so that power divergences must vanish and the naturalness problem is circumvented. This has the problems that you mention.

Instead, I am proposing something different: that at fundamental level only adimensional couplings exist. Then, power divergences must vanish because they have mass dimension but there are no masses. Scale invariance would just be like baryon number in the SM: an ACCIDENTAL symmetry broken by quantum corrections. In such a context, scales can be generated by quantum corrections, and this paper proposes how the weak and the Planck scale can be generated http://arxiv.org/abs/1403.4226

22. **Steven Chan**
April 17, 2014

The greatest physical and social scientists are the ones that can adjust their thinking as new facts and data come in. The thing is rejecting existing believes are hard. At least the supersymmetry debate is generally peaceful; remember what happened to Galileo and Corpenius, or Darwin and Huxley!

At least the debate of heliocentrism and evolution is essentially philosphical and theological, the debate with fancy physics has became a war of career and face. It is hard to accept new ideas when your job depends on not knowing them.

23. **vmarko**
April 17, 2014

AS,

"http://arxiv.org/abs/1403.4226"

I assume you are one of the authors of this paper? It is actually an excellent example of what I've been trying to say regarding dimensional transmutation.

The key is the third requirement in eq. (44), which says that the Planck mass is proportional to the vev of the scalar field S. You don't seem to explicitly calculate that vev anywhere in the paper (but only note that it is nonzero due to Coleman-Weinberg mechanism). But if you actually try to do it, you'll find that the vev of S is proportional to the renormalization scale \mu. This is the only possible choice, since there are no other fundamental scales in the theory. Consequently, M_pl ~ \mu as well.

But this is in start contradiction with the classical (Newtonian) limit, where one measures M_pl ~ const at \mu->0.

Therefore, the model described in the paper is indeed scale-free, but the induced Planck scale runs along with renormalization scale, and goes to zero in the IR sector. The same holds for the Higgs scale, since all induced scales in the model are proportional to \mu. Therefore, all SM masses (fermions, Higgs, Z/W bosons, etc.) also go to zero when \mu->0.

In experiment, however, we observe that all these masses remain nonzero in the IR limit, which indicates that the fundamental theory must feature at least one mass scale other than \mu, and is therefore not scale-invariant.

I'm afraid we are getting off-topic here. Since I believe I've made my point already, I wouldn't like to pollute Peter's blog with this any more. 🙂 We can discuss this further privately if you wish.

Best, 🙂
Marko

24. **Peter Woit**
April 17, 2014

vmarko,
No objection to your discussion with AS, it actually is on-topic, the kind of thing the SciAm article was discussing as an alternative to SUSY.

25. **Ravi**
April 17, 2014

It is good to know that Nima and several others are still betting/predicting that LHC will find SUSY by 2016. Not finding it would then mean that the next run of LHC will provide a further blow to SUSY, as it cant be argued that it was not expected to be found anyway.

Also if fine tuning arguments of the hierarchy problem are to be believed, and if SUSY is not already ruled out for the next run — finding it in the next run always has a higher probability than not finding it but finding it at the next collider at an even higher energy scale….if you think of each energy doubling of collider as a run or as a new collider then probability of finding SUSY particles will go as "p, p/4, p/16 etc." for "run 1, run 2 (but not at run 1), run 3 (but not at run 2 or 1) etc.". p/4 + p/16 + p/64 +…. = p/3. So the next run of LHC (ie LHC at 13 or 14 TeV) has roughly 3 times greater chance of finding SUSY than all the future machines.

26. **Peter Woit**
April 17, 2014

Ravi,
The latest bet was from September 2011. Now that pretty full results from Run 1 are in, it would be interesting to know whether Arkani-Hamed and other signers of that bet are still willing to bet on SUSY in the first year of Run 2.

27. **Ravi**
April 17, 2014

There is a slight correction to the above — the probability will go down by factor of 2 with each doubling not factor of 4…… so the sequence we need to add is p/2 + p/4 + p/8 + …. = p. So LHC at 13/14 TeV has the same chance (p) of finding SUSY, as all future colliders would have together (if LHC doesn't find it).

28. **Ravi**
April 17, 2014

Yes Peter it would be very interesting to find out their bets given that LHC's 7/8 TeV results are fully out. However by Sept 2011 results from 1 fb-inverse data were available. So I don't think their bets on SUSY particles would change. Anyway will be good to know what their prediction/bet would now be for finding SUSY at next run of LHC.

29. **tt**
April 17, 2014

"Perhaps the no-SUSY side decided that they wanted to win on the merits rather than on a technicality?"

i'll try that with my bookie next week

30. **AS**
April 17, 2014

yes, I am the author AS. I insist that dimensional transmutation works in the same sense in which it works in QCD.

In the usual Coleman-Weinberg mechanism the effective potential develops a minimum, which roughly is at the special RGE scale at which a running quartic coupling vanishes. Using the running coupling is just a trick to simplify the computation. The effective potential does not depend on the RGE scale mu.

In the gravitational case the situation is somehow different, and again the simplified argument based on the RGE running is just a trick that allows to establish that a flat-space minimum can arise, without computing the effective potential away from flat space.

31. **Curious George**
April 17, 2014

Some 50 years ago particle physicists hoped to derive masses of "elementary" particles from a deep underlying principle. Are we getting there? Is it still a goal?

32. **paddy**
April 17, 2014

Were R. Feynman to be involved in this betting..he might have insisted on a sometimes used Blackjack rule: early/late surrender. This would allow the 2011 SUSYphiles to pull out their bet now (if they so wish) at the cost of only 0.375 liters of brandy.

33. **Chris Austin**
April 18, 2014

Perhaps a comparison with the AS + AS proposal, discussed above, could help to illustrate why it might still be worthwhile to study models based on compactifications of M-theory, notwithstanding the lack of encouragement from the LHC so far. If I understand the AS + AS paper correctly, they envision that the fundamental theory of physics, including gravity, is a power-counting renormalizable quantum field theory in 4 dimensions, like the Standard Model, that is defined by some discrete choices of gauge groups and matter representations, plus around 20 real number parameters, whose values have to be determined by experiment – and once those real number parameters have been measured, no further understanding of their values can ever be achieved. In contrast to this, M-theory compactifications attempt to explain both the discrete and the continuous data defining the Standard Model, starting from purely discrete data that specifies, for example, the topology of a 6 or 7 dimensional manifold, plus some quantized fluxes and stacks of branes wrapping some cycles of the manifold.

Attempting to realize the SM by an M-theory compactification can also suggest possibilities that might otherwise go unsuspected, and could eventually have technological applications. An example is provided by large volume compact extra dimensions, with a quantum gravity scale in the range from say 10 TeV to 100 TeV. Here the biggest challenge is no longer the lack of encouragement from the LHC, but BICEP2: the de Sitter radius during inflation would be unlikely to be much smaller than the curvature radius of the compact dimensions, so the tensor-to-scalar ratio r would be far too small for BICEP2 to detect. However about half the BICEP2 B-mode signal could arise from primordial magnetic fields rather than primordial gravitational waves, (Bonvin et al), so if the remainder could arise from under-estimated foreground contamination, (Armitage-Caplan et al), lvced could remain viable. Something must then keep the proton adequately stable, and one possibility is a gauged baryon or lepton number, that is broken down to a Z_2 gauged discrete symmetry by a gaugino condensate, (Fileviez Perez and Wise). Isolated protons are then stable, but dibaryon annihilations turn on above about 10 TeV. If something could then catalyse dibaryon annihilations, the prospects for practical interstellar travel could be improved, because it would be possible, in principle, for a rocket engine to convert a substantial fraction of the rest mass of ordinary matter to the kinetic energy of light decay products such as charged pions, and to utilize a significant fraction of that kinetic energy for propulsion. Proton decay can be catalysed by magnetic monopoles in grand unified theories, (Brihaye et al), and CMS and ATLAS are searching for baryon number violation and magnetic monopoles.

34. **Giotis**
April 18, 2014

AS wrote:
"Using the running coupling is just a trick to simplify the computation. The effective potential does not depend on the RGE scale mu."

In theory it doesn't but in practice it does. In theory to remove the dependence on the renormalization scale you have to sum up the whole perturbation series but in practice you can do perturbation only to a certain order; this way the dependence on the normalization scale is inevitable.

So I wouldn't call it a trick.

35. **cormac**

April 18, 2014

I dislike all this talk of 'crisis' and 'panic' in science magazines and blogs, I suspect it has more to do with science journalism than science. I met several of the early pioneers of SUSY through my father and I never heard one of them give any indication that they felt it was a symmetry that 'must' be realised in nature.
Theoreticians like to explore different models, as you know, not to dictate to nature how to behave. Of course, a certain investment arises when apparatus is built to test theories, but that's what they are – tests.
There always was, and always will be, the possibility of a desert. Crisis my arse!

36. **vmarko**
April 18, 2014

AS,

"I insist that dimensional transmutation works in the same sense in which it works in QCD."

I agree with that. The point I am trying to make is that dimensional transmutation in general — in your model, in QCD, and anywhere else — is just another way to introduce a mass scale into a theory by hand. There is no conceptual difference between postulating a mass scale term in the classical action and postulating a mass scale term in the first loop correction of the action. One way or another, you introduce the scale by hand.

"In the usual Coleman-Weinberg mechanism the effective potential develops a minimum, which roughly is at the special RGE scale at which a running quartic coupling vanishes."

Sure, a nonzero minimum does exist for that RGE scale, and all scales below it. The problem is that the **position** of that minimum is not determined by the theory. Your equation (43) which determines this position is a first-order differential equation, and it determines where the minimum is up to an arbitrary multiplicative dimensionful constant.

In order to fix the position of the minimum (i.e the vev for S), you have three choices:
(1) choose it to be zero, in which case the theory still does not have any scale, and is in contradiction with experiment;
(2) choose it to be proportional to the RG scale \mu, in which case the theory contradicts experiment in the IR limit;
(3) choose it to be proportional to the Planck scale, in which case you are putting the Planck scale into the theory by hand.

The option (3) is actually in contradiction with your principle from the beginning — that nature does not have a mass scale. There is nothing being "dynamically generated" by the theory in any profound fundamental sense. The third requirement in (44) is actually a postulate that nature **does** have a scale, and this scale fixes the position of the vev for S.

That is why I characterized dimensional transmutation as a cheap trick — the presence of the scale in the theory has to be **postulated**, one way or another, so that the theory does not get excluded by experiment. This is necessary in your model, in QCD, in superconductivity models, etc. — everywhere where spontaneous symmetry breaking is generated by quantum corrections.

Hopefully now I made myself more clear. 🙂

Best, 🙂
Marko

37. **Peter Woit**
April 18, 2014

Curious George,
"Are we getting there?" No
"Is it still a goal?" Yes

38. **Kavanna**
April 18, 2014

I've always felt that supersymmetry is a compelling idea in general. But the perturbative "carbon copy" approach to implementing this symmetry seems unimaginative. Nature surely has something more clever. Peter makes an essential distinction here in his discussion of the Dirac operator.

When field theorists talk about "dimensional transmutation," they mean a dimension comes into the theory upon solution or integration — something to do with boundary and/or initial conditions. It's not part of the dynamics per se. There are plenty of such examples in physics of scale-free dynamics whose solution picks up a scale when the dynamics are integrated and you impose boundary/initial conditions.

Three issues are being elided here: one is that the dynamics are scale-free; another is that there *must be* such a scale in the general solution to the theory, without saying what value that scale takes. Then there's the specific value itself, the third.

The issue of initial/boundary conditions is always a headache when you're thinking about a general theory of the universe. Initial/boundary conditions come from the "outside" in the canonical approach. But here there's no "outside." You have to go to metaphysical speculation or multiversality. Landau used to put it by saying that science is about differential equations, and religion is about boundary conditions.

39. **Tom Andersen**
April 18, 2014

Curious George, Peter,

As late as the 1950's, Einstein was asked if he could explain the confusion of hadron particles which were being found in ever increasing numbers. He replied, "I would be happy just to know what an electron is!"

Anyone know an accurate source for that? I found only un referenced versions of this on my somewhat quick internet search.

40. **Andrew Foland**
April 18, 2014

Thanks to vmarko, kavanna, and others for the illuminating discussion of how scales enter these theories.

41. **AS**
April 19, 2014

Marko, I would say that a running quartic crosses zero at some scale, and that scale (whatever it is) can be called “Planck scale”.

To be concrete, let us consider a simpler toy a-dimensional model with no gravity: QCD with scalar quarks. Do you agree that the natural value of their quantum-generated masses is the QCD scale?

This is the problem that needs to be solved: finding if the Higgs mass hierarchy problem can have a similar interpretation. To achieve this, one needs a model of quantum gravity where (differently from the usual string models) there are no Planck-scale particles significantly coupled to the Higgs.

Once that one can compute physics above the Planck scale, one can worry about an issue somehow related to what you say: running couplings can indeed set bigger scales via Landau poles.

42. **vmarko**
April 19, 2014

AS,

“Marko, I would say that a running quartic crosses zero at some scale, and that scale (whatever it is) can be called “Planck scale”.”

Sure, you can do that, but it doesn’t really help. The RGE for the quartic coupling is again a first-order differential equation, and determines the running of \lambda up to a dimensionful constant. Fixing the initial condition \lambda(\mu~M_pl)=0 is again a postulate, rather than a consequence of the theory.

In the paper you have explicitly calculated beta functions for all coupling constants in the model (a formidable task, I might add), but they all determine effective values of the couplings up to some arbitrary initial conditions, each involving a dimensionful constant, i.e. a scale. So regardless of how you set up the theory, you need to introduce the scale — or scales — by hand, they are never predicted by the theory.

“To be concrete, let us consider a simpler toy a-dimensional model with no gravity: QCD with scalar quarks. Do you agree that the natural value of their quantum-generated masses is the QCD scale?”

Sure. And do you agree that this QCD scale is completely arbitrary and not fixed by the model itself? Rather, it needs to be specified through an initial condition, external to the theory?

“This is the problem that needs to be solved: finding if the Higgs mass hierarchy problem can have a similar interpretation. To achieve this, one needs a model of quantum gravity where (differently from the usual string models) there are no Planck-scale particles significantly coupled to the Higgs.”

I fully agree that this is a legitimate research direction for discussing the hierarchy problem. Please don’t get me wrong — I am not criticising your work in general, it’s certainly an interesting idea. I am just criticising the postulate “nature has no scale” that you have mentioned both in the paper and in a comment on this blog. My statement is that such a statement cannot be postulated consistently, since eventually you need to introduce scales in the model, and the only way to do it is by hand, contradicting the postulate. The dimensional transmutation doesn’t really help with that in any way.

Aside from obvious deficiencies of the model (presence of ghosts, as noted in the paper), the material presented is actually quite good and interesting. But my advice is to just drop the postulate, and present the model without any reference to it — the presentation will be conceptually cleaner and less confusing regarding how scales arise in the theory.

Best, 🙂
Marko

43. **Low Math, Meekly Interacting**
April 19, 2014

Is it fair to say, at this point, that “naturalness”, at least as far as SUSY is concerned, is all but disproven? Even ignoring previous objections to the idea, it would appear that the combination of the current LHC run and some recent precision measurements should lead us presently to conclude, with a fair degree of confidence, that sparticle masses (if they exist) are beyond the reach of the LHC. I.e., there’s scant reason to expect that doubling the energy of the LHC and running it for another 20 years is going to tell us much about SUSY that we don’t already know. Excluding fanatics, this is a line of reasoning even the most ardent believer in SUSY would find difficult to dispel. Correct, or incorrect?

If correct, I fail to see why it’s a crisis, instead of a momentous opportunity to shift course. This ought to herald a paradigm shift worthy of the title. Of course, the peril of a shift to anthropic reasoning exists, I but can’t imagine a preponderance of young physicist could stomach such a travesty.

44. **Nathalie**
April 19, 2014

Dear vmarko,

Nature doesn’t care about what we consider to be natural. She has her own plot. The upper bound on the cosmological constant was so small that a number of distinguished physicist believed that its only “natural value” must be zero and constructed models in accordance with their wishes. Well, the cosmological constant turned out to be unnaturally small but not zero. In 1950’s four Nobel Laureates proposed the two-component neutrino theory whereby the neutrino masses were naturally zero. This was taken over by the inventors of the Standard Model who excluded right-handed neutrinos. They had no reason to do so, except the desire for simplicity.

As the old cliche says: history keeps repeating itself.

45. **David Berman**
April 22, 2014

So, as one of the instigators of “the bet”, please note the question was not whether the you believe in supersymmetry. The question was whether it would be found by LHC by a certain date. (The renegotiation was to take into account the LHC accident a subsequent further two year delay and to allow the next run). I suspect many people on the list who said that susy would not be found still believe in supersymmetry at higher energy scales.

46. **Anon**
April 22, 2014

If they believe in SUSY at higher scales, they also believe that it is standard model till higher scales. They are putting their eggs in both baskets.

47. **Peter Woit**
April 22, 2014

I have no idea what fraction of theorists would say they "believe in supersymmetry at higher energy scales", but there's an obvious problem with taking that position. Post-LHC it's likely to be a very long time before we see data from much higher energy scales, and, unlike the naturalness argument for SUSY by the TeV scale, there's no serious argument for why SUSY should show up at something like a 10 TeV scale. So, "belief" is very much the operative word, with no prospect of experiment telling believers if they're wrong. That's an unfortunately plausible scenario for the future, but not one the physics community should be comfortable with.

48. **Tim**
April 22, 2014

Dear Peter,

As you are not an advocate of string theory nor one of supersymmetry, do you have an opinion on what are likely candidates (if there are any) for a viable fundamental theory of nature? (Apologies if this has been addressed elsewhere.)

49. **Peter Woit**
April 22, 2014

Tim,
That is off-topic, but a FAQ, so I've added something here:
http://www.math.columbia.edu/~woit/wordpress/?wp_super_faq=if-not-string-theory-what-is-your-unified-theory-of-everything

50. **Sideways**
April 26, 2014

This is why I only study the mathematical structures of the nonlinear Bethe-Salpeter type equations.

51. **Sebastian Thaler**
April 27, 2014

Excellent additional perspective from Marcelo Gleiser: http://www.npr.org/blogs/13.7/2014/04/26/306747481/why-won-t-susy-come-home

Raising the Bar

April 23, 2014
Categories: Uncategorized

If you're looking for something to do next Tuesday evening here in New York, an event called Raising the Bar has recruited 50 people to give talks at bars around the city. There are some quite interesting talks on the list, but I'll have to miss them, since I'm scheduled to talk about What We Don't Know About Fundamental Physics at the Blind Tiger on Bleecker Street at 8:30pm. Not sure yet exactly what I'll talk about, but the general idea is to start by explaining that the current situation is that we have a fundamental theory (SM + GR) that is frustratingly good in terms of agreement with experiment, but also frustratingly incomplete. I'll see what I can do to explain the ways in which the SM and GR are incomplete, and what current prospects are for doing better.

Comments

1. **ptmalloy**
   April 23, 2014

   Wish I lived in NYC, sounds fun.

2. **Michael Barton**
   April 23, 2014

   I've been a (silent) follower of your blog for many years. Now I've had an "it's a small world" moment. I live on the West Coast and cannot make your talk. But do say hello to Kate Dulcich, my wife's niece who tends bar at the Blind Tiger!

3. **Peter Woit**
   April 23, 2014

   Thanks Michael, will do!

4. **Goosebumps**
   April 23, 2014

   Peter,

   Is there any way you can make your talk available online? I'd love to be able to attend it but I'm in a different part of the world.

   The incompleteness of the SM and GR that you refer to – do you have separate reasons to feel that both are individually incomplete, or is it just the lack of a fundamental theory including quantum gravity that you're talking about?

   Thanks!

5. **Peter Woit**
   April 23, 2014

   Goosebumps,
   Much of what I was thinking of talking about is basically chapter 8 of my book, which lists the things about the Standard Model that it looks like there should be some deeper explanation of (for instance "Why SU(3)xSU(2)xU(1)?"). These are purely internal to the SM. There is of course also the issue of whether and how to quantize the metric.
   I doubt they'll be video, but in any case I'm not really going to be saying anything that's not in the book or fairly often mentioned here.

6. **Jim Akerlund**
   April 23, 2014

   This sounds like the New York's version of Colorado Café Scientifique. I've been to a few of the Colorado ones, and the format is, half hour talk, followed by a "beer" break, then another half hour question and answer period. The website you point too doesn't give a format for the talks, at least that I was able to see, do you know what the format will be?

7. **Peter Woit**
   April 23, 2014

   Jim Akerlund,
   They're saying 45 min talk + 15 min question and answer. I may cheat by leaving more time for questions. The list of things we don't understand about the SM is pretty short…

8. **srp**
   April 23, 2014

   It might be wise to explain to your audience what you mean by "understand." I've found that there are many people who think that it's currently possible to completely derive the observed structure and behavior of protons or even nuclei from the SM. (They get that notion from the prevalent rhetoric that the SM, which is more "fundamental," is so well understood that it's hard to find things it can't explain.) But there are two different senses of understanding in play between the physicists and the laypeople.

9. **anonymous**
   April 24, 2014

   Kind of off topic for this post but on topic for this blog in general. Here's a link to your colleague Brian Greene's article discussing the recent BICEP2 results. It is as fair and balanced as you can hope. He takes special care to introduce the speculative section toward the end with plenty of warning: "Finally, let me address an issue I've so far carefully avoided, one that's as wondrous as it is speculative. A possible byproduct of the inflationary theory is that our universe may not be the only universe." (With plenty of context, he even uses the expression "seems almost too beautiful to be wrong.")

10. **Tim Howells**
April 24, 2014

I guess you've seen this one:
http://www.condenaststore.com/-sp/A-man-walks-past-a-sign-advertising-a-discussion-entitled-Is-string-theo-New-Yorker-Cartoon-Prints_i8546213_.htm

11. **Igor Khavkine**
April 24, 2014

Peter, I applaud your idea of critically discussing the outstanding problems, or lack thereof, with the quantum field theories of the SM and GR. However, as you are probably well aware, many discussions of the problems with the quantization of the metric are fraught with misconceptions, misinformation, and various aesthetic and philosophical prejudices, often despite even the best intentions. My take on it is that there are more perceived than actual problems there. Not long ago, I gave a conference talk with a brief critical review of these issues and some supporting arguments. It was recorded and is available on YouTube: Gravity: an exercise in quantization (Munich, 2013).

12. **Peter Woit**
April 24, 2014

Tim Howells,
Yes, there's a copy of it hanging in my office…

Igor Khavkine,
Thanks! About quantum gravity even more than other subjects, part of the problem seems to be that we don't really understand what it is that we don't understand…

13. **Shantanu**
April 24, 2014

Peter somewhat OT, but would like to know your comments on strominger's recent talk
at PI. Much of it is same as his talk at Harvard some years back which you blogged about,
but still would be interested in your take in the update.

14. **Peter Woit**
April 24, 2014

Shantanu,
Looks to be much the same as the talk from four years ago, see
http://www.math.columbia.edu/~woit/wordpress/?p=3206
I think including exactly the same slide for a "report card of string theory". The same comments continue to apply.

15. **Roger**
April 24, 2014

SM + GR is frustratingly incomplete? That is a purely theoretical opinion, as there is no known experiment that demonstrates any incompleteness or incompatibility.

16. **Neil**
April 24, 2014

I am still laughing about that New Yorker cartoon. It is priceless, and so appropriate to this post.

17. **Chris Austin**
April 25, 2014

Roger, to the extent that the de Sitter radius can be calculated within SM + GR, it tends to come out around the Planck length, about 10^{-35} metres, which is too small by a factor of about 10^{-61}. Minimal theoretical frameworks that tend to lead to this conclusion include asymptotic safety, (see the discussion around (58) on page 13), and causal dynamical triangulations.

18. **Peter Woit**
April 25, 2014

All,
Sorry, but this is not a good place to debate quantum gravity. Enough.

19. **Richard**
April 26, 2014

Peter,

You might want to catch Nathan Seiberg's talk, "Where is Fundamental Physics Heading?", which will be held at the Simons Foundation in NYC on April 30 (Go to the Eventbrite site, and Google "Seiberg" to register*.).
Take care.

— Rich

* Registration is free.

20. **A**
April 26, 2014

Thanks Igor for posting that talk! Really wish that more people would explicitly mention the difference between perturbative and non-perturbative behavior.

21. **Peter Woit**
April 26, 2014

Richard,

Already planning on attending that. Having it in a bar though might be better…

22. **S. Molnar**
April 26, 2014

I'm not sure if this is, as suggested above, inspired by Café Scientifique, but one might as well raise a glass to the founder, who just died: http://www.theguardian.com/science/2014/apr/24/duncan-dallas

I'm too far away to attend, but I was drawn to the talk titled "The Rise of Greek Culture" until I realized that it's "Geek Culture". After my recalibration, I was then interested in "Powerful Women in Geek Tragedy" (Carly Fiorina?), only to find that I had made the opposite mistake. I guess it's just as well I can't make it: I'll never get the hang of this.

23. **Anna**
April 27, 2014

Good luck with the talk – wish I could go – but it's a pity that the promoters chose a picture that perpetrates all the worst cliches about scientists – men in white coats in laboratories. Well, aprons anyway in this case. I'll bet you have never worn a lab coat since your undergrad days, or possibly even high school. Or entered a laboratory with beakers and the like. And some of us are even women.

24. **Art**
April 27, 2014

Nice to see you're sold out, but seriously, at a bar? Is alcohol consumption down in NY, or is this Manhattan irony? There are these places called "libraries"…

25. **tt**
April 27, 2014

wouldn't the librarian say "sshhhh" ?

26. **Tommaso**
April 30, 2014

Hello Peter,

so how was the event ? Don't leave us in the dark !
Cheers,
T.

27. **Peter Woit**
April 30, 2014

Hi Tommaso,

I think it went quite well. Nice crowd, partly people there for the event, partly people just at the bar for the evening. Most seemed to be paying attention and getting something out of it (except maybe the couple necking in one corner…). After talking for about 45 minutes, I then spent another hour or so talking to people individually, got to meet quite a few of them, including some students.

I'm sure many people didn't understand a lot of what I was saying, but hopefully I got across some of the flavor of the current state of this kind of theoretical physics. This was the first time this kind of thing has been organized, I think it was a big success, so they may do it again, and people in other cities evidently have expressed interest in doing something similar.

I did get one beer out of it, and the bar-owner seemed very pleased about the whole thing.

Quick Links

April 28, 2014
Categories: Uncategorized

- The Defense Department has awarded a $7.5 million grant to Steve Awodey of CMU, Vladimir Voevodsky of the IAS and others to support research in Homotopy Type Theory and the foundations of mathematics. I had thought that getting DARPA 10 years ago to spend a few million on Geometric Langlands research was an impressive feat of redirection of military spending to abstract math, but this is even more so.
- On some kind of opposite end of the spectrum of government spending on mathematics, there's the story of the NSA, the largest employer of mathematicians in the US. Tom Leinster has an article in New Scientist about the ethical issues involved. More at the n-category cafe.

Seven years after the NSA-backdoored NIST standard was discovered by Microsoft researchers, and seven months after Snowden documents confirmed this (see here), the NIST has now removed the backdoored standard from its random number generator standards. As far as I know there has never been an explanation from the NIST explaining how the backdoored algorithm was made a standard, or why anyone should trust any of the rest of their cryptographic standards at this point. Earlier in the year they issued a Draft report on their standards development process which explained nothing about what had happened. The language about the NSA in the report is:

> NIST works closely with the NSA in the development of cryptographic standards. This is done because of the NSA's vast expertise in cryptography and because NIST, under the Federal Information Security Management Act of 2002, is statutorily required to consult with the NSA on standards.

which seems to indicate they have no intention of doing anything about the problem of NSA backdoors.

- On the Langlands front, for those who don't read French Vincent Lafforgue has produced an English translation of the summary version of his recent summary of his recent work on global Langlands for function fields (already proved by his brother, but he has a way of doing things without using the trace formula).

Langlands continues to add material to his web-site at the IAS. See for instance his long commentary on some history at the end of this section and his recent letter to Sarnak with commentary at the end of this section, where he gives his point of view on the state of the understanding of functoriality and reciprocity.

- Sabine Hossenfelder has some interesting commentary on her experiences in the academic theoretical physics environment here.

Mark Hannam has some related commentary on academia at his new blog here.

- I'm still trying to finish a first draft of notes about quantum mechanics and representation theory (available here). I recently came across some similar notes which are quite good by Bernard, Laszlo and Renard.

David Renard also has here some valuable notes on Dirac operators and representation theory.

- Last Friday and Saturday at the University of South Carolina there was a Philosophy of the LHC Workshop, with talks here. Many of the talks were about the nature of the evidence for the Higgs and its statistical significance. James Wells talked about the supposed Higgs naturalness problem. He argues (see paper here) that you can't base the problem on the Planck scale and quantum gravity since you don't know what quantum gravity is (I strongly agree…). Where he loses me is with an argument that there must be lots more scalars out there than the Higgs (because string theory says so, or it just doesn't seem right for there to only be one), and these cause a naturalness problem. Of course, once you have the naturalness problem, SUSY is invoked as the only known good way to solve it.

   April 29, 2014

   A quick addendum: Vincent Lafforgue claims a proof of the "automorphic to Galois" direction of the global Langlands correspondance – attaching Galois representations to automorphic representations, the ""easy""" direction – for any reductive group over a function field, while his brother Laurent has established both directions but only for GL_n.

   Re Dual_EC_DRBG:

   * Designing cryptographic standards for the US government has always been half of the NSA's mandate, and they do that work in collaboration with NIST. This has never been a secret. Usually it's a good thing because they do employ a lot of talented people, and the US government does have an interest in using cryptography that can't be broken by, say, China. If you kick out the NSA, someone still has to design crypto and no one can be trusted to do it. The only solution is to publish the algorithms and let hordes of academic cryptographers try to break them in the hope of getting a paper out of it. That works against NSA subterfuge too.

   * There was something obviously screwy about Dual_EC_DRBG even before Shumow and Ferguson worked out the details. Cryptographic primitives that need quasi-random initialization constants normally use so-called nothing up my sleeve numbers, such as digits of pi. Dual_EC_DRBG uses mysterious constants that were provided by the NSA without explanation. Given that it's also based on elliptic curves (the EC in the name), it's easy to guess that the mysterious constants are some sort of public key.

   * I don't think published Snowden documents confirmed that Dual_EC_DRBG was backdoored; they just said the NSA was trying to insert back doors into cryptographic primitives, and everyone (or just The Guardian?) assumed it was Dual_EC_DRBG because that was already under suspicion. I'm not completely sure about that, though. Regardless, the Shumow and Ferguson paper was not what caused the initial suspicion, later confirmed by Snowden—the paper was itself a confirmation of what anyone would suspect from looking at the standard.

   * Dual_EC_DRBG is only breakable by whoever has the private key. It's not breakable by, say, China. This was obviously a design goal. The thing is that it seriously constrains the design, which is why Dual_EC_DRBG is so obviously suspicious. Public keys are big (200+ bits for ECC, thousands or millions of bits for other public key systems). If an algorithm only uses nothing-up-my-sleeve numbers, there isn't enough room in the design for a public key. You could still design in a subtle flaw not based on public-key cryptography, but anyone who noticed that flaw could exploit it, and there's no way to predict when, say, China would notice it. You can sort of see how NSA decision-makers could justify Dual_EC_DRBG as within the NSA's mandate, but a deliberate flaw that might leave US communications totally exposed to anyone is a different matter. So I'm not personally too worried about other NIST cryptographic standards.

3. **Peter Woit**
   April 29, 2014

   Ben R.,

I don't see any reason at all to have faith that NSA-introduced backdoors will only ever be usable by the NSA. Do you really think that everyone who works for or has worked for the NSA except for Edward Snowden is completely devoted to keeping their secrets secret and will never slip up on this?

The argument seems to be that it was obvious from the beginning that this was bad crypto, which makes even stronger the main concern here: how and why did the NIST introduce a bad crypto standard? They have done nothing at all to address this, and from all appearances the reason is they feel they have a legal mandate to allow the NSA to use them for this purpose. That the specific mechanism for this involves mathematics and mathematicians makes this an issue that should be of concern to the math community.

4. **Ben R**
April 29, 2014

I do think that the NSA can keep a private key secret. Private keys, unlike Powerpoint slides, never have to be seen by anyone. They can be stored in tamper-resistant hardware decryption modules kept under physical guard, and probably detached from any network most of the time.

I agree it's worrying that this actually became a standard, and that it took so long to become a scandal despite the signs being there from the beginning. It means the open cryptographic community is not paying enough attention. I just don't think it means that the NSA could be secretly subverting other standards without their knowledge. You can look at existing standardized primitives and see that they aren't suspicious in the way that Dual_EC_DRBG is, and there certainly won't be another one like it in the future after this fiasco.

5. **Roger**
April 29, 2014

Blaming NIST is a little strange. It has released dozens of security standards, and its track record is extremely good. Nobody's private info was compromised by Dual_EC_DRBG, as far as anyone knows. On the other hand, Google, Facebook, and Yahoo have compromised 100s of millions of users with the Heartbleed bug. There is more reason to trust NIST for crypto than those companies.

6. **David Ben-Zvi**
April 29, 2014

Peter – As Simon Pepin Lehalleur points out, Vincent Lafforgue's work goes far beyond reproving his brother's results without the trace formula. His work applies to arbitrary reductive groups, which is a huge breakthrough since representation theory works in profoundly different ways outside of GL_n. In particular the "other direction" (Galois to automorphic) doesn't even make sense in the same way as for GL_n, since representations now come clustered together in "L-packets" labeled by Langlands parameters (a labeling we finally have thanks to this work of V. Lafforgue). Together with the giant breakthroughs of Gaitsgory and collaborators in the geometric setting this is a really exciting time for representation theory over function fields!
(…not to mention the advances in the number field setting, which are far too numerous and fast paced for me to even keep up on a hearsay level).

7. **Peter Woit**
April 30, 2014

Simon and David,
Thanks for the comments about the V. Lafforgue work, that's very helpful.

10. **Zathras**
April 30, 2014

"I had thought that getting DARPA 10 years ago to spend a few million on Geometric Langlands research was an impressive feat of redirection of military spending to abstract math, but this is even more so."

I'd say this is backwards, with much more potential for applications for homotopy-type theory, as compared to Langlands."

11. **Anm**
April 30, 2014

"I'd say this is backwards, with much more potential for applications for homotopy-type theory, as compared to Langlands."

I feel the same. Homotopy-type theory seems (to me) the most exciting idea anyone proposed in many years.

12. **eitan**
May 2, 2014

Apart from formal theorem proving, type theory has been used in the past to verify the correctness of protocols in large complex mission critical systems where you really dont want to have bugs, race conditions or infinite loops. I know of at least one very large DARPA grant of this nature which was handed a few years ago. As far as I understand (not an expert) its still not clear how constructive (hence useful) the new univalent approach is, but one can certainly see why DARPA would be interested in exploring this.

In applications, one needs highly qualified programmers who also know theory in this approach to protocol verification, this might explain the large sum. Geometric Langlands is really interesting, but I dont see the DARPA connection, but who knows higher math is sometimes useful in surprising ways.

    Here's a quick link of possible importance related to Bicep2, which you discussed a while ago:

    http://resonaances.blogspot.co.uk/2014/05/is-bicep-wrong.html

16. **Peter Woit**
    May 12, 2014

    Thanks George,
    That looks like big news, but I know nothing beyond what Jester has. I'll repeat my standard advice that Resonaances is a blog anyone seriously interested in HEP physics should be following. If the BICEP2 result does fall apart, will be interesting to see if that gets anything like the often-fevered coverage of the initial claim. It's certainly not going to be advertised as evidence against the multiverse…

17. **theoreticalminimum**
    May 13, 2014

    See this instead:

    > As for Falkowski's suggestion in his blog that the BICEP has admitted to making a mistake, Pryke says that "is totally false." The BICEP team will not be revising or retracting its work, which it posted to the arXiv preprint server, Pryke says: "We stand by our paper.

Quillen Notebooks

May 6, 2014
Categories: Uncategorized

Daniel Quillen, one of the greatest mathematicians of the latter part of the twentieth century, passed away in 2011 after suffering from Alzheimer's. For an appreciation of his work and an explanation of its significance, a good place to start is Graeme Segal's obituary notice, and there's also quite a bit of material in the AMS Notices.

It's very exciting to see that the Clay Math Institute now has a project to make available Quillen's research notebooks. Segal and Glenys Luke have been working on cataloging the set, producing lists of contents of the notebooks, so far from the earliest ones in 1970 up to 1977. Quillen's work ranged very widely, and for much of the 1980s he was very much involved in what was going on at the boundary of mathematics and quantum field theory. His work on the Mathai-Quillen form provided a beautiful expression for the Thom class of a vector bundle using exactly ingredients that formally generalize to the infinite-dimensional case, where this provides a wonderful way of understanding certain topological quantum field theories. The Mathai-Quillen paper is here, see here for a long expository account of the uses of this in TQFT.

I've just started to take a look through the notebooks, and this is pretty mind-blowing. The Mathai-Quillen paper is not the most readable thing in the world; it's dense with ideas, with motivation and details often getting little attention. Reading the Quillen notebooks is quite the opposite, with details and motivation at the forefront. I just started with Quillen's notes from Oct. 15 – Nov. 13, 1984, in which he is working out some parts of what appeared later in Mathai-Quillen. This is just wonderful material.

Besides his own ideas, there are notes taken based on other people's talks. See for instance these notes from a private talk by Witten in Raoul Bott's office on Dec. 15, 1983.

I was already having trouble getting done a long list of things I am supposed to be doing. Having these notebooks available is going to make this a lot worse….

Comments

1. **Staffan Angere**
   May 7, 2014

   What a nice coincidence, I just started reading "Homotopical Algebra"!

   More generally, these notes are an absolute goldmine for people like me, who are interested in the philosophy of mathematics but not working mathematicians. So much of the process of creating mathematics gets lost in the preparation of mathematical papers: to an outsider, it seems like proofsm theorems and definitions appear almost magically in the mathematician's mind. Reading notes helps us see that they are mostly just hard working but usually smart people.

   Btw, this is my first comment here, although I've been following the blog for a couple of years. Thanks Peter for keeping up the good work!

2. **Igor Khavkine**
   May 7, 2014

   Just a curiosity, but does anyone know why Quillen never followed up his PhD work on overdetermined PDE systems and changed his focus so radically?

3. **Peter Woit**
   May 7, 2014

   Igor Khavkine,
   If you look at the notebooks from the late 1970s, Quillen did return to analysis. I'd also be curious to know about the shift to topology and algebra from his thesis, although perhaps what is surprising is that as a student of Bott he was working on PDEs at all.

4. **Igor Khavkine**
   May 7, 2014

   Peter, it's worth noting that not all work on PDEs is in analysis. In fact, Quillen's work was on the so-called *formal theory of PDEs*, which is mostly geometric and right around the time of the early 1960s it received a healthy dose of homological algebra, under the influence of the ideas of Donald Spencer. In his thesis, Quillen exploited the homological algebra ideas of Spencer to show that any overdetermined linear differential operator fits into a formally exact sequence of differential operators, each operator completely characterizing the integrability conditions of the preceding one, which is sometimes called the *compatibility complex*. He also showed some technical results on the ellipticity of this complex. This result is quite important in the formal theory, though apparently it was known much earlier. However, earlier proofs relied on non-geometric, heavily coordinate dependent methods that were developed by Janet and Riquier. Quillen's solution was on the other hand coordinate independent and fully geometric, in line with the spirit in which the ideas of Spencer were introduced.

   I'm not sure of the history of Bott's interest in the formal theory of PDEs, but it is recorded in his *Notes on the Spencer resolution* which were circulated around 1963.

5. **Sakura-chan**
   May 8, 2014

   Wow the notes are wonderful. Thank you Peter for bringing them to our attention!

6. **Deane**
   May 16, 2014

   Igor,

   I'm curious about why you ask why Quillen abandoned the formal theory of overdetermined systems of PDE's. Do you use this formal theory yourself?

   My view is that he shifted to new directions (which involve similar formal structures) that had a more profound impact on mathematics. In fact, many of the people who worked on this back then, including Spencer, Quillen, Guillemin, Sternberg, Goldschmidt, did their best work on other subjects. It seems to me that the modern formal theory of PDE's has had relatively little impact on other areas of mathematics.
   As far as I know, only Robert Bryant and his students, who use the classical approach of E. Cartan have been able to use the formal theory effectively, usually in applications to differential geometry.

7. **Deane**
   May 16, 2014

It is indeed a little mysterious why Quillen worked on the formal theory of PDE's for his thesis. Around that time, Guillemin, Sternberg, and Quillen were around and working on such things. But it seems like Sternberg would have been the more natural choice as an advisor for this topic.

8. **Igor Khavkine**
May 18, 2014

Dean,

Yes, mysteries all around. You say: *"It seems to me that the modern formal theory of PDE's has had relatively little impact on other areas of mathematics."* In a way you are right, but more is the pity! There are a few, not totally connected, islands where it has been continuously applied. I'd say that much of the potential utility and the power of the formal theory still remains untapped. I for instance have been finding more uses for it (in the mathematical structure of field theory, for instance) the more I've learned about it, including the results due to Quillen.

9. **Cynthia (Quillen) Cohen**
June 1, 2014

Firstly I think that "Quillen" (my Dad) would be very pleased that you are enjoying what he called his "diary". He was always trying to get us kids to write diaries, he spoke to us of Samuel Pepys, and it seems, like him, that Dad left something meaningful behind.

I thought I'd add a little info as to how he worked for the benefit of Staffan Angere (and anyone else interested). Certainly in the years of my life (I was born in 1980) Dad did two types of writing. The first was day to day writing which he did on scrap paper, notebooks etc, and the second was the "diary". The diary was where he would write up, in a more organized way, his thoughts and what he was working on.

10. **Peter Woit**
June 2, 2014

Thanks Cynthia,

It's reassuring to know that the notebooks are a second, more polished summary of your father's day to day work. It was kind of frightening to contemplate the possibility that he was directly writing out texts of this high quality without going through a much more confused stage of the sort where the rest of us spend most (if not all…) of our time.

BICEP2 News

May 13, 2014
Categories: Uncategorized

Recall that this past March results from BICEP2 were announced, claiming a greater than 5 sigma detection of a primordial B-mode signal in the CMB polarization. This result received a huge amount of world-wide attention (and see some commentary here). Yesterday saw a very curious situation, with Adam Falkowski at the Resonaances blog claiming that the BICEP2 foreground analysis was flawed, and that "Various rumors place the significance of the corrected signal between 0 and 2 sigma." Adrian Cho at Science magazine has a story about this, quoting Clement Pryke, co-PI of BICEP as saying "We stand by our paper", while acknowledging that, with respect to a plot of Planck data they used to estimate the foreground "It is unclear what that plot shows".

The controversy surrounds slide 6 of this presentation, with the BICEP foreground analysis evidently relying on scraping data from this slide. The claim at Resonaances is that they didn't take into account the "Not CIB subtracted" notation on the slide:

> However, it seems they misinterpreted the Planck results: that map shows the polarization fraction for all foregrounds, not for the galactic dust only (see the "not CIB subtracted" caveat in the slide). Once you correct for that and rescale the Planck results appropriately, some experts claim that the polarized galactic dust emission can account for most of the BICEP signal.

This is backed up by David Hogg's report of a talk by Raphael Flauger at NYU yesterday:

> At lunch, Raphael Flauger (NYU) gave a beautiful talk on foreground uncertainties related to the BICEP2 results. He built his foreground models as did the BICEP2 team by scraping data out of Keynote ™ presentations posted on the web! I have to say that again: The Planck team showed some maps of foregrounds in some Keynote presentations and posted them on the web. Flauger (and also the BICEP2 team before him) grabbed those presentations, scraped them for the all-sky maps, calibrated them using the scale bars, and worked from there. The coolest thing is that Flauger also simulated this whole process to account in his analysis for the digitization (scraping?) noise. Awesome! He concludes that the significance of the BICEP2 results is much lower than stated in the paper, which makes him (and many others) sad: He has been working on inflation models that produce large signals.

It sounds like this issue is not going to get resolved until there is something more substantial from Planck about this than a slide suitable for data scraping. In the meantime, blogs are your best source of information. Or maybe Twitter, where Erik Verlinde tweets from the Princeton PCTS workshop Searching for Simplicity that:

> News from Princeton: BICEP2 polarization data are due to dust foreground and not caused by primordial gravity waves.

Update: There's also a New Scientist story here. It should be emphasized that the BICEP team are denying that there is any need to revise what is in their paper, with New Scientist quoting John Kovac of BICEP as follows:

> Kovac says no one has admitted anything. "We tried to do a careful job in the paper of addressing what public information there was, and also being upfront about the uncertainties. We are quite comfortable with the approach we have taken."

See comments in the comment section here from Sesh Nadathur and Shaun Hotchkiss explaining why there may not be very much significance to this issue.

Update: Sesh Nadathur has a detailed post up now about this, New BICEP rumours, nothing to see here. Bottom line is:

> The BICEP result is exciting, but because it is only at one frequency, it cannot rule out foreground contamination. Other observations at other frequencies are required to confirm whether the signal is indeed cosmological. One scenario is that Planck, operating on the whole sky at many frequencies but with a lower sensitivity than BICEP, confirms a gravitational wave signal, in which case pop the champagne corks and prepare for Stockholm. The other scenario is that Planck can't confirm a detection, but also can't definitively say that BICEP's detection was due to foregrounds (this is still reasonably likely!), in which case we wait for other very sensitive ground-based telescopes pointed at that same region of sky but operating at different frequencies to confirm whether or not dust foregrounds are actually important in that region, and if so, how much they change the inferred value of r.
>
> Until then I would say ignore the rumours.

Peter Coles also has a blog post here, with bottom line

> I repeat what I've said before in response to the BICEP2 analysis, namely that the discussion of foregrounds in their paper is disappointing. I'd also say that I think the foreground emission at these frequencies is so complicated that none of the simple approaches that were available to the BICEP2 team are reliable enough to be convincing. My opinion on the analysis hasn't therefore changed at all as a result of this rumour. I think BICEP2 has definitely detected something at 150 GHz but we simply have no firm evidence at the moment that it is primordial. That will change shortly, with the possibility of other experiments (specifically Planck, but also possibly SPTPol) supplying the missing evidence.
>
> I'm not particularly keen on the rumour-mongering that has gone on, but then I'm not very keen either on the way the BICEP2 result has been presented in some quarters as being beyond reasonable doubt when it clearly doesn't have that status. Yet.

Update: There will be a talk about this issue in Princeton tomorrow morning, see here.

Update: Slides from the Flauger talk at Princeton are here. I'll leave discussion of the results presented to the better-informed, but will comment that this work appears to definitely involve new heights in the technology of data-scraping from Keynote presentations.

Update: Video of the Flauger talk is here. Quite interesting are the introductory remarks of Paul Steinhardt, and the concluding remarks of Lyman Page. See also new blog posts from Jester and Sesh Nadathur. Sesh (via Eiichiro Komatsu at Facebook) includes a transcription of part of Page's comments on the situation:

> This is, this is a really, peculiar situation. In that, the best evidence for this not being a foreground, and the best evidence for foregrounds being a possible contaminant, both come from digitizing maps from power point presentations that were not intended to be used this way by teams just sharing the data. So this is not – we all know, this is not sound methodology. You can't bank on this, you shouldn't. And I may be whining, but if I were an editor I wouldn't allow anything based on this in a journal. Just this particular thing, you know. You just can't, you can't do science by digitizing other people's images.

From looking at all this, and seeing what the people in Princeton are saying, my non-expert opinion is that the BICEP2 result should be interpreted as an observation of B-mode polarization, but there's no convincing data yet about the crucial question of whether this is foreground or cosmological. The BICEP2 data could not address this, and the relevant Planck data is not yet available (other experiments will soon also provide the data needed to resolve this question). The BICEP2 press release claiming "the first direct evidence for cosmic inflation" now looks like it may have been a highly premature claim.

Update: Talks ongoing at Caltech today about this at a workshop, videos later here. On Twitter, you can follow the BICEP/Planck fight via Sean Carroll:

> At Caltech CMB workshop. #BICEP2 folks seem completely unconcerned about recent worries about galactic foregrounds. Wait for Planck paper…
>
> Zaldarriaga on CMB grav waves vs. dust: sane answer is "let's just wait." On the other hand… we just can't. No scientist is that patient…
>
> MZ: Planck hasn't measured dust in #BICEP2 region. But extrapolating from where they did measure, apparently can fit B-mode signal.
>
> MZ: "I'm not happy this is on Facebook and Twitter."

Seems to me we're now stuck with Planck saying they think this is dust, BICEP saying they think it's not. Planck is the side that has data about dust, BICEP is the side that has something they scraped off a slide of a Keynote presentation…

Update: Excellent article about this in the Washington Post from Joel Achenbach: Big Bang backlash.

Update: Zaldarriaga: I believe the case in favor of a detection of primordial B modes is not convincing (hopefully just temporarily). See more here and here.

Comments

1. **Sesh**
   May 13, 2014

   I don't see that this rumour has materially affected our knowledge about BICEP results in any way. In particular, the quoted value of r=0.2 was obtained assuming *zero* foreground dust contamination (which everyone knew was unrealistic), and that certainly hasn't changed. They also tried a handful of different foreground dust models, all expected to be only approximations to the real dust contamination – only one of which was extracted from this Planck slide – and found that all these approximate dust models gave a foreground contamination that was an *order of magnitude* too small to account for the B mode signal seen.

   Now, nobody really believed these dust models were entirely accurate (at least I hope not). One of the handful turns out to probably be slightly less accurate even than that. So what's new? The most probable answer to the question of how much of the signal is due to dust contamination is still "not a lot". And the answer to the question of how precisely we trust any one of the dust models they used is also "not a lot".

   What's interesting is that it now seems unlikely that Planck is going to be able to tell us what the real dust contribution in the BICEP region is, but this doesn't fit with the rumoured narrative of "BICEP shown to be wrong".

2. **Nick**
   May 13, 2014

   I am not a physicist (computer engineer), but am very much interested in this area. Normally I read through a lot of this stuff and sometimes research more, and sometimes just say wow. On this particular issue though, I really have to ask to ensure I'm reading what I think I'm reading. They took a slide from a presentation and scraped points off of it, and used that as their data points?! Why would someone even bother to do that? Isn't the original data that was used to generate the slide in the first place available in a more appropriate form, so that screen scraping wasn't required? Couldn't the whole exercise be repeated again, but use the original data (instead of the flawed screen scrape data) to validate the results or get more accurate results?

3. **Peter Woit**
   May 13, 2014

   Nick,
   As you can see from Sesh's comment, the argument is that this was being used to show that this source of foreground was an order of magnitude too small to account for what they were seeing (to be clear, I have no idea who is right about this, other people are making other claims). So, from this point of view, it didn't matter much whether they had an accurate version of the Planck data, the slide was good enough.

   This does show that the relationship between the Planck and BICEP teams isn't exactly one of close cooperation…

4. **Seyda**
   May 13, 2014

   Erik Verlinde only tweets the science magazine blog post. So no new information really.

5. **Nick**
   May 13, 2014

   Peter (and Shesh),

   Thanks for the addition clarity. I think the big item here (beyond the accuracy of the original claim) is actually that screen scraping was required at all. Saying close cooperation doesn't exist seems to be an understatement if people are willing to go to those types of extremes to get good data.

6. **AdamT**
   May 13, 2014

   This is pretty silly behavior for scientists. Apparently the Planck team would not release the raw data to the BICEP2 team which caused them to go for the screen scrape:

   > "Part of the problem is that the Planck team has not made the raw foreground data available, he says. Instead, BICEP researchers had to do the best they could with a PDF file of that map that the Planck team presented at a conference."

   So here we have two very high profile groups with talented researchers bickering and competing resulting in 'digitizing' a screen scrape off a PDF file.

   The things they work on are cosmic in scope and the results of potentially huge import for the future of science, but the behavior of the individuals is decidedly middle school in scope and (should be) embarrassing for scientists.

7. **Krzysztof**
   May 13, 2014

My personal bet is that at the end, we will meet mid-way, at rho ≈ 0.1 – anyone interested?

8. **Curious Mayhem**
   May 13, 2014

   The two BICEP talks that I've heard were a bit opaque on their relationship with the Planck collaboration. Certainly, the slides would be good enough for an order of magnitude estimate, or better than an order of magnitude. To get fine detail and the level of confidence they claim, though, requires better information than that. But as Sesh points out, the BICEP team has a number of other ways of checking their result, and they all agree, within uncertainties. Of course, they agree even better if the uncertainties are larger than BICEP initially claimed. The BICEP talks all stressed the multiple independent checks of their results.

   The refusal of the Planck team to share their raw data is disturbing. This is potentially one of the most important scientific discoveries of the last century. I assume, as scientists, we outgrow this behavior in high school or college.

9. **Shaun Hotchkiss**
   May 13, 2014

   Slightly further to Sesh's comments it should be stressed that within the patch of sky BICEP has measured, the dominant noise in Planck's measurement is Planck's instrumental noise (or so I have been led to believe). That this is probably true can be seen by the fact that in Planck's recent paper on polarisation (http://arxiv.org/abs/1405.0871) the BICEP patch is part of the region that has been masked because it lacks sufficient signal (dust) to noise (instrument).

   Therefore, any attempt to reconstruct the expected dust foreground for BICEP by analysing Planck's preliminary "polarisation fraction" maps slide is probably going to end up mistaking a fair bit of Planck's instrument noise for dust. Obviously, Planck's instrumental noise has nothing to do with the BICEP detector. So, as Sesh stressed, Planck might not be able to, even in the long run, determine the dust foreground along BICEP's line of sight accurately enough to have an impact on BICEP's measurement. This seems kind of obvious to me in hindsight, or Planck would have detected BICEP's signal long before BICEP did!

   Planck will only ever be able to make a statistical detection of tensors by analysing B-modes over the whole sky and saying the average signal isn't consistent with zero, but it won't be able to say that along one specific line of sight the B-mode signal is x \pm y, like BICEP has.

   At least, this is the picture as I've understood it over the last week of discussion.

10. **emile**
    May 13, 2014

    There can be good reasons not to share your "raw" data: you are possibly not done with the analysis and what you have shown up until now are preliminary results, or you think that the raw data would likely not be interpreted correctly by the other experiment (for example, raw data from a large particle physics experiment could not (should not) be used by another experiment). If the Planck results were published in a paper and hence not preliminary, then to give the the numbers used to make a plot used for the publication should be a simple courtesy however.

11. **piscator**
    May 13, 2014

    Some of these comments are really quite silly. At the time of the BICEP announcement no Planck polarisation papers had appeared. Preliminary results that appear in talks are just that, preliminary. No experiment should be under any obligation to release its results or data before they are ready to their own satisfaction.
    Once Planck releases its fully analysed polarisation data, uncertainties on foregrounds will come down. Until then, the uncertainties are higher. The basic obligation experimentalists have to the community is to be correct.

    BICEP chose to announce their results via press conference, using the full amplification of the news media. IMO publishing in this manner means you have to be right – there can be no excuses if foregrounds turn out larger than your best estimate, it is either Stockholm or go home.

    I hope it's the former, as the science is enormously exciting if they are correct.

12. **JG**
    May 13, 2014

    Shaun Hotchkiss

    even if Planck can't get an accurate dust map for the specific patch of sky measured by BICEP2 the fact that the polarization signal (from dust) is so high in the rest of the map would make it hard to argue how the small BICEP2 patch might avoid such contamination.

13. **Shantanu**
    May 13, 2014

    Adam T,
    situation in astronomy is much better than in HEP.
    At least they release their data after some years of proprietory period.
    In HEP experiments no one releases ANY data to outside world even decades
    after experiment has ended.

14. **AdamT**
    May 13, 2014

    piscator,

    The news reports suggest that Planck scientists are passing around rumors tsk tsking the BICEP2 folks for screen scraping and saying that the raw data interpreted correctly lowers confidence in BICEP2's results. If that is true and the they refuse to let the BICEP2 folks have access to the raw data, then this is very bad form from the Planck investigators.

    This is not middle school. The science should be held as a higher goal than trying to pass around rumors and withholding data from a rival experiment that might illuminate a discovery of this magnitude.

15. **Sesh**
    May 13, 2014

    JG: That argument could be quite simple actually, since the level of dust contamination varies across the sky – there's obviously more dust in the line of the galaxy than in other regions. BICEP's window was specifically chosen to be in a region that was believed to have low dust emission. The fact that Planck is perhaps unable to distinguish dust emission from instrument noise in that part of the sky could even be an encouraging sign that dust emission is actually small there (I'm obviously making some assumptions about noise properties which could be wrong, but that's kind of the point – people making assumptions without knowing the details can wind up at any kind of conclusion).

As several others have said, it's silly to blame the Planck team for not releasing preliminary data: they're still working on it and checking it, that's why it's preliminary.

16. **Tony Smith**
May 13, 2014

Could Planck's failure to release data be related to the fact that

Planck 2013 results. XXXI. Consistency of the data
has NOT yet been released – although the http://www.sciops.esa.int web site says
that it has been in 2014 "Submitted to A&A"
but NOT yet Accepted by A&A.

Tony

17. **CIP**
May 13, 2014

Just a point of psychology. Anybody who thinks that the same instincts, impulses and motivations that impel us in middle school aren't still at work in middle age hasn't been paying attention. Read some history, or better, Watson's version of the Double Helix.

If Watson and Crick hadn't surreptitiously swiped Franklin's X-Ray diffraction, they wouldn't have won the Nobel. If Pauling had seen it, he would have collected his third Nobel Prize.

18. **JG**
May 13, 2014

Thanks Sesh

and also I noticed from reading other blogs and comments that Shaun Hotchkiss is fully aware of my trivial point (and has stated it more accurately)

I also agree that Planck have no moral obligation to release raw data before they have accurately modelled influences from instrument noise and other contamination sources

19. **layman**
May 13, 2014

There is one factor nobody mentioned: some BICEP2 scientists are on the Planck collaboration! and they have therefore access to all the raw data.

20. **pion**
May 14, 2014

It seems to me that Planck is not our best hope to settle this issue mainly due to the fact that it is a satellite, and information from certain ground-based telescopes might be more credible.

Since the CMB polarization level is obtained from differencing two intensity measurements toward the same direction on the sky, any optical imperfection of the detectors can potentially leak the dominant intensity to the faint B-mode polarization. A few of these spurious signals can be potentially mitigated by the telescope's scanning strategy; basically, each pixel in the field is observed multiple times with (ideally) different orientations of the polarimeter. Ideally, this would suppress a large fraction of the systematic but not entirely.

Most ground-based telescopes benefit from the earth rotation, others use half waveplate, and in general the scanning strategy could be optimized for minimizing the intensity-to-B-mode leakage. Satellites in orbit, however, are limited and their typical scanning strategy is sub-optimal if not poor. We know, as a fact, that Planck never published their B-maps, and I guess that this is partially due to the issue of B-mode systematics which is always a challenge, for satellites in particular. I'm not sure how much would the Planck team have to say in October.

My best bet is that a joint effort of ground-based instruments (which are located off the pole) might ultimately provide a conclusive answer to this thorny issue. The problem with this alternative, though, is that ground-based experiments are limited to a relatively narrow frequency window. Hopefully, two or three frequency bands will suffice for the construction of a reliable polarized dust model, but this is not apriori guaranteed.

21. **AdamT**
May 14, 2014

CIP,

Just because some people haven't moved on from middle school mentality does not negate that some of is have and that more should.

All defending Planck for not releasing prelim data,

Fine if it is prelim and unsure they should stop spreading nasty rumors about he competing project. Put up or shut up.

22. **JG**
May 14, 2014

AdamT

Planck aren't spreading rumours, it's casual blogosphere discussions causing the stir, the fact that some pretty well respected bloggers are involved has made it a bigger story than it should be, but your reaction is unjustified.

Planck have "put up" their results in an orderly professional manner, and they will deliver the final results later this year

The title of the talk at Princeton tomorrow sounds like something from the social sciences or philosophy: "Towards an Understanding of Foregrounds in the BICEP2 Region" – maybe there is a little humour/sarcasm implied by the title?

23. **M Mahin**
May 15, 2014

The PDF has just come out for the Princeton talk on BICEP2 foregrounds.

http://www.pctp.princeton.edu/pcts/SpecialEventSimplicity2014/Simplicity.pdf

Read it and frown if you're a BICEP2 advocate.

Go to page 39 of the presentation. One corrected model shows 7 out of 9 BICEP2 observation points within the area predicted by a combination of dust foregrounds and gravitational lensing. The other corrected model also shows 7 out of 9 BICEP2 observation points within the area predicted by a combination of dust foregrounds and gravitational lensing.

If you use the BICEP2/Keck combination for the observation points, then it's basically 9 out of 9, with nothing that needs to be explained by cosmic inflation.

24. **Anonymous**
May 15, 2014

The video of the Princeton talk is now available too.

25. **Chema**
May 20, 2014

One thing to remember from this story will be for sure Flauger's work on reproducing the data from the pdf file and "correcting" for the pipeline (starting on healpix maps) effect. Bravo! (note to myself, go back to transparency slides in your next talk)

26. **Nick M.**
May 20, 2014

Yesterday, Matt Strassler finally weighed in on the current BICEP2 controversy with his blog post "Will BICEP2 Lose Some of Its Muscle?" A very interesting read, and, as always, a very balanced presentation. (And please forgive me, Peter, if this link has already been provided elsewhere in your article, or in subsequent visitor postings.)

Walter Burke Institute for Theoretical Physics

May 14, 2014
Categories: Uncategorized

Caltech has just announced the establishment of the Walter Burke Institute for Theoretical Physics, with Hirosi Ooguri as director. It will have a permanent endowment of around \$74 million, with \$30 million of that new funds from the Sherman Fairchild Foundation and the Gordon and Betty Moore Foundation.

To get some idea of the scale of this, the recent worries about HEP theory funding in the US have been due to a drop in funding by the DOE of university research from around \$27.5 million/year to \$24 million/year. So, a few million/year from this endowment should help make up for that, while continuing the trend of changing over theoretical physics funding from government support to philanthropy by the .01%.

Update: In other developments from the .01%, Physics World has the news that nominations are now open for the \$3 million Milner prize in physics. You can submit nominations here. Nominations close June 30, announcement of winners will be November 9.

There's also now a website for the Milner/Zuckerberg \$3 million mathematics prize. Not much info there except that it will reward "significant discoveries across the many branches of the subject." I'm guessing that, like the other prizes, initial picks will be from Milner/Zuckerberg themselves, with those people going on to form the committee to pick future winners.

Comments

1. **CU Phil**
   May 15, 2014

   Hastening a return to the days when gentleman-scientists were supported by royal benefactors. Delightful.

2. **Jon Orloff**
   May 15, 2014

   Any indication that the benefactor wants to choose the topics of research?

3. **Peter Woit**
   May 15, 2014

   CU Phil,
   The trend to private funding does mean that our current equivalent of royalty will be the ones deciding what research gets done. But one difference is that they believe in paying people pretty well: those getting funded shouldn't need a family trust to support themselves.

   Jon Orloff,
   I assume Burke is willing to leave the choice of research topics to the Caltech physicists, although the donation reflects a personal decision that he likes what they are doing more than what other groups are doing. The effect of this move to private funding is more to concentrate control of research directions in certain hands: DOE money is allocated by panels reflecting a broad community, this money will be allocated by Ooguri and a few others.

4. **Low Math, Meekly Interacting**
   May 15, 2014

   The short-term alternative to the 0.01% anointing certain disciplines with cash while public funding dwindles is that public funding dwindles anyway. Easy enough to see a benefit in that context.

   Long-term, however, I worry that the rate of decline in public funding will accelerate in response to a new expectation that the 0.01% will eliminate the need for it.

5. **domenico**
   May 16, 2014

   I think that there is a difference between the Sherman and Betty funds, and the Milner prize: the first will lead to certain (small or large) results in Theorical Physics, the second is a loss of money from a billionaire to a millionaire pensioners.

6. **Sam**
   May 17, 2014

   A couple of points:

   1) Much of the privately funded research, especially the prizes, is solely directed towards the 'intellectual merit' criterion of NSF's two fundamental criteria (broader impacts and intellectual merit.) The funding broader impact activities is very important for the scientific well-being of the nation and this is so recognized in Congress. Funded broader impact activities are visible, and accessible, to members of Congress and their staff. I don't think private funding, prizes especially, will drive the nation out of the funding of science.

   2) Private funding, e.g. the Simons Institute, can be more nimble and experimental. Further, Simons is run by folks that have a deep understanding and experience in the academic research model. There is every reason to hope that new and exciting funding mechanisms/ideas will be brought forth and adapted/adopted in the public sphere.

   Folks are too pessimistic; there are opportunities and changes coming. Not all will work out but some will.

7. **srp**
   May 17, 2014

   An influx of private funding to replace government funding of pure research would be most welcome, especially if the sources are diverse and controlled by diverse groups of scientist/administrators. Up until World War II, almost all important U.S. science was privately funded. Hale was able to build giant telescopes, the biggest science of his day, entirely through private donations. Fields such as geochemistry and chemical engineering were sired by companies and foundations. Especially as government funding of research in the U.S. becomes more unified behind overarching umbrella programs run by a shrinking number of decision-making groups, we should hope for even more entry by the philanthropic into pure research funding.

8. **PhilAnthropy**
May 18, 2014

Let's hope some of this money takes the lead from Jim Simons, for more brad-based support, rather than from the steroid-enhanced star system of Milner. The tendency of the .01% of money to fund the .01% of physics and math doesn't help anyone except the egos of those concerned.

9. **Rob Meyer**
May 26, 2014

Dear domenico and PhilAnthropy:

Here are a few instances where Breakthrough Prize funds (physics and life sciences) are being handed down from the winners to students and other research efforts.

Cheers, Rob

10. **domenico**
May 27, 2014

Dear Rob Meyer:
I don't understand: why to use a prize to reward an old glory, then the old glory could reward a promising young scientist, if is there the direct method to reward the promising young scientists and young research works? Is not these moneys be better spent?

11. **domenico**
May 28, 2014

I have to apologize with the Breakthrough Prize laureates that support the next generation scientists: I had forgotten that the smart choices are in the intelligent people.

Quick Links

May 25, 2014
Categories: Langlands, Multiverse Mania, Uncategorized

Just returned from a few days in Boston, will try and catch up here on various topics:

- This past week I was able to attend some of the talks at the conference in honor of David Vogan's 60th birthday. I'm still trying to make sense of Bernstein's talk on Stacks in Representation theory, where he argued that the category of equivariant sheaves on a certain stack is a better-behaved construction than the category of representations. I've always wondered whether this would be helpful in the case of representations of a gauge group, where the stack has something to do with equivalence classes of connections. It was his first use of Beamer, and some slides went by too fast. I noticed that a few people were documenting talks for themselves with phones/tablets taking pictures of slides/board.

  Among the other interesting talks, Jim Arthur discussed the conjectural automorphic Langlands group, along the lines of this older paper. He indulged in some speculation I'd never heard before, that Langlands functoriality might imply the Riemann hypothesis (somehow by analogy to something from Langlands about the Ramanujan conjecture appearing in Deligne's proof of the RH in the function field case). Unfortunately the laptop being used to show his slides decided to start installing Windows Updates two-thirds of the way through his talk. For whatever reason, I didn't manage to follow his comments at the end of the talk about something new having to do with Weil's explicit formula in number theory. Consulting with some experts later though, I couldn't find anyone optimistic about the Langlands implies RH speculation.

- Also last week, the draft P5 report on a strategic plan for US HEP over the next 20 years was released, with discussion at an HEPAP meeting. Besides planned LHC upgrades, high priority goes to neutrino physics based at Fermilab, with a plan to attract more international participation. Other directions getting a high priority are on-going dark matter experiments and CMB research. A continued move of funding from research grants to construction projects will likely keep pressure on grants to university theory groups. Research into muon colliders is down-played, with a recommendation to "consult with international partners on the early termination of MICE."
- Skepticism about the BICEP2 primordial gravitational wave claims continues, with for instance this story at Science, and this preprint. In retrospect, it's curious that the possible problems with foregrounds did not get more attention at the time of the original high-profile announcement.

  See here for a Caltech workshop on the BICEP2 results. Andrei Linde's talk started with his complaining about the popular and textbook coverage of inflation. He said that when journalists call and ask him what BICEP2 will tell us about Grand Unification, he responds "nothing". At the end of the talk, Sean Carroll asked him about the multiverse, with Linde's response emphasizing what a great thing it is to have a theory that can't be disproved:

  > If you cannot disprove it, then you have this powerful weapon of thinking about and explaining things around you in an anthropic way.

- This coming week here in New York there will be lots of events associated to the World Science Festival. One aimed not so much at a popular audience that I'll likely attend will be a day-long Symposium on Evidence in the Natural Sciences, which will be at the Simons Foundation. It will end with a discussion between Jim Baggott (author of the recent Farewell to Reality) and Brian Greene (sold out now I fear).

Update: The Princeton crowd now has a preprint out, with the detailed argument that BICEP2 can't distinguish "gravitational waves" from "galactic schmutz", see here.

Comments

1. **Bernhard**
   May 25, 2014

   The anecdotal arguments Linde uses to "defend" eternal inflation at the end of the talk are something else. Who needs to confront experimental data when you can talk about black and white footballs?

2. **Curious Mayhem**
   May 25, 2014

   Indeed. The tensor polarization result doens't prove or disprove eternal inflation; it is consistent with it, but consistent with some other kind of inflation.

   The disappointment about eternal inflation is that it excludes overt quantum gravity considerations almost by design, while dovetailing with GUTs, of course. Avoiding the emptiness of string cosmology, quantum gravity means a Wheeler-DeWitt equations that includes the inflaton. Shades of the 1980s. This is more interesting scientifically.

3. **TonyK**
   May 26, 2014

   Your "Farewell to Reality" link is missing a colon.

4. **Neil**
   May 26, 2014

   Was Linde's comment made with his tongue in his cheek, I hope? I find it hard to believe he seriously thinks that a theory that cannot be tested, even in principle, can be explanatory.

5. **Peter Woit**
   May 26, 2014

   Neil,
   You can judge for yourself, the exchange with Carroll starts at about 1:49:35 in the video I linked to. He sounds serious to me…

   TonyK,
   Thanks, fixed.

6. **Martin L**
   May 27, 2014

   Another quick link(s). Sadly, I saw that Prof. Gerald Guralnik passed away last month. Further trimming the number of Higgs theorists who are still alive.

   Brown Univ Coverage:

http://www.browndailyherald.com/2014/05/01/death-physics-prof-remembered-mentorship-imagination-contributions-nobel-winning-work/

NYT and Wash Post Coverage:
http://www.nytimes.com/2014/05/04/us/gerald-guralnik-77-a-god-particle-pioneer-dies.html
http://www.washingtonpost.com/national/health-science/gerald-s-guralnik-particle-physicist-linked-to-higgs-boson-dies-at-77/2014/05/06/5cafa35e-d4c9-11e3-95d3-3bcd77cd4e11_story.html

7. **Nick Gresham**
June 2, 2014

Would the slides of Bernstein's talk be available?

8. **Peter Woit**
June 2, 2014

Nick,
Unfortunately Bernstein's slides haven't been posted, perhaps someone can get them from him, or get one of the organizers like Pavel Etingof to do so.
On the other hand, Arthur's slides are now there, so people can see more about his comments on functoriality and the Weil explicit formula.

9. **A.K.**
June 15, 2014

indeed the 'quasiclassical' approach to the RH has a hidden Langlands-like structure; it is a mystery to me that nobody saw it until now (apparently).

This Week's Hype

May 25, 2014
Categories: This Week's Hype

About every three years KEK issues a hype-filled press release announcing that Jun Nishimura and collaborators have used a supercomputer to get evidence for string theory. Back in 2008, the announcement was of a numerical simulation on a supercomputer of a supersymmetric QM system that supposedly showed that superstring theory explained the properties of black holes (press release here, preprint here, blogging here). In 2011, the claim was of a numerical simulation on a supercomputer that used superstring theory to understand the birth of our universe (press release here, preprint here, blogging here). Both of these papers were published in PRL.

The 2014 press release is now out (see here), based on this preprint from last December. The latest claim is that the authors have solved the black hole information paradox, have shown that we live in a hologram, as well as showing that string theory provides a self-consistent quantization of gravity, all by doing a numerical simulation of a QM system. Even better, they have made the quantum gravity problem just as well-understood and tractable as QCD:

> In short, we feel that problems involving quantum gravity have become as tractable as problems involving the strong interaction. The latter can be studied by simulating a gauge theory on a four-dimensional (4D) lattice, and such a method has recently been used to reproduce the mass spectrum of hadrons (28) and the nuclear force (29). We can now apply essentially the same method to study quantum gravity, which has been thought to be far more difficult.

This latest version of the KEK-hype has gotten a lot more attention than the previous two versions. Based on the preprint, late last year for some reason Nature covered this with a story about how Simulations back up theory that Universe is a hologram and this got a lot of media attention (see here for example).

The paper has now been published, and this time it's not in PRL, but in Science magazine (submission there was a month after the preprint came out, could it be that PRL wouldn't have it?). Science is giving it a high profile, including together with it a piece by Juan Maldacena, which claims the paper as "further evidence of the internal consistency of string theory". Science provides the following one-line summary of the Maldacena piece:

> A numerical test shows that string theory can provide a self-consistent quantization of gravity.

One obvious problem with this is that even if you take the most optimistic view of it all, what is being described is quantum gravity in 10d space-time. The Japanese authors deal with this problem with a footnote:

> Theoretical consistency requires that superstring theory should be defined in ten-dimensional space-time. In order to realize our four-dimensional space-time, the size of the extra six dimensions can be chosen to be very small without spoiling the consistency.

Remarkably, Maldacena has another answer: the multiverse, which now he seems to take as accepted fact.

> Of course, the 10-dimensional space under consideration here is not the same as the four-dimensional region of the multiverse where we live. However, one could expect that such holographic descriptions might also be possible for a region like ours.

Absurd hype about string theory is a continuing problem, and it's not one that can be blamed on journalists, with this latest example getting help from HEP lab press releases, a highly reputable journal, and an IAS faculty member.

Comments

1. **rfp**
   May 25, 2014

   From what I can tell, these aren't simulations (in the usual sense). There is no dynamics, nothing is evolving. They simply used a computer to compute a partition function. The integral is too hard to compute analytically so they discretized it and evaluated it numerically. From what I can tell, that's the only reason a computer was involved. As there is no Hawking radiation or dynamics in the calculation, I don't think it gives any direct insight into the information problem.
   …
   As for the result, maybe I can try to summarize what they did and someone more knowledgeable can correct me. On the "gravity side" they considered a 10 dimensional black hole. It is a solution of Einstein gravity with some extra higher curvature terms in the action. They computed this black hole's Hawking temperature and entropy in the usual way, and then they integrated dE=TdS to find its internal energy as a function of temperature, E(T).
   …
   On the "gauge theory side," they considered a specific gauge theory action and computed its partition function, Z, in the usual way. Then they took a derivative with respect to inverse temperature to get E(T) = \partial_\beta Z. They showed that this matches the E(T) of the black hole. It's another consistency check of AdS/CFT.

2. **lun**
   May 25, 2014

   rfp, they are simulating a quantum state numerically. If they did everything right, the partition function is all the dynamics they need.

   That said, I have another issue: if you read this paper, they achieve something conventional lattice theorists are _very_ far away from doing (simulating a supersymmetric theory, with Fermions and everything) using a tower of assumptions:
   the field theory is reduced to quantum mechanics, the regulator is a momentum cutoff, fermionic complex phases are ignored, a complex partition function is artifically truncated, etc.

   Peter, perhaps, given your expertise, you could comment on whether these assumptions are plausible from a numerical point of view.
   I am disturbed that the only calculations made with this method are the ones which "test the theory". No exact solution or toy model exists which shows that the approximations are under control.

   I am sure Science has conducted refereeing, but on the other hand Maldacena is not a lattice theorist, and no other research group working in numerical field theory is using this approach and nd some of them are working on supersymmetric problems.

3. **Curious Mayhem**
   May 25, 2014

   This sounds very dubious and not different from what Peter was complaining about. There's no control in their approximations, and they've simply skipped over all the hard parts that keep the lattice gauge theory people sweating. That amounts to cheating and then making crazy claims afterwards.

It certainly does nothing to prove string theory, or even that such a theory exists. It is merely another check (if it can be called even that) on the CFT on AdS space. Everything else is conjecture.

4. **Geoff**
May 26, 2014

On a somewhat related aside, Renate Loll just gave a talk at Perimeter advocating for greater utilization of numerical simulations in checking various solution spaces of competing theories of quantum gravity. Interesting and worth watching (in my opinion).

http://pirsa.org/14050138/

5. **theon**
May 26, 2014

Dear Peter,
you go too fast. I am still recovering from a lose cable that made neutrinos exceed the speed of light. And of a false understanding of a snapshot of a map presented in a meeting that proved inflation at 2 10^16 GeV. I must admit that the former would have broken all bounds, while the latter extrapolates no more than a mere 29 orders of magnitude from its observations at 3K. Now you come with stories that we live in a 10d multiverse, string theory is proven, quantum gravity is established. Is anybody wondering which questions, if any, we will leave for posterity?

6. **QG**
May 27, 2014

One obvious problem with this is that even if you take the most optimistic view of it all, what is being described is quantum gravity in 10d space-time.
^
if this is the most optimistic view of it all are there other less optimistic views and theoretical reasons not to be optimistic?

7. **Yatima**
May 27, 2014

…and then it turns out they put in the wrong sign in a forgotten corner of badly reviewed FORTRAN crud.

8. **FNesti**
May 27, 2014

Is anybody wondering which questions, if any, we will leave for posterity?

Don't fear, if we go on like this, there'll be lots of questions of physics we leave them, and actually we'll add some more – like the important one: "How could this happen?"

9. **Curious Mayhem**
May 27, 2014

(After looking at the papers) Much less than the hype. As many have pointed out, any semiclassical theory of gravity has to produce the general form for black hole entropy. The numerical calculation gets you, in addition, some dimensionless factors for that particular model. Not much new. It certainly doesn't prove string theory, whatever that would mean.

Comparing quantum gravity theories through numerical simulations is not a bad idea IF the approximations are controlled. We do need to shake off another piece of hype, that simulation constitutes a "third branch" of science, along side Experiment and Theory. Actually, simulation (if done right) is just another part of Theory. It's another set of approximations leading to approximate answers. If done without control over the approximations, simulation is just a poorly constructed "model," or really, just Bad Theory.

10. **Shantanu**
May 27, 2014

Peter, something OT.
See this nice paper by Avi Loeb on how there were prejudices against new ideas(which later turned out to be correct) which hurt the subject
http://arxiv.org/abs/1405.2954
Can you (or someone else) think of similar examples in particle physics

11. **Jack Lothian**
May 27, 2014

Shantanu
All humans are biased, it is in our nature. For every case of someone rejecting a valid new idea because of prejudices against new ideas, there are many more cases of someone rejecting a valid old idea in favour of their new idea that later turns out to be wrong. Cherry picking cases studies to support your thesis is a form of bias & is a very unscientific way to conduct research.

Off topic – I know – sorry

12. **jd**
May 29, 2014

Check out Nature for this week. I no longer admit to being a theoretical physicist.

13. **Marcus**
May 30, 2014

jd, when you say "check out Nature for this week" I assume you refer to the article by Amanda Gefter
Theoretical physics: Complexity on the horizon
A concept developed for computer science could have a key role in fundamental physics — and point the way to a new understanding of space and time.

At the moment I do not have ready access to the article, can you tell us a bit about it?

14. **jd**
May 30, 2014

Marcus

Yes, you have the correct article.

Let’s see if I can summarize this. The news article quickly goes over Susskind’s latest ideas on how to solve the “firewall problem” and how to go much further. Susskind is apparently wearing a T shirt these days that says “I heart Complexity,” with the heart being a Mandelbrot set, or as much as you can get on a T shirt. The complexity is referring to computational complexity. Black holes, worm holes, computational complexity, AdS/CFT, and more are all invoked in the picture. Basically, the firewall does not exist (it is not needed) because the information just outside the event horizon is too complex to grab and take inside the event horizon. Then you can not violate the no-cloning theorem. The article goes on to mention that there may be connections between the length of a wormhole and complexity and, therefore, also time. Furthermore, entanglement is somehow related to space. Susskind is quoted. “I do not know where all of this will lead. But I believe these complexity-geometry connections are the tip of an iceberg.” I wonder if the lookouts on the Titanic said something similar.

Oh, there was also, “Things fall because there is a tendency toward complexity.”

15. **Lun**
May 31, 2014

Jd: this is hilarious… Perhaps peter can do a post about
Fred kantor, a curious character (former phd student) who hangs around
The Columbia physics department advertising his theory
Known as “information dynamics”
It’s basically this article, the same ideas and the same level of “rigor”

16. **Davide Castelvecchi**
May 31, 2014

Amanda Gefter’s story, like all of Nature News’ content, is available to read for free. Here’s the link:
Theoretical physics: Complexity on the horizon

17. **johnnythelowery**
June 3, 2014

David Castelvecchi: That link is disturbing! Looking forward to our host’s views on the ideas.

18. **Neophyte**
June 9, 2014

What’s wrong with the idea that computational complexity has a role in physics?

Big Bang Blunder Bursts the Multiverse Bubble

June 4, 2014
Categories: Multiverse Mania

This week's Nature has an article by Paul Steinhardt, with the title [Big Bang blunder bursts the multiverse bubble](). The subtitle of the piece describes the BICEP2 frenzy of last March as "premature hype", and the description in the body of the article is:

> The results were hailed as proof of the Big Bang inflationary theory and its progeny, the multiverse. Nobel prizes were predicted and scores of theoretical models spawned. The announcement also influenced decisions about academic appointments and the rejections of papers and grants. It even had a role in governmental planning of large-scale projects.

Given recent arguments that BICEP2 may be seeing dust, not primordial gravitational waves, the March media frenzy quite possibly was highly premature, if not completely misguided. Steinhardt goes on to argue that in the future

> announcements should be made after submission to journals and vetting by expert referees. If there must be a press conference, hopefully the scientific community and the media will demand that it is accompanied by a complete set of documents, including details of the systematic analysis and sufficient data to enable objective verification.

He also takes the occasion to note the odd fact that while BICEP2 results have been claimed to be proof of inflation and the multiverse, if they turn out to be wrong, that's fine too:

> The BICEP2 incident has also revealed a truth about inflationary theory. The common view is that it is a highly predictive theory. If that was the case and the detection of gravitational waves was the 'smoking gun' proof of inflation, one would think that non-detection means that the theory fails. Such is the nature of normal science. Yet some proponents of inflation who celebrated the BICEP2 announcement already insist that the theory is equally valid whether or not gravitational waves are detected. How is this possible?
>
> The answer given by proponents is alarming: the inflationary paradigm is so flexible that it is immune to experimental and observational tests. First, inflation is driven by a hypothetical scalar field, the inflaton, which has properties that can be adjusted to produce effectively any outcome. Second, inflation does not end with a universe with uniform properties, but almost inevitably leads to a multiverse with an infinite number of bubbles, in which the cosmic and physical properties vary from bubble to bubble. The part of the multiverse that we observe corresponds to a piece of just one such bubble. Scanning over all possible bubbles in the multi-verse, everything that can physically happen does happen an infinite number of times. No experiment can rule out a theory that allows for all possible outcomes. Hence, the paradigm of inflation is unfalsifiable…
>
> Taking this into account, it is clear that the inflationary paradigm is fundamentally untestable, and hence scientifically meaningless.

Steinhardt was on a panel last Friday night here in New York at the World Science Festival, which can be watched [here](). The panel included Guth and Linde (who earlier in the week got $1 million for their work on inflation), as well as John Kovac of BICEP, and Amber Miller, Dean of Science here at Columbia. The last part of the video includes an unsuccessful attempt by Steinhardt to pin down Kovac on the significance of the BICEP2 evidence for primordial gravitational waves claim, as well as an exchange with Guth and Linde. They both defend inflation as the best model of the alternatives.

Multiverse promotion continues apace, with Steinhardt one of a rather small number of physicists publicly objecting. On Monday Alexander Vilenkin will explain to the public at the American Museum of Natural History that "the Big Bang was not a unique event in cosmic history and that other Big Bangs constantly erupt in remote parts of the universe, producing new worlds with a great variety of physical properties" (see [here]()). A [recent story on livescience]() has Brian Greene on the multiverse. Over at Massimo Pigliucci's Scientia Salon Coel Hellier is starting a multipart series arguing against multiverse skeptics with [The multiverse as a scientific concept — part I](). Nothing in Part I about the problematic issues (untestable claims that fundamental physics is "environmental"), maybe in Part II…

Comments

1. **AcademicLurker**
   June 4, 2014

   After watching how carefully managed the release of the LHC results was, I was kind of surprised at how they jumped the gun with BICEP2. I know they're completely different projects and organizations, but still…

   Maybe the BICEP2 team could take some PR lessons from CERN.

2. **Florin Moldoveanu**
   June 4, 2014

   IMHO the paper in Nature is too harsh. See here the reaction of Andrei Linde to the original BICEP2 news:

   https://www.youtube.com/watch?v=ZlfIVEy_YOA

   Pay particular attention to 1:57-2:14 This is the reaction of an intellectual honest person. The original excitement and the media hype on BICEP2 was premature, but I feel the Nature paper is also a knee jerk reaction but in the opposite direction.

3. **anonymous**
   June 4, 2014

   The BICEP2 youtube video with Andrei Linde was so awkward. He seemed wise enough to be skeptical of the results, yet was forced to act nice and happy because people brought this celebration to his front door and video taped it.

4. **Peter Woit**
   June 4, 2014

   Florin/anonymous,
   Linde has inflationary models with any value of r you want, so he had no particular reason to set great store in the BICEP2 number being right. This is the same Linde quoted by SciAm as saying
   "suddenly we have something which I firmly believe is experimental evidence in favor of the multiverse," Linde says. "Those people who say the theory of the multiverse

does not have any experimental confirmation have not paid enough attention."
I noticed that when engaged in discussion with Steinhardt he doesn't say nonsense like that, sticks to the "my theory sucks less" argument.

5. **Peter Woit**
June 4, 2014

AcademicLurker,
I think of lot of the questionable choices BICEP made can be attributed to their competition with Planck. A defensible claim from BICEP would have been "we have observed the right kind of B-modes for the first time, but we'll need Planck's results to know if this is dust or primordial gravitational waves." Instead they went for what now seems a not very solid argument that "we don't need Planck", and a claim for a Nobel for themselves.

It would have gotten very interesting at CERN if ATLAS and CMS had very different characteristics, and one of them saw something that could be the Higgs, but knowing this would require a study of backgrounds that only the other could do. Things would have gotten interesting…

6. **physicsphile**
June 4, 2014

Peter,

I think you and Steinhardt are being a bit harsh. The key thing is that we can learn about inflation by doing experiments. Any improved measurement of r will cut into the space of possible potentials for the inflaton field. If r is sufficiently large then we can hone into a very small subset of possible potentials by using improved observations. So I don't think its right to say inflation is just philosophy. Observations have and can further be used to get a better understanding of how inflation happened. Inflation can be falsified if a better theory is found that predicts new observations which only a very contrived version of inflation could produce. It would be great if one could take a simple Popperian view on falsability but I think the reality of how science actually works is a bit more complex.

7. **Curious Mayhem**
June 4, 2014

The BICEP2 hype may be have been premature. But proof of inflation is not in any way proof of the "multiverse," which is unprovable by its nature.

Inflation is by the far the best extension of the hot Big Bang we have. While it's consistent with Linde's "eternal inflation," it doesn't require it.

And, again, inflation has nothing whatever to do with the multiverse in the "landscape" sense.

8. **Person**
June 5, 2014

No matter if the BICEP2 results turn out to be true or not, they are not good science. Therefore, the claim that the hype was premature is quite accurate and not too harsh at all. Publications that are based on scraping the presentation slides of other groups should be flat out rejected. That is no clean process and should not be allowed within the science community.

On an other note, I dont understand how one can conclude from inside our universe on the existence of other universes or bubbles. That makes no sense. We are unable to understand how the natural constants come to their values, even if we accept the (any) inflation model to be correct. Taking our not-understanding as proof of a multiverse concept is grotesque. It is religious at best, comparable to the invention of a creator of the world as a model for the existence of the world in ancient times. The multiverse is in its nature not falsifiable. It should have no in science.

9. **Garbage**
June 5, 2014

There're so many misleading statements in Steinhardt's article there's no point really to argue. One should write a similar argument complaining about how he's changing his mind every time a new bound on local non-Gaussianity comes about… We all know inflation makes well defined predictions, however, as usual with physical theories, one has to explore parameter space. One could have said the same about the Higgs 40 years ago, until experiments pushed to the ultimate "limit" and found it, or whatever else would've replaced it. We know there's a GW signal at large angles from inflation, gravity is universal, that's why this is so exciting! Moreover, we know there's an ultimate level of non-Gaussianity with a very specific shape, provided inflation happened with vacuum fluctuations. Under very mild assumptions we have more than enough observables to test the theory. So far inflation is the only framework where we can *calculate*, the scale invariance of the perturbations comes out beautifully and many well motivated assumptions make predictions than can be tested, like a large value for r. I don't see how else are we supposed to do science. Inflation is not a unique theory, so isn't the standard model for that matter, no one has ever found a way so far to predict the values of masses and mixing angles. This is not a very constructive article, on the contrary. We all know we don't understand Lambda and the hierarchies in physics, but proposing no alternative explanation and bashing the attempts which have produced the most amazing fit to the data so far, is just absurd IMHO…

10. **Patrick M. Dennis**
June 5, 2014

Peter, is it your opinion that inflation resides in the same "not even wrong" boat as string theory and multiverse(s)? …. Also, do you find the Everett version of the latter to be equally "not even wrong"?

11. **Anonyrat**
June 5, 2014

Why worry? In some alternate universe, multiverse is recognizably not science.

12. **Peter Woit**
June 5, 2014

Patrick M. Dennis,
About inflation, see some comments in the latter part of
http://www.math.columbia.edu/~woit/wordpress/?p=6782
"Many worlds" is a completely different (off)-topic.

All,
I'm getting on a plane soon and will be traveling for a few days, unclear how much I'll be able to deal with the blog. Please don't feed the trolls…
If you want to discuss this topic, I highly recommend the Scientia Salon site I linked to, where Massimo Pigliucci does a great job of moderating the discussion.

13. **Jeffrey Herrmann**

June 5, 2014

Steinhardt argues "Scanning over all possible bubbles in the multiverse, everything that can physically happen does happen an infinite number of times. No experiment can rule out a theory that allows for all possible outcomes."
Then why not quit. If every possible experiment is incapable of distinguishing between Theory X and the theory of eternal inflation because even if Theory X is right, both theories predict the same observed data, what is the point of continuing to observe more and more data?

14. **TomH**
June 5, 2014

is Steinhardt still a strong proponent of the "Ekpyrotic" big bang model?
If so, it surely accounts for part of his harsh criticism of inflationary models.

But Ekpyrotic model relies on existence of unobserved and/or unobservable higher -order dimensions , "branes" floating in the "bulk" , and such — yes?

To this layman, that seems almost as speculative and unfalsiable as any multiverse hype … although if BICEP2 results are validated, doesnt that falsify Ekpyrotic models??

15. **Monty**
June 6, 2014

I watched the video from the World Science Festival. Could I ask Peter, or the commenters, what would be wrong with the following response to Steinhardt's complaint that whatever the BICEP2 results had been, they could be made to fit with some variant of inflationary theory: yes, the observation of B-mode polarisation (let's assume it's not an artifact of foreground dust–this will be shown one way or the other soon in any case) cannot by itself prove inflation. But it lets us choose appropriate candidate theories from within the previous set of inflationary theories, and, more importantly for inflation-backers, it adds another item to the list of things requiring explanation for any competing theory. So now we have not only isotropy, flatness, absence of relics, and large-scale structure to explain, but we also have otherwise unexplained B-mode polarisation of the CMB. An appropriately narrowed inflation model can account for all of those things at once; that makes it correspondingly harder for an alternative theory to be equally successful. Doesn't that make it a stronger theory than it was this time last year?

16. **JG**
June 7, 2014

Monty

Not really, if the observable B-mode signal was a *favoured* prediction of inflation then the BICEP2 observation would certainly have a strong impact on the credibility of inflation. But there are many models of inflation which predict a non-observable B-mode polarisation, so the BICEP2 result just narrows the parameter space for inflation models – it doesn't say anything definitive about their truth – despite all the hype about a "smoking gun".

TomH

Steinhardt has admitted the Ekpyrotic model is dead if BICEP2 are correct.

Jeffrey Herrmann

Because Steinhardt doesn't believe the multiverse is correct, *that* is why there is still a point in making observations and doing science!

Garbage

Maybe if they didn't (practically) claim the scientific debate is over and award million pound prizes in hollywood style ceremonies to the "victors" the opponents might not make such a public "fuss". Pointing out obvious deficiencies in the science is a necessary, and useful public service. 🙂

17. **Monty**
June 7, 2014

JG – thanks, but I acknowledged all that you said in my comment. Let me try again: the BICEP2 observation doesn't confirm anything, because the range of inflationary theories would have encompassed any result of those observations. But isn't it true that (if the polarisation holds up as being in the background) it adds to the list of things that inflation takes care of, and that a competing theory would need to address? I thought inflation was widely held to be an appealing theory because it explained so many things at once. Now it explains "so many plus one". A competing theory now doesn't just have to account for flatness, isotropy of the CMB and large-scale structure, and the lack of magnetic monopoles, but it also has to explain where the heck these swirls in the polarisation of the CMB come from.

18. **JG**
June 7, 2014

Monty

Ok, sure, inflation was a pretty nice theory already before BICEP2 announcement. It's just that most of the popular inflation models inspired by string theory disfavoured an observable B-mode signal. So I don't see how an observation by BICEP2 which wipes out the majority of inflation models is a good argument in favour of inflation. In fact, ironically, it may lead to a non-inflationary model like string gas cosmology becoming a serious contender, and note that sgc solves a really big problem that inflation does not – why 3 large spatial dimensions?

Even if Planck raise major doubts about the BICEP2 observation the string theorists have loads of *other* inflation models which "predict" weak B-modes.

So although I think inflation is a nice (and even compelling) idea, I'm not convinced BICEP2 should have been sold to the public as confirmation of it.

But I also agree, that any competing model (such as sgc) must solve the problems of flatness, isotropy, lack of relics at least as cleanly as inflation does.

19. **Neophyte**
June 7, 2014

What is a "relic"?

20. **Mark**
June 7, 2014

I was astonished by Steinhardt's comments. I have great respect for him, as one of the few physicists who has made major contributions in both cosmology and condensed matter physics (quasicrystals). But he seems to have jumped the shark with his statement that the unfalsifiability of inflation removes it from the scientific paradigm.

Paul (and I hope you read this): Supersymmetry makes many predictions and is the basic of most particle physics research over the past 25 years. Yet if it is not seen in the next run at the LHC, many of its proponents will focus on slivers of remaining parameter-space, or make small modifications. Thus, low scale supersymmetry isn't really falsifiable. Does that mean you believe that supersymmetry is not part of the scientific paradigm?

21. **Monty**
June 7, 2014

Neophyte: relic particles would be the surviving exotic particles predicted by hot big bang models to have been created in the extremely energetic conditions of the very early universe. Magnetic monopoles are one type of relic. One thing inflation does is explain why we don't actually observe any such thing.

22. **Yatima**
June 8, 2014

One thing inflation does is explain why we don't actually observe any such thing.

Not really. Explaining that unicorns live in faraway lands over the rainbow "explains" why we don't actually see unicorns in the woods. But in very wrongheaded away.

23. **Monty**
June 8, 2014

Yatima: would you say it's incorrect that hot big bang theories without inflation predict exotic relics?

Because if they do, then your analogy isn't very fair. There's no reason to believe we should find unicorns in the woods in the first place.

24. **GoletaBeach**
June 8, 2014

"And this time, the announcements should be made after submission to journals and vetting by expert referees."

Has the Flauger/Hill/Spergel paper been vetted by expert referees?

Sometimes theories have unknown parameters like r… r didn't/doesn't have to be big to support inflation.

Just re-read the story of some of the first new scientific results from E.O.Lawrence's program of cyclotrons circa 1933. His team totally messed up the parameters of the deuteron & neutron… they thought the neutron was lighter than the proton. Rutherford's team corrected them with results from a linear accelerator. The Berkeley team eventually got it right, and indeed, circular machines dominated particle physics until the present (OK, there is SLAC too).

So BICEP2 maybe messed up. Big whup. They pushed the envelope. Wouldn't be the first time something went wrong, but they still deserve commendation and respect for getting the envelope moved forward.

Without hype, there will be insufficient funding. The real world knows this. The real world also knows that overly strong bloodletting over mistakes is counterproductive.

25. **Peter Woit**
June 8, 2014

About the argument that inflation "explains" the non-observation of magnetic monopoles. One should keep in mind that magnetic monopoles are not expected in the standard model. The lack of magnetic monopoles is a problem that only occurs in various GUT models. Given the lack of success of GUTs on all other fronts (e.g. no proton decay) there's no need for an "explanation" by inflation of why we don't see magnetic monopoles, given the much simpler explanation that GUTs don't work.

26. **Monty**
June 9, 2014

Peter, thanks, I wasn't aware of that and retract my suggestion that Yatima's unicorn analogy was unfair! I'm assuming it's still fair to say that inflation provides a nice explanation for those other things (large-scale structure, homogeneity of the CMB, flatness).

27. **Rob Heusdens**
June 10, 2014

If we are comparing Inflation theory and String theory, then at least I would say that inflation theory makes testable predictions which after observation confirm the predictions. There are different models, each have different properties and lead to different observables, so we can rule out some models. That is far better as we can think of in String theory.
Inflation theory is not saying in first instance that 'there is a multiverse' and/or that 'any outcome is correct', but that comes as a by product of it. It was not 'invented' for that reason. Even so, a theory could in principle be correct, without being thoroughly falsifiable. All claims inflation theory makes about other universes are untestable. Only the claims inflation makes about our universe we can test and see if they conform to that model of inflation. Standard science practice. We should not by definition rule out a theory because it makes more predictions then can be tested for.

Past the End of Science

June 8, 2014
Categories: Multiverse Mania, Uncategorized

I haven't yet seen a copy of Marcelo Gleiser's new book, but this weekend the Wall Street Journal had a review by John Gribbin, author of the 2009 multiverse-promotional effort In Search of the Multiverse. I don't know how Gleiser treats this, but Gribbin emphasizes the multiverse as new progress in science (for some reason he's now calling it the "metaverse"):

> Within the metaverse, the story goes, there are regions that form inflating bubbles. Our universe is one such region or bubble. As Mr. Gleiser explains, the implication is that there are other universes, other bubbles far away floating across an inflating sea.
>
> This seemingly speculative idea counts as a genuine scientific hypothesis, because it makes testable predictions. If other "bubble universes" exist in the metaverse, it is possible that, long ago, one or more of them may have collided with our universe, like two soap bubbles touching and moving apart. One effect of such a collision, Mr. Gleiser points out, would be to make ripples in the space of both bubble universes; they would leave a distinctive if faint ring-shaped pattern, known as a "cosmic wake," in the background radiation that fills the universe. Data from the Planck satellite is being used to test this prediction right now. Is the metaverse real? We may well know in the next year or so.

This seems to be a reference to work by Matthew Kleban and collaborators, which I saw Kleban talk about recently (see here). My impression from that talk is that the actual state of affairs with Planck is that it has already looked for and ruled out most hoped-for signals of "bubble collisions". I don't know anyone besides Gribbin who believes that the next round of Planck data is going to answer the question "Is the metaverse real?".

The really odd thing about the review is that Gribbin uses the multiverse to argue that John Horgan's claims about physics in *The End of Science* are wrong. This is just bizarre. Gribbin and his multiverse mania for untestable theories provides strong ammunition for Horgan, since it's the sort of thing he was warning about. Actually, I don't recall anything in Horgan's book about the multiverse, and suspect the idea that physics would end up embracing such an obviously empty idea was something that even he didn't see coming. As the multiverse mania gains strength, physicists are blowing past the "End of Science" to something that has left conventional science completely behind.

Update: I took a look again at a copy of *The End of Science*, and, as I remembered, the chapter on "The End of Physics" has no mention of the multiverse pseudo-explanation of why one can't ever understand the parameters of the Standard Model. Horgan ends the chapter with a vision of physics descending into "ironic science", endlessly studying untestable string theory models and interpretations of quantum mechanics. With the multiverse we may already have gone past that point.

In the next chapter though, "The End of Cosmology", there's a long section about Linde and his "self-reproducing universe theory", so Horgan more than 20 years ago already was writing about the place we're ending up. I was interested to see the comment he got at the time from Howard Georgi about this kind of model:

> quite amusing. It's like reading Genesis.

Georgi also is quoted as describing inflation as:

> a wonderful sort of scientific myth, which is at least as good as any other creation myth I've ever heard.

Of course what is different now is that 20 years ago the theory establishment saw Linde's multiverse as kind of a joke, not at all part of science. Things have changed…

Update: While my favorite local bookstore doesn't have a copy of the Gleiser book *The Island of Knowledge*, you can see parts of it on Google Books. Searching on "multiverse" you can read chapters 15 and 16 of the book which deal with the issue of the testability of the string theory multiverse. Reading these shows that Gribbin seriously misrepresents what Gleiser has to say about the multiverse. The context of his discussion of "Cosmic Wakes" and the possibility of seeing them in the Planck data is to argue that even if this happened (which he describes as having an "extremely small" probability), all that would show is evidence for a neighboring universe, not a multiverse:

> However, I stress again that even a positive detection of a neighboring universe would not prove the existence of a multiverse. Within the present formulation of physics the multiverse hypothesis is untestable, however compelling it may be.

Comments

1. **M**
   June 9, 2014

   A collision between two bubble-universes would have left huge ripples, unless their vacuum energies happen to be quasi-degenerate: searches ate done for this atypical fine-tuned scenario of small ripples because the typical scenario was already excluded.

2. **Pacific**
   June 9, 2014

   The evidence crisis

3. **J**
   June 9, 2014

   "the next round of Planck data": isn't the Planck mission over? (wikipedia says it was deactivated in October 2013)
   Or if there is still some data to be exploited, what is it?
   Thanks

4. **Peter Woit**
   June 9, 2014

   J,
   Planck is still at work on the data analysis, especially on the polarization data, with rumors of release set for October. There is a lot of interest in this, around the question of whether there will be evidence for primordial B-modes in this data. Gribbin is the only person I know of though who seems to think that "cosmic wakes" from other universes, not seen in the rest of the Planck data, will somehow show up in the new polarization results.

5. **Avattoir**
   June 9, 2014

In addition to writing about Linde in his book, Horgan's discussed the context at least three different times I specifically recall (my impression is of even more) with science writer George Johnson on their occasional appearances together on Bloggingheads.tv (all of which can be retrieved at its current website).

One of the problems I have with Horgan on Linde is that he always has seemed to have trouble separating Linde as a social person from Linde as a scientist. He'd met Linde several decades back in the context of a sort of socializing that's not unusual around conferences in places like Aspen, and what struck Hogan was the image of Linde as a gregarious party animal full of jokes and magic tricks. Hogan's written and oral descriptions of his interviewing Linde combine that image with Linde's speculations on the existence of a multiverse. The things Linde's done otherwise, Horgan has never really dealt with (and to me he's neither equipped nor inclined to discuss anyway), particularly Linde's academic and research work on inflation in Russia more than a decade before Guth's first paper on it was published, as well as Linde's work in the U.S. in the 1980s following publication of Guth's paper, which corrected a number of shortcomings in Guth's hypothesis and otherwise expanded on its implications.

6. **Peter Woit**
June 9, 2014

Avattoir,
I just reread earlier today the section of Horgan's book dealing with Linde. He certainly does deal with Linde's scientific work on inflation, in Russia, and post-Guth. Yes, his treatment of this is non-technical, but no more so than any of the rest of the book, which is not a technical book.

The material there on Linde does portray him as a bit of a joker, but it's clearly there for color (this is a popular book, you want to keep people awake), and to give a bit of context to the things Linde says. For instance he quotes Linde going on about how maybe the universe was created by some cosmic engineer who created it in just such a way that a message for us to read would be encoded in the CMB. Without a context for Linde's sense of humor, this would just come off as making Linde look crazy.

7. **abbyyorker**
June 9, 2014

Georgi calls inflation an amusing myth? Surely the scientific consensus is that inflation is a strong candidate for how the universe operates. Is Georgi referring to something else or is his comment out of date?
Sry…Im just a layman who takes most everything literally.

8. **Peter Woit**
June 9, 2014

abbyyorker,
Georgi does call it not an "amusing" myth, but a "wonderful" and "scientific" one. This was in the early-mid 1990s, after inflation had been around for a decade or so, and hadn't lived up to its promise as telling us something about GUTs. I'd guess Georgi was referring to the lack of any compelling prospects at the time for testing the idea. I don't know whether the more recent claims about connection to CMB experiment have changed his mind, or whether he's in the Steinhardt camp on this.

9. **Curious Mayhem**
June 9, 2014

Georgi's take on inflation is all about the failure of GUTs, which he and Glashow started in the 1970s. From the point of view of cosmology, inflation is a perfectly viable and testable class of theories.

Horgan's vision of an increasingly empty academic theoretical physics, titillated by speculative manias, has turned out to be depressingly relevant.

10. **Bee**
June 10, 2014

I got a review copy of Gleiser's "Island of Knowledge" and I'm presently reading it (half through). I will probably have a review on my blog within the next weeks.

11. **Roger**
June 10, 2014

In March, Horgan wrote [Why I Still Doubt Inflation, in Spite of Gravitational Wave Findings]. He also posted [My 1992 Profile of Cosmic Trickster and Inflation Pioneer Andrei Linde]. So yes, inflation skepticism is part of his end-of-science theme.

12. **Curious Mayhem**
June 11, 2014

It was a good review, but Peter's post might have left a misimpression.

Gribbin uses the term "metaverse" to refer to the larger inflating background à la Linde. It's not the "multiverse" as typically used, but a connected spacetime, and one connected to us. It's likely that Gribbin was consciously avoiding "multiverse" so as to not give aid and comfort to that lunacy. The only error he makes is his implication that inflation requires the Linde-an metaverse or "eternal inflation." It's consistent with it, but Linde's form of inflation is not required.

Gribbin's review eschewed the "multiverse" term altogether and didn't mention string theory at all. I find that pretty telling. Furthermore, Gribbin emphasizes the non- or anti-scientific nature of claims of a "final theory." That's the point of the book's title, that our science is an island (a growing island, to be sure) in a sea of ignorance, probably an allusion to Newton's famous quote.

(The only place "multiverse" occurs in the Journal review is mention of the title of Gribbin's book, "In Search of the Multiverse," in the author blurb at the end.)

13. **TRP**
June 11, 2014

Two would be already a multi-, no? 😉

14. **Yatima**
June 14, 2014

"A collision between two bubble-universes"

What does that even mean? Wouldn't ekpyrotic fire emerge from every single point in space? Or is that another framework? What about if a universe is a holographic representation from a lower dimensional manifold and THESE ram each other in the night? How about if a Tegmark Level III universe rams one that is Tegmark Level

IV? I’m so confused. It’s like reading Perry Rhodan stories.

15. **Roger**
June 14, 2014

Horgan says: “Thanks, Peter. I couldn’t have said it better myself.“

Evidence in the Natural Sciences

June 9, 2014
Categories: Uncategorized

I recently spent a day at the Simons Foundation in midtown, attending a symposium on Evidence in the Natural Sciences. Of the scientific program talks, I got the most out of the one by Thomas Hales on the question of checking the proof of the Kepler conjecture. For the latest on the project to produce a formal, computer checkable version of the proof, see the Flyspeck Project page.

The program ended with a discussion/debate featuring Brian Greene, Peter Galison and Jim Baggott, with the contentious issue basically "has physics gone too far?" in a speculative direction, unable to get back to a point where connection can be made to experiment. Baggott gives a summary of what he had to say at Scientia Salon, which would be a good place to discuss these issues (so I'm leaving comments off on this posting). Both Greene and Galison were much more taking the position that things haven't gone off the rails, that one needs to trust the leaders of the field and the physics community to do the best they can. This blog's readers shouldn't have much trouble guessing which side of this I'm more sympathetic to. I didn't notice the event being recorded, perhaps it was.

The symposium was co-sponsored by the Templeton Foundation, with no theology or religion in sight. I think they're mostly these days keeping the physics/math and theology apart, with this symposium and FQXI two good examples, and I'm happy to see that. My other main complaint about Templeton was always that they were pushing multiverse research since that fit into their agenda. These days I don't see them doing so much of that, with multiverse mania being driven by much more dangerously influential sources. But maybe I'm less critical of them because they invited me to a very nice dinner after the talks…

Update: Videos of the talks are now available here.

Large Hadron Collider Physics Conference

June 9, 2014
Categories: Uncategorized

While I was away last week Columbia was hosting the Large Hadron Collider Physics (LHCP) conference here on campus. Talks are available here. Matt Strassler posts about some of the new Higgs results, which basically see some of the inconsistencies in Higgs mass measurements disappearing. Right now everything is quite consistent with a pure Standard Model Higgs.

In the final plenary session, the theory talk from John Ellis ended by claiming the LHC results as a success for SUSY (the "success" is that simple classes of SUSY models said the Higgs couldn't be too heavy, also that the Higgs couplings should be much like those of the SM, so any SM success is a SUSY success). Another argument was that "SUSY is increasingly the best solution that we have" (here he was following Nathaniel Craig's summary talk), illustrated by two discouraged soldiers under bombardment in a foxhole, one saying to the other "Well, if you knows of a better 'hole go to it!". It's interesting to note that the arguments from Ellis work just as well if SUSY is not found at Run 2, a likely possibility he's getting ready for.

The conference included a Friday afternoon panel discussion that you can watch here. This began with an excellent presentation from Fabianola Gianotti about the possibilities for next-generation colliders. The discussion moderated by Dennis Overbye of the New York Times focused to some extent on the budgetary challenges facing US HEP, with Steve Ritz, the chair of the P5 panel, commenting on the tough situation reflected in that panel's recent report. Many speakers expressed frustration over the US budget level for HEP and what to do about it. Enlist the public? Do a better job of convincing Congress? Get billionaires to help fund HEP? Get billionaires to fund a Super PAC that would buy us a Congress with a better attitude?

Most of the discussion was about the experimental side, but Arkani-Hamed also had comments about the theory side, noting that the job market for theorists, which improved after his grad school days in the mid-90s, has now worsened and gone back to that level. He also noted that successful young theorists are increasingly ending up in faculty jobs outside the US after starting their careers as students and postdocs here.

Comments

1. **Manny**
   June 10, 2014

   "He [Arkani-Hamed] also noted that increasingly successful young theorists are ending up in faculty jobs outside the US after starting their careers as students and postdocs here."

   Was the point that other countries are successfully luring away American-trained talent? or that even these successful young theorists can't find positions here and must leave the US for jobs?

2. **paddy**
   June 10, 2014

   Manny: It is for you to make of Arkani-Hamed's statement what you will.

3. **Peter Woit**
   June 10, 2014

   Manny,
   You can find some heated argument about this in the comment section here:
   http://www.math.columbia.edu/~woit/wordpress/?p=6398

   That some of the best young Princeton-trained string theorists are ending up with jobs outside the US is what I think Arkani-Hamed is referring to. I described this situation provocatively as US physics departments not buying what Princeton is selling. I think an accurate description of the situation is that the people in question could get jobs in the US, but are offered better ones outside the US. One can argue about why that is.

4. **Curious Mayhem**
   June 11, 2014

   It's combination of things. But what Arkani-Hamed is referring to specifically is that US physics departments stopped their hot pursuit of string/M-theory/multiverse hiring around 2007. Possibly not coincidentally, this happened about a year after Peter and Lee Smolin's books about the folly of string theory appeared.

   There was a general recession in hiring from 2008 to 2011. Since 2011, hiring has picked up modestly, but, so far, no sign that the bubble in pseudo-physics hiring has been reflated. Perhaps the Federal Reserve will step in and do some hiring in this area, along with buying up some securitized student debt, to cover up that crisis.

   (I'm partly being facetious with the last comment, although not completely. But Wall Street's mass hiring of physics theory students has also stopped, after reaching its peak in the early 2000s.)

5. **Peter Woit**
   June 11, 2014

   I just noticed an interesting profile at Physics Today of theorists Brian Wecht and Ben Lillie and their "Story Collider" project, see here

   http://scitation.aip.org/content/aip/magazine/physicstoday/news/10.1063/PT.5.9016

   On the hiring issue, Wecht, an American ex-IAS postdoc in string theory/formal theory, now has a faculty position in London, and comments:

   "I moved to London a bit more than a year ago for a permanent job at Queen Mary [University of London]. It was such a relief to get it. I was a postdoc for eight years—which is increasingly typical for someone in my field. London is amazing, not only because it's a great city, but also because it's the only place in the world that's hiring people in my field these days."

6. **Mesa**
   June 11, 2014

Great presentation by Ms. Gianotti.

Wall Street used to hire physicists for a good balance of theoretical and practical knowledge to model market phenomenon. I suspect that the reduction in hiring recently is due to some of the move in theory towards unverifiable esoterica, but also the rise of the big data comp sci guys as well.

7. **Slynx**
June 20, 2014

As a young scientist it seems to me like it would be overall productive and beneficial to the STEM ecosystem if some of the postdocs and grads went on to industry and government rather than academia or big data jobs and represented scientists everywhere. The people at eg Goldman Sachs do this quite effectively.

I've read articles in science and nature going back twenty years that talk about giving the students real career prospects but I don't yet really see how this is built into the academic business model in a constructive way. Appreciate it's a hard problem.

Strings 2014

June 15, 2014
Categories: Strings 2XXX

This coming week and the next Princeton will host both the big yearly string theory conference [Strings 2014](), and [Prospects in Theoretical Physics 2014](), a program designed to train young physicists in string theory.
Princeton is definitely the right place for this, since it now is very much a singular point in the world-wide theoretical physics research community. At the IAS the director is a string theorist, so is the past director (now faculty member). Of the other four senior HEP theorists, three are string theorists and one might be described as a fellow-traveller. Over at the university, of the nine faculty in HEP theory, all are string theorists except for one junior faculty member.

One will be able to follow the Strings 2014 talks live [here](), and video and slides should be posted [here]().

The Strings 20XX conferences provide a good place to see what the latest trends in string theory are, with the talks chosen to highlight what some of the most influential people in the field consider the most interesting work. I've written posts on the blog here about [previous such conferences](), which one can compare to this year's to see how the field has evolved. Looking at the list of over 70 talks and their topics, some things that strike me (in many cases, much the same things as in other recent years):

- Talks actually about strings are a small minority (20%), something that has been true for quite a few years. The percentage may have grown from a minimum back in 2011 when some of the speakers were mentioning the small role strings were playing at a string theory conference.
- AdS/CFT and holography remain a dominant theme, as they have for many years. Possible applications of this to condensed matter physics are a continuing hot topic. The previous hot topic of this kind, applying AdS/CFT to heavy ion physics, now seems to be dead, something people would rather not talk about anymore since it never worked out as advertised.
- Amplitudes are the other big hot topic.
- Discussion of the LHC and hoped-for LHC results in the past was often a major topic at these conferences. Now that the LHC results are in and a huge disappointment (no SUSY or extra dimensions), it looks like there's a chance the LHC will not be mentioned at all at this year's conference, with "string phenomenology" in general the topic of only a very few talks.
- String phenomenology does have its own yearly conference (see [here]()), but at least as far as the US participants go, the top US research institutions are not represented there, whereas they are heavily represented at the Princeton conference. Whatever "string phenomenology" is these days, it's not popular at all among the Princeton crowd. It's no longer being done at the most prestigious US institutions, and in Europe is concentrated in certain places (popular in England for some reason, not at all in France).
- While research into string theory unification schemes now seems to be very unpopular at Princeton, for some reason it's a topic that the young must still be trained in. The PiTP program includes a series of lectures on string compactications, for which the Princeton people needed to bring in Martijn Wijnholt from Munich, one of the places still doing this kind of thing.
- To the extent there's anything about connection to experiment, B-modes are the hot topic.
- There was a time when mathematicians were sometimes invited to Strings 20XX, but that's over and done with. It seems most prominent string theorists no longer want to hear anything from mathematicians.
- Finally, zero about the multiverse or the landscape. Clearly some on the organizing committee still have strong opinions and are not going to tolerate that kind of nonsense.

  Witten will just give a 15 min welcoming speech. In the past, David Gross has ended the conference with a "vision" speech. This year there will be five "vision talks", and it may be interesting to see a wider range of opinions on where the field is heading.

Update: One more notable thing about this version of the yearly conference is that (as far as I can tell), it's the first one in many years that has not included a promotional public talk about string theory. It may very well be that this was considered unnecessary in Princeton.

Update: Martin Wijnholt's lectures to the students and postdocs in Princeton about string compactifications are available [here](). Lots of nice material on Calabi-Yaus and algebraic geometry, nothing at all about extracting the standard model from all this. One thing that has always surprised me is how little most string theorists know about the state of the art of getting particle physics out of the theory. This is less surprising now after seeing the kind of lectures they get on the subject.

Comments

1. **Bernhard**
   June 15, 2014

   If Witten himself is not giving a scientific talk, I guess that speaks about the health of the subject.

2. **Bob Jones**
   June 15, 2014

   Stringy mathematics is being discussed at a different conference:

   http://www.ihes.fr/jsp/site/Portal.jsp?document_id=3481&portlet_id=14

3. **layman**
   June 15, 2014

   Bernhard,

   Or the fact that he is on the *local* organizing committee and therefore not allowed to speak. This has been the policy forever.

   You are embarrassing yourself.

4. **Peter Woit**
   June 15, 2014

   Bernhard,
   That's not necessarily true, since Witten is one of the local organizers, and there's some prejudice towards not having organizers invite themselves to speak (a few of the local organizers will speak, but this may be the only major conference that Arkani-Hamed doesn't speak at).

   Bob Jones,

Not a whole lot of either string theory or physicists at that one…

5. **Peter Woit**
June 15, 2014

layman,
Since three members of the local organizing committee are speaking, seems to me that it's you that are embarassing yourself. Of course, since you're hiding behind anonymity, that's not a problem for you I guess….

6. **piscator**
June 15, 2014

Not quite sure why you say string phenomenology is popular in England but not in France – quite a lot of people in the Paris area do some variety of string pheno. There are probably more students in England doing string pheno, but France (for cultural reasons?) has very few PhD students full stop.

7. **Peter Woit**
June 15, 2014

piscator,
Perhaps you're right, I may have been over-generalizing from an impression of Oxford vs. IHES. I do think there's a lot of evidence for a strong US pattern of string phenomenology not being pursued at the highest-ranked institutions, wonder if there's any similar pattern in Europe. Of if not, why not. England was an example where I could think of string phenomenologists at well-known institutions, France not, but perhaps this is just due to less familiarity with the French system.

8. **piscator**
June 15, 2014

Peter,

There are a lot of places in Paris so I forget who is exactly where, but an immediate list of names in this area or thereabouts is Bena/Dudas/Goodsell/Grana/Halmagyi, and then there are people like Antoniadis who are there some of the time – I think some of these are at the Grandes Ecoles as well.

Generally I think string phenomenology is much stronger in Europe than the US – in Germany there is the very large Lust group in Munich, and then big groups at Bonn and DESY, in Spain there is Madrid (Ibanez, Uranga, Marchesano)…not sure why there is such a difference to the US, where there is almost a void between people working on BSM x-dimensional models and the mathematical physics side of string theory.

9. **Bob Jones**
June 15, 2014

What are you smoking, Peter? Almost every single one of those speakers is working on some aspect of mirror symmetry…

10. **Navneeth**
June 16, 2014

This year there will be five "vision talks", and it may be interesting to see a wider range of opinions on where the field is heading.

Perhaps Dr. Witten will provide a surprise final talk in which he reveals that all five visions can be considered as different facets of an over-arching M-Vision. 😉

11. **Andy**
June 16, 2014

"It seems most prominent string theorists no longer want to hear anything from mathematicians."

It seems you're unaware of the existence (since 2011) of a conference called String-Math, attracting crowds of the same order of magnitude as (if not higher than) Strings itself.

12. **Peter Woit**
June 16, 2014

Andy,
I'm well aware of it. Most prominent string theorists go to Strings 20XX, few go to Strings-Math 201X. I think it's undeniable that most of those on the Strings 20XX organizing committee are less interested in interacting with mathematicians now than they were at many points in the past.

I'm not claiming there is no active field of research involving mathematics and string theory, with many mathematicians participating, just that most US physics departments and most physicists working in string theory have little interest in it (and less than in the past).

13. **Andy**
June 16, 2014

Peter,

most prominent string theorists go to String-Maths. A quick look at the list of speakers (which is a fortiori strictly included in the list of participants) of SM2012 in Bonn will prove you wrong. I also disagree that "most" people in the organising committee are less interested in the interaction with mathematicians now than in the past. Except perhaps for Verlinde, I think this is precisely false for each and every of them (especially Arkani-Hamed and including Witten – just have a look at his scientific production during the last year)

My considered, possibly misplaced and certainly fully biased opinion is that the StringsMaths interaction has rarely been as active as today: the easiest example to pick is the huge amount work on AGT ("huge" is the right word), which is largely a string-theoretic and/or string-motivated subject, and a top research priority for – my turn to say it now – most prominent senior string theorists (Nekrasov, Gaiotto, Gukov, Moore, Vafa, Witten himself, amidst lots of others): something with few-to-none precedents after the SW paper 20 years ago.

I think – and I'm sure that the two of us will agree on this – this is only good news for the subject.

14. **Peter Woit**
June 16, 2014

Andy,
The concept of the Strings 20XX conferences has always been to cover all areas where something interesting is happening in string theory, not just areas not covered at other conferences. It's traditionally not supposed to be a conference specializing in only certain areas. If it has devolved into mainly a specialist conference on AdS/CFT + amplitudes, that's a phenomenon worth taking notice of.

I looked earlier at the speaker list of Strings-Math 2014 and just took a look at the ones for 2012 and 2013. I disagree that these lists contain a significant fraction of the most prominent string theorists. To quantify the matter, one definition of the most prominent string theorists would be the winners of Milner's $3 million award. Zero of these were speaking at the Strings-Math conference last week, four will be speaking at Strings 2014, with three more on the local organizing committee so presumably there but not speaking, and two more (Strominger and Vafa) this year's runners up for the award. That makes nine versus zero….

15. **Peter Woit**
June 16, 2014

Andy,
I just noticed that Princeton has a press release out, claiming over 600 participants at Strings 2014. For Strings-Math 2014, looks like about 125. Not sure that's the same order of magnitude…

Also in the press release: they're covering the "many strands of modern string theory". If math is one of them, for some reason mathematicians aren't part of it.

16. **Bob Jones**
June 16, 2014

The Strings conference also has mathematical talks (see the ones by Cheng, Kachru, and probably also Cordova, Moore, and Vafa).

17. **Peter Woit**
June 16, 2014

Bob Jones,
Sure, of the 70-odd talks, some will have material of mathematical interest. My comment was just that mathematicians aren't the ones being asked to talk about this.

18. **Brian Dennehy**
June 16, 2014

Apologies for being off-topic but 'layman's comment is sadly a reminder that things like meanness to others is not entirely absent in the research community. I can only assume that 'the health of the subject' is something that 'layman' has become emotionally invested in.

19. **Peter Woit**
June 16, 2014

Brian,
Researchers ("layman" appears to be one, coming from a major research institution) responding to criticism anonymously with arrogant and mis-informed denunciations of others as being idiots doesn't really look good, and may very well have something to do with why so few US institutions are willing to hire young string theorists. In my experience, most string theorists are perfectly reasonable people, no more arrogant than your average academic. There are however some unfortunate exceptions, including prominent bloggers and others who like to take advantage of blog comment section anonymity.

20. **Jeff M**
June 16, 2014

Uh, Peter, hate to be pedantic, but 600 and 125 are the same order of magnitude (2, to be exact). 🙂

21. **Peter Woit**
June 16, 2014

I dunno Jeff, maybe it's the physicist in me, but I'd say 600 is the same order of magnitude as 1000, and 125 is the same order of magnitude as 100, so….

22. **Chris Herzog**
June 16, 2014

I often like your posts Peter, but this one came across as a bit too knee jerk for my taste.
1) AdS/QCD is not dead but has maybe left the purview of formal string theory. To name one success, the idea of measuring viscosity with respect entropy density has left a lasting impact on the heavy-ion community.
2) I agree with Andy 100% that the strings/math connection is alive and well everywhere, from Korea to the U.S. to Europe. The fact that mathematicians are not speaking at Strings I view as an accident. Who knows? Perhaps the mathematicians read your blog and decided to turn the organizers down…
3) The absence of string phenomenologists at top US research institutions is in my mind an indication that US institutions may no longer be as top in theory as they used to be, compared with the rest of the world. We continue to train the world's finest for the moment, but many of them now choose (or are forced) to go elsewhere for jobs.

23. **Peter Woit**
June 16, 2014

Hi Chris,

I agree that strings/math is alive and well (although, as in physics, the strings are often disappearing, and we're really talking about qft/math). Would be interesting to know if the conference organizers invited mathematicians, I still suspect not, that the overlap with math is something that physicists in general have drawn back from (which is too bad).

My own take on the absence of hiring at top US institutions of people working on models for getting the SM out of string theory is that the best theorists, string theorists and otherwise, have for a while now realized this is an idea that doesn't work, or at least one that is going nowhere until someone comes up with some very different idea. The dozen or more string theory faculty at Princeton are the best in the business and they're still hiring in the area, but not "string phenomenologists". I'm not aware of them trying to hire such a person and failing because they lost out to another institution. What I don't understand is why this is still so popular in Europe.

As for AdS/QCD, maybe my comment about the death of the application to heavy ions was a bit over the top, influenced by some over the top claims about the successes of that subject that were common in the past.

Glad to hear you often enjoy the posts, despite some disagreements…

24. **piscator**
June 17, 2014

A European perspective on this is that string theory faculty at Princeton are just not the best in the business anymore, unless the `business' is defined as the uber-narrow area of mathematical physics inspired by string theory. Whereas the Strings conference has a theoretical mandate to cover the whole of the subject, in practice there has been a narrow focus on topics popular at Princeton.

Most of the talks at Strings – this year as at previous year – are only tangentially related to what `physics' historically means. If you never work on any kind of phenomenology, and your advisor never worked on any kind of phenomenology, you are not going to know very much about it. Most physicists really doesn't think six-d N=(2,0) theory is an interesting problem to be thinking about.

A slightly broader perspective on this is that each generation, there are certain tools and abilities required to really advance the subject. Physics for 30 years after the second world war was not so mathematical. This created a ripe environment for the fusion of mathematical and physical ability so exemplified by Witten (and others of that generation) to be perfect for making great leaps forward. It's very unclear that this style of work now is what is really needed.

25. **Pneno**
June 17, 2014

In fact there are many strong groups working on string phenomenology in the US.
To name a few : Harvard (L. Anderson (Heterotic and more) , Heckman, Vafa (who have done very important work on F-theory Unification),
Princeton (H. Verlinde; Maldacena and Klebanov on string cosmology; Witten on axions); The Penn group (M. Cvetic, B. Ovrut, Donagi);
Stanford (Silverstein leading work on string cosmology; also Kachru, Kallosh and others); Wisconsin (G. Shiu; L. Evertett); Santa Cruz (M.Dine);
Mc Allister (Cornell); Many others on different aspects of compactifications like D.Morrison, Taylor, Wecht, Halverson; Many other well known physicists work part time on string phenomenology aspects (S. Dimopoulos (axiverse),
L. Randall (e.g. flavour physics from F-theory), N. Arkani-Hamed (landscape), R. Bousso (landscape), S. Raby (heterotic models), P. Langacker, M. Gaillard, and a very long etc.

26. **Chris Herzog**
June 17, 2014

Pneno.

A very interesting list. To clarify, I really meant a relative absence. My position is simply that more faculty lines should be devoted to string phenomenology in the US.

27. **chris**
June 17, 2014

"the idea of measuring viscosity with respect entropy density has left a lasting impact on the heavy-ion community."

sorry, but i have to strongly disagree with this. there was some interest a few years back, but not much lasting impact i would say. if there is a distant field with a strong influence on heavy ions it is probably cosmology at the moment. the cmb/fireball comparison is much more taked about at the moment than any ads/cft result.

28. **Peter Woit**
June 17, 2014

piscator,
As I keep pointing out, little of what the many string theorists in Princeton are doing has much to do with mathematics, it seems they chose no mathematicians to speak at the Princeton conference, and few of the many talks there have much to do with mathematics. If you don't like the current Princeton vision of "string theory", I don't think it's fair to blame it on "mathematics".

Pneno,
There is some interest in "string cosmology" at top US institutions, especially Stanford, but I think comparing your list to the Strings 2014 speaker list makes my point. Only Anderson, Bousso and Vafa are speakers, with Anderson the only one speaking about phenomenology. And she's now at Virginia Tech, not Harvard.

29. **Peter Shor**
June 17, 2014

What people seem to be arguing about is whether the pre-eminent conference in strings is being run by a small group of famous string theorists who have dismissed phenomenology, mathematics, and the LHC, or whether the predominant sentiment in the field as a whole is to dismiss phenomenology, mathematics, and the LHC.

I don't know which of these alternatives I find more disturbing.

30. **Elbi Gilgen**
June 18, 2014

It puzzles me that anyone could think that amplitudes are "hot". Look at the arxiv. In particular, the "Amplituhedron" is deader than any doornail has a right to be.

31. **David Meltzer**
June 18, 2014

Elbi,
The amplitudehedron work by Nima is probably the most mathematically sophisticated work on amplitudes there is. Probably the only people working on it are Nima, Trnka and maybe a few of his other students. It's not surprising if it appears dead right now just because so few people are working on it. The amplitudes program is much larger though and a few names I could recommend looking at the papers by Lance Dixon, Zvi Bern, and David Kosower, they really got the subject started and were awarded the Sakurai prize for their work.

Theres a lot of other names I could list but my best recommendation would be to look at one of the amplitudes conferences for more details.

32. **Jesper**
June 18, 2014

Peter – I just noticed that you posted this comment in "Strings 2XXX". I wonder if this choice of label is a show of optimism – or pessimism? You could also have chosen

Strings XXXX, Strings XXXXX, or – in what I think would be in the optimistic end of your spectrum – Strings 20XX.

33. **Peter Woit**
June 18, 2014

Jesper,
Yes, extrapolating from the last twenty years, I think there will be a Strings 2100 conference. Might not even be that different than the current ones. I'm much less sure of Strings 3000, but who knows….

34. **Shantanu**
June 19, 2014

Peter somewhat OT to this thread but not blog
The talks of the recent dark matter conference at CFA are online and in
Lisa Randall's talk
https://www.youtube.com/watch?v=rahKgEDX1yM&feature=youtu.be
she is mentioned that supersymmetric models were in trouble even before LHC started
and none of them obey occam's razor

35. **Bernhard**
June 19, 2014

Pneno,

Since you seem to know well about string phenomenology, I wonder how much do you believe of real phenomenology the work you mention on your list contains. What I have in mind are realistic string theory models that can connect with experiment. The obvious names that come to mind are Lisa Randall and Arkani-Hamed with extra dimension models, but I think it is fair to say whatever realistic models they built they were more "string inspired" than actual stringy models.

My comment has a direct connection with Peter's comment about "how little most string theorists know about the state of the art of getting particle physics out of the theory". Perhaps it doesn't apply to this list of prominent people, but still, even for them, I have a very hard time finding work that could be directly meaningful to an experimentalist, and at some point this should be the goal of phenomenology, wouldn't you agree?

36. **Pneno**
June 19, 2014

Look, Bernhard. Writing a phenomenological model which can be tested at the LHC or other experiment is trivial. Add a few extra dimensions here and there; extra vector-like particles or non-perturbative stuff; etc. But that is not what we want.
We want to learn what lies beyond the SM and understand the involved principles within a fundamental theory, and, lets face it, the only serious candidate for that is string theory. Thus we want to learn how string theory might contain (or not) something resemblingg the SM at low energies. This we have to do taking into account both experimental information and mathematical consistency, and both are very constraining. This is a tough job since string theory is technically demanding and one also has to have the physical intuition of what phenomenological problems can and may be addressed. These include issues like the structure of fermion masses, strong CP problem, SUSY breaking, hierarchy problem, cosmology….
This may take time but some of us prefer that than producing random BSM models which are testable by an experimentalist NOW.
String theory already provided answers to those questions in much firmer grounds than previous BSM traditional model building.
And much more will come, while our knowledge on compactifications accumulate. In addition string theory has been the source of many of recent ideas physics BSM. I certainly reccomend the young phenomenologists to learn string theory compactifications if they want to be sufficiently prepared for doing BSM physics in the future. GUT's and SUSY are no longer enough.

37. **Peter Woit**
June 19, 2014

Pneno,
From your description, string phenomenologists have given up on being able to do anything relevant to LHC-scale physics, although they have the capability of generating "random BSM models" if they want to (but you seem to realize that isn't a very meaningful activity). The same argument applies to VLHC or any other conceivable HEP physics experiment, so you've given up on the conventional idea that a better theory is supposed to predict something different and distinctive that can be tested.

You seem to indicate that what is worthwhile to do now is to just try and get the SM out of a sufficiently complex string theory model. There seems to be no evidence that such things are so tightly constrained that you can't get the SM, so there is no way for anyone to ever show that what you are doing is wrong. But if you "succeed", get a string model that gives the SM, what have you accomplished other than embedding a relatively simple model in something much more complicated? How will you ever know that what such a complicated creation has anything to do with the real world?

38. **akame**
June 22, 2014

Peter,
"But if you "succeed", get a string model that gives the SM, what have you accomplished other than embedding a relatively simple model in something much more complicated? How will you ever know that what such a complicated creation has anything to do with the real world?",

such a theory would describe particle physics as we know it, and also be a consistent theory of quantum gravity. The embedding of SM into string theory solves the problem of quantum gravity, is that not a worthwhile thing? And if it describes both gravity and particle physics, doesn't it per definition have a lot to do with the real world? At the very least, it is some "effective theory of everything", which in itself is no small feat. You can't reject a theory because "it seems too complicated". Of course, a simpler model is preferable, but then there needs to be such an alternative.

39. **Peter Woit**
June 22, 2014

akame,
First of all, arguing that this is a consistent theory of quantum gravity is rather dubious since you don't know what the theory is (remember, "what is string theory" is still an unanswered question).
But, even giving you that, I still don't believe that replacing a simple model by an incredibly complicated, completely untestable one is progress in any sense, no matter what your argument is that your untestable model has some better formal property.

40. **akame**
June 24, 2014

Peter, such a model would be in principle testable, but maybe not at accessible energy scales. Moreover, it is not obvious to me that the theory would be all that much more complicated than the standard model. Even the SM requires us to fix a particular gauge group, a particular particle content, a Higgs sector, there is some weird mechanism for neutrino-masses, 3 generations, there must be something there to explain dark matter, maybe some axion, presumably there also needs to be something new out there other than the Higgs and so on. Maybe all this seems simple because you are used to it, but it really isn't all that simple. My hope is that an embedding into string theory, maybe using F-theory, could have a similar amount of complexity, just phrased in a very different language, i.e. pick a CY, have some fluxes, place some branes/some elliptic fibration, maybe some O-planes, and get a reasonable model. The amount of data needed could be comparable to the amount you actually need for a non-stringy model of particle physics. And again, a model being "complicated" is not a valid criticism. Physics is about describing nature, you can't and shouldn't necessarily require models to be "simple", whatever that term even means.

41. **Peter Woit**
June 24, 2014

akame,
In the kind of modeling you're talking about, as far as I can see, all you're doing is putting together mathematical components (Calabi-Yaus, elliptic fibrations, etc.) that are much more complicated than the components of the SM (simple Lie groups and their simplest finite-dim representations), according to a conjectural set-up in which you expect to be able to map the complicated structures to the simpler ones of the SM. As far as I can tell, no one has been able to turn this set-up into one that allows you to reliably extract the SM parameters (couplings, mixing angles, Yukawas) as a function of the inputs, except perhaps in special unphysical limiting cases.

This kind of set-up has zero predictive value, because much more is going into it than is coming out. The hallmark of a theory with predictive power is that you put something simple in and get non-trivial complex, testable physical predictions out. Here you're doing the reverse, having to provide more complex inputs than the physical predictions you are getting out. Yes, you can "model" all sorts of physics this way, but you can't predict anything, and you're not doing science in any conventional understanding of the term. Some people think you're doing mathematics, but I'd disagree with that too.

Yes, you can hope that a miracle will happen, and some particular choice of inputs will provide the complexity of the real world. People have been doing this now for 30 years with no success at all (this idea looks much less promising now than it did in 1985). Hoping for a miracle is just wishful thinking, not science.

42. **Nick M.**
July 3, 2014

Peter,

The link that you have given to Martin Wijnholt's lecture at Princeton about "String Compactification" (in the second "Update") seems to have gotten broken. I *"think"* the correct (current) links are " Wijnholt notes UPDATED" and "Lecture 1 slides" and "Lecture 2 slides". Only trying to be of help.

43. **Nick M.**
July 3, 2014

Sorry Peter, but I forgot to mention that there is also a third set of slides for the third lecture; "Lecture 3 slides".

44. **Peter Woit**
July 3, 2014

Thanks Nick,
I've updated the link to the notes, and people can follow your links to the slides.

Smoking Gun No Longer Smoking

June 19, 2014
Categories: Uncategorized

The BICEP2 paper is now out in Physical Review Letters, with major revisions to its conclusions from the preprint/press conference version of last March. For another sort of associated revision, compare this (from a March 17 Stanford press release):

> Linde, now a professor of physics at Stanford, could not hide his excitement about the news. "These results are a smoking gun for inflation, because alternative theories do not predict such a signal," he said. "This is something I have been hoping to see for 30 years."

to this (from an interview with Linde in the latest New Scientist):

> I don't like the way gravitational waves are being treated as a smoking gun.
>
> If we found no gravitational waves, it wouldn't mean inflation is wrong. In many versions of the theory, the amplitude of the gravitational waves is miserably small, so they would not be detectable.

Last month, Resonaances broke the news that there was a problem with the BICEP2 claims, specifically with the bottom line (and punch line) of their preprint abstract:

> Subtracting the best available estimate for foreground dust modifies the likelihood slightly so that r=0 is disfavored at 5.9σ.

Back then the BICEP official reaction to the Resonaances claim that they were admitting to a mistake was "We've done no such thing." Post-refereeing, there have been extensive changes in the paper (for example, the "DDM2" dust model based on scraped Planck data is gone), and the bottom line of the abstract has been changed to:

> Accounting for the contribution of foreground, dust will shift this value downward by an amount which will be better constrained with upcoming data sets.

If the BICEP collaboration is still not admitting a mistake in their treatment of Planck data or the bottom line of their preprint, then it seems that referees have told them they can't publish these in PRL.

Back in March the BICEP2 results made the front page of the New York Times with a Dennis Overbye story Space Ripples Reveal Big Bang's Smoking Gun, but today the NYT has Astronomers Hedge on Big Bang Detection Claim, which explains well what has been going on.

Update: Nature has a story out about this, which includes the news of a recent presentation at a Moscow cosmology conference by Jean-Loup Puget of the Planck collaboration:

> Using for the first time the newest Planck maps available, Puget and his collaborators have directly examined the polarization of dust in these high galactic regions rather than extrapolating from dustier regions in the plane of the Milky Way. Averaging over some 350 high-galactic-latitude patches of sky similar in size to the region observed by BICEP2, Puget reported that polarization from interstellar dust grains plays a significant role and might account for much of the BICEP2 signal that had been attributed to inflation-generated gravitational waves. Puget told Nature that an article detailing these findings would be published in about six weeks.

Update: I've been watching Paul Steinhardt's talk at Strings 2014, where he's giving a dramatic attack on the way inflationary cosmology is being pursued as in violation of the scientific method. One thing he does is put up exactly the Linde quotes from this posting.

Comments

1. **Florin Moldoveanu**
   June 19, 2014

   It's a good thing PRL decided to make this available for free, but what happened to their length limit? I recall that the maximum accepted size was four. At the 25 page mark, this paper has a War and Peace size by PRL standards. Does this mean that anyone can now submit papers up to 25 pages to PRL? Somehow I strongly doubt it.

2. **Dave**
   June 19, 2014

   I've heard of PRL trying to lure papers from other journals by relaxing the page limit, but that was for six or seven pages, not 20+. Maybe the preprint was intended for ApJL and PRL managed to coax the authors away.

3. **Bernd**
   June 19, 2014

   There's an editorial explaining the unusual format:
   http://journals.aps.org/prl/edannounce/10.1103/PhysRevLett.112.240001

4. **Jeff M**
   June 19, 2014

   Pardon the stupid question, but if they've removed the scrubbed Planck map, how exactly do they claim to account for dust?

5. **Peter Woit**
   June 19, 2014

   Jeff M,

   The preliminary Planck data they got off a slide was just one of several things they were using to estimate the effects of dust. My non-expert understanding is that how they used that has been challenged, other ways they were estimating dust are not completely convincing, and since the time of the preprint Planck released more data about dust which might raise their estimates. So, they're stuck with no solid statement about dust, just that the effect of dust is "an amount which will be better constrained with upcoming data sets."

   By the way, in the interview, Linde refers to a rumor that Planck will release relevant results about dust sooner than their full polarization results (which are planned for October), possibly this summer, "any time now".

6. **srp**
   June 19, 2014

   I find this type of dispute refreshing. It's about the quality of observations and interpretation of data–BB relic or interfering signal from relatively nearby dust? More data from different instruments and some careful thinking will sort out which of these is more likely in a few years at the outside.

   One interesting sidelight on this issue is the question of what Harry Collins calls "methodological individualism versus methodological collectivism." The former stance holds that each individual paper and announcement should be a definitive claim of a finding one way or the other, complete in itself. The latter stance holds that each paper is just one piece of equivocal evidence and overall conclusions should be derived by the community after seeing many such papers over time. The advantage of methodological individualism is that researchers are forced to think hard about what they actually believe and do a lot of work to make their results credible, thereby incentivizing quality work and avoiding publication bias of spurious weak but confirming signals . The advantages of methodological collectivism are that weak individual signals may be collectively strong and that other researchers are less likely to toss out intriguing but less-than-definitive findings if they see others are seeing similarly weak-but-suggestive things.

7. **anonymous**
   June 20, 2014

   Come on, Peter. The vast majority of the paper is the same as before, about as much as you'd expect following a typical peer review. The evidence against synchrotron and synchrotron-correlated dust has, if anything, strengthened. The caveats about the rest of dust were already in the penumbra of the original paper. For all that you decry sensationalist headlines, you have been the pot calling the kettle black for the last few months. If the rumored Planck paper gets arXiv-dumped soon, you should preliminarily treat it as being as reactionary as the rest of the unreviewed Flauger/Seljak/anyone analysis.

8. **Bob**
   June 20, 2014

   Those two back-tracking quotes from Linde are quite extraordinary, almost funny if it didn't reveal such a dreadful way to do science: "If the experimental result is true, the theory is definitely proven. And if the result is false, the theory is still probably correct." Simply dreadful.

   Inflation: well worth a million dollar prize.

9. **Peter Woit**
   June 20, 2014

   anonymous,
   I don't think a typical peer review changes the conclusion of the paper from "we've discovered something revolutionary at greater than 5 sigma" to "could just be dust".

   The PRL peer review isn't that significant in that this change in conclusion had already become widely known, with a lot of public discussion of the problems with the 5 sigma claim and a new consensus that "could be dust" is a significant possibility, not a one in 3.5 million possibility. To see the change in consensus, all one has to do is listen to Linde…

10. **OMF**
    June 20, 2014

    Bottom line, all I see here is the scientific method in action. Public discussion and scrutiny of the data lead to the most rigorous conclusion.

    The real problem here was the media hyping of preliminary results and the pressures which this placed on the entire investigation and potentially the peer review itself. This kind of modern pressure will end up interfering with future large scale experiments unless methods are found for dealing with it.

11. **Alex**
    June 20, 2014

    @Bob

    Aren't these two new quotes never the less correct? My understanding of inflation is that it's a theory with free functional forms (let alone free parameters) and that even if r came out to be some other value, an inflationary theory could be found to be consistent with that value.

12. **Bob**
    June 20, 2014

    OMF: it wasn't the media hyping the initial results, it was the bicep team who did that. That last sentence of the original Bicep preprint will live in physics infamy.

13. **Bob**
    June 20, 2014

    Alex: It would have been more impressive if Linde had said no gravitational waves is a blow for inflation, but it does not neccessarily kill it. He's basically saying the result is irrelevant to the theory – unless it supports the theory. That's poor.

14. **Jeff M**
    June 20, 2014

    Linde's comments remind me of why I switched from physics to math way back in the early 80's. Even back then the parameter space was plenty big enough to accommodate all sorts of experimental results, which drove me nuts. At least from what I remember once you got a result and adjusted the relevant parameters you would then restrict things enough that you got some real predictions which could be checked, and if they didn't work then the theory would be falsified. As far as I can tell, nowadays you can adjust one parameter to account for an experimental result without limiting the value of any other parameters at all, there will always be an infinite number of theories available to fit any data you have.

15. **Peter Woit**
    June 20, 2014

    Jeff M,
    Linde's behavior and the whole inherently untestable multiverse approach to fundamental physics that he represents (together with a willingness to say outrageous things to the press…) are very much outliers in physics in general. Few people behave that way. It's an interesting question what the physics community can do to keep this kind of thing from discrediting more serious parts of the subject.

16. **anon.**
June 20, 2014

anonymous wrote:

If the rumored Planck paper gets arXiv-dumped soon, you should preliminarily treat it as being as reactionary as the rest of the unreviewed Flauger/Seljak/anyone analysis.

One important claim that first appeared publicly (as far as I know) in the Mortensen and Seljak paper was that BICEP's argument that the frequency-dependence of the signal disfavored dust at 2.2 sigma was wrong, because the correct thing to test was not pure dust but dust + lensing. The published version of the BICEP paper now shows a test of dust + lensing and, indeed, the significance has dropped down to 1.7 sigma. The Seljak paper may not be "reviewed" but this part of its argument is validated.

17. **crime**
June 20, 2014

http://en.wikipedia.org/wiki/Smoking_gun
The term "smoking gun" was originally, and is still primarily, a reference to an object or fact that serves as conclusive evidence of a crime

18. **paul hughes**
June 20, 2014

A smoking gun is conclusive proof. The absence of a smoking gun in not conclusive disproof. Maybe that is what Linde was saying, and I actually think from these quotes alone that it was (the absence of a smoking gun does not disprove the theory). To reiterate, it sounds (from these quotes alone) that in the second quote he was saying that, even if the results turn out not to be a smoking gun, the theory is not disproved; and that he is complaining about people misusing his "smoking gun" quote to imply or infer that such absence is disproof. Seems fairly straightforward to me unless one has an axe to grind.

19. **Peter Woit**
June 20, 2014

paul hughes,
I don't think there's anything at all unclear about what Linde is saying, and the comments by Bob above have it right. It's perfectly consistent, but it also shows clearly that he's now arguing for a way of pursuing science immune to falsification.

As for his complaints about people "misusing" what he said back in March, I just don't think anyone is "misusing" anything. When you're part of a press release claiming that the discovery of X proves you are right (and possibly getting part of a $1 million prize because of this…), you're going to regret that press release when it starts to look like the discovery may really have been of "not X".

20. **Robert Rehbock**
June 20, 2014

"I'm 95 percent convinced it's true, but extraordinary statements need extraordinary proof. If these results are correct, they are among the most spectacular results in observational cosmology obtained in the 21st century. We should wait a little before they are analyzed and confirmed by other observers."
Linde said on March 21st. Your selective quotes are as unwarranted as declaring the discovery is premature.

21. **Peter Woit**
June 20, 2014

Robert rehbock,

This is about linde's claims about the significance of the result if it were true, not about any claims concerning the correctness of the result. Of course like everyone he was aware the results might not hold up and needed confirmation.

22. **paddy**
June 20, 2014

I do like the phrase used in the Nature article PW referenced: "…a popular but outlandish theory…."

23. **srp**
June 20, 2014

Not a multiverse fan, but Linde's logic is in no way anti-scientific. You have a theory you believe is more likely true than not and then someone comes along with a potential piece of clinching evidence that would raise credibility to 100% if it held up. If it doesn't hold up, that just drives your credibility back to its original more-likely-than-not level. There's nothing wrong with that–it's common sense.

24. **Peter Woit**
June 20, 2014

srp,
What's unscientific about this scenario is that you're claiming that your relation to experiment is a no-lose one. Heads you win, tails you get a do-over. What makes it science is when you can lose. If a significant primordial gravitational wave signal of r around .2 really is a smoking gun for inflation, corresponding to what you expect in the simplest models, with the expected (GUT) scale, then a very small r is evidence against inflation, because you are forced to move away from simplest versions and original scenario to something more complicated. Put differently, if the viability of the idea of inflation is insensitive to r, then r=.2 was not a smoking gun. Linde would like to have it both ways, his predictive gun smoking when it looked like r=.2, not smoking now that maybe r is much less.

25. **Avattoir**
June 21, 2014

"Puget reported that polarization from interstellar dust grains plays a significant role
and might account for much of the BICEP2 signal … attributed to inflation-generated gravitational waves"

The key bits of phrasing being: "a significant role" and "might account for much", in contrast with, say, 'may explain entirely', and 'might account for all'.

It's one thing to assert that the BICEP2 team overstated their findings in relation to primordial b-modes; it's quite another to assert that the Planck satellite team is asserting their own findings utterly negate the former's findings. The title to this post purports that Planck is promising to gut BICEP2's findings. In fact, the words used by the Planck representative makes no such promise, directly, indirectly or impliedly, and indeed is not even reasonably interpretable as promising anything of the sort.

But that doesn't even get to the half of it, because the phrase "might account for much" means, more precisely, by necessary implication, 'might account for some of what BICEP2 detected, but not all'. And thus, the question becomes, Even accounting for the full potential of possible signal noise due to dust within this galaxy, what, OTHER THAN PRIMORDIAL B-MODES, would account for the rest?

Resume dancing on the BICEP2's coffin while you still can without appearing ridiculous.

26. **Dan C**
June 21, 2014

What's the difference between the situation here, i.e. parameterizing some cosmological parameters (say, the inflationary Hubble parameter via the tensor-to-scalar ratio), and something like dark matter searches, where one is looking for, say, the mass of some dark particle?

In both cases one cannot seriously argue that a non-detection, i.e. a bound on the parameters, is not scientific progress because it is not a "win-or-lose" situation.

They are both win-or-lose situations for a variety of concrete models with some explicit parameters, dynamics, etc. But they are hardly win-or-lose for the general paradigms.

On the other hand, an actual detection of either of the parameters would be a huge triumph for the theory.

I think this is all Linde is pointing out, although he can indeed say it somewhat dramatically. BTW, I don't agree that the GUT scale is "expected" in inflation unless one has a gambling addiction. An enormous range of energy scales can be easily made consistent with observation.

27. **Peter Woit**
June 21, 2014

Avattoir,
The title to the post is obviously mainly referring to Linde's change of story, secondarily to the related change in the BICEP2 paper conclusions. The Planck news was added later as an update. Of course I have no idea what they will show about dust and how much if any of the BICEP2 result will survive.

28. **Stuart**
June 21, 2014

Someone once said "Absence of evidence is not evidence of absence" Perhaps this is what Linde is alluding to.

29. **Tom Cohoe**
June 21, 2014

If it goes through here, it's a goal. If it doesn't, it's not a miss.

Nice game.

30. **srp**
June 21, 2014

If somebody finds a murder weapon in a wastebasket, that might clinch a theory that X is guilty, but not finding it in the wastebasket might not drive the probability much below the original belief in X's guilt. Especially if there are thousands of places the weapon could have ended up.

There are many asymmetric evidentiary situations where the impact of finding something specific is much more consequential than not finding it. Perhaps you could make the reverse argument, though, that even a finding of the polarization might not support inflation, because other things could have caused it. In fact, I heard Roger Penrose on NPR make exactly that point a few weeks ago.

31. **Curious Mayhem**
June 22, 2014

I agree with srp. No evidence for or against inflation right now means that inflation remains a viable, theoretically compelling, but unproven theory, just as it was on March 16.

Meanwhile, I strongly suspect that the BICEP2 result will be watered down to lower confidence, but not enough to scotch the whole conclusion.

We do need a way to deal with prepublication / preprint / media hype mania. The media makes para-scientific pronouncements that are continuously pseudo-authoritative. Results like that in science are very important but uncommon.

32. **Peter Woit**
June 22, 2014

Curious Mayhem,
I don't see the problem here being the media. The media coverage of BICEP2 has quite accurately reflected what prominent scientists are saying. Back in March the experimenters were holding press conferences to announce a 5 sigma discovery, most experts were saying this looked good (none of them were bringing up the dust problem), and Linde and other prominent theorists were issuing press releases about this being a "smoking gun" for inflation, providing evidence for the multiverse, etc. This got accurately reported.
More recently, the media coverage has also done a good job of reporting the news that problems were found with the BICEP2 claims. Linde is unhappy that his own "smoking gun" press release claims will make him look bad if the BICEP2 result collapses, but I don't think he has a legitimate complaint.

33. **John Gribbin**
June 23, 2014

A small but important point. None of this is about the Big Bang. Inflation preceded the BB. That's the whole point of the idea.

34. **Garbage**
June 23, 2014

Say soon after the BEH mechanism was discovered they'd have gone around saying: 'Here's the smoking gun: A fundamental scalar around 10 GeV' In fact, 'the Higgs' itself was a response to the referee asking for such thing. Then after many attempts LEP comes and the Higgs is not there at 115 GeV. 'No longer smoking?' No so fast, we have a lot of EWPD that fits the SM very well. We also know there's a threshold. The LHC was built and ultimately the Higgs found around 125 GeV. Inflation fits all data we have from early universe cosmology, but like the SM with the Higgs, it's got a few free parameters. –We do not have any alternative to inflation that works– There's a threshold somewhat similar to the TeV scale for the EW theory. In fact, we know there's an irreducible level of non-Gaussianity (NG) which is correlated to the size of r and ns, the tensor-to-scalar ratio and scalar tilt. Unfortunately the size of the NG may be too small to be detected in the near future, but nonetheless it is a well defined ultimate prediction of inflation. (There is also the celebrated $n_t + r/8 \sim 0$ for simple models.) For the case of GWs, simple models do predict a size comparable to 1-ns (there's this factor of 8 in between). But we can easily have a world where those two are unrelated. In this case the level of GWs may be undetectably small in the near future, this is also related to the relation between r and super-Planckian field range. I'd claim that a very small r would be unnatural, but we are still far from ruling out even the simplest models of inflation… as the case of the Higgs, don't kill a theory that works, just go ahead and keep on pushing experiments!

35. **philh**
June 23, 2014

Here is an additional attack on the inflation hype but also a defence:

Attack: even if the BICep 2 signal is confirmed there seems to me a further piece of evidence that is needed. That is the tilt in the primordial gravity wave sepctrum . As I understand there are alternatives to inflation that predict blue tilt for this spectrum , with inflation predicting red tilt. If the spectrum was shown to be blue tilted that might disfavour inflation. Hence measuring the existence of the signal is not enough. I saw very little mention of this in any press coverage.

Defence: As I understand inflation predicts gravitational waves but does not say exactly what energy scale these will be driven from and what value of r it should be detected at.
Similarly the hypothesis that life exists on other planets does not tell you which planet it will exist on. If you found what you thought was life on Mars , that would be a smoking gun for the Et hypothesis. If you then found the evidence was shoddy that doesn't mean your hypothesis was wrong.
Whilst it was overhype to say BICEP 2 confirmed inflation , (see my attack above) what I think is true is that the discovery of B mode would significantly improve the evidential picture for inflation over certain other rival models as ekpyrotic , CCC etc. But not finding doesn't disprove inflation, just as not finding life on Mars doesn't disprove the ET hypothesis.

June 23, 2014

Garbage says: "don't kill a theory that works"

But not everyone thinks it works, e.g. Penrose. It is a contrived model that unsuccessfully tries to explain a small set of facts about the universe. It creates more problems than it tries to solve. Why bother with it?

I agree "keep on pushing experiments".

37. **Peter Woit**
June 23, 2014

Garbage,
If back in 1964 after the Anderson-Higgs mechanism was discovered, say Brout and Englert had issued a press release claiming that some recent possible bump at 10 GeV was a "smoking gun" for the Higgs particle, people would have thought they were probably nuts. If, several months later after the bump started to look dubious they had gone to the press to complain that they had been taken seriously earlier, all doubt about their craziness would have been removed.

38. **Curious Mayhem**
June 23, 2014

Inflation is emphatically not a contrived theory. It was designed originally to solve one problem (topological relics) and ended up solving three, and quite elegantly. Penrose is simply wrong about this.

Penrose is correct that inflation leaves unanswered the cosmic entropy questions that he and others rightly think are important. But before inflation, no one had an answer for those either. Actually, the questions had never been posed that way before the 1980s, although there were Dirac and others with "large cosmic numbers," an earlier version of this line of thought.

Peter, you're right that, on BICEP2, the media has been fairly responsible in its own right, and its hype in this instance is mainly a reflection of hype from prominent scientists. But that doesn't mean the media hasn't engaged in its own hype in other cases.

The pre-publication mania that I referred to has both components, from prominent scientists and from the media itself, and it's an issue that scientists, journals, and the media all need to recognize and contain.

39. **Curious Mayhem**
June 23, 2014

And if the gun is smoking, *what* is the gun smoking anyway? 🙂

40. **Garbage**
June 24, 2014

If the bump was consistent with a fundamental scalar particle, nobody would have thought they were nuts. I want to believe people would have been really excited! If after the bump had disappeared in the 'dust' they would have said "well there's still a lot of room for the Higgs to show up," they'd be absolutely correct, and time would prove them right. You're purposely ignoring the point. The Higgs particle is a smoking gun of the mechanism, the same way GWs are. But there isn't a unique possibility for the scale at which it decides to show up. (Some may even argue that the fact that $m_h \sim m_Z$ is a score for SUSY.) Given a set of initial conditions, Inflation *predicts* a scale invariant power spectrum with a small tilt. The simplest models produce negligible non-Gaussianity, as observed by Planck. These models would give $r\sim0.1$. To that extent it is an extremely interesting time for cosmology. However, there are many simple extensions which lower r and yet give basically the same fit with data. In fact, String-inspired models often "predict" lower values. Until we don't cross the non-Gaussianity threshold (the irreducible level predicted by inflation) we will never be able to tell for sure.

Speaking about quotes. Steinhardt has changed his discourse so many times after a bound on fnl^{loc} comes about that Linde's comments are innocuous. Like he said: "[Inflation] is the worst form of [theory] except all the others that have been tried."
There are so many problems with Steinhardt's proposal there's no point in arguing. Like a famous mathematician once told me, "as long as you keep using '~' signs you're good"

41. **Simeon Every**
June 24, 2014

The problem isn't that stringy/multiversey theories are inconsistent or incompatible with other scientific theories. The problem is that there seems to be no limit to how many experiments must be done to establish which particular stringy/multiversey theory accounts for the existence of the observed universe (if indeed it is even possible to select one particular theory based on observing only the observed universe) and no experiment that can be done that indicates that no stringy/multiversey theories correctly account for the existence of the observed universe. If the latter is the case, how will you ever find out?

42. **Peter Woit**
June 24, 2014

Garbage,
Back in 1964 postulating a Higgs particle explained nothing about anything (the use of the Higgs mechanism to provide an electroweak theory was years in the future), which is why anyone invoking "smoking gun" evidence for it would not have been taken seriously.

I strongly recommend looking at Steinhardt's Strings 2014 talk, where he discusses the Linde quotes and explains in detail the obvious problem with them.

43. **Garbage**
June 24, 2014

'Model of Leptons' – 1967. Although it is true the original motivation for BEH is lost in time (same as the YM theory) I think is pretty clear what we're talking about unless you want to divert the point. The original motivation for Inflation (horizon problem, monopole, etc.) is also lost in time if you want; but the theory survives, like the Weinberg model does, with quantitative predictions. (Here I think Mukhanov deserves a lot of credit by the way.) What people fails to realize is that there's a very natural connection between an accelerated expansion and quasi-scale invariance, the fact that many models fit data is because of the robustness of this simple (yet powerful) idea.

I am pretty sure if a Higgs-looking resonance had shown up in the 70's (or even 80's) around 10GeV a lot of people would have gotten really excited, and that's 40 (30) years before they found the Higgs.

I've seen Steinhardt in action many times, making the same points over and over. I also suggest you go back and see his own claims about his model and how he changes his mind all the time. I also wish we would understand how to make sense of the big picture with inflation, but given what we observe, there's nothing like it, it is just too simple and idea that works extremely well… I think you're confusing this with the multiverse, the measure, etc. I'm not even touching upon things I cannot measure/prove. But please, learn a little bit cosmology and you'll see how you'll be yourself driven towards inflation like the most compelling explanation.

44. **physics PhD (experimental optics)**
June 24, 2014

In fairness to Linde, it seems that his press release was driven by the Stanford media relations office. As is typical in press releases, "quotes" are often written / scripted / massaged by media flack, and quickly run by the "speaker."

Had Linde been fortunate enough to work at a publicly traded company, his words would at least be reviewed by a lawyer, to protect the company from any liability or blow-back.

Yes, he needs to stand by his words, and eat them if necessary. But overactive University PR organizations are also part of the problem.

45. **Jesper**
June 27, 2014

Peter – do you know where one can watch the Paul Steinhardt's talk you mention? I've looked for it but only found his slides.

46. **Peter Woit**
June 27, 2014

Jesper,
I watched the talk in real-time via the streaming site. Presumably video of the talks is being processed and will show up later.

47. **S. Molnar**

It's old news by now, but there is an interview with David Spergel about this in the Simons Foundation magazine: http://www.simonsfoundation.org/quanta/20140703-a-bold-critic-of-the-big-bangs-smoking-gun/

2015 Breakthrough Prizes in Mathematics

June 23, 2014
Categories: Uncategorized

The first set of winners of the $3 million Milner/Zuckerberg financed Breakthrough Prizes in mathematics was announced today: it's Donaldson, Kontsevich, Lurie, Tao and Taylor. There's a good New York Times story here.

When these prizes were first announced last year, I was concerned that they would share a problem of Milner's Fundamental Physics Prizes, an emphasis on rewarding one particular narrow area of research. I'm happy to say that I was wrong: the choices made are excellent, including a selection of the absolute best people in the field, working in a wide range of areas of pure mathematics. The prize winners are mathematicians who are currently very active, doing great work. It's clear that there was an effort to avoid making this a historical prize, i.e. giving this to people purely for great work done in the past (which to some extent the Abel Prize is doing). The recipients are on average in their 40s, at the height of their powers.

One oddity is the award to Kontsevich, who already received $3 million from the Fundamental Physics prize. Given my interests, I suppose I shouldn't criticize a prize structure where physicists get $3 million, mathematicians $3 million, and mathematical physicists $6 million.

While this prize doesn't suffer from the basic problem of the Physics prize (that of rewarding a single, narrow, unsuccessful idea about physics), it's still debatable whether this is a good way to encourage mathematics research. The people chosen are already among the most highly rewarded in the subject, with all of them having very well-paid positions with few responsibilities beyond their research, as well as access to funding of research expenses. The argument for the prize is mainly that these sums of money will help make great mathematicians celebrities, and encourage the young to want to be like them. I can see this argument and why some people find it compelling. Personally though, I think our society in general and academia in particular is already suffering a great deal as it becomes more and more of a winner-take-all, celebrity-obsessed culture, with ever greater disparities in wealth, and this sort of prize just makes that worse. It's encouraging to see that most of the prize winners have already announced intentions to redirect some of the prize moneys for a wider benefit to others and the rest of the field.

Update: Among the private reactions I've heard from prominent mathematicians this morning, one is the desirability of funding a new "sidekick" prize for collaborators of the $3 million winners…

Comments

1. **Als**
   June 23, 2014

   Interesting.

   I think it has the potential to challenge the Fields medal in the long run if the committee chooses wisely the next recipients.

2. **someonesomewhere**
   June 23, 2014

   Well, the Nobel prize was initially also awarded to people who already were famous, so it's not a new concept to initially award the prize to already famous people, so that the fame of the past winners shines on the new ones.

3. **Bill**
   June 23, 2014

   All of them are great mathematicians and deserve the award as much as anyone else, but the selection seems a bit random. Some of them are obviously rewarded for old breakthroughs, not for recent work, and some for work that nobody really understands to call it a breakthrough. What is the main criterion? Starting from next year when only one person gets the award, is it going to turn into another lifetime achievement award or will they reward genuine recent breakthroughs? Why not turn this into a Fields Medal without age restriction – reward for genuine breakthroughs in the last few (4?) years? Actually, the award is big enough to share among possible coauthors (Birkar- Cascini-Hacon-McKernan, Marcus-Spielman-Srivastava, etc).

4. **Bill**
   June 23, 2014

   Shouldn't this be "2014 Breakthrough Prizes in Mathematics"?

5. **Peter Woit**
   June 23, 2014

   Bill,
   These prizes will be awarded in November at a ceremony for the prizes in physics and biology officially called the 2015 prizes. I see the Milner site is naming them not by year, but as "Inaugural". It seems though that the plan is to award the math ones each year at the same time at the others, and next year's will be the 2016 ones, so 2015 seems a better choice than 2014…

6. **Bill**
   June 23, 2014

   From NYT: "The size of the award, I think it's ridiculous," he said. "I didn't feel I was the most qualified for this prize." But Dr. Tao added: "It's his money. He can do whatever he wants with it."

   Not true that he can do whatever he wants with it, you can say no and encourage others to say no, if you believe this is not a good idea. Mathematics community can put Milner's money to good use, but on their terms.

   Also, any rumors that Wiles refused the prize? Obviously, they didn't even dare to ask Perelman. By the way, more kids would be inspired to do mathematics if mathematicians acted more like Perelman. This prize is not going to make them into celebrities in that sense.

7. **Als**
   June 23, 2014

"Update: Among the private reactions I've heard from prominent mathematicians this morning, one is the desirability of funding a new "sidekick" prize for collaborators of the $3 million winners…"

The problem of the side-kick award is that it could feel like an insult. I would be very uncomfortable telling Taylor he gets the "Wiles's sidekick award" for instance.

8. **John Doe**
June 23, 2014

New prizes like this tell me more and more how pointless prizes are becoming.

This post hits the target. What is the purpose of a prize? Why do prizes include money and if they do, how much should it be?

If the purpose of a prize is to 'help Mathematics' (whatever that means) at large, this prize has a big risk, since it puts a lot of power (money is just a measure for power) in the hands of few mathematicians, not lelected for their choices regarding power, but for their solutions to mathematical problems. It is pretty much up to them what they do with it. It is interesting how the piece you link says that Tao tried to reject it but in the end took it because it is up to this guy what he does with his money. He is just going along with the system. If he keeps it, that sounds fake. If he does something else to 'help Mathematics' with it, whatever that is, it is as if he had become a jury for the prize, which shows how pointless this prize is.

I don't think 3 million dollars are going to help these guys to do better math, and I don't think it's going to make any difference other than to their wallets. They'll keep doing what they do, just a bit richer.

9. **Als**
June 23, 2014

BTW, the Milner website says Taylor proved the "Taniyama-Weil conjecture". I wonder who wrote the blurb and kept Shimura out….

10. **Peter Woit**
June 23, 2014

Als,
I think how insulting this might be would depend strongly on the size of the check. At, say $1 million, I think most mathematicians would overcome any sense of grievance about being a "sidekick".

About Taniyama-Weil I also noticed that. If Serge Lang were still alive, it would kill him.

11. **Peter Woit**
June 23, 2014

Bill,

The people Milner chose are relatively young (all younger than me…), and have major results from within the past few years, which would be one reason Wiles is not on the list, not that he turned it down.

I don't want to start a Perelman pro/con discussion, but I disagree with you about Perelman as a role model. I do think though he almost surely would have turned down the money.

12. **Thomas**
June 23, 2014

It would be great if one could read Clozel's exposition of the recent work by Taylor, Patrikis: http://www.institut.math.jussieu.fr/projets/tn/STN/files/annonce-7-4-14.pdf

13. **M.K.**
June 23, 2014

"it's still debatable whether this is a good way to encourage mathematics research"

I disagree on the seemingly obvious conclusion that a high-doted distinction distributed among a small number of already famous mathematicians would lead to less 'encouragement' of mathematics research than a distribution among a higher number of lesser known mathematicians. Given such prizes are also in the latter case based on past achievement of people working on established mathematical institutes (thus established mathematical areas) it is very difficult to see how such prizes would lead to something else than to a substitution of public funding by private or corporate funding. Further, it is very difficult to imagine indeed how a non-mathematical jury, or a random jury, could have the expertise to decide if non-mainstream ideas could be fruitful or not, while indeed the present price-winners are with a relatively high probability capable to decide this. So as usual in our society, everything depends on the good-will of individuals in a system that is organized on questionable measures and aims in general.

14. **Ian**
June 24, 2014

If this prize allows these mathematicians to not apply for grants (for some number of years), then it may serve a useful purpose. Not only would it free up time that might be taken applying for grants and allow them to conduct research unconstrained by grant proposals, but it should also allow others to have a better chance of obtaining them (such as NSF grants, which are getting less funded over time).

15. **Peter Woit**
June 24, 2014

Ian,
That's an interesting point, but given the way these awards are set up and the positions of the people getting them, they generally won't replace NSF grants. One could take a look at what happened in physics, where a quick search shows
http://www.nsf.gov/awardsearch/showAward?AWD_ID=1314311
Although the IAS physics faculty each got $3 million awards in 2012, the IAS is still applying for and getting NSF grants to pay for postdocs and overhead to the institution.

The people getting these awards don't really need research grants to conduct their own research, they typically apply for grants to fund students, postdocs, and their institution. The prize money goes directly to their bank account, not to the institution. If they want to use the money for students, postdocs, their institution they could do this, but would have to set this up themselves, which would likely be every bit as time consuming as the grant application process.

That said, I'm sure some of the prize money will end up being used by the recipients to support research in ways that a grant might have in the past, and can replace some NSF grants. It's not at all clear though how much of that is happening for the physics grants, and how much will happen for the math grants.

16. **Peter Woit**
June 24, 2014

Put differently, the explicit goal and structure of these prizes is to make the recipients personally rich and famous, not to support their research. Once they are rich, in principle they can devote their time to philanthropy and support research, but it's unclear how much of this will happen, will be interesting to see.

17. **Bobito**
June 24, 2014

Why doesn't Xiuxiong Chen or Yan Soibelman deserve a bit of the cake?

18. **Jess Riedel**
June 24, 2014

Two alternative ideas for structuring the prize:

(1) Make it more about honor. Give the mathematician a few hundred thousand dollars, but use the bulk of the money to endow a research position in the mathematician's name. (An MIT professorship is $3M: http://giving.mit.edu/priorities/faculty/)

(2) Give the money to the awardee, but require them to pledge to not write grant proposals for 5 years. Maybe unfeasible since they need to write grants to support their students, postdocs, and institution, but part of the award could go to cover this.

19. **Peter Woit**
June 24, 2014

Jess,
Good suggestions. I've often wondered why more of this private money isn't going into the traditional philanthropic path of endowing positions, which would have a big, long-term effect on the health of the field (Simons has the "Math + X" program, but I can't think of many other examples).

If each year, instead of giving a $3 million personal check to a string theorist the Breakthrough Prize people endowed a position in string theory, the effect on the subject would be huge (and would do a lot more to encourage young people to go into it).

20. **Bork**
June 24, 2014

I agree that this is a double-edged sword, even for the winners. Now they have to worry about what to do with all that money. If they spend it on themselves, they will be criticized, or are likely to feel so, and if they try to distribute it somehow, in some sort of "fair" way, that could eat up time and cause a headache and ironically take them away from research. And their choices could, again, be criticized.

Of course the type of mathematician who likes being a big honcho would love that, but my guess is these are not of that sort. They probably would much prefer just to, basically, be left alone. Perlman was only the extreme version of that.

What a research mathematician really needs is: more free time, plus a modicum of financial stability, plus a good research environment. A good research environment includes: happy colleagues, and good basic education.

This is why Simons' donations seem much more creative and better thought out,
and much more likely to be effective.

One of the great things about mathematics as a human endeavor and a part of human culture and as a path through life, is the relative equality and openness
compared to other realms of activity. This sort of prize might end up doing more harm than good to the overall culture and enterprise of mathematical life and mathematical research.

I say, give a $100,000 prize, and then just give half the remaining $$ to Simons to spend as he sees fit, and give the other half to lobbyists in support of: the NSF funding of basic research, and a bigger NSF budget; and basic school education reform: not Bill Gates style (test, test, iPad, test) but small class sizes, sabbaticals and better salaries for teachers, real books for kids, as well as bringing back instruction in music, cursive writing, PE…oh and math and physics I suppose, why not…

21. **Patrice Ayme**
June 25, 2014

Milner is a celebrity. And a financial manipulator who became immensely wealthy with what Roosevelt and the Bible called contemptuously "money changing". He profited immensely of a system, plutocracy, that is mostly about oligarchy pushed so far, that even the character of those "leaders" become diabolical.

It's diabolical to make us believe that mathematics will progress more by giving more power to those who have more than enough to do good math.

Overall, science and mathematics do not have enough practitioners. A striking example is antibiotic research where a small effort needs to be done to find new antibiotics. To have a few individuals who are much richer will have no positive effect whatsoever. This is certainly true in math and physics.

In biology, immense greed has clearly undermined research (individuals have made up to half a billion dollar a year in that field, but one cannot find the modest finance for new antibiotics research). Making a few persons very rich promotes greed.

So why is Milner doing this? Maybe it's subconscious. The oligarchic principle is that humanity is unworthy, but for a few celebrities who never get enough. This is what Milner is truly rewarding. His reason for being what he is. Someone obsessed by individual power.

Want to help science and math? Finance studies on how to persuade governments to finance enough advanced public free instruction in science and math, starting in preschool. Through heavy taxation of the richest celebrities, starting with Milner and his kind.
http://patriceayme.wordpress.com/

22. **Bill**
June 26, 2014

Jess Riedel,

Endowing a research position is the best idea I've seen so far. I would add that such a position should not be given permanently to one person until his/her retirement but instead given for a period of, let's say, 10 year to an active researcher.

23. **NLR**
June 26, 2014

Endowing a research position is a good idea, but the problem with the Milner Prize is similar to a remark made by Norbert Wiener said in his book "Ex-Prodigy," that, often, people who are already well-known and well-rewarded get more awards, resulting in a "pyramid of awards." However, the people who could most benefit from such awards are lesser-known researchers who do not have financial stability.

Also, the idea of making mathematicians celebrities is completely at odds with the reason to do mathematics. The value of math does not come from fame or money, but from the intrinsic interest and value of mathematics. In fact, I would think that many people study math precisely to engage with a part of the world that has nothing to do with things such as money or celebrity.

24. **Anders**
June 27, 2014

In Economics we have something called tournament theory to try and explain the very large CEO remuneration you often see in the US. Basically the idea is that you overpay the CEO to get people further down in the organization to work very hard, to have a shot at the CEO position. Maybe these prizes in science can work the same way, they do not change the productivity of the recipients but maybe of other researchers that have a decent chance of getting a prize later in their career.

Pierre van Baal 1955-2013

June 23, 2014
Categories: Obituaries

I only recently heard about the death late last year of Dutch particle theorist Pierre van Baal. Pierre was my office mate when we were both postdocs at Stony Brook during the mid-eighties, and he was one of the people I most enjoyed talking with about physics during those years. He arrived at Stony Brook after completing a Ph.D. with Gerard 't Hooft, and later went on to CERN and ultimately a professorship in Leiden. I last saw him at a conference in Stony Brook in 2008 (described here) where he told me that he had suffered a serious stroke in 2005. Pierre was quite modest, and always a cheerful and optimistic presence in the room. In 2008 he was still very much himself, but more halting in his speech. From what I remember, he told me that he was resuming teaching, but was frustrated that he was no longer capable of engaging in research work.

The lecture notes of his class on quantum field theory are available (an online version here, a published version here). Like Pierre himself, they're a model of clear and concise thinking and exposition. Last year a book with a selected collection of his papers was published, see here.

A major theme in Pierre's work was the study of quantum gauge theory via semi-classical methods, for the case of a system in a "box", i.e. finite extent in space and time dimensions. In the Euclidean picture, periodic boundary conditions in time correspond to doing computations at non-zero temperature, inversely proportional to the size of the time dimension. As a result, this work is quite relevant to the study of QCD at finite temperature, including the expected deconfining phase transition.

While Pierre was not really a lattice gauge theorist, his work was highly relevant to lattice gauge theory, where computer simulations inherently take place in a finite box, and understanding the effects of this on the physics is crucial. As a result, Pierre was well-known in the lattice gauge theory community. This week Columbia University is hosting Lattice 2014, the big yearly meeting for lattice gauge theorists (plenary talks are streamed on livestream.com). This morning I attended the talk by Michael Mueller-Preussker on Recent results on topology on the lattice, which was given in memory of Pierre. The slides have a lot more information about Pierre and his work, as well as surveying the latest on lattice results involving the topology of gauge fields.

For more about Pierre, see this site, which has an appreciation written by Chris Korthals Altes (in English here), as well as pieces by 't Hooft and Hans van Leeuwen (in Dutch).

String Theory Visions

June 27, 2014
Categories: Strings 2XXX

Strings 2014 ended today, with five separate "vision" talks, giving a good picture of where the leaders of the string theory community see the subject going. I saw the talks on streaming video, presumably they should appear on the conference website in the next few days.

- Michael Green led off by noting that string theory had at one point been intended as a unified theory, but now has "blossomed into something much more significant", a framework covering all sorts of things. He went on to say that he would avoid discussing the grand questions, and instead just give a summary of what he found interesting about work reported at the conference. The main area that he covered in the talk were the many different kinds of results about scattering amplitudes that are under study. He seemed to be somewhat of a skeptic about Arkani-Hamed's widely publicized "Amplitudehedron", saying it had some ways to go before it was useful for computations (unlike other methods).
- Juan Maldacena gave a talk that had nothing to do with string theory, mainly about the conceptual issues of black holes and quantum theory. He claimed that the BICEP2 results showed that quantum gravity was now an experimentally-based subject, answering those who were skeptical about studying an untestable subject.

  At the end of the talk he gave an answer to the question "What is String Theory?":

  > **S**olid **T**heoretical **R**esearch **I**n **N**atural **G**eometric **S**tructures

- Andy Strominger gave his own answer to the "What is String Theory?" question:

  > anything that anybody in this room or any of their friends has ever worked on.

  He did note that there were hardly any strings anywhere to be seen at recent string theory conference talks.

  About the LHC and any conceivable follow-on higher energy accelerator, his comment was that it was now highly unlikely that string theory could make predictions relevant to them, and that he didn't want this to be a defining goal of the field. Clearly, the failure to find SUSY at the LHC has now pretty much killed off most hopes that string theory unification is relevant to particle physics in any testable way. Like Maldacena, he pointed to BICEP2 as showing that quantum gravity was now an experimental subject.

  He ended by explaining that he had sent around emails to a hundred people asking for their suggestions about what problems there would be progress on over the next 5-10 years. He got 80 responses, and quickly put up some slides with them. No time to really read these, but he says that they'll be posted online soon, and that should be a quite interesting document

- The last talk was by David Gross, who pointed out that he has given many of these things before. He then went on to discuss Paul Steinhardt's impassioned talk earlier in the week, which included a video of Richard Feynman discussing "Cargo Cult Science" and theories that were too vague to be testable. Steinhardt had been arguing that inflation was so vague and flexible a theory that it could not be tested and so was not science. Gross like many others realized that you could replace "inflation" by "string theory" in Steinhardt's argument. He then gave a long and very defensive discussion of why string theory might still be science, invoking the recent book by Richard Dawid and telling the audience they needed to read it so they could defend their subject against the accusations it is facing.

  I wrote here last year about the Dawid book, including an explanation of Dawid's three main arguments for string theory. Gross went through these in detail, and I think what I wrote last year also responds to what Gross has to say. He did include in the "Meta-Inductive Argument" the argument that SUSY is a related research program to string theory and that it will be vindicated at the LHC in the next few years. It will be interesting to hear what he has to say at a future Strings 20XX after this hasn't worked out. He announced that Strings 2015 will be in Bangalore, Strings 2016 in Tsinghua, Strings 2017 in Israel, Strings 2018 in Japan and Strings 2019 in Belgium.

  He explicitly addressed the fact that many in the field were experiencing depression and anxiety due to things not working out, pointing out that even if the first derivative of progress in a field is negative, there can be jump discontinuities. So, although things don't look good, maybe a big piece of progress will come along out of nowhere.

There was one more vision talk, but I'll discuss that in a separate posting.

Update: Strominger's slides are available here, and include the 80 responses he got from others about the open problems of the field.

Update: Videos of the talks are now available.

Comments

   June 27, 2014

   The discussion here about the LHC, SUSY, and strings reminds me of the argument about BICEP2, gravitational waves, and inflation. Absence of SUSY at LHC is taken here as a blow to strings, but finding SUSY wouldn't have been seen here as supportive of string theory unification. So the asymmetry is similar to Linde's attitude that it would have been a "smoking gun" for inflation had gravitational waves been found but no crushing blow had it not.

2. **Peter Woit**
   June 27, 2014

   srp,
   I'm not sure what you mean. The prospect of SUSY at the LHC was always advertised as the main prospect of experimental vindication of the string theory picture, and the failure of it to show up is behind both the "depression and anxiety" Gross describes, as well as the disappearance of mention of the LHC from the conference.

   Gross and some others are still holding out for vindication from LHC Run II, but I think most string theorists are now agreeing with Strominger. Once you give up on experimental HEP as having any relevance to what you do though, you have to face the fact that other physicists are going to now be skeptical about whether you're still doing science. Both Strominger and Maldacena tried to address that by invoking BICEP2, but that comes with its own problems. This concern was also clear in Gross's talk.

3. **srp**
   June 27, 2014

   Please allow me to clarify. I'm not concerned with who advertised what in advance, but with the logical structure of the inferences being made. In this case I agree with your position, but it is inconsistent with how you approached the BICEP2 affair.

In the "Smoking Gun" thread, a bunch of people (including me) argued that it was not inconsistent to see the BICEP2 finding of gravitational waves as a "smoking gun" for inflation if true but not a showstopper for inflation if false. In other words, we believe that this kind of asymmetry of inference based on a particular piece of evidence may be completely rational. One commenter drew an analogy with discovering life on another planet–that would be a smoking gun for the non-uniqueness of terrestrial life, but failing to find life on that particular planet wouldn't measurably change your prior belief in extra-terrestrial life existing somewhere.

Then this post made me realize that you were arguing (implicitly) for the same kind of asymmetry in the case of SUSY and the LHC. A positive finding of SUSY would NOT have led you to accept string theory unification as true, but the negative findings to date DO lead you to significantly decrement your probability that it is the right theory. I agree with this stance and simply point out that it is logically the same kind of asymmetry that you criticized in the case of inflation. Of course you may disagree with this assessment, but perhaps my contention is now clear.

4. **Peter Woit**
June 27, 2014

srp,
Actually a discovery of SUSY would have led me to dramatically revise my views, whereas what happened didn't because it was what I expected. But this is really off topic, enough.

5. **Claudine Gérard**
June 28, 2014

Dear Peter,

looking through the slides of the conference and your summary of the vision talks I am doubly puzzled. First, as you said, only few talks are about strings and membranes. But on top of that, no talk is really about unification itself! Even in the vision talks, the speakers avoid the issue. I am puzzled that string researchers seem not to pursue unification any more. Not giving a public talk is surely a natural consequence of this change. But what then is the reason for this conference?

It sure looks as if a group of smart people heard, about 30 years ago, some voice shouting "Unification is in that green pasture over there!" They all run there, ploughed the field, found nothing, and now are saying to each other: "But we are in a beautiful field, aren't we?" This might well be, but why are they there in the first place?

Isn't this avoidance to even talk about of unification – see how openly Green and Maldacena avoid it – the real proof that string and M theory has failed? Peter, we do not need you any more to point out the failure of string theory: the field's elders do it all by themselves.

If the conference invites five people to give a vision talk, and nobody of these five people talks about prospects for unification, then something is wrong. Deeply wrong.

Peter, allow me a conjecture. In theoretical particle physics, it has become common to label people who work on unification as foolhardy or presumptuous. The conjecture is that string theorists now do it among themselves. It seem that they do not dare to even think about unification any more. Is there any hope for change?

6. **Peter Woit**
June 28, 2014

Claudine,
Strominger did address the unification issue, basically saying that he thought it didn't work: he thinks there is no way string theory is going to say anything about particle physics (as opposed to quantum gravity).

While some string theorists still work on unification, they generally weren't invited to talk at this conference. I think that's not because they're perceived as foolhardy by the organizers, but because the organizers are aware those ideas are not working. Why invite someone to talk about a very old research program that has been shown not to work, unless they have found a way to get around the problems?

7. **SUSY**
June 29, 2014

LHC Run II – how long after 2015 will results be announced on SUSY? other than SUSy what other physics do they hope to see at 13TEV?

8. **Peter Woit**
June 29, 2014

SUSY,
There might be some early results on SUSY summer 2015, I'd guess results based on a data set of similar size to Run I would start winter 2016. I'm sure there will be searches for all the same things as Run I: extra dimensions, Zprime, black holes, you name it.

9. **Maurice Carid**
June 29, 2014

Hi Peter,
when Strominger calls the progress
of the last 30 years "incredible" and
likens the present with the situation
of physics in the early 20th century:
is this whistling in the dark, propaganda
or does he really believe this?
cheers maurice

10. **Peter Woit**
June 29, 2014

Maurice,
Calling the last thirty years a period of "incredible" progress is just hype, and I doubt he or anyone else believes this in a serious way.

Likening the present to the early 1900s is a common way of expressing hope for some imminent arrival of new, successful revolutionary insights into physics analogous to relativity and quantum theory. I don't see any argument there, just an expression of wishful thinking for major progress to come soon (unlike the "incredible" progress of the last 30 years…)

11. **Elbi Gilgen**
June 29, 2014

The progress of the last 30 years *has* been incredible, strominger is absolutely right. The only problem is the sign.

12. **Christian Müller**
June 30, 2014

The numerous answers that Strominger collects miss the following:
– The origin of the mass of the electron
– The origin of the fine structure constant
– The origin of the other standard model parameters
So not it seems that not only Strominger, but also all his colleagues have given up on these issues.

It remains amazing how a whole field is digging its own grave in public. A big change is needed: both in the approach and in the required optimism.

13. **Shantanu**
June 30, 2014

Peter or others: can someone point me to the videos of these talks.
I couldn't find them from
http://physics.princeton.edu/strings2014/Talk_titles.shtml
but maybe they are elsewhere
Thanks

14. **Peter Woit**
June 30, 2014

Shantanu,
As far as I know videos have not been posted yet, but the intention is to do so at some point at the page you link to. My comments based on watching the talks were based on watching some of them in real time (they were being streamed live).

15. **Christian Marks**
July 5, 2014

Richard Dawid was very recently interviewed by Richard Marshall of 3AM Magazine about his book, "String Theory and the Scientific Method."

16. **Peter Woit**
July 7, 2014

Christian,
Thanks! Will write something about this interview soon.

17. **peter hickman**
July 8, 2014

With reference to the interview:
Richard Dawid was very recently interviewed by Richard Marshall of 3AM Magazine about his book, "String Theory and the Scientific Method."

The message from string theorists "there is no alternate theory, supports their view that string theory is the so called final theory" is naïve.
There was no alternative to Newtonian physics for c.200 years, until the advent of Special Relativity and Quantum mechanics.

Feynman quote summaries what the scientific process is:
In general we look for a new law by the following process. First we guess it. Then we compute the consequences of the guess to see what would be implied if this law that we guessed is right. Then we compare the result of the computation to nature, with experiment or experience, compare it directly with observation, to see if it works. If it disagrees with experiment it is wrong. In that simple statement is the key to science. It does not make any difference how beautiful your guess is. It does not make any difference how smart you are, who made the guess, or what his name is – if it disagrees with experiment it is wrong. That is all there is to it.
chapter 7, "Seeking New Laws," p. 156 [as presented in edited book]

This is the salient point for any theory: "It does not make any difference how beautiful your guess is".

Peter

A PS on Peter Hickman's comment: The book in question is *The Character of Physical Law* (1965).

Physical Mathematics and the Future

June 27, 2014
Categories: Strings 2XXX

The "vision" talk at Strings 2014 that I found most interesting was that of Greg Moore, whose topic was "Physical Mathematics and the Future". He has a very extensive written version of the talk here, which includes both what he said, as well as a lot of detail about current topics at the interface of mathematics and physics.

I think what Moore has to say is quite fascinating, he's giving a wonderful survey of where this intellectual subject is, how it has gotten there, and where it might be going. I'm very much in sympathy with his historical discussion of how math and physics have evolved, at times closely linked, at others finding themselves far apart. He's concerned about an issue that I've commented on elsewhere, the fact that physics and math seem to be growing apart again, with no mathematicians speaking at the conference, instead attending their own conference ("Strings-Math 2014"). Physics departments increasingly want nothing to do with mathematics, which is a shame. One reason that Moore gave for this I found surprising, the idea that

> most mathematicians are not as fully blessed with the opportunities for pursuing their research that many theoretical physicists enjoy.

It seems there's a perception among many physicists that research mathematicians labor under some sort of difficult conditions of low pay and high teaching loads, but I think this is a misconception. Moore may be generalizing too much from the situation at Rutgers, where very unusual positions were created for string theorists at the height of that subject's influence. From what I've seen, the salaries of top research mathematicians and theoretical physicists are quite comparable (if you don't believe me, do some searches in the on-line data of salaries of faculty employed by public universities). Senior mathematicians do sometimes have slightly higher teaching loads, although often with a freedom to teach what they want. At the postdoc level, it is true that theoretical physics postdocs typically have no teaching, while similar positions in math often do require teaching. On the other hand, the job situation in theoretical physics is much more difficult than in mathematics. I'd say that working in an environment where you know you're likely to find a permanent job is much preferable to one where you know this is unlikely, with doing some teaching not at all a significant problem.

On the question "What is String Theory?", Moore's take was that the "What is M-theory?" question is no longer getting much attention, with people kind of giving up. There was a very odd exchange at the end of the talk, when Witten asked him if he thought that maybe people should be emphasizing the string question, not the M-theory question, and Moore responded that the emphasis on M-theory was something he had learned from Witten himself.

His main point about this though was one I very much agree with, that the more interesting question now is "What is QFT?". The standard way of thinking about QFTs in terms of an action principle doesn't capture much of the interesting things about QFT we have learned over the years. Moore emphasizes certain examples, such as the (2,0) 6d superconformal theories, but discusses in his written version the relation of QFT to representation theory of some infinite dimensional groups, which I think provides even better examples of a different and more powerful way of thinking about QFT.

The written version contains a wealth of information surveying current topics in this area, is highly recommended to anyone who wants to try and understand what people working on "string theory" and mathematics have been up to. It appears that this document is a work in progress, with more material possibly to come (for instance, there's a section 4.4 on Geometric Representation Theory still to be filled in). I look forward to future versions.

Comments

1. **Giotis**
   June 28, 2014

   All these questions about the meaning of QFT etc. originated and formulated in a meaningful way within String theory, so trying to decouple them is unnatural to say the least; they can be understood and addressed only within this general framework provided by String theory.

   In the future the degree of convergence between the two will increase even more and I believe at some point there would be no distinction in practice between a Quantum field theorist and a String theorist.

2. **Peter Woit**
   June 28, 2014

   Giotis,

   I see that you're using Strominger's definition of "string theorist".
   The great thing about Moore's talk was that it had a lot of serious ideas and content, wasn't just the sort of "math shows that string theory rules" sloganeering that goes on in "vision" talks like this.

3. **george ellis**
   June 28, 2014

   Towards the end he says "On the other hand, the relative lack of reliance of Physical Mathematics on laboratory experiments is viewed – with some justification – as dangerous by many physicists. The dangers of relying on "pure thought" when divining the secrets of Nature are well-known and illustrated by multitudinous examples."
   Just so. The name Physical Mathematics is well chosen: virtually all the topics he discusses have have no clear relation to the physical properties of the real universe, so its mathematics rather than physics.
   And that seems to apply also to the references to QFT in the paper ("Moore emphasizes certain examples, such as the (0,2) 6d superconformal theories"). Is there something useful there about the 4-d QFT that apparently describes the real universe? Or are these QFT theories physical mathematics rather then mathematical physics?

4. **Peter Woit**
   June 28, 2014

   george ellis,

   I think we already know the QFT that describes the real universe, it's called the Standard Model (sure, it has a problem with quantizing gravitational degrees of freedom, but hundreds of physicists will tell you they know what to do about that…). To me, the question is whether we can understand that QFT better, in particular finding explanations of aspects of it that now look rather ad hoc. The conjecture that a better understanding of a QFT like the SM is going to require a deeper understanding of QFTs in general (or at least of a class of them) seems reasonable, and such a deeper understanding may very well involve new ideas about the relation of qfts to mathematics. That there is a vast amount we don't understand about qfts and mathematics is undeniable. One can't be sure that understanding more will help understand the real world, but one can be sure that it will lead to new mathematics. In any case, it seems to me more worth doing that most of what theorists working on fundamental physics spend their time on these days.

My own personal take on promising ways to go forward with this overlaps in some places with Moore's, not at all in others.

5. **martibal**
June 28, 2014

Giotis: there is at least one area of mathematical physics which is asking very strongly and deeply what qft is, and it has nothing to do with string theory. This is called algebraic qft.
There is at least one other area of mathematical physics which is asking very much why the standard model is as it is, and it has nothing to do with string theory. This is called noncommutative geometry.
Is it asking string theorists too much to have a little bit of culture out of their field ?

6. **Giotis**
June 29, 2014

Martibal,
I really don't want to argue since the purpose of my comment wasn't to claim that there is no QFT research outside String theory but to highlight the fact that the two are so intimately interrelated nowadays that one is forced to treat them within the context of one general, unified theoretical framework.

BTW saying that non commutative geometry has nothing to do with String theory is absurd. The very presence of D-branes renders space non commutative. Non commutative geometry is a hot topic in String theory research.

7. **martibal**
June 29, 2014

All the noncommutative geometry approach to the standard model (in Connes framework) has nothing to do with string theory.

That string theory is so intimately interrelated with qft that one is forced to treat string theory within the context of qft may be true, I do not know.
The converse obviously is not true.

8. **chris**
June 30, 2014

the MSSM is so intimately connected to the standard model that in fact it is equivalent to it in a certain, well-defined limit. it is fair to say that they are so much connected, that one is forced to treat both the SM and MSSM in the context of one general, unified theoretical framework 🙂

9. **Jesper**
June 30, 2014

@ Chris – the noncommutative formulation of the standard model coupled to gravity in terms of spectral triples and an almost-commutative algebra does not permit MSSM (see http://arXiv.org/pdf/1211.0825.pdf). It is possible (but not natural) to incorporate supersymmetry in this framework, but there is certainly no equivalence.

10. **Urs Schreiber**
July 2, 2014

@martibal,

in fact the spectral (Connes's NCG-type) perspective on geometry, where Riemannian geometries are characterized by the quantum mechanics of superparticles roaming in them (that's what a spectral triple encodes) is a simplified version of how effective target space geometry is encoded in string theory as whatever the quantum superstrings roaming in them sees, as witnessed by their worldsheet SCFT.

See here for more discussion of this relation, with more pointers to the literature: http://physics.stackexchange.com/a/104299/5603

11. **also**
July 3, 2014

To add to Urs' comment:

If I remember right, Connes' original version of con-commutative standard model had a crisp prediction for the Higgs mass. A prediction that was immediately ruled out by Femilab, even before LHC.

Now one could argue whether Connes-like noncommutativity could be embedded in string theory. I am no expert on that, but my first gut reaction on hearing about it at the time, was: "no". So I was happy that it was ruled out pretty instantly. It seemed way too much like a UV Lorentz-violating theory, but maybe I am forgetting.

12. **Yatima**
July 4, 2014

If I remember right

You seem to remember wrong:

1) Original "prediction" 160–180 Gev (not Tevatron range for sure)
2) Experimental: 125 GeV/c^2, Goddammit!
3) Fixed in [Resilience of the Spectral Standard Model]()

For reference:

[Higgs-mass predictions]()

13. **martibal**
July 4, 2014

@Urs: thank for the references. I did not know them so I will have a close look before commenting further. But at first sight I do not see where the "super particle roaming" in Connes description of the NCG are. Besides a Riemannian manifold and its Dirac operator, one has a finite dimensional algebra acting on a finite dimensional Hilbert space and a "finite dimensional Dirac operator" (in practical: a mass matrix). The fermions are the basis of this finite dimensional Hilbert space, the bosons (including the Higgs) are obtained as gauge fields (using a noncommutative generalization of a connection). I do not see super particles there. But I have to study your reference.

14. **martibal**
July 4, 2014

@Yatima and also: the prediction of the Higgs was indeed around 170 GeV (the uncertainty is mainly due to the uncertainty in the Top mass), and it has been ruled out by Tevratron in 2008. In Resilience of the Spectral Standard Model, Chamseddine and Connes have shown that by taking into account a new scalar field (proposed by particles physicist to cure the instability of the electroweak vacuum due to the "low" mass of the Higgs), then it was possible to get the correct mass for the Higgs. In the above mentioned paper, the way to introduce this new field following the "rules" of NCG was a bit rough. This has been made smoother in a successive paper of Chamseddine, Connes and v. Suijlekom [at this point I hope Peter will allow me to break the non-self-publicity rule to say that another way to generate the new field within the NCG framework had also been proposed by a "Napolitan team"]

15. **Peter Woit**
July 4, 2014

All,
Enough about NCG, thanks.

Quick Links

July 8, 2014
Categories: Uncategorized

- Jim Simons is profiled in the Wall Street Journal yesterday, the New York Times today. The WSJ piece is partly about a recent $50 million donation to the Simons Center for Quantitative Biology at Cold Spring Harbor, but it reports that Simons is moving away from "broad institutional support", in favor of "collaborative, goal-driven science". Recently Simons has funded the Simons Array of telescopes that will be looking at polarization in the CMB, and the NYT piece reports that he was talking to Stanford physicists working on experiments looking for the axion. Simons is estimated to have a net worth of $12.5 billion, the Simons Foundation now has $2 billion.
- Quite a few years ago I started a trip to Paris by getting off the plane from New York and heading directly to attend talks at the Seminaire Bourbaki. The main thing I remember now of that is an epic struggle to stay awake, since I hadn't slept on the plane, and the room was rather overheated. There's now a much better way to enjoy talks from this historic program, which since its inception in has been the source of some of the great expositions of new mathematics. Talks are on Youtube, links are on the latest program (learned about this from Emmanuel Kowalski's blog).
- In other news from France, this year's Baccalaureat exam features questions about the Higgs and the LHC. They start off with a quote from Carlo Rovelli about the Higgs discovery being "as important for intellectual history as Newton's law of gravitation". Rovelli's reaction: "I've never thought such a stupid thing." For more on the mini-controversy, see here.
- For more videos to watch, Oxford has an interview with Atiyah here, Penrose here. Cambridge has a large collection of such video interviews, including Peter Swinnerton-Dyer, John Coates, Martin Rees and John Polkinghorne.
- The AMS has been encouraging discussion in the mathematical community of the implications of the Snowden revelations about the activities of the NSA, supposedly the largest employer of mathematicians in the US. This month's Notices includes pieces from Keith Devlin and Andrew Odlyzko, introduced by Michael Harris and Allyn Jackson. Further contributions to this discussion are encouraged.
- On the abc conjecture front, perhaps the planned lecture series this September by Go Yamashita will give mathematician's a fighting chance to understand Mochizuki's claimed proof. While the talks will be in Japanese, presumably Yamashita will be producing something written in English.

4. **Bill**
   July 16, 2014

   Will you have a discussion of a recent Quanta article on your blog? It was an interesting article, curious to hear what people think about this.

5. **Hendrik**
   July 20, 2014

   There is a very enjoyable article by Carlo Rovelli on
   http://www.newrepublic.com/article/118655/theoretical-phyisicist-explains-why-science-not-about-certainty

6. **Jakob**
   July 21, 2014

   I totally agree with Bill. Would love to hear your opinion about those recent fluid-quantum experiments, that may lead to a comeback of the disfavoured Bohmian mechanics

7. **Peter Woit**
   July 21, 2014

   Jakob and Bill,
   I haven't followed that closely, my impression is that it just shows you can find a macroscopic classical system with features described by the Schrodinger equation. This may be useful for visualizing some aspects of elementary QM, but I don't see how it tells you anything fundamental about QM or gets rid of any of the problems of Bohmian mechanics.

   Anyway, sorry, but I'm just profoundly unsympathetic to the whole idea of replacing the beautiful mathematical structure of QM (that I'm writing a book about) with classical pdes. If people want to discuss this, they need to find somewhere else, run by someone with enough interest to moderate a discussion.

8. **Marcus**
   July 28, 2014

   The video of Steinhardt's talk has been posted at the Strings 2014 website.
   It is 28 minutes long including a brief exchange with Raphael Bousso at the end.
   The presentation is a model of calm and cogency, IMO. Worth watching.

String Theory and Post-Empiricism

July 10, 2014
Categories: Favorite Old Posts, Uncategorized

Note: This is being published simultaneously here and at Scientia Salon. Discussion will be at the Scientia Salon site.

Last month's Strings 2014 conference in Princeton included two remarkable talks by prominent physicists, both of whom invoked philosophy in a manner unprecedented for this kind of scientific gathering. On the first day, Paul Steinhardt attacked the current practice of inflationary cosmology as able to accommodate any experimental result, so, on philosophical grounds, no longer science. He included a video clip of Richard Feynman characterizing this sort of thing as "cargo cult physics". On the final day, David Gross interpreted Steinhardt's talk as implicitly applying to string theory, then went on to invoke a philosopher's new book to defend string theory, arguing that string theorists needed to read the book in order to learn how to defend what they do as science.

The book in question was Richard Dawid's String Theory and the Scientific Method, which comes with blurbs from Gross and string theorist John Schwarz on the cover. Dawid is a physicist turned philosopher, and he makes the claim that string theory shows that conventional ideas about theory confirmation need to be revised to accommodate new scientific practice and the increasing significance of "non-empirical theory confirmation". The issues of this kind raised by string theory are complex, so much so that I once decided to write a whole book on the topic (*Not Even Wrong*). A decade later I think the arguments of that book still hold up well, with its point of view about string theory now much more widespread among working physicists. One thing I wasn't aware of back then was the literature in philosophy of science about "progressive" vs. "degenerating" research programs, which now seems to me quite relevant to the question of how to think about evaluating string theory.

I've written a bit about the Dawid book and earlier work of his (see here and here), although as for any serious book there's of course much more to say, even if I lack the time or energy for it. Recently an interview with Dawid appeared, entitled string theory and post-empiricism, which summarizes his views and makes some claims about string theory critics which deserve a response, so that will be the topic here. In the interview he says:

> I think that those critics make two mistakes. First, they implicitly presume that there is an unchanging conception of theory confirmation that can serve as an eternal criterion for sound scientific reasoning. If this were the case, showing that a certain group violates that criterion would per se refute that group's line of reasoning. But we have no god-given principles of theory confirmation. The principles we have are themselves a product of the scientific process. They vary from context to context and they change with time based on scientific progress. This means that, in order to criticize a strategy of theory assessment, it's not enough to point out that the strategy doesn't agree with a particular more traditional notion.
>
> Second, the fundamental critics of string theory misunderstand the nature of the arguments which support the theory. Those arguments are neither arbitrarily chosen nor uncritical. And they are not decoupled from observation. String theory is indirectly based on the empirical data that drove the development of those theories string theory aims to unify. But more importantly for our discussion, the arguments for the viability of string theory are based on meta-level observations about the research process. As described before, one argument uses the observation that no-one has found a good alternative to string theory. Another one uses the observation that theories without alternatives tended to be viable in the past.

Taking the second part of this first, Dawid seems to be claiming that Smolin and I don't understand what he calls the "No Alternatives Argument" (discussed in detail in his book, as well as in this recent paper). In response I'll point out that one of the concluding chapters of my book was entitled "The Only Game in Town" and devoted explicitly to this argument. To this day I think that a version of such an argument is the strongest one for string theory, and is what motivates most physicists who continue to work on the theory. The version of this argument that I hear often privately and that has been made publicly by theorists like Edward Witten goes something like:

> ideas about physics that non-trivially extend our best theories (e.g. the Standard Model and general relativity) without hitting obvious inconsistency are rare and deserve a lot of attention. While string theory unification hasn't worked out as hoped, we have learned a lot of interesting and unexpected things by thinking about string theory. If they see a new idea that looks more promising, string theorists will shift their attention to that.

This is a serious argument, one that I tried to seriously address in the book. Beyond that, more naive versions of it seem to me to have all sorts of obvious problems. Of course, if you really can show that alternatives to a given model are impossible, that's a convincing argument for the model, but this is rarely if ever possible. Working scientists beating their heads against a hard problem are always in the position of having "no alternatives" to some flawed ideas, until the day when someone solves the problem and finds the alternative. The only example I can recall seeing from Dawid of a successful example of the "No Alternatives Argument" is the discovery of the Higgs, and I find that very hard to take seriously. Pre-2012, the Standard Model was a very precise and exhaustively tested theory, providing a huge amount of indirect evidence for the Higgs. There were plenty of alternatives (technicolor, SUSY, etc.), all much more complicated and with no evidence for them. Making a "No Alternatives Argument" for a theory with overwhelming experimental evidence behind it is something completely different than trying to do the same thing for a theory with zero experimental evidence.

As for the other mistake that Dawid thinks string theory critics make, that of believing in some unchanging notion of empirical theory confirmation, the first thing to point out is that of course every theorist is well aware that one can can't just demand experimental predictions and confirmation for ideas, that one spends basically all one's time working on better understanding ideas that are far from the point where empirical confirmation comes into play. The second thing to point out is that I agree completely with Dawid that as experiments become more difficult, one needs to think about other ways of evaluating ideas to see if they are going anywhere. The last chapter of my book was devoted to exactly this question, arguing that physicists should look carefully at how mathematicians make progress. Mathematics is certainly "post-empirical", and while logical rigor is a constraint, it is not one that necessarily points mathematicians to fertile new ideas. There is a long history and a deeply-ingrained culture that helps mathematicians figure out the difference between promising and empty speculation, and I believe this is something theoretical physicists could use to make progress.

The epigram from that last chapter though was something that kept going through my head when thinking about this, a line from Bob Dylan's "Absolutely Sweet Marie":

> But to live outside the law, you must be honest.

Yes, theoretical particle physics is in a stage where empirical results are not there to keep people honest, and new and better "post-empirical" ways of evaluating progress are needed. But these must come with rigorous protections against all-too-human failings such as wishful thinking and Lee Smolin's "groupthink", and I just don't see those anywhere in Dawid's proposal for new kinds of theory confirmation.

I'd like to thank Massimo Pigliucci for the opportunity to write something here at Scientia Salon, and hope it will generate an interesting discussion. Contributions from philosophers to this kind of debate in physics I believe are very much needed, on this issue and others. Don't even get me started about the multiverse…

Update: Frank Wilczek, unlike Gross and Schwarz, is not a fan of Dawid. From Twitter:

> Wheeler: "Mass Without Mass", "Charge Without Charge", "Field Without Field" http://bit.ly/1p2cWQv
> Dawid: "Physics Without Physics"

Update: Sabine Hossenfelder blogs about this here, with a response from Dawid here. Dawid writes

> My claim is that a strong record of empirical confirmation in a research field under certain conditions can increase the probability of the viability of other theories in the field that have not been empirically confirmed. The currently predominant philosophical conception of theory confirmation (Bayesianism) equates confirmation

> with the increase of the probability that a theory is true or viable. For that reason I speak of "non-empirical theory confirmation".

This seems to just be an argument that HEP theorists have been successful in the past, so one should believe them now, an argument in conflict with the argument that things have changes due to the difficulty in getting relevant experimental data.

Categories: Langlands

- For an Oxford conference last week, Langlands contributed a one-hour video talk, filmed in his office. One hour was not enough, so hours two and three are also available, as well as a separate text, and some additional comments.
- The latest AMS Notices has a long section of excellent articles about Friedrich Hirzebruch and his mathematical work.
- Also in the AMS notices is a long defense of the NSA, written by a mathematician who worked there for 41 years. About the main recent controversy here, the Snowden revelation of an NSA backdoor in an NIST standard, all the author has to say is:

  > I have never heard of any proven weakness in a cryptographic
  > algorithm that's linked to NSA; just innuendo.

  This seems to me to exemplify pretty well the disturbing tactic of the US security establishment of claiming there is no problem while refusing to discuss anything problematic since it is classified.

- Bhargava, Skinner and my colleague Wei Zhang have a new paper out proving that better than 66% of elliptic curves satisfy the BSD conjecture. It seems not implausible that they or others might in the not too distant future get to 100%. One should note though that showing 100% of elliptic curves satisfy BSD wouldn't be the same thing as showing all elliptic curves satisfy BSD, so wouldn't be eligible for the $1 million Millennium prize.
- With the ICM less than a month away, I find it outrageous that no one has yet leaked to me the names of the Fields Medal winners. All I've heard is speculation, and the only name I'd bet any money on is Bhargava.

Update: For something both ICM and Langlands related, Michael Harris on his web site has his ICM contribution Automorphic Galois representations and the cohomology of Shimura varieties. Many of the ICM 2014 proceedings contributions are already available on arXiv, via this search.

Comments

1. **egan**
   July 16, 2014

   For the Fields medal winners, my money is on Bhargava, Lurie, Avila and, perhaps, Scholze.

2. **Douglas Natelson**
   July 16, 2014

   Peter, can you explain how proving that 100% of elliptic curves satisfy BSD is not the same thing as proving that all elliptic curves satisfy BSD? Is this some mathematician's definition of 100% that does not mean "all", or is the particular prize question in terms of a single general proof rather than breaking the result into subcategories? (Bhargava gave the single most impressive math talk I've ever seen, and he used only a blank transparency and a felt-tip marker.)

3. **Cartan**
   July 16, 2014

   Douglas Natelson,

   100% of numbers in the interval [0,1] are not 1/2 but not all numbers in [0,1] are not 1/2.

4. **newcomer**
   July 16, 2014

   @Douglas,
   for example another statement: 100% of integers are not prime.

5. **Peter Woit**
   July 16, 2014

   To expand on the remark of Cartan, the standard conjecture I believe is that if you order elliptic curves by height, in the limit as you go off to infinity, 50% will have rank 0, and 50% will have rank 1. Of course there are plenty of elliptic curves of higher rank, and to prove BSD you need to prove it for them. In the limit though, these do make up 0% of the curves.

6. **Douglas Natelson**
   July 16, 2014

   Got it. It's an issue of measures. Thanks!

7. **Bill**
   July 16, 2014

   Speculation is that there will be a female Fields medalist.

8. **Tom Leinster**
   July 16, 2014

   NSA mathematician Richard George protests that talk of the NSA deliberately weakening cryptographic algorithms is "innuendo". But over at the *n*-Category Café, user bgg points out another piece of evidence to the contrary: the NSA's own 2013 budget request, which says the NSA will use funds to:

   > Insert vulnerabilities into commercial encryption systems

   and

Influence policies, standards and specification for commercial public key technologies.

9. **Jeff M**
July 16, 2014

Peter,

Not that it matters now, but perhaps better than 100% is "almost all." Then again, I guess someone will ask what that actually means. How about "except for a set of measure 0." I'm hoping no one asks for a definition of "measure." 🙂

10. **Peter Woit**
July 16, 2014

Bill,
I'll raise you: I'm hearing speculation of TWO female Fields medalists.

Tom,
That "innuendo" business is just outrageous. Does anyone believe the NIST issued a warning not to use that standard based on "innuendo"???? Someone should write into the Notices about this. Makes me agree with Beilinson's point of view…

11. **BCnrd**
July 16, 2014

It cannot be emphasized too strongly how much the relatively short paper of Bhargava, Skinner, and Zhang rests on tremendous amounts of substantial prior work of the 3 authors separately (e.g., item [15] in the bibliography).

Also, though it will be spectacular to know some day that "0%" of elliptic curves over Q have higher rank (and that "100%" satisfy the rank-BSD conjecture), the "0%" case can of course occupy a substantial % of the proof of a big theorem: recall the crucial role of a higher-rank elliptic curve in the solution of the Gauss class number problem for imaginary quadratic fields, that only finitely many elliptic curves in each characteristic p are supersingular yet every elliptic curve over Q has infinitely many primes of supersingular reduction (though the set of such primes is 0% in the non-CM case), and that the Gross-Zagier paper devotes a lot of space to primes of supersingular reduction.

12. **Bill**
July 17, 2014

Actually, the whole process of awarding Fields medals reminds of "top 10 world's best place to travel" published by many magazines. Yes, Paris is great, but a mountain campsite can be pretty awesome too. The difference is that nobody really takes these top 10 lists seriously. On the other hand, I suspect there are many more travelers qualified to compare various travel destinations then there are mathematicians qualified to judge top 4 mathematicians under forty.

13. **Jonathan41**
July 17, 2014

Speculation from outsiders is one thing, but leaks from insiders would be shocking IMHO.

I do hope the "female winner rumor" is true though, there are several exceptional ones this time around, so statistically out of four winners there's no reason for it not to happen.

14. **Urs Schreiber**
July 17, 2014

In his Oxford lecture "Problems in the theory of automorphic forms — 45 years later" Robert Langlands had some noteworthy points to make about the field. Specifically in the survey pdf that goes with the video lectures there are comments on the effects of Fields medals and on specialization.

p. 5: "Since Fields medals are taken quite seriously by a large number of mathematicians and by whatever part of the general public takes an interest in mathematics, the lack of perspective is regrettable. […] These specialists are all excellent mathematicians, but one wonders again whether the influence of these medals, and other prizes with wide recognition, on the course of mathematics and on our understanding of it is entirely beneficial."

and more on specialists:

on p. 8 "I find, however, that they are excessively focussed. We can, I am sure, not do without them; they however appear to prefer problems with circumscribed, more modest goals! I fear that those with a larger view of the subject will have to learn from them; on the other hand, they themselves, so far as I have observed, have no desire to learn anything was ihnen nicht in den Kram paßt."

On the other hand, regarding the broader perspective of geometric Langlands correspondence and in particular its claimed incarnation within string theory:

p. 6 "I am still puzzled by the notion of mirror symmetry and, in general, am curious what 'theoretical physicists' have in mind when they speak of the "Langlands program."

More of this cautioning that there remains mathematical substance to be added to a handwaving story is in the first video lecture and was also pronounced earlier this year in a coment to a message to Sarnak:

"One popular introduction to the topic is Frenkel's Bourbaki lecture, 'Gauge theory and Langlands duality'. On the first page, he describes electro-magnetic duality as an aspect of the Maxwell equations and their quantum-theoretical form or, more generally, as an aspect of four-dimensional gauge theory. This duality is quite different than the functoriality and reciprocity introduced in the arithmetic theory. It entails a supplementary system of differential equations. Moreover, it has to be judged by different criteria. One is whether it is physically relevant. There is, I believe, a good deal of scepticism, which, if I am to believe my informants, is experimentally well-founded. Although the notions of functoriality and reciprocity have, on the whole, been well received by mathematicians, they have had to surmount some entrenched resistance, perhaps still latent. So I, at least, am uneasy about associating them with vulnerable physical notions. On the other hand, as strictly mathematical notions this duality and various attendant constructions, such as the Hitchin fibration, appear to have proven value, especially for topologists and geometers. Whether it is equal to that of functoriality and reciprocity is open to discussion."

This seems to show that even the idea that the string theoretic argument is supposed to be a purely mathematical argument remains unclear.

In my own talk at the end of the Oxford meeting I took the liberty of picking of that theme, arguing that what is urgently missing is a general mathematical theory of higher codimension quantization that would allow to turn statements about ‘t Hooft operators, Wilson operators etc. into precise definitions, clear statements and formal proofs. Some indications in this direction are here.

15. **jsm**
July 17, 2014

To put the Bhargava, Skinner, Zhang result in perspective, we’ve known for 80 years that the Hodge conjecture is true for almost all abelian varieties (in terms of the moduli space), but this has helped not at all in our efforts to prove the Hodge conjecture for all abelian varieties.

16. **Chris W.**
July 18, 2014

Urs,
Is there a transcription error in this sentence from your quotation of Langlands?

> So I, at least, am uneasy about associating them with ~~vulnerable~~ **venerable** [?] physical notions.

17. **Urs Schreiber**
July 19, 2014

Chris W., that seems a weird question of yours, unless I am missing something. Follow the link I gave to see that this is not transcribed but typed by RL himself.

Also, your suggestion for how to change the wording indicates that you may be missing what I think is the point of the statement. The point of the statement is that RL does not wish to have associated with the mathematical program named after him non-rigorous claims whose alleged validity he feels might well not stand the test of time, to the extent that they are based just on physics-inspired ideas and not on secure proofs.

18. **Cplus**

19. **Anonymous**
July 20, 2014

As a member of a standards committee involved the removal of the mentioned algorithm from a standard, none of the members believe the “innuendo” theory, and all believe it was deliberately weakened. In fact, the possibility of potential weaknesses were noted during the NIST analysis. At a minimum, there is something very, very fishy about the algorithm in question.

20. **Anonymous**
July 20, 2014

This site:

http://blog.cryptographyengineering.com/2013/09/the-many-flaws-of-dualecdrbg.html

Has an excellent discussion of the flaws in Dual_EC_DRBG. Either (1) NSA was ignorant of these mathematical details, and therefore can’t be trusted based on cryptographic incompetence, or (2) they knew exactly what they were doing, and can’t be trusted because they intentionally put a backdoor in the algorithm. Your choice.

Someone really needs to publish a rebuttal to what is probably NSA backed propaganda in a published journal.

21. **Anonyrat**
July 21, 2014

I have never heard of any proven weakness in a cryptographic algorithm that’s linked to NSA; just innuendo.

This could be true, with less subtlety than the “100% versus all” (100% is less than all by something of measure 0). The author may have only read about proven weaknesses, not heard of them, and so on.

22. **Bill**
August 6, 2014

Peter, actually, giving Fields medals to two would make sense since it would take the pressure off one of them being the first female Fields medalist. There are female candidates, like Mirzakhani or Serfaty, who definitely deserve it as much as anybody else.

Any news of who will get the Fields next week?

The NSA, NIST and the AMS

July 21, 2014
Categories: Uncategorized

Among the many disturbing aspects of the behavior of the NSA revealed by the Snowden documents, the most controversial one directly relevant to mathematicians was the story of the NSA's involvement in a flawed NIST cryptography standard (for more see here and here). The New York Times reported:

> Classified N.S.A. memos appear to confirm that the fatal weakness, discovered by two Microsoft cryptographers in 2007, was engineered by the agency. The N.S.A. wrote the standard and aggressively pushed it on the international group, privately calling the effort "a challenge in finesse."

The standard was based on the mathematics of elliptic curves, so this is a clearly identifiable case where mathematicians seem to have been involved in using their expertise to subvert the group tasked with producing high quality cryptography. A big question this raises has been what the NIST will do about this. In April they removed the dubious algorithm from their standards, and published the public comments (many of which were highly critical) on a draft statement about their development process.

At the same time a panel of experts was convened to examine what had gone wrong in this case, and this panel has (on a very short time-scale) just produced its report (associated news stories here, here and here). The rules of how such panels are set up evidently require that each panelist provide an individual report, rather than attempt to have a consensus version. The new NIST document gives these reports together with minutes of the meetings where the panelists were provided with information. It seems that the NSA provided no information at all as part of this process, and they remain unwilling to answer any questions about their actions.

Appendix E contains the individual reports. These include, from Edward Felten:

> The bottom line is that NIST failed to exercise independent judgment but instead deferred extensively to NSA with regard to DUAL_EC. After DUAL_EC was proposed, two major red-flags emerged. Either one should have caused NIST to remove DUAL_EC from the standard, but in both cases NIST deferred to NSA requests to keep DUAL_EC…
> at the time NIST had nobody on staff with expertise in elliptic curves.
> NSA's vastly superior expertise on elliptic curves led NIST to defer
> to NSA regarding DUAL_EC, while NIST people spent more of their limited time on other parts of the standard that were closer to their expertise.

From Bart Preneel:

> There is no doubt that the inclusion of Dual EC DRBG in SP 800-90A was a serious mistake…
> The explanations provided by NIST are plausible, but it seems that not all decisions in the standardization process of SP 800-90A are properly documented; moreover, we did not have access to the source documents. This means that it is impossible to decide whether this mistake involved in addition to clever manipulation of the standards processes by NSA also some form of pressure on the technical and/or management staff of NIST. It is also not clear whether there would be any traces of such pressure in documents. Without access to the documents, it is also diffcult to decide whether or not NIST has deliberately weakened Dual EC DRBG…
>
> However, it seems that NSA (with its dual role) seems to be prepared to weaken US government standards in order to facilitate its SIGINT role. This undermines the credibility of NIST and prevents NIST reaching its full potential in the area of cryptographic standards. In view of this, the interface between NSA and NIST and the role of the NSA should be made much more precise, requiring an update to the Memorandum of Understanding. At the very least, the terms "consult", "coordination" and "work closely" should be clarified. Ideally, NIST should no longer be required to coordinate with NSA. There should be a public record of each input or comment by NSA on standards or guidelines under development by NIST.

From Ronald Rivest (the "R" in "RSA"):

> Recent revelations and technical review support the hypothesis that, nonetheless, the NSA has been caught with "its hands in the cookie jar" with respect to the development of the Dual-EC-DRBG standard. It seems highly likely that this standard was designed by the NSA to explicitly leak users' key information to the NSA (and to no one else). The Dual-EC-DRBG standard apparently (and I would suggest, almost certainly) contains a "back-door" enabling the NSA to have surreptitious access. The back-door is somewhat clever in that the standard is not designed to be "weak" (enabling other foreign adversaries to perhaps exploit the weakness as well) but "custom" (only the creator (NSA) of the magical P,Q parameters in the standard will have such access).
>
> NIST (and the public) should know whether there are any other current NIST cryptographic standards that would not be acceptable as standards if everyone knew what the NSA knows about them. These standards should be identified and scheduled for early replacement. If NSA refuses to answer such an inquiry, then any standard developed with significant NSA input should be assumed to be "tainted," unless it possesses a verifiable proof of security acceptable to the larger cryptographic community. Such tainted standards should be scheduled for early replacement.

One way this goes beyond the now-withdrawn NIST standard is that the committee also looked at other NIST current standards now in wide use, which in at least one other case depend upon a specific choice of elliptic curves made by the NSA, with no explanation provided of how the choice was made. In particular, Rivest recommends changing the ECDSA standard in FIPS186 because of this problem.

For a detailed outline of the history of the Dual-EC-DRBG standard, see here. Note in particular that this states that in 2004 when the author asked where the Dual-EC-DRBG elliptic curves came from, the response he got was "NSA had told not to talk about it."

Also this week, the AMS Notices contains a piece by Richard George, a mathematician who worked at the NSA for 41 years before recently retiring. Presumably this was vetted by the NSA, and is a reasonably accurate version of the case they want to make to the public. Personally I'd describe the whole thing as outrageous, for a long list of reasons, but here I'll just focus on what it says about Dual-EC-DRBG, since it now seems likely that it is all we will ever get from the NSA about this. It says:

> I have never heard of any proven weakness in a cryptographic
> algorithm that's linked to NSA; just innuendo.

The reaction from a commenter here (publicly anonymous, but self-identified to me) was:

> As a member of a standards committee involved the removal of the mentioned algorithm from a standard, none of the members believe the "innuendo" theory, and all believe it was deliberately weakened.

Read carefully (and I think it was written very carefully…), note that George never directly denies that the NSA back-doored Dual-EC-DRBG, just claims there is no "proven weakness". In other words, since how they chose the elliptic curves is a classified secret, no one can prove anything about how this was done. All the public has is the Snowden documents which aren't "proof". This is highly reminiscent of the US government's continuing success at keeping legal challenges to NSA actions out of the courts, even when what is at issue are actions that everyone agrees happened, on the grounds that plaintiff can't "prove" that they happened, since they are classified. Snowden's release of documents may yet allow some of these cases to come to a court, just as they were the one thing capable of getting the NIST to acknowledge the Dual-EC-DRBG problem.

I hope that there will be more response to the NSA issue from the Math community than there has been so far. In particular, Rivest's call for the removal from NIST standards of material from the NSA which the NSA refuses to explain should be endorsed. The innuendo from George is that the NSA may be refusing to explain because they used superior technology to choose better, more secure elliptic curves. If this is the case I don't see why an official statement to that effect, from the NSA director, under oath, cannot be provided.

On the many other issues the George article raises, I hope that the AMS Notices will see some appropriate responses in the future. Comments here should be restricted to the NIST/NSA story, with those from anyone knowledgeable about this story most encouraged.

Update: The NIST has made available on its website the materials provided to the panel looking into this.

One remarkable thing about the panel's investigation is that the NSA evidently refused to participate, in particular refusing to make anyone available to answer questions at the panel's main meeting on May 29 (see page 12 of the report). This appears to be in violation of the Memorandum of Understanding that governs the NIST/NSA relationship, which explicitly states that "The NSA shall … Be responsive to NIST requests for assistance including, but not limited to, all matters related to cryptographic algorithms and cryptographic techniques, information security, and cybersecurity." All evidence I've seen is that the NSA sees itself as above any need to ever justify any of its actions. I can't see any possible argument as to why they did not have an obligation to participate in the work of this committee.

Update: A new development in this story is a letter from Congressman Grayson to NSA Director Clapper asking exactly the right questions about what happened at the NIST. Will be interesting to see if a member of Congress can get anything out of the NSA beyond the usual stone-walling.

Comments

1. **QM**
   July 21, 2014

   > "The innuendo from George is that the NSA may be refusing to explain because they used superior technology to choose better, more secure elliptic curves. If this is the case I don't see why an official statement to that effect, from the NSA director, under oath, cannot be provided."
   >
   > Is it in the NSA's interest to leave this an open question? If they chose a better curve, and say so, do their targets gain confidence, and are encouraged to use it more? If they say it's back-doored, do their targets abandon it? Uncertainty surely works in their favor here, as usual.

2. **Peter Woit**
   July 21, 2014

   QM,
   In this case, no one with any interest in the security of their communications is intentionally using Dual-EC-DRBG, the potentially backdoored standard, anymore.

   I think you're right that they want uncertainty, about this and about everything else they may or may not be doing. Life is much easier if you never have to justify anything you do.

3. **jeremy78**
   July 21, 2014

   How do these memo confirm that the NSA did anything? I keep seeing the phrase "appear to confirm" in all of these articles. Notice the word "appear" as a qualifier. Why don't they reveal what it is exactly in these memos that confirms all of this? Because this vagueness is the exact same thing the NSA is doing, but you seem alright with it because it confirms your previously held worldview. Why aren't you demanding more clarification from them?

4. **Peter Woit**
   July 21, 2014

   jeremy78,
   You and Richard George are right that nothing is "proved": the NY Times reporters only claimed that memos "appear to confirm" that the NSA introduced a back-door. The quote the NY Times gives "Eventually, NSA became the sole editor" of the standard is pretty much confirmed by the NIST description of what happened back then, but proves nothing about a back-door.

   The importance of the Snowden memos is not that they revealed exactly what the NSA did, but that they caused people to go back and look carefully at how the standard was developed. Like George, you're completely ignoring the facts that are the main evidence for a problem. I'm not making vague claims but linking to the new NIST report and quoting it. The bottom line is that the experts who have looked into this mostly think there is an NSA back-door.

   Is this proven? No, and it never will be as long as the NSA keeps classified the method used to produce the elliptic curves. I really only see three possibilities:
   1. The method was something innocuous, some random choice.
   2. The method used something classified to get something more secure than random, so they need to protect this.
   3. The method was designed to weaken the standard so that they could attack it.
   If what happened is 3., it makes sense the NSA would behave exactly as it has. If it was 1. or 2., there is no reason they could not simply make a public statement to that effect (giving the details in case 1, keeping those secret in case 2.).

5. **jeremy78**
   July 21, 2014

   You say that you're not using the Snowden memos as evidence, but that is clearly false. Many of those experts refer to "revelations" which show a clear bias going in.

   Maybe it's just me, but I take an evidence based view of the world. Regardless of what experts think, I look at the evidence. Right now there is no direct evidence, which you agree with.

   I thought the evidence based approach was the purpose of this blog. If we go with your current view, then perhaps those string theorists are right. They have no evidence, but they're experts so their opinions must be right in spite of the lack of the evidence. I don't know. Perhaps, you think in complex social situations, we should default to the experts till we have direct evidence, but I think that is a mistake.

   Also, let's be honest. Even if the NSA did exactly what you said they should do, I'd doubt you believe them or it would change anything. It's hard to prove a negative.

6. **jeremy78**
   July 21, 2014

Sorry for the double post, but I just wanted to point out the similarities of this situation to string theory and the multiverse hype.
1. Untestable hypothesis-"Is this proven? No, and it never will be as long as the NSA keeps classified the method used to produce the elliptic curves."
2. Trusting experts without question-"The bottom line is that the experts who have looked into this mostly think there is an NSA back-door."
3. No direct evidence -"proves nothing about a back-door"

7. **Matt**
July 21, 2014

I think this is far less cut and dry than mathematicians and the media are making it out to be. The NSA is a gigantic organization, and we give it a lot of credit to think these conspiracy theories are so nicely carried out. I'm not saying it is impossible.

I went to a talk given by one of the 2 Microsoft people that discovered the flaw. He is wholly unconvinced that it was intentionally done by the NSA, which I found pretty convincing. No one really wants to hear that side though.

8. **Peter Woit**
July 21, 2014

jeremy78
I've now written several long blog postings about this, with many links to detailed documentation and the evidence I'm aware of. It seems to me to provide a rather strong case that the NSA was up to something in this standards process other than providing the best possible encryption. This evidence is not incontrovertible. There's doubtless a lot more to the story which is known only to those at the NSA. If you want to take the attitude that only incontrovertible, direct evidence will convince you that there's a problem at the NSA, that's your choice. Arguments about the multiverse are almost all a complete waste of time, I don't think they provide insight into this topic.

If the NSA provided a plausible explanation of the source of the elliptic curves, that definitely could change my mind. I'm not someone who believes that NSA officials regularly lie to the public. On the whole the most damaging accusations from Snowden have not been denied.

Matt,
I don't think this is a story about a "conspiracy", it's a story about an organization with a professed agenda (getting access to encrypted internet communications) pursuing that agenda. If you read the NIST report I linked to and look at its authors, I don't think you can say this is a case where "no one wants to hear the NSA's side". The NSA was specifically asked to meet with the committee for that purpose and refused to do so (see page 12).

9. **Peter Woit**
July 21, 2014

All,
Enough trolling and arguing with trolls, I've just deleted a bunch of it. If you've got something knowledgeable to say I'd love to hear it, if you want to have a dumb argument, please go elsewhere.

10. **Pawl**
July 22, 2014

I would call attention to Preneel's mention of possible pressure involved in the decision-making process, in conjunction with a pattern in the leaked documents, saying that the NSA should "leverage" decisions, access to information, and so on. What sort of leverage, exactly, has been applied? To whom?

11. **Tom Leinster**
July 22, 2014

It seems to me that Richard George's statement is demonstrably false, *independently* of political opinion or evidence from the Snowden papers. Here's what he wrote again:

> I have never heard of any proven weakness in a cryptographic
> algorithm that's linked to NSA; just innuendo.

This says nothing about intent. It's the flat-out assertion that no cryptographic algorithm linked with the NSA has a proven weakness. (Or at least, no weakness that George has heard of — but we can safely assume that he has heard of this one.)

In his February *Notices* article, Tom Hales notes: "It is a matter of public fact that the NSA was tightly involved in the writing of the standard" (NIST SP800-90A). So, George is asserting in particular that *this* standard has no proven weakness. But Ferguson and Shumow, on whose work Hales's article is based, conclude that

> The prediction resistance of this [pseudorandom number generator] is dependent on solving one instance of the elliptic curve discrete log problem.

And as I understand it, that's a serious weakness *even if you don't believe the NSA did anything sneaky*. In that case, George's suggestion that no cryptographic algorithm linked to the NSA has a proven weakness is simply false — as a scientific fact, regardless of politics.

So I can't see how to escape the conclusion that the NSA was, at the very least, incompetent. It pushed through a cryptographic standard with a serious vulnerability. Even if you trust the NSA politically and ignore its stated intention to "insert vulnerabilities into commercial cryptosystems", this episode provides a reason not to trust it with designing the world's cryptographic standards.

12. **Peter Woit**
July 22, 2014

Tom,
I think George would argue that's not a "proven weakness". My reading of Ferguson/Shumow is that they are pointing out that whoever chose P and Q could do it in such a way that they know e, and thus a backdoor. The NSA chose P and Q and refuses to discuss how they chose them, so NSA defenders can claim that maybe they chose them randomly, or in a way that used secret sauce to make things even more secure. My understanding is that one unusual thing about this is that, unless you find e yourself (which is supposedly impossible), you can't prove that there is a backdoor. From the outside world's point of view, "this could be backdoored in a way that only the NSA could know" is a weakness, but from the NSA's point of view, it's not.

What George is basically saying is "you can't prove we did anything", not "we didn't do anything", and I think the difference is intentional.

13. **Tom Leinster**
July 22, 2014

If George doesn't call Ferguson and Shumow's discovery a "proven weakness" in the protocol then he's using words in a different way from ordinary human beings. This is of course a stock-in-trade of intelligence agencies issuing carefully-worded denials, but none the better for it. Any ordinary person would say that if a cryptographic system is untrusted (as this one now most certainly is), that's a weakness: who wants a system they can't trust?

In the long NIST report that you link to, Edward Felten (professor of computer science at Princeton, specializing in computer security) defines a "pure trapdoor" as one in which "NSA is the only party who can possibly exploit it". He continues:

> [A]ll of the suspected NSA trapdoors in NIST standards are impure trapdoors. In every case discussed below, if the suspected trapdoor does exist, its existence reduces the security of users against attack by other adversaries, including organized crime groups or foreign intelligence services.

This includes the caveat "if the suspected trapdoor does exist". But whether or not it does, the *possibility that it might* is a weakness in itself.

14. **Peter Woit**
July 22, 2014

Tom,
Still, the NSA's point of view is that for all you know they chose the numbers randomly and there is no trapdoor, and no weakness. So, you have no proof (or any hope of getting one, unless a mathematician version of Snowden appears…) that there is a trapdoor and thus a weakness in the standard. I think it highly likely that George and whoever vetted his piece at the NSA are well aware of the Ferguson/Shumow argument, and they chose their language carefully so that they could claim what they said was true. Yes, it's highly misleading, but we know that misleading people about what they do they see as part of their mission.

My initial reading of this was "this guy George must be some senile incompetent claiming to be unaware of the Dual-EC-DRBG story", I changed my mind after re-reading carefully.

15. **Tom Leinster**
July 22, 2014

I agree, it's carefully worded, but I still think it's plain wrong. If he'd said that there's no "proven *backdoor*", then I wouldn't be able to contradict him. But he said that there's no "proven *weakness*", and a backdoor isn't the only kind of weakness a cryptographic system can have.

John Kelsey of NIST wrote this about choosing parameters for Dual EC:

> * It is possible to choose (P, Q) so that you know a backdoor […]
>
> * It is also possible to choose (P, Q) so that you can prove you don't know a backdoor.

Let's call the system **unbackdoorable** if (P, Q) has been chosen in the second way, and **backdoorable** otherwise. A backdoorable system may or may not actually be backdoored. Still, for a system to be backdoorable is a serious weakness, because it makes it untrustworthy, even if you don't know that a backdoor actually exists.

As I understand it — and I hope someone will correct me if I'm wrong — it's a matter of black-and-white fact that this particular system is backdoorable. That, then, is the proven weakness. And that's why this system has been abandoned in a hurry: because we know it's backdoorable, even though we don't know whether it's backdoored.

Of course, this whole conversation that I started is in some sense absurd, since it deliberately makes no assumptions about the intentions of the NSA, despite all the documentary evidence in front of us.

16. **Peter Woit**
July 22, 2014

Tom,
My reading of the same document you're linking to is that nothing is known about how the NSA chose (P,Q). All it says is that on 10/27/04 he was told "could be generated randomly, but that NSA had told not to talk about it" and in Oct. 05 NSA said they "generated (P,Q) in a secure, classified way" (a huge mystery here is why NIST then decided to include in the standard a way people could generate their own (P,Q), but not mention that if you didn't do that, you had to trust the NSA's (P,Q) not to be backdoored. The current answer from NIST is basically "we were incompetent and made the mistake of trusting the NSA").

So, as long as the NSA stonewalls about how they chose (P,Q), George can claim that it can't be proven that they did it in a backdoorable way. Maybe they did it in an unbackdoorable way. The story about DES that George tells refers to the fact that the NSA in that case knew how to choose parameters in a better, more secure way than what was publicly known, and suspicions they were putting in a backdoor turned out to be wrong: they were actually making things more secure (of course at the same time they were insisting on a key length short enough for them to break by brute force…). He's telling that story to raise the possibility that this is what happened here, that NSA chose (P,Q) by some highly secure method they can't talk about.

My take is that if they had done that they would have consistently just said so, which would not have revealed anything classified. In particular they would have shown up at the NIST panel meeting and defended what they did back in 04/05, if only by reading a vetted statement saying "we chose (P,Q) in a secure, classified manner that we cannot reveal to you, we do not have a back-door". That they are not doing this, instead letting their relationship with NIST be poisoned to the point of collapse seems to me to be the dog that didn't bark here.

17. **ScentOfViolets**
July 23, 2014

Isn't the proper course of action pretty much a no-brainer? If someone wants me to invest funds in their business venture, it's on them to show me that there's a reasonable expectation that it will succeed; not on me to show that it won't. Similarly, given the costs of bad crypto, why should I use it if it's not known to be secure? IOW, default burden of proof requirements should be on the systems defenders to prove that the crypto is trustworthy, not on other people to prove that it's untrustworthy. The statements released by the NSA seem deliberately crafted to get people to buy into the reversal of those requirements in the hope that this will forestall any significant revision of the current standard. If this isn't evidence of bad faith — particularly since the costs of a backdoor to the community at large is far larger than the benefits which accrue only to the NSA — I don't know what is.

18. **Rob Fawcett**
July 23, 2014

Is another perspective to ask not even whether a back-door was implemented, but how credible it is that the NSA did not internally have insight into the possibility of such a back-door? Appreciation of the possibility would necessitate accounting for the integrity of the (P,Q) generation. After all, encryption is terminally compromised once the credible practicable possibility of an existing back-door is established, irrespective of proof of successful decryption. The NSA need not have flagged any insight, they need only have accounted for the (P,Q) generation to make the standard robust.
I for one can but snort at the notion that they knew of the potential back-door, nobly abjured use of it but chose to obscure the (P,Q) derivation anyway, thereby ultimately dooming the standard from the start.

19. **Mike Sharples**
July 25, 2014

Why are people so hung up on what is and isn't proven? This is not an exercise in mathematical certainty it is an evaluation of risk. There is a risk that the standard is compromised. Obfuscation by the NSA does nothing to remove that risk (quite the contrary). Therefore the standard should be considered unsafe.

20. **Chris W.**
July 26, 2014

See the latest post from Scott Aaronson:

> The issue reached a comical extreme last October, when Adi Shamir, the "S" in RSA, Turing Award winner, and foreign member of the US National Academy of Sciences, was prevented from entering the US to speak at a "History of Cryptology" conference sponsored by the National Security Agency. According to Shamir's open letter detailing the incident, not even his friends at the NSA, or the president of the NAS, were able to grease the bureaucracy at the State Department for him.

With the NIST episode as context, what could this mean?

21. **Peter Woit**
July 27, 2014

Mike Sharples,
The discussion about what can be "proven" was purely about the question of whether the AMS notices piece defending the NSA was a bald-faced lie or not. Of course there is plenty of evidence with respect to the NSA's activities that does not rise to the level of "proof", and people should act accordingly.

Chris W.,
I think this is just one more example of the out-of-control US security establishment, of which you can easily find a hundred more. It should also remind people that when trying to figure out what has happened in stories like the NIST/NSA one, you can't use the argument "the NSA can't possibly have done X because that would be irrational, stupid, and damage US interests".

22. **Nick P**
July 29, 2014

I agree with ScentofViolets. The burden of proof, even by NSA standards (eg Common Criteria), is on the person delivering a piece of tech to show that it's trustworthy. There's many ways to do this. There's also the lifecycle requirement that, once problems are found, you explain and/or fix them. NSA is a world-class crypto organization that's tied to numerous problematic submissions in crypto standards, even amateurish mistakes their own evaluations look for. Whether incompetence or malice, they can't be trusted to deliver good crypto.

Another angle is "reasonable suspicion" vs "proof." The BULLRUN slides clearly say they're trying to manipulate standards and commercial products. That their own highly protected document says this is proof that they do it. At this point, a submission of theirs automatically has a reasonable suspicion that it might be backdoored. That's good enough for rejecting it. If we find a potential backdoor and they are who submitted it, then there's reasonable suspicion that they put it there due to the other proof (BULLRUN). If they refuse to even talk about it, even more reasonable suspicion to think they might be guilty. I maintain that the BULLRUN slides alone are enough proof that their submissions should be considered backdoored unless proven otherwise as they have capability, intent, and history. And untrusted until proven otherwise is the default in INFOSEC on top of that.

(Note: That said, this particular backdoor didn't bother me as much as most people. The problem with NSA is their *mandated* mission of collecting everything, along with difficulties they encounter. Subversion is their solution with many making us weaker. Yet, contrary to the claim by Felten, this particular subversion was a win-win as they tried to provide us protection while creating a way for only them to get in. If they're going to sneak in backdoors, I'd rather it be something like this than a buffer overflow or weak backdoor like that found in a recent FPGA.)

Still, there's enough people doubting their negative impact on security that I decided to look at the big picture to identify evidence they weaken it. The main problem I noted was "backdoor." The truth is that any flaw that lets them circumvent a security policy is a backdoor in practice. All they have to do is encourage flaws, not tell people about existing flaws, or introduce flaws. They can do this at many levels. So, I wrote an essay on Schneier's blog (main spot I post) showing the many ways NSA's actions provably weaken our security, both intentionally and incidentally:
https://www.schneier.com/blog/archives/2014/03/friday_squid_bl_420.html#c5226750

23. **Nick P**
July 29, 2014

I forgot to add a link to our smoking gun in all these discussions with key points conveniently highlighted:

http://www.nytimes.com/interactive/2013/09/05/us/documents-reveal-nsa-campaign-against-encryption.html?ref=us&_r=0

Quantum Connection Could Revitalize Superstrings

August 4, 2014
Categories: This Week's Hype

Finally back from vacation, postings may appear somewhat more regularly…

Science journalist Tom Siegfried has been one of the most vociferous proponents of string theory for many, many years (see here), but even his faith seems like it might be failing as the decades roll on. His latest on the topic starts out:

> Sometimes it's nice to reflect nostalgically on the last couple of decades of the 20th century. You know, the era of Madonna and Duran Duran, Cheers and The X-Files, McGwire and Sosa, the Macarena, and superstring theory.

The article does try and mount an argument that string theory may not be moribund, with the hope for the future coming from a new paper by Bars and Rychkov entitled Is String Interaction the Origin of Quantum Mechanics?. The idea here seems to be that if you assume you somehow have a fully consistent string field theory, not based on quantum mechanics, then the occurrence in this theory of non-commutative phenomena would "explain" quantum mechanics. To me, this seems to deserve some sort of award for the most desperate attempt yet to justify string theory, but Siegfried is a fan, explaining:

> For decades, explaining why nature observes the mysterious rules of quantum physics has perplexed physicists everywhere. Nobody could explain why those rules worked. The connection between string physics and the quantum math may now lead the way to an answer.

I'll write more soon about those "mysterious rules of quantum physics", but I just don't see at all how string field theory (which supposedly is based on quantum mechanics…) makes anything about quantum mechanics less mysterious.

Siegfried of course is not just a fan of string theory, but also of the multiverse, so he ends with:

> On top of all that, the string-quantum connection suggests an intriguing insight into the nature of reality. Quantum physics is notorious for implying the existence of multiple realities, as articulated in the "many worlds" interpretation of quantum mechanics. Superstring theory has also annoyed many physicists by forecasting the existence of a huge "landscape" of different vacuum states, essentially a multiverse comprising multiple universes with a wide range of physical properties (many not suitable for life, but at least one that is). If string interactions really are responsible for the rules of quantum physics, maybe there's some connection between the multiple quantum realities and the superstring landscape. For fans of the late 20th century, it seems like an idea worth exploring.

One thing remarkable about this is that he has another piece that recently appeared, an interview with Katherine Freese, where he tries to convince her about the multiverse, but doesn't get anywhere:

> **Theory predicts vastly more vacuum energy than the amount actually observed. Wouldn't this huge disparity be explained if there are multiple universes, a multiverse, and each has a different density of vacuum energy? Then the reason we have a low amount in ours is because that's the only way we could exist in it.**
>
> I don't like that idea. A lot of people like it because of string theory. Originally people thought that string theory would give a unique solution to the vacuum-energy equations. But it turns out that in string theory there are maybe 10-to-the-500th different vacuum states. So the idea is that they're all out there, but we have to live in one with a value of the cosmological constant close to the one we have. But I don't like anthropic arguments. They rely on the fact that human life can only come to exist under certain conditions, so that of the many universes out there it's not surprising we live in the one that supports our type of life. That's not a good enough explanation for me. I feel there are physics problems that we have to answer, and we can answer them in this universe, in this piece of the universe we live in. I think it's our job to try to do that, and it's not good enough for me to give up on it and say, well, it has to have this value because otherwise we couldn't exist. I think we can do better than that. I know, I'm old-fashioned.
>
> **Isn't part of the question whether there is a multiverse or not? If you had really strong evidence that there is a multiverse, then the anthropic explanation becomes better motivated. Inflation, the rapid burst of expansion right after the Big Bang, supposedly can produce a multiverse by way of "eternal inflation."**
>
> I do believe in inflation, so can inflation give you a multiverse or not? Because if it can, then I'm forced to consider this possibility. I recently wrote a paper with Will Kinney on this. We concluded that what we observe in the cosmic microwave background radiation is not giving rise to eternal inflation. So how do you know that ever happened?
>
> **Are the recent results on the cosmic microwave background from the BICEP2 experiment relevant to this issue?**
>
> If you take the BICEP data literally, which I'm not saying you should, you never have eternal inflation. So you don't have to have eternal inflation, if you ask me. I was very happy about that.

Comments

1. **comment**
   August 4, 2014

   It is unfortunate that Sigfried honed in on Bars' paper and that Peter amplifies it for the purpose of painting string theorists as desperate and intellectually dishonest. No independent theorist would vouch for Bars' claim to have derive quantum mechanics based on what has been demonstrated.

   The matrix-like interaction of open strings is closely related to non-abelian gauge symmetry. So if open string field theory proves quantum mechanics, I think you could claim that Yang-Mills proves it as well. But, unfortunately, quantum mechanics is more than a noncommutative algebra.

   I recently attended a very interesting conference on string field theory in Trieste. Some new results include:

   1) A nonperturbative proof of background independence in open string theory. This result addresses a major point of criticism for string theory opponents.

   2) New constructions of spacetime actions which may provide a systematic underpinning for superstring perturbation theory. This is another "weak link" which is a major target of critics.

   3) Powerful numerical techniques for mapping the space of two-dimensional boundary conformal field theories and conformal defects, with potentially useful applications to condensed matter physics.

It is aggravating that this real progress is ignored on this blog and elsewhere. Incidentally, Bars also gave a talk at the conference, but it is fair to say that his recent paper was not the focal point of excitement.

2. **Peter Woit**
   August 4, 2014

   comment,
   First of all, I'm not painting anyone here as intellectually dishonest. The "string theory implies quantum mechanics" claim here isn't being made underhandedly. It's straightforward, but it's just bizarre and nonsensical.
   As for "desperate" though, yes, I think this kind of thing reeks of desperation. I don't think you can read Siegfried's article as anything other than a desperate grasping at straws to avoid acknowledging the failures of the theoretical ideas he has been spending the last couple decades writing promotional books and articles about.

   I think your basic problem is not with me, but with the part of the string theory community which puts out nonsense like this and the journalists who are taken in by it.

3. **comment**
   August 4, 2014

   Itzak Bars is not "part of the string theory community." He is an individual, and his views represent his alone.

   Of course I have a problem with you posting about this, since it further amplifies the significance of an obscure idea which is not indicative of trends even in a very specialized subfield of string theory. But I understand that your interest is generally painting string theory in a negative light, and further amplifying noise gives people the impression that the subject is vacuous.

   My purpose was simply to provide a different point of view and remind people that progress is being made on fundamental questions, even within this minor subfield.

   I noticed that you took no interest in the main results presented at the recent conference. If you thought about and took a critical view of this work, it might be a more interesting starting point for debate on merits and progress in the field.

4. **David Roberts**
   August 4, 2014

   @comment

   links to these talks/abstracts/papers/results?

5. **R-bot**
   August 4, 2014

   @comment,
   Is Bars not part of the string theory community? What are you saying? If he is not, why he had been invited for that conference as a speaker? His personnel website even introduces himself as "My current interests include String Field Theory, and Two-Time Physics and Cosmology." Even he has just a minor of minor-alone view on a certain small subject (like some others on that field), he himself believes he is one of string community, and even he was invited for a string conference.

   Anyway I partly agree with you on your point (no high light for recent developments on the field). But this posting is criticizig its media-hype part of it, so you guys point at different directions. Also, as you may have noticed from Strominger's vision talk at Strings 2014, nobody even knows for what string community should head in the future and what exactly the theory is. So the main criticism point on that field from this site is still relevant and no critical recent developments to defense.

   @David Roberts,
   Maybe this one: http://www.sissa.it/tpp/activity/conferences/SFT2014

6. **Cathy Dupont**
   August 5, 2014

   @comment

   Background independence is not an important argument against or for string theory. Established physics is not background independent at all. The requirement has been "invented" by loop quantum gravity people to discredit string theory, but that is unfair: background independence does not help in making a theory that fits with observations or one that makes predictions. Background independence is a red herring.

   The test of a theory is that it agrees with observations. And also your other two points are red herrings in this respect …

7. **comment**
   August 5, 2014

   @ R-bot

   Bars is certainly a member of the community, but he alone does not represent "part" in the sense of a non-infinitessimal fraction. This is the sense of "part" that I was referring to.

   I don't want to denigrate Bars' and Rychkov's work. I am glad they are excited about something. Wild proposals can be fodder for interesting conversation and new ideas… but only if you have the right context. There is certainly a correct analogy between string interactions and some equations in quantum mechanics, but I don't think this analogy means what it sounds like it means. But perhaps Bars and Rychkov can exploit it for interesting purposes.

   See the following recent papers:
   http://arxiv.org/abs/1401.7980 about using string field theory to uncover the space of boundary conformal field theories and defects.
   http://arxiv.org/abs/1406.3021 for a proof of background independence.
   http://arxiv.org/abs/1403.0940 and http://arxiv.org/abs/1312.2948 for a new approach to the field theory of superstrings.
   I think these results are in fact relevant to some criticisms of string theory, though I doubt they would impress Peter much. Perhaps Strominger is not certain where the field should be heading, but he does not speak for me personally.

   @ Cathy Dupont

   One main focus of the conference was string field theory. This is a formal subject whose main motivation is trying to find the "right" definition of string theory. It has little to say about connecting Planck scale physics to measurements. If this is what you care about, then there is not much interesting to report from the conference.

But I think recent work charting the space of BCFTs could easily have quantitative applications to measurements of real world physical systems. But this is really an application of certain technology developed in the context of string theory to another field. It has no implications for the viability of strings as a description of Planck scale physics.

8. **Curious Mayhem**
August 5, 2014

Plus, "eternal inflation" à la Linde is historically prior to and independent of string theory and the "landscape." Linde's eternally inflating background metric is a connected spacetime, not a collection of separate realities. The two ideas have nothing to do with each other. That aspect of the whole bandwagon (not just Siegfried) *is* intellectually dishonest.

As Katy points out in the interview, it's very difficult to get inflation to work in string theory. And the current evidence is unfavorable to all but a small subset of "string-inspired" cosmologies and inconsistent with "eternal inflation." In fact, the current data suggest something pretty old-fashioned, a quantum universe tunneling to a false vacuum, setting up the initial conditions for inflation. A simple version of this is presented in Kolb & Turner's textbook.

As always, more and better data will winnow down the field of contenders. The exciting thing is, we'll probably see this moment soon.

9. **Lee Smolin**
August 5, 2014

Dear Peter,

For what its worth, can I mention that I wrote a paper in 2002 showing that quantum mechanics can be derived from a matrix formulation of string/M theory: arXiv:hep-th/0201031?

Dear Cathy Dupont,

Background independence is for sure a principle of "established physics", it is the general principle behind both the diffeomorphism invariance of general relativity and the local gauge invariance of Yang-Mills theory. It can be tied directly to the experimental success of GR, QED and the standard model, for example the experiments which verify these theories are pure spin 2 and pure spin 1, respectively.

Furthermore, it is funny that you think that background independence was ""invented" by loop quantum gravity people to discredit string theory"; the idea was rather invented by Einstein, Weyl and others early in the 20th century as part of the invention of GR and local gauge theory. Look up, for example, the history of the "hole argument" in Einstein's work between 1911 and 1916, followed by Weyl's invention of local gauge invariance in 1919.

btw the two comments are related because the 2002 paper deriving QM from string/M theory was part of a series of papers proposing a cubic matrix model as an approach to a background independent formulation of string theory.

Best,

Lee Smolin

10. **Arash**
August 6, 2014

Lee,

It's kind of old story by now, and I'm aware you've heard this question several times before, but wouldn't you call AdS/CFT a background independent formulation of string theory in asymptotically AdS spaces? (Asymptotic boundary conditions are allowed in ("background independent") classical GR on non-compact manifolds, right?)

@comment,

From what I've gathered, what you call `noise amplification' is in a sense one of the main purposes of this blog; to amplify what insiders (and enthusiasts) of string theory consider insignificant, while they should probably take them seriously. I don't think many of the readers of this blog would find any interest in reports on recent technical progress.

11. **Peter Woit**
August 6, 2014

Arash,
Do you really consider trying to have the same old empty argument with Lee about "background independence" and AdS/CFT to be anything other than your own form of "noise amplification"?

I suppose you're right though that one of the purposes of this blog is to do something string theory enthusiasts consider insignificant, correct the outrageous hype in the media about string theory.

By the way, I think you'd be very surprised to know who many of the readers of this blog are and what their interests are.

12. **Arash**
August 6, 2014

Point taken, Peter!

13. **David Roberts**
August 7, 2014

@R-bot – thanks, but there's a lot of abstracts linked to purely by the name of the speaker. I haven't the inclination to go through all of them and try to find the talks that comment described.

14. **Chris W.**
August 7, 2014

As an amusing sidelight on the above, Bars and Rychkov very recently posted another paper entitled "Background Independent String Field Theory" (arXiv:1407.4699). The abstract ends with this sentence:

A byproduct of our approach is an astonishing suggestion of the formalism: the roots of ordinary quantum mechanics may originate in the rules of non-commutative interactions in string theory.

15. **lun**
August 7, 2014

Comment
I do not think that what you call "background independence" is the same as what General Relativity people call background independence.

Correct me if Im wrong, but Maccaferri et al give a recipe to construct a solution in another background given a solution in a certain background. "Background independence" means that these two solutions are in some sense locally indistinguishable for a given observer. Maccaferri et all did not prove this.
Or am I wrong?

16. **Bill Radley**
August 7, 2014

A comment for Comment:

The point is that Siegfried did promote the Bars paper, and that makes it news for a blog about unjustified string+ theory hype. Of course there are better ideas out there, from all sides of the argument, but the point, as ever here, is that they are losing out – in terms of public and media attention, funding, and serious scientific attention – to an increasingly questionable consensus. Some development from string theory may of course still turn out to have a deep contribution to make to our understanding of the universe. But what would be useful for all of us would be for its proponents to refrain from describing tentative, partial, speculative,ultraspecific or unproven abstract results as key insights into the nature of the universe.

17. **Peter Woit**
August 7, 2014

Bill Radley,

There are always going to be people making dubious claims for their speculative ideas. Their sensible colleagues will just ignore them. The question is what to do when the press picks these things up. For random speculation that no one is paying attention to, probably best to just ignore such press stories unless they get widely spread.

Dubious claims of the specific "I've found the answer to the problems of string theory!" variety are a common subclass though, and the fact that they get press attention has a lot to do with the long history of resistance by string theorists to any public acknowledgement of failure. For decades now there has been little to no willingness of string theorists to complain to those hyping the theory. They do seem to be willing to complain to me though…

18. **srp**
August 8, 2014

"The good ideas, the ones that eventually find their way into the textbooks, are out there, all right–but they are out on the shelf surrounded by all kinds of junk, which is packaged by its authors as attractively as possible and, of course, is never clearly labeled 'junk.' It's not that people are out to fool you. They may be just confused or mistaken. Or, more commonly, they are doing work that is correct, in the sense of not containing errors, but not useful for progress. The work is too speculative or too safe; it loses contact with reality or remains narrowly earthbound."

One of my favorite quotations, from Frank Wilczek and Betsy Devine's Longing For the Harmonies. It applies in many fields besides physics.

19. **Titus Weisstein**
August 10, 2014

The origin of quantum mechanics was stated by the old masters, like Werner Heisenberg and Niels Bohr: quantum mechanics follows from the existence of hbar. That is why Heisenberg used to wear a golden tie needle with hbar on it in the second half of his life. Just hbar.

Stating that quantum mechanics follows from string theory would mean that string theory can explain why hbar exists.

But string theory does nothing of the sort. Nor does loop quantum gravity. Therefore, proponents of both camps are just making wind.

Putting yourself above Heisenberg and Bohr in this issue puts you in a bad light…

20. **Lee Smolin**
August 10, 2014

Dear Titus,

No one is putting themselves above Bohr and Heisenberg, far from it, but that doesn't mean we can't make efforts to understand questions they left unresolved.

I agree that LQG does not explain either quantum theory or the value of hbar, it is entirely an application of conventional quantization to GR. But in the work I mention I give a derivation of QM from a particular limit of a matrix model for string theory, to be precise the bosonic part of the BFSS model. There, in hep-th/0201031 I do give an explicit formula for hbar in terms of the parameters of the matrix model, it is eq 109.

Thanks,

Lee

21. **Georg Zwiebel**
August 11, 2014

Lee,

formula 109 relates hbar to several other parameters that are unknown, unmeasured and whose existence is unconfirmed. And even time appears in it.

Speculations and fantasies are ok. But you are not really convinced that this is an explanation of hbar, or are you?

22. **Lee Smolin**
August 11, 2014

Dear Georg,

This is a model, not a theory. It serves as an existence proof of several ideas I think are worth exploring further. Among them 1) non-local hidden variable theories exist which reproduce Schrodinger quantum mechanics for an N body system, 2) there may be a simultaneous solution of the measurement problem of quantum foundations, unification and quantum gravity, and 3) hbar may indeed be a function of physical coupling constants and the number of degrees of freedom of that unified theory.

btw t is not time, it is temperature, scaled by a power of the size of the matrices and some coupling constants. See eq 47.

Thanks,

Lee

Fall QM Course

August 11, 2014
Categories: Quantum Mechanics

This year I'll be teaching a new version of the same course on quantum mechanics aimed at mathematicians that I taught during the 2012-3 academic year (there's a web-page here). During the last course I started writing up notes, and have spent a lot of the last academic year working on these, the current version will always be here. At this point I have a few of the last chapters to finish writing, as well as a long list of improvements to be made in the earlier ones. I'll be teaching the course based on these notes, and hope to improve them as I go along, partly based on seeing what topics students have trouble with, and what they would like to hear more about.

I've learned a lot while doing this, and it now seems like a good idea to write something on the blog discussing topics that don't seem to me to be dealt with well in the standard textbook treatments. Johan de Jong's Stacks Project has recently added a sloganerator (written by Pieter Belmans and Johan Commelin), which has inspired me to try to organize things as slogans. Slogan 0 to appear soon….

Comments

1. **QGravity**
   August 11, 2014

   It would be great if all of the problem sets be posted on the web page of the course so one can follow things better.

   Thank You!

2. **Per**
   August 11, 2014

   Being a physicist myself I always enjoy a clear and not to technical math description of fields in physics. I've read the first 15 pages or so and first impression is very good. Thanks for posting.

   Cheers, Per

3. **Peter Woit**
   August 11, 2014

   Per,
   Thanks. Feedback about how to make this document more readable by physicists is definitely welcome.

   QGravity,
   The problem sets from the previous course are at
   http://www.math.columbia.edu/~woit/QM/oldprobsets.pdf
   As I get problem sets for the new course written, they'll appear on the course page. Solutions won't ever appear there, since I want to be able to reuse the problems…

4. **ktahn**
   August 11, 2014

   Exciting stuff! Thanks for making it available. Would be looking out for notes and exercises.

5. **Daniel McLaury**
   August 12, 2014

   Prof. Woit,

   As someone who doesn't know a lot about physics, I've started reading the linked notes, but I've hit a snag a few pages in. In particular, at the bottom of page 4 I read

   "Given an observable O and states psi_1 and psi_2 that are eigenvectors of O with eigenvalues lambda_1 and lambda_2, the state

   c_1 psi_1 + c_2 psi_2

   may not have a well-defined value for the observable O. If one attempts to measure this observable, one will get either lambda_1 or lambda_2, with probabilities

   |c_1^2|/(|c_1^2| + |c_2^2|)

   and

   |c_2^2|/(|c_1^2| + |c_2^2|)"

   However, these numbers don't appear to be well-defined. For instance, if psi_1 is a lambda_1-eigenvector for O then 2 psi_1 is also a lambda_1-eigenvector for O, so we could regard the state

   2 psi_1 + psi_2

   as either

   2 (psi_1) + 1 (psi_2),

   giving us a 4/5 chance of observing lambda_1 and a 1/5 chance of observing lambda_2, or we could regard it as

   1 (2 psi_1) + 1 (psi_2),

   giving us a 50/50 chance of observing either lambda_1 or lambda_2. Are there perhaps some constraints on the psi_j here, say that they should be unit vectors with respect to the Hermitian form on H? (That interpretation seems to match up with something you wrote in the blog post above, assuming that this is the same thing as Born's rule.)

Or have I misinterpreted something?

And of course thanks for writing this up, making it publicly available, and taking the time to engage with your readers!

6. **woit**
   August 12, 2014

   Thanks Daniel,
   You're right, that's ambiguous. I was trying to be clever and write things in a normalization-independent way, but for what I wrote you need psi_1 and psi_2 to be normalized the same way, e.g. by having unit norm. I'll fix this right now.

7. **Charlie**
   August 13, 2014

   After scanning the first four chapters, I'm really excited about these notes. Many thanks for making them available!
   Could you record a version number and/or date last updated on the cover page?

8. **Peter Woit**
   August 13, 2014

   Charlie,
   There should be a date on the first page of the pdf.

What’s Hard to Understand is Classical Mechanics, Not Quantum Mechanics

August 11, 2014
Categories: Favorite Old Posts, Quantum Mechanics

For a zeroth slogan about quantum mechanics, I’ve chosen

> What’s hard to understand is classical mechanics, not quantum mechanics.

The slogan is labeled by zero because it’s preliminary to what I’ve been writing about here. It explains why I don’t intend to cover part of the standard story about quantum mechanics: it’s too hard, too poorly understood, and I’m not expert enough to do it justice.

While there’s a simple, beautiful and very deep mathematical structure for fundamental quantum mechanics, things get much more complicated when you try and use it to extract predictions for experiments involving macroscopic components. This is the subject of “measurement theory”, which gives probabilistic predictions about observables, with the basic statement the “Born rule”. This says that what one can observe are eigenvalues of certain operators, with probability of observation proportional to the norm-squared of the eigenvector. How this behavior of a macroscopic experimental apparatus described in classical terms emerges from the fundamental QM formalism is what is hard to understand, not the fundamental formalism itself. This is what the slogan is trying to point to.

When I first started studying quantum mechanics, I spent a lot of time reading about the “philosophy” of QM and about interpretational issues (e.g., what happens to Schrodinger’s famous cat?). After many years of this I finally lost interest, because these discussions never seemed to go anywhere, getting lost in a haze of complex attempts to relate the QM formalism to natural language and our intuitions about everyday physics. To this day, this is an active field, but one that to a large extent has been left by the way-side as a whole new area of physics has emerged that grapples with the real issues in a more concrete way.

The problem though is that I’m just knowledgeable enough about this area of physics to know that I’ve far too little expertise to do it justice. Instead of attempting this, let me just provide a random list of things to read that give some idea of what I’m trying to refer to.

- About 4000 articles a year are appearing on the arXiv at quant-ph.
- Maximilian Schlosshauer’s Decoherence and the Quantum-to-Classical Transition and The quantum-to-classical transition and decoherence.
- Wojciech Zurek’s Decoherence and the Transition from Quantum to Classical – Revisited, and Quantum Darwinism.
- David Lindley’s book Where Does the Weirdness Go?.
- Jess Riedel blogs about some of this here.

Other suggestions of where to learn more from those better informed than me are welcome.

I don’t think the point of view I take about this is at all unusual, maybe it’s even the mainstream view in physics. The state of a system is given by a vector in Hilbert space, evolving according to the Schrodinger equation. This remains true when you consider the system you are observing together with the experimental apparatus. But a typical macroscopic experimental apparatus is an absurdly complicated quantum system, making the analysis of what happens and how classical behavior emerges a very difficult problem. As our technology improves and we have better and better ways to create larger coherent quantum systems, thinking about such systems I suspect will lead to better insight into the old “interpretational” issues.

From what I can see of this though, the question of the fundamental mathematical formalism of QM decouples from these hard issues. I know others see things quite differently, but I personally just don’t see evidence that the problem of better understanding the fundamental formalism (how do you quantize the metric degrees of freedom? how do these unify with the degrees of freedom of the SM?) has anything to do with the difficult issues described above. So, for now I’m trying to understand the simple problem, and leave the hard one to others.

Update: There’s a relevant conference going on this week.

Update: I’ve been pointed to another article that addresses in detail the issues referred to here, the recent Physics Reports Understanding quantum measurement from the solution of dynamical models, by Allahverdyan, Balian and Nieuwenhuizen.

Comments

1. **Bernhard**
   August 11, 2014

   This is nice. Your slogan is more or less the same as my first supervisor’s when I was still in undergrad school. He was an expert in dynamic systems and just couldn’t accept people wanted to “understand quantum mechanics without understanding classical mechanics” – which according to him, was way much harder. The “measurement problem” was his favorite subject.

   And finally; “But a typical macroscopic experimental apparatus is an absurdly complicated quantum system, making the analysis of what happens and how classical behavior emerges a very difficult problem. ” Was the main reason I didn’t first want to get involved with experimental physics when I was young. How the heck people believed what were they measuring…. ? 🙂

2. **Peter Morgan**
   August 11, 2014

   “But a typical macroscopic experimental apparatus is an absurdly complicated quantum system, making the analysis of what happens and how classical behavior emerges a very difficult problem.” When we enter into experimental contexts in which QFT is necessary for accurate description of the statistics of recorded measurement events, the complexity becomes even more impossible. My related (admittedly idiosyncratic) worry is that for sufficiently detailed classical theories we would expect nonlinearity whenever we consider elaborate waveforms, whereas the Wightman axioms (and practice more generally) require linearity when we consider elaborate waveforms (because quantum fields are required to be operator-valued distributions, even though such a structure is not necessary for us to be able to construct a Hilbert space).

   One doesn’t need to understand classical trajectories to understand that quantum theory describes the statistics of observed and (computer-)recorded discrete measurement events, which may sometimes be obviously lined up but more generally are separated by far enough and mixed-up enough that we can’t be sure that they’re on trajectories at all (but nonetheless there *are* statistics of events).

3. **Matt Leifer**
   August 11, 2014

"About 4000 articles a year are appearing on the arXiv at quant-ph."

Come on dude! The vast, vast majority of those articles have nothing to do with the problem you are talking about. The largest portion are about quantum computing, quantum information et. al., there is a portion on the sorts of approach to quantum foundations that you have indicated you have no interest in, and then there is a bunch of people writing papers about how to solve the Schrodinger equation and related differential equations, i.e. basically doing traditional applied math sorts of things. That leaves probably not more than a dozen or so papers per year that you would actually judge as relevant.

More broadly though, I disagree with you, as you might imagine. The whole literature on decoherence mostly ignores the problem of ontology, i.e. what actually exists. It is one thing to get out of the formalism something that looks approximately like the Liouville or Hamilton equations, but quite another to be able to argue that this means that there are things that actually exist in the world that approximately look like classical particles and fields obeying these equations.

Further, there is the whole problem of interpreting experiments that are thoroughly within the quantum world, e.g. things like nonlocality and contextuality. You are not going to be able to understand those things just by looking at a classical limit. And we are actually making both conceptual and mathematical progress in studying these things. It is not just interminable debates that go round and round in circles, as it may have been when you last looked.

Even disregarding all of this, you are just flat out wrong that understanding the emergence of classicality has nothing to do with the structure of the theory. The same ideas about group representations and so forth that go into understanding how to quantize a classical theory show up in a dual role in decoherence and related subjects. Ignoring one whole side of this seems a bit strange. For the category theorists out there, it is like studying a functor without studying the adjoint functor.

4. **Tim Campion**
   August 11, 2014

   A couple of nitpicks: In this post, when you describe the Born rule, I think you mean to say that the probability of measuring observable \$O\$ of a state \$\psi\$ to have value \$\lambda\$ is given by the modulus-squared of the projection of \$\mid \psi \rangle\$ into the eigenspace of \$O\$ with eigenvalue \$\lambda\$.

   Also, I started flipping through your notes and I noticed that on the bottom of page 12, your definitions of irreducible and indecomposable representations are flipped around from what I learned in Fulton & Harris, or what you can find [on wikipedia.]

5. **Peter Woit**
   August 11, 2014

   Matt,
   I think you're missing the repeated parts of this posting where I explain that I'm well aware I know very little about what is going on in "quantum foundations" these days. The period I was referring to when I did make an attempt to follow this was back in the 1970s, quite likely before you were born. I was trying to be polite by not giving examples of what I meant by people going over the same kind of thing being discussed back then. To be slightly more specific I'll just say I was thinking of several physicists and philosophers with a high public profile who go on about these issues in this way. The positive reference to the huge quant-ph literature was meant to indicate that there seem to me to be a wide variety of different sorts of interesting things going on with some relation to the "interpretation" question, too many for me to hope to follow.

   I repeat that I honestly would like to hear good suggestions for things to read to get a grasp of what people are working on, e.g. review/expository pieces aimed at surveying the subject for non-experts.

   We all have our own intellectual prejudices, one of mine is that I've never gotten any insight into anything from a discussion about ontology, but maybe I just haven't read the right discussion.

   I don't doubt that ideas about group representations and other aspects of the fundamental mathematical structures of the subject I've been writing about show up for instance in the analysis of decoherence. I just haven't seen evidence though that thinking about decoherence feeds back into the kind of question I mentioned about fundamental structure. Again, quite possibly this is just because I don't know that much about this, and if so I'd love to be enlightened.

6. **Peter Woit**
   August 11, 2014

   Tim,
   Thanks. You're right, here in the blog posting what I wrote assumes all eigenvalues distinct.

   You're also right about the notes. I was trying to keep things as simple as possible dealing with the "reducible but not decomposable" phenomenon as something beginners were encouraged to skip, but I messed that up. Will rewrite, maybe right now…

7. **ScentOfViolets**
   August 11, 2014

   We all have our own intellectual prejudices, one of mine is that I've never gotten any insight into anything from a discussion about ontology, but maybe I just haven't read the right discussion.

   And I thought it was just me. Maybe 'Shut up and calculate' is subsumed in 'I am now very bored with these sorts of discussions'. Really. In fact, let's turn this around: has anybody ever gotten much in the way of insight in these types of discussions? Personally, I know a few people who have been motivated by them, but when pressed, they uniformly admit nothing much ever came out all the jaw-jaw.

8. **Chris W.**
   August 11, 2014

   I think Peter Morgan is touching on my nagging worry, which is properly understanding the complexities of the system being observed in conjunction with the experimental apparatus is, *on the face of it*, essential to making the observations, and properly drawing conclusions from them about the theory being tested.

   To put it another way, we don't want to quantum mechanics to be just a formalism. We want it to be the basis of an empirical science, and grappling with the absurd complexities of actual experimental apparatus as quantum systems would be seem to be an unavoidable part of this. Of course, generations of physicists have been somehow negotiating these complexities day in and day out with a fair degree of self-assurance. The question is how they can manage to do this without kidding themselves.

   Maybe the answer is that they *never* know for sure that they aren't kidding themselves. All they can do is think up and carry out various kinds of consistency and sanity checks, and design experiments that facilitate those checks. The basis of their confidence is the accumulated history of all that work. So the best policy is to attend to the specifics of such techniques and solutions, and avoid getting tangled up in "ultimate" questions that lead nowhere.

   Of course, this kind of practical response is great until it gets deeply stuck…

9. **Peter Woit**
August 11, 2014

ScentofViolets,
"Shut up and calculate" is not my perspective, which is all about trying to understand why certain kinds of calculations work. The point of the posting was to identify a specific aspect of QM calculations that works for reasons I don't understand (the Born rule). Understanding this seems to be a different sort of problem than that of those parts of theory where calculations work for reasons that I do think have a compelling explanation.

The comments in the posting were intended to indicate what seem to me the reasons this is hard and I don't understand it. I'm perfectly willing to believe others do though and could point me to something enlightening.

10. **abbyyorker**
August 11, 2014

I thought that the Everett long thesis was worth reading, even if you do not like many worlds.

August 11, 2014

"I repeat that I honestly would like to hear good suggestions for things to read to get a grasp of what people are working on, e.g. review/expository pieces aimed at surveying the subject for non-experts."

If you like topos theory, you may want to read this paper explaining Isham's research program : http://arxiv.org/pdf/0803.0417v1.pdf

12. **Justin**
August 12, 2014

Woit,

Given your reaction to the comments on 't Hooft's foundations of quantum thread, I think this thread was a bit dangerous. Hopefully it doesn't turn into that thread all over again. I've browsed and known people who are interested in these foundational issues. I find a lot of them (not all by any means) dogmatically defend Einstein's views on quantum mechanics, and therefore these discussions always lead to advertising hidden variables, most notoriously Bohmian mechanics. If you're actually interested in getting into this stuff, I think you will have to work hard to distinguish serious attempts to understand what is going on versus countless papers containing large quantities of pseudoscience about 'photons telepathically mind-reading backwards in time' (that's almost an exact quote from one person I know working on this stuff). I wish you the best of luck.

13. **Bee**
August 12, 2014

I'm not sure your distinction is between classical and quantum, it seems to be between small and large systems. It is typically the intermediate regime that is difficult, the quantum – classical transition, the microscopic-macroscopic transition, the regime where N is neither small nor infinity that is difficult.

I change my mind on this every couple of weeks, but every once in a while I find it quite possible that our failure to find a theory of quantum gravity stems from us having missed something in the process of quantization, that maybe we're just doing it wrong and at very high energies it works differently. Then again I think the string is the thing and then again I think asymptotically safe gravity is it, and then I start it all over again. So recently I've been doing some reading on statistical mechanics and it's quite interesting how much progress has been made there in the 'difficult' regime of finite N, fluctuations and non-equilibrium and quantum things. Who knows, maybe that's where the answer will come from.

14. **Ralph B**
August 12, 2014

I was reading Griffiths "Consistent Quantum Theory" when Wilzcek pronounced it "bracing." I was delighted!

15. **Francois**
August 12, 2014

Dear Peter,

Like Ralph B, I also liked Griffiths' book, and along the same line of thougt, Roland Omnes' review in Review of Modern Physics is quite clear. I recently tackled Bernard d'Espagnat's book (Traité de Physique et de Philosophie… I gather from your postings you read french ?). It has two parts, one about physics (quantum physics really) one about philosophy of science. He has quite a philosophical approach throughout the whole book, but it is written in a pedagogical manner accessible to the non-philosopher.

16. **Jasper**
August 12, 2014

I've been studying the measurement problem for the past year, and I'm currently satisfied with decoherence as a solution to the preferred basis problem & "unobservability" of superpositions: how a measurement can only be performed in certain bases and why superpositions disappear in the macro setting. This is because of the form of possible interactions in physics. We cannot measure in the basis corresponding to non-local superpositions because all(/most) interactions are local, i.e., the environment becomes entangled with the local parts of a superposition. In the end this results in the fact that the predictions for the system while disregarding the environment are done using a diagonal density matrix in the basis defined by the system-environment interactions.
Most importantly the timescale on which this occurs can be calculated given the system and the interactions with the environment.

The unsolved problem of single well-defined outcomes: QM tells us the probabilities for the possible outcomes, but why does an experiment give a single outcome?
In my opinion this cannot be solved in QM, since the system becomes more and more entangled with the environment and the measurement apparatus and all the options within this whole state never disappear because of unitary evolution in QM. To me this is an interpretational problem of QM.

To me, it comes from wanting QM to describe single runs, which it seems it does not. Most importantly one has to think of what a pure state means. Experimentally these states are only defined by a class of preparation procedures and can only be obtained by first doing rigorous statistical testing of these procedures. Simply put, I think pure states should be regarded as representing an idealized(!) state of a system with the most definite property obtainable in quantum theory for some set of observables.

The assumptions that are necessary to identify a single quantum system with a pure state:

1. During the verification of the preparation procedure any possible deviation in the final measurement statistics due to a finite ensemble are neglected. Also, the final

measurement statistics are dependent on additional assumptions on the quality of the measurement apparatus, such as the efficiency, the number of false detections (dark counts), and the dead time.
2. The final selective measurement during the verification of the preparation procedure is assumed to be able to distinguish between all possible (non-degenerate) results perfectly.
3. The fundamental and experimental uncertainties in the preparation procedure are neglected.
4. The entanglement of the system with the preparation apparatus is neglected and the state of the system is characterized solely by the outcome indicated by the final measurement device instead of the full entangled state between preparation apparatus and system.
5. The produced state is not affected by the presence or absence of the final measurement apparatus.
6. The ubiquitous interactions between the system and the environment, which can also include the system's internal degrees of freedom, are neglected.

If the pure state is an idealization, it becomes quite difficult to talk about single runs, and it seems one can only talk about ensembles.
