In the course of work on the inverse geometrodynamics problem the author was able to construct a set of quantitative relations among invariants of different-scale physical processes. To date it is already complete enough, which allowed quantitative comparisons of most important physical processes with an accuracy close to the modern possibilities of experimental metrology. In particular, this pertains to the relations between atomic and astronomic systems of units of time, distances, masses. (For separate quantities the calculation accuracy proved higher than their experimental measurement accuracy, see "Monstrous moonshine" and Physics in this book.) "
Now it is time for some words about above mentioned geometrodynamics equations. In seventies Michael V. Gorbatenko and Alexander V. Pushkin made important observation, following early idea of Y.A.Romanov (A.D.Sakharov colleague). They modernized Hilbert variation procedure in Palatini approach to affine connection space. They understood that usually putting to zero field variations on boundary may be wrong; such operations may contradict to causality. So they put nonholonomic constraints on variations by using Lagrange multipliers A , and equate to zero corresponding components. As a result they received the equations of general relativity (1), where stress-energy 4-tensor is expressed via A□ and metrical tensor gik: (2). These equations are invariant under conformal (gauge) transformations (3) , where – arbitrary function of four coordinates. We see that Aα – Weyl vector. So it is possible to transform them in some domain to the simplest Einstein form: (4), and this transformation correspond to changing of connectivity from Riemann to Weyl type: (5) (more about it you could find in [1 –General relativity and gravitation,2002,Vol.34 , No.2, P.175-188;2002, Vol. 34, No. 2, P.1131-1133; 2002, Vol.34, No.1, P.9-22.]) . Certainly, it is possible to start with (4, 5) and receive (1, 2). All this approach goes back to Herman Weyl, but equations (2) appeared seemingly first time in [2- VANT, 1984, in Russian]. I will call them as Gorbatenko – Pushkin (G-P) equations. Just these equations Pushkin received as the result of quantization of vacuum Einstein equations. As he explained G-P equations are sufficient for describing of all physics from smallest parts to cosmology scales in spite of absence any dimensional or dimensionless constants. You could see also on them as on basic dissipative medium equations in accordance with `Hooft idea. It is possible due to stress-energy 4-tensor structure (2) which resembles the structure of the usual tensor for dissipative fluid.
For first acquaintance with Pushkin theoretical universe let us see on the abstract of report which was presented by him on 2-nd Sakharov Conference on physics, Moscow, 1997.

"MONSTROUS MOONSHINE" AND PHYSICS

A.V.Pushkin

The paper presents some results obtained by the author on the quantum gravitation theory. This theory proves related to geometry of Cayley projective plane and the algebraic structure of the theory to the commutative nonassociative Griess algebra. The theory symmetry group is the automorphism group of Griess algebra: "Monster" simple finite group. Knowledge of the theory symmetry allows observed physical quantities to be computed in the "zeroth" approximation. Results of the calculations, including those for ~ 1/137 and , are presented, with the theory-controlled accuracy of the "zeroth" approximation being higher for some of them by 1–1.5 orders of magnitude than the accuracy of modern measurements.□
For me it was most amazing theoretical paper.
And what is about SS? Here I place one more citation from Pushkin book. "In the superstring theory a striking progress has been achieved recently: as few as five theories remain which are actually based on two lattice types in 16-dimensional space. Moreover, it has been proved that they are non-perturbative equivalents and as such are the limiting cases of the more general single theory. What last step should be made in the superstring theory in the direction of the construction of a single theory? Of course, this step is the gravity quantization, which will result in disappearance of the last dimensional scale in the theory, viz. the fundamental string scale. Then the theory will possess the local scale invariance properties and may perform quantitative calculations with non-perturbative methods by translating algebraic relation between physical quantities to different scale levels, including to the level of ordinary phenomena appearing in continuum motions in standard conditions.
In geometrodynamics, i.e. upon the gravity quantization, even this last dimensional scale disappears. In the language of the lattice theory in spaces this means that there should be the only possibility to avoid the need of appearance of dimensional scale: the fundamental root amount is equal to infinity (i.e. there is no separated cell) and the Weyl vector is therewith light-like, i.e. , which also requires no a priori scale. It is evident that the last requirement is readily formalizable at the level of the elementary problem of Diophantine equation solutions (see Problem 5.5). Having solved it, you will find those values of dimension of hyperbolic spaces , which determine the lattice arrangement of the geometrodynamics."
I think it is enough, because it is impossible to envelope unbounded. If you want some additional information try LANL arHiv (mainly gr-qc), where placed few papers written by Gorbatenko and Pushkin, and where are additional papers only of Gorbatenko. You can try also the recent publication: arXiv:0711.20113v1 [gr-qc] by

M.V.Gorbatenko and me. If you know Russian, is it possible to find much more papers which were published by RFNC VNIIEF (Voprose atomnoi nauki I techniki). Now extended English translation of the Pushkin’s book is ready and we (me and Gorbatenko, part of pushing group) are seeking for foreign publishers. P.S. If somebody prefers Loop QG approach, I add that knots appear very naturally in Pushkin s theory.
Happy New Old! (Russian) Year (13 January) and Russian (Orthodox) marry Christmas (7 January).

This Week’s Hype

January 3, 2008
Categories: This Week's Hype

New Scientist had the good sense to pass on last week’s hype about string theory testability, but is responsible for this week’s hype on the subject, with an article entitled String theory may predict our universe after all. It’s unclear why the article is appearing now, since it is based on a six-month-old preprint from a group at Oxford entitled Triadophilia: A Special Corner of the Landscape.

The authors basically just point out that there are very few known Calabi-Yau manifolds with small Hodge numbers, which thus have a small enough Euler characteristic to give just three generations. They speculate that some unknown dynamical vacuum selection mechanism favors these particular manifolds. In their paper they look only at the topology of the manifolds, so the only “prediction” about our universe is that the number of generations will be small, and this “prediction” is based on assuming an unknown dynamics that favors small numbers of generations.

There has been a huge industry since the late 1980s devoted to trying to extract physics out of the sorts of Calabi-Yaus studied by the Oxford group. This hasn’t gotten very far, with rather elaborate mathematical constructions being used to try and get the quantum numbers of the standard model particles to come out right. One problem with this is that one is not even sure that this is what one wants, since maybe the LHC will find more particles. The groups pursuing this strategy don’t seem to have taken much interest in the Candelas et. al paper, since SPIRES shows that no one has cited it during the last six months.

It looks like 2008 is not going to show any slackening of the promotion by string theorists of bogus “Despite what the critics say, string theory really is predictive!” stories to the press. This one contains quotes from Polchinski that the paper is “neat” and “Maybe it gives us a clue”, and from Strominger that it is “beautiful”. Strominger also minimizes the fact that the Landscape is a problem for string theory, saying:

> I don’t think it is incumbent upon string theory to solve the problem of the landscape… If we can’t make the landscape go away, it doesn’t mean that string theory is wrong. It just means it is not a complete solution to all our problems.

Michael Duff says the paper makes “some mathematically sound and interesting observations”, but does note that it doesn’t explain what selects small Hodge numbers, which is about the only slight amount of non-hype that makes it into the article.

Update: As a commenter here points out, the New Year also brings new progress on the scientific investigation of the landscape/multiverse, with a preprint from Don Page about how God loves all universes, not just ours.

Comments

1. **luny**
   January 3, 2008

   This: http://arxiv.org/abs/0801.0246

   might count as a prediction with some people 🙂

2. **T**
   January 3, 2008

   Peter,

   I know this isn’t exactly the topic of the post, but can you expand more on the Templeton foundation. I’m a hep-ex and know very little about this, but it appears to be almost an inside attack on science from religion. Is this too harsh?

3. **cwj**
   January 3, 2008

   The Templeton Foundation doesn’t seek to overturn accepted science, as do the creationists in their various mutations, but to interpret modern science in such a way as to make it “safe” for non-fundamentalist religion, for example, does QM give us free will? Does the unlikeliness of the universe suggest the existence of God? A bit misguided or silly, I’d say, although not as nefarious as the Discovery Institute (some will disagree here): Templeton doesn’t want to attack science so much as to co-opt it.

4. **Coin**
   January 3, 2008

   The authors basically just point out that there are very few known Calabi-Yau manifolds with small Hodge numbers, which thus have a small enough Euler characteristic to give just three generations. They speculate that some unknown dynamical vacuum selection mechanism favors these particular manifolds.

   Well… okay, never mind the dynamical vacuum selection problem for a minute. Let’s say we just *dictate* there are three generations, since that’s what experiment seems to indicate, and say that we’re only interested in those string theories that have the appropriate characteristics to get those three generations (small Hodge numbers etc). It’s certainly not a “prediction”, but does this at least significantly cut down on the size of the “landscape”?

   (Assuming the Hodge thing is valid at all, of course? You say there are very few “known” manifolds with this property. They say the number of manifolds with this property “appears to be” small… nobody sounds very confident here.)

5. **alex**
   January 3, 2008

   “but does this at least significantly cut down on the size of the “landscape”?”

   Sure it does! It has been known for a while that there are very few vacua that are actually relevant for phenomenology. Unless you care about tuning the cosmological constant, the vast landscape of flux vacua is pretty much irrelevant for model building. Lubos and others including Jacques have been saying this all along and for people who actually do computations of sparticle spectra from string compactifications the whole talk about 10^500 vacua bears little significance.

6. **Peter Woit**
   January 4, 2008

The number of generations is given by a difference of Hodge numbers, so you can get 3 in lots of ways, using Calabi-Yaus with large Hodge numbers. These authors are suggesting that one only look at ones with small Hodge numbers, which cuts down the number of Calabi-Yaus to look at. I guess with the small Hodge numbers one will also not have exponentially large numbers of flux vacua.

As far as I can tell, they just completely ignore the problem of the vacuum energy, so all their suggested vacua will have a CC off by more than 100 orders of magnitude. It's true that if you want to ignore the CC problem you can ignore the huge numbers of flux vacua, and until recently this is what most model-builders were doing. What Lubos has been "saying all along" is that he thinks one should do what these authors do and just ignore the CC problem, Jacques has been saying something different; he has some argument that even if you do use flux vacua to get the CC right, you will not completely use predictivity.

7. **JV**
January 4, 2008

Hi Peter,

I read so much on what is wrong with string theory on your blog (which by the way is good criticism, so I like refering to this site often); may I then ask just what is right about string theory?
(In outline form please… I'm no expert on the subject).

JV

8. **Peter Woit**
January 4, 2008

JV,

There's a lot one could say about this, but it is off-topic…

Very briefly, the two areas string theory has had the most success in are in algebraic geometry, where the topological string allows computations of invariants that are new, and in the study of strongly coupled gauge-theories via a string dual (AdS/CFT). String theory is a huge subject, and there are certainly other interesting things it has led to that can be pointed out.

It's really in one main area that it has completely failed, that of providing unification via a 10/11d theory. Unfortunately, this idea was its main selling point, and people are having trouble acknowledging it doesn't work.

9. **Roger**
January 4, 2008

If the number of generations were, hypothetically, measured to be 10000000, would this then disprove string theory ?

Its a prediction Jim, but not as we (experimentalists) know it.

10. **alex**
January 4, 2008

"The number of generations is given by a difference of Hodge numbers, so you can get 3 in lots of ways, using Calabi-Yaus with large Hodge numbers."

Sure, but only three CY manifolds with \chi=+/- 6 have been found so far after several decades of search.

"As far as I can tell, they just completely ignore the problem of the vacuum energy, so all their suggested vacua will have a CC off by more than 100 orders of magnitude."
In the Heterotic M-theory the tree-level CC can dynamically relax to zero due to a perfect square structure of the potential. There is a cancellation between the flux and the non-perturbative terms when one takes into account the warp factor. The higher order terms may be tuned away as well but I don't know the details since I'm not familiar with the Heterotic M-theory flux compactifications well enough.

11. **?**
January 4, 2008

Actually, one of the main issues to think about in studying the "landscape" is that there are local constructions that can easily given three generations, and fit into the manifolds that give exponentially large numbers of vacua. So regardless of whether this is true of the Candelas examples or not, it is quite false that three generations alone cuts the number of models down to a very small number, at least as far as we know at present. Three generations plus much more stringent phenomenological cuts could still reduce the number of models to 1 (or zero), consistent with present knowledge. Several groups (in Germany, at Rutgers and MIT etc) have actually tried to estimate what fraction of models give 3 generations, and their results are consistent with their being many, many such models.

12. **Savage**
January 4, 2008

Don Page's paper is not science but metaphysical nonsense. Where is the proof of one God loving one universe, forget about the proof of the existence of a muliverse. String theorist Leonard Susskind has now "created" a megaverse which is those worlds in the multiverse which are actualized. What nonsense. I see Page quoted discussions with Dawkins, which I'm sure, totally disagrees with him.

13. **m**
January 4, 2008

by the way, the only reason why the compactification space should be a Calabi-Yau (which is a very peculiar choice) is that many theorists believed that we need N=1 supersymmetry to solve the hierarchy problem. But now the hierarchy problem can be solved without supersymmetry, by invoking anthropic arguments. Calabi-Yau are no longer needed.

14. **luny**
January 4, 2008

Regarding Don Page's paper, it is not the first time that a physicist dabbled in methaphysics or theology (see Schrodinger or Einstein).

But the fact that this stuff appears on a PHYSICS PREPRINT site is genuinely new. And its not a sign of progress.

15. **wolfgang**

January 4, 2008

luny,

> But the fact that this stuff appears on a PHYSICS PREPRINT site is genuinely new.

worse stuff has been posted.

16. **Yatima**
January 4, 2008

"worse stuff"

A truly Fortean Link! I never thought that Spontaneous Combustion was connected to Poltergeist Phenomena. Then "sexual neurons" are mentioned. I like it 😉

17. **luny**
January 5, 2008

Yes, but not by a leading physicist with lots of great accomplishments.

18. **JV**
January 5, 2008

Hi again Peter,

[Sorry for the off-topicness of my previous and current posts], but now that you mention string theory's main 'achievements', may I ask which paper/s are the most important – or groundbreaking, or fundamental – in understanding the above-mentioned topics (technical and/or nontechnical)?

If string theory is, or is not, really up to the task it claims itself of being able to achieve, i.e. theory unification, may I then (with some skepticism as to its actual viability / realizibility) request the following…

(occasionally, or if possible, more frequently) Request various expert guests – who agree beforehand to attend – from both sides of the debate – in an 'e-townhall' meeting-style format – to present their specific pro- or o- points of views and let the global physics blogosphere ask very probing questions on each point / set of points presented by each, respective, guest.

This – I think – can go a long way to address your, and likely many others', concern/s of why string theory is arguably not the promised idea it claims itself to be.

{Of course, the debate should be *moderated* at all times to keep ad hominem and random attacks to a minimum or (ideally) zero level}.

Seems like a good idea (in theory at least); but I don't know if that could be realized when many foremost string theorists don't seem comfortable taking criticism – or at the prospect of having their research endevours publicly criticized – lightly!
!! This should be a sufficient reason – 🙂 – to present them with a challenge like this. !!

19. **a quantum diaries survivor**
January 5, 2008

Wow, Page speaks of "christian cosmologists"… The idea that there are cosmologists whose scientific research is confined and biased by their religious beliefs is disturbing! I thought the era of Teilhard de Chardin was long gone… I am obviously suffering from delusions.

Cheers,
T.

20. **Hans**
January 5, 2008

In this paper here:
http://arxiv.org/pdf/0801.0247
Don Page even "calculates" the probaability" for "pre death experience" at page 9.

Why is this stuff accepted on a physics preprint server?

(more disturbing is, whom he thanks in this crap. Some persons he aknowledges are:

David Deutsch, Bryce DeWitt, Gary Gibbons, Stephen Hawking, George Ellis, Andrei Linde, Lee Smolin, Bill Unruh, Alex Vilenkin, Steven Weinberg, Paul Shellard, Leonard Susskind, Alan Guth, James Hartle

(If my name would appear on such "work", i would take some effort, to get it removed)

21. **anon.**
January 5, 2008

> (If my name would appear on such "work", i would take some effort, to get it removed)

Those people are (with a couple of exceptions like Smolin) string believers and/or believers in uncheckable 'multiverse' interpretations of quantum mechanics and other religions crap.
That's probably why Page has cited them. Maybe they helped get his papers endorsed and on arxiv in the first place? 😉

22. **Tony Smith**
January 5, 2008

Hans mentions a few of the people acknowledged by Don Page in 0801.0247 but the list is very long. Also acknowledged there were:

Sean Carroll

Mark Srednicki
Richard Dawkins

They are of course able to speak for themselves as to how they feel about those acknowledgements (they were also acknowledged in 0801.0146).

It is interesting that both 0801.0246 and 0801.0247 were among "… a series of lectures sponsored by the Templeton Foundation and given at Shandong University in Jinan, China, autumn 2007 …".

I wonder what the Chinese (who invented gunpowder, the magnetic compass, eyeglasses, etc) thought of the first sentence of 0801.0247

"… Modern science developed within a culture of Judeo-Christian theism for several reasons … For example, the idea of a lawgiver for nature (i.e., God) encouraged belief in laws of nature …".

Tony Smith

23. **Tony Smith**
January 5, 2008

Sorry about a typo where I put 0801.0146 instead of 0801.0246.

Also, anon. speculates Don Page getting his "… papers endorsed and on arxiv …".
Don Page does not need endorsement of others. The arXiv says:
"… Don N. Page … Is registered as an author of this paper.
Can endorse for astro-ph, gr-qc and hep-th. …".

Tony Smith

24. **Peter Woit**
January 5, 2008

JV,

I'm afraid this is off-topic and I'm on vacation, so I'm not going to try and get together references for you. Perhaps someone else here can help. For AdS/CFT, there are lots of review articles, for parts of string theory that have been useful in algebraic geometry, that's a complicated subject, and what's worth reading depends both on your background and on what you hope to get out of the material.

I'd be happy to participate in the sort of debate you describe, but I don't think you're going to find many string theorists willing to go along with the idea. Lee Smolin and I both put a lot of effort into carefully putting into words our arguments about string theory, and I think both of us have been discouraged by how little serious response this led to (the two exceptions I can think of are reviews by Aaron Bergman and Joe Polchinski). The lack of this serious response, and a sizable amount of rather appallingly unserious response, has led to the present situation where even string theory partisans write publicly that string theory has lost the public debate.

The string theorists most likely to want to particpate in an internet-forum debate are those that have blogs, and there are only three active ones that I can think of. Of these, Jacques Distler and Clifford Johnson have explicitly announced that they refuse to read my book or Lee's. The other one is Lubos Motl.

I've privately talked to many string theorists about these issues, and found that we generally agree on quite a lot, although they're unwilling to enter into public discussions due to the level of personal hostility they see going on. I've heard that many prominent string theorists turned down the opportunity to respond to my book and Lee's in various publications. My take on all this is that they are well aware that on the central issue here of whether string theory has failed as an idea about unification they know very well that the case for their side is weak, so have decided it is best to keep quiet and hope this blows over, perhaps with the LHC changing the debate in some unknown way.

By keeping quiet, unfortunately the most sensible string theorists let their field be represented largely by people who are doing a good job of alienating anyone who might be sympathetic to their point of view.

25. **wolfgang**
January 5, 2008

Hans,

> Don Page even "calculates" the probaability" for "pre death experience" at page 9.

I wish you and everybody a lot of pre death experience 😎

26. **JV**
January 5, 2008

Hi Peter,

"Lee Smolin and I both put a lot of effort into carefully putting into words our arguments about string theory…"

I have a copy of your book – by the way – but to my immediate knowledge it does not contain a list of selected specific references of the sort I was hoping to receive (from you, or otherwise) {… I may be wrong as I don't have the copy with me while I'm writing this…}.
[I actually have not completed reading the book in its entireity as yet since many parts are currently beyond my technical understanding; but perhaps as an online Appendix to the work references may prove useful to readers who have the prerequisite background/s.]

This may help to clear up a great deal of confusion – no doubt much unfavorably brought on by excessive sensationalism from general media sources – regarding the program's specific and credible merit, and future relevance and prospectives … especially for theory unification.

If, however, such an attempt fails, I don't think there is much to be said regarding string theory and the question of its dominance in current hep theory research – it's here to stay and there's no point trying to oppose it – whether on scientific or otherwise grounds!

(I hope that doesn't occur; my hunch is that many people will only actually take a greater note of your points on string theory's unviability if you provide a more 'scholarly-like' setting to your blog -> book section, even if the general string theory community feels uncomfortable reading / responding to your work directly).

Hope, anyway, you get the time to reflect upon my proposition once you return to academic duties. Let me know.

Regards,
JV

27. **Michael Bacon**
January 6, 2008

"David Deutsch, Bryce DeWitt, Gary Gibbons, Stephen Hawking, George Ellis, Andrei Linde, Lee Smolin, Bill Unruh, Alex Vilenkin, Steven Weinberg, Paul Shellard, Leonard Susskind, Alan Guth, James Hartle"

"Those people are (with a couple of exceptions like Smolin) string believers and/or believers in uncheckable 'multiverse' interpretations of quantum mechanics and other religions crap."

Hans and Anon. You guys have to be kidding, no? When you guys contribute half of the "crap" these folks have, then maybe you'll be secure enough of your status in the scientific community not to worry about whether you are revealed to have had conversations with other (albeit goofy) researches, even if you don't agree with much of what they have to say.

Peter, I agree with you generally regarding the failure of the string theory project to acheive its stated objectives, but please don't encourage this type of know-nothing behavior by ignoring it. Thanks.

28. **Hans**
January 6, 2008

Michael Bacon wrote: Hans and Anon. You guys have to be kidding, no?

Well,
The persons whom Don Page thanks must indeed not worry about their status. But that is not the problem.

With his long list, to whom Page thanks to, he wants to create the impression that he has discussed such topics among the leading figures of the physics community and therefore, this stuff is acceptable to a physics preprint server.

So, the people who are listed there are, in some sense, a support for this crap. Don Page might have put them in their paper without even asking them.

The problem is not, that Steven Weinberg and others would have to fear about their status. Thats certainly not the case.

The problem is, that in a true world, leading figures should take pains, not to appear in such pseudoreligious crap. They should distance themselves from this paper forcefully.
They should make clear, that the opinions of Don Page are minority opinions, having nothing to do with physics or science at all and should ask arxiv to remove this crap.

I hope there is nobody out there, who wants more papers like this on arxiv org (maybe with more "supporters" listed to).

29. **Chris W.**
January 6, 2008

While the appropriateness of Don Page's preprint on arXiv.org might well be questioned, given its theological content, I think it should be acknowledged that it is not bad as these things go. Page is a committed Christian, but he is also a first-rate physicist. His arguments are hardly comparable with the kinds of evasions typically indulged in by ID advocates (never mind creationists). The paper's preface specifically addresses the question of appropriateness to the arXiv.

By the way, Page's undergraduate alma mater, William Jewell College, is an interesting place. (Donald Marolf is another of its graduates.) Four years ago the college lost the financial support of the Missouri Baptist Convention, with which it had a longstanding connection, because it stood up to a challenge by the MBC of the College's teaching of evolutionary biology.

Leaving aside the theology, the paper does not offer much reassurance to those who regard the putative existence of the multiverse as a horrendous epistemological can of worms for scientific cosmology and physics itself.

30. **Peter Woit**
January 6, 2008

About the Page paper and its acknowledgements.

Perhaps the hep-th moderator had the good sense to at least insist that it couldn't be posted there if that's where it was originally submitted.

I don't think you can make people responsible for the content of papers in which they are thanked, but in this case, many of those thanked are among those promoting anthropic pseudo-science. It continues to surprise me how few prominent people in this subject are willing to publicly criticize this kind of nonsense in any way. David Gross is one of the few examples I can think of. The problem is not so much a few serious theorists posting obviously silly preprints on the arXiv, arguably anyone who has done serious work in the past should be allowed to make a fool of themselves at least a couple times. The problem is the increasing infiltration of the field by pseudo-science, as almost everyone tolerates an ever-increasing level of it without comment.

31. **Michael Bacon**
January 6, 2008

"The problem is, that in a true world, leading figures should take pains, not to appear in such pseudoreligious crap. They should distance themselves from this paper forcefully. They should make clear, that the opinions of Don Page are minority opinions, having nothing to do with physics or science at all and should ask arxiv to remove this crap."

Hans, I guess these folks, notwithstanding their other accomplishments, just don't have your keen sense of intelligence when it comes to how they should behave when asked to discuss certain limited scientific issues by a fellow scientist (even one that's a little nuts). Hopefully your clear sighted comments on how to treat these types of situations will become more widespread. What a much better place the scientific world will be when we can finally be rid of the misbehavior of Hawking, Deutsch and their ilk. 🙂

32. **Coin**
January 6, 2008

The number of generations is given by a difference of Hodge numbers, so you can get 3 in lots of ways, using Calabi-Yaus with large Hodge numbers. These authors are suggesting that one only look at ones with small Hodge numbers

Hm, okay, that answers at least one of my other questions. Do you mind if I poke at this a bit more? (I'll admit upfront that I'm only asking because I think their diagram on page 4 of the PDF is real pretty, and I'm curious what it means.)

What exactly is a Hodge "number"? I am having trouble finding a clear definition on that. The closest I can find are the dual explanations of [this](#):

> The Hodge number is the analog of the Betti number on real manifolds for complex manifolds.

and [this](#):

> the Betti number of a topological space is, in intuitive terms, a way of counting the maximum number of cuts that can be made without dividing the space into two pieces.
>
> This defines, in fact, what is called the first Betti number. There is a sequence of Betti numbers defined… the k-th Betti number… of the space X is defined as the rank of the… k-th homology group of X

Hm, okay, but why do you need two indices to identify a Hodge number, and why are the only indices the Triadophilia people are interested in h^11 and h^21?

Is there some kind of "intuitive" explanation of the Hodge numbers, or h^11 and h^21 in specific, analogous to the "cuts" explanation for the first Betti number?

33. **Peter Woit**
January 7, 2008

Coin,

Calabi-Yau manifolds are complex (Kahler) manifolds, and in such a situation the cohomology, instead of being graded by a single number is graded by a pair of numbers. The easiest way to see this is using the deRham model of cohomology, where the n-th Betti number is the dimension of the space of differential forms of degree n that are harmonic (Laplacian on them gives zero). If you have a complex manifold that is Kahler, such differential forms break up according to the number of dz's and dz-bar's in the differential form of total degree n. For the details of this stuff, you really need to consult a book on complex manifolds, Chern's short one is relatively readable.

34. **King Ray**
January 7, 2008

Peter, is this the Chern book you meant?

http://www.amazon.com/Complex-Manifolds-without-Potential-Theory/dp/0387904220/ref=sr_1_10?ie=UTF8&s=books&qid=1199729426&sr=1-10

35. **Peter Woit**
January 7, 2008

King Ray,

Yup, that's it.

36. **Coin**
January 7, 2008

Thanks Peter/Ray, that helps a lot.

37. **King Ray**
January 7, 2008

Peter, thanks. I don't think I have that one, so I may pick up a copy.

Kind of an odd title, "Complex Manifolds WITHOUT Potential Theory."

Maybe some string theorist should write a book titled "String Theory WITHOUT Testable Predictions."

38. **King Ray**
January 7, 2008

Coin, you're welcome. I was curious to see the book recommended by Peter so I looked it up on Amazon.

The formulas for the connection and curvature tensors are so much prettier and simpler on complex manifolds.

39. **Xerxes**
January 8, 2008

Three is small now? I've been talking to large-Nc people, and they tell me that three is approximately equal to infinity. I guess three is a small number of generations, but a large number of colors. Is it a large or small number of spatial dimensions?

40. **Matteo Martini**
January 8, 2008

If I can, I would like to ask a question to Peter Woit and all the people who maybe interested to reply to me.

I admit this question is a small derail from the topic, but I would like to have the question written here, rather then ask the question by Email to any of the posters.
I ask pardon to Peter for that.

I would like to know if you think there is any future for particle phyisics after the current state of knowledge.
As far as I have understood, after the LHC will go online in the summer of this year, there will be no other plans of building more powerful accelerators (as the ILC simply adds luminosity, but not more electron volts).

Since most part of the human progress in the last 50-100 years has been done in fields such as electronics, semiconductor industry, biochemistry and related (informatics, pharma), etc, which are more or less related to advancement in basic physics done in the last 50 years or more, I do not think it is baseless to say that, once we will hit the

wall in the current progress in quantum physics (have we already hit that wall?) we will also (sooner or later) hit the wall in finding new ways to progress our knowledge in many fields, with this potentially ending human progress forever.
Without new and more powerful accelerators coming online after the LHC, it may be that new theories after the standard model could not be written as there will be no accelerator powerful enough to provide the necessary data/testing conditions.

Am I the only one to think this?
Again, sorry for the derail and for lowering the average technical level of the comments of this thread.

41. **chris**
January 9, 2008

hi matteo,

if we knew what the lhc would show us, we would not even need to switch it on. maybe there is no future for large collider rings. but there is also some natural limit to refractor lense sizes, which was reached about 100 years ago. still this was not astronomys death. we'll just have to wait and see.

42. **DB**
January 9, 2008

Matteo,
It's quite a big derail from the topic, but if Peter will undulge me I'll give you some pointers.
Be sure of one thing, the LHC will fundamentally alter our picture of particle physics. It will give us a much clearer idea of the merits of the Higgs mechanism and supersymmetry and this will be crucial for future theoretical and experimental progress.

The ILC is dead, flavor physics has been dealt a serious blow with the axing of BaBar, and the US is not interested in building a successor to the LHC on its territory. It will continue to participate heavily in particle astrophysics but even here NASA is under great budget pressure. If NASA pulls the plug on particle astrophysics, the European Space Agency will help plug the gap.

Future particle accelerators will not be planned until the LHC delivers its results, and if they are built the effort will be led by CERN, and, for cost reasons, will have to be a globally funded project, as with ITER. The US may well decide to participate financially. It's a long way off, but we have waited 30 years between LEP and the LHC (pace the excellent work done at the Tevatron) and we have learned to be patient. Remember also that there is more to HEP than the LHC and its successor. The most significant advances in HEP in recent years (neutrino mass/oscillation and the solution of the solar neutrino problem) have come from modest neutrino experiments in Canada (Sudbury) and Japan (Kamiokande).

We have not hit the wall in quantum physics, far from it. If you check the LCLS project at SLAC and its equivalent XFEL at DESY you will discover how rich are the prospects for useful advances in this area in return for comparatively modest expenditures, although the fact that two machines are being built tells me that HEP still hasn't learned its lessons with regard to needless duplication of effort.

As the ISS has shown, the only viable model in the future for big science is a global one and I have no doubt that we will see plenty of exciting developments along these lines in the years to come.

Be of good cheer, we are nowhere near the end of this game.

43. **Matteo Martini**
January 9, 2008

DB,
thanks for your explanation.
Again, sorry for the derail.

Matteo

44. **J.F. Moore**
January 9, 2008

Just a note on DB's comment: LCLS and XFEL are not HEP projects. In fact, SLAC is now administered as a BES lab, in recognition of where the bulk of their funding is coming from. These two machines are also being created as user facilities, so even if they had identical photon beam properties (they don't), having one on the same continent is a big plus for a 'user', which in practice can be a small academic group with travel funds.

My side-advice to Matteo is to get out there and talk to people, read their papers and see what moves you. Eventually it becomes clear what you must do.

45. **chris**
January 10, 2008

DB,

as j.f. moore remarked, lcls and xfel are no hep projects. xfl once was a sideline of the ilc-predicessor tesla. tesla is dead now, and its hosting lab, desy, is also transforming from a hep into a material science lab. so this particular game was lost by hep.

46. **WiCoB**
January 18, 2008

What I found interesting in the NewScientist was a subtle manipulation of figure captions and suggestions of something mysterious in the triangular shape of the plot of known C-Y manifolds. I am not sure if it is still within reasonable scientific journalism, or if the hunt for news item has gone too far this time?

More on FY 2008 HEP Budget Cuts

January 10, 2008
Categories: Experimental HEP News

The disastrous US HEP budget cuts that were announced just before Christmas, a quarter of the way into the fiscal year, have been getting a lot more attention from bloggers now that the holiday season is over, and their implications are starting to become clear. There are new blog posts from HEP bloggers Tommaso Dorigo, Alexey Petrov, Gordon Watts, and Michael Schmitt (as well as non-HEP blogger Chad Orzel).

It seems to me that Gordon Watts has it about right, entitling his posting "Screwed by the Democrats". As far as I can tell, very few people know who it was that made the last-minute decision to hit HEP with these huge budget cuts targeted at its future programs or what their justification for this was. Presumably this was done by certain staff members of the heads of the relevant Congressional committees. Gordon explains how all the evidence points to physics getting cut precisely because the relevant parts of the executive branch had made it a priority in their proposed budget. When the Democrats lost the game of chicken that they and the White House were playing with the budget, and had to find some way to make cuts at the last minute, things that were an administration priority were first in line to get cut. So, HEP lost out here not because it has done a bad job at making its case, but because it did too good a job….

One reason that these large cuts had to be made was the decision by the Congressional leadership not to do what they had done last year, which was to cut all earmarks from the DOE budget. A new AAAS analysis concludes that the new budget contains $4.5 billion in R and D earmarks, and that the DOE and Department of Agriculture were the most heavily earmarked R and D agencies.

Some bloggers have suggested that physicists need to redouble their efforts in public education about HEP, but I think Gordon is a bit closer to the right idea, as he has sent $250 as a campaign contribution to Bill Foster, a Fermilab physicist who is running for Congress. Probably even more effective would be if the APS would put out a web-page explaining exactly which of our Congressional representatives were responsible for deciding to hit HEP with these cuts. If they would do that we could then all write to these people saying that we appreciate their public service and include a large check for a campaign contribution, at the same time mentioning that HEP funding happens to be a big personal concern. This seems to be how US democracy works these days: you need to pay to not get screwed, and we haven't been paying…

As for what the effects of these cuts are, there's more news coverage here, here, here, here, and here (Fermilab has a web-page of links here). Here is the text of SLAC director Persis Drell's talk at an All Hands meeting there. The effect of the cuts on SLAC will include having to lay-off 125 people and shut down the B-factory at the beginning of March. Layoffs will be announced in early February, with people leaving their jobs in early April. Senator Durbin of Illinois is talking about an effort to add money for Fermilab to the Iraq War "emergency funding" bill the Senate will be taking up this spring, but says "It won't be a huge amount… I don't want to suggest to anyone we will make them whole." It's unclear whether this is a realistic possibility, or just Durbin trying to look like he is doing something about this.

Update: Here's a letter about this from Dennis Kovar at the DOE. There's a detailed article about the situation by Adrian Cho at Science magazine.

Comments

1. **Peter Woit**
   January 10, 2008

   A reminder: informed comments are welcome, but uninformed commentary on any issue. but especially this one, isn't. If you want to engage in discussion of this issue at the level of "it's better to fund (socially desirable goal X) than HEP", please do this elsewhere.

2. **Zathras**
   January 10, 2008

   I reiterate my earlier comment that this would never have occurred if HEP had a competent lobbying organization. This is never a problem in other sciences, such as biology and chemistry, which have strong, focused lobbying help from Big Pharm.

3. **Paul Guinnessy**
   January 10, 2008

   Physics Today will be looking closely at the science policies of the presidential candidates at http://blogs.physicstoday.org/politics08. We're still adding material of the moment, but there's enough there for some conclusions on the future of science and HEP under the next administration. Feel free to comment on the site, or submit a longer article for posting.

4. **Nugae**
   January 10, 2008

   Isn't this all a bit supine?

   Why not announce the immediate and indefinite closure of all HEP programs, giving the reason that modern science requires reliable funding? Instead of trying to beg for a little more money here, a little more there, say clearly and straightforwardly that you appreciate the careful reasoning that went into the legislators' decision and that you accept that the United States as a country is simply too poor nowadays to be able to afford big science. Express the hope that Europe and China may be able to continue human progress in this field.

   Don't go grovelling to the people who voted this in: instead, make sure that everyone knows who has brought the entire country its biggest international humiliation since Sputnik.
   If your only response to spiteful budget cuts is an indignant whimper, you deserve to suffer them.

5. **woit**
   January 10, 2008

   Thanks Paul. Would be interesting to hear what the candidates think about Congressional R and D earmarks.

   Nugae,

   I see a few minor possible problems with your plan…

   The first is that I still can't figure out who is actually responsible for this. It would be nice to know who they were, and what their justification for these actions was. Once they're identified, then we can argue about whether it's likely to be more fruitful to try and publicly shame them or pay them off so they don't do it again.

6. **Gordon Watts**
January 10, 2008

Just a quick point — it wasn't just HEP that got cut. ITER, for example, got hit pretty hard as well. There was also an across the board cut of about 1% (which combined with inflation makes it more like 3-5%). But clearly, part of the problem seems to be that we did lobby effectively, got the WH on board, and it looks like that raised the profile enough to make us a target.

7. **woit**
January 10, 2008

Thanks Gordon,

I agree. If it were only HEP that got cut, then the explanation could just be that some people think HEP shouldn't be funded since it isn't aimed at practical applications. ITER is very much aimed at an important practical application, and it too was cut. It looks like someone decided to go after the physical sciences initiative of the Bush administration, especially large projects it was supposed to fund.

8. **Yatima**
January 10, 2008

"*pay them off so they don't do it again*"

Commissioner: "What a nice little HEP budget you have there. A shame if something should happen to it…"

Physicist: "I do think, sir, that you will very much appreciate this somewhat stuffed brown envelope…"

Commissioner: "Thank you. It's a pleasure discussing the future of science with you. If you will excuse me, I have an important meeting concerning urban waste management."

9. **nobody**
January 10, 2008

Legislators will not continue to spend money funding big science. Here's why.

If the research done would be done instead in Europe or China, then the benefits of that research would still go to everyone, right? That is, a major physical discovery of the laws of nature would identically benefit those who funded and those who did not fund the research, so why fund it? Let the Europeans pay for it.

It can be argued that someone should fund the research, since it benefits everyone.

But the fallacy in that reasoning is that pure research by definition takes decades before it concretely benefits anybody. Sometimes longer than that. No congressman, and few of his constituents, is likely to be in office – maybe even alive – by the time any research benefits come to fruition. By comparison, social programs have immediate benefits: criminals are incarcerated; people are given health insurance; the poor and minorities are helped; and so on.

The political support for science in the United Science was, historically, anomalous, driven mainly by the unique circumstances of the Cold War. I don't think it can continue.

10. **chris**
January 11, 2008

hey, nobody,

let me recapitulate… 1938, nuclear fission was discovered. 1945 the first bomb was dropped.

yes, let china lead the way into exploring ewsb, dark matter&co. sure the us will benefit equally from it :-).

11. **Dave Miller**
January 11, 2008

Chris,

Your example actually proves "nobody's" point, doesn't it?

Fission was discovered in Nazi Germany; the US built the bomb.

This example (and it would be easy to give many others) demonstrates that the pure-science discovery and the practical applications often occur in different countries.

When I was a doctoral student at SLAC around 1980, faculty openly joked about the fact that the feds kept funding us simply because physicists had created the bomb and the politicians feared we might come up with something else of the same sort. The joke of course was that nobody could come up with any plausible scenario by which this could happen — the feeling was that we were putting one over on the dumb politicians.

Well, at least on this issue, the politicians seem to have gotten the joke.

Of course, HEP funding is such a tiny fraction of the budget that it really hardly matters fiscally. But this does leave it vulnerable to the sort of political infighting Peter describes.

And, Peter, I doubt that there are anywhere near enough physicists in the country to affect such matters by their campaign contributions. There is also the problem that quite a few of us care more about other issues than HEP – for example, my top issue this year is this fraudulent war, not HEP funding: I'd guess this is the case for many other physicists.

Dave

12. **Roger**
January 11, 2008

As the previous posters have pointed out, it is very difficult to get across the message to a national government that it should fund HEP.

I suspect this is especially true in the US since, in order to make progress, one has to perform big research in the context of international collaborations. In such circumstances, it is difficult to realistically say that the US is the undisputed “leader”, something which politicians may well want to hear.

I believe that HEP needs a rethink, not only in the US, but also in the rest of the world regarding how we sell the subject.

13. **Peter Woit**
January 11, 2008

Dave,

The beauty of the current US political system is that your ability to influence government policy just depends on how much cash you can devote to doing this, not on how many people agree with you. And also this has nothing to do with whether you want the person you are paying off to be re-elected or not. If you think their opponent would be better, all you have to do is give money to both, more to the one you would most like to see elected, but enough to both to make sure they pay close attention to details of spending bills they otherwise couldn’t care less about, so they don’t screw you and your scientific field.

We really do though need to first actually identify the right people to pay off. Especially if they’re from small states with safe seats, the sums needed should not be exceptionally large. Just one ex-physicist now working for a successful hedge fund and willing to devote a non-trivial percentage of his latest bonus check to this cause would probably do the trick. My understanding is that the way this is done is that you actually hire a professional fixer (a “lobbyist”) to figure out how to, within the constraints of the law, get the biggest bang for your buck.

By the way, in case this isn’t obvious, I’m not really joking here. I do think this is probably the best way to get the US government to continue funding HEP research as it has done in the past. And I also think this is completely appalling and disgraceful.

14. **Zathras**
January 11, 2008

Peter,

What you say about the importance of lobbying is in on the right track, but enormously over-simplified as to how it actually works. Look at it from the perspective of an overworked congressional staffer. He or she has literally thousands of projects to wade through, deciding which to recommend and which not to. It is impossible for a staffer to make an informed decision on his own about every project. Here’s where a lobbyist comes in. A lobbyist explains the worth of the project he is lobbying for. It’s about access and the efficient, targeted spread of information (as opposed to putting up a website which nobody in Congress likely has ever seen.

Forget about campaign finance. The dollar amounts needed now are too high for a small collection of non-billionaire individuals to reach a meaningful set of legislators. Reaching some random legislator will not help, since he or she needs to be on the right committee-otherwise, he’s just one out of hundreds.

In the past, lobbying the executive branch was enough. Lobbying the legislative branch is now at least as important, and that is where the hole has been in physics lobbying.

15. **Peter Woit**
January 11, 2008

Zathras,

Thanks. Of course I was over-simplifying for effect. But it still seems to me that to get “efficient, targeted spread of information”, you need “access”, and what is going on these days is that this is effectively being bought and sold.

I’d still like to know who the relevant congress-people are in this case. I’m assuming it’s a very small number. Maybe these people are unusually high-minded and I’m overly cynical in my assumption that money could be effectively used to get them and their staffers to pay more sympathetic attention to the HEP funding problems.

I’m also curious to hear an estimate as to what sums of money would be useful for this purpose. While presumably these are beyond the reach of the average person living on an academic salary, there are increasingly large numbers of people out there with physics backgrounds enjoying exponentially larger incomes. While, these are not large enough to fund HEP research, but they may be large enough to convince people in Congress to do so.

16. **Haelfix**
January 11, 2008

I do have friends up high in NSF who told me that the primary reason this occured was someone up high in the Dems wanted to make a point along the lines of

‘The R’s forced us into a meager budget, so we had no choice. If you want your budget back, vote for us and we will increase spending’

Scientists are a loyal Democrat voting block, so this might compel them to come out and vote in an election year.

Anyway its maddening. Republicans do the right thing and fund HEP in general, but their reasoning is wrong and a relic of the cold war. Democrats have this nasty tendency to leave NSF a low priority, but have the correct reasoning as to why Science is important.

17. **Haelfix**
January 11, 2008

Its also become horribly obvious that we do indeed need to do a better PR job. For smart people you would have thought this would have been blindingly obvious a long time ago.

eg: Taking a percentage of the NSF budget and sticking it into a private lobbying group would likely pay for itself and then some.

I also noticed that Mr Gates privately funded part of an astrophysics project. It would be nice if that would cascade throughout the legions of uber wealthy americans who do so much for charity. I for one have no problem with having a Microsoft logo on my future pet linear accelerator.

18. **Visitor**
January 11, 2008

Let me see if I understand this correctly. Scientists are a “loyal Democratic voting block”… so the Democrats decided to gut their appropriations – thereby informing them that if they (the scientists) want their funding back, they had better vote Democratic in the upcoming election – which the scientists would do ANYWAY even without the budget slashes. And the scientists should vote Democratic so that the funding will be restored A YEAR FROM NOW – i.e. AFTER the damage is done.

Does it ever occur to anyone here that the Democrats have NO need to be concerned about your votes BECAUSE you are Democrats who have NO intention of EVER voting Republican. Why should they care about it, if you are so staunchly Democratic that they need not compete for your votes? If you were potential Republican voters, the Democrats would not dare to slash your appropriations.
Not only is the rationale reported by Haelfix unconvincing, but am I the only one who remembers civil rights demonstrations against NASA for spending money that (the demonstrators thought, I suppose) would otherwise end up in "anti-poverty programs" and similar pork-barrels? There might be OTHER constituencies in the Democratic Party that are either anti-science-funding, or are more important to placate than scientists, or BOTH, y'know?

How about THIS: the scientists vote NOT for the Democrats, who are willing to gut the science budget this year, but vote for the REPUBLICANS in the upcoming elections, because it is the REPUBLICANS who want to give priority to science spending and the DEMOCRATS who want to CUT it.

19. **AGeek**
January 11, 2008

I see repeated calls here for essentially using public money to lobby politicians for more public money. Surely anything along these lines would be illegal? If not, it should be… but anyway, it would be good if somebody who knows the legal facts could enlighten us about them.

Regarding wealthy ex physicists, it occurs to me that they presumably left for a reason. I wouldn't necessarily count on them to be sympathetic to those who didn't (yet).

20. **Haelfix**
January 11, 2008

Thats just what I was told roughly, I have no reason to doubt the party. Obviously its a little more complicated, as all budget fights are. Not just in congress but in the heart of the NSF and DOE.

21. **JC**
January 11, 2008

Are there any other physicists in congress, besides Rush Holt and Vernon Ehlers?

http://en.wikipedia.org/wiki/Rush_D._Holt,_Jr.
http://en.wikipedia.org/wiki/Vern_Ehlers

With respect to lobbying, maybe these two would be the easiest to approach first concerning physics funding issues.

22. **J.F. Moore**
January 13, 2008

Note that the IL governor's letter to the president a few days ago is less balanced than that of the two senators plus one representative sent in December. It discusses cuts to Argonne as "drastic" but Fermilab as "substantial". The press release names two projects at Argonne, but specifies none at Fermi. I do not know if these implications are deliberate.

http://tinyurl.com/32mfyo

@Zathras

Chemistry and biology are in general doing better than physics, but very few university and national lab based programs benefit from a pharma lobby. Many research programs are cut every year and research groups do struggle and die despite producing very well regarded work – but you don't usually hear about them because they aren't high-profile, billion dollar level projects like ILC or ITER.

23. **DB**
January 14, 2008

J.F.
I didn't get that sense from the governor's letter but I expect that in practice, politicians do distinguish between user facilities which have been created out of old HEP accelerators and which are designed to be useful to industry, and HEP facilities such as Fermilab.
The cuts at Argonne are to the Intense Neutron Source and the Advanced Photon Source, if I understand correctly, both are mainly used by material scientists and chemists. However, there are alternatives to the APS (not that the APS is being shut down, just on a reduced schedule), such as the National Synchrotron Light Source at Brookhaven, the Advanced Light Source at Lawrence Berkeley. And there are other pulsed neutron sources (Lujan at Los Alamos, the Spallation Neutron Source at Oak Ridge) most of which seem have remarkably similar missions. And there will be the coherent x-ray lasers coming onstream at SLAC and DESY in years to come.
So material scientists and chemists would seem to be doing pretty well out of the conversions of old HEP facilities at least according to this:
http://www.sc.doe.gov/bes/BESfacilities.htm

24. **J.F. Moore**
January 14, 2008

@DB,

In no way do I want to debate HEP versus other science priorities, but I did find some misconceptions in your comment that I think do need to be clarified.

1. The user facilities named are in a different office and budget category than HEP, called basic energy sciences (BES).

2. A small minority of those facilities are "conversions of old HEP facilities"; the APS, NSLS, and ALS, for example are 100% greenfield, many others are modestly leveraged.

3. Cuts to BES affect programs at all of these facilities, not just at Argonne, so the whole user community is competing for dwindling beamtime.

4. It is not always simple for a user to simply move to a different facility. Some are based locally, others have experiments that took years to build. Perhaps a useful analogy would be a very small detector for an HEP machine and its associated collaboration.

5. The users of these facilities include many physicists, biologists, and engineers as well as chemists and materials scientists. Industry represents a small fraction of the users. In addition, the staff at these places contribute to accelerator technology; many freely move between BES and HEP machines (or the foreign equivalent).

6. Cuts at Argonne are not just to IPNS and APS – for example, there is a high energy physics division that is obviously affected. The budget hasn't resolved at the level of the smaller programmatic divisions yet; it was simply bad enough overall that lab management recognized it had to make some drastic changes immediately by closing

IPNS.

My initial comment was just meant to point out that I think, for whatever political reason, the defense of ANLs budget seems to be stronger than FNAL at the moment – not that I think it is proper or justified at all. History has demonstrated that when scientists attack each other over budgets that usually everybody involved loses.

25. **Zathras**
January 14, 2008

J.F Moore,

In your response to me, you are comparing apples to oranges. The fact is that big pharm has lobbied strongly for all the big dollar biology and chemistry projects, such as the Human Genome Project. In contrast, there has not been significant industry lobbying (at least in Congress) for the big physics projects.

While it is true that there may not be specific lobbying for most of the smaller bio/chem projects, there is still a trickle down effect such that, once the people who need to know understand the importance of the big bio/chem projects they are more likely to understand the importance of the smaller projects. The smaller projects may not be directly connected to the big ones, but the smaller project PI's still know how to word things to make them appear related. Almost any human genetics grant proposal or other funding request brings up the HMG.

26. **DB**
January 14, 2008

JF,
Your initial comment drew attention to your perception of the governor's possible preferential defence of Argonne over Fermilab. Argonne is now principally funded by BES while Fermilab is mainly HEP funded.
I was simply drawing attention to what is the major trend within DOE laboratories formerly dedicated to HEP research, namely, their repositioning as BES-funded user facilities for use by materials scientists and chemists with a view to doing research with practical applications to industral problems, while leaving the pursuit of HEP increasingly to foreign powers.
Right now, SLAC is the typical example: BABAR is shut down early, while parts of the old linac are being converted to house the LCLS, whose funding will transition from HEP/BES funding this year to full funding by BES next year.
While some believe that the recent cuts to the HEP budget are the result of Congressional shenanigans and revenge, others view this as a smokescreen which obscures the continued implementation of a well-thought-out strategic decision.
If, as you seem to suspect, the governor is pushing Argonne over Fermilab, then he is also pushing BES over HEP (and yes, I know there are some HEP projects at Argonne) and perhaps he is doing this because he believes this approach is consistent with federal priorities.
I am not interested in debating the merits of such priorities, I just want to understand what is really going on.

27. **J.F.**
January 14, 2008

@Zathras – I think we disagree on too much to comfortably hash it out here.

@DB – You are certainly right about the trends. I was mainly nitpicking above, but I also want to deflate the common assumption that HEP folks seem to make: that all other scientists have no serious budget problems.

Thanks to Peter for hosting a venue where some of us can puzzle this out, and hopefully share info as its learned.

28. **DB**
January 15, 2008

JF,
You might find the following just published interview with Stephen Weinberg of interest.
http://www.thespacereview.com/article/1037/1
In it he spends a good deal of time attacking the budget priorities of NASA.
The example of the 1 billion $ European-built Alpha Magnetic Spectrometer which NASA now says it won't launch is yet another interesting example of how the US is treating its international "partners".

29. **Al Newmann**
January 15, 2008

This seems to me to be just another example of the Great Sucking Sound Ross Perot talked about. The US continues to lose industrial and scientific capabilities to foreign lands. It will not be too much longer until the only jobs left in the US will be Government programs for managing the unemployed and protecting Government officials and our ruling elite from the poor, hungry, and homeless.

30. **nobody**
January 16, 2008

Why do physicists so often attack the funding of other science projects?

Weinberg, in his interview, argues at length that NASA funds would be better spent on other scientific research.

The budget is about $1.2 trillion. NASA's budget is $9 billion. Some NASA funds do help science. So why does Weinberg not complain about expenditures in the remainder of the budget, most of which does not help science in any way?

I am not trying to make a political point here – I am truthfully confused at why scientists so often attack other scientists' funding. Wouldn't it be more productive for scientists to argue that science as a whole should be better funded?

(I have heard the red herring that science funding is a fixed pool so it's a zero-sum game, but that's false. In the 60s, for example, both NASA and research science were much better funded than they are now.)

31. **Peter Woit**
January 16, 2008

nobody,

I think one could describe Weinberg's not as attacking the funding of any science projects, but the funding of manned space missions, which are not the same thing. In practice, the problem of such funding causing science projects to end up defunded at NASA is a very real one, and I think most scientists share Weinberg's view of the problem and frustration about what is happening. Just saying that everything should get funded isn't very realistic or likely to be taken very seriously.

32. **Arun**
    January 29, 2008

    Via CapitalistImperialistPig – Bush said this in the State of the Union address:

    http://www.whitehouse.gov/stateoftheunion/2008/index.html

    To keep America competitive into the future, we must trust in the skill of our scientists and engineers and empower them to pursue the breakthroughs of tomorrow. Last year, Congress passed legislation supporting the American Competitiveness Initiative, but never followed through with the funding. This funding is essential to keeping our scientific edge. So I ask Congress to double federal support for critical basic research in the physical sciences and ensure America remains the most dynamic nation on Earth. (Applause.)

33. **Peter Woit**
    January 29, 2008

    Arun,

    Looks just like a replay of last year: the administration will propose sizable increases. Quite likely Congressional committees will hold hearings and approve them. Then, several months into the fiscal year, the actual budget will come out.

    This is an election year, so I doubt there will be a budget before early November, and depending on what the results are, perhaps the new budget won't happen until next January, after the new Congress and president are in place.

Update on Plagiarism Scandal

January 10, 2008
Categories: Uncategorized

Last summer I wrote here about a plagiarism scandal involving more than 60 arXiv preprints, more than thirty of which were refereed and published in at least 18 different physics journals, some of them quite prestigious ones (see also the page at Eureka Journal Watch). At the time I wondered what action the journals involved in this scandal would take in response to it. Nearly six months later the answer to this question is now in: essentially none at all. As far as I can tell, almost uniformly the journals involved don't seem to have a problem at all with being used to publish plagiarized material.

Unlike the journals, the arXiv has taken action. It has withdrawn the papers, replaced their abstracts with lists of where they plagiarized from, and put up a web-page explaining all of this. After the scandal became public, one journal, JHEP, did withdraw the one rather egregious example of plagiarism it had published. This was only done after JHEP originally refused to do anything about this when first contacted last March, arguing that since the plagiarized articles were cited in the paper it was all right, and besides, they would only consider doing something if the plagiarized authors filed a formal complaint. Copies of the correspondence about this (and much else) are at this web-site.

The nature of the plagiarism varied greatly among the papers withdrawn by the arXiv. Sometimes all that was involved was self-plagiarism (large parts of one paper were identical with others submitted by some of the same authors), but mostly what was being plagiarized was the contents of papers by others. Mustafa Salti, a graduate student at METU, had his name on 40 of the withdrawn papers, many of which have been published in well-known journals. I checked a few of the online published journal articles corresponding to the withdrawn papers and, besides the JHEP paper, I didn't find any others where the online journal article gave any indication that the paper was known to be plagiarized.

A more complicated case is that of Ihsan Yilmaz, where the arXiv lists three of his eight arXiv preprints as withdrawn due to plagiarism and one as withdrawn due to "excessive overlap" with two other papers of which he was co-author. Very recently one of his Physical Review D papers, a paper that was not one of the ones on the arXiv, was retracted with the notation:

> The author withdraws this article from publication because it copies text, totaling more than half of the article, from the articles listed below. The author apologizes to the authors of these papers and to the publishers whose copyright was violated.

After the scandal broke, Yilmaz had a letter published in Nature where he justified the sort of plagiarism found in his articles, claiming "using beautiful sentences from other studies on the same subject in our introductions is not unusual." Evidently the editors of the journal General Relativity and Gravitation agreed with Yilmaz. They decided not to do anything about the papers they had published that were withdrawn from the arXiv, writing an editorial in which they defended the papers, while noting that "we do not regard such word for word copying of introductory and descriptive material by others as acceptable."

I heard about the GRG editorial via an e-mail from a group of the faculty at METU, who write that:

> The note is clearly quite unacceptable and insufficient in the fight against plagiarism. We cannot help but ask whether the Editors seriously believe that those who cannot compose their own sentences are in fact capable of producing genuine research worthy of publishing in General Relativity and Gravitation.

and note the retraction of the Physical Review D article, which they regard as a much more appropriate response

Update: Someone helpfully sent me pdfs of the two GRG articles, marked up to identify the plagiarized passages. Looking at these, I find it hard to understand why any journal would not withdraw such papers if they made the mistake of publishing them.

- Topological defect solutions in the spherically symmetric space-time admitting conformal motion, I.Yilmaz, M. Aygun and S. Aygun. This was gr-qc/0607104, published version Gen.Rel.Grav. 37 (2005) 2093-2104. The arXiv describes it as "having excessive overlap with the following papers also written by the authors or their collaborators: hep-th/0505013 and 0705.2930."
- Magnetized Quark and Strange Quark Matter in the Spherical Symmetric Space-Time Admitting Conformal Motion, C. Aktas and I. Yilmaz. This was arXiv:0705.2930, published version Gen.Rel.Grav. 39 (2007) 849-862. The arXiv describes it as "it plagiarizes astro-ph/0611537, astro-ph/0506256, astro-ph/0203033, astro-ph/0311128, gr-qc/0505144, astro-ph/0611460, and astro-ph/0610840."

Update: The journal Astrophysics and Space Science is retracting four of the plagiarized papers, by putting up errata on-line which appeared today and are dated January 11, 2008, saying:

> After investigation and at the request of the President of the Middle East Technical University (METU), Ankara, Turkey, the Editors of Astrophysics and Space Science have decided to retract this paper due to extensive plagiarism of work by others.

The papers involved are gr-qc/0505079, gr-qc/0602012, gr-qc/0508018, gr-qc/0509022.

Comments

1. **functor**
   January 11, 2008

   The reaction from some folks with secure jobs will be – no one is reading these papers anyway, so in the end the problem takes care of itself.

   The problem comes when one is competing for a job with the young guy with 40 publications in a system where all that matters in job applications is the number of papers published weighted by impact factor. Or when the dean with whom he is plagiarizing is the dean of the school to which one is applying for a job. Then this is a serious matter.

   The other observation is this: folks learn how to behave from their advisors and the other folks in their environment when they are grad students and postdocs. Too many basically decent folks learn this way to think that awful habits are professional and normal. This is why it is important that there be voices exposing what goes on.

2. **functor**
   January 11, 2008

   The GRG editorial is not so bad. An author who copies word for word introductory material from his own article is in no sense a plagiarist (can one plagiarize oneself?). This person has done nothing unethical if the new article, in which the copied introductory material is used, reports substantially different results than did the original article. What's so horrendous about copying one's own definitions? If one quotes one's own theorems, one might very well have good reason to quote them as one wrote them originally, particularly if one wrote the thing well the first time. There is a problem if the author is submitting to different journals articles which are essentially the same, in the sense that the results they report are essentially the same; this is unethical, though it is also not plagiarism – it's also quite common, at least in a mollified form

– we all know researchers who publish four papers on a given topic when one would have been enough – and we know they do this to inflate their paper counts (and their citation counts – sometimes they and their collaborators publish a series of interciting and repetetive papers on the same theme) – and many of them do this without seeing anything wrong with it – rather, they think this is what is their job – publishing papers. This is unethical because it means the originality of the papers submitted is misrepresented and if the paper is published space is taken up by something repetetive, when it could have been used to publish something noval.

If copying is genuinely limited to copying one's own introductory material, I don't see much wrong with it – the problem is that in the cases identified by the ArXiv administrators this was not what happened.

3. **Tansu KUCUKONCU , PhD**
   January 11, 2008

   Nothing happened to 15 plagiarist with 70 plagiarised publication
   announced by arXiv.
   Education writers of some biggest nation-wide journals did not write anything about arXiv plagiarism scandal.
   In spite of this, arXiv scandal became the most popular mass plagiarism scandal which found place in Turkish media history.
   ————————————
   Osman Demircan announced himself as the investigator of 2007 COMU Plagiarism Ring (6 plagiarist, 20+ plagiarised publications) declared by arXiv.
   First day he spoke to journals :
   "These are not plagiarised.
   These are libels by Turkish and foreign scientists who are against Turkey."
   ————————————
   Who is Osman Demircan :
   He is vice president of COMU since more than 8 years who decides who can work in COMU and who must be fired only according to his and his rings' partisanship criteria.
   He is a member of physics dept. which the 6 plagiarists of COMU belong to.
   He gave jobs in COMU to all these 6 plagiarist.
   He is the head of this plagiarism ring, and much more.
   ————————————
   In 2001 and 2002 he claimed me to YOK (Higher Education Council; or the Higher Ideologic Despotic Counsil) and other university and
   wrote that I should be dismissed since I am guilty since I'm a PhD student in that other university.
   He illegally made me dismissed me from PhD education just a few months before completion of it.
   He is one of the main organizers of the underground relations who illegally prevented me to have my PhD diploma for 5 years.

4. **Peter Woit**
   January 11, 2008

   functor,

   The problem with the GRG editorial is that this is not just about authors copying some small amounts of text from the section of another of their articles. Sure, they're nothing especially wrong with that, and I don't think the arXiv would act to withdraw a paper because of that. In the case of one of the GRG papers, the copying was from other people's papers, and in the judgment of the arXiv administrators, was extensive enough to make them withdraw the paper. The judgment of the GRG editors was very different, not to take any action at all, even not to add a note that extensive parts of the paper were plagiarized from others. Lacking the arXiv's software, I'm not able to automatically identify which parts of the GRG paper are plagiarized, but I trust them to not have withdrawn a paper simply because of small amounts of use of other people's language in an introduction.

   One other thing to keep in mind is the author's retraction note for his PRD paper, where he acknowledges that more than half of the text of the paper was plagiarized.

5. **Peter Shor**
   January 11, 2008

   I wonder whether these journal editors are doing nothing because they are lazy, because they are embarassed that their journals accepted these papers, or because they don't see anything wrong with plagiarism. I'm not happy with any of these reasons for inaction.

   This is somewhat off-topic, and I don't want to encourage excessive splitting of results over several papers, but I do want to give a small word of caution. There is a danger in combining all your results into one big paper. If you stick a result into your big paper which is only tangentially related, people may not realize that it is there, and may publish other papers duplicating your result.

   I have come to conclusion that the right way to judge whether you should split your paper is that every paper should have one story to tell (it may be a long and complicated story, or a short and simple one), and anything that doesn't fit into this story should be put into a different paper.

6. **Peter Woit**
   January 11, 2008

   Someone helpfully sent me pdfs of the GRG articles, marked up to identify the plagiarized portions. See the update at the end of this posting for links to these.

7. **ali**
   January 11, 2008

   I think the university involved in this scandal is totally rotten. The president of the university apparently tried to cover up the scandal and had it not leaked to the media, they would not do anything about it. Another issue I am concerned about is the responsibility of the supervisors of the Ph.D. students expelled for plagiarism. Where were these folks while the students were publishing plagiarised papers on their own? I think the guilt lies way higher in the rank in this case and the university tried to cover up the issue not to punish the supervisors and as far as I am aware, no action was taken against them in any way.

8. **Scott Aaronson**
   January 11, 2008

   The next time anyone tries to tell me how important traditional journals are for quality control, and how conferences, the arXiv, etc. just don't provide high enough standards, I will show them the following "cut & paste is OK with us!" letter from JHEP, which I think deserves a special place in academic history.

   Dear Professor Akbulut,

   We have looked to your letter regarding plagiarism.

First of all, in matters of plagiarism it is the injured party that must take action. We are not involved in administering justice.

The authors of the paper in question seem to cite the articles from which they copy sentences or paragraphs. This weakens the case.

It may be that the paper should not have been published and that thereferee erred. Unfortunately weak papers get sometimes published.This may happen when the work is in a rather minor subject or not in anactive and competitive field. If the results are oustanding or contradict well known physics this would not happen.

Therefore we fear that we cannot help you in this case.

Sincerely yours,
JHEP Journal

9. **Jimbo**
January 11, 2008

I used to teach upper-div physics at one of the universities in Oregon. After grading mid-terms using an `instructor's-only' solution manual provided by the publisher of the text, I noticed one student repeatedly gave answers which were verbatim copies of the ones in my manual.
I showed them to the chair, undeniable evidence of cheating by a physics senior, only to be told in so many words "Tut, tut, my boy: work around it "!!!
So these journals not being overly perturbed by plagiarism is ALL in the spirit of the age: Go with the flow…Don't rock the boat….
I chose to rock the boat and failed the student.

10. **wb**
January 12, 2008

As a journal editor I find the letter quoted by Scott Aaronson disturbing in several respects. Authorship and attribution are part of the reward and recognition system of science. Peer-reviewed journals play a prominent role in that system. While it may be the that as editors we are not "instruments of justice," neither should we be the instruments of fraud and misrepresentation. Publication of plagiarized work does harm the journal by lowering its academic and ethical credibility; a journal and its editors does have standing as an injured party.

Rejection of papers that misrepresent authorship and even informing an authors institution of academic misconduct (after appropriate procedures) is part of our ethical responsibility. The inclusion of a citation is not exculpatory when a author represents substantial potions of another's work as his own. That applies whether one plagiarizes others or himself (yes functor, self-plagiarism is recognized as a form of academic misconduct; it may also be a civil tort of copyright infringement). This past year I have rejected 4 papers for self-plagiarism.

I would be surprised if the large majority of editors of scientific journals did not have similar views. To be sure instances of misconduct do get b; hopefully with better plagiarism detection software on the horizon the number of such cases will diminish. Even so, good refereeing is our best line of defense.

11. **DB**
January 12, 2008

Jimbo, wb,

The practice of "not rocking the boat" and sweeping embarrassing incidents under the table is part of the "don't let's wash our dirty linen in public" philosophy that permeates most professions. Physics, to be fair, is probably a lot less culpable in this area than, for example, the medical profession, where lawsuits often fail when professional colleagues close ranks to protect "their own".

That journals would be reticent to act, I can understand, if not condone. But that JHEP would pen such a response as quoted above is astonishing. A massive gaffe. That journal better undertake some damage limitation, and quickly.

12. **functor**
January 12, 2008

Peter,

You're right that an article which plagiarized (necessarily work of other authors) should be rescinded, and that in that sense the GRG editorial is inadequate. Whether this is due to naivete or to pressure from the publisher or to some other motivation, I cannot say.

There are journals that behave properly; there are many more that do not. The best ones are the ones for which the profit motive is not important, often those published by university departments or professional societies. The problematics journals are, no surprise, mostly published by Elsevier, Springer, etc.

What's going on with the commercial journals is simple. There is a cadre of professors who want to publish papers, and want to do so in journals with big impact factors; these journals provide that service, though at a handsome price (Which is, however, born by the researcher's institution's library's budget rather than the researcher). Some of these unscrupulous individuals wind up as editors, and their editorial motivations are anything but publishing the best papers, or seeing to it that articles are refereed in a timely or fair fashion. There's certainly no interest in bringing attention upon themselves of publishers of nonsense with low standards.

Look at the quality of the editing of the English in many of these publications. It is lousy. Any journal publishing in English but unable or unwilling to make the effort to guarantee that the articles which it publishes are written in correct English is likely cutting other corners too. This happens much less in certain journals than in others – it is one indicator of the seriousness of the editors.

Outright plagiarism and dishonest copying of ideas are huge problems. Repetitive publication of the same result is a problem too, but of a different nature; it is stupid, perhaps unethical, but not as fundamentally dishonest. Decent blokes can be deceived into thinking it a reasonable way to go. There are a lot of folks not having success with their research programs, but with a lot invested in trying to, with families to feed and mortgages or rent to pay, who lack the courage to suffer the consequences of their own limitations and engage in questionable but easily rationalized practices; this is humanity. Plagiarists and thieves are a different matter.

The upper tier of US universities has less of this nonsense, but in countries with undeveloped or developing research communities it is more common – there are not enough researchers of quality, and their voices are perhaps not even heard, so that even those within the community of serious (in the professional sense) researchers are able to tell the good from the bad. Also if one learns in an environment in which dishonest practices are the norm, then one learns that those practices are ok. This is why often famous researcher A develops a legion of students who behave like a mafia; they learned more than physics from A.

13. **a.k.**
January 12, 2008

..Tansu, characterizing the whole turkish scientific community as modeling their scientific research on mafia-like structures and habits seems possibly, not that I had deeper knowledges of the context involved, a bit too stereotype. Even if it matches your personal experience, it may suffice to feed well-known stereotypes in the 'western' world, regarding the scientific culture of islamic countries. As it seems the above linked two pdf-files mostly display self-plagiarism (the blue marks?), and some copy&paste of more or less peripheral blah-blah, which could clearly be induced by insufficient mastery of the english language (one could wonder how many US-scientists spoke turkish, by the way). So while multiplying its own contributions by excessive self-plagiarism *is* unethical, at least from my point of view copying motivating verbal formulations in the exact sciences to compensate for insufficient english is not, one should possibly focus on the actual *content* of the papers in question, it is not impossible to plagiarize the essential content of whole books without even using one sentence of the plagiarized work explicitly. It is obvious that, again , the 'little fishes' get all the attention while the 'big ones' remain in shades.

14. **Peter Woit**
    January 12, 2008

    DB,

    I think JHEP already took as much damage control as they intend, by withdrawing the paper. The e-mail quoted was sent long before this became public, at which point they seem to have realized that their response to the e-mail was untenable.

    I suspect that if one contacts any of the rest of the journals involved to ask why they don't withdraw the papers, one will get a similar response. Unless you're a member of the press or one of the plagiarized authors threatening legal action on copyright issues, in which case they might actually do something.

    The GRG response seems more disturbing to me. Ultimately JHEP did the right thing, and changed their initial untenable position, which was in a private e-mail. The GRG editors considered these papers carefully, then despite the obvious serious problems with them, publicly defended them and refused to withdraw them.

15. **Peter Woit**
    January 12, 2008

    a.k.,

    "mostly display self-plagiarism"

    I can't believe we're looking at the same files. In the second one, none of the plagiarism is self-plagiarism, and most of the first half of the paper is nothing but directly plagiarized material from other papers. In the first, there is some self-plagiarism, but also lots of plagiarism from other sources. The blue section (which is the main content of the paper) is described not as word for word plagiarism, but as following closely two other papers which are not cited, one of which is by the same authors, one of which isn't.

16. **a.k.**
    January 12, 2008

    ..I wasn't aware of the exact meaning of the 'blue marks', if the second paper on which this section relies, is not at least associated to the working environment of the authors, it is without any doubt severe (non-self) plagiarism. In the second paper, the first half seemed more or less what I characterized as blah-blah, as long as at least most of this plagiarized material is taken from cited papers, this could still be a 'boundary case'. In any case, the affair also puts a light on isolated scientific contexts, the best way to avoid plagiarism is not by electronic tools but by global non-formal communication and personal networks, which could detect those attempts very early. In this sense, one should avoid putting the stigma of mafia-like structures and dishonesty on whole scientific communities and cultures, this does not help to avoid but to enforce exactly those structures.

17. **Jack Lothian**
    January 13, 2008

    Self plagiarism is persistent and wide spread. I know of a number of well known names in numerous fields who recycle essentially the same paper. The level of self plagiarism varies tremendously from mild variants of previous papers that have been mostly re-written to almost perfect copies. Stopping this is almost hopeless for several reasons. First, submission, acceptance, publication cycles are long & it is easy for multiple copies to be in the system unknown. Second, who is going to cross read all this stuff? Third where do we draw the line here? Fourth, is recycling your own writings & ideas a problem? Lastly in all its manifestations, this problem is huge for all journals.

    I see even severe self-plagiarism as a judgmental call by the journal's referees and editors. It depends on their goals, policies or standards. Low tolerance standards for self-plagiarism may be a negative reflection on the journal but not on the author's morals. I do not see a big issue here.

    Plagiarism of another author is another issue though. A clear line has been crossed.

18. **Jack Lothian**
    January 13, 2008

    It should be noted that legal exclusive rights such as copywrite trademark & patent all clearly state that no one has exclusive rights to either ideas or words. People just are not allowed to duplicate exactly how you use the ideas or words.

19. **Roger**
    January 13, 2008

    I see self-plagiarism as simply scientists "playing the career game". To reduce its incidence job and promotion awarding bodies have to look beyond a paper count. I think this is easier said than done. The culture of "publish (a lot) or die" is everywhere and I can't see any serious moves to tackle it.

    As an experimentalist, I'm lucky that I've never had the pressure to self-plagiarise and produce X papers a year. On a large collaboration it is normal and accepted that an active physicist can only be expected to perform the data analysis for and publish around 1 paper per year. My other papers such as conference and summer school proceedings will undoubtedly look very similar to each other (though never word-for-word identical). However, it would surprise me if anyone could legitimately classify them as examples of unethical self-plagiarism – the remits of each invited paper were often the same.

20. **mo**
    January 13, 2008

    There is one more dimension to this plagiarism scandal: withdrawing papers published online, or even altering online content smacks of rewriting history and compromising the historical record. (I mean JHEP. As is well known the print edition of JHEP ceased with 2000 and from 2001 and on JHEP is published online only.) Once you start on this slippery road with the best of intentions you can end up in hell.

21. **Moshe**
    January 13, 2008

Scott, isn't your comment along the lines of "let's not bother doing something if it cannot be done perfectly"? just imagine a world when you don't have to pass any bar before your publication appears on your CV or in a popular science magazine (OK, bad example, but hopefully you get my point).

22. **milkshake**
January 14, 2008

there was a high-profile scandal like this, in organic chemistry last year.

http://pubs.acs.org/isubscribe/journals/cen/85/i11/html/8511sci1.html

For some years professor Armando Cordova from university of Lund has been developing a reputation of a odious young man who acquires information about unpublished research from competing groups and repackages them as his own "contribution". Eventually he got caught in the act when he tried to rip-off results from another group – and he clearly misunderstood the results that he was trying to pass as his own!

The investigation done by his university concluded that yes, Cordova is the unscrupulous bastard that everybody says he is – and the outcome was to give him a warning not to do it againg in the future – and provide him ethical counceling. The department head would also oversee Cordovas future publication activity. (Meanwhile Cordova tried to re-publish yet another ethically-challenged paper.)

23. **milkshake**
January 14, 2008

I realized Cordova is at Stockholm Uni, not Lund. Sorry for the error.

24. **amused**
January 14, 2008

To Scott Aaronson and anyone else who thinks that journals are ineffective for quality control I issue the following challenge:

(a) Write a deliberately trivial/uninteresting paper on an issue of central importance for some subcommunity of serious researchers (the specific choice of topic is yours) and see if you can get it accepted for publication in a major journal, e.g. one of the Physical Review journals. (Of course, if you actually manage to do this you should tell the editors afterwards that it was just an experiment to test publication standards and that they shouldn't publish the paper.)

or

(b) Same as (a), except the issue addressed in the paper may be anything you like (not necessarily of interest to any serious researchers) and the target journal you have to get it accepted in is Physical Review Letters.

And no, it isn't enough just to find some previously published paper that you consider to be an example of (a) or (b). If the quality control is really as bad as you claim it is then you should easily be able to manufacture such a paper yourself!

Imo the current plagiarism spectacles don't disprove the value of journals; they simply show that when evaluating someones publication record one needs to consider not just the names of the journals and number of publications but also the topics and issues addressed in the papers (whether or not serious people care about them, how centrally important they are in the general scheme of things..). (Of course, for PRL publications the latter consideration is superfluous 😉) I've already elaborated on the reasons for this in tedious detail elsewhere so will try to resist doing it again here.

25. **Peter Woit**
January 14, 2008

The Journal Astrophysics and Space Science has just announced that they are retracting four of the plagiarized papers, noting that this was done "at the request of the President" of the METU. See the update to the posting.

26. **Peter Woit**
January 14, 2008

It's interesting to see here that people from fields outside theoretical physics (e.g. Scott and Peter Shor) are appalled by this story, those from within (e.g. Moshe and amused) seem mainly interested in defending the current refereeing system.

I don't think there's any need to try to submit fraudulent papers to a range of theoretical physics journals to see what happens. The experiment has been done now by Salti et. al, and the results are known. The question is what should be done about the fact that the refereeing system in this field is seriously broken.

To keep amused happy, I'll stipulate that this doesn't apply to PRL, and advise our librarians that, when they cancel all subscriptions to theoretical physics journals on the grounds that they're no longer worth the paper they're not even printed on anymore, PRL should be spared.

27. **Brett**
January 14, 2008

I am a particle theorist who is certainly outraged by this plagiarism, and the reticence of some journals to withdraw the offending papers is both surprising and worrying. However, I can see a reason why theoretical physicists in particular might be less phased by this than researchers in other fields: because new research results in theoretical physics are not communicated via journals.

28. **David Nataf**
January 14, 2008

Do you think it would have been easy to verify that all the material was original, is there software available for this that does this well?

29. **Peter Woit**
January 14, 2008

David,

The arXiv has some software for this, I don't know if it's publicly available. Once you know that there is plagiarism involved, it's fairly easy to find the sources just by picking phrases from the article and using Google. One can argue about whether the referee should have realized that the paper was plagiarized, but once the plagiarism became known, it's remarkable that the journals involved were unwilling to immediately retract the papers (and many have still not been retracted).

30. **Moshe**
January 14, 2008

In talking to people on the subject of journals and peer review, the main difference I see is where people are from, and that includes myself. When I was a postdoc, benefiting from a constant stream of inside information, I too was tempted to think that most people know which papers are correct and worthwhile without having to rely on other people's judgment. I now realize this is not true, and view peer review as service to the community at large. By and large I still think it is done well in my community.

So, I am not convinced that there is a wide-spread problem, certainly not in the hep-th community I am part of. In any event, I am confused about the logic of the argument of those outraged by what they see as lack of quality control: surely getting rid of journals and peer review altogether is only going to make thing worse…

31. **AGeek**
January 14, 2008

Milkshake, that (the Cordova scandal at Stockholm U) is interesting. If you enjoy this kind of digging, see if you can find the (pretty obvious) link to JHEP and JCAP…

32. **Peter Woit**
January 14, 2008

Moshe,

I don't see anyone here arguing for the elimination of all peer review. Rather, there is a very real question about whether many journals actually are doing a legitimate job of it. If they aren't willing or able to put the effort necessary into it, they shouldn't be selling a product that claims to be something it isn't. The attitude towards plagiarism demonstrated by the GRG editors and by whoever at JHEP responded to the initial plagiarism complaint should be disturbing for this reason, even though they don't seem to bother you.

Several people have pointed out to me that the problem of journals publishing plagiarized or incompetent articles is one that people at elite institutions in the West are able to ignore because they can just ignore those articles, and the people making hiring decisions are able to recognize that they aren't serious scientific work. For people at less elite institutions, where hiring decisions are often in the hands of authorities able to only count publications and journal impact factors, the problem caused by the behavior of these journals is very serious. In particular in this case I think it seems that what happened was that this sort of plagiarism worked well for one or more people in terms of advancing their career, encouraging others to join in and do the same thing. Those that weren't willing to work this way had to compete for jobs with those who were. For such people, seeing the refusal of journal editors to do anything about this is profoundly discouraging.

33. **amused**
January 14, 2008

Peter,

Scott has a couple of papers in Phys.Rev.A., looks like he might be a semi-physicist.. Same goes for Peter Shor, who seems to have quite a fondness for PRL..

My impression (and someone please correct me if I'm wrong) is that none of the papers in this scandal can be characterized as addressing issues of central importance to some subcommunity of serious researchers. So Salti and his fellow plagiarists haven't already done the experiment I challenged Scott to perform. For this class of papers my impression is that refereeing standards are generally pretty good, and I expect the odds of Scott being able to complete the challenge are very small. When he fails I hope he will reconsider his view that journals are ineffective for quality control.

Besides that, I see this scandal as being the extreme edge of the well-known phenomenon that lots of rubbish is being published in physics journals. The minor ones are full of it, and some of it seeps through to the major ones. That is of course a serious problem for people working at institutions where they are evaluated simply by counting number of publications. The solution: stop doing it! That might be easier said than done though, since I imagine that at many such institutions the people with power got there through publishing rubbish in junk journals and won't be keen to change a system that worked for them. But simply getting rid of journals isn't going to solve the problem…

At any rate, thanks for sparing PRL 😉

34. **Moshe**
January 14, 2008

Peter, it is a small step between "the journal system is broken" (a statement I disagree with) to "let's not bother with journals, everyone reads the ArXiv anyhow". But maybe this is not what Scott meant…in any event I think we both would like to see a stronger peer review system, any ideas on how to produce one? as you probably know JHEP decided to give a small financial reward to their referees, seems like a good start.

35. **Peter Woit**
January 14, 2008

Moshe,

I'm afraid I see things in a different order than you. It seems to me that "let's not bother with journals, everyone reads the arXiv anyhow" is already the de facto situation. Jacques Distler doesn't seem to have submitted some of his papers in recent years to journals and from what I can tell he's not the only one. Most particle theory papers are sent to JHEP to be published, and Mustafa Salti did a good job of showing what their standards are. The letter from JHEP responding to the fact that they had published a plagiarized paper is quite remarkable. If you are looking at a paper on the arXiv, you could check to see if it had been refereed and published in JHEP, but would that really tell you much? I suspect that people rarely actually do this, partly because of what "amused" describes as "lots of rubbish" being published in physics journals, including some in the major ones like JHEP.

Given that that's where we are, I think the problem is that people won't go to the next step and acknowledge that there even is a problem with the journals, partly since fewer people are paying any attention to them. The obvious answer to low refereeing standards is to raise them. That's could be done, but it's hard to get people to do if supposedly there is no problem.

While the problem of refereeing in this day and age is a complicated one, the question of papers involving significant amounts of plagiarism like the GRG ones isn't. They have no place in scientific journals, and if editors don't see this, it's hard to believe they're going to ever address even tougher problems.

36. **Moshe**
January 14, 2008

Yeah, there is a small minority of people who think journal publication is redundant, and I strongly disagree with them. Not sure about Jacques, never discussed the issue with him, but my impression from his comment was that Scott is leaning that way, and that as usual he may have interesting reasons for his position. Anyhow, looks like it is too late for that, maybe next time…

37. **functor**
January 15, 2008

Peter,

The point you make about what happens outside the elite institutions needs to be reiterated (it may happen inside too – I don't know, I'm not there). In a country such as Spain the use of paper counts and impact factor is institutionalized to the extent that often by law the ranking of candidates for positions or contracts is based on a score in which an impact factor weighted paper count plays a prominent part. This encourages self-replicating publications and has a corrosive effect on notions of what is a good researcher. The goal of every Spanish jefe is to be one of the ISI most-cited researchers, and this goal can be accomplished most easily by the following scheme: jefe and coauthors A and B and former students X, Y, Z, etc… write repetitive, silly papers of short length which are published in mediocre Springer and Elsevier journals with unjustifiably large impact factors and which cite other articles by the same authors (preferably a disjoint subset of said authors, because this avoids the self-citation problem); since no one else but the others in the circle is terribly interested in the properties of the twelve times iterated tangent bundle, it is almost guaranteed that the referee will be a sympathetic collaborator. After some years, researcher A has 100 papers, each with 3 or 4 citations, and he can present himself as a researcher of quality to bureaucrats and persons working in other areas, so he is easily funded and has no trouble ascending to the position of chair of the institute he founds, and in which he employs B, X, Y, Z (and maybe some students of a friend of Z in France).

Usually A does not exactly copy his own papers, but when A is operating in some small rural place rather than Madrid or Paris, he might go a bit further. Secure in the knowledge that absolutely no one is reading his papers, and that absolutely no one will read his papers (he assigns his students to read the papers of his thesis advisor in France, a very famous man, so that they will know how good he is, being the student of a famous man), he begins to copy them wholesale and send them for publication in obscure journals like the Former French Colony Low Energy Physics Journal (fictitious example which somehow has on the editorial board his friend B), and he rationalizes this behavior with the good feelings that come from having lent the prestige of his highly cited first world (well almost) name to a journal published in a developing country.

I suppose most of the readers of this blog can continue the story.

What creates the dynamics whereby this sort of behavior is rewarded and even encouraged is the false profesionalization of scientific inquiry and the weird conflation of frequency of publication with quality.

38. **Arun**
January 15, 2008

In all cases where I've seen "broken systems" it was because people were responding rationally to incentive systems, but the incentive systems were perverse. (Also, most people have the attitude, I didn't make this system, I just live with it.)

Every scientist ought to occasionally step back and review what it is that he/she really wants to accomplish and whether the "system" is helping them get there.

39. **Reynold**
January 15, 2008

One of the plagiarized papers (according to arXiv) is gr-qc/0011027. It was published in PRD and according to Spires it has 1 citation by other authors, 2 in total.

Its clone, gr-qc/0505079, published in Astrophys.Space Sci., has 37 citations, at least 15 of which are by non-Turkish authors.

It's interesting how the clone was so much more successful attracting citations than the original.

40. **JC**
January 15, 2008

Peter, David,

Isn't there some online service that many universities subscribe to, which checks for plagiarism in students' term papers against stuff that is online and/or from "essay mills" (like schoolsucks.com and others)?

Maybe arxiv has a program similar to this. I would imagine the algorithms would be very similar, in systematically comparing long strings of words + characters against one another.

41. **JC**
January 15, 2008

Article about arxiv plagiarism detector program.

42. **Off-topic noise**
January 15, 2008

I'm surprised by arxiv's stance on plagarism in papers. It may take 10^500 string theory papers to investigate the landscape fully, and most will achieve similar results (failures). In this case, plagarism (repetition) of the text in each paper would seem appropriate, whereas making up different wording for each paper's introductory paragraphs and conclusions is irrelevant because nobody is interested in reading 10^500 variations of the same basic message. The difference between each paper will be the numerical moduli values guessed for the particular Calabi-Yau being ruled out. Why bother making up different wording for each paper? Plagarism is sensible for such situations.

43. **JC**

"Plagiarism Detection in arXiv"
by Daria Sorokina, Johannes Gehrke, Simeon Warner, Paul Ginsparg

44. **Roger**
January 15, 2008

Reynold.
It may be that once a paper starts picking up citations (in this case by the Turkish physicists) it is somehow seen as having an impact. Other authors may well then be more willing to cite it as work which has been taken seriously by the community.

45. **a scientist**
January 17, 2008

I found this comment at the Ars Mathematica blog, made by prof. Irfan Acikgoz.

http://www.arsmathematica.net/archives/2007/08/22/plagiarism-at-arxiv/#comment-55199

does anybody have informations about this letter was or wasn't sent to arXiv and if the arXiv admins gave any answer?

thanks

46. **Peter Woit**
January 17, 2008

a scientist,

I assume that letter was sent, but don't know what if any response they got. There's nothing in it likely to have changed the minds of the people at the arXiv who decided to withdraw the paper. Three of the signatories of the letter are the authors of the JHEP paper that I provided a link to marked up to show the plagiarism. That paper is just about completely plagiarized, and their is no way to deny this.

47. **D. Eppstein**
January 18, 2008

Looking at the annotated pdfs, I'm struck by how they've cut together a mishmash of many sources. To someone more knowledgeable in the subject area, do these papers read as coherent arguments or do they seemingly flit from topic to topic in the same way that they cut from one plagiarized paper to another? If the latter, how did they ever get accepted?

48. **Takyon**
January 18, 2008

Reynold wrote that
"It's interesting how the clone was so much more successful attracting citations than the original."

Dear Reynold,
another interesting search would be to look who are cited in these plagiarized papers and also who cites these papers.

It may be possible that this mafia-like organization is more deep then what the community thinks.

49. **a scientist**
January 18, 2008

I am studying the subject of plagiarism as a science and communication sociologist.
The turkish plagiarsim scandal raised some complex questions: no doubt about plagiarsim, if not detected, can raise an "author" visibility and help his carrer. But it's true that if it is detected (and we see how it's easy to do it today), the sanctions are very strong.
So, why a researcher should run this mortal risk? this is the question I ask myself when I try to consider all the variables which affect the case. The first answer that I give to this question is that the search for visibility is a weak reason, if compared to the eventual destiny of the plagiarist. Then, I try to think for a moment how hard to treat are the concepts of originality and relevancy in a scientific communication context.

Acting out of the theoretical physics context it's a bit hard for me to analyze some specific aspects of your scientific communication.
That's why I'd like to ask you (Peter) and all the physicists who will reply, one question, that you may find silly:

I don't know exactly how many paper a year are published in theoretical phys, but from my data I can suppose that the number is expressed in terms of thousands.
My question, therefore, is:

is it reasonably and scientifically possible to produce thousands of papers every year in your field, which content being ORIGINAL and also RELEVANT for the progress of knowledge or are relevancy and originality two complex concepts, hardly translated in communication practices?

This is a very important point for me to understand how much the "publish or perish" pressure does affect the quantity and the quality of scientific literature and how much originality and relevancy are true features of this literature

Thanks in advance

50. **dr**
January 18, 2008

I have checked that the h-value of Salti=10 in WOS!

51. **Peter Woit**
January 18, 2008

a scientist,

Your estimate of several thousand papers/year in theoretical physics is the right order of magnitude. Most such papers now are on the arXiv, so you can get a good count just by looking at their yearly totals in the theoretical categories.

As for relevancy and originality, they're hard to quantify, and this varies by subfield. In a healthy subfield where progress is being made, while there are a lot of unoriginal papers everyone ignores, there are also a lot with something original, even if of a minor sort. Unfortunately, I think that particle theory and general relativity are not very healthy fields at this point, partly because the problems remaining to work on are very hard. When it is extremely hard to come up with something original and relevant, most of the literature ends up being papers that fail to do so. What's remarkable about this scandal is both the number of unoriginal plagiarized papers that got past referees, and the attitude of some of the journals after these were exposed. This situation is much worse than I've seen in other fields or at other times.

52. **Tansu KUCUKONCU , PhD**
January 18, 2008

"a scientist" ,
as I said above, in Turkey plagiarism and lots of other things done by partizans are unwritten policy. It's supported and protected.

Nothing happened to 15 Turkish plagiarists with ~70 plagiarism works announced by arxiv.

2 of them are from METU. Their education paused for a while.
That's all.
Moreover METU did not do this immediately.
Those two were assistants in METU. According to laws they must be fired.
But METU did not do this.
METU's academicians are discussing METU's behaviour between them.

The rest of the plagiarists are under protection of their universities.

——————————————–

Ramazan Aydin : head of the comu plagiarism ring.
president of comu for 8.5 years (till march 2007) who was promoted as president by junta.

Interesting thing he was a faculty of METU physics dept.
even he was president of comu.

Osman Demircan : 2nd head of the comu plagiarism ring.
vice president of comu for 9+ years who was the main partner of Ramazan Aydin.

Interesting thing he was a faculty of METU physics dept.
for a short term in 80's.

————————————

"a scientist"

if you are interested in and if you think that I can help you
in your research on plagiarism as a science and communication sociologist, you can communicate with me.
I have lots of material about Turkish plagiarism.

53. **amused**
January 18, 2008

a scientist,

I suggest you take a look at this Nature article about the scandal. It gives this explanation for why they were able to get away with it for so long, and presumably why they expected to be able to continue to get away with it:

"Many of the papers concern an obscure theory of gravity known as the Møller version of general relativity. Few people would be likely to check such work, allowing the students and professors to build their publication record without fear of being caught, says Ginsparg. "They were following the optimal strategy." "

As for why they did this to begin with, the explanation given by the Turkish prof at METU who caught them was this:

" "They're isolated, their English is bad, and they need to publish," says Sariolu. "So they plagiarize, I guess," he says of the alleged plagiarizers. "

As well as that, it sounds like what they were doing wasn't particularly unusual in the environment they were in.

However, one important thing that isn't at all clear from what I've read about this so far is the nature of the plagiarism. Did Salti & co plagiarise other peoples research results, or did they simply lift introductory and background material from others' papers? The former is much more serious than the latter, and imo the arxiv folks and journals should have stated explicitly which of these was the case when they retracted the papers. The default assumption when someone is accused of plagiarism is that they plagiarised research results, and if Salti & co didn't actually do this then I can understand them feeling hard done by in this situation.

Regarding the GRG editorial, I think it was actually quite reasonable. It was quite brave of the editors to decide not to retract the papers after they had already been retracted by the arxiv, and they gave a clear explanation of their reasons for not doing so. The point is that the actual research results of the papers were original and judged worthy of being published in GRG, and that is the most important thing. Having said that, it certainly doesn't give a good impression about the paper when the authors feel the need to fill up so much of the paper with introductory and background material that has already been written elsewhere. The normal thing to do would be to briefly summarize it and refer to the previous papers for the details. Otherwise it looks like the authors are just sticking it in in an attempt to distract from the fact that their original material in the paper is shallow and uninteresting.

Finally, let me just mention that it's not at all difficult to write lots of physics papers containing shallow and uninteresting results. If the topics and issues addressed are obscure then referees often can't be bothered to put in the time and effort to see how shallow the paper is and are likely to just take the easiest option and recommend publication, especially if the paper is submitted to a minor journal. On the other hand, if such a paper addresses an issue of central importance to a subcommunity of serious researchers then it will usually get found out and rejected.

54. **Peter Woit**
January 19, 2008

amused,

The Salti JHEP and two GRG papers, marked to show those parts of them whose plagiarized sources are known, are linked to from my posting. Note that it is entirely possible that some parts not marked as plagiarized are plagiarized, but the source is not known.

I strongly suggest that you look at these documents. In the Salti JHEP paper, there is very little there that is not direct plagiarism.

I don't think the GRG editorial accurately reflects the extent and nature of the plagiarism in the two papers it discusses, and note the retraction by PRD of one of the author's other papers as being more than one-half direct plagiarism.

Before defending the plaigiarists on the grounds that "what they were doing was not particularly unusual", you might want to think a bit about what it must be like to be an honest Turkish theorist, competing unsuccessfully with not-honest people who have long publications records built on plagiarism. Hearing that the editors of the publications involved won't do anything about this, and physicists like you think it's all right, is really maddening to them

55. **dr**
January 19, 2008

e. vagenas,yu-xiao liu,t. grammenos, i. radinschi,t. harko,w. schleich, r. sharma and a. pradhan had sent some mails to plagiarists.

http://sozluk.sourtimes.org/show.asp?t=fizikte+bilimsel+asirma+skandali

Did someone look at those people's publications?

56. **amused**
January 19, 2008

Peter,

Do you agree or disagree that it is important to distinguish between plagiarisms where the authors lifted research results and where they lifted introductory and background material? I had already looked at the 2nd GRG paper before writing the previous comment, and have just looked at the marked up JHEP paper. In both cases it is not at all obvious to me that the authors have plagiarised any previous research results. Did you or anyone else check this? In the case of the GRG papers it seems that the editors have seriously looked into this and concluded that the plagiarism consisted entirely of introductory and background material. And the authors seem to cite the papers from which they "borrowed", which is a mitigating factor.

"I don't think the GRG editorial accurately reflects the extent and nature of the plagiarism in the two papers it discusses,…"

How is the nature of the plagiarism different from what the editorial describes?

If I was an honest Turkish physicist I wouldn't be losing much sleep about colleagues getting away with lifting introductory and background materials from others' papers, as long as their research results were their own. The thing that would be maddening to me is that the Turkish system is apparently set up to reward those who publish lots of papers containing shallow and uninteresting results, rather than those who have the skill and put in the time and effort to produce interesting results (which takes longer and results in a lower number of publications).

By the way, I have some personal experience with this. At the time i was starting out in research and published my first few papers, I somehow acquired a "fanclub" of researchers in a certain developing nation (not Turkey) — they wrote a number of papers putting rather shallow and uninteresting (and sometimes simply wrong) twists on the stuff I had done, sometimes lifting background material verbatim from my papers (but always with a citation, and never to the extreme extent of Salti & co). Their papers were mostly published in lesser journals, but one got into NPB and another in PLB. I never found this upsetting, in fact i was amused and quite flattered. My main concern was that "serious" people might think I was part of their club and therefore dismiss my work without giving it a fair assessment. If this was happening to me it must surely have been happening to many others as well (there was nothing great about my papers), so it seems that this kind of plagiarism lite is not at all unusual and has probably been going on in many places for a long time.

57. **Peter Woit**
January 19, 2008

amused,

If a published paper contains large amounts of plagiarized material, I don't see the point of going through it line by line and arguing about what is "background" and what is "new". If a student I'm teaching hands in a paper that I see is half plagiarized text from other sources, I'm not going to argue with him about whether or not he has original ideas in the other half. Instead I'd tell him to never do this again, and rewrite the paper, in his own words, making explicitly clear what he has done that is original. If the GRG editors think that there are worthy research ideas in the two papers at issue, they should still have withdrawn the plagiarized versions and insisted that the authors provide a new unplagiarized version that makes clear what is their own original research and what isn't. As published, it is nearly impossible to separate out in those papers what is original and what isn't, certainly impossible for a typical reader who doesn't have access to the marked up pdfs.

The GRG editorial explicitly claims that in the first paper the only plagiarism is self-plagiarism, but if you look at the marked pdf, you will see that this is not true. Also, the way it is written, it does not make clear how extensive the plagiarism in these papers is. It's not an honest evaluation of the plagiarism in the papers, but an attempt to excuse it.

I just don't see why anyone thinks it's a good idea to bend over backwards to defend these papers. One look at the marked-up version should be enough to convince one that these are not things that belong in the scientific literature. Recall that this all broke when someone noticed that Salti, a grad student who, at his oral exam, didn't seem to understand what he was talking about, had 40 papers, many published in respectable journals. The situation is outrageous, and I just don't see why people want to defend the indefensible, other than in a misguided attempt to prop up a collapsed refereeing system.

58. **Tansu KUCUKONCU , PhD**
January 19, 2008

2 of 6 plagiarists of comu ring,
Sezgin Aygun and his wife Melis Aygun,
were my students.
They failed in my course.
They were very unqualified.
I lectured them when they were junior (3rd year ; 2nd semester)
students of comu phys. dept.
Till then more than %50 of their courses were empty.
They were unaware about what most of the courses in their transcripts were about.
This is the general view of comu and lots
of universities in Turkey.
Whole class had no hope about a career related to physics,
and were trying to have the right to be primary school teachers.

They were accepted to msc then phd, and as assistants
due to their political, mystical, and beneficial relations.
Grad education is worser than undergrad education in comu
and in lots of universities in Turkey.
The results are appearent.
You see what is taught and valueable in comu.

An assistant of comu physics dept. caught lots of phys. dept. students when cheating in the exam. What happened : comu punished the assistant, tried to end his job appointment, more than 1 year blocked him to start phd in other universities.

—————————————

amused,

"The thing that would be maddening to me is that the Turkish system is apparently set up to reward those who publish lots of papers containing shallow and uninteresting results, rather than those who have the skill and put in the time and effort to produce interesting results (which takes longer and results in a lower number of publications)."

There is one rule of the Turkish university system :
– there is no rule !
Junta order.
Acadocracy order.
Juristocracy cover.
A partizan without any qualification, without any publication
promoted always.
In most of the Turkish universities a scientist having very high qualifications regarded world-wide has no chance against a
partizan.
As expected there are lots of unqualified partizans.

These all occur in front of students and public.
Students learn that to obey the despots is valuable,
and honor, ethics, knowledge, human are worthless.

A few years ago, as a part of joining EU, Ethics law accepted for
who work for the state.
This law has exceptions : acadocracy, juristocracy, and miitary.

15 plagiarists announced by arxiv are not individual plagiarists or small plagiarist rings.
They are the mirror of Turkish university system.

In the explanations of 15 Turkish plagiarists' which are travelling in the internet, they are saying that the main target of who blame them for plagiarism is all Turkish physicists and all Turkish academia.

—————————————————

A few years ago a president of a university blamed for illegalities and sent to jail first time in Turkish history.
YOK (higher education council, or higer despotic council) president
with presidents of universities went to Ministry of Justice and threated the Minister, went to court and threated the juristocrats.
That time presiden of YOK was a law (constitution, organic law) professor.
YOK president said that
"to blame a president of a university for illegalities is to blame
republic, is to threat republic,
to defend that president is to defend the republic".
What happened :
– juristocrat who blamed that president fired,
all of his rights to work using his law diploma in Turkey were banned.
– juristocrats who sent that president to jail were sent to courts far away from that city.
– when in jail that president was still the president of that university.
– new juristocrats left that president.

————————————————-

Partizan plagiarists' strategy is similar.
Partizans' strategies are always the same.

59. **amused**
January 19, 2008

Peter,

The value of a paper, and the credit the authors get for it in the eyes of their peers, is determined primarily by original research results it contains. So I insist that plagiarism of results or ideas is much more serious than plagiarism of background material (and yes there is a clear distinction between them). Maybe we will just have to agree to disagree about this.

Anyway what can be done about this lifting of background material? In the future these authors will probably do the same but change the wordings by a small but sufficient amount to beat the plagiarism detectors. Somehow I just don't think this is a big deal in the general scheme of things. Physics research isn't about writing eloquent introductions etc, the point is to produce interesting new results.

"Recall that this all broke when someone noticed that Salti, a grad student who, at his oral exam, didn't seem to understand what he was talking about,…"

So what. Some people just don't perform well in those type of situations, get muddled, forget stuff etc. Physicists should be judged first and foremost on the original research results they produce. (It could be that Salti's role on the papers was just cut and paste, but his co-authors should be able to say what his contributions were.)

“I just don’t see why people want to defend the indefensible, other than in a misguided attempt to prop up a collapsed refereeing system.”

I’m not defending anything, just describing the situation as I see it. The system is semi-collapsed for papers addressing obscure issues (since few people can be bothered to properly referee them), but still seems to be working fine for papers addressing central physics issues.

60. **Peter Woit**
January 19, 2008

amused,

Yes, you are defending the indefensible, e.g. your excuses for Salti, and your defense of the idea that there’s nothing wrong with publishing heavily plagiarized papers as long as there’s something original in them somewhere.

It’s somewhat of a separate issue, but I also strongly disagree with your defense of the the current journal system as “working fine for papers addressing central physics issues.” A central physics issue is the testability of string theory, and there’s a flood of anthropic pseudo-science on the topic being published, if not in your darling PRL, then in JHEP, which is arguably the most prominent and respected place to publish HEP papers that are not letters. Even at the best journals, the quality of what is published is always going to depend upon what referees see as the current standards of what is good HEP research, and I fear that’s a monotonically decreasing standard. This standard may have gotten so low that even conventionally completely out of bounds behavior, like plagiarism, is now being defended as a legitimate part of scientific research.

61. **Ali**
January 19, 2008

Hi Peter,
I think (and all senior faculty at top tier instituions would agree with me) that the citations determine the fate of any paper so you can go ahead and produce 200 clone (i.e.plagiarised) papers in chinese physics letters that do not contain any new piece of physics in them. Needless to say, nobody will ever cite them and they will be lost in journal pages so the question is who cares? Nobody judges any scientist with his publication list these days for any academic job. It is your citations(or h-number) that count. If you have 200 garbage papers each of which has 3 citations you have 600 citations altogether and that is nothing. Therefore, your arguments do not hold. Those lengthy publication lists only impress people outside academia. It is a well-known fact that publications coming from third world countries garner very few citations so they do not contain any substance thus the long term impact is mimimal. Coauthor responsibility is a far more serious issue than plagiarism. In a 15 author Nature paper, what did the 9th author do for that paper really? Does his name really deserve to be there for instance?
Also the arguments made by some sources that the plagiarist students did not perform well during their undergrad years and in their qualifiers is also ridiculuous. From my experiences as a scientist, there is very little correlation between people’s performances in their qualifiers and their research performances. They may have been nervous etc. Again the central question is “Did these plagiarists produce substantial amount of new physics that was unknown before”? If the answer is yes, I think the papers are worth staying in the literature. I think this issue is that simple.

62. **Peter Woit**
January 19, 2008

Ali,

Obviously I don’t believe these plagiarized publications are going to get the people involved positions at top-tier research institutions in the US or Europe. The problem is that they have been used to get them positions in Turkey, over other, more competent and more honest physicists.

As for h-indices, from what one commenter says, Salti has a relatively high one of 10. I don’t understand why you and amused think it’s worthwhile to make up excuses for him, while assuming the faculty members who examined him and realized there was a problem were some kind of idiots. Obviously they have examined many, many students before, and this was a case they found unusual.

I happen to strongly disagree with you, amused and the editors of GRG about the whole idea of ignoring huge amounts of plagiarism in papers if you can find original ideas in the paper. There are very good reasons why plagiarism is considered anathema by most academics in all fields, and the amount of defense of plagiarism I’m seeing from theoretical physicists I find shocking. In any case, as far as I can tell the papers under discussion contain minimal, not “substantial” amounts of new physics. If the world’s greatest genius chose to submit a paper to a journal with a completely plagiarized introduction followed by revolutionary new results that won him a Nobel prize, I don’t see why he shouldn’t be told that such a thing could not be published, that he had to rewrite it in his own words.

63. **Ali**
January 19, 2008

Hi Peter,
I am originally from Turkey but my advanced degrees are not from there. Those two students involved in this pagiarism scandal are not going to get positions anywhere in turkish system. I can assure you that much. System may be broken but not that much. I am more concerned about the remaining senior folks whose names appear in the articles. Were they really aware of what had been going on and if so what is the level of their involvement? In what kind of university grad students can publish papers on their own without any supervisor’s approval? I mean this is not a gas station obviously.

64. **Coriolis**
January 19, 2008

It is hard to understand some of the commentators` arguments. Some people have no idea of what they are talking about. Let me just point out a couple of simple facts .

1) Ali thinks that these people will not get jobs. He can check the following link and see that some of these people are professors already (and one of them is a dean!)

http://arxiv.org/new/withdrawals.aug.07.html

2) One claimed that h-index of Salti is 10. Well, spend 2 more seconds to get a number that makes sense. His h-index less than
1 (ONE) if you remove his self-citations. In fact, do a careful count, you will observe that, removing the citations that he got from the other plagiarizers from Turkey (including his collaborators), his h-index becomes about 0.7.
Well, some might argue that even this number is good for a grad student. If so, let us continue our analysis and ask from which papers he got these citations (16 in total after, 7 `withdrawn’ papers are removed). If you look carefully, these citations come from the papers whose authors were heavily cited by these guys.
Just do a count of Xulu`s citations, for example.

Some commentators argue the following
1)OK Try to fish out some novel results in these papers, maybe there is some. (My answer, don`t be funny, 90% of the paper is plagiarized, whose job is it to fish for novelty out of this garbage ?)

2) OK they did get published, so what, they wont get jobs.
(My answer: you know nothing about this issue, don`t waste your time thinking about it)

Anyway, Phys Rev D, JHEP and Astrophysics and Space Science seem to have corrected their terrible mistake by withdrawing these articles. GRG, on the other hand, has lost real credibility.

65. **Coriolis**
January 19, 2008

Correction: My comment about the h-index is wrong. I meant the average citation per paper is less than 1. Sorry about that.

66. **Tansu KUCUKONCU , PhD**
January 19, 2008

Ali,

"Those two students involved in this pagiarism scandal are not going to get positions anywhere in turkish system."

On the contrary to the laws they are stiil assistants in turkish system.

Moreover nothing happened to members of the other plagiarism
rings.
Even, comu's plagiarist dean is still dean.

Turkish system has and had throughout its history lots of examples of this kind of trashes.
Some of them are internationally very famous cases like that of the empire of Turkish university system (a 50+ year-old case), like that of Alemdaroglu, the ex- president of Istanbul Uni..
These trashes include lots of university presidents, deans,
law professors, members of highest courts, deputies.

comu plagiarism rings choose their equippes from partizans
when choosing new grad students, new academicians for comu.
Honest qualified people has no chance against them.
Then leaders of this rings teach and conduct how to plagiarize.
Grad students' role is to obey the orders of their leaders.
This is the answer of your question :
"Were they really aware of what had been going on and if so what is the level of their involvement?"

comu plagiarism rings plagiarize not only journal and conference papers, but msc and phd theses. Even completely, without adding their one own word.
I have enough examples of plagiarized comu msc theses in my archieve.
I informed comu and YOK (higher education/despotism council)
several times about a completely plagiarized msc thesis approved by arxiv's plagiarist Husnu Baysal and Servet Senyucel.
At last they had an symbolic investigation about it and covered the subject. Investigator of that case was Mehmet Emin Ozel,
the head of comu's grad school for natural sciences, who was, for some years in 80's, also a member of METU physics dept.
Regardless of the relation of Mehmet Emin Ozel with comu plagiarism rings, he obeyed what ordered to him.
Otherwise he would have been attacted by others.

If partizan academicians attacks, threatens, tortures someone,
if he apply justice for these,
partizan juristocrats continue to increase the pressure on the contrary to the laws, instead of applying laws.

67. **Ali**
January 19, 2008

Coriolis, I meant the two grad students involved in this issue. Read my comment more carefully. I am aware that the other people were professors in Podunk State University. I raised my concern about their involvement as well. Tansu, I am aware that these students stayed as assistants but I don't think you can do much about it legally in a country like Turkey because TA appointments at state universities are lifetime jobs for some stupid bureucratic reason and I don't think there is any sanction like sacking these students from their appointments for plagiarism that is why they must be still TA's BUT the university keeps the right not to graduate them (I mean ever) so I am curious to see whether they will be awarded a Ph.D. degree after all this mess.

68. **Coriolis**
January 19, 2008

Ali,
These two grad students (and the other ones cited in the arXiv note)
are harboured by the plagiarizing professors in the "Podunk State Universities". No doubt they will get positions there. There is more in this story than meets the eye. One has to follow the names, the affiliations, the advisors and so on. It has been about a year since I heard of this story and no real punishment seems to have been given to the professors. Salti seems to have left to one of these universities to continue his PhD under the supervision of one of the plagiarizing professors (again cited in the arxiv note). Obviously they cant get a job in an established, known university but they seem to bosonize in certain univerties without much effort and with much comfort. Again, to gain a real insight of what is going on, one needs to do a tedious check of names, places etc.

69. **Tansu KUCUKONCU , PhD**
January 19, 2008

Ali,

that's not the case. Assistantships are the easiest to fire position in Turkish uni.s .
Moreover, according to the laws punishment of academicians for plagiarism is to fire, to get back academic titles, to invalidate diplomas, etc.
This is valid for all academic positions and titles.
YOK (higher education/despotic council) applied this in the last year in a very controversial case just for political and partizanship reasons.
But YOK did not apply this in hundreds of very obvious case, and covered those cases.
For now YOK followed its tradition for arxiv plagiarists.

Traditionally nothing happens to partizan plagiarists,
but most of the time who make plagiarists publicly known
are punished worstly.

It seems it's almost impossible for those 2 plagiarist grad students
to have a phd diploma from METU. But it will not be surprising that if they have phd diplomas from their partizan uni.s .

70. **Tansu KUCUKONCU , PhD**
January 19, 2008

Ali ,

I don't remember the rest of 15 plagiarists, but 3 plagiarists of comu ring are grad students. Nothing happened to them. comu will give phd diplomas to them as it did before to lots of plagiarists. Then comu will promote them to assistant professorships.

71. **amused**
January 20, 2008

Peter,

"Yes, you are defending the indefensible, e.g. your excuses for Salti, and your defense of the idea that there's nothing wrong with publishing heavily plagiarized papers as long as there's something original in them somewhere."

Please stop misrepresenting what I write. Re. Salti I just made the point that physicists should be judged primarily on the results of their research. Is that controversial? Why do you characterize it as an "excuse"? (Btw, this isn't implying that the results of Salti & co's research are any good — I suspect they probably aren't.)
About papers containing plagiarism, I never said that it is ok "as long as there's something original in them somewhere." If the paper plagiarises some research result or idea then that is a very serious offence regardless of whether or not the paper contains other original material. On the other hand, plagiarism of background material, while still wrong, is much less serious imo.

I try to be careful not to misrepresent what you write, can you do the same for me?

"I also strongly disagree with your defense of the the current journal system as "working fine for papers addressing central physics issues." "

Well that will teach me not to sacrifice precision for brevity in discussions with you. In previous comments I repeatedly spelt this out more precisely as "working fine for papers addressing issues of central importance to a subcommunity of serious researchers". Interesting that you ignored that but then seized on it on the one ocassion when I tried to be more brief. (As for the anthropic string landscape stuff, my attitude is that if smart people want to try that then good luck to them, but I won't believe that they can get anything significant out of it until I see them publishing in PRL 😉)

As for whether JHEP is "arguably the most prominent and respected place to publish HEP papers that are not letters", I think that depends. People working on strings, branes and other more speculative stuff prefer JHEP, while it seems that those working on topics more directly connected to "real physics" prefer PRD these days. For example, PRD is generally the first choice journal in lattice gauge theory (except for some continental Europeans who can't stand the thought of publishing in an American journal).

I disagree with you about there being a possible correlation between the occurance of plagiarisms like in the present scandal and the appearance of "anthropic pseudo-science" in the literature. My own experience of plagiarism lite which I mentioned in a previous comment was from 10 years ago, well before the anthropic landscape stuff got going. I expect that it has been going on for a long time (although Salti & co seem to have taken it to new heights).

72. **amused**
January 20, 2008

Coriolis,

"Some commentators argue the following
1)OK Try to fish out some novel results in these papers, maybe there is some. (My answer, don`t be funny, 90% of the paper is plagiarized, whose job is it to fish for novelty out of this garbage ?)"

In case it is me you were referring to, that is not what I was actually arguing. My thinking on this is as follows: If the referees of these papers correctly assessed the results and found them deserving of publication then the most important issue here is whether they were published on a fraudulent basis, i.e. whether the results, or some of them, were plagiarised. So I simply ask if anyone can point to any result in any of these papers which was presented as new but which was in fact plagiarised. Is that unreasonable?
Answering this question doesn't mean "try to fish out some novel results in these papers", it means find what the authors say are their new results and check if they really are new.
(Whether the results are interesting and really deserving of publication is a seperate issue. Of course, it is far from certain that the referees actually did assess the results of these papers correctly and competently. I wouldn't be at all surprised if they have failed in this.)

73. **collaps**
January 20, 2008

Notice! arXiv:0706.1294v1 "Reply on Brane-World Black Holes and Energy-Momentum Vector" by Gamal G.L. Nashed:
"We show that the energy distribution of the brane-world black holes given by Salti et al. in the context of teleparallel theory is not right. We give the correct formula of energy of those black holes"

I hope that somebody else would like to check the results in all papers containing plagiarism.

74. **Coriolis**
January 20, 2008

amused,

The issue is extremely simple. Let me go through it with an example. Consider the JHEP paper. It was submitted to the journal, the referee or the referees accepted it and it got published. (At this point, we have no idea yet of how good a job the refs did.) Then, as the story unfolds a little, JHEP defends the publication of this paper by saying that " OK bad papers sometimes get published." and when the story really unfolds JHEP apologizes for publishing the paper and withdraws citing 'plagiarism". That means for the first time around the refs did a terrible job, the second time around JHEP spent more time on the paper and understood what went wrong. Do you think it is

easy for JHEP to be humiliated like that ? When JHEP publishes a paper, you think that it has some novel results because the refs. must have observed that, but when the same JHEP withdraws the paper
you are stuck to their first, wrong opinion. Why is that ? (you don`t need to answer .)
This much said, let me be more concrete with you.

I spent a couple of hours looking on that JHEP paper trying to see what novelty it might have. Well that depends by what you understand from novelty: the parts of the paper that might potentially have some novelty are obtainable from another paper in just a couple of minutes. I won`t go into detail, since you can actually do it on your own : just find the relevant uncolored equations and compare them with equations of a relevant paper they actually cite. Well, I told you, you need to spend a little time.

This is a really simple case for those who understand what plagiarism means. People who "sell" what they have created
cannot hide what they have created in a pile of what they have stolen. A reader of a paper assumes that all the sentences and ideas belong to the author unless proper citation and quotation is made. For example, even in this simple comment, what I have written above belongs to me, as you correctly assumed while reading. Otherwise an honest dialogue is not possible.

A guy stills a car and changes its mirrors, now is that his car ?
(Well in fact, in this case, he steals the mirror from another car :)
Can he sell the car ? If he manages to sell it, and gets caught, can he argue that he actually wanted to sell the mirror and the rest of the car was `attached' to the car so that the mirror sells good ? 🙂

I rest my case.

75. **Marty Tysanner**
January 20, 2008

"amused," Ali, and others with similar viewpoints about different levels of plagiarism,

Defending some kinds of plagiarism as acceptable as long as the primary content of the paper is original can run into problems and inconsistencies. For example:

1. *The introductory material sets the tone for an article, and is an expression of its authors.*

One of the broader purposes of writing papers is to teach a wider community about one's findings, and thereby advance human knowledge. There is more to writing than just staking a claim of priority (in industry, patents serve the role of claiming priority). To someone who takes pride in their ability to teach, clear yet concise writing can be an end in itself, and can require creativity and insight into the minds of the readers. Introductory material can take significant effort to craft, and to plagiarize it is an affront to its author, not at all unlike a novelist copying passages from another ("the plot is different, so what's the big deal?"), or an artist copying the style of another ("the subject of the painting is different, so who cares?").

This issue is independent of the primary research findings in a paper. If introductory material is well written, a reader is more likely to continue reading the paper and make the effort to understand its primary purpose. They have become engaged. To plagiarize another author can turn what should remain a unique expression into something generic.

2. *Writing introductory material requires a knowledge of the larger context of the research.*

It can take significant effort to understand the broader context of a research finding. It takes a lot of reading to understand the existing literature on a subject, and it takes an organized mind to see how a new paper will fit in. The introduction presents this context to a reader: if it is well done and reasonably complete, the reader will probably attach more credibility to the rest of the article. That is because, through the introduction, the author has already demonstrated a certain mastery of the subject and has anticipated some of the reader's possible concerns. For one author to cheaply steal this credibility from another is not just unethical — it can dishonestly lead readers of a paper to believe its author is more knowledgeable about the validity and meaning of the "key findings" of the paper than he/she really is. In effect, successfully copying introductory material dishonestly insulates the author from an important reality check that knowledgeable readers could otherwise perform.

3. *By plagiarizing introductory material, an author has unambiguously demonstrated that he/she is willing to steal the work of others. Having proven this, it is merely a question of where the author will stop.*

It is very much like lying. A person who lies to avoid personal embarrassment has demonstrated that he is willing to directly deceive others for personal benefit. Now it is just a question of where the person will draw the line: he could limit himself to "little" lies, or the lying could be much more systematic and deep. If an author plagiarizes "something little, like introductory material" there is no reason to trust that the author hasn't gone further and stolen other, more important ideas (possibly unpublished) as well. That makes defending "a little plagiarism" tricky and possibly naive, unless possibly one personally knows the author and his/her ethics. (Still, it is hard to believe an ethical person would resort to plagiarism at all, although allowances for very limited self-plagiarism could probably be made.)

That explains why I disagree with this comment by "amused" :

> If the paper plagiarises some research result or idea then that is a very serious offence regardless of whether or not the paper contains other original material.
> On the other hand, plagiarism of background material, while still wrong, is much less serious imo.

Once an author has conclusively demonstrated a willingness to plagiarize, why should anyone assume that the same author hasn't also plagiarized research results or ideas to some degree? If such an assumption is unsafe, why make a distinction between plagiarism of support material and plagiarism of the main idea?

In overlooking or defending *any* plagiarism of the work of others, one gives up the ethical high ground and reduces the issue to pragmatism and power politics. There should be *some* segments of society which strive to keep noble human pursuits noble, which consider individual intellectual and artistic contributions to be valuable ends in themselves. The arts and the academy are two such segments.

Of course, there can be, and often are, substantial differences between what "should be" and what "is." But those are failures of individuals or groups, not more generally of the segments of society which honor noble pursuits for their own sake.

76. **Jonathan Vos Post**
January 20, 2008

Re: "Once an author has conclusively demonstrated a willingness to plagiarize, why should anyone assume that the same author hasn't also plagiarized research results or ideas to some degree?" — the underlying legal concept has been quite clear for ~ 2 x 10^3 years.

To cite from wikipedia
[List of Latin phrases (F–O)]:

falsus in uno, falsus in omnibus

"false in one thing, false in everything"

"A Roman legal principle indicating that a witness who willfully falsifies one matter is not credible on any matter. The underlying motive for attorneys to impeach opposing witnesses in court: the principle discredits the rest of their testimony if it is without corroboration."

Coincidently, I just used this in a sonnet… but that's rather a different kind of literature. How authors of prose, drama, and poetry use citations and react to their abusers, is off-topic.

77. **amused**
January 20, 2008

Coriolis,

I agree that the JHEP editors handled this very badly. They should have checked out the paper properly when the first accusation was made, decided what to do about it, and then stuck to their decision. I guess they were just choosing what they saw as the path of least humiliation by retracting the paper after it was retracted on the arxiv. They come out of this looking like spineless wimps.
I can't help admiring the GRG editors though. It was a courageous decision of them not to retract the papers, considering the pressure they must have felt after the papers were retracted on the arxiv and the knee-jerk outrage they must have known would be directed at them.

No I'm not "stuck to the first decision" of JHEP — they never gave any proper explanation of how they arrived at it, or any indication that they had seriously looked into the situation (unlike the GRG editors). I simply asked the question whether the results of the paper (which provided the basis for publishing it) were plagiarised or not.

I'm glad you took the time to look into the JHEP paper. Your findings confirm what I suspected, that the "new results" there are shallow in the extreme. Considering how much of that paper was lifted from elsewhere, it would have been very surprising if the authors had managed to do anything nontrivial in the little space left over. (Not impossible though.) This is a striking example of how poor refereeing standards can be for the "more obscure" papers.

In response to the rest of what you wrote: When I look at a research paper on a topic of interest to me the only thing I really care about is whether it presents interesting new results. The introduction, background material etc that the results are embedded in don't matter much at all. They are like wrapping paper. (Attractive wrapping paper is always nice, but it's what's inside that matters.) Is this a unique viewpoint? (I doubt it.)
Stealing is always wrong, but if someone steals wrapping paper to wrap a potentially valuable object should that be regarded as just as bad as stealing the object itself?

78. **themanwithaplan**
January 20, 2008

I agree, entirely, with "amused". The point is a very simple one: papers with only intros etc. plaigarized are *orders* of magnitude less harmful than the ones where contents themselves are plaigarized — since the *only* contribution of a research paper is the new content, not the eloquent intros.

No one is defending any of the above two types. However, I couldnt care less about the first type of plaigarism, and I suspect that's true of most of the researchers in any area. So yeah, one can legitamately complain about the first type of plaigarism, but that's kinda like complaining that non-english researchers have bad grammer in their papers. Its a problem, but an insignificant one.

79. **Peter Woit**
January 20, 2008

amused,

Apologies for any misrepresentation of what you have to say, but I continue to find appalling and depressing your defense of plagiarism and characterization of GRG's decision not to withdraw plagiarized papers as "courageous". That the words appearing under someone's name must be their own and not stolen from someone else is a principle of scholarship that I never thought I'd see anyone question. Several people have repeatedly explained here the obvious reasons why this is important, I'm not going to repeat them. Students get regularly kicked out of school and faculty members fired for this kind of behavior. The theoretical physics community will bring great discredit upon itself if it becomes known that many of its members, including journal editors, have quite different ideas about this than almost everyone else in academia.

80. **amused**
January 20, 2008

Coriolis,

From what you wrote it sounds like the "new results" in the JHEP paper might be effectively plagiarised (if they are just simple rewrites of equations in a previous paper). I will follow your example and check this for myself.

Marty,

I disagree with your analogies. E.g., the value of a novel is often determined at least as much by the quality of the writing as by the plot. This is not at all the case for research articles.

About your second point, you are right that when authors plagiarise introductory and background material it can result in readers being misled about their level of knowledge. This can trick readers into investing time in the paper when it isn't worth it. It can also trick referees into thinking that the authors know what they are talking about, and unfortunately that is sometimes all it takes for them to recommend publication (especially when the paper addresses some obscure issue that the referee doesn't care about). So this is a nontrivial problem. But imo it is nowhere near as serious as plagiarism of actual research results.

In reply to your 3rd point, I'll just mention that authors who do this kind of thing will definitely pay for it with their credibility (assuming they have any to begin with). If I heard about anyone in my field doing this they would for sure go down in my estimation; I'd become suspicious about the quality of their actual research and less likely to invest time reading their papers. Well, if I already knew their work was good i'd still follow it of course, but I've never heard of any good researcher who liked to lift large chunks of background material from others papers. It always seems to be the crappy ones who do this.

81. **Coriolis**
January 20, 2008

amused

You declared JHEP editors spineless wimps and stopped short of handing a gold medal for GRG editors. OK How about PRD editors ?
PRD retracted a paper written by Yilmaz, who is the co-author of the two papers that appeared in GRG. Below is the note in PRD in case you cannot reach. So what is your opinion about PRD editors,
and the Author (because he seems to accept his guilt) ?

a) spinless wipms ?
b) bravehearts ?

82. **amused**
January 20, 2008

Coriolis,

I don't think there is any one obviously right approach for editors to take in this situation. The PRD editors decided that the amount of copied text was intolerable to them, and asked the author to withdraw the paper on that ground, which he agreed to do. The actions of the editors and author here are all perfectly reasonable and understandable.
On the other hand, the GRG editors decided that they would let the text copying pass in this instance (but with a warning not to do it again in future). In reaching this decision they took into consideration that (i) the copied text didn't include what was supposed to be the new results of the paper, and (ii) the author had cited all the works that he copied from. I think that is also a perfectly defensible decision (and a brave one).

If I was a journal editor in this situation I would probably take a similar approach to the PRD one. But that doesn't mean I think the GRG editors were "wrong". Like i said, there isn't an obviously right approach here.

83. **Tumbledried**
January 21, 2008

Pardon me to interject, but I thought I should mention that, provided that the material is cited appropriately, it does not seem at all wrong to me for the author of a paper to provide large amounts of background material in, say, a large paper such as a dissertation – since this helps clarify and motivate the component of their submission that is original. Particularly in highly technical areas, such as theoretical physics and mathematics, it is common for there not to be too much leeway in the rewriting of proofs of well known theorems/lemmas pertaining to a particular area. Surely, provided the author clearly mentions where these background results are coming from, it is not a crime to include them?

84. **amused**
January 21, 2008

An interesting thing abut all this is that it shows the dilemmas that arise when the desire to maximally facilitate progress in research comes into conflict with the desire to maintain scholarship standards re. things like copying of text. To highlight this even more, here's a remarkable story I heard a few months ago from a scientist from a certain foreign developing country (while we were in a room together waiting to be interviewed by our funding agency.) I swear that the following is a true recount of what I was told.

A scientist from that guy's home country (not a physicist, it was a chemist if I remember rightly) had done some work he thought was great and wanted to get it published in Science. But he knew that to have a chance the paper would have to be written in a "certain style". Having no experience of this, and limited English skills, he didn't think he could manage it. So he contacted a scientist he knew in USA who had published previously in Science and offered to pay that guy to write the paper for him. The US guy agreed, and the fee was US$8000. The paper was written, and after some back-and-forth with referees it was eventually accepted in Science. (The name of the US guy who wrote the paper, but who hadn't contributed to the research, was not on the paper.)
As a result of this publication, grant money flowed to the lab of the developing country scientist. His $8000 outlay proved to be a very good investment.

Well, this should be a fun one for the moralists out there. Should the scientists involved in this be condemned for unethical behaviour? The words appearing under the name of the developing country scientist on this paper are certainly not his own! On the other hand, wasn't this all to the benefit of progress in science? The results of the developing country scientist's research, which presumably formed the basis for accepting the paper, have now been recognised and disseminated in a way that wouldn't have been possible if he had written the paper himself.
The approximate parallels with the Turkish text-copiers are obvious. (If we are going to be moralistic and focus on questions of principle then it isn't relevant that the Turkish guys' work was of more dubious quality.)

85. **Peter Woit**
January 21, 2008

Tumbledried and amused,

You're both still engaged in a remarkable exercise of trying to defend something indefensible, now by positing quite different circumstances than what actually is at issue.

Tumbledried: these are not "large papers" such as dissertations, nor do they need lots of background material, of a sort that is always going to be roughly similar. They are short papers, large parts of which, not only in the introduction, are cut and pasted from other papers, ones which are sometimes credited, often not. In no case is the material put in quotes, and the reference to the paper the material was stolen from, if it is there, is not associated with the stolen text. This is a case of direct plagiarism on a large scale, not a case of someone using roughly similar background material, properly credited.

amused: I don't see any problem with people getting others to improve the English in their papers, it's actually a good idea for people whose English is not very good to do this. If the help on a paper went beyond improving the English, and someone hired someone else to do scientific research which they then published under their own name, that's a problem, but a different one that has nothing to do with plagiarism.

Sorry, but I absolutely don't understand the reaction of many commenters here of trying to defend plagiarism, again I find it really disturbing and depressing. We're talking about behavior that would get pretty much anyone at my institution fired if they engaged in it, for good reason. Any students or young researchers reading this blog are going to get the idea that a large fraction of the theoretical physics community just doesn't see anything very wrong with plaigiarism, and is willing to even go far out of its way to defend it. This is potentially a huge problem, as now any plagiarist who gets in trouble can point to the discussion here to show that they were not violating the academic norms of the physics community. Already, I'm sure this will be of huge help to the Turkish plagiarists, who can point to your support as they try and portray themselves as serious scholars wronged by the arXiv.

86. **puzzled**
January 21, 2008

This reminds me of a discussion where one side says that shoplifting must not be tolerated, and the other argues that it is not such a big deal and there are worse crimes. Both are right, I think.

As for what younger (and older) scientists should be doing the answer I think is pretty simple. Every time you use someones help — acknowledge it. If some background material is borrowed, or an idea is used–say where you learned it. If someone corrected your English or style, you should thank that person in the paper. If you made a mistake, correct it either as an erratum, or in a new arxiv version, or in a later paper.

What is here to argue about?

87. **amused**
January 21, 2008

"I don't see any problem with people getting others to improve the English in their papers, it's actually a good idea for people whose English is not very good to do this"

That has absolutely nothing to do with what I wrote.

"and someone hired someone else to do scientific research which they then published under their own name,…"

That has absolutely nothing to do with it either.

Let me try the kiddies summary of what happened:

Developing country scientist: Dude, here are my research results, now go write them up as a paper for Science under my name. I'll pay you $8000.
U.S. scientist: Ok, sure.

Your description of me as "defending plagiarism" is completely ridiculous.

"…huge help to the Turkish plagiarists, who can point to your support as they try and portray themselves as serious scholars wronged by the arXiv"

If they bother to actually read what I wrote they will see that lifting large chunks of background material from others' papers will lead to them not being taken seriously. In case it wasn't already clear, let me spell it out again: The default assumption about physicists who do this is that they must be crappy researchers. No one has ever heard of good researchers doing this, only crappy ones.

88. **Peter Woit**
January 21, 2008

puzzled,

Obviously your list of how people should behave is accurate, but it's about different topics. The question here is what journal editors should do faced evidence that a paper they have published is heavily plagiarized, very specifically the papers for which marked-up copies are linked here to show (part of) the extent of the plagiarism. Historically, the conventional view in academia has been that such a paper should be retracted, and the arXiv took action according to that standard. Now it seems that many physicists disagree with this standard, to the extent of characterizing as "courageous" those editors who refuse to follow it. This seems to me a rather remarkable and not at all desirable change in standards of scholarship.

89. **Peter Woit**
January 21, 2008

amused,

Let me try the kiddie summary of what I wrote:

Your hypothetical has nothing at all to do with what is at issue here, bringing it up is a smokescreen to avoid defending your indefensible claim that it is "courageous" behavior by editors to refuse to withdraw heavily plagiarized papers that they have published in their journal. And yes, you are defending plagiarism, not as good science, but as something not outside of normal academic practice, just an indication, like many other possible ones, that the authors are lousy scientists.

90. **Peter Woit**
January 21, 2008

puzzled,

To clarify: the problem here is not that some people are pointing out that there are worse crimes than shoplifting, the question is, what do you do about this kind of shoplifting? The attitude of the GRG editors, and it seems of quite a few other physicists, is that it is not even necessary to make the shoplifter give up what he has stolen. The crime is so inconsequential that it's fine with them if the thief keeps the stolen goods.

91. **Ali**
January 21, 2008

Peter, like I pointed out before, it is the meat in these papers that matters (i.e. scientific substance) not the introduction. If there was no substance(and there seems to be none as far as I gather. I am not an HEP person), these papers will not receive any citation and they will be lost in journal pages so the central question is whether that was original research or not. Tansu, you are complaining that these students wil lget faculty positions at Podunk State University. So what? Who cares? Why do you feel so bitter about it?

92. **puzzled**
January 21, 2008

Peter Woit,

I think there is no universal answer to "what journal editors should do faced evidence that a paper they have published is heavily plagiarize". It all depends on the ethical standards in the relevant subfield of science, of which I have no inside knowledge. You do, so let me ask you this. Suppose that instead of "cuting and pasting" background material, the authors would change the wording slightly in each and every sentence. Would this be okay?

My guess is that many people borrow background material from other papers and the decision on providing references depends on whether the background is already "common knowledge". If yes, many people do not bother to cite the place where they first learned it.

93. **Peter Woit**
January 21, 2008

Ali,

The plagiarism here is not just in the introduction. Look at the marked-up versions.

I just don't agree that the central question is whether there are significant original research results here (although there don't appear to be, the question of why journals are publishing such low quality stuff is a separate one). I'm repeating myself, but, again: there is no justification for the journals to not do what the arXiv did: retract the papers since they are heavily plagiarized. If the authors have original results, they are welcome to resubmit them to a journal in unplagiarized form.

puzzled,

I have never heard of any subfield of science (or scholarship in general) where the ethical standard is that publishing heavily plagiarized material is considered acceptable.

As for your hypothetical question, I just don't think it's relevant. Sure, there's a continuum of degrees of plagiarism with plenty of gray areas. Although I appear to be a "moralist", I'm not interested in spending my time debating hypothetical situations, without any specifics. The plagiarism at issue here is of a specific, documented variety, and the question is whether this, specific, documented plagiarism is such that the papers should be withdrawn. The arXiv, JHEP, PRD and Astrophysics and Space Science say yes, many journals seem to be ignoring the issue, GRG says no, and amused feels that this is courageous of them.

94. **amused**
January 21, 2008

Peter,

Considering all your previous pontificating about "tone" in blog discussions I find it absolutely hilarious that you accuse me of lying about that story ("your hypothetical"). So this is what happens when someone tries to have a good faith debate with you and persists in having a viewpoint different from yours..

In a previous comment you wrote:

"That the words appearing under someone's name must be their own and not stolen from someone else is a principle of scholarship that I never thought I'd see anyone question. "

Would you find it less distressing if the words were bought rather then stolen? Assuming not, then here's a hypothetical for you:

Imagine that the Science editors find out about what happened in the case I mentioned. What should they do? Retract the paper? If the editors decided not to retract it, and justified their decision by saying that they were prioritizing progress in science (as represented by the genuine results of the paper) over retribution for authors whose words weren't their own (while warning that this kind of thing wouldn't be tolerated in future), would you slam them for that? I wouldn't. And if they made their decision after a preprint version of the paper had already been withdrawn by the administrators of a prominent preprint server, and knowing that they were going to have a lot of knee-jerk outrage directed at them, I would go as far as to describe their decision as courageous.
Same for the GRG editors decision. The quality of the papers is very different but the principle is the same.
(Now you can hopefully see that my mentioning of that story wasn't a "smokescreen".)

95. **Peter Woit**
January 21, 2008

amused,

I did not in any sense accuse you of lying (by "hypothetical" I in no way meant to imply any questioning of the veracity of your story), I did accuse you of evading the issue, which you continue to do. As for tone, stop it with the "kiddie version" shit, I'm not a kiddie.

You persist in wanting to discuss something completely different than what is at issue here: the GRG decision to not withdraw two specific heavily plagiarized papers. Besides not being a kiddie, I'm not an idiot, and of course am aware that authors get help with their writing of various sorts and the usual academic standard that people's words should be their own takes this into account. In such cases it would be a good idea if they acknowledge this in the paper. In some cases there would be real ethical issues raised by this, and when considering them, the question of how unacknowledged help affected scientific results would be a relevant one.

But, again, this is not what the GRG editors were deciding or what I was criticizing. I have been assured that they had those marked-up pdfs in their possession when they made their decision. If you want to discuss the specific cases at issue here, I'll be glad to. If you want to keep on discussing other, different, cases, I'll keep pointing out that you're evading the issue and doing so to defend the indefensible.

96. **Jonathan Vos Post**
January 21, 2008

A scientist owns only two things:

(1) Reputation;

(2) Intellectual Property.

He who steals my Intellectual Property — whether introductory text or results or equations — is an extential threat to me. The thief indirectly reduces my reputation (by dilution) and directly reduces my Intellectual Property.

Of course this is the equivalent of a capital crime — like falsification of laboratory data. Of course the thief loses his/her job, once the theft is proved under Due Process.

Cf. "bubble reputation" [Shakespeare, As You Like It, II.7]

If a nation condones plagiarism on a wholesale scale, it is akin to a Cause of War.

None of this is exaggeration. I am just (for now) talking about the Scientific Literature, not the parallel world of novel, story, screenplay, and song.

Anyone who does not understand this is more criminal than scientist, more fool than ignoramus. Peter Woit is entirely right to insist on clarity at the basis of the matter. Those who "praise with faint damn" are accessories after the act.

This is not about alternatives to Intellectual Property under the law, as in the Open Source Software movement. Scientific Literature is parallel, the goal being unfettered distribution of scientific results. The mixture of law and academic protocol and publishing protocol is a jumble of 2nd order effects.

The axioms of plagiarism are unambiguous.

97. **metin**
January 21, 2008

Ali says: "I am originally from Turkey but my advanced degrees are not from there. Those two students involved in this pagiarism scandal are not going to get positions anywhere in turkish system. I can assure you that much."

I, too, am from Turkey, and I don't see how you can be so confident about this. I know of previous cases where people with documented cases of plagiarism have not only obtained professorships, but have been appointed to academic positions with considerable power.

This is an extremely important issue for the Turkish academia, and the professors who have been fighting against plagiarism have been doing an extremely valuable service to the community. I don't think slighting their efforts by uninformed comments is appropriate.

Turkish academia does not consist solely of a handful of "elite" institutions. There are honest, talented people fighting for positions in what you call "Podunk" state universities, and they have to compete against the plagiarists. There are cases where the plagiarists are well-connected politically, and honest people have been threatened to be fired after demonstrating the plagiarism of others.

I am not sure whether you think of these problems at "Podunk" etc. as non-issues, but they are very real for people honestly trying to live the under-paid life of an academician in Turkey. They are real for the students at those universities, too. And believe me, they are real for the quality of the education system in Turkey.

98. **Coriolis**
January 21, 2008

Peter,

It seems to me some people writing to your blog have not looked at these papers. After spending just 1/2 an hour on these papers would remove any doubt in anybody who has written any kind of paper (be it scientific or non-scientific) or who knows anything about plagiarism.

Some people defend the plagiarizers more than plagiarizers defend themselves: the guy admits that he had plagiarized, what else do you want ? You want to catch him while he is actually doing the plagiarizing ? 🙂 (And perhaps broadcast it on Cops .)

About the action of Gen. Relativ. and Grav. Editors, they have lowered their standards so much that I might actually try publishing
in GRG simply plain garbage, just for the heck of it. I would like to write a paper in which I simply collect every sentence, every equation from different papers and I will make sure that my own contribution is absolutely zero. I am sure it will get published. It wont be worse than those two papers.

99. **amused**
January 21, 2008

Peter,

Well then, I'm a bit mystified by what you meant with the "hypothetical". Nevermind. As for my "kiddie version" line, the reasons for the frustration that gave rise to it will be obvious to anyone who goes back and reads that comment.

"I'm […] of course am aware that authors get help with their writing of various sorts and the usual academic standard that people's words should be their own takes this into account."

How many times do I have to repeat: that is not what happened in that story. It has absolutely nothing to do with it. The only difference between that case and the Turkish cases is that the words were bought rather than stolen. Why do you continue trying to insinuate something different?

So you don't think my previous comment addressed the GRG editors decision, whether it is justifiable or not? Well then I really am wasting my time here.

One reason I have so little sympathy with you on this is that the outrage could be so much better spent on other things. Those young Turkish grad students, are they really just intrinsically bad characters? Is academic physics really such a lucrative and prestigeous career in Turkey that they would choose it without actually caring about the subject? How did they end up in this situation? Those wonderful METU faculty members who caught the plagiarists, where were they while Salti & co were putting out 1-2 papers a month over 2 years? (They didn't notice?) What kind of environment and values were they and their colleagues propagating? Perhaps you can consider directing some outrage at them Peter, if you have any left over after you are finished with the journal editors.

In the immortal words of Danny Lundsford: I'm done here.

100. **Peter Woit**
January 21, 2008

amused,

By “hypothetical” I just meant that you insist on discussing not the documented case at hand, but other issues. The Science case you talk about is different and you are constructing a hypothetical situation in which it is the same, except for the bought/stolen difference. The editors at Science have not had a situation documented, complaints filed with them, and been asked to adjudicate something, the GRG ones have. I don’t believe the situation you describe is exactly the same except for the bought/stolen distinction, but even if it were, so what? What’s at issue here is a specific example of plagiarism, I don’t see the point of arguing about other issues, other than to avoid confronting this one.

As for one reason for the outrage, read the comment above from “metin”. You may disagree, but to me another reason is what I see as the ever-decreasing scientific standards in theoretical physics, which have now gotten so low that some people seem to think there’s no reason to sanction even heavily plagiarized papers.

I can explain my reasons for wasting my time on this, I really can’t understand yours for spending time defending plagiarism and plagiarists. The one you give that you think my outrage is misdirected and should be redirected at the faculty members who exposed the plagiarism doesn’t make a lot of sense to me.

101. **amused**
January 21, 2008

Ok, one final comment

“After spending just 1/2 an hour on these papers would remove any doubt in anybody who has written any kind of paper (be it scientific or non-scientific) or who knows anything about plagiarism”

any doubt about what?
(you don`t need to answer .)
Are you related to Lubos by any chance? The style of argumentation is quite similar.

“the guy admits that he had plagiarized, what else do you want ? You want to catch him while he is actually doing the plagiarizing ? 🙂 (And perhaps broadcast it on Cops .) ”

The guy had already discussed his plagiarism in a Nature letter from Oct. 10. (before the GRG editorial and PRD retraction) He never tried to hide it, only to excuse it. (If he really wanted to hide it I don’t think he would be citing the papers he plagiarised from.)

102. **Coriolis**
January 21, 2008

amused,

I am almost sure that you have not looked at carefully in these papers.
In his Nature paper : he admitted to `borrowing beautiful sentences” ONLY in the introductory material. Please check the PRD retraction and see how much he plagiarized.
We are discussing something concrete, it is out there, just check it.

No, I am not related to Lubos, I don`t know him, I am not familiar with his writing. I am sure you are not Yilmaz, not that you don`t think a like, but that your English is infinitely better 🙂
But, there is still a good chance that you might be a GRG editor 🙂

Anyway, I still have to thank for this discussion: I did learn one more time that some people enter a discussion not to learn and perhaps contribute but simply argue for the hell of it. This is not productive. Please first go and read these papers, and then come back to argue specifically on them. Not on some abstract, irrelevant issues that takes nobody nowhere.

103. **Tansu KUCUKONCU , PhD**
January 21, 2008

Discussion here turned out to fun.

There is a famous saying, what is definitive is where to look,
not what to look.

Who is where in this discussion ? 🙂

Some defend plagiarism and Turkish plagiarists with fuzzy, implicit sayings.

Turkish plagiarists and supporters, defenders, protectors,
promoters of them are doing the same thing.
No one defends plagiarism explicitly in front of public.
But they plagiarize explicitly in front of public,
and say that it is not plagiarism.
If anyone dare to falsify them they brake the wood on his head,
since they have the power.

Turkish university system is a deep bog whcih connected to other bogs of Turkey.

You see and are talking about only 15 flies which you noticed shitted 70 times in a garden near you.

Some say, so what, what happened if they shitted.
And they add that this is not a tribute to shitting.

———————————-

Ali ,
” Tansu, you are complaining that these students wil lget faculty positions at Podunk State University. So what? Who cares? Why do you feel so bitter about it? ”

I am victim of these Turkish plagiarists and supporters, defenders, protectors, promoters of them for 7 years.
Moreover normally any honest Turkish citizen and any honest non-Turkish academician especially who may be competent in international projects (such as EU projects (even comu plagiarism rings (osman demircan and co.) have some such applications)) with Turkish plagiarists.

— — — — — — — — — — — — — — —

There is a basic rule valid for most of the social cases :
follow the money.
What's about applying this rule to journals which insist on
publishing of arxiv's Turkish plagiarizes' plagiarism works ?!
Can the editors who joined this discussion reply to this
question ?

104. **Ali**
January 21, 2008

Tansu, there is no funding for theoretical HEP anywhere in the world right now so I do not think their fake papers are gonna help the pagiarists a bit to get funding from EU or Tubitak. I do not think writing theoretical HEP papers is a lucrative way to get rich anywhere. I however admit that it may help them to get an academic position in Podunk State University(i.e. rural state universities in Turkey) BUT I want to remind you that writing three dozen papers is not a prerequisite to get that job and they probably would get that position with three papers anyway so why do you think they bothered with this? Besides, as it was pointed out by someone, these are underpaid positions anyway so I do not think these plagiarists are after wealth by any means. If you think you are a high-caliber scientist, why are you competing against these folks at Podunk State Universities? There are elite private universities in major cities which pay european level salaries to qualified scientists. I can assure you that they do not hire plagiarist clowns. Why don't you try one of them?

105. **Tumbledried**
January 21, 2008

Hi Coriolis, I presume you may have tangentially been also addressing me when you wrote these comments:

"It seems to me some people writing to your blog have not looked at these papers."

"Anyway, I still have to thank for this discussion: I did learn one more time that some people enter a discussion not to learn and perhaps contribute but simply argue for the hell of it."

I think I should stress a few things:

(i) Yes, I have looked at these papers, and, yes, I do not think that they are worth the paper they are printed on. Yes, this is a terrible indictment of the acceptance standard of certain journals;

(ii) Regardless, there are deeper issues here that I thought merited a quick word;

(iii) It sometimes pays to have a look at the bigger picture before making sweeping generalisations and casting broad denunciations.

(iv) My comment was made in good faith. I was certainly not "arguing for the hell of it". We are all scientists here. Surely we can discuss important matters like this in a civilised manner without having to constantly throw thinly veiled vituperation at each other?

Anyway, like amused, I am also going to bow out of this discussion. Enjoy your mudslinging.

106. **Tansu KUCUKONCU , PhD**
January 21, 2008

Let me complete my sentence :
Moreover normally any honest Turkish citizen and any honest non-Turkish academician especially who may be competent in international projects (such as EU projects (even comu plagiarism rings (osman demircan and co.) have some such applications)) with Turkish plagiarists should care about plagiarism and the bog which it was originated from.

Otherwise the famous anecdot tells :
they took a-s I said nothing,
they took b-s I said nothing,
……
they took z-s I said nothing,
when they come to take me,
there is noboby who can say any thing for me.

I am a victim they took.
I was saying what I belived before they took me,
I am saying now what I belive,
I will continue to say what I belive.

107. **amused**
January 21, 2008

Coriolis,

"I am almost sure that you have not looked at carefully in these papers."

Now that really is quite Lubosian. Are you *sure* you aren't related?

In the Nature letter he doesn't make any statement to the effect "we only borrowed for the introductory material". He makes some statements that *suggest* that that was all he did, but that isn't the same.
Good grief, why are we wasting time arguing about this…

"But, there is still a good chance that you might be a GRG editor 🙂 "

Ellis or Nicolai? No, i don't think so. But I'll take that as a compliment 😉

I also thank for this discussion. It reminded me of one of the reasons I went into physics (besides the obvious one): it is one of the few human endeavors where smug confidence in the quality of your reasoning won't get you anywhere if it is rubbish.

Ok now I really, *really* am done. Goodnight.

108. **Coriolis**
January 21, 2008

Tumbledried

I must have missed your earlier short comment, but somehow I managed to offend you. I just read it. Sorry, I think it just proves my point.

1)Please, go back and check the papers to see if they always cite or not.

2) No, these are not review papers, thesis etc.

Beforehand, if the journals knew the extend of copy-pasting, do you think they would publish these papers ?
There are many questions but the story has left origin long ago.

amused,
This is the first blog I am reading and the first discussion I am involved in. I aint Lubos, I don`t even know the guy and from what I don`t know, I don`t think I even like him 🙂 Hey, it occurred to me I might even be a woman.

Anyway, how anybody could possibly defend such blatant plagiarism
is really disturbing me. I do not understand why would one defend these papers? What is the reason? Why lower the standards of publication any further ?

109. **Geoffrey A. Landis**
January 21, 2008

I have to point out that the phrase "self-plagiarism" is an oxymoron.
Literally, if that phrase had any meaning, it would mean "passing one's own work off as being one's own work."
I do understand the point here, of course, and perhaps people who copy their own work and represent it as being new are, in these cases, exactly the same people who copy the work of others.
But nevertheless, I would call the two qualitatively different, and you seem to be debasing the intellectual crime of plagiarism by lumping so-called "self-plagiarism" into the same category.
Couldn't you perhaps think of a different word? What you mean to say is "the crime of violating the explicit terms of the publishing contract which the author signed to indicate that the work is unpublished and has not been submitted elsewhere."

110. **Peter Woit**
January 21, 2008

Geoffrey,

I agree that self-plagiarism is a quite different issue than plagiarism. In all cases here where I was using the term "plagiarism", I was using it to refer to plagiarism from others. The main problem with the papers at issue is the way in which they plagiarize the work of others.

111. **Tumbledried**
January 21, 2008

Hi Coriolis,

Thank you for your comment. I apologise for my slightly acerbic tone, and sorry if I offended you in turn! I am quite aware that these were research papers, not review papers. I'm not sure I made myself entirely clear – my intent was to attempt to point out that legitimate research can and does borrow/use excessively from that which proceeds it. ie it was not directly related to the papers in question, but a meta-comment. "Standing on the shoulders of giants" etc. But I see that I clearly made a mistake in trying to discuss this here, since evidently this upsets Peter, which on reflection is understandable since a reader skimming this discussion might confuse this observation with a defense of the sort of plagiarism that occurred in the Turkish papers.

Anyway, this should be my last comment. And a final apology for my clear ignorance on these matters and my offtopic remarks. I hope everyone here has a splendid day.

112. **Tansu KUCUKONCU , PhD**
January 21, 2008

Ali,

I don't know you are, what your background is, and where you are now.
One thing is clear that your approach is strange.

— — — — — –

"Tansu, there is no funding for theoretical HEP anywhere in the world right now so I do not think their fake papers are gonna help the pagiarists a bit to get funding from EU or Tubitak. I do not think writing theoretical HEP papers is a lucrative way to get rich anywhere."

As I said these you can meet these plagiarists every where not only in theoretical hep domains.
For example plagiarist Husnu Baysal approved lot of plagiarized computer enginering msc theses.
The list is very long.

— — — — — —

"I however admit that it may help them to get an academic position in Podunk State University(i.e. rural state universities in Turkey)"

"Podunk State University" : this naming does not cover the whole view.

A term like “Billboard University”
(to mean very unqualified, even very less qualified than qualified lyceess) is more appropriate for more than 2/3 of the universities (not only state universities but including private universities) in Turkey.

————-

“BUT I want to remind you that writing three dozen papers is not a prerequisite to get that job and they probably would get that position with three papers anyway so why do you think they bothered with this?”

Follow the money (+power, +maximum ego satisfaction), you will find the answers.

—————

“Besides, as it was pointed out by someone, these are underpaid positions anyway so I do not think these plagiarists are after wealth by any means.”

Relativity :-).
There are competents to take a piece from this underpaid pie.
Underpaid : according to international standards not Turkish standards.
That much is the highest ratio paid for a physics diploma (and for lots of other diplomas) in Turkey.
And other benefits are also generally the highest.
Moreover they can be doubled, tripled, quadrapled easily.
Let me estimate comu’s plagiarsit dean Ihsan Yilmaz’s income from the university, it is between 5.000 ytl to 20.000 ytl per month
(~ 4.000 usd to 16.000 usd) .
He can not easily gain more than 1.000 ytl anywhere else in Turkey with his diplomas.

—————————

“If you think you are a high-caliber scientist, why are you competing against these folks at Podunk State Universities? There are elite private universities in major cities which pay european level salaries to qualified scientists. I can assure you that they do not hire plagiarist clowns. Why don’t you try one of them?”

My story is long. I summerized a few part of it whic is related to arxiv scandal.
Almost every Turks know Turkey and Turkish university system spent thousands of high-caliber scientists.
That’s why plagiarists are running horses today.
I am not competing against these worthless people.
I am victim of them.
Why I was comu (canakkale) : in short, canakkale is my home town,
my family lives there, and my family needed me then.
I was unaware that much of comu, Turkish university system, and Turkey.
When I was awared it was very late.
For 7 years I’m under attack.
5 years I struggled to rescue my phd diploma which was illegally blocked by academic and juristocratic mafia.
I wrote thousands of papers in my search for justice,
instead of writing tens of scientific papers in my expertise areas.

Searching justice against academic mafias and juristocratic mafias in Turkey causes lot of gates, which normally should be open, to close, unfortunately.

You assure everything…..
Unfortunately you can meet plagiarists every uni. in Turkey where they are promoted to president of universities and to higher.
Only meeting frequency changes.

113. **Arun**
January 22, 2008

Observation, prompted by Tansu K – competence is a threat to the incompetent; when incompetent people obtain positions of power and influence, they will try to close the gates to the competent. This is generally true. It can take a generation or more to repair the damage, if ever.

114. **amused**
January 22, 2008

Arun, I agree completely. That’s why I think that rather than obsessing over what editors did about copied text it would be more productive to consider what can be done to encourage and support competent researchers in developing countries who are disadvantaged in systems that reward quantity (of junk, copied or uncopied) or political connections over quality.

Ciriolis, my “defence of blatant plagiarism” is merely to say that I find GRG’s response adequate (and yes, brave considering the circumstances). The authors were shamed by having their text copying discussed in an editorial which also stated that it was unacceptable and would not be tolerated in future. You and Peter obviously have more of a lust for retribution than me.

Peter, how would you rate the embarrassment and damage to the field caused by the GRG decision compared to that caused by the media spectacle resulting from Smolin’s hyping of the surfing independent physicist and his “theory of everything” (unrefereed and inviable)? Where was your outrage in the latter case? Funny how your reactions always seem to correlate with your interests in these situations — not speaking out against your ally Smolin’s deplorable hyping, but turning on the outrage in a situation where you see a chance to promote your hypothesis about the journal system being “collapsed”.
(Yes, I decided to start using the same tactics of response that you have been using to me. If you want to lower the tone further I’ll follow you all the way down.)

115. **Peter Woit**
January 22, 2008

amused,

You’re still trying to change the topic from your defense of the indefensible, now to your fanatical hatred for Lee Smolin. In order to “lower the tone” I’ll avoid commenting here on your behavior in the Lisi affair, and just state that I stand behind every word I’ve written about it (the Lisi affair), here and elsewhere.

116. **amused**
January 22, 2008

"You're still trying to….." "your defense of the indefensible…" etc etc

If you make these pronouncements often and vehemently enough they might actually become true. Try it!

117. **Tansu KUCUKONCU , PhD**
January 22, 2008

amused,

are you Ellis of GRG , or someone in relation to him ?

fun increases 🙂 :

" That's why I think that rather than obsessing over what editors did about copied text it would be more productive to consider what can be done to encourage and support competent researchers in developing countries who are disadvantaged in systems that reward quantity (of junk, copied or uncopied) or political connections over quality. "

he he 🙂
Turkish comics magazine Leman has given Tulip Awards for years.
You can start to give Scientific Tulip Awards to competent lonely scientists whose papers' abriged versions you promotionally publish in a residual corner if others leave.

———————————

Follow the money rule 🙂 :
What is the market value of this ?
What is the share of Turkish universities in this market ?
What is the risk of threating the ducks on Turkish market and other markets ?

118. **derridux**
January 23, 2008

Who could have said that the editors of "Social Text" would have the last laugh after all? They must still be laughing.

For several years more than five dozen papers full of BS were published by many HEP and gravity journals, including several of the most respected and prestigious ones, which didn't even notice the hoax.

It's true that plagiarized material is different from made-up nonsense. But it's also true that social scientists need not know anything about GR, they just trusted Sokal. Here we have the supposed experts swallowing rotten fish in wholesale quantities.

Not surprisingly, all the big names that came out at the time to tell how social sciences were in deep trouble now seem to be silent, at least publicly.

119. **amused**
January 24, 2008

Tansu,

I tried to reply to the comment you addressed to me, but Woit deleted it.

I used to think that this blog was run by a person with integrity, motivated by genuine concern about real problems that exist in the present day hep physics community. But it has become clear that he is just another demagogue, out to ram his own judgements down our throats and with very little interest in engagінging in good faith debate on the issues.

The points I tried to make in this discussion — that it is important to distinguish between plagiarism of results and copying of background text, and that the GRG decision to allow the papers to remain in the journal in this instance because their results are original, while declaring the text copying unacceptable and stating that it won't be tolerated in future, might actually be quite reasonable — have been met with: "Defender of plagiarism! Supporter of plagiarists! You're just trying to prop up a collaped journal system!" (Of course, my attempts to distinguish between which aspects of the journal system were in trouble and which were still functioning ok was completely ignored — everything is black-and-white when you're a demagogue.) Other commenters gleefully joined in with mocking and derision, just as good followers of a demagoge are supposed to do. ("If you actually bothered to look at those papers you would know that…" etc etc.)

Woit sometimes bemoans the fact that so few serious phyicists are willing to participate in discussions here. He puts that down to too many people making "uninformed comments". Well I think there is another reason, and it has become pretty obvious.

120. **RILED UP**
January 24, 2008

"amused " you are totally missing the point. Your position is completely unethical, and people are quite rightly criticizing you for it. You are condoning actions that cause actual harm, as you surely realize.

121. **Eric**
January 24, 2008

I agree with Amused that copying background material can be acceptable, so long as adequate references are given and it's clear to the reader that the background material is not original. In my experience, this just makes it easier to connect an author's new results with the existing body of work. Especially when their exist different conventions and syles for a particular subject, it is helpful to have a common source of material so that different researchers can all speak the same language. I would wager that in all liklihood those in this thread grandstanding on this topic are not active researchers who publish papers regularly, e.g. Peter Woit.

122. **Stan**
January 24, 2008

Eric,
Should we assume you are an active researcher copy-pasting material without even citing ?

123. **RILED UP**
January 24, 2008

There is no doubt that “amused” was condoning activities that any reasonable person would call plagiarism. There’s no excuse for dressing it up as something else. And “Eric” I would suggest you stick to non-gambling sources of income.

124. **amused**
January 24, 2008

Riled up,

I’m sorry, but stating things vehemently is not by itself sufficient to show them to be true. I’m open to debating this issue, explaining the reasons for my views (which I don’t think are at all unique), and even to changing my mind about them if someone convinces me that they are untenable. But what I encounter most of the time here is not arguments but proclamations. E.g., your comment is just a string of proclamations, with any arguments. It is a classic tactic of demagogy: say something often and vehemently enough and it will become the accepted truth, with dissenters being cowed into silence.

You say that I am “condoning actions that cause actual harm, as you surely realize.” Well no I don’t realize that at all. GRG shamed the culprits by discussing their text copying in an editorial, and stated that it was unacceptable and would not be tolerated in future. I happen to think that is a sufficient response and don’t agree at all that it is causing actual harm. We can debate it if you want to.

Let me ask you this: Do you think the GRG editors — Ellis and Nicolai — are people of limited integrity who don’t take ethical issues seriously? Do you think they were lying when they wrote in the editorial that they had seriously considered this issue? They are both renown, highly respected physicists with extensive experience as journal editors; probably they have thought more about journal-related issues, including ethics, than any of us. So perhaps it is appropriate to be a bit more open to the possibility that they may have made a reasonable decision, rather than rushing in with knee-jerk outrage. (Of course, a demagogue with an anti-journal agenda won’t have much willingness for that.)

125. **Peter Orland**
January 24, 2008

Wow, I can’t believe what I am reading.

At my institution, students in my classes who copy phrases
from a published source with no citation not only flunk,
but are referred to the VP for academic affairs and
out on probation.

126. **Peter Woit**
January 24, 2008

amused,

The reason your comment was deleted was that it did little more than question the professional competence of those physicists at METU who exposed this plagiarism, and sneer about the difficulty of finding any competent Turkish physicists at all.

Anyone who reads this exchange here can make up their own mind about who is engaging in demagoguery.

127. **amused**
January 24, 2008

The credit the students get for their assignments comes from how well they answer questions, solve problems etc. Obviously if they plagiarise something that is going to affect their credit then it’s a very serious offence. (And if they are being judged in part on their writing then anything they plagiarise affects the credit.)
The credit physics researchers get for a research article is determined entirely by their results. No one gives a sh*t about their eloquent introductions and background material. They get absolutely no credit for it.
Like I said before, stealing is always wrong, but stealing wrapping paper to wrap a potentially valuable object is surely a less grevious offence than stealing the object itself. Now you’re all going to shout at me again that I’m “defending plagiarism”, right?

128. **amused**
January 24, 2008

“…question the professional competence of those physicists at METU who exposed this plagiarism, and sneer about the difficulty of finding any competent Turkish physicists at all.”

That is an outright lie. Once again you are misrepresenting what I wrote to serve your own agenda.

129. **Peter Orland**
January 24, 2008

Amused,

I am not shouting (not even metaphorically) but yes, you are defending plagiarism.

130. **amused**
January 24, 2008

Peter O.,

To my mind, that’s like saying I am “defending murder” if I say that a drunk driver who kills a pedestrian has committed a less grievious offence than someone who kills in cold blood.

131. **Peter Woit**
January 24, 2008

Here is the deleted comment from amused. People can judge for themselves whether I was right to delete it or have “lied” in my characterization of it. But please, discussing it has nothing to do with the topic of this posting: plagiarism and its toleration by journals, please stick to that here. If you want to insult me as a demagogic liar or praise me as a fearless defender of high standards of ethics, you can do so by e-mail, not in this discussion section.

“”You can start to give Scientific Tulip Awards to competent lonely scientists”

Well I would love to do that, Tansu, but first we have to find some competent Turkish scientists. (Do you insist that they must also be lonely?) None of the plagiarists in this scandal are in the least bit competent… but how about the METU faculty who exposed them, would any of them qualify?"

132. **Peter Woit**
January 24, 2008

amused,

What you're doing is defending as brave and admirable the decision not to sanction, in your analogy, a drunk driver who has killed a pedestrian. This is why it is accurate to say that you are defending plagiarists and their plagiarism. It's also why most people think you are defending something indefensible.

Except Eric I guess, who goes further and suggests that drunk drivers killing pedestrians is a good thing…

133. **Peter Orland**
January 24, 2008

Amused,

Socially unacceptable behavior can be characterized in degrees. That isn't the point.

At most accredited schools and universities, any student who has been found to copy published material is (and should be, in my opinion) in serious jeopardy of being expelled. If this activity is unacceptable in our classes, shouldn't it be utterly unacceptable in our journals?

134. **amused**
January 24, 2008

Woit, you are just unbelievable. The GRG editorial decared the text copying to be unacceptable. I agreed with the GRG editorial. So no, it is *not* analogous to sanctioning the drunk driver, it is analogous to saying that he/she should get a lesser punishment than the person who kills in cold blood.

Peter O.,
I am *not* trying to say that plagiarism is ever acceptable. But I think it is appropriate to treat different kinds of plagiarism differently. When a physics researcher copies background text it is unacceptable, but at the same time a much less grievous offence that plagiarising research results. I can't believe we are disagreeing about this.

As for my previously deleted comment that Woit misrepresents as deriding Turkish scientists: No that was not how it was intended. I decided to respond sincerely to show up the leering sarcasm of the person I was responding to. I know absolutely nothing about Turkish science or scientists, except that the plagiarists in this case seem to be lousy ones. I think it would be a genuinely good idea to show some recognition to good Turkish scientists in the present situation. The obvious place to start when looking for them would be the people who exposed this scandal. Also, that commenter had been insinuating in many posts that Turkish academia is corrupt to the bone, so drawing his attention to the fact that it was Turkish scientists who exposed this plagiarism is a way of confronting him with reality.
Having said that, I do find it strange that Salti & co were able to put out 1-2 papers a month for 2 years before anyone got suspicious and looked into it. If grad students had been doing that at any of the uni's i've been at I'm sure people would have been onto it much sooner. When grad students start doing this kind of thing it reflects badly on the environment and values in a department, something which surely all faculty share responsibility for.

135. **Eric**
January 24, 2008

I think there should be a distinction made between paraphrasing someone elses work while giving a reference and whole-sale copying without any reference. The first is definitely not plagiarism, while the second case is clearly unacceptable. However, from the narrow arguments of Peter et. al., even copying the LaTeX for a formula or table from another paper is plagiarism.

136. **amused**
January 24, 2008

Peter O.,
Adding to my previous reply: Yes, it is a perfectly reasonable opinion that activity that isn't aceptable in classes should also not be acceptable in journals. I wouldn't say that you or anyone else who held that view was wrong. At the same time, I think the GRG editors' view — that the paper may remain in the journal because its results are all new, but that the authors are shamed by having their copying pointed out in an editorial, which states it is unacceptable — is also a defensible position. I just don't think there is only one "right thing" to do in this situation. The GRG editors handled it one way, the PRD editors another way, and both were completely reasonable in my opinion.

137. **Peter Woit**
January 24, 2008

amused,

My apologies if I misread the intent of your question about whether any of the METU faculty who exposed this plaigiarism are competent, which I read in the context of your earlier sneering comment about "those wonderful METU faculty members":

"Those wonderful METU faculty members who caught the plagiarists, where were they while Salti & co were putting out 1-2 papers a month over 2 years? (They didn't notice?) What kind of environment and values were they and their colleagues propagating? Perhaps you can consider directing some outrage at them Peter, if you have any left over after you are finished with the journal editors."

In any case, questioning whether the people who exposed this plagiarism are professionally competent seems to me to be a highly inappropriate diversion from the issue of what to do about the plagiarists. I think I was correct to delete your comment, and will delete any further attempts to turn this into a discussion of the competence of the people responsible for bringing the plagiarism to the attention of the arXiv and the journals.

There's a standard, minimal, conventional and appropriate sanction for plagiarism: withdrawal of the paper. At most institutions, the sanction for this kind of plagiarism is actually much more severe than this, often including dismissal from one's academic position. In this case, one can reasonably argue about how the institutions involved should sanction the authors caught plagiarizing, but I don't think there is any reasonable argument for not withdrawing the papers, and requiring the authors to resubmit them in unplagiarized form.

The arXiv, PRD, JHEP and Astrophysics and Space Science editors decided this was serious plagiarism and took the appropriate action, the GRG editors decided instead to defend the publication of the papers, despite their heavily plagiarized nature and not to even put any note on the papers that they consist largely of plagiarism. You consider this brave behavior and forceful criticism of it to be demagoguery, I think most scientists strongly disagree with you about this. Right now, anyone who looks up these papers in GRG will find no indication that they are looking at a heavily plagiarized document. If they happen to run across the GRG editorial (not so easy to find…), they'll get the impression that there was a small amount of irrelevant plagiarism in these papers. The only way they are likely to know that the plagiarism was serious and extensive is if they look up the arXiv version and see the withdrawal statement there. Journals are supposed to be more reliable sources of information, with higher standards than a preprint server, but quite the opposite is true in this case.

Eric,

I've not entered into the issue of deciding how much copying has to go on before something is sanctionable plagiarism. Obviously there are grey areas. What I have said, and stand behind, is that if you look at the marked-up pdfs of the two GRG papers, they are undeniably examples of extensive plagiarism, of a sort that should not exist in an academic journal. Any journal that makes the mistake of publishing something this heavily plagiarized should withdraw it, not leave it on-line with no indication it is plagiarized material.

138. **Hans**
January 24, 2008

GRG did also publish some papers of the Bogdanovs. After it came out, that their papers were simply a joke, GRG did not withdraw even these strange papers.
At this time, one of the editors of GRG, Nicolai, gave an interview in the german magazine "Die Zeit" in which he stated, that if these papers would have appeared on his desk, he would have rejected them. He said that he would try to improve the standards of GRG.

Seems that he failed, or that GRG is such a problematic journal, that it cannot defend itself from garbage. scary..

139. **Peter Woit**
January 24, 2008

Hans,

The Bogdanov papers were not published in GRG. One was published in Classical and Quantum Gravity, which is what you are thinking of. That journal did not withdraw the Bogdanov paper.

The statement by Nicolai you quote refers to that journal, where he was an "honorary editor". An e-mail signed by him and the journal publisher, see

http://math.ucr.edu/home/baez/bogdanoff/

said that the journal editorial board had determined that the paper should not have been published, but decided not to withdraw it.

A later version of this statement, see

http://listserv.nd.edu/cgi-bin/wa?A2=ind0211&L=pamnet&T=0&F=&S=&P=3647

deleted the language about the editorial board having determined that the paper should not have been published, and reads purely as a defense of publication of the paper.

140. **Hans**
January 24, 2008

Peter, Thanks, sorry, I confused class quant grav with gen rel grav.

141. **amused**
January 24, 2008

Peter W.,

I regret making that "wonderful METU faculty members" comment. While the length of time it took for the situation to get noticed and looked into there does seem strange, I don't know anything about the goings on and so shouldn't have made that comment.

I agree with your criticism about GRG not mentioning the situation about these papers on their (the papers) websites. They should definitely add a note about it with a link to the editorial.

As for the rest of GRG's handling of this, I can't really say anything more than what I've said already. The authors have been shamed, the text copying was declared unacceptable, and intolerable in the future… to me that seems sufficient. You suggested the authors should have to rewrite the papers in their own words — sure, I wouldn't object to that, just don't see what it would achieve that hasn't been achieved already (apart from giving them some extra punishment and English practice).

About demagoguery (also spelt more efficiently but still legitimately as demagogy): that wasn't directed at your criticism of GRG but at the way you were responding to my comments. When you and others challenged my views I always responded with detailed step-by-step responses to your points. It would have been nice to get something similar in return. Instead I got misrepresentations of what I had said (for strawman arguments) and ex cathedra proclamations that I was a "defender of plagiarism" etc. Ok, I know that you are busy and have other things to do (so do I). But that kind of response comes across as you wanting to ram your judgement down our throats rather than engage in a discussion in good faith.

142. **Tansu KUCUKONCU , PhD**
January 24, 2008

amused,

you're defending plagiarism and unethical behaviours.
Your style is clanic. Strange.
Probably I know who you are.
Normally your approach is unacceptable especialy for who holds positions like yours.
I am trying to understand your role in this game.

Do you have a plagiarismmeter which you decide according to it
such as this much is acceptable, this much is more acceptable,
etc ?

"

1.
it is important to distinguish between plagiarism of results and copying of background text, and that the GRG decision to allow the papers to remain in the journal in this

instance because their results are original,
2.
while declaring the text copying unacceptable and stating that it won't be tolerated in future, might actually be quite reasonable
"

Let us assume part 1 is true.
Why don't you and GRG defend this in part 2 then ?
Let us assume part 2 is true.
Why do you and GRG defend this in part 1 then ?
You are falsifying part 1 in part 2 and vice versa.

This means that ohh our folks have caught on job,
let's not apply the rules for them.
In Turkish there is an idiom for this : belly dancing.

Future ? Which one ?
100 years later ? 1000 years later ?
Or the future when the plagiarists are the
ones who don't need to be defended by you and GRG ?

" GRG shamed the culprits by discussing their text copying in an editorial, and stated that it was unacceptable and would not be tolerated in future. "

Why does GRG accept things now which it declares will be unacceptable in an unknown future ?

" I happen to think that is a sufficient response and don't agree at all that it is causing actual harm. "

Relativity again.
Harm for what or who ?

——————————–

" Do you think the GRG editors — Ellis and Nicolai — are people of limited integrity who don't take ethical issues seriously? "

This is the general view of lots Turkish academicians, juristocrats, etc even at top positions.

Clanic style. You say :
obey the masters.
This is very ordinary in Turkey.
But GRG is not in Turkey, and it's not Turkish.

——————————-

" The credit physics researchers get for a research article is determined entirely by their results. No one gives a sh*t about their eloquent introductions and background material. They get absolutely no credit for it. "

This is not generally valid for Turkish system which is based on partizanship.

———————————

I couldn't find an image of Leman's Tulip Awards.
Anyone see it guesses whom it is given for what 🙂 .

Showing lonely competent scientists as candidates for it was an irony.

Language game. Greetings to Wittgenstein.

———————————

METU, my university at the same time,
corresponds to MIT etc of US and
Cambrigde etc of amused's island.

It is impossible in Turkish system that
everything can be alright for METU.
YOK's (Higher education/despotic council) ex-president and his
ex-team who were METU faculties were the most despotic ones,
and they gave the highest harm to Turkish university system
and Turkey. They covered hundreds of plagiarism cases.
As I said comu's ex-president and head of comu plagiarism ring
was a faculty of METU physics dept., so was comu's vice president and 2nd head of comu plagiarism ring.
In spite of these, average of METU in lots of subjets is very high
that others.
METU equip exposed arXiv plagiarism case,
in spite of some faults of METU
(by others who are not in that equip),
the other 13's cases are trying to be covered.
METU equip's work would have been more difficult
if METU plagiarists were faculties, deans, etc.
But it's also difficult to meet such plagiarists in METU,
since METU has an internationally respected name
to be kept.

In short,

amused, yes,
mentioned METU equip consists of very qualified scientists.
They are not lonely, and they don't have any trouble to
publish their qualified works.

But there are lots of lonely (or unpartizan) qualified scientist in Turkey which have not much chance to progress if support to plaiarists and other unqualifieds continues.

So your proposal to think about what can can be done
is similar to giving pies of good boys to bad boys then
giving candies to good boys to make them forget their pies.

— — — — — — — — —

Is there any more complex complo theories
behind supporting plagiarism in a developing country ?

— — — — — — — — — —

Eric, let me repeat what Stan said :
Should we assume you are an active researcher copy-pasting material without even citing ?

— — — — — — — — — —-

I wonder
what would happen if arXiv plagiarists were not Turkish,
but for exampe Amerikan, for example from MIT or like
not from METU,
or for example from amused island from Cambridge or like
not from METU ?
What would be the trend of the discussion here then ?

143. **Ali**
January 24, 2008

Tansu, METU is NOT MIT of Turkey. It is not anywhere close to it. In the recent top 500 universities of the world listing of The Times, there were 5 turkish universities AND METU was not in that list. You should realize you are not the only one who has PhD in this forum so you should try to provide accurate information if at all possible. Plus, like I suggested to you before, you should try your chances in other high-caliber universities if you think you are really such a great scientist. I do not understand why you are so obsessed with comu and metu. I enjoy your sarcastic comments but I would prefer if you can quit this chip on the shoulder attitude.

144. **amused**
January 24, 2008

Tansu,

Yes, I'm defending plagiarism, murder, and lots of other terrible things.

Good luck with working out my identity from my strange clanic style 😉 (hint: if you think i have a "significant position" you're sadly mistaken).

My role in this game: a random physicist blog commenter who doesn't know when to keep his mouth shut. Now you know 😉
No I haven't finished building the plagiarismmeter yet, so for the moment can only distinguish between plagiarised results and copied background text. Some people think this is already sinful enough.

In answer to your questions about 1 and 2: I guess the GRG editors are hoping that people will heed their warning and not submit more papers with copied text, or that the software will catch them if they do. In that case the editors can avoid having to do what they don't want to do, which is to retract papers which their referees have already deemed publishworthy. But if it happens again in future they will of course have to take stronger measures, i.e. retract the offending papers.
The idea of giving people a warning before taking stronger measures against them seems quite foreign to you… Ideally it should work as a deterrent.

"Relativity again.
Harm for what or who ?"

Anything or anyone. If you disagree, can you explain precisely where the harm is (caused by the GRG decision to shame the authors, declare what they did unacceptable, but allow the paper to stay in the journal because the only part of it that counts for anything — the results — are not plagiarised.)

"Clanic style. You say :
obey the masters."

No, it's just natural to respect people who've earned it.
(I'm sure you'll have some fun with that.)

"But there are lots of lonely (or unpartizan) qualified scientist in Turkey which have not much chance to progress if support to plaiarists and other unqualifieds continues."

And I've been supporting the plagiarists in this case, right? By pointing out that their text-copying isn't as bad as plagiarising research results, and suggesting that the sanctions GRG took were already sufficient…
Come on, any competent researcher (lonely or not) should be able to outcompete these clowns on merit, and that won't be made any more difficult by the clowns' copying of background texts. So if the clowns are winning it means the system is not based on merit (i.e. rewarding quality ahead of quantity of junk) — that's where the real problem lies.
Why are you so much obsessed about "plagiarism rings" and so little concerned about the merit issue? It seems you wouldn't mind the system rewarding lousy researchers as long as they hadn't plagiarised anything..

145. **Tansu KUCUKONCU , PhD**
January 25, 2008

Ali,

may you explain who you are, what your background

and foreground are, what your position is ?
It should not be needed to hide yourself.
To compare METU with other Turkish universities
(except a few ones) is funny.
This is the list you mentioned :
Bilkent (most of its faculties are METU graduates),
Cukurova, Istanbul Technical, Istanbul, and
Sabanci (lots of its faculties are METU graduates).
You said you studied abroad.
Did you meet or hear anyone (faculty, researcher, high skilled employee, etc) in any top level university, research center,
company, who is a graduate of Cukurova uni. which is 30+
year old ?
or who knows its name ?
There are thousands of such METU graduates all around the world
(in MIT, Stanford, Berkeley, Yale, Oxford, Cambridge, …..
in research centers of NASA, Microsoft, IBM, Sony, Google, Boeing,
….).
You can easily meet people in scienfitic, research, high skilled company, etc communities all around the world who know some about METU.
METU (which is 50+ year old) is the #1 Turkish university in being known globally.
#2 (Bosphorus, which is 150+ year old),
#3 (Istanbul Technical, which is 230+ year old), and
#4 (Bilkent, which is 20+ year old)
follow it far behind in this regard.

One another important thing, you know this well :
Nationwide University Entrance Examination (UEE).
This is the primary way to start to study in a Turkish university.
Rank in that exam is the main criteria.
Students prefer where to study according to their ranks,
and they're automatically accepted according to their ranks
and preferrences.
METU's almost all the students, during almost all of its history,
have ranks between 1 to 1000, or 0.1 to 1%.
Last year 1.500.000+ students took that exam.
Preferrence by the top level students shows its relativistically correspondence to USA's top level universities.
Bosphorus' student spectrum is similar to this.
There is no other university having an overall similar student
spectrum.
To meet UEE's rank 1 students between METU students
is very ordinary.

Did you meet or hear any student who has a rank in the
first few thousands (not 1000, or 100, or 10) and
preferred to study in any dept. of Cukurova ?

— — — — — — — — — — — — — — —

" I do not understand why you are so obsessed with comu and metu. "

I am victim of mafias of comu, Turkish university system, and
Turkish juristocracy which has deep conjunctions with others.
Lots of my human rights have been violated.

— — — — — — — — — — — — — — — -

amused,

may you explain who you are, what your background
and foreground are, what your position is ?
It should not be needed to hide yourself.
Don't make your readers wonder who is behind this defence.

" The idea of giving people a warning before taking stronger measures against them seems quite foreign to you… "

You are saying as if plagiarism were newly discovered
and announced as an unacceptable thing.
It can be extended, as you said, to
"murder, and lots of other terrible things".
Hey folks, others dislike what you did, no problem for us,
be careful and don't be caught next time,
otherwise it will be difficult to protect you next time.
Yes, this is clanic.

— — — — — — — —

" it's just natural to respect people who've earned it. "

Defending plagiarism is a very great risk to lost all the
respect earned till then.

— — — — — — — — —

" So if the clowns are winning it means the system is not based on merit (i.e. rewarding quality ahead of quantity of junk) — that's where the real problem lies. "

Yes what I basically say is this :
Turkish university system is not based on merits,
it is based on partizanship.

” Why are you so much obsessed about “plagiarism rings” and so little concerned about the merit issue? It seems you wouldn’t mind the system rewarding lousy researchers as long as they hadn’t plagiarised anything.. ”

That ‘s completely wrong.
My main issue is the merits and lackness of merits.
But this is country-wide problem in Turkey noy limited to universities.
As I said, for ex., juristocracy is supportings all the faults
in universities.
“Plagiarism rings” are not just “plagiarism rings”.
They are mafia rings at the same time, deeply connected to
other mafias.

— — — — — — — — — — —

” Anything or anyone. If you disagree, can you explain precisely where the harm is (caused by the GRG decision to shame the authors, declare what they did unacceptable, but allow the paper to stay in the journal because the only part of it that counts for anything — the results — are not plagiarised.) ”

Yes, let me explain :

1. Turkish system traditionally is trying to cover the 13 of 15 plagiarists’ cases.
GRG is giving support to this coverage to be done easily.
Turkish plagiarists’ are saying that “who are blaming us as plagiarists are the enemies of Turkey, they’re nothing else.
arXiv is just an unimportant archieve,
look that GRG published our articles and GRG is defending us
against who are blaming us”.
These are clowns, but very dangerous ones.
GRG’s support is preventing Turkey to get rid of these clowns.
arXiv scandal is the first internationally exposed mass Turkish plagiarism case. This may be a great opportunity for Turkey to brake
plagiarism tradition. But GRG’s support is a wall in front of this.
What happens if nothing happens to this 15 plagiarists ?
It will be very difficult to catch them on job again.
They will try to be more careful.
An assoc. prof., prof. holds his position in university during life time in Turkey without being interested in science, without producing,
withot teaching. He gains 3.000 (~2400 usd) ytl to 100.000+
(80.000+ usd) ytl per month.
Such clown academicians close all the gates to qualified academicians, and open all the gates to their partizan clowns.

Is that much harm of GRG to Turkey and to Turkish qualified
scientists enough ?

2. GRG’s support to plagiarism encourages plagiarists
all around the world, and cause similar harms to
especially developing countries as explained in (1).

146. **Ali**
January 25, 2008

Tansu, I have a PhD in theoretical condensed matter physics from USA and I live in Canada at the moment. I have no relation with metu or comu in any way. I did not study there. Yes I met lots of metu graduates personally. My impression is that metu used to be one of the top (if not the top) universities in turkey 20 or 30 years ago alongside with itu and bosphorus (all public schools for non-turkish readers) but when private universities started in 1980’s and 1990’s (like, bilkent, sabanci and koc) metu lost its lead and it is way behind these schools at the moment. The metu graduates who are in positions you mentioned graduated long time ago. They are not recent graduates. The recent metu graduates I met were mediocre students to put it mildly. Again, back to my original statement, you need to try your luck somewhere else if you think you will not be able to get into metu and comu. This whining is not gonna take you anywhere. Good luck

147. **Tansu KUCUKONCU , PhD**
January 25, 2008

Ali,

I don’t know why, but you are chainging the route of the discussion.
This is passively or indirectly doing something.
Do not hide yourself, who you are, where did you study, where you are now.
There is an allergy to METU and METU graduates in Turkey
by some since it’s top level and very different than others as in the example of its behaviour in case of arXiv scandal.
This allergy caused the trials of closing METU completely, and
closing of METU for 1 year in 70’s.
It seems that you have that kind of allergy.
What you said about METU is not true.

I don’t want to go into details of comparison of Turkish universities,
but what I said about METU is valid for almost 50+years since
almost its constitution.
“METU’s almost all the students, during almost all of its history,
have ranks between 1 to 1000, or 0.1 to 1% in UEE.”
So they always had and will have positions in top level institutions and companies all over the world.
“There is no other university having an overall similar student
spectrum.” Neither bilkent (which is 20+ year old ; lots of its faculties are METU graduates),
nor sabanci (which is 10+ year old ; lots of its faculties are METU graduates),
nor koc (which is 10+year old ; lots of its faculties are METU graduates), nor others.

Nothing has changed. And there is no sign of that it may change in the near future.

— — — — — — — —

" you need to try your luck somewhere else if you think you will not be able to get into metu and comu. "

The problem here is arXiv plagiarism scandal and Turkish plagiarism and the tradition behind it.
You are tactically changing the route to the wrong way.
I didn't say anything that I wanted to get into metu or comu.
I very explicity said :
" I am a victiom of comu mafia and other mafias in connection with it
and these mafias have violated lots of my human rights for 7 years.
Moreover I could not make my voice to be heard in Turkey during these 7 years due to country-wide effectiveness of these mafias.
So I am in search of justice for these violations for 7 years
and will keep searching till whereever it goes. "

148. **amused**
January 26, 2008

Tansu,

You want to know my background, foreground and position? Really, I am no one important. I don't have any connection to the people involved in this and have nothing personal at stake. The only reason I joined in this discussion was because I thought there were some relevant points that were not being made, and I felt like making them. What difference would it make if you knew my name — it would mean nothing to you. (Btw, Woit knows who I am, so I'm not completely anonymous here.)

First of all, I am sympathetic to your situation and wish you and everyone else fighting against academic corruption wherever it is best of luck.

Second, the GRG editors' response was in no way a defense of those papers. They shamed the authors by writing an editorial about their text copying, saying it was unacceptable. Yes, they distinguished between the nature of the plagiarism in this case — copying of background texts — and the much more serious plagiarism of results which didn't happen in this case. Well, that is a reasonable and fair distinction to make in my honest opinion, even though some commenters here apparently think it is sinful to make such a distinction. But if the plagiarist authors are presenting the GRG response as a defense of them then they are totally deluded. Anyone who reads the editorial can see that (despite the misrepresentation of it by a demagogue with an anti-journal agenda.)

The main message from what you have been saying seems to be this: there are mafia-style groups operating in Turkish academia for their own profit (financially and status-wise) without contributing much (anything?) of actual worth to their fields. They thwart the careers of competent honest researchers by "rigging the game" in various ways. Now they have been caught out for large-scale copying of others' background texts in their papers. (They were too careless and lazy to change the words a bit to avoid this situation, even though it would have been easy.) Understandably, the honest Turksh academics want to seize on this as an opportunity to hit back against the mafia and loosen its grip. And they are disappointed with the GRG response, because if GRG had gone further and retracted the papers (like the other journals did) it would have given the mafia opponents even stronger ammunition than they already have. Well, I can sympathise with that. However, it is wrong to expect GRG to become a player in the Turkish situation, and taylor its response so that it maximally benefits the good guys in that struggle. Journals, like newspapers, should remain detached from such things and do what is right in their independent judgement (for obvious reasons). That is what the GRG editors have done in this situation. I happen to think they made a reasonable, or at least defensible, judgement (although not the one I would have made); others disagree.

In any case, in the long run the only way the mafia situation can really get fixed is if an academic culture is established were rewards are based first and foremost on merit. Let's imagine you get what you want out of the current situation: this mafia gets smashed and its members are expelled from Turkish academia. What next? In the absence of a merit-based reward system, other characters will emerge whose talents for scheming and manipulation are inversely correlated with their competence as researchers; they will band together and take the place of the previous mafia. The names and faces change but the situation stays the same.
So if you are really going to change anything, the main focus has to be on the academic culture, changing it to one where rewards are based on merit. For this, it is infinitely more important to expose the lousy quality of the mafia members academic output than to expose instances where they were too lazy to even change the words in the background texts they copied.

149. **Aaron**
February 10, 2008

Amused: I am perplexed by your insistence that only the results matter for a paper, not the language. How results are presented are crucial to how well other people can understand and use new results. As an extreme case, are all review articles worthless in your world? Why?

Withdrawal of the paper is not to punish the plagiarists — it's a return to the status quo ante. It is also vital for the credibility of the journals. Journals are a type of database of who has contributed what. Having these databases filled with false information is little better than not having them at all.

Have Cosmologists Lost Their Brains?

January 15, 2008
Categories: Multiverse Mania

There's a peculiar long article in the New York Times science section today by Dennis Overbye, entitled Big Brain Theory: Have Cosmologists Lost Theirs? It's about the debate raging among a small number of cosmologists about "Boltzmann Brains", and the article does a pretty good job of explaining what the debate is about.

This seems to be a debate that is mostly taken seriously by people who live near the coast in California, with the article quoting Susskind and Linde (Palo Alto), Lisa Dyson and Raphael Bousso (Berkeley), Hartle and Srednicki (Santa Barbara), Albrecht and Sorbo (Davis), and Sean Carroll (Pasadena). One of the few from further inland who is quoted is Don Page (Edmonton), described as a "prominent voice in the Boltzmann debate" who argues with Hartle over the issue of whether to count humans differently than insects since we have consciousness. Page's recent arguments that God may like having lots of universes around are not quoted. On the other hand , Andrei Linde has a lot to say about what all this has to do with reincarnation, with the article ending with this quote from him:

> "If you are reincarnated, why do you care about where you are reincarnated?" he asked. "It sounds crazy because here we are touching issues we are not supposed to be touching in ordinary science. Can we be reincarnated?"
>
> "People are not prepared for this discussion," Dr. Linde said.

Overbye does note that:

> If you are inclined to skepticism this debate might seem like further evidence that cosmologists, who gave us dark matter, dark energy and speak with apparent aplomb about gazillions of parallel universes, have finally lost their minds.

and, while he doesn't quote any such skeptics, I suspect the title of the piece and the way he quotes some of the sillier things respectable cosmologists are saying indicates some sympathy for skepticism about this.

If you do take all this seriously, you might want to discuss it over at Cosmic Variance where Sean has a posting on the topic. In the NYT piece he is quoted as saying:

> When you break an egg and scramble it you are doing cosmology

to which his ex-colleague Jeff Harvey from Chicago responds in the comment section:

> When I break an egg and scramble it I'm making breakfast. I guess that is the difference between cosmologists and particle physicists.

Update: The New York Times is listing this article as the most popular article on their site (in terms of how many people are e-mailing it to others).

Comments

1. **Joe**
   January 15, 2008

   I was reading this this morning at the doctor's waiting room, and I could not helping thinking that these people must have got their probability calculations way off.

   The chance for amino acids to randomly line up to become a functional protein is incredibly small — for a chain of 27000 amino acids that's 20^-27000. There are not enough multiverses around even for a single molecular of such protein to emerge randomly. The chance for the human genome to auto-assemble is 4^-3000,000,000. This is presuming the required small organic molecules are in abundant supply. Then these randomly formed gaint molecules must fold properly and appear in huge concentrations and close approximity to each other and assemble into the correct cellular struture. The chance for that would be 100^(-10^24) or smaller! And even then you got only a dead, decaying brain.

   The only way for sentient brains to arise is through exponential Darwinian amplification, an process far more powerful than cosmic inflation and bubble universe regeneration – Darwinian amplification simply acts faster and over-powers all of these puny cosmic processes. A suitable universe that supports Darwinian processes is the most likely one to be observed by concious minds.

2. **David Nataf**
   January 15, 2008

   Joe,

   What is exponential darwinian amplification?
   It sounds like some new age notion.

   And while there are certainly enough multiverses around (if they exist they're infinite) to have 10^-10^30000 events occur every so often, I personally prefer the hypothesis that these calculations are wrong because they are missing physics/chemistry we have not yet observed or taken into account.

3. **Peter Woit**
   January 15, 2008

   If you think it's worth your time to discuss this kind of calculation, please do it over at Cosmic Variance. I don't want to spend my time trying to figure out how to moderate a discussion that seems to me completely absurd.

4. **Bee**
   January 15, 2008

   Likely, we will be reincarnated as a Simpsonian Brain then. In terms of probability, it's cheaper.

5. **KesheR**
   January 15, 2008

   I don't believe in this, but it's funny and tricky, like every paradox, right or not.

For you Spanish talkers around the world, I have translated the wiki from English:

http://es.wikipedia.org/wiki/Cerebro_de_Boltzmann

6. **Kea**
January 15, 2008

I don't know whether to laugh or cry. Absurdity may be inevitable when physics reaches such a state, but to this level? Thanks, Bee, for the picture of Darth Vader. Cute touch.

7. **Xerxes**
January 15, 2008

> I suspect the title of the piece … indicates some sympathy for skepticism

Don't forget that journalists do not choose the headlines for their stories. That job is done by copy editors (because it's mainly dictated by the constraints of page layout and column width), and the journalists often are unhappy with the results.

8. **Bee**
January 15, 2008

Hi Kea,

Glad you like it, I couldn't resist. A paper titled 'Return of the Boltzmann Brains' seemed to beg for it. I just noticed though that I lost a bet I had running with a friend, the paper didn't get published (within 12 months). And while I am at it, neither did this paper get published nor that. Maybe he just doesn't bother? Best,

B.

9. **rrtucci**
January 15, 2008

And then Physicists wonder why their funding is being cut.

It's sad that these bozos are well funded whereas people trying to do real physics (e.g., quantum computing) go hungry.

10. **Arun**
January 15, 2008

I would expect that the "overall density" (whatever that means) of Boltzmann brains would be the same as in our observable volume of universe.

11. **capitalistimperialistpig**
January 15, 2008

I think that there is a real physics puzzle here despite all the silly rhetoric and anthropic absurdity. The problem is that we don't have any good way to explain the initial low entropy of the Universe. We can take it as given boundary condition, but it does assort somewhat poorly with other notions cosmologists hold dear. I think Sean Carroll is reasonably clear on this.

12. **Eric H**
January 16, 2008

There seems to be a misconception that intelligent people must be nerdy in the most extreme sense. It seems to be an archetype that the public buys into ever since they saw their first Jerry Lewis movie when he was still with Dean Martin. So the more over the top and delusional the idea the more the average joe in the NSF and the hiring committees at universities say to themselves "I don't get this. He must be onto something". Of course it helps if the person with the idea has complete overwhelming confidence in the non-ridiculousness of the idea.

13. **chris**
January 16, 2008

capitalistimperialistpig,

the entropy of the universe is quite easily understandable with the help of classical rg arguments, see e.g. http://arxiv.org/abs/0706.0174v2
only die-hard string believers seem to have problems explaining it.

14. **alex**
January 16, 2008

Lubos has a sane, reasonable and I think correct article on why these sorts of calculations are wrong.

http://motls.blogspot.com/2008/01/new-york-times-about-reincarnation-in.html

15. **oohay**
January 16, 2008

Actually LM's article is completely insane even by his standards. In particular, Sean C goes to great lengths to make it clear that neither he nor anyone else believes in the existence of B Brains, but of course LM thinks that all of the cited authorities do believe this. In fact his whole style of reasoning is very typical of people suffering from paranoia. For example, he thinks that it is wrong to ask why the initial entropy of the world should have been low, since asking such a question means that you are conspiring to subvert the second law of thermodynamics.

Anyway his post serves a useful unifying role: we are told that Sean Carroll's errors are essentially the same as those of people who believe in global warming. Ergo, if you think that LM is full of it on climate issues, you can safely deduce that his views on the foundations of thermodynamics are absolute crackpot material. Which indeed is how people in the field regard them.

16. **Bee**
January 16, 2008

Eric: So the more over the top and delusional the idea the more the average joe in the NSF and the hiring committees at universities say to themselves "I don't get this. He must be onto something". Of course it helps if the person with the idea has complete overwhelming confidence in the non-ridiculousness of the idea.

I have no idea why you think this is the case, but this impression is definitely completely off. Funding and hiring is in my impression still based on very conservative evaluation of a person's research program. If hiring committees would set up their shortlist based on the criteria 'I don't get this.', I'd throw a couple of my unpublished more wacky drafts on the arxiv and stop worrying about getting tenure. Without meaning to insult anybody, I think one can afford working on such stuff if one has reached a certain level of seniority and doesn't have to bother any longer what people think of it. (That is to say, I will leave the wacky stuff in the drawer until I'm 60.) Sean has to make quite some effort to clarify what the actual physics is behind that more bizarre discussion. Media attention might become a factor of increasing importance for funding and hiring – that could indeed be, and it is a development I dislike very much. Best,

B.

17. **Eric H**
January 16, 2008

Bee,
I agree with your last sentence about media attention and consider it an echo chamber between that and funding and hiring decisions by administrators. Ultimately, I was having fun with them because they deserve it for being spineless and sucking the air out of the room for other scientists more deserving. I agree with an earlier comment about using thermodynamics and conservation of information as the final arbiter to decide if something is wrong. Until the people in control of these decisions start doing that they deserve any derision they get. ("Funny" is always better than "rude" in targeting one's derision, and generally more effective.)

18. **capitalistimperialistpig**
January 16, 2008

Chris,

I checked out the paper you mentioned. If I'm not mistaken, the authors assumed that the universe started in a pure state with entropy zero. That should simplify the task of getting an initial low entropy Universe.

19. **Gazouille**
January 21, 2008

Peter & guys,

I'm not on topic but.. well

Today, somehow by clicking on links this site I ended up here
http://www.volny.cz/lumidek/crackpot-not-even-wrong.html
Where did I click was my question :).

Pathetic page, but still I listened to that Susskind's interview.

He's pretty clear on that the only thing wrong with string theory and the landscape is Peter Woit and Lee Smolin. We're saved, phew.

20. **Manuel Pace**
January 21, 2008

"What is consciousness but the animal feeling of being alive."
Charles Saunders Peirce.

21. **John Gribbin**
January 30, 2008

All the people who say that the numbers involved are so extreme that they can be ignored are way off beam. If the multiverse is infinite, anything can happen an infinite number of times, provided it has non-zero probability. No matter how large a number is, it is literally infinitesimal compared with infinity.

22. **jpd**
January 30, 2008

Not quite, there are many types of infinities.
if there are possibilities corresponding to the Real numbers,
and if there are successes corresponding to the Natural numbers:
both are infinite but the probability of success is still zero.

Updates

January 16, 2008
Categories: Experimental HEP News, This Week's Hype

- On the HEP budget problem front, Adrian Cho has an interview with Ray Orbach of the DOE. Orbach is not very encouraging on the prospects for a supplemental FY 2008 appropriation:

> … my assumption is that the last thing that Congress or the president wants is a decorated supplemental. Because, you come in for the Office of Science, and there will be somebody else coming in, and before you know it, the thing will be enormous. … My guess is that it would be very hard to single out a particular program for a supplemental.

He does promise a very healthy FY 2009 proposed increase:

> Now, I can't tell you, obviously, the details of the president's budget for '09, but I can tell you that it will be a wonderful budget request. And because '08 has been difficult for us, the gap between '08 and '09 will be large.

He notes that the DOE and the president are convinced of the importance of supporting HEP research, that the problem is with the Congress:

> I think now the high-energy physics community understands how Congress feels and has a job on its hands to explain why it should be supported at the level of the president's request.

He doesn't shed any light on the continuing mystery of who exactly in Congress made the decision to target HEP for cuts or what their thinking was, leaving it still unclear who it is that the HEP community is supposed to be making its case to. It would be nice to know this before next Christmas, since if this person or person doesn't change their minds before then, most of the US experimental HEP community may want to make permanent plans to either emigrate or go into a different line of work.

I've heard nothing about the effects of the FY 2008 budget on particle theory or string theory funding. Perhaps the plan of whoever is responsible for this is that the US should shift out of supporting experimental HEP research, and concentrate on string theory and anthropic landscape research, where it continues to hold a leadership position.

- Nature has an article entitled Experimental cosmology: cosmos in a bottle about condensed matter analogs of black holes and physics related to cosmology. One topic covered is the recent bogus claim to "test string theory" using interfaces in liquid helium to model branes. Paul Steinhardt notes one of many problems with this idea, that "string branes are flat and attract one another, whereas the helium-3 'branes' are curved and have no attractive force." Joe Polchinski on the other hand is more enthusiastic, since any prediction could have a big impact. "You never know what you might find" he says.
- The string theory hype machine remains in overdrive, putting out nonsense press releases at an unparalleled rate. This week's string theory hype is from Japan, where KEK has put out a press release claiming Interior Structure of a Black Hole Computed Using Superstrings, which tell us that:

> It is expected that superstring theory will develop further and play an important role in solving interesting problems such as the evaporation of black holes, the state of the early universe and the creation of everything.

The actual calculation behind the hype is a numerical simulation of a supersymmetric quantum mechanics system, which is described here.

Comments

1. **c.r.**
   January 16, 2008

   the link to the numerical simulation paper on the arxiv is broken….

2. **Peter Woit**
   January 16, 2008

   Thanks c.r., fixed.

3. **J.F.**
   January 17, 2008

   Even though the answers were not so pleasant, those were some incisive questions, I am impressed. Enough so that I'm going to restart my membership to AAAS. I've always considered our scientific societies as a soft lobby, so this is one way to help. The APS, for example, will help with anyone who wants to meet their congress member or senator (as a constituent) by scheduling the meeting and providing concise talking points.

4. **String Fan**
   January 18, 2008

   You might want to call attention to the KITP program `Nonequilibrium Dynamics in Particle Physics and Cosmology.' So far every online talk has been about the application of AdS/CFT duality to RHIC physics: no hype, it is just that these methods work. For what is arguably the hardest problem in quantum field theory – nonequilibrium strongly coupled physics – string theory has provided the solvable `harmonic oscillator,' which both matches experiment better than any other model, and provides a standard of comparison for any other theoretical approach.

5. **jon**
   January 18, 2008

   Witten an Kontsewich jointly awarded half of crafoord prize for "for their important contributions to mathematics inspired by modern theoretical physics".

   The longer quote finishes with "The laureates have resolved several important mathematical problems related to string theory and have in this way paved the way for its further development." which could be hyped either way I guess depending on where the emphasis in this sentence is put…

6. **Peter Woit**
   January 18, 2008

   "String Fan",

While I think string theory has failed as a fundamental theory, it may very well lead to useful calculational methods in some strongly-coupled physical systems. But please, off-topic overhyped advertisements from anonymous "Fans" aren't really informative, closer to the dozens of spam comments this blog gets each day.

7. **DB**
January 18, 2008

Chapter 4 of the just published National Science Board report helps to put HEP spending in a US and international context here:
http://www.nsf.gov/statistics/seind08/pdf/c04.pdf

As Orbach explained back in September, FY07 was a jump over FY06 which had only progressed 0.9% over previous year. FY09 is set to repeat this cycle vs FY08. But what is important is to see how areas get treated when the budget is tight. In FY09 HEP will probably be ok and people will breath a sigh of relief. They will probably pay up for ITER and its even looking as if NASA might get an extension on the shuttle and so launch the AMS. But this alternating cycle can mislead people, and in tandem with political finger pointing can hide the underlying trends.

One outfit that doesn't get much attention but is undoubtedly one of the master puppeteers in playing off Congress vs the administration is the Office of Management and Budget, a basically independent bunch of bean counters who are like departments of finance in other countries, i.e., their function is to reign in the ambitions of spending departments. They harbour a pathological hatred of all big science projects. Over the last 50 years of cancellations of key US science projects their role has been absolutely pivotal, as in Apollo, Project Nerva, the supersonic passenger aircraft, SSC, Space Station Freedom etc.

The best and most scholarly analysis of the roles the different actors have played during these budgetary crises I've seen is James Dewar's study of Project Nerva: To the end of the Solar System, which despite its apparently narrow focus, gives a thorough and fascinating insight into how budgets for big science projects have been managed historically. His conclusion is that without a very powerful sponsor in the Senate, large science projects invariably get eviscerated by the backroom bureaucrats.

8. **srp**
January 18, 2008

If only the OMB guys had managed to kill the space station. A greater waste of resources is hard to imagine. The SST was also pretty much a no-brainer. The SSC is more of a borderline case, but the overruns on it destroyed its credibility.

You should read Freeman Dyson's essay about big science and small science in Eros and Gaia. It is balanced and wise.

9. **amused**
January 19, 2008

Re. the string hype from KEK: At least these people had the decency to document the worth of their work by publishing it in PRL before issuing misleading hype to the press. Unlike the surfing independent physicist and Boltzmann Brain enthusiasts…

10. **Suvrat Raju**
January 19, 2008

Hi Peter,
This paper is not about supersymmetric black holes. I remember looking at this when it came out and it is about non-supersymmetric Schwarzschild type D0 black holes in IIA theory. This system is dual to Matrix quantum mechanics with 16 supercharges.

While the underlying theory is supersymmetric note, that the black hole itself is not.

Calculating the black hole entropy is a question of simulating this matrix quantum mechanics at strong coupling. The KEK group seems to have done a fantastic job in doing that, and they find answers that match precisely with gravity.

These results have not received much attention, perhaps because they are numerical and the technicalities are hard to grasp for many people, but they seem to be tremendously important.

best,

Suvrat

11. **amused**
January 19, 2008

As I understand it, the main result of the KEK paper is that supersymmetric quantum mechanics with 16 supercharges can now be simulated numerically, and the internal energy agrees at low temperature/strong coupling with a previous calculation (in Ref. [27], from 1996) from a stringy black hole geometry (via gauge/gravity duality) while at high temp/weak coupling it agrees with previous results from high temperature expansion. In the summary of the paper, the authors describe this as significant evidence for gauge/gravity duality in the non-conformal case. They don't seem to be claiming to have calculated any new properties of stringy black holes; rather, they are reproducing the previous result of Ref.[27] via gauge/gravity duality.
The press release gives a completely different impression though…

12. **Suvrat Raju**
January 19, 2008

Hi,

I dont wish to be involved in a long debate here. Where supergravity is valid, the properties of the black holes are, evidently, well described by classical supergravity.

The point is that they have reproduced the predictions of type IIA supergravity in 10 dimensions, from a totally different calculation in 0+1d quantum mechanics. Second, this is a genuine strong coupling calculation, that does not rely on BPS non-renormalization theorems(as many calculations in AdS/CFT — including the original Strominger/Vafa calculation for the D1-D5 system — are forced to do). Finally, the black-hole involved is, itself, non-supersymmetric.

This, I think, is a fairly remarkable and interesting achievement.

best,

Suvrat

13. **DB**

January 19, 2008

srp,

I'm not going to debate the merits of all the projects the OMB has torpedoed, because they have won in that the US has clearly decided that basic science better be cheap if it is to be funded at all. Unlike politicians, the OMB plays a long game, which is why only a senior senator can hope to be around long enough, and be influential enough, to see these multi-year projects through in the teeth of the OMB's (unelected) opposition.

In relation to HEP, killing off the ILC and the Nova experiment tells me that they still have it in for High Energy Physics, that their real target is Fermilab. Others console themselves with the thought that all that's happening is that HEP research is being concentrated at Fermilab. To which I say, don't be fooled by any FY09 sweeteners.

String theory is the perfect answer to the OMB's concerns with HEP. It's really cheap, and doesn't lead to any predictions which can be tested, so no need for expensive labs. It still claims to be HEP, even though many physicists view it as mathematics masquerading as physics, as evidenced by the application of Ads/Cft duality to RHIC physics: big deal, it's just another mathematical tool and further evidence that the string theory program can create useful mathematical tools. It's also environmentally friendly.

14. **amused**
January 19, 2008

Hi Suvrat,
What you wrote seems to be in agreement with my previous comment, so I'm happy to agree with it. And also about this work being a remarkable and interesting achievement. (I'm less enthused about the press release though.)

15. **Another String Fan**
January 19, 2008

Indeed, this paper looks like serious and hard work. They continue the efforts of (and claim to do better than) Kabat (your colleague at Columbia University, Peter), Lifschytz and Lowe. The matching of the 12-year-old Klebanov-Tseytlin calculation (Ref. [27]) of the charged 10-d black hole entropy looks quite good, but to be even more sure about the scaling with temperature one needs to reach even lower T. The press release is somewhat strongly worded, and will not get a prize for scientific journalism, but we cannot blame the KEK for being proud of their hard work, and of their Hitachi supercomputer. Some amount of `hype' is inevitable because the science writers think that they have to `rise above the noise' and to address those who have heard of Hawking but do not know much else.

Also, Peter, I wish you stopped trashing the press releases about some of the recent PRL's. It is a current PRL policy to encourage the authors to contact their local press offices to try to inform the general public of their work. The authors of a few such recent press releases were just following these instructions. These press releases might be imperfect, but in the judgement of PRL (a flagship journal of the APS) they serve a useful purpose of educating the public. They have to involve a very recent paper, so it is always too early to tell how important this work will be in the long run. But what is wrong with trying to give people some glimpses of current research in theoretical physics?

16. **Peter Woit**
January 19, 2008

Another String Fan,

First of all, if you're actually a professional physicist who knows something about this subject, I really wish you would consider post comments like this using your real name and not hiding behind anonymity and referring to yourself as a "string fan".

Sorry, but I intend to continue to trash over-hyped press releases about string theory based on PRLs. I don't believe this is about "trying to give people some glimpses of current research in theoretical physics", it's about a continuing campaign of claims of string theory "progress" towards a unified theory that is not honest, and that is designed to try and mask the fact that this is a failed research program. I don't think you inform the public or get their respect by putting out press releases that are not true, the effect of this is quite the opposite.

17. **just a fan**
January 19, 2008

I was wondering if there was any way an average person could help get congress to restore your funding?

18. **Zathras**
January 20, 2008

DB,

The Office of Management and Budget (OMB) is not an independent in any way; it is part of the executive branch and submits exactly what the president want it to submit. What you are describing sounds more like the General Accounting Office (GAO), although I do not think they had anything to do with this. This cutting decision was done by the Congressional Budget Office (CBO).

PW: *….the continuing mystery of who exactly in Congress made the decision to target HEP for cuts or what their thinking was….*

This statement disguises a bit how decisions are made. The problem wasn't that anyone was *against it*; it was that there was nobody *for it*. Without a patron in the CBO this type of cut was inevitable.

19. **eddie**
January 20, 2008

I get the impression that 'big science' isn't really about science at all. The 'big' part is about the flow of cash;

tax dollars –> construction co's –> campaign contributions

Outside of the community of researchers, the debate about SSC, and other projects, was about which politician could get it built on their patch for electoral kudos.

I suspect that the OMB was set up to cut out the middle man…

20. **J.F.**
January 21, 2008

just a fan,

If you want to help, on thing you can do is write your senators and members of congress a letter (actual paper, not email). Contrary to what some believe it is NOT a futile act. My understanding is that the staffers for people on Capitol Hill often include bright, knowledgeable people who would like to support (for example) basic research science, but find it difficult to do so without an outpouring of constituent support. Your letter may even carry more weight as a patron than one of the many from people employed in the profession.

Here is a website that has some info in case you need it:

http://www.citizenredress.com/

Thanks for asking!

21. **DB**
January 22, 2008

Zathras,

No, I was and am thinking of the OMB, not the CBO or the GAO, although I don't rule out some minor involvement by the CBO. Incidentally, the CBO was set up by Congress in 1974 in order to take some power back from the OMB – which Congress correctly perceived was usurping its constitutional authority – by establishing a non-partisan watchdog and analysis body to keep an eye on the OMB. But the CBO doesn't prepare budgets so what a "patron" would achieve there is unclear to me. HEP needs a senior senator on its side in the way that NASA has senators fighting its corner. Now that most US terrestrial HEP is concentrated in Illinois, Senators Durkin and Obama are the obvious choices.

The OMB aggregates the spending desires of the executive departments, then makes recommendations on those programs which should be cut to meet the overall budget targets and goals. It is here, and in the continuing to and fro with Congress, that OMB officials get to influence projects they deem undesirable. I suspect Orbach spends as much time arguing with the OMB as he does with congressional appropriations committees.

Here is the presentation his staff made sometime in 2006 to the OMB:
http://www.science.doe.gov/ober/berac/staffin04_05.ppt
I draw your attention to slide 22 which shows the variance of FY06 vs FY05 and ask, plus ca change?

just a fan,

Senator Durbin is up for reelection in 2009 so is an obvious target for lobbying.

Science, and a Bit of Religion

January 22, 2008
Categories: Uncategorized

Some things I've run across in the last few days:

This month's Scientific American is devoted to The Future of Physics, a special report made up of three excellent articles on the LHC machine, the standard model and its discontents, and plans for the ILC. The articles all avoid hyping string theory or other science fiction and instead stick to real, serious material about HEP. Congratulations to the people at SciAm, everyone should go out now and buy a copy of this month's magazine to encourage them. Chad Orzel and other non-HEP physicists are peeved that the "Future of Physics" business is a misnomer, since it should have been titled the "Future of HEP Physics". They're right. Still, the articles are good, so they shouldn't hold the headline business too much against the magazine.

The LHC still has no up-to-date schedule available, but looking at the latest news about the commissioning and comparing to old schedules, it seems to me that if all goes well from now on, the machine should be cooled down and ready to be checked out in late summer, with beam commissioning during the fall, and, maybe, a short physics run late in the year.

Witten and Kontsevich were awarded the Crafoord prize, for "for their important contributions to mathematics inspired by modern theoretical physics". This is certainly well-deserved for both of them. One doesn't know where to start in listing Witten's contributions of this kind, and Kontsevich's ideas about "homological mirror symmetry" have had dramatic impact on mathematics, leading to a whole new field of study. There's an article about this at Science where Witten claims to be "totally startled" to be recognized for his achievements in mathematics. Not sure why a Fields medalist would get startled about this… Witten and Kontsevich get $125,000 each.

The first Eisenbud prize for a paper written during the last 6 years that brings together mathematics and physics was awarded to Ooguri, Strominger and Vafa for their 2004 paper Black Hole Attractors and the Topological String. They share $5000.

Last week there was a conference at the Fields Institute in Toronto on Mathematical Physics and Geometric Analysis, featuring series of talks by Victor Guillemin and Shlomo Sternberg, with lecture notes available online. Sternberg's lectures give a careful discussion of some of the differences in conventions between physicists and mathematicians, the Higgs mechanism and Weinberg angle, various facts about spinors, and the models he worked out with Ne'eman that use superconnections to unify Higgs and fermions. In these models he gets a prediction of the Higgs mass, as twice the W-mass, about 160 Gev. Coincidentally, Tommaso Dorigo reports on the Higgs search at the Tevatron, which is getting close to being able to exclude the existence of a Higgs in a small energy range: around 160 GeV.

From Dave Bacon, an odd story about a recent arXiv withdrawal. I have no idea what this is really about.

The Templeton Foundation continues to spend a lot of money on a wide variety of projects, many having something to do with physics. At FQXI, the request for proposals to be funded in 2008 is now closed. Their community web-site includes several interesting articles on topics in theoretical physics. In "breaking news", they report proudly that several of their members were in the recent NYT article on Boltzmann Brains.

Also funded by Templeton is the CTNS STARS (Science and Transcendence Advanced Research Series) grant program, which recently announced $100,000 grants to five groups, one of which includes my Columbia colleagues Brian Greene and philosopher David Albert.

Yet another Templeton-funded endeavor is a new science and religion library at Cambridge University, where, at a cost of $2 million or so, the International Society for Science and Religion will choose 250 books for the library, coming out to about $8000 each. I haven't yet heard from them, but will be happy to provide a copy of my book at a modest fraction of that price.

Comments

1. **a quantum diaries survivor**
   January 22, 2008

   Hi Peter,

   about science and religion, I would like to mention the recent querelle with the failed visit of Pope Ratzinger at the Rome University "La Sapienza".

   In a nutshell, the pope had been invited to give a speech at the starting ceremony for the new academic year. A public letter of dissent by Marcello Cini, a senior professor of physics in Rome, had been followed by a private, shorter one where 67 other physicists – among which several big names – expressed to the rector their support of Cini's dissent, arguing that Pope Ratzinger's lectio magistralis would be a incongruous way to open the works of the University, a place of autonomous research, the more so given the opinions of Ratzinger on the process to Galilei, which he had expressed 17 years earlier, when still a cardinal. Ratzinger's reactionary views however are known to most.

   The letter was made public two months afterwards. This created a wave of protest, with students manifesting against the visit, many other academics joining the petition of the 67 physicists, and the pope finally declining the invitation.

   The aftermath shows a real defeat for scientists, citizens, politics: on one side we have cardinals and clerics lamenting that the pope was prevented from speaking (as if he does not speak to a billion people every saturday), and accusing scientists of oscurantism. On the other side, we are assisting at the lynching of a few of the signers of the private letter. In particular one very bright scientist, Luciano Maiani, former director of CERN and INFN, recently nominated to head the CNR – a very important research institution in Italy – has to defend against accusations from catholic politicians who want to bar him from the nomination.

   I really feel for this crazy situation… And not accepting Maiani as head of CNR is a disaster. He is by far the best candidate for the job.

   (read more in my blog if you wish, including the interview to Maiani).

   Cheers,
   T.

2. **Peter Woit**
   January 22, 2008

   Thanks Tommaso,

   You're right, I should have mentioned this story, since it's about a rather more influential religious organization than Templeton. I encourage people to read about this over at Tommaso's blog, and to discuss it there….

3. **Chris W.**
January 22, 2008

I assume you meant David Z. Albert, Frederick E. Woodbridge Professor of Philosophy at Columbia.

4. **Peter Woit**
January 22, 2008

Chris W.,

Oops, yes. Spelling fixed.

5. **Kris Krogh**
January 22, 2008

Dave Bacon's story concerns a suspicious paper attacking Gravity Probe B, a NASA experiment measuring two effects predicted by general relativity. After many delays, their results for the Lense- Thirring effect (also called frame-dragging or gravitomagnetism) are scheduled to be announced around June. Various parties have claimed previous measurements, using other satellites, although each has been touched by dispute in some way.

The author of the paper in question was given as:

Gerhard Forst
FGP
Behrenstr. 1
10117 Berlin

Finding no trace of this person or an organization called "FGP," I wrote ArXiv questioning the paper's authorship. (Copy of the message in the comments here.) My guess was that actual author was one of the Gravity Probe B competitors, whose work I've discussed here. The motive would be to undermine the GP-B result in case his previous measurements are not borne out.

As Dave mentions, the comments added by ArXiv after withdrawing the paper seem to point the finger at someone else. They may know something I don't. Certainly its a bizarre situation!

6. **Coin**
January 22, 2008

As far as the anti-Gravity Probe B paper by "Gerhard Forst" goes: Was the paper actually any good? I mean, did it make a solid point?

7. **Kris Krogh**
January 22, 2008

Hi Coin,

I didn't find anything of substance in the paper, but plenty of fabrication. There were references to some old papers, claiming those predicted the specific problems Gravity Probe B has been having. I looked those up, but there was nothing related to the actual problems experienced. The author also claimed no one except those those connected GP-B will be able to analyze the data for themselves. All data connected with the experiment are going into a public archive, so that's nonsense.

8. **Coin**
January 22, 2008

Ouch.

9. **YBM**
January 22, 2008

The Bogdanov's brothers just begin to promote Lubos Motl's book "L'Équation Bogdanov" ("The Bogdanov Equation") on low grade TV shows these days (very very low). Nothing much about the book itself besides that "It's not written by us" and "It is written by a professord at 'Harvard' "…

The book is supposed to be available in bookshop this week.

10. **Tom Whicker**
January 23, 2008

I just got a promo in the mail from Sci American. If I re-subscribe, I get a special bonus report called "Parallel Universes". The ad copy says " Is there a copy of you in another universe reading this sentence? The most popular cosmological model today suggests the answer is yes………Welcome to Parallel Universes which examines each of four possible configurations for such a multiverse"

11. **Alex Mikunov**
January 23, 2008

Peter, shouldn't it be: Witten and Kontsevich get $125,000 each

12. **Peter Woit**
January 23, 2008

Tom,

Thanks, quite a mixed bag there now at SciAm…

Alex,

Thanks, mistake corrected.

13. **Professor R**
January 23, 2008

hi Peter, excellent blog as always…
One query – are you saying the FQXI foundation is funded by Templeton? I managed to miss this, despite throwing in an application…Cormac

14. **Peter Woit**
January 23, 2008

Professor R,

Yes, FQXI is funded by Templeton. I believe that their hope is that this is just an initial grant, that they will find other sources of funding in the long term.

15. **Clark**
January 25, 2008

Regarding the title of the recent Scientific American articles, I find it refreshing that the "Future of Physics" is not String Theory. As a lay reader of popular physics, I've encountered many such announcements over the last 15-20 years, only to discover that the fabulous future was String Theory and all its strange, untestable components. Weary of all the string cheerleading, I expected more of the same. What a pleasant surprise to read the recent Scientific American articles.
I can understand where non-HEP physicists would be upset, but there is a perception in the interested public that String Theory is the light that will lead us out of Plato's Cave, largely due to mainstream publications using similar titling to promote it.
What a shock for Joe Public Broadcasting to find out that the future may have a different angle.

16. **DB**
January 25, 2008

Refreshing also, that Chris Quigg has written the article on the Standard Model and its Discontents. Fermilab's Quigg is a fine popularizer of the subject and someone who has been committed to outreach for a long as I can remember. He will also be familiar to physics professionals from his 1980s classic: Gauge Theories of the Strong, Weak and Electromagnetic Interactions, still in print, and I understand it is due to benefit from a completely new edition in 2008.

2007: Year of the Unparticle

January 25, 2008
Categories: Uncategorized

One can get some idea of what progress there might have been in particle theory during 2007 by querying the SPIRES database for 2007 papers that already have lots of citations. Doing

find topcite 50+ and date 2007

turns up 20 papers of which 6 are experimental papers. Remarkably, the 14 other papers are all about one topic: unparticles. These all refer to Howard Georgi's initial [Unparticle Physics] paper from March 2007, in which he describes a possible effective field theory that would be scale invariant and correspond to unusual phenomena potentially observable by collider experiments, phenomena he describes in terms of "unparticles". In less than a year Georgi's paper has accumulated 118 citations, with the blogger at Resonaances [making fun] of the phenomenon of "unpapers" with abstracts such as:

> We consider unparticles in whatever uncontext. You are encouraged to forget the paper as soon as soon as you add it to your citation list.

but also making the very relevant comment that this does seem to be getting attention because it is a legitimately new idea:

> I must give the credit to Howard for drawing our attention to a whole wide class of collider signatures. Besides, I appreciate Howard's writing style. He is probably the last man on Earth who truly enjoys particle physics.

As far as I can tell, unparticles don't solve any of the problems of the Standard Model, but they are theoretically possible phenomena of a different kind that experimentalists can look for, and having as many as possible of such phenomena is very worthwhile. The more different things people are looking for, the more likely they'll find something unexpected that otherwise might not have been noticed.

This week New Scientist has a long and quite good [cover story] about unparticles, and recent attempts to use them to explain dark matter, which ends with:

> Georgi reserves judgement on whether his unparticles really could be the key to solving the dark matter problem until more work is done, but he's pleased that people are investigating the possibility. "All I knew was that I had found something cool and I wanted other people to take a look and see what kinds of weird things they might be capable of doing – what mysteries they might solve," he says. "I'm happy because that's exactly what people are now doing."

The story has also made it into the [Telegraph].

Besides the unparticle phenomenon, there appear to be very few 2007 theory papers that anyone is paying much attention to. I've tried to search around and come up with a list of 2007 papers that have so far gotten 25 citations or more, and a list follows. I'm probably missing some . The main themes shared by most of these papers are AdS/CFT and attempts to construct metastable vacua as part of a study of the landscape .

- Metastable vacua and D-branes at the conifold (Argurio, Bertolini, Franco, Kachru) 54 citations.
- Gluon scattering amplitudes at strong coupling, (Alday, Maldacena) 47 citations.
- The Bulk RS KK-gluon at the LHC, (Lillie, Randall, Wang) 38 citations.
- Supersymmetry breaking, R-symmetry breaking and metastable vacua, (Intrilligator, Seiberg, Shih) 35 citations.
- Electroweak constraints on warped models with custodial symmetry, (Carena et al.) 33 citations.
- The Supersymmetric Parameter Space in Light of B-physics Observables and Electroweak Precision Data, (Ellis et al) 31 citations.
- Simple Scheme for Gauge Mediation, (Murayama, Nomura) 31 citations.
- Non-perturbative and Flux superpotentials for Type I strings on the Z(3) orbifold, (Bianchi, Kiritsis) 31citations.
- Phase Structure of a Brane/Anti-Brane System at Large N, (Heckman, Seo, Vafa) 30 citations.
- Thermodynamics of the brane, (Mateos, Myers, Thomson) 30 citations.
- On the Singularities of the Magnon S-matrix, (Dorey, Hofman, Maldacena) 29 citations.
- On the Strong Coupling Scaling Dimension of High Spin Operators, (Alday et al.) 29 citations.
- Charged Lepton Flavour Violation and (g-2)_mu in the Littlest Higgs Model with T-Parity, (Blanke et al.) 29 citations).
- Split states, entropy enigmas, holes and halos, (Denef, Moore) 28 citations.
- Computation of D-brane instanton induced superpotential couplings, (Cvetic, Richter, Weigand) 28 citations.
- Towards an Explicit Model of D-brane Inflation (Bauman et al.) 27 citations.
- MadGraph/MadEvent v4: The New Web Generation, (Alwall et al.) 26 citations.
- Physics of String Flux Compactifications, (Denef, Douglas, Kachru) 25 citations.
- A Measure of de Sitter entropy and eternal inflation, (Arkani-Hamed et al) 25 citations.
- Explaining the Electroweak Scale and Stabilizing Moduli in M Theory, (Acharya et al.) 25 citations.

SPIRES has yet to compile a 2007 "topcites" list, but it looks like the pattern should be very much the same as the last few years:

- increasing dominance of research into AdS/CFT (597 citations of Maldacena's paper in 2007, versus 551 in 2006)
- particle theory basically died at the end of the 20th century with the only post 1999 paper getting more than 150 citations the KKLT one reflecting the rise of landscape research.

Comments

1. **piscator**
   January 25, 2008

   the positive side of 2007 is the preparation of lots of people for the model bonfire that the folks in geneva are warming up (or rather cooling down) for. frankly, the last thing particle theory needs now is another over-hyped and over-cited model solving all open problems (insert your favourite example)

   i think there is a lot of retooling going on in preparation for the LHC, there will soon be a large parting of the ways between those primarily interested in physics as an experimental subject and those interested in more formal topics.

2. **Big Vlad**
   January 25, 2008

   piscator is right. There's a big divide at the moment between the more formal side of particle physics, which seems to be in the doldrums, and the experimental/phenomenological side which is booming thanks to the forthcoming LHC. Of course, the former should feed off the latter and hopefully this will be the case over the next few years.

3. **Bee**
January 25, 2008

We had a post on the topic in September, see [Unparticles].

4. **Domenic**
January 25, 2008

Hey, how cool—today is exactly the day that Georgi arrives at Caltech (where I'm currently being an undergrad) to give a talk on unparticles. I put it on my calendar because it looked more interesting/introductory/understandable than most talks, so I've actually been looking forward to this for a week. Nice to know that it's an interesting idea; should be fun!

5. **grad student**
January 25, 2008

Two (I think) interesting papers missing from your 2007 list

Mateos, Myers, Thomson

http://arxiv.org/abs/hep-th/0701132 30 citations

Denef and Moore

http://arxiv.org/abs/hep-th/0702146 28 citations

there are probably others…..

6. **Peter Woit**
January 25, 2008

grad student,

Thanks a lot, I've probably missed quite a few. Just added those two, information about any others that should be added is very welcome.

7. **hepph**
January 25, 2008

Quite a few papers missing from the hep-ph side that *weren't* unparticles. Granted these don't necessarily all resemble theoretical breakthroughs but they represent a sampling of things that the community is working on:

J.~R.~Ellis, S.~Heinemeyer, K.~A.~Olive, A.~M.~Weber and G.~Weiglein arXiv:0706.0652 31 citations

B.~Lillie, L.~Randall and L.~T.~Wang hep-ph/0701166 38 citations

M.~Blanke, A.~J.~Buras, B.~Duling, A.~Poschenrieder and C.~Tarantino hep-ph/0702136 29 citations

M.~S.~Carena, E.~Ponton, J.~Santiago and C.~E.~M.~Wagner hep-ph/0701055 33 citations

H.~Murayama and Y.~Nomura hep-ph/0701231 31 citations

J.~Alwall {\it et al.} arXiv:0706.2334 26 citations

8. **alex**
January 25, 2008

Acharya, Bobkov, Kane, Kumar, Shao; hep-th/0701034 25 citations

9. **David Nataf**
January 25, 2008

In terms of particle physics in 2007, I think an interesting result would be the Auger experiment's confirmation of the GZK effect.

10. **stan**
January 26, 2008

Initially, "Unparticles" seemed like a joke to me but now after all these citations, I can`t even laugh. Add an `Un` to every particle physics process and write a paper and cite everyone that wrote before you. I might write an UNString theory paper to see what is going on.

11. **grad student**
January 26, 2008

Another interesting one (although it is not exactly "particle physics")

Elvang and Figueras

http://arxiv.org/abs/hep-th/0701035 25 citations

12. **Peter Woit**
January 26, 2008

hepph and alex,

Thanks for the additions, it is true that they reflect a wider variety of activity in hep-ph than in hep-th.

grad student,

Thanks for pointing that out, but I won't try and keep track of papers like that one that are much more gr-qc than hep-th.

13. **Eric**
January 26, 2008

Perhaps you should add the string phenomenology papers hep-th/0703028 and arXiv:0707.1871 to your list.

14. **Peter Woit**
January 26, 2008

Thanks Eric,

I added the first of those, the second only has 15 citations so far, below the cutoff of 25.

To make explicit the obvious, the list compiled here is weighted towards papers from early in the year, which have had more time to accumulate citations. As such, to rank them by how much they're being cited, you really should weight by when they appeared. My idea in accumulating this list was more to see what papers are getting significant numbers of citations, even if in a crude way. One thing this crude method does is it tends to ignore papers from late in the year, but in any case it is too early to get much of an idea of how often they'll be cited as time goes on.

To make explicit the even more obvious: citation counts are about sociological, not long-term scientific impact.

15. **Jon Lester**
January 27, 2008

I find very silly to try to consider importance of papers in a year by their citation number. In about 30 years the only criterion used by particle physics community to decide what is good and what is bad is fashion. This is clearly seen also in the peer-review process and I think the merit of arxiv and its creator will be manifest in a few years when we will realize that the most important papers are those that were systematically overlooked in the year they appeared and was also rejected by the highest ranked journals.

Jon

16. **Somdatta Bhattacharya**
January 27, 2008

This idea of unparticles, it's utter nonsense. Does it solve any of the outstanding problems of SM? Is there any motivation for it coming from anything at all?

17. **piscator**
January 27, 2008

For the clearest evidence of why citation counts do not directly measure scientific impact, do the following:

1. Look up the two Randall-Sundrum warping papers.

2. Take the ph paper, convert the 'p' to a 't', and look up the hep-th paper with the same number.

3. Look at the topic of this paper and the papers that cite it, and decide for yourself where these citations were intended.

Conclusion: citation counts sometimes measure neither scientific merit, nor sociological trends, but rather the touch-typing proficiency of particle theorists 🙂

18. **string-dude**
January 27, 2008

Hi Somdatta, why should it solve the "outstanding" problems of the standard model for it to be interesting?

Unparticles are talking about a possible low energy phenomenon which might have gone un-noticed because we never thought of looking for it. This in itself is a valid thing to consider, whatever ones prejudices against high energy physics might be.

But the fact that you claim that unparticles are "utter nonsense", an THEN ask questions about it, makes me think that you form your opinions a tad quicker than I do…

19. **Somdatta Bhattacharya**
January 27, 2008

Dear String dude,
Just because I wrote the questions after the statement doesn't necessarily mean that the latter is not a consequence of the former.
One could come up with numerous theories or scenarios that supplement the SM but there must have to be a "motivation" for them. For me investigating them just because they are a possible scenario with possible experimental signatures is like putting the cart before the horse. Since experiments at the next energy scale are near, it makes no sense to just go on increasing upon the number of possible scenarios that might be there, especially when there is no motivation to do such things. If it solved or aspired to solve some problem like the hierarchy problem or that of the abundance of parameters in the SM or the unification one, I would see a point to it. Otherwise its just a load of c***.

20. **gambler**
January 27, 2008

Somdatta Bhattacharya, if you want to win the lottery, you have to buy the tickets before the drawing.

21. **Thomas D**
January 27, 2008

Neubert had a nice paper 0708.0036 showing that 'unparticles' are actually rather similar to strongly interacting particles, in terms of the supposedly distinctive experimental signature.

Also, as soon as you couple them to the SM their conformal invariance will be explicitly broken (whether to a small or large extent), which somewhat, or completely, spoils their original neat rationale.

So between experiment and theory, I don’t know what is supposed to be attracting us towards them. As I said some time ago: there is a continuous infinity of field theory models of new physics, we would like to have some coherent rationale to choose some directions in this infinite space of theories. Experimental considerations do play a role: if a model has clear collider signatures that otherwise would be overlooked, for example. It’s not clear to me whether there really is one clear signature of unparticles.

Of course, had the LHC turned on in 2005-6, as was hoped some time ago, there would very probably be no-one saying ‘unparticle’ today at all. Theorists need something to keep their minds active.

22. **Somdatta Bhattacharya**
January 27, 2008

Thanks Thomas D,
For answering gambler’s question.
However, yes, theorists might need to keep their minds active, but it would do them helluva lot of good if they, especially people like Georgi, came up with things that are worthwhile, otherwise its a waste of time not only for them, but for the whole community. Because had I published such a paper, no one would have payed any attention, but since it came from Georgi, everyone decided to latch on.

23. **string-dude**
January 28, 2008

>Because had I published such a paper, no one would have payed
>any attention, but since it came from Georgi, everyone decided to
>latch on.

I agree that there is truth in this statement, but I find it hardly worth getting so upset about. Science is an enterprise that involves primates working in groups. Mavericks and rebels have to work their way up the hierarchy by paying their dues. I promise you that once you produce a paper of sufficient import, your next paper, even if it is mediocre, will have a fan-following.

Mind you that I am not endorsing this phenomenon. But I somehow think that this meta-level anger, righteous indignation, etc., is completely useless. The only real way in which to make sure that people work on good ideas is to OFFER them a good idea to work on. What is the point in bitching about other ideas? The oldest rule of progress in science is to work on *something* rather than nothing, and I can’t really blame the troops for latching on to a moderately new idea.

That said, I looked at the paper that Thomas D talked about and agree that unparticles suddenly seem a lot less interesting than what I had thought after reading the original paper by Georgi (which I bothered to do only after seeing Peter’s blog).

Sleep tight and don’t let the bedbugs bite,
Chethan Krishnan (aka string dude)

24. **Somdatta Bhattacharya**
January 28, 2008

>I promise you that once you produce a paper of sufficient import, >your next paper, even if it is mediocre, will have a fan-following.

I hope not everybody thinks like this. In the enterprise of physics, it’s not fan-followings that one is after, but the truth. Mediocre papers ought to get the treatment they deserve, which is complete disregard.

>What is the point in bitching about other ideas?

In case you haven’t noticed, this IS the place to bitch about other ideas, to thrash things out with people like you.

25. **Professor R**
January 28, 2008

hi Peter,
I was delighted to see one of the top-cite papers you list (Supersymmetry Breaking, R-Symmetry Breaking and Metastable Vacua) gives the proper reference for the O’ Raifeartaigh Model for a change – and so it should, as the model is heavily referenced and mentioned on every page!

It strikes me once more that one of the drawbacks in the way citations are counted is that there is no distinction between a passing citation, and a model that is the central to the entire paper…part of the reason I still having difficulty persuading Dad’s own countrymen that his work was important….Cormac

26. **Coin**
January 28, 2008

Neubert had a nice paper 0708.0036 showing that ‘unparticles’ are actually rather similar to strongly interacting particles, in terms of the supposedly distinctive experimental signature.

Also, as soon as you couple them to the SM their conformal invariance will be explicitly broken (whether to a small or large extent), which somewhat, or completely, spoils their original neat rationale… It’s not clear to me whether there really is one clear signature of unparticles.

Hm, so this is very interesting to me. So is there *ANY* detectable difference between a SM+unparticles unparticle and a strongly-interacting particle? That is to say, if we detected a particle signature for some new strongly-interacting particle, would there be grounds to distinguish whether it was an actual particle or a disguised unparticle?

I guess I’m still trying to understand exactly what the unparticle stuff is. I’d be curious to know whether I have this right: It appears that an unparticle field is a just a QFT field (I.E., you can’t ever have say an electron unparticle– qft fields consist of either all particles or all unparticles) except that field has a particular property (conformal invariance) which is mathematically well-defined, but which we don’t ever consider in normal physical theories. Is that about it?

Given (let’s assume that we go looking for unparticles and don’t find any) that there don’t seem to be any unparticles in nature, is this something that needs to be explained? Is there some natural or obvious reason why only fields without the unparticle property would be selected to exist in nature, besides “that’s what we observe”?

27. **David B.**
January 28, 2008

Coin:

Unparticle events would just be like hadronic jets in a hidden sector. Jets usually involve many particles in the final state and give different energy curves for how much energy was dumped into them than single particle production. If you can not see the particles, your only signature is missing energy. So long as the perturbations from conformal invariance are small, the `unparticle' calculation is for the most part fine, unless you are below treshold for production of unparticles (which could have a tiny mass).

Unparticles is in the end just another nickname for conformal field theory (in practice all you need is an approximate scale invariant sector). It is the fact that conformal field theories have scaling properties that lets you do a calculation without a specific model of high energies. This is why it is looked at. It covers many possible models of ultrahigh energy physics with very few parameters (a scaling dimension, and the strength of some coupling constants).

Regarding the use of Conformal Field Theories in the rest of physics, I suggest you look at the theory of second order phase transitions in condensed matter systems: those are conformal field theories that can be realized in laboratories, and the scaling exponents can be measured quite precisely.

Unparticles do not have to be there. They are also not forbidden from being there. There doesn't necessarily need to be an explanation for why nature is the way it is. That is a theoretical prejudice. You have to be open to the idea that there might be surprises in physics and some might just have to be due to no particular reason whatsoever. If you care about phenomenology, you want to figure out which of all the possibilities are realized in nature. You might have to do that by excluding all theories on a case by case basis, in which case you need to have a proper accounting of all the possibilities out there.

28. **Professor R**
January 30, 2008

Peter, re your comment
"This week New Scientist has a long and quite good cover story about unparticles, and recent attempts to use them to explain dark matter"…
I agree it is a nice article and thanks for pointing it out.
However: did you notice the clanger in the introduction?
"Georgi…pioneered suspersymmetry, a theory he proposed in 1981 with Stavros Dimopoulos at Stanford University…."
Surely this is quite a howler!

Most particle physicists agree that the theory of supersymmetry was originally proposed in the late 1960s by Soviet theorists Gol'fand and Likhtman, and developed by Julius Wess and Bruno Zumino in 1973. Indeed, simple models of supersymmetry breaking (the O'Raifeartaigh Model) had already emerged by 1975.

Presumably the NS meant that the first realistic supersymmetric version of the Standard Model was proposed in 1981 by Georgi and Dimopoulos….the trouble with errors like this is that one is left wondering how accurate the rest of the piece is…..Cormac

29. **Peter Woit**
January 30, 2008

Cormac,

I did notice that howler. Georgi certainly isn't responsible for the idea of supersymmetry, or even for supersymmetric gauge theories, which were well known by 1981. From what I remember, he and Dimopoulos were working on supersymmetric versions of GUTs, and I guess as part of that may have been the first to note that one should think about the minimal supersymmetric extension of the Standard Model, together with all possible soft breaking terms (the so-called MSSM).

30. **Martin Bauer**
February 1, 2008

I don't really get whats the new idea here. There are a lot of papers out there, assuming hidden sector physics. Is it the conformal invariance? If so, I don't even get the point why it should be (only) conformal invariant. Why not just take some arbitrary symmetry group?

(I should probably add that all my knowledge in the field comes from a talk I just attended.)

31. **Hrvoje Nikolic**
February 7, 2008

As I argue in http://xxx.lanl.gov/abs/0801.4471
unparticle can be viewed a particle with an arbitrary mass.

This Week’s Hype

January 28, 2008
Categories: This Week's Hype

This week’s press release trumpeting a bogus “test of string theory” comes from the University of Illinois at Urbana-Champaign, which is headlined [Scientists propose test of string theory based on neutral hydrogen absorption](), and informs us that

> Ancient light absorbed by neutral hydrogen atoms could be used to test certain predictions of string theory, say cosmologists at the University of Illinois. Making the measurements, however, would require a gigantic array of radio telescopes to be built on Earth, in space or on the moon.
>
> String theory – a theory whose fundamental building blocks are tiny one-dimensional filaments called strings – is the leading contender for a “theory of everything.” Such a theory would unify all four fundamental forces of nature (the strong and weak nuclear forces, electromagnetism, and gravity). But finding ways to test string theory has been difficult.
>
> Now, cosmologists at the U. of I. say absorption features in the 21-centimeter spectrum of neutral hydrogen atoms could be used for such a test.

One peculiar aspect of this press release is that it seems that the relevant paper is not yet publicly available. Supposedly it has been submitted to PRL and accepted, but it has not yet appeared in PRL, and I don’t see a preprint on the arXiv (the authors do have a PRL paper with an arXiv preprint from last year on a different topic, one that also came with a press release, but this one didn’t mention string theory).

As far as I can tell from the press release the idea behind this “test of string theory” is the same as lots of other similar ones that invoke cosmic strings. Among the huge variety of string theory backgrounds and the many possible ways to try and use such backgrounds to model the big bang, some will (just like some non-string theory GUT models) produce macroscopic “cosmic strings”. Astronomers have looked hard for evidence of such things and found none, but one can always imagine that, miraculously, such things exist, with characteristics exactly such that they wouldn’t have shown up so far, but would in some new, improved astronomical observations. In this case, I guess to come up with some new possible observation not already ruled out, the authors of the paper invoke a possible radio telescope with an area of a thousand km^2.

There seem to be at least a couple reasons for the recent flood of bogus “we’ve found a test of string theory” press releases. One is that PRL evidently encourages authors to issue press releases whenever they have a paper appearing in PRL. Another reason is that string theorists are on the defensive, and some of them have decided that finding some way to claim that string theory really is testable, no matter how dubious, is the way to fight back. Earlier this month, one such claim hyped in New Scientist carried the headline “slammed for their failure to explain how our particular universe came to exist, string theorists are fighting back.” In an interview with string theorist Thibault Damour in today’s edition of the Swiss paper le Temps, he promotes three possible tests of string theory. One is the possibility (which he describes as “very speculative”) that one might observe extra dimensions at the LHC, another is cosmic strings, and finally there are his claims that string theory leads to violations of the equivalence principle. Lubos Motl strongly disagrees. Lubos also has a posting about this latest hype, where he comments:

> Such possibilities highlight that creative people may often solve questions that look too difficult at the beginning. They also emphasize how incredibly idiotic are the aggressive crackpots’ proclamations that modern theoretical physics in general and string theory in particular is untestable.

Not clear who it is who believes that “modern theoretical physics” is untestable. While at Lubos’s blog, you might want to see what you can make of his posting on his new book *The Bogdanov Equation: the secret of the universe?*

Update: This story is appearing lots of places, including the UPI newswire, and at Wired, where the writer seems to realize that the bogosity level here may be problematic, including the unusual disclaimer:

> Disclosure: I have no idea whether this makes sense.

Update: A correspondent points me to another recent “test of string theory”, one where for some reason the authors don’t seem to have issued a press release. The article is Toward a test of string theory using Rydberg atoms, and it begins by referencing my book and then claiming that

> … measurable effects are predicted by String Theory on normal quantum scales, which the current criticisms have apparently overlooked.

What is discussed in the paper is actually not string theory, but just the idea of adding spatially non-commuting terms to the Heisenberg commutation relations. Certainly such terms should have experimentally observable effects. I suppose you can claim that such terms, of any size you want, come from a “string theory background”, but, as with all these “tests of string theory”, what is going on here just reflects the fact that you can pretty much get anything you want out of string theory, which is why it’s not testable…

Comments

1. **Glenn**
   January 28, 2008

   Not related to this post, but have you seen the article about someone’s “prediction” of a different set of Higgs masses such that the W/Z-binding Higgs is far above current accelerator limits but that other Higgs (that haven’t been being searched for) could be detected with current hardware.

   Slashdot pointed to this link:

   http://sciencenow.sciencemag.org/cgi/content/full/2008/123/3

   But I haven’t looked at it, not being qualified to tell BS from science…

2. **Peter Woit**
   January 28, 2008

   Glenn,

   There’s no prediction of Higgs masses there. The minimal supersymmetric extension of the standard model has lots and lots of extra parameters, and extra Higgs particles. For some values of these parameters, one of these could be relatively light, but still not have been seen at LEP. I assume the Tevatron experiments have looked for these sorts of things, don’t know what the limits are. It’s not just a matter of having enough energy to produce Higgs particles, you also need a large enough event rate to distinguish them from background. The Tevatron presumably has already produced Higgs particles, just not enough to distinguish them.

3. **Glenn**

January 28, 2008

In other words, it's yet another example of the billion-knobs problem.

I expected that, but like I said, I'm not savvy enough to tell the hype from the hope.

That's *your* job.

Thanks for the info.

4. **Coin**
January 28, 2008

Astronomers have looked hard for evidence of [Cosmic Strings] and found none, but one can always imagine that, miraculously, such things exist, with characteristics exactly such that they wouldn't have shown up so far, but would in some new, improved astronomical observations. In this case, I guess to come up with some new possible observation not already ruled out, the authors of the paper invoke a possible radio telescope with an area of a thousand km2.

Would the information the authors want to gather with this hypothetical telescope (the "absorption features in the 21-centimeter spectrum of neutral hydrogen atoms"?) be for any particular reason useful data to have even in a universe where no cosmic strings exist?

Also: Is there *any* difference between the phrases "cosmic string" and "one-dimensional topological defect"? Or in other words, would a detection of cosmic strings actually prove string theory, or would *any* cosmological theory with one-dimensional topological defects predict cosmic strings too?

5. **Peter Woit**
January 28, 2008

Coin,

Since there's no paper, I don't even know exactly what the signal is they are saying one should look for, or whether it could come from other sources or tell us anything about them.

"Cosmic strings" are topological defects of 1d of astrophysical dimensions. They also occur in simple GUTs. There's an industry of papers out there on the question of how to try and tell the difference between GUT cosmic strings and ones coming from a fundamental superstring. I gather you need a network of the strings and consider their interactions.

6. **lostsoul Ph. D.**
January 29, 2008

I know that this is off-topic, but cannot of think where else to ask. How has Simon's Renaissance Technology been getting along recently? Is his crew truly a band of financial magicians, or has the whole thing been revealed as hype?

7. **DB**
January 29, 2008

"Astronomers have looked hard for evidence of such things and found none"

Actually Bevis' group at Imperial College, London are claiming to have detected traces of cosmic strings in the WMAP data which maps the afterglow of the Big Bang. Bennet, the head of WMAP isn't buying it and calls it a statistical fluke.

I'll you just one guess as to where this report appeared. What? New Scientist? How on earth did you guess that?

http://tinyurl.com/3xkrbm

8. **Not Even Woit**
January 29, 2008

PW – you are either a megalomaniac or cynically trying to shift a few more copies of your book (maybe even both). Physicists have been trying to come up with ways to test string theory long before you started your little crusade. Perhaps you have been too busy with your blog to notice the huge advances in observational cosmology that have been made in the last few years, for example. To think that theorists are suddenly "fighting back" (against what exactly – a popular book written by somebody who has made zero impact in theoretical physics?) is to misunderstand how science makes progress. But like I said, I guess that's not what interests you.

9. **Peter Woit**
January 29, 2008

Not Even Woit,

Sure, BS claims to have a "test of string theory" are not new, but I've been following them for years and they're a lot more common now than they used to be.

"slammed for their failure… string theorists are fighting back" are not my words, but those of the headline writer for New Scientist. Take it up with them…

10. **Not Even Woit**
January 29, 2008

Your words, PW: "string theorists are on the defensive, and some of them have decided that finding some way to claim that string theory really is testable … is the way to fight back."

I will ask again, PW: what/who are they fighting? Your argument is circular. You start with the unsubstantiated (and therefore quite possibly bogus) claim that string theorists are on the defensive, and then try to fit everything they do around that claim.

Unless your blog is just a blatant PR blurb for your book, one can only conclude that you are living in a fantasy world.

11. **Peter Woit**
January 29, 2008

Not Even Woit,

I seem to be repeating myself, but the substantiation of my claim is that it comes from a New Scientist headline. They may not be reliable about science, but I do think they accurately reflect popular perception.

As for doing PR for my book, the only person who has mentioned it at all here is you. Thanks!

12. **Not Even Woit**
January 29, 2008

Your book appears as a prominent thumbnail on your homepage, PW.

So let me get this straight: you are claiming that theorists are publishing (where there's a press release there's usually a peer-reviewed paper) potential tests of string theory in response to the negative public perception of their field.
What is your evidence? Surely there is more to it than a single headline written by someone trying to sell a magazine story last summer?
How can you be sure that the increase in the number of papers reporting potential tests of string theory is not the result of genuine progress in science (both theory and observation)?
Shouldn't you be more rigorous in your reasoning, given that you claim string theory is a failed research program based on its lack of falsification criteria? Or is that one of the luxuries of living in a fantasy world?

13. **Peter Orland**
January 29, 2008

Hi Peter,

Please do not argue with Not Even Woit. Just delete his comments.

Thanks,
Peter O.

14. **Peter Woit**
January 29, 2008

Not Even Woit,

The headline is not from last summer, but from earlier this month. I suppose I could waste a lot of time gathering together similar quotes from news stories, but I doubt that would convince you. OK, here's one more, since I just ran across it this morning. The opening lines of a story at Wired:

"The apparent inability of physics' string theory to be proved right or wrong is one of the stickiest – and argument-generating – problems in modern science."

followed by

"But because none of these descriptions of the universe offered any obvious way to be tested or proven, skeptics have called string theory "not even wrong" – meaning that it doesn't fulfill the most basic requirement of a proper scientific theory, the ability to be be proven wrong.

Now Illinois cosmologist Benjamin Wandelt, along with graduate student Rishi Khatri, say that some of these predictions can be tested, or at least addressed…"

The reason I'm sure that the papers reporting tests of string theory don't represent genuine progress is that I've read them.

Just saw Peter Orland's comment and he has a point. Unless you've got something new to say, or are at least willing to hiding behind anonymity and tell us who you are, explaining your qualifications on this issue, enough is enough…

15. **dan**
January 29, 2008

So what if this detection device was built according to the specifications outlined in the article, and NO evidence for the cosmic strings in the form of hydrogen spectra lines were observed (as described in the popular press article), what aspects of string theory would now be falsified?

16. **Peter Woit**
January 29, 2008

dan,

No aspect of string theory would be falsified, that's the problem.

17. **Somdatta Bhattacharya**
January 29, 2008

The only thing going for String theory seems to be that it is a finite theory. As far as I know, in it calculations beyond 3 loops are unsurmountably hard. So has the finiteness been substantiated consensually? Or is it that what still exists is only wishful thinking with regard to strings interacting over an extended region as opposed to a point? And even that argument is a bit dubious owing to the fact that there would be regions of the moduli space where the string length (it can be looked upon as one of the moduli) goes to zero, signaling the possibility of a field theory like divergence here as well (from that part of the moduli space). So one really needs to check order by order in perturbation theory. Supergravity theories have been shown to be finite to a high loop order, but they fail beyond a certain order.
My point is, even apart from the fact that they are non-falsifiable, can they ever live up to their other more radical promises?

18. **Peter Woit**
January 29, 2008

Somdatta Bhattacharya,

The topic of the finiteness of superstring amplitudes beyond 3 loops is a highly technical one that has been the subject of fierce arguments here and elsewhere, and I'd rather not reopen those here unless there's something new about the subject to discuss. As far as I know a fair summary of the situation is that two-loop amplitudes can be explicitly written down and are definitely finite (work of d'Hoker and Phong). At higher loops there are some proposals for explicit amplitudes, and plausibility arguments for finiteness, but no rigorous proofs of finiteness.

Again, this is quite off-topic, and the kind of thing that attracts heated comments about a very technical issue that spread more heat than light. Unless you have accurate and relevant new information about this, please avoid trying to discuss it here.

19. **Shantanu**
January 29, 2008

Not even Woit, I do know that many people who used to work on string theory
have moved on to different fields (long before Peter's book). Also I do agree with Peter that something is weird with a theory which predicts BOTH violation of equivalence principle as well as its sanctity

20. **Somdatta Bhattacharya**
January 29, 2008

Peter,
I just wanted to be apprised of the current understanding on the issue. As I had suspected, there exist only plausibility arguments and no rigorous proofs. I am aware of the "heat and light" that you mentioned. I have nothing new to offer except what I said in the previous post which is that even the heuristic argument that is usually offered seems to be dubious.

21. **Kevin McCarthy**
January 29, 2008

I think that the idea of testing a theory means something quite different to physicists than it appears to mean in science reporting and press releases. I just stumbled onto this blog today and I've enjoyed reading it, and feel maybe I can contribute to a discussion here. It seems to me that a press release is in order defining exactly a "test of a theory" means.
I'm going to shoot for a definition here, with some preamble, that I think most physicists could agree on, though its probably more likely that in trying to please most it could end up pleasing none. Here goes.
Physics is a rigorous, skeptical, and ultimately empirical science. A claim for evidence or observation of new phenomena must be held to stringent standards. A true "test of a theory" first involves the postdiction of known physics where feasible, because if a theory explicitly contradicts observed phenomena, it must be discarded. This at least establishes the viability of a theory. The second, and more rigorous aspect of a test, is the observation of phenomena uniquely predicted by that theory (to separate it from other preciously viable theories which do not predict the same observations) and generically predicted by that theory, so that the observation represents a true test of the theory as a whole and not a constraint of parameter space.

By this definition, or by any other real definition of what a scientific test should be, press releases and science journalism too often use the words "test of a theory" to generate buzz about a project that, while it could provide interesting and new experimental data, doesn't really test a particular theory.

On another phrase that seems to pop up in every article about string theory, what truly establishes it as "the leading contender for the theory of everything"? (besides more public awareness of its existence and a large community of people working on it). Reading back, I realize that sounds a bit sarcastic or condescending, I'm not trying to make people angry, but its a legitimate question of mine. In the absence of observational evidence, what separates string theory from any other theory that could also claim to reduce to QFT and GR in appropriate limits?

22. **Peter Woit**
January 29, 2008

Kevin,

The "leading contender" business is a phrase designed to emphasize the sociological fact that string theory remains a dominant research program for finding a TOE, even though the scientific case for this has weakened dramatically in recent years.

As far as the "test of string theory" business goes, I don't think the problem is that of science journalists understanding this in a different way than scientists. I see two sources of the bogus "test of string theory" claims, one being non-string theorists who don't really understand what the state of string theory is, but hope that some very different sort of physics they know about is somehow relevant. The other is string theorists who are well aware that string theory has not been able to make the kind of predictions necessary for a legitimate test, but have chosen to try and muddy this issue and mislead people when speaking to the public. In such cases you often find quite different claims in the scientific papers and in the press releases.

23. **Eric**
January 29, 2008

Kevin,
The main reason for string theory being considered the 'leading' (really, the only) contender for a theory of everything is that it is presently the only known way to consistently combine gravity with quantum mechanics. String theory only works because of number of nearly miraculous anomaly cancellations. It is because of this that it is studied, despite the fact that it has not yet been possible to make definitive experimental predictions.

24. **Peter Woit**
January 29, 2008

Eric,

If you have something substantive to say, please do so. But your repetition of stale, nearly 25 year old hype is off-topic. If Kevin cares about the science here, I'd suggest he read Brian Greene and Lee Smolin's books to see both sides of this argument.

25. **Eric**
January 29, 2008

Peter,
There is no need for you to be testy or defensive, and certainly the point that I made is not insubstantive or a 'repetition of 25 year old hype'. You may not like to admit it, but the anomaly cancellation is in fact an extremely important test of any potential quantum theory of gravity. It is perhaps useful for you to ponder why string theory is still taken seriously when there is very little hope of it making any experimental predictions in the near future. Well, here's your answer, and it is not hype. It is cold, hard fact.

26. **Shantanu**
January 29, 2008

Peter the paper by Khatri and Wandelt is now posted on the preprint archive

27. **N. Nakanishi**
January 29, 2008

Eric,
I believe the anomaly cancellation in superstring is a meaningful condition only if the corresponding QFT has gravitational anomaly. The existence of gravitational anomaly in QFT was claimed by Alvarez-Gaume and Witten (Nucl. Phys. B 234 (1984) 269), but their reasoning contained a serious mistake: They were not aware of the fundamental difference between T-product quantities and T*-product ones. Both coincide for chiral current but not for energy-momentum tensor, because the expression for the latter contains time differentiation. The genuine anomaly must be considered for T-product quantities, but what they considered are T*-product ones, because only T*-product quantities can be calculated by Feynman integrals and path integrals. I have explicitly shown in the 2dimensional case that what they called gravitational anomaly arises from the difference between T-product and T*-product. Thus,
at least in the 2-dimensional case, the gravitational anomaly in the genuine sense is non-existent in QFT. It is quite likely that the same is true in the 10-dimensional case.
B. Schroer completely agreed with me.
For details, see Abe and Nakanishi, Prog. Theor. Phys. 115 (2006) 1151 or arXiv hep-th/0503172 v2.

28. **chris**
January 30, 2008

eric,

there is absolutely no problem formulating a quantum theory of gravity without any speculative ingredients. and there is extremely strong evidence, that it is consistent. see e.g. arXiv:0708.1317

29. **Peter Orland**
January 30, 2008

Eric,

1) Peter W. was not being testy or defensive (though he did seem
somewhat irritated). I am not reading his mind, just reading what he wrote.

2) More seriously, how does the gravitational-anomaly cancellation test (your word) string theory? It just provides a constraint on matter multiplets. 10-dimensional String theory, with the gauge group SO(32) or E(8)XE(8), satisfies this constraint. So what?

A bit of history: gauge-anomaly cancellation was regarded as
good evidence for SU(5) or SO(10) GUTS back in the late 70's
(when I started grad school). But really any model with the right
charge assignments is fine – so it really provides no evidence at all.

More history: anomaly cancellation wasn't regarded as evidence
for string theory even in 1984. It simply removed the main reason
why theorists weren't considering string theory before then. I
remember this quite clearly. As a postdoc, I was reading Schwarz's
1982 Physics Reports. People were trying to talk me out spending
time on it because of the problem with gravitational anomalies.

30. **dan**
January 30, 2008

Hello Peter,
Since GUT and SUSY-GUT's presumably can be emdedded in some string framework, is as you say, and I quote "macroscopic "cosmic strings". Astronomers have looked hard for evidence of such things and found none" constitute a falsifiable prediction of GUT and SUSY-GUT's (i.e do GUT's generically predict observable cosmic strings arising form the Big Bang – as the Big Bang does predict other observations such as nucleosynthesis and CMB — that have, thus far, been failed to confirmed)

31. **Eric**
January 30, 2008

Peter O:

"More seriously, how does the gravitational-anomaly cancellation test (your word) string theory? It just provides a constraint on matter multiplets. 10-dimensional String theory, with the gauge group SO(32) or E(8)XE(8), satisfies this constraint. So what?"

Are you joking? Since any putative theory of quantum gravity must be completely free of both gravitational and gauge anomalies, this provides a stringent theoretical test. String theory is the only theory known that passes this test.

32. **Peter Orland**
January 30, 2008

Eric,

"Are you joking? Since any putative theory of quantum gravity must be completely free of both gravitational and gauge anomalies, this provides a stringent theoretical test. String theory is the only theory known that passes this test."

No, any theory with the same matter content passes this test in 10 dimensions.

33. **woit**
January 30, 2008

dan,

Some GUTs have stable cosmic string solutions, some don't. The standard model doesn't. The existence of such solutions depends on the structure of the Higgs sector of the theory.

Problem is, it's not just a matter of whether such solutions exist. To predict whether you'll see them, you need a model of what happened during the big-bang, i.e of the inflationary period and how the universe emerged from it. So, even if your GUT has cosmic string solutions, whether or not you expect to see such things depends on something different, your model of inflation.

34. **metamars**
January 30, 2008

I quoted Nakanishi at Lubos Motl's blog, and he replied:

[material copied from Lubos's blog deleted]

First of all, this topic has nothing at all to do with the posting. Secondly, please do not copy material wholesale from other people's blogs here, trying to drag them into the discussion at this site. If a discussion about an off-topic comment here is going on at another blog and you think people should be aware of this, just give the link here, and discussion of the issue should take place on the other blog, not here.

35. **Eric**
January 30, 2008

Peter O,
Are you sure you aren't forgetting about conformal invariance of the world-sheet?

36. **dan**
January 30, 2008

hi PW,
thanks for replying. I understand that string theory dosn't offer a falsifiable prediction regarding an (non)observation of cosmic strings (through gravitational lensing, hydrogren spectra, or othersie,) and, to quote "that's the problem" but isn't any worse than "GUTs have stable cosmic string solutions" which don't offer a falsifiable prediction b/c if what you say is true "So, even if your GUT has cosmic string solutions, whether or not you expect to see such things depends on something different, your model of inflation" would you regard this class of GUT physics research to be as hoplessly misguided as string theory, for consistency sake? If you'd like me to clafiy I'd be happy to do so but I wonder whether you regard GUT physics research as much a failed idea of unification as stringy unification research.

regards,
Dan

37. **chris**
January 31, 2008

eric,

are you joking? how can a sane person argue like this?

let me reming you that
a) there is no gravitational anomaly with SM matter content in 4D
b) there is very strong evidence, that gravity in 4D is consistent
c) experimentally, D=4 to a very high accuracy
d) some bizarre model that lives only in 10D has some restrictions of its mater content that excludes SM alone

and this you call evidence for the bizarre model? excuse me.

38. **Peter Orland**
January 31, 2008

Eric,

Nothing inherently stringy is required for gravitational-anomaly
cancellation. It just provides a condition on the matter content.

39. **Eric**
January 31, 2008

Peter O,
I presume by 'matter content' you mean the number of bosons and fermions on the world-sheet, described by a CFT on the world-sheet?

40. **Peter Orland**
January 31, 2008

Eric,

No, I mean the number of Fermions and Bosons in space-time
(target space to the string theorists). Green and Schwarz's 1984
paper just started from the classification of gravitational anomalies of
Alvarez-Gaume' and Witten; who did not use any
string theory.

41. **Peter Woit**
January 31, 2008

dan,

The situation of research into GUTs is a complicated topic. One difference with string theory is at least for GUTs it is clear what one is talking about. GUT models are well-defined and one can calculate exactly what they imply and see if the simplest ones can be used to make testable predictions. As string theorists love to point out, if you start looking at arbitrarily complicated GUT models, as with string theory, you're not going to get any testable predictions.

There are two implications of simple GUT models that show a non-trivial agreement with experiment, but they're both kind of marginal and not completely convincing.

One is the fact that a single generation of SM particles fits nicely into one SO(10) spinor representation. The other is that the ratio of observed gauge couplings you expect in SO(10) supersymmetric GUTs comes out close.

On the other hand, many initial hopes for GUTs have failed. The biggest failure was the prediction by non-supersymmetric SU(5) and SO(10) models of observable levels of proton decay, which were not seen. I think it is also fair to say that initial hopes that GUTs would make distinctive, testable predictions about the early universe have not worked out. Here the situation actually is much like that of string theory, with people going on about how cosmology will be used to test the theory, just the way they used to with GUTs, despite the lack of plausible ideas for how this is going to happen. The best hopes there are that somehow we'll observe cosmic strings or something similar, but the fact of the matter is that there is no evidence for such things, and both string and GUT models don't at all require them to be there.

42. **metamars**
January 31, 2008

"First of all, this topic has nothing at all to do with the posting. Secondly, please do not copy material wholesale from other people's blogs here, trying to drag them into the discussion at this site."

Please accept my apologies.

43. **otto schtirlitz**
January 31, 2008

Peter O.
"No, I mean the number of Fermions and Bosons in space-time
(target space to the string theorists). Green and Schwarz's 1984
paper just started from the classification of gravitational anomalies of
Alvarez-Gaume' and Witten; who did not use any
string theory."

The hexagon anomaly which arises at ONE LOOP is cancelled by the TREE LEVEL diagram coming from the B-field exchange. Clearly, one has to go beyond the supergravity approximation to demonstrate the cancellation.

44. **Peter Woit**
January 31, 2008

I don't think this kind of discussion of anomaly cancellation is enlightening anyone about anything, and it's off topic anyway. Enough already.

In any case, the "miraculous cancellations" occur for d=10, and for E8 or SO(32) gauge groups from what I remember, which would be pretty exciting if we lived in d=10 or observed those gauge groups, but…

45. **Peter Orland**
January 31, 2008

Peter,

Sorry, but I can't resist. I won't object if you delete this response.

Otto, using the B-field is clever duality trick to turn a loop
diagram into a tree diagram. The anomalies cancel in the
field-theory limit. No string theory is required.

OK, I misbehaved and will shut up about this matter.

46. **Dan**
January 31, 2008

Dear PW,
Thanks for replying, I think we agree that GUT research is similar to string research. The simplest GUT models (i.e SU(5) have been ruled out, and to evade experimental falsification, both research programs have been made more complicated.

47. **amused**
January 31, 2008

From the press release:

" "If we embed brane inflation into string theory, a network of cosmic strings is predicted to form," Wandelt said."

This seems to be at odds with what Woit wrote:

"Among the huge variety of string theory backgrounds and the many possible ways to try and use such backgrounds to model the big bang, some will […] produce macroscopic "cosmic strings" "

Can the experts out there clarify: is formation of a cosmic string network a generic prediction of brane inflation embedded in string theory, or isn't it? Are there other known viable ways to model the big bang using string theory besides this?

48. **Peter Woit**
February 1, 2008

amused,

To get an idea of the range of models "string cosmologists" are investigating, you might want to take a look at any one of a number of summary talks on the subject. One example would be Renata Kallosh's talk at PASCOS 2007

http://www.pascos07.org/programme/talks/Kallosh.pdf

On pages 15-6 and 17 of her slides she describes two classes of models with no cosmic strings.

Restricting to "brane inflation" models, as far as I know, you can get a huge range of possible "predictions", depending on the specific model and parameters you choose, ranging from far too many, already falsified by experiment, to so few you have no hope of observing their effects. Wandelt for some reason doesn't mention this…

49. **amused**
February 1, 2008

Ok, so brane inflation is one of several scenarios that the string cosmologists have come up with. But within that scenario they say that cosmic string networks are indeed generic for the various specific models. E.g., from the abstract of Tye's review paper hep-th/0610221:

"Another generic consequence of brane inflation is the production of cosmic strings towards the end of inflation. These cosmic strings are nothing but superstrings stretched to cosmological sizes. The properties of these cosmic superstrings and their subsequent cosmological evolution into a scaling network open up their possible detections in the near future, via cosmological, astronomical and/or gravitational wave measurements. At the moment, cosmological data is already imposing strong constraints on the details of the scenario…."

Tye goes on to claim on page 2 of the review that the various parameters in the brane inflation models can be overconstrained by observational data (presumably in the future). In that case the scenario will either be falsified or lead to a predictive cosmological model.

Well, clearly it is misleading for a press release to describe a paper about an observable imprint of cosmic strings as a way to "test string theory" (rather than a way to test one of the main string-inspired cosmological scenarios). But it seems just as misleading to give the impression that there is nothing interesting or worthwhile about this paper or the other ones mentioned in these "hype!" posts. (Working out an imprint that cosmic strings would leave in the hydrogen absorbtion spectrum, and how it would constrain various cosmological models, sounds pretty neat, as does working out collider signatures for distinguishing between different geometries in braneworld models.) I wouldn't want to work on any of this kind of speculative stuff myself, but people who want to disparage it should first come up with something more promising themselves. It's a lot easier to disparage the work of others that to find something interesting yourself.

50. **Peter Orland**
February 1, 2008

This is off-topic, but…

"It's a lot easier to disparage the work of others that to find something interesting yourself."

Amused,

It's time to stop inserting such remarks. You don't effectively
advocate a position by saying someone you disagree with is somehow not qualified. In this case, not only does this remark undermine your position, but is incorrect. Peter W. is NOT unqualified. I say this as someone who does not always agree with him (though in the interest
of full disclosure, I will tell you that we are friends). For example, some papers Peter has written on topology and the lattice with many more citations than most on this topic (and were influential beyond the number of citations). You should also be aware that the number of papers per year written by a typical mathematician is much less than the number written by a typical physicist.

If we are going to argue our positions on the basis of our
qualifications, all of us are vulnerable. One can look at anyone's record and put a negative spin on it.

51. **Peter Woit**
February 1, 2008

amused,

Insulting me is a lot easier than acknowledging that what I wrote is accurate, isn't it?

I actually agree with amused that I should be spending more of my time working on positive things, and less dealing with the problem of string theory hype in the media. In any case, the current rate of BS press releases every few days is beyond my capability of keeping track and commenting on. I do think someone should be pointing this out and no one else seems willing to do this. So I intend to keep doing so, but postings about this will be shorter.

One thing that really is a complete waste of my time is defending myself against the personal attacks of people like amused. So, sorry folks, I'll just delete any more discussions pro (Thanks Peter O.!) or con of my competence here, and continue to let what I write speak for itself.

If you have something interesting to say about the topic of a posting, please do so. If you don't know anything about it, but want to use it as an excuse to insult me or anyone else, please go away.

52. **JC**
February 1, 2008

One of the first few string papers I read was Witten's 1985 paper on cosmic strings. At the time I was in grad school and was naive enough to buy into it as if it was a "holy gospel". I became more skeptical of the idea as time went on.

53. **amused**
February 1, 2008

No I wasn't questioning Woit's qualifications etc. The point had nothing to do with that. It's really simple: if someone wants to disparage work addressing some issue (in this case finding a theoretical underpinning for inflation) then they should provide a more promising approach to addressing the issue. I don't find the string-inspired stuff at all appealing, so I don't work on it, but at the same time I don't disparage it since I don't have any better proposal for the issues they are trying to address. Isn't that a reasonable attitude that everyone should have? It has nothing at all to do with assessing peoples qualifications, publication lists etc.

So what was I trying to do here? First, ask questions to try to find out the actual situation about this paper, what was hype and what wasn't. Second, react against the negativity directed to this and the other PRL papers in the "hype" posts.

"…If you don't know anything about it, but want to use it as an excuse to insult me or anyone else, please go away."

When you turn up on the blogs of Jacques Distler and Clifford Johnson to harangue them about their discussion of some string theory topic, their reaction is probably "please go away" as well. They are too polite to actually write it though. You don't "go away" though, because you think you have some valid points to make and are determined to make them. What a surprise that you should encounter someone with the same attitude on your own blog. It's funny to see how you deal with it.

"Insulting me is a lot easier than acknowledging that what I wrote is accurate, isn't it?"

I asked a couple of questions; you answered one of them (sort of) and I acknowledged it with "Ok,…" at the beginning of my comment. You didn't answer the other one (about whether cosmic strings are a generic prediction of brane inflation) so I went and found the answer myself. Btw, both questions were relevant to the topic at hand, wouldn't you agree?

54. **Peter Woit**
February 1, 2008

JC,

Cosmic strings certainly have a very long history by now. The early hopes for how to use them were conclusively killed off by the WMAP results, but people can always come up with new ones that can't be shot down anytime soon by experimental results. For one of many disconfirmed predictions in this area, see this 1986 Time magazine article

http://www.time.com/time/magazine/article/0,9171,962896-1,00.html

where Ostriker is quoted as follows:

"We still don't know that there are such things as cosmic strings," he says, "or that they are necessarily superconductors or will in fact carry large currents. But all these things are quite possible. Within a few years, superconducting strings will have either transformed our view of the large-scale universe — or be entirely forgotten."

55. **JC**
February 1, 2008

Peter,

It was the repeated disconfirmations over the years which eventually led to my skepticism of cosmic strings. Even back then, many of my former astro colleagues thought the idea was sort of a joke.

56. **Peter Woit**
February 1, 2008

amused,

Yes I did accurately answer your question about brane inflation, and not with vague hype about "generic predictions".

Sadly, you have turned into a prototypical internet troll, devoting your time to posting hostile comments about things you know virtually nothing about. Before criticizing me for what I write about the hype problem in string cosmology, you might want to first go and learn the first thing about the subject.

57. **amused**
February 1, 2008

Well, people can make up their own minds about whether the questions I asked and the rest of the comments were reasonable or not, and the same for Woits answers. Not much point in continuing with this.

58. **anon.**
February 2, 2008

'The point … It's really simple: if someone wants to disparage work addressing some issue (in this case finding a theoretical underpinning for inflation) then they should provide a more promising approach to addressing the issue. I don't find the string-inspired stuff at all appealing, so I don't work on it, but at the same time I don't disparage it since I don't have any better proposal for the issues they are trying to address. Isn't that a reasonable attitude that everyone should have?.'

– amused

Amused, it's unreasonable because if you ban attacks on popular ideas that are failures – unless the person who is attacking has a better approach to the problem – then the need for a better approach to be developed may never arise. It's then Catch-22 because, *only when a failed idea has first been found wanting, is there a need to develop a better approach*.

If you insist that a better approach be developed before criticising failures in the current ideas, 1) nobody will listen because they'll think you're just trying to hype a new theory, and 2) you will eliminate the usual two-step route to advance, whereby a failed idea is first attacked, then replaced by new developments that are inspired by the faults in the existing ideas.

Historically, the two-step route to progress (discredit a bad idea, then afterwards develop a better approach) is more common that a one-step process of replacing an idea in one go without first making the case widely understood for why the idea needs to be replaced.

Your suggestion that criticism must always be constructive, while fine in an ideal world, will eliminate a lot of progress in this (real) world by preventing the two-stage progress model from working. People aren't motivated to fix things that aren't first known to be broken ('if it isn't broken, don't fix it'). If an error is being made, the sooner it is publicised, the sooner it can be fixed. Any censorship of criticisms just slows down progress.

59. **Peter Woit**
February 2, 2008

anon,

I should point out that what I'm doing here is criticizing misleading press releases about scientific results, not the scientific results themselves. Universities should not be in the business of issuing press releases about the work of their scientists designed to mislead the public about its significance, and when they do, someone should call them on it. I'd be very happy if someone else would be the one to do this.

It used to be that these press releases most of the time got pretty wide distribution, through articles in places like New Scientist, and on web-sites like Slashdot. Among the recent flood of them, most seem to not be getting much attention beyond the sites that carry all such press releases. Perhaps this is an indication that journalists covering physics have caught on to what has been going on. I suppose this is progress, but it isn't a good thing that journalists and the public now are likely to be skeptical of the credibility of press releases about physics research put out by major universities.

60. **amused**
February 3, 2008

anon,

Sure, criticising an approach, discussing its shortcomings etc is good and healthy. But that's not what I see happening here. The impression from this post is that the paper under discussion is of no interest and worth but is just a vehicle to propagate more string hype. From reading the press release I got a quite different impression. So I asked a couple of questions to try to find out what the real situation is. The paper is apparently discussing an observable (in principle) imprint that cosmic string networks in the early universe would leave, and how it would give information on the brane inflation that gave rise to those networks if that's what they came from. The level of PW's criticism in this post seems to be that this is junk because you can get anything you want out of string theory so there's no reason to care about what some or other string scenario might predict. But from what (little) I read about this in the string literature it sounds like the situation is quite a lot better than that. Apparently brane inflation is one of just a few scenarios that string cosmologists have been able to come up with, and within that scenario they say that cosmic string networks are a generic prediction. If that is true then the current paper seems not at all worthless and uninteresting.

In light of those observations, the right way to go about criticising this work would be to argue, at the technical level, that one or more of the reasons for being interested in it is flawed. E.g., if someone could show that there are lots and lots of different inflation scenarios (compatible with observational data) that can arise from string theory, and most of these do not predict cosmic strings. Or, alternatively, show that the arguments for why cosmic strings are a generic prediction of brane inflation are flawed. If someone can show either of these things they should write it up and publish it as a research article — that's the way criticisms of scientific approaches are supposed to go.

The way scientific criticisms are not supposed to go is simply pouring buckets of negativity over the research efforts of serious scientists who are following their best judgement in a difficult situation — unless you have a better proposal for the issues they are trying to address.

61. **anon.**
February 3, 2008

'The paper is apparently discussing an observable (in principle) imprint that cosmic string networks in the early universe would leave,…' – amused

Amused, you're missing the point: please see Woit's point in reply to my comment above also applies to your comment:

'…what I'm doing here is criticizing misleading press releases about scientific results, not the scientific results themselves. …'

It's the press release about making a 'prediction' that is being criticised, not the paper. Without knowing definite initial conditions for a cosmic string, are you in a position to make a falsifiable prediction about how big it will become after the assumed inflation occurs within a minute fraction of a second after the universe? Are you even sure that your model for inflation is accurate? It hasn't won any Nobel Prizes yet.

'… the right way to go about criticising this work would be to argue, at the technical level, that one or more of the reasons for being interested in it is flawed. E.g., if someone could show that there are lots and lots of different inflation scenarios (compatible with observational data) that can arise from string theory, and most of these do not predict cosmic strings. Or, alternatively, show that the arguments for why cosmic strings are a generic prediction of brane inflation are flawed.' – amused

Basic research work (to establish validity of claims) is something that the people making such claims need to do *themselves, before actually issuing press releases hyping the claim*. This isn't the same situation as when issuing a preprint about a speculative idea.

It's for the people making claims to investigate the main problems, not for the critics to do that after press releases have been issued. The problem is not that people are doing this research, but that there are very serious problems that are being glossed over in popular hype. It's a bit like popular claims that supersymmetry 'makes predictions' because it requires a so far unobserved partner for ever observed particle. If the theory is wrong, you would never be able to find out: you would keep searching at every higher energies, for ever edging towards the Planck scale. There is no evidence why the theory is correct, and there is no possible way of ever showing it is wrong.

If the search for cosmic strings is actually a *checkable* test of string theory (unlike supersymmetry, gravitons, and brane worlds), then that would be a massive step forward.

62. **Peter Woit**
February 3, 2008

amused,

You just keep on ignoring what this posting is about: a misleading press release. I did not claim the paper was worthless, I do claim that the press release about it is intentionally designed to mislead people about the results of scientific research.

63. **piscator**
February 3, 2008

anon,

Supersymmetry as a solution to the electroweak hierarchy problem is perfectly testable – it's either around the weak scale or it doesn't stabilise the Higss mass. There are good reasons for susy to exist at the weak scale – this is an answerable question, the LHC has the reach to answer this question and will answer this question.

piscator

64. **Coin**
February 4, 2008

Supersymmetry as a solution to the electroweak hierarchy problem is perfectly testable – it's either around the weak scale or it doesn't stabilise the Higss mass.

Okay, which I think is a good point. But the problem is, even if "susy as a solution to the electroweak hierarchy problem" is falsifiable, that still leaves the question of what about "susy as a method of getting matter into string theory". It seems likely that work on susy would continue even if the hierarchy problem justification were removed.

Last Week’s Hype

January 30, 2008
Categories: This Week's Hype

I was concerned that my “this week’s hype” headlines might be less than accurate, counting only 3 separate over-hyped string theory stories during the past month rather than four. Turns out that I missed one (although a commenter here didn’t), involving yet another university press release based on a PRL-published paper about cosmic strings. To be fair to the authors, the press release and paper don’t contain that much hype, nothing about how they are “testing string theory”. What they do is fit the CMB data using an additional parameter they call f_{10}, which has to do with the fractional contribution of cosmic strings to the temperature power spectrum at multipole l=10. They claim to get a slightly better fit to the data with a non-zero version of this parameter and power-law tilt $n_s=1$, versus the usual fit with gives a n_s less than one. When they also take into account non-CMB data, the effect goes away.

This isn’t really convincing of anything, so it’s unclear why it deserves a press release. According to the New Scientist story on this, which is pretty reasonable and hype-free, the chief scientist for WMAP, Charles Bennett thinks it’s a statistical fluke:

> Calling it a detection is odd… I’d be very surprised if cosmologists were excited about this at this stage.

For other press stories about this, featuring misleading headlines, see String Theory Gets A Boost at physorg.com, and String Theory slightly preferred… or at least, not disfavored! at Canada Free Press, where the author does note:

> To listen to people speak about string theory is a lesson in ambiguity. No one is willing to commit to a solid opinion, on either side of the coin, and they dance upon the fence as if they were auditioning for a Garfield strip.

Comments

   January 30, 2008

   Peter quoted an author as saying: “No one is willing to commit to a solid opinion, on either side of the coin” He has obviously neither read “Not Even Wrong” nor visited this website!

2. **Indrajeet**
   January 31, 2008

   Hi Peter, I don’t know whether you know this…If you try to link to Motl’s blog from your posting, it is showing a message which contains disparaging remarks about you and your blog.

3. **Peter Woit**
   January 31, 2008

   Indrajeet,

   Yes, I’m well aware of this…

Today’s Hype

January 31, 2008
Categories: This Week's Hype

The rate of appearance of press releases hyping string theory has now passed the the one-per-week mark. Today’s [example](#) is from the press office of the University of Wisconsin, and again is based on the appearance of a paper in PRL. The [preprint](#) of the paper appeared 8 months ago on the arXiv. Since that time, it has been cited exactly once by later papers, in another paper by some of the same authors.

   January 31, 2008

   You might also get a kick out of US Patent#6025810 for a Hyper-Light-Speed Antenna which claims: “The present invention takes a transmission of energy, and instead of sending it through normal time and space, it pokes a small hole into another dimension, thus, sending the energy through a place which allows transmission of energy to exceed the speed of light.”

   http://www.patentstorm.us/patents/6025810-fulltext.html

   It reminded me of how Brown University’s Greg Landsberg, when interviewed by BBC Horizon’s Dr. Brian Cox earlier this week, explained that one of the reasons we may not see gravitons is that perhaps they spend most of their time in extra dimensions. (Incidentally the above patent reference turns up at the end of one of Landsberg’s old presentations here:
   http://hep.brown.edu/users/Greg/Talks/Moriond01.pdf)

   You can see the interview with Landsberg here (near the end):
   http://tinyurl.com/ywpu8j

   Apart from this, Tuesday’s Horizon programme was a pretty good and hype-free popular survey of the issues surrounding current efforts to detect gravitons.

2. **Cornelius R. Morton**
   January 31, 2008

   Reference
   http://www.patentstorm.us/patents/6025810-fulltext.html

   The US Patent Office has just bent Special Relativity and certified the existence of higher dimensions!?! Also noted in the description that use of this device will stimulate plant growth. Why?

3. **Coin**
   January 31, 2008

   Okay, now this one confuses me. So they are actually suggesting that the graviton is in the TeV range and could be detected at the LHC by the particles it decays into? I guess I don’t really know whether the idea of gravitons being generated in a particle accelerator is all that strange or not, but how’s the graviton-decay thing work? Shouldn’t gravitons be really really long-lived, like photons or something, in order for gravity to work in the first place?

   Or is the idea that their model somehow contains *both* “KK gravitons” and normal gravitons, and the KK gravitons are the ones that appear in the TeV range and decay quickly, and the normal gravitons just cause gravity? (Their cite, hep-ph/9909255, talks about there being a “tower” of gravitons somehow related to the different “KK excitations”, which seems to make it sound like there’s more than one kind of graviton; and searching there actually seem to be a *lot* of papers writing about the “KK graviton tower”. I don’t think I quite understand any of this. What’s a graviton “tower”?)

   Also why do they talk about “5-d warped extra dimensions”? Don’t we need ten for strings? Or do they just mean that among the six “extra” dimensions in the 10d string model, exactly five are warped?

4. **Yatima**
   January 31, 2008

   Why?

   “As you know, Bob” the use of tachyonic communication devices causes resonant vibrations in the background pan-galactic morphogenetic flux field. This trivially causes water-protein complexes in plant tissue to undergo quantum algorithmic boost processes leading to hitherto unreached efficency in cell growth.

   At least one can definitly say that there is no “prior art”.

   (Sorry for the noise.)

   Anyway, Peter, I propose you add a “hype chart” to the blog sidebar for easier consultation, like they do at that “Homeland Security” outfit.

5. **chethan krishnan**
   February 1, 2008

   Dear Coin,

   Here is what people mean when they talk about a Kaluza Klein tower.

   The wave function for a field has to come back to its starting value when you move around a compact dimension (think of a circle) because wave functions are believed to be, well, functions, i.e., they are single-valued.

   Now, momentum is the generator for translations (which is just a fancy way of saying that i.p.x is what shows up in the exponent in the wave function, just believe me on this point if you don’t know why. I don’t know your background.). So this condition can be translated to the condition that momentum components in the compact dimenions are quantized as n/R, where R is the radius of the circle, and n is an integer. (Because ip (x+2 pi.R) – ip x, should be a multiple of 2i pi. n)

Now, if you write down the equation of motion for the field (example: think of a Klein-Gordon equation) the derivatives in the compact dimensions bring down (the square of) the quantized mometum and it looks just like a mass term. So if you want to talk about all the n's together, we can talk about a "Kaluza-Klein tower" of fields. Depending on the size of the compactification, all of these except the n=0 (massless) case might be too heavy to be detected in accelerators. This is where "large" extra-dimensions etc. (larger size= smaller mass) can give rise to possibly new phenomenology.

If you notice, I tacitly assumed that the compact dimension was flat. (Circles have zero intrinsic, i.e., Einstein-like, curvature). What the paper that you pointed to is considering, is the possibility that this need not be the case, you can consider more general spaces for compactification. The word warped means there are some conformal factors that show up in pieces of the metric. It turns out that this warping is a beautiful way in which we can explain away the heirarchy between say electroweak and Planck scales. The word "graviton" comes up because the higher dimensional metric, with some legs in the compact dimensions, is what get interpreted as lower dimensional fields.

Randall-Sundrum as it is, is a phenomenological model. So it doesn't have to be motivated by string theory. But the interesting thing is that it *is* motivated by string theory. Randall-Sundrum like scenarios are more or less easy to implement in string theory by considering one of the "compact" dimensions expected from of string theory to be non-compact, warped, etc.

Of course this was just the general story, but that should give you the bearings.

Chethan.

US HEP News

February 1, 2008
Categories: Experimental HEP News

Today and yesterday at Fermilab there is an HEPAP meeting designed to gather information necessary to prioritize decisions on how to spend the US HEP budget over the next few years. Many of the talks there are on-line and give a good idea of what future possibilities look like. The main issues being discussed are:

- Whether to go ahead with project X at Fermilab, a proposal for a high-intensity proton source.
- The state of the ILC project, given that it was zeroed out in this year's US and UK budgets. Barry Barish emphasizes the continuing goal of being ready to make a decision about whether to build such a thing soon after LHC results arrive, presumably starting in 2010. The state of CLIC and other multi-TeV lepton collider possibilities is reviewed by Tor Raubenheimer of SLAC, who puts a likely date for a multi-TeV electron collider at 2030-40, a muon collider after 2050. These things are a long ways away…
- Whether to run the Tevatron in FY 2010, with presentations about how the Tevatron is currently performing, and from CDF and D0 advocating for a run past FY2009. Both experiments make the case that they are getting close to being able to either see evidence of the Higgs or rule out its existence over most of the expected mass range. More about this from Tommaso Dorigo of CDF here. Since the Tevatron is about the most successful and exciting thing going on in US HEP, I personally don't see the case for planning on shutting it down until solid results are in from the LHC about the Higgs, which should be sometime in FY2010 at the earliest. Who knows, maybe the LHC will see something that the Tevatron is a good tool to study further. Seems more likely than that it will see black holes…

The involuntary furloughs of Fermilab employees begin today. No news regarding the supposed efforts by the Illinois Congressional delegation to lobby for a supplemental appropriation to keep Fermilab from having to layoff around 200 people. At least one of the relevant people is undoubtedly too busy with other things to pay attention to this. The Congress and the White House are negotiating an emergency bill to deal with the recession and job losses that have started recently. Since government spending is bad and tax cuts are good, their plan seems to be to continue to throw people out of their jobs with budget cuts in HEP and elsewhere, while handing out cash to as many voters as possible.

For a presentation by DOE Undersecretary Orbach about the DOE budget problem, see here, and analysis from Richard Jones of the AIP here. The FY 2009 budget request from the White House will come out on Monday, and Orbach promises that

> The President's request for FY 09 will be wonderful, again, for the physical sciences. While I can't go into details here, I can say that it will continue the funding request consistent with the American Competitiveness Initiative and the America COMPETES Act. The problem for all of us is that, faced with essentially flat funding for the physical sciences in FY 08, the President's Request for FY 09 will appear as a very large percentage increase for the three ACI agencies. The danger is that basic research in the physical sciences will again be 'donors' to other programs.

meaning I guess that Congress will be tempted to strip these out in order to fund other things.

Gordon Watts notices that in Bush's State of the Union speech he explicitly advocated increased funding for basic physical science research, something which is extremely unusual in such a speech:

> Last year Congress passed legislation supporting the American Competitiveness Initiative, but never followed through with the funding. This funding is essential to keeping our scientific edge. So I ask Congress to double federal support for critical basic research in the physical sciences and ensure America remains the most dynamic nation on earth.

The physics community seems to have done a great job of convincing the administration to support basic physics research in general and HEP in particular, which normally would be a very good thing. But the same was true last year, and it seems to just have had the effect of painting a big fat bullseye on HEP funding for someone in Congress looking for a place to cut. At least this year people are aware of what might be coming, and maybe something can be done to head off a repeat of this year's disaster.

The general budget politics don't look favorable at all though, with the Bush Administration evidently proposing to heavily cut Medicare and Medicaid spending. Congress has very different priorities, and it seems all too likely that they will fund restoration of the health-care cuts by cutting things like the DOE basic research budget. This fall will be different though, with a new Congress and president elected at the beginning of November, but not taking office until January. I wouldn't be surprised to see the government run on a continuing resolution at FY2008 levels until after a new president takes office.

Update: The proposed FY2009 budget is out, DOE here, NSF here. The DOE budget contains a huge increase for HEP, from $688 million in FY2008 to $805 million in FY2009. The NSF budget doesn't break out the HEP component, but the total budget for math and physics is supposed to go from $1167 million in FY2008 to $1403 million in FY2009. These are huge and very healthy proposed increases, but unfortunately it is not at all clear that they will actually make it into the final budget.

Update: There's a story today in the New York Times about this. Also a message from the Fermilab director, saying he has no choice but to go ahead with the plan to start laying off employees of the lab. In practical terms, the proposed budget increases appear to be meaningless, with the likely situation no increase at all in FY2009 of any kind until a budget gets passed, which most likely will not happen until already deep into the fiscal years. He writes:

> …every Washington expert tells me to prepare for a continuing resolution that might last into the new administration. Such a continuing resolution would extend the present difficult budgets well into FY09. At the same time, relief in FY08 in the form of a supplemental appropriation is not guaranteed and is at best several months away.

Comments

1. **John**
   February 3, 2008

   I wouldn't be surprized if HEP funding was cut. Given the current economic woes it's bound to happen that 'esoteric' fields with no direct, immediate consequences should bear the brunt of funding cuts.

2. **Peter Woit**
   February 3, 2008

   John,

   According to new stories today, Bush's plan is to blow out the FY2009 budget with a $400 billion or so deficit, leaving the mess of dealing with that to the next president. He probably doesn't have any choice about this if he wants to finance the war in Iraq at a high level and avoid a recession by stimulus spending at home. The Democrats seem to lack any serious interest in stopping the war by refusing to pay for it, and they too like to give cash payments to voters, so it looks like $400 billion or so will be the size of the deficit (larger if there's a recession).

A healthy budget increase for HEP would be about one-tenth of one-percent of the planned deficit spending, lost in the rounding errors of the things like Medicare spending that the Congress and the White House will fight over. Supposedly, this week Bush will announce the details of the proposed budget and it will include a healthy increase for HEP, we'll know the details soon. Unclear what the Congress will do, we may not know until nearly a year from now, far into the fiscal year. What a way to run a country….

3. **J.F.**
   February 3, 2008

   In the category of "bigger fish to fry", note that Senator Durbin has serious egg on his face on the abrupt cancellation of the FutureGen coal plant by DOE, AFTER a siting decision was made for IL and against the TX sites. One can only wonder if his eye was on the wrong ball back in December, or even if he got deliberately played by the administration (e.g. FutureGen was never coming to IL, and he should have been fighting for Fermi and other things).

   I don't think the state of the union bit helps at all. Even when Bush was more popular and not a lame duck, all the "lets go to mars" rhetoric did was reprioritize NASA money, and DOE is far more compartmentalized, so even if we wanted other science and tech to suffer for HEP it won't happen.

4. **Gordon Watts**
   February 4, 2008

   But we don't want other science and tech to suffer for HEP! That attitude, btw, is exactly the best way to get science funding and HEP shot in the foot.

   One thing about this budget. If this works out as the last one has — will Bush even be in office? And will the politics be such a mess they just decide to do a continuing resolution for the full year — as they did previously?

   At anyrate, the horse trading that involves HEP and science in general comes at the very end — as Peter points out the amounts are so small compared to the elephants roving the room. This is why we were all blind-sided.

   Finally, don't make the mistake of thinking that only HEP got it last time. Several branches got it (NIST, ITER, for example). It should be on every scientists mind: how to increase funding for all sorts of science in the USA, not just their particular branch. I'd really love to see general increases and then the peer review system or experts figure out how to allocate it. Maybe we could stop talking about man on mars then…

5. **J.F.**
   February 6, 2008

   Gordon: I agree completely regarding priorities, I mentioned it as an absurd extreme but was not clear.

   As an interesting sidenote, Bill Foster, formerly of Fermilab and running in that district, apparently won his primary tonight. His competition in the March special election is a perennial candidate who has never won office and is not liked by the state party, so there is a significant chance Foster will be in congress soon. Personally I think it is obvious that Fermi got cut a month after Hastert resigned precisely because they had no seat at the table to defend them.

Steinhardt: The Anthropic Landscape Has Run Its Course

February 3, 2008
Categories: Uncategorized

Over at John Horgan's blog, he quotes an e-mail from Princeton cosmologist Paul Steinhardt, who corrects Horgan's account of a recent conversation between them, writing

> I said that I thought that the idea of a string landscape and the notion of anthropic selection had run its course. I think it is too early to give up on string theory.

While Steinhardt sees anthropic selection of our universe out of a multiverse as an idea that has run its course and is on its way out, it's still quite popular in certain quarters. The Templeton Foundation, through the FQXI organization, is a major source of funding for anthropic multiverse research. FQXI's web-site has a new story up entitled Philosophy of the Multiverse, which asks "On what side of the borderline between science and philosophy are multiverses?" The writer evidently couldn't locate anyone to take the "it's philosophy, not science" side of the argument, quoting Sean Carroll, Anthony Aguirre, Alexander Vilenkin and Aurelien Barrau as supporters of anthropics as science. Barrau suggests that we may need to change the definition of science to accomodate the multiverse.

Whatever Steinhardt says, at least the Mormons are getting on the multiverse bandwagon, with their journal Dialogue recently publishing a long article entitled Eternal Progression in a Multiverse: An Explorative Mormon Cosmology. The article begins:

> This article is an examination of the Mormon doctrine of eternal progression within the context of big-bang cosmology, a description of a finite universe that appears to contradict that doctrine. I argue that a multiverse cosmology, a theory that posits a multiplicity of universes, resolves many of the problems posed by big-bang cosmology.

and goes on to explain how the multiverse agrees well with the doctriine of "eternal progression" in Mormon theology:

> In a Mormon multiverse cosmology, God does indeed manifest his infinite creative prowess in the respect that God (any god along the infinite chain of gods) creates children, some of whom progress to become gods, who in turn create their own universes and children, some of whom progress to become gods, and so on, forever. Each universe in the ensemble of universes becomes an extension and continuation of the creativity of every "ancestral god" in an eternal family of deities. The creativity and glory of each god increases exponentially with the production of new universes. In this cosmology, the multiverse is a hallmark and witness of the infinite work and glory of God and the dwelling place for an infinite number of eternal progressing beings.

While solving the problem of justifying eternal progression, the multiverse idea leads to all sorts of new possible research directions:

> In a Mormon multiverse cosmology, many questions remain open. Are there communication and movement of the gods and other premortal and postmortal beings between universes? When a universe experiences a big crunch or big freeze, does the god of that universe generate a new universe or "relocate" to another universe fit for carrying out the "great plan of happiness" for a new household of spirit children? Did God, our Father in Heaven, achieve godhood in this universe or a prior one? If God was exalted in a prior universe, how many universes has he governed? Jesus Christ is the redeemer for this universe, but is he the redeemer for others? Are some universes "stillborn" in the sense that they do not have the required values of the physical constants for a universe capable of sustaining life? Because the multiverse is infinite, are there replicas of us in other universes as postulated by the replication paradox? Cosmologists speculate whether the physical laws are the same across the ensemble of universes, but what about the spiritual laws? Are the spiritual laws "multiversal" or just "universal"? As multiverse cosmologies develop scientifically, these questions and others will stimulate much discussion.

The author ends the piece with a quote from Andrei Linde: "Universes can have babies — it's nice."

Comments

1. **JC**
   February 3, 2008

   If this is true, then maybe the anthropic landscape stuff being decoupled from physics and being isolated in the Templeton domain is what may possibly end up happening. That will show what the merits of all that anthropic stuff is really all about.

2. **John Stevens**
   February 4, 2008

   Dr. Woit, I have two questions for you: How did you learn of this Dialogue? Are you LDS? (A Mormon?) Second: Are you trying to make the claim that the Anthropic Landscape is on the same level as Mormon Theology? Thanks?

3. **Eric H**
   February 4, 2008

   It's interesting that just as some cosmologists and theoretical physicists are farther along in their total rejection of string theory, others are just starting the journey via their disavowal of the anthropic and mulitiverse ideas. Paul Steinhardt seems to be on the path of escaping from the clutches of string theory, but has not quite reached escape velocity yet. And finally there are the really backward individuals jumping onto the caboose and not realizing the locomotive miles in the distance is just careening off the cliff…

4. **Peter Woit**
   February 4, 2008

   John Stevens,

   No, I am not LDS, this came up in a Google search for something else.

   I know just about nothing about Mormon theology, and would suspect that this argument is something that conventional Mormon theologians might think of as "pseudo-theology": not interesting because it is pure speculation, with no way of ever deciding if it is true or not using the investigational methods of Mormon theology (whatever they might be).

   The study of the string theory landscape using anthropic arguments is certainly different than theology, Mormon or otherwise, but I'm not the only one who feels that it has more in common with theology than it does with science.

5. **Anthony A.**

February 4, 2008

Hi Peter,

I'm sorry that the FQXi article rubbed you the wrong way. A short article like this can't do much justice to the complexities of an issue like this. In my own view, there certainly are things one might call a 'multiverse' that are essentially philosophy (though I do not use that word synonymously with 'evil' or 'rubbish'), and others that are clearly not. But in terms of your post I think a few things are worth commenting on from the perspective of accuracy:

1) If you are discussing multiverse research supported by FQXi, I think a more accurate statement would be that "FQXi (funded in large part by Templeton) is a major supporter of multiverse research.", because the Templeton Foundation plays no role in deciding what projects FQXi supports.

2) Your entry gives the sense that FQXi is, as an organization, supportive of the multiverse. FQXi has no such 'ideology', and supports the best of the proposals it receives. I think I can safely say that FQXi has not rejected a single serious proposal explicitly opposing the 'anthropic multiverse', and has funded a number of proposals that work to provide alternatives to string theory, as well as anthropic ideas.

3) On my personal views, you may be interested to know that although it does not really come across in this article, I have actually been one of the leading critics of anthropic reasoning, starting with my first paper http://arxiv.org/abs/astro-ph/0106143, where I discuss how Weinberg's cosmological constant argument can be subverted. Later papers pointed out in detail how incredible hard anthropic/probababilistic reasoning in a multiverse is. However, in my view 'critic' means to take something seriously and show what works and what does not, rather than dismissing it categorically. Also (as mentioned in that same FQXi article), I have been working hard lately on the possibility of directly observing signatures of other (eternal inflation) 'universes'.

4) Much of the interest by cosmologists in 'multiverses' comes directly from the acknowledgement that generic inflation models do this, and that inflation is a really nice idea. Steinhardt and others have worked heroically to give alternatives to inflation, and I think we should all support these. But I think it is fair to say that the vast majority of cosmologists have yet to be swayed by their charms…

5) Pointing out how multiverses are now being discussed by some paper by Mormons is fun, but I think you could easily do the same using any scientific theory (e.g. the big bang, quantum mechanics, etc.) and various religious groups, some respectable and some not. So I'm not sure what your real point is with that…

best,

Anthony

6. **Zany Zebra**
February 4, 2008

This is great.

The Mormon religion has more to do with the "new thought" (now we call it "new age") movement of the 1800's and early 1900's than it does with orthodox Christianity, but it comes from a time when people developing alternative religions felt a lot of pressure to pretend to be Christian. (These days alternative religions that don't pretend to be Christian have an easy time getting started, but have a hard time sustaining themselves… The bible-based churches that look like warehouses on the outskirts of your time are the survivors of a natural selection process that included Scientology, Hare Krishnas, the Divine Light Mission, the Jesus Freaks and thousands of others.)

The article is a good example of the imaginary that surrounds anthropic and other cosmologies: the kind of cosmology that's fashionable at a given time depends as much on people's emotional needs as on real science. I remember the pre-inflation days when many cosmologists had a preference for omega < 1 because a universe that expands forever just seemed too lonely.

7. **Peter Woit**
February 4, 2008

Anthony,

Thanks for the interesting and sensible response to my rather hostile posting. You raise a lot of issues worth more discussion, here are some thoughts.

Yes, the Mormon theological document was a cheap shot. But still, I think it provides a useful reminder of where you end up when you stop paying close attention to what is legitimate science and what isn't. A lot of what I see reputable cosmologists going on about these days seems to me to have gone over the line. Why is Linde being quoted in the NYT about reincarnation??? If he has a sensible scientific point he should be avoiding theological concepts like the plague when trying to make it to the public.

Barrau's suggestion that standard criteria of what is science and what isn't may need to be changed is dangerous nonsense. It's well known that there's more to this question than falsifiability, but the issues surrounding this are the same as in any science. Whether the multiverse can be invoked to provide a conventional scientific, testable understanding of anything is a real and complicated question, but you can't cheat by changing the rules. This issue is worth debating if one can agree on the ground-rules of what is science and what isn't. If not, there's not much point in going any farther.

I thought both the FQXI article and the recent NYT article were disappointing in that they don't reflect the fact that many if not most physicists are not sold on the idea that this is actually science. Steinhardt would be a good example. Promoting uncritically this kind of research to the press is really a bad idea, it threatens to discredit physics research in general, as much of the public can recognize all too well that some of what is going on can't be legitimate science.

As for Templeton, I did not mean to imply that they have any influence over your grant decisions. But, blurring the distinction between what is science and what is religion is something that fits well with their agenda, and their decision to fund FQXI seems to me to have been taken knowing that it would be an organization sympathetic to anthropic multiverse research, something they probably saw as an argument in its favor.

8. **Struwwelpeter**
February 4, 2008

@Peter Woit:
"If he has a sensible scientific point he should be avoiding theological concepts like the plague when trying to make it to the public."

He never mentioned the plague, which, by the way, is not a theological concept but a disease (especially useful in curses).

9. **Peter Woit**
February 4, 2008

Struwwelpeter,

OK, OK, so this comment wasn't up to my usual standards of excellent grammar and great clarity. It has been a busy day so far…

10. **Bee**
February 4, 2008

I am actually quite fond of philosophical questions, but my biggest problem is always to figure out the actual meaning that is attached to a word. Good philosophers do at least try to start with a sensible definition, yet when I hear people 'philosophizing' they just fight over their interpretation of words which for a scientist can be pretty tiresome. Likewise, I find the multiverse discussion in the broad sense somewhat odd because different people seem to attach different meaning to the 'multiverse' to begin with. In some cases, it could have a scientific content, in others not.

E.g. the sentence (from the fqxi article) "So wouldn't it be strange if there were just one universe?" is already quite comical and illuminates this confusion, given that the [Online Etymology Dictionary] explains:

universe – lit. "turned into one," from unus "one" (see one) + versus, pp. of vertere "to turn"

If the universe is the one and all there is, there can by definition be no other universes? But leaving that aside, for some the rest of the 'multiverse' (of whatever kind) outside 'our own' (whatever that means) is by construction unobservable, in other cases there are observable consequences, which makes the essential difference as to scientific content.

Also, I'd acknowledge that sometimes a change in perspective can lead to progress even if that view itself isn't actually a testable hypothesis. Take e.g. the free will question. In practice it doesn't make any difference whether you do in fact have a free will, or all your decisions are predetermined but you don't know it. It does however make a difference to how you think about yourself and what you believe how the world works. Questions like this and the prevailing culture and sociological atmosphere in which scientists work do without doubt influence how we invest our brain time. Here as always however, I'd appreciate more clarity on what is science, what is scientific uncertainty, and what has nothing to do with science. For the scientists working on it that might be perfectly clear, but in the communication to the public one has to be extremely careful the scientific content doesn't get reduced to 'reincarnation as a BB' or an 'infinite amount of duplicates of yourself'.

11. **Coin**
February 4, 2008

I think I can safely say that FQXi has not rejected a single serious proposal explicitly opposing the 'anthropic multiverse'

Although I don't mean to denigrate your point here (i.e. that FQXi has no "official" stance on the multiverse and is simply promoting papers, multiverse/string or otherwise, that are found of quality) I do kind of wonder about this specific statement. How *could* you receive proposals explicitly opposing the anthropic multiverse?

Is it even *conceptually possible* to form an objection or line of attack on the anthropic multiverse idea, of the kind that could be actually be submitted to FQXi as a grant proposal? After all, the primary criticism of the anthropic multiverse concept in the first place is based on complaints of unfalsifiability– that is, claims that no scientific basis exists for attacking (or evaluating) the proposals of the anthropic multiverse idea.

12. **Eric H**
February 4, 2008

Bee,
I think you made a lot of good points. I find a connection between the motives for individuals in their theological thinking and the motives of scientists in their thinking about the physical world. There seems to be a similar motivation but the distinction seems to come from their reaction to anthropomorphication in religion.

I was brought up in a heavily Christian home, but like many people I ultimately rejected the human centered interpretation of God and his followers. Just too much projection of our own emotional desires onto symbols in religion. While still trying to adhere to the major tenets I've rejected the cloaking of those tenets behind ideas that set man as separate from the universe. So for me science, and physics especially, is sort of a spritual quest to move from the specific (human beings) to the general.

I think there is a dichotomy in people's basic nature, with many people in science anthropomorphizing their emotional needs in a way similar to how organized religion often does. I think it exposes itself in projecting "infinite universes" or an "infinite God". I think for some people it would be actually frightening to believe the universe is a closed system. But if the universe is not closed, i.e. energy or information can be injected spontaneously without a counterbalance somewhere else in the system, then what would be the point of science. It would all be for nought. I think most people don't realize a closed system is a GOOD thing!

February 4, 2008

@Peter Woit
No,no, Peter, I wasn't criticising you in the least.
It was a not so clever meta-level-joke and my only excuse is that I found it amusing to make a wordplay in what is not my mother tongue.

I am a great admirer of your chronicle (that's what they call blogs in my 1920 Berlitz English course, in which fans are still mechanical ventilators, not admirers) and am very grateful to you for all I have learned in it, both in mathematics and physics.
Cordial wishes, S.

14. **Peter Woit**
February 4, 2008

Eric H. (and others),

Please, I really don't want discussion of religion here. It's a topic that people have an infinite amount to say about, of which I'm only interested in a very small part, and that's the part that has nothing at all to do with science, so is off-topic here.

Mostly I quite happily just ignore people who want to engage in metaphysical discussion. When I can't ignore it and have to pay attention to it (as in when the field of particle theory starts being infected by it as it gets used to prop up a failed research program), it raises my blood-pressure and causes me to stop being my normal mild-mannered self and get hostile. Please help me stay healthy and not frothing at the mouth by sticking to science and leaving religion to other venues.

15. **Eric H**
February 4, 2008

Peter,
Sorry to get your dander up. I perhaps shouldn't have cloaked my argument in terms of religion. My real emphasis was the idea of bringing in infinite universes, and infinite, or near infinite, tuneable cosmological parameter combinations in string theory comes from the same drive as the worst parts in religion i.e. that the essential nature of the universe is something not ultimately knowable, no matter how much progress is made over time. Just because it's not known yet doesn't mean it can't

ultimately be known. String theory is just the wrong road. The right road is in accepting the universe as a closed system – you know, the first law of thermodynamics.

16. **milkshake**
February 4, 2008

usefulnes of ideas can be figured by proposing the exact counter-ideas. If one has no way of telling the two cases apart, by looking at this world, then his way of thinking belong to philosophy, psychology, poetry, marxism or other forms of religious experience

17. **Shantanu**
February 5, 2008

Peter, changing the subject a little, there is another paper on Boltzman brains
yesterday Btw do you think this
is a serious problem for inflation?

18. **Peter Woit**
February 5, 2008

Shantanu,

I saw the Gott paper, and tried to restrain myself from adding a hostile mention of it here, but since you brought it up… No, I don't think Boltzmann Brains are a serious problem for inflation (they're only a problem for the anthropic multiverse), but do think they are a serious problem for physics, with the field of Boltzmann Brain studies full of nonsense which makes theoretical physics look bad when it gets publicized. Some of Gott's arguments are just beyond absurd:

"The BB does not count as an intelligent observer because it is observer dependent and does not pass the Turing test. It can be distinguished from a human because even if it answers 20 questions successfully in a row, it will likely fail to answer the next question."

19. **Anonymous**
February 6, 2008

Mein Gott!

20. **Gilbert Awad**
February 8, 2008

Krauss, et al., have just published a paper in PRL where they argue that anthropic reasoning proceeds from ignorance more than knowledge. They try to demonstrate that anthropic lines of reasoning reveal more about the biases of the arguer than lead to any terribly useful knowledge. Unfortunately, they also claim that the end of anthropocism, if it comes, will be a long, slow death. Still, anthropics always having left a bitter taste in my mouth, I welcome their effort with open arms.

Krauss, Maor, and Starkman,"Anthropic Arguments and the Cosmological Constant, with and without the Assumption of Typicality," Physical Review Letters 100, 041301 (2008)

21. **Marcus**
February 8, 2008

Gilbert,
is that article by Krauss Maor and Starkman a retitled version of
http://arxiv.org/abs/0709.0502
"Anthropics and Myopics"?

22. **Gilbert Awad**
February 11, 2008

Marcus,

I'm not much of a gambling man, but that one looks like a pretty sure bet. In a word, yes. And thanks for pointing it out; I hadn't seen the Arxiv preprint.

23. **Shantanu**
February 21, 2008

Hi all,
See also this bizarre talk by Don Page at here

24. **Seth R.**
April 3, 2008

Sorry for re-visiting a conversation that has run its course. I'm not much of a scientist, so I can't speak to that. But I am Mormon and well acquainted with the small world of Mormon blogging and intellectual debate.

"Dialogue" is considered to be a rather unorthodox and fringe publication within the Mormon religion. Many believing Mormons consider such publications to be a frivolous waste of time at best and misguided apostasy at worst. There is certainly an anti-intellectual current in Mormonism, like there is in many religions. But occasionally you get intrepid believers who like to push the boundaries and venture into new theological territory.

My own experience is that Mormon attempts at cosmology are usually either wholly, or in large part, a reaction to mainline Christian attacks on Mormon theology. Mormon apologists and other Christian apologists get in their little spitting matches over whether Mormons are monotheists, whether they believe in Jesus, and whether they are being presumptuous by putting God in the same ontological category as human beings.

I won't bore you with all that. But to get to the point, there is a growing awareness in the world of LDS apologetics that the central divide between Mormons and other Christians is, not trinity, or scripture, or anything else, but the doctrine of "creation ex nihilo" – the idea that God created the universe out of nothing but His own power. For traditional Christian theologians, the entire universe can be divided into two ontological categories: 1. God – who is uncreated and self-existing and 2. everything else – which was all created by God. That ontological distinction is absolutely crucial for traditional Christian theology and their entire notion of the "trinity" is an attempt to preserve that ontology.

Mormonism collapses that ontological distinction and posits that not only are God and humanity the same species, but that creation ex nihilo is a false and groundless notion. Mormon doctrine states that all matter is eternally pre-existent. God never created anything out of nothing. He is only creator in the sense that a painter is a "creator" – i.e. He takes pre-existing materials and creates something from them. All matter has existed eternally in some form or other. So has the most foundational part of human identity.

That's what Mormonism claims, and it directly attacks the foundational assumptions of traditional Christianity about God and the universe.

Now, whenever a Mormon-Christian debate comes around to the topic of creation ex nihilo, the traditional Christians inevitably cite "The Big Bang" as cast-iron proof of their ontological claims. They cite the Big Bang as the moment when God spoke, and the universe burst into being. Mormon apologists, of course, are only too happy to ally (as best they can) with modern quantum physics in attacking this assertion.

This theological debate hasn't fully matured yet because theologians on both sides are still in the process of discovering the central controversy of creation ex nihilo. But at present, it seems very much like the traditional Christian theologians are positing a universe based on a fundamentally Newtonian model of physics. Increasingly Mormon theologians – the new kids on the block – are turning toward modern developments in quantum physics to undermine and refute the Newtonian-based theology of mainline Christianity.

String theory, of course, offers a real grab-bag of possibilities for the Mormon theologian. How can a physically present God be omnipotent and everywhere? How can the idea an infinite past (an assertion of Mormonism) overcome the problem of infinite regress of causes? How can a human become god and yet not surpass his or her own Creator? Fun stuff, if you're into that kind of thing.

I know this isn't a theology blog. But you cited the Dialogue article, so I thought you might be interested in the environmental impulses and demands that probably gave birth to it.

Microsoft Research New England

February 4, 2008
Categories: Uncategorized

Microsoft announced today that they'll be opening a new research lab, in Cambridge, which will be called Microsoft Research New England. The director of the lab will be mathematical physicist Jennifer Chayes, with deputy director her husband Christian Borgs, who is also a mathematical physicist. For an interview with them, see here, for a story in today's New York Times, see here.

Jennifer and her ex-husband Lincoln Chayes (also a mathematical physicist, now at UCLA) were my class-mates during graduate student years in Princeton, as well as frequent companions on trips down to City Gardens in Trenton to see bands like the Ramones. The two of them at the time had even more impressive leather outfits than the Ramones.

Update: There's more about this at the Xconomy web-site.

1. **Someone**
   February 5, 2008

   Your friends are doing OK. Congratulations to them and to you.

   Apart from that, what is the relevance of this post to the subject of this blog?

   This post's title should be "not even relevant".

2. **woit**
   February 5, 2008

   Someone,

   Well, one argument for relevance is that mathematical physics is perhaps the central concern of this blog, and Microsoft is opening a large, very well-funded lab next to MIT to be run by two mathematical physicists.

   As for the personal color and my reminiscing about my grad school days, surely you can just ignore that. Now, stop complaining or I'll write a blog posting about my views on politics, who I just voted for and why, etc., etc….

3. **Someone**
   February 5, 2008

   «Microsoft is opening a large, very well-funded lab next to MIT to be run by two mathematical physicists.»

   But their main focus won't be mathematical physics will it? If I understand this at all, it won't be physics related at all.

   "we want to combine core computer science, especially the more mathematical and theoretical aspects of it, with the social sciences, and we want to do it in an environment in which we won't just have researchers doing fantastic research side-by-side, but they also will be helping to create new fields at the boundary of computer science and the social sciences."

   «Now, stop complaining or I'll write a blog posting about my views on politics, who I just voted for and why, etc., etc….»

   Please don't. I really think you do a great job with this blog and would hate to have it "tainted" by your personal view on those subjects.

   We already have some "huge variance" blogs for that. No need to loose this great blog to that inner demon.

4. **George Bell**
   February 5, 2008

   After hearing Jennifer talk at a recent MAA meeting, I'd categorize her more of a Mathematician/ Computer Scientist. Perhaps they are going to try to create a search engine that can beat Google in this think tank?

5. **Ali**
   February 5, 2008

   Hi Peter,
   From the links you provided, it seems like there will be only 4 staff members in this "large" research center, including Chayes and her husband. I do not understand what makes this worthwhile to be a news article in NY Times.

6. **Peter Woit**
   February 5, 2008

   Ali,

   My understanding is that 4 is just the number of people starting the center, that the intent is for it to ultimately be much larger. Microsoft Research Cambridge (England) was started about 10 years ago with 3 researchers, now employs over 100, and I'm guessing that the intent is to reproduce that sort of thing in the other Cambridge.

   Not sure why the NYT chose to write about this, perhaps partly with the idea that anything new Microsoft is doing is newsworthy. It also is unfortunately true that the number of research centers of this kind, funded by corporations, but not devoted to directly applicable research, is extremely small, so this is noteworthy for that reason.

7. **AGeek**
   February 6, 2008

On a more general level, so not specifically about this particular institute, am I the only one bothered by the deputy director being literally in bed with the director? Something about healthy organizations having checks and balances, and about not mixing private and professional roles…?

8. **Chris Oakley**
February 6, 2008

   This new institute is probably a good thing. Maybe they will be able to persuade MS that (i) ISupportErrorInfo ought to be made to work in VB/VBA for module functions returning an HRESULT as well as COM classes [they ignored me when I pointed out the inconsistency a few years ago] and (ii) that allowing user-defined garbage collection schemes, as is currently possible for COM, would be a useful feature for .NET as well.

9. **Peter Woit**
February 6, 2008

   AGeek,

   In this case I think de facto the two people involved will be jointly filling the same role of directing the center, so as long as they can work effectively together, I don't see a problem. This situation is becoming pretty common in academic departments, where spouses are often hired together. It does open up all sorts of potential problems, but in practice these normally are not so difficult to deal with, and institutions find that dealing with them is better than dealing with faculty struggling with a two-body problem in other ways.

   Chris,

   I suspect that some problems in computer science will always remain beyond the capabilities of researchers to ever understand and solve…

10. **Peter Shor**
February 6, 2008

    I suspect that there will be a small portion of the new center devoted to statistical mechanics. This is the research area of its directors, and they have already shown that statistical mechanics can be of some use to Microsoft's business.

11. **Ali**
February 6, 2008

    Ageek and Peter, I do not think there is any two-body problem involved here. As far as I know, Chayes and Borgs were hired in 1997 as separate individuals to Microsoft. Their marriage took place after they started working for Microsoft. There is no such thing as two-body hire in industry to the best of my knowledge. Two-body hires mostly occur in academia.

12. **Peter III**
February 6, 2008

    Two-body hires definitely occur in industrial labs; I have seen them. Industrial labs are just as interested in getting really good people as academia, and if they have to hire another fairly good person to do so, why should they hesitate?

    In fact, in academia, sometimes Dept. A is unwilling to even consider hiring the spouse of somebody Dept. B is hiring, even if they are clearly better than many of the people currently in Dept. A, because they think it makes them look bad. I suspect this is less likely to occur in industry.

13. **Henry Cohn**
February 7, 2008

    I don't think it would be appropriate for me to get involved in speculation or debate here (I am one of the four initial MSR New England researchers), but I can report two things:

    The lab will definitely grow to be much larger than four people, and Jennifer and Christian were already married when they came to Microsoft.

14. **oz**
February 7, 2008

    My question is – who will stay in the redmond research lab?
    Loosing four of its core members, including the two directors,
    will there still be a viable theory lab there? who is going to replace them?

15. **Henry Cohn**
February 7, 2008

    My question is – who will stay in the redmond research lab?
    Loosing four of its core members, including the two directors,
    will there still be a viable theory lab there? who is going to replace them?

    There are several internal changes. Yuval Peres is replacing Jennifer and Christian as manager of the theory group at MSR Redmond, and Kristin Lauter is replacing me as manager of the crypto group. Eric Horvitz is taking on Jennifer's role as the research area manager to whom both groups report.

    The crypto group still has almost all of its members. The theory group is losing a larger fraction of its members, but Oded Schramm and David Wilson are staying there along with Yuval, and I believe they intend to do some hiring. Yuval and Kristin have great plans for their groups, and Eric is very supportive, so I'm sure everything is going to go well.

16. **Peter Shor**
February 7, 2008

    If just Yuval and Oded stay at Redmond, they will still have an incredibly strong group. Attracting new hires should not be a problem.

This Week's Hype

February 6, 2008
Categories: This Week's Hype

This week's media hype promoting a new observational test of extra dimensions is based on the recent arXiv preprint Transient Pulses from Exploding Primordial Black Holes as a Signature of an Extra Dimension. Stories about it have appeared already in Nature and in New Scientist.

Some of the authors are part of a group at Virginia Tech that is working with a radio-telescope array they call the Eight-meter-wavelength Transient Array (ETA). The possible astrophysical sources they are looking for include primordial black holes. The press articles however, aren't about this, but about the new preprint, which makes claims not about conventional primordial black holes, but about ones involving extra dimensions:

> For a toroidally compactified extra dimension, transient radio-pulse searches probe the electroweak energy scale (~0.1 TeV), enabling comparison with the Large Hadron Collider. The enormous challenges of detecting quantum gravitational effects, and exploring electroweak-scale physics, make this a particularly attractive possibility.

In the New Scientist piece, astrophysicist Avi Loeb makes the comment:

> There are a lot of layers here of nonstandard assumptions… If nothing could be observed in this context, then it would not surprise me.

According to the ETA web-site and the New Scientist article, as far as the extra-dimensional business is concerned, the project is led not by the faculty members involved, but by first author Mike Kavic, a graduate student in the department. Unlike most recent examples of such hype, which appeared in conjunction with the acceptance or publication of a paper in PRL, this one is based solely upon the submission of a paper to PRL.

Comments

1. **Coin**
   February 6, 2008

   I guess at least this one is a step up, relatively speaking, in that it could be realistically experimentally tested in the near term?

2. **broken pot**
   February 6, 2008

   'Unlike most recent examples of such hype, which appeared in conjunction with the acceptance or publication of a paper in PRL, this one is based solely upon the submission of a paper to PRL.'

   Ah. Next time I submit to Physical Review Letters, I'll send a press release off immediately.

3. **Peter Woit**
   February 6, 2008

   Coin,

   There really isn't any sort of usual testable prediction here. To even consider the issue of whether there's evidence of extra dimensions, first one has to find a signal from a nearby exploding primordial black hole, and that seems to not be likely to happen anytime soon (although of course it is worth trying).

4. **Thomas Larsson**
   February 8, 2008

   Not related to any of the topics in this posting, but still sort of on-topic, the following comment was censored from cosmic variance:

   More about aether compactification can be found here

5. **woit**
   February 8, 2008

   Thomas,

   While I disagree with Lubos about a lot of things, his two postings about Sean Carroll's promotion of Boltzmann brain research and now highly unmotivated extra dimensional research seem to me to be pretty much on target. It's too bad Sean is not allowing links to them.

   I would like to think that blogs have an important role to play in dealing with the problem of overhyped speculative theoretical physics research. Unfortunately the otherwise mostly sensible Cosmic Variance blog has recently been actively spreading this kind of thing, whereas the otherwise mostly not sensible Reference Frame has been actively fighting it.

6. **Professor R**
   February 28, 2008

   For once, I thought the NS article on this subject was reasonably balanced.

   I liked the inclusion of Loeb's comment above, but I also have sympathy with Kavic's statement …"while definitely a gamble, the payoffs from such a search would be enormous…the successful detection of the kind of black hole explosion would confirm not only the existence of extra dimensions, but also of primordial black holes"

   Some very good experiments have sometimes resulted from such speculative ideas….it seems to me that the real problem is that NS (and other publications) give such articles the same weighting as conventional science – where they should really be put in a section marked 'speculative papers'…….Cormac

Worth Reading

February 6, 2008
Categories: Experimental HEP News, Uncategorized

The latest issue of the Cern Courier contains a wonderful article entitled From BCS to the LHC by Steven Weinberg. It is based on a talk he gave at a recent conference celebrating the 50th anniversary of the BCS theory of superconductivity, and explains the relation between electroweak symmetry breaking and superconductivity, by way of telling about some of the history, in which he played a central role.

From the Mathematical Intelligencer, there's an excellent review by Leila Schneps of a book which contains much of the correspondence over the years between two of the greatest mathematicians of the last century, Grothendieck and Serre. The review covers not just the mathematics, but also the very different personal styles that were part of what was such a fruitful interaction. She refers to the existence of "a much larger collection of existing letters" from the later period in his life when he had begun to stop regularly doing mathematics which are still unpublished, one of which answers Serre's question about why his mathematical research program had come to a halt. She ends with the summary:

> In some sense, the difference between them might be expressed by saying that Serre devoted his life to the pursuit of beauty, Grothendieck to the pursuit of truth.

Barry Mazur has a new article giving his very personal take on the philosophy of mathematics: Mathematical Platonism and its Opposites.

MSRI celebrated its 25th Anniversary last week, and Dan Freed gave a talk on Chern-Simons-Witten theory (slides here). He is careful to put a warning label in red on the standard path integral definition of the theory, writing "this path integral is only a motivating heuristic". Together with collaborators Mike Hopkins and Constantin Teleman he has been working on coming up with a very abstract definition of the theory, far removed from the path integral, but at the end he notes that in the stationary phase approximation one can make sense of the path integral, putting up a page from one of his old papers where this was shown calculationally.

The latest Physics Today has a long article about the disastrous budget situation for HEP in FY2008. The politics of this are described as follows:

> Congress and the administration took turns blaming each other for the bad news. The omnibus bill "turned its back on Congress's concern for competitiveness," Marburger said, by wiping out most of the increases for science and technology that had received strong bipartisan support in the America COMPETES Act, which was signed into law in August 2007.
>
> But the White House was hardly without fault. Bush's 11th-hour refusal to negotiate with Democrats on a spending ceiling he had imposed forced lawmakers in the dead of night to trim back spending bills that had been assembled and approved in a far more thoughtful process. In doing so, they unsurprisingly took their red pen to presidential priorities. The increases for the physical sciences were part of Bush's American Competitiveness Initiative to revitalize US technological leadership. Marburger said he had little doubt that Congress has deliberately chosen the science programs for the budget-cutting scissors.
>
> Ironically, House Speaker Nancy Pelosi's (D-CA) "Innovation Agenda" proposed to double nondefense R&D spending over 10 years. Admitting that funding levels this year fall short of the 7% annual increases needed to meet the goal, Pelosi assured the scientific community in a letter that her commitment to growing the physical sciences budgets "remains strong and steadfast."

In the Chicago Tribune, Fermilab director Oddone describes what he thinks about the budget process. He now has to fire 200 people, while a huge budget increase is proposed by the administration, which the Congress probably won't act on until deep into the next fiscal year, with no indication now of what they will do:

> This is not the way a developed country manages a scientific enterprise… It's more like a banana republic.

Update: One more. A popular talk by Richard Taylor about reciprocity laws and density theorems (such as Sato-Tate) in number theory.

Comments

1. **DB**
   February 8, 2008

   Chapter 21 section 6 of Weinberg's The Quantum Theory of Fields Vol.2 (pp.332-352) contains a useful technical treatment of how symmetry breaking relates to superconductivity and the BCS theory. Although a superconductor is a material in which just the electromagnetic gauge invariance is spontaneously broken, he explains some of the interesting parallels between it and the electroweak theory, for example, the distinction between Type I and Type II superconductors which is mirrored by a corresponding distinction in the electroweak model between theories where the scalar mass is less than or greater than the W and Z masses.

2. **wb**
   February 8, 2008

   RE: "Oddone describes what he thinks about the budget process. He now has to fire 200 people, while a huge budget increase is proposed by the administration, which the Congress probably won't act on until deep into the next fiscal year."

   Oddone's situation is mirrored by that at other labs. By September hundreds will be off the job. If Congress were actually pass the President's budget or something close to it regarding science, the national labs (FNAL and SLAC in particular) would see enormous increases (well over the President's FY2008 levels) that they would be greatly understaffed to spend wisely. One might have wished that DOE had been wise enough identify this year of disaster opening as a golden opportunity to rebuild the university science infrastructure while still bringing the Labs to a state of health. Alas the top management of America's great universities have not yet been wise enough to communicate this to the Administration. But it is Congress that writes the checks, so let them begin.

Is Big Physics peddling science pornography?

February 7, 2008
Categories: Uncategorized

There's a new round of nonsense about theoretical physics making its way through the media, especially the British tabloids. The original source is a preprint from a few months ago by Aref'eva and Volovich entitled Time Machine at the LHC (it refers to another earlier one by other authors If LHC is a Mini-Time-Machines Factory, Can We Notice?). These papers discuss the possibility that the LHC will produce not just black holes, but also wormholes that would be "Mini-Time-Machines" (MTMs).

New Scientist now has a cover story based on this which begins:

> As you may have heard, this will be the year. The Large Hadron Collider – the most powerful atom-smasher ever built – will be switched on, and particle physics will hit pay-dirt. Yet if a pair of Russian mathematicians are right, any advances in this area could be overshadowed by a truly extraordinary event. According to Irina Aref'eva and Igor Volovich, the LHC might just turn out to be the world's first time machine.

The article invokes work by Nima Arkani-Hamed and others to justify the idea that the LHC will produce black holes and possibly wormholes, and Kip Thorne to justify the possibility of time travel. Several physicists are quoted in favor of the plausibility of the underlying idea, it not its practicality.

The story has now made it to the Sun, which has two stories: Time Travel Russia's in and Visits From Crack to the Future. According to the Sun, the LHC will be switched on in May (not true….) and from that time on time travel will be possible:

> The laws of physics suggest that no one from the future will be able to travel back any further than when the machine was switched on — with 2008 being Year Zero.

According to the Daily Mail:

> Time travel could be a reality within just three months, Russian mathematicians have claimed. They believe an experiment nuclear scientists plan to carry out in underground tunnels in Geneva in May could create a rift in the fabric of the universe.

The Telegraph has Time travellers from the future 'could be here in weeks', but the article at least has some skeptical quotes, for instance from David Deutsch, who describes the idea as "not cranky", but unlikely to work.

New Scientist does seem to realize that this kind of silliness may have gone too far, publishing an article by Michael Hanlon entitled Is Big Science peddling science pornography?. I think Hanlon raises extremely important questions that the physics community needs to address, although he makes a mistake by pinning this on "Big Science". The people working hard to make projects like the LHC a reality are not the culprits here, irresponsible theorists are. Hanlon writes:

> Physics and cosmology stories are like this these days. Once it was all hard sums and red-shifted galaxies; awesome enough one would have thought. Now it's time machines and universe-eating particles.
>
> Does any of this bear any relation to reality? Or is Big Physics guilty of some serious sexing-up, drifting away from the realm of hard data and into the softer universe of science pornography?
>
> As well as accidental time machines we are told of cosmic strings – gigantic filaments of super-stuff that warp and tear space-time like ladders in a pair of celestial stockings – and crashing branes, titanic slabs of maths that give rise to the big bang in the exotically lovely ekpyrotic universe of Neil Turok.
>
> Not crazy enough for you? What about the multiverse? One of the biggest sell-out lectures at last year's Hay-on-Wye festival in Wales starred the UK's astronomer royal, Martin Rees, who entertained his audience with a discussion of the possibility, indeed the probability, of multiple worlds – endless parallel realities existing in a gargantuan super-reality that makes what we think of as the universe as insignificant as a gnat on an elephant's backside. Or there's the simulation argument, philosopher Nick Bostrom's delicious idea that since it should be possible to replicate an entire universe in a computer, and that this could be done countless times, statistical cleverness proves that we are not the real McCoy but the figments of some electronic entity's imagination.
>
> …Scientists, and people like me who stick up for science, are happy to pour scorn on astrologers, homeopaths, UFO-nutters, crop-circlers and indeed the Adam-and-Eve brigade, who all happily believe in six impossible things before breakfast with no evidence at all. Show us the data, we say to these deluded souls. Where are your trials? What about Occam's razor – the principle that any explanation should be as simple as possible? The garden is surely beautiful enough, we say, without having to populate it with fairies.
>
> The danger is that on the wilder shores of physics these standards are often not met either. There is as yet no observational evidence for cosmic strings. It's hard to test for a multiverse. In this sense, some of these ideas are not so far, conceptually, from UFOs and homeopathy. If we are prepared to dismiss ghosts, say, as ludicrous on the grounds that firstly we have no proper observational evidence for them and secondly that their existence would force us to rethink everything, doesn't the same argument apply to simulated universes and time machines? Are we not guilty of prejudice against some kinds of very unlikely ideas in favour of others?

Update: The time travel story has even made it to the Chronicle.

Comments

1. **Steve Myers**
   February 7, 2008

   Science porn — a good term since it's a substitute for the real thing.

2. **Chris Oakley**
   February 7, 2008

   "Pornography" may have been the term used by *New Scientist* but *The Sun* runs the genuine article in mild form on Page 3 each day in the form of a un- or scantily-clad babe (the "Page 3 girl"). They missed an opportunity in not combining this with their article about the LHC:

   "Delicious Debbie (19) from Dagenham, Essex, is looking forward to the opening of the LHC in May. "Yeah, it's gonna be great: I mean, just last week I left my lip gloss in a taxi. If there was time travel I could've gone back in time and put it in my bag before I got in." Did Debbie take an interest in theoretical physics, we asked? "Oh, no," she replied, "I couldn't get in to drama school, so I got a job as a secretary, didn't I?""

3. **Bee**
February 7, 2008

I had plenty to say about the topic, but I've said it all before, therefore I'll just link to [Fact or Fiction?]()

4. **Yatima**
February 7, 2008

Well, I don't care about the SUN – getting steamed up about their science reporting is not truly worthwhile, but New Scientist had a perfectly good article on mass extinctions not being caused by random asteroid impacts but cyclic world-wide resurgences of bacterial populations – an awesome idea. They could have used that for the cover page and relegated the time travel speculation to a footnote instead. The editor needs to be handed a fist-sized raspberry.

In related news, Garrett Lisi is interviewed in the lengthy cover article of the french popular scientific mag "Science&Vie" of January.

5. **David Nataf**
February 7, 2008

Yatima,
That's pretty consistent of New Scientist magazine.
They will in general have a sensationalist cover story, with interesting popular science articles on the inside. The sensationalism is always about how theoretical physics is breaking down. Superstrings, loops, the ether, time machines, et cetera.
The best popular science magazine for the educated layman is American Scientist.

6. **Big Vlad**
February 7, 2008

i despair of this sort of rubbish. We as scientists have no grounds on which to dismiss ghosts and fairies while this stuff is being printed. It's not even as if the sun has made this up – it's based on an actual arxiv preprint!

I really can't wait until the LHC results come in and destroy 99% (100%?) of the currently fashionable theories, and then experimenters and phenomenologists will take over the world.

7. **Janus**
February 7, 2008

The difference, of course, is that people actually believe in ghosts, UFOs, homeopathy, creationism, etc. They don't think of it as interesting remote possibilities that may be tested experimentally one day. They believe in them so strongly that they're willing to spend considerable amounts of time, money, and/or energy on these things.

I don't think scientists should refrain from formulating hypotheses, even hypotheses that seem crazy to most laymen, as long as they acknowledge that they are merely hypotheses. If anyone needs to be criticized, it's the ignorant media people who blow everything out of proportion.

8. **Peter Woit**
February 7, 2008

Janus,

The question is not whether scientists should refrain from formulating hypotheses, but whether they should issue press releases or otherwise encourage mass media to write about these hypotheses when they are extremely speculative. No media person is going to write anything about a new scientific result if the scientist involved tells them that it's something that is very unlikely to be true and shouldn't be promoted to the public. The media may be swallowing too much hype, but it is scientists who are feeding it to them.

9. **chris**
February 8, 2008

janus,

are you sure that – say – suskind does not *believe* in the multiverse? i would not bet at least.

and to attribute this 'simulated world' idea to anyone in particular is just so plain silly. back when i was young, i discussed this over a beer with my school buddies and heck, there even where holywood films about it already.

my lingering suspicion on why these subjects are so popular is that once you got into the mood (i.e. the community recognizes you as 'serious' contributor) you can crank out a paper per month with minimal effort. compare that (and the possibility of getting media attention) to a 4-loop qcd calculation and it should be obvious why baseless speculation is so sexy to researchers.

10. **Anonymous**
February 8, 2008

Who has more investment in nonsense?

The difference, of course, is that people actually believe in ghosts, UFOs, homeopathy, creationism, etc. They don't think of it as interesting remote possibilities that may be tested experimentally one day. They believe in them so strongly that they're willing to spend considerable amounts of time, money, and/or energy on these things.

For people, it is a hobby or obsession. For physicists, it is a career, a life's work.

11. **Mark Wallace**
February 9, 2008

It seems like too many professors in this decade confuse their love of science fiction with the discipline of physics. I was a physics undergrad in the early 80's (Berkeley), and I recall that all my professors back then would become extremely irritated by persistent undergrad questions about time travel and other such nonsense. I appreciated their attitude at the time, and wish it were more prevalent now.

12. **Chris W.**
February 9, 2008

Mark,

I guess what you're saying is that we could use a bit more willingness to humorlessly dismiss such stuff as a muddle-headed waste of time.

There *are* ways to discuss time travel seriously, as a way of getting at subtle aspects of the laws of physics. The trouble, the people who ask about the topic are usually not that interested in the laws of physics.

13. **Peter Shor**
February 9, 2008

I remember reading some popular article by Kip Thorne where he said that he was very reluctant to publish his work on time travel, I think because it was too speculative and science-fictiony to be considered serious science. He therefore spent a lot of time thinking about the consequences of time travel before he published anything.

There should be some correlate to "extraordinary claims require extraordinary proof" along the lines of "extraordinary speculations require extraordinary groundwork." If you're going to introduce unconventional ideas, you should spend a lot of time figuring out as many of their implications as you can.

14. **William Straub**
February 9, 2008

Physicists have never lacked for exciting theories and ideas, but now they're being sexed up to sell magazines and cable science shows as well as to court purse-string politicians. But why is nutty physics being popularized to such an extent today?

As a lay person, I think the answer follows from the previous comments about belief in UFOs, homeopathy, ghosts and creationism. Sometimes I think that's all physics is to these believers — just another means of legitimizing a lot of non-scientific nonsense. And I will add to that my assertion that most of today's popularized high energy physics and cosmology is nothing but entertainment being hawked all too often by respected authorities in their fields using flashy, bewildering computer graphics and preposterous ideas with little or no educational or informational value.

Dumbing-up sounds like a good idea, but I don't see it working.

15. **Peter Shor**
February 10, 2008

When I was growing up (1960's and 1970's), I remember thee being extensive belief in UFO's, new age medicine, and so on. But I don't remember high energy physicists going out on limbs popularizing nonsense the way they're doing now. Of course, maybe I couldn't have told the difference between serious physics and nonsense at the time. But I suspect it was because high energy physics was going through a very exciting time (the Standard Model was being discovered and experimentally tested) and there was lots of real physics to popularize.

Of course, there's exciting physics to popularize now. Dark matter, dark energy, inflation, neutrino mass, all sorts of interesting exoplanets, stars and galaxies the astronomers are seeing, etc. But the particle theorists and string theorists are left out, and maybe some of them want to play, too.

16. **DB**
February 10, 2008

"But the particle theorists and string theorists are left out, and maybe some of them want to play, too."

There is probably something in this, particularly as much of the hype is coming from theorists who have spent the last twenty five years vainly struggling to create a successor to the Standard Model, and have precious little to show for it. Many are now over 45 years of age, and in mathematical physics it's extremely rare to make important breakthroughs after that age. So these individuals, many of them in eminent positions at prestigious institutions, are in an invidious position. Do they shut up and let the world pass them by, or do they try to "talk their book" in the hope of persuading young talented theoreticians to take up the torch, while helping their postdocs make tenure by exaggerating the importance of the field and its achievements to date. I'm convinced that it's the latter process that's at work here. It's about legacy and jobs.

17. **Anonymous**
February 10, 2008

As an outside observer who loves math and physics, I don't think that there is necessarily anything wrong with speculative ideas. I think the problem is when those speculative ideas are just that, ideas, and not well reasoned arguments for why something is possible.

We don't live in a special time in this regard, certainly there are plenty of earlier examples of theories that were later proven completely ridiculous. I think the danger is similar to what we see in the intelligent design debate; where people are willing to tell lies under the banner of science, simply because they call the lie a "theory".

Such things undermine legitimate science, and shakes the public's confidence in the ability of science to provide answers.

18. **Eric**
February 10, 2008

What's really sad is that Discover magazine has a special issue this month devoted to Einstein. One article in the magazine is a listing of the 'next Einstein'. Number one is the famous surfing, independent physicist who just 'published' a paper. Ed Witten is listed as number six. This is really deplorable.

19. **Peter Woit**
February 10, 2008

Eric,

I don't know about Witten as the "next Einstein", I think he's more kind of the "current Einstein". As for the "next" one, I don't see many convincing candidates.

Funny, but you don't seem to be bothered by the feature article in that issue of Discover by a string theorist about time travel (from a forthcoming book).

20. **Eric**
February 10, 2008

Peter,
The book by Kaku that you link just seems to be a variation on the 'Physics of Star Trek' theme of Lawrence Krauss who is most definitely not a string theorist.

The hyping of Lisi is an absolute travesty. How can anyone conclude that his inclusion in this article as nothing but a product of the alternative physics hype with which you sympathize and support? If the public cannot tell the difference between a real physicist and someone like Lisi, how can we ever expect proper financial support from the US government for serious projects?

21. **Migo**
February 10, 2008

It may be somewhat unrelated, but for some different kind of nonsense about theoretical high energy physics, you might want to have a look at the preprint 0802.0216. There the author claims to have found an argument proving that the mathematical structure of QFT is inconsistent. Unfortunately, he does not know what a representation of the translations is in QFT, and is therefore led to false conclusions. This example really makes we wonder where theoretical physics is going these days …

22. **Peter Woit**
February 10, 2008

Eric,

If you pay attention to this blog, I think you'll see that the only "alternative physics" hype that I really sympathize with and support has to do with the idea that some active topics of mathematical research like geometric Langlands have important relations to quantum field theory, and better understanding this may someday lead to new physics. My attempts to hype this don't seem to have gotten very far. Of the people on the Discover magazine list of "new Einsteins", there's only one I support, who shares a bit my point of view, and I don't think he's very "new".

I don't know what "alternative physics" is. If you mean "alternatives to string theory", since string theory has failed as a TOE, I support people looking for alternatives, even if they're ones I don't personally find very promising. Sure, Lisi-mania was an unfortunate example of media hype, but I just don't think there's the slightest danger that NSF and DOE funding of Lisi studies will crowd out conventional theoretical physics research. If this shows any signs of happening I'll devote postings here to the Lisi-hype problem.

23. **Peter Woit**
February 10, 2008

Migo,

The arXiv is just a preprint server, and as such has a large helping of wrong and otherwise worthless submissions. Most of these are just completely ignored by everyone. For this one in particular, your comment is probably the only attention it has ever gotten or ever will get. I don't think there's the slightest danger it will be come the subject of media hype…

24. **Migo**
February 10, 2008

Peter, you are right, one should probably just ignore stuff like that. But given the far-reaching claims this preprint makes, and the potential for confusion it might cause among people not knowing QFT very well, I thought it would be a good idea to have some trackback to a short discussion indicating that it's wrong. Yes, plain wrong in this case, instead of not even wrong …

25. **Peter Woit**
February 10, 2008

Migo,

I deleted the "trackback" part of the your link, because it was mal-formed, wouldn't have worked anyway (except in certain special cases, trackbacks to this blog are censored by the powers-that-be at the arXiv), and the last thing I want here is extended discussions of what is wrong with every worthless preprint posted to the arXiv, (this would be a huge and extremely unrewarding topic).

26. **neo**
February 11, 2008

Some of the ideas are really goofy, others are not. They seem to have been bundled together haphazardly. For example, the ekpyrotic theory is no more speculative and certainly philosophically more pleasing that eternal chaotic inflation.

27. **Chris Oakley**
February 11, 2008

I will be interested to see if Kaku has corrected an error in his previous book where he claims that my great-uncle W J van Stockum was Scottish when the only time he lived in Scotland was when he was doing doing his Ph.D. (1935 to 1937) – not that I care much, BTW, as I really doubt that GR is more than a weak-field approximation, but getting details like that right does help to boost peoples' confidence.

28. **Valerie Jamieson**
February 11, 2008

Yatima, I'm one of the physics features editors at New Scientist and take some responsibility for what goes on the cover. Why do we (and other popular science magazines) put so many theoretical physics and cosmology stories on the cover? Because big physics sells. At this time of funding cuts in the UK and US and worries over student numbers, surely it's heartening to find so many people getting excited about the big questions that physics addresses.

29. **anon.**
February 11, 2008

'At this time of funding cuts in the UK and US and worries over student numbers, surely it's heartening to find so many people getting excited about the big questions that physics addresses.'

Valerie,

New Scientist, as I'm sure you know, has been promoting speculative, non-checkable ideas since string theory came to fame over two decades ago. The fall in student numbers, see http://www.buckingham.ac.uk/news/newsarchive2006/ceer-physics-2.html doesn't correlate to Woit's blog or even to the popularity of the internet, but it does correlate to the rise of speculative stuff on your front covers:

'Since 1982 A-level physics entries have halved. Only just over 3.8 per cent of 16-year-olds took A-level physics in 2004 compared with about 6 per cent in 1990.

‘More than a quarter (from 57 to 42) of universities with significant numbers of physics undergraduates have stopped teaching the subject since 1994, while the number of home students on first-degree physics courses has decreased by more than 28 per cent. Even in the 26 elite universities with the highest ratings for research the trend in student numbers has been downwards.

‘Fewer graduates in physics than in the other sciences are training to be teachers, and a fifth of those are training to be maths teachers. A-level entries have fallen most sharply in FE colleges where 40 per cent of the feeder schools lack anyone who has studied physics to any level at university.’

One thing that is clear is that hype of speculative uncheckable string theory has at least failed to encourage a rise in student numbers over the last two decades, assuming that such speculation itself is not actually to blame for the decline in student interest.

However, it’s clear that when hype fails to increase student interest, everyone will agree to the consensus that the problem is a lack of hype, and if only more hype of speculation was done, the problem would be addressed. Nobody will believe that a reduction in speculative hype could possibly address the problem, or that changing the focus of the front cover of New Scientist to more solid areas of physics would help. Electronics and computing innovation of the real world variety (not quantum computing hype from qubit/Deutch) for example, has been censored from New Scientist as too boring. I’m not including my name here as this isn’t a personal matter.

Maybe the vast number of excited readers of New Scientist physics sci fi hype who don’t take up A-level physics as a result, take up writing science fiction or take up religious orders, instead?

30. **Chris Oakley**
February 11, 2008

Anon.,

Forgive me for pointing out the obvious, but one of the reasons that fewer students are taking A-level physics is that there are more options available for the technically-minded student, mostly related to electronics and computing, which have come on in leaps and bounds, both theoretically and practically, since then.

31. **anon.**
February 11, 2008

Chris,

Thanks, but those technically-minded students of electronics and computing could also do an A-level in physics (which is an allied subject), instead of avoiding it like the plague which is what currently occurs.

32. **JC**
February 11, 2008

anon, Chris

A better question to ask from an historical perspective is, did science hype/pornography increase the number of engineering, physics, and math majors back in the 1960’s? Or did the increase in engineering, science, and math majors have more to do with Sputnik era increases in science funding? Or was it a more mundane reason like the sheer large numbers of baby boomers attending university in the 1960’s?

33. **anon.**
February 11, 2008

JC: this is about a fall in the *percentage* of students doing physics, not a fall in birth rate. Disillusionment with physics is the problem, otherwise physics would be widely taken in *addition* to electronics, chemistry, computing, or maths.

‘Or did the increase in engineering, science, and math majors have more to do with Sputnik era increases in science funding?’

Here in the UK, the funding of physics isn’t the key problem, which is student numbers. Funding has to follow students. You can’t really save a department with no students by increasing funding. It’s really not a money-related. When physics ‘hype’ stopped being tied to facts and went sci fi, physics became a not just nerdy but really weird and cult-like, which didn’t appeal to the technically-minded.

34. **Thomas Love**
February 11, 2008

JC, The increase in science majors in the 1960’s was at least in part due to the fact that a man was more likely to obtain a draft deferment if he was a math, science or engineering major. This was true at least with my draft board.

35. **Tony Smith**
February 11, 2008

JC asked “… did science hype … increase the number of engineering, physics, and math majors back in the 1960’s? …”.

My personal experience may be merely anecdotal,
but
I was born in 1941 and grew up reading stories (even in comic books) about such things as:
the idea of nuclear chain reaction fission;
nuclear fusion related to elliptical pool tables with a hole at one focus;
computers (rooms of tubes with punch cards) that could calculate stellar structure and evolution;
rockets sending sputniks (and cosmonauts) into orbit;
transistors for little radios and for calculators more accurate than a slide rule (and for smaller computers); and
nuclear submarines that could stay under the sea for as long as the crew could tolerate.

Those things were the hype of that time,
and they did in fact motivate me to study science and math,
because
they were REAL and they really CHANGED the world.

In contrast, today’s superstring hype does not deal with anything that is really changing today’s world, and is so far detached from reality that the superstringers have yet to connect their ideas with even the esoteric reality of existing results from high-energy particle physics experiments.
Whether or not some future experiment might or might not connect with some idea from the superstringers is an open question,

but
the hard cold fact is that as of now there is no such connection with existing experimental results.

So, if I were growing up now, I would see a lot of superstring hype
but
I would NOT see any connection between the hype and reality,
unlike
the connections with nuclear, computer, rocket stuff that was really REAL when I was growing up.

Tony Smith

PS – It is also interesting to compare two types of recent hype:

1 – superstring with no connection to reality

2 – hedge-fund-type finance, with very clear connection to the reality of the world's economy

and to observe that a lot of people over the past years have left the unreal world of superstrings for the real money hedge-fund world.
(Whether or not they constructed a flawed monster whose collapse could cause a depression is another story, but either way their economic construct is quite real.)

In short, hype connected with reality attracts people to work on a subject,
but
hype without reality (superstring theory, TV/movies/games about vampires, witches, magic, etc) is viewed by most people as mere fantasy,
not worthy of being taken seriously as life-work.

36. **a quantum diaries survivor**
February 11, 2008

Mark Wallace Says:
It seems like too many professors in this decade confuse their love of science fiction with the discipline of physics. I was a physics undergrad in the early 80's (Berkeley), and I recall that all my professors back then would become extremely irritated by persistent undergrad questions about time travel and other such nonsense. I appreciated their attitude at the time, and wish it were more prevalent now.

Mark, the undergrads of the early eighties are the professors of today… A generation of misfits 🙂

Cheers,
T.

37. **Anton Szautner**
February 13, 2008

A NewScientist cover story breathlessly touts 2008 as the incipient "Year Zero" and repeats the new-and-improved time-travel mantra: "…travelling into the past is only possible – if it is possible at all – as far back as the creation of the first time machine."

Well, for crying out loud already: what's the universe if it ISN'T already a "time machine"?

All this mindless hooplahype ignores that the LHC is less than a factor of ten more powerful than Fermilab's Tevatron – a very small incremental increase in a vastly larger energy scale nature plays with. If those energies are what permit MTMs, then the big bang already made them in vast abundance and Year Zero remains Year Zero.

Yet, so what? Where are the time travelers beating a path through their past to us from a "future" that hasn't happened yet? Are we to presume the implication that all of those potential futures are already somehow coagulated into a "present" configuration which allows for the existence of time travelers? If so, we're dealing (as the last sentence implies) with a past-tense version of a future 'already' formed.

Ridiculous.

38. **Vicky**
February 13, 2008

In response to anon:

In terms of declining student enrollment, I suspect that it has more to do with the lack of jobs at the end of the road than whether the professors are too "sci-fi." If one wants a job in academia or a public sector laboratory, the competition is fierce, and if you want a job in industry, engineering may be a better path.

Because of this, I have read some argue elsewhere that more money spent on physics will create more jobs which will entice more students to fill them. Sadly, that is unsustainable.

Most people will not excel at their career. A mediocre engineer works as a mediocre engineer. A mediocre mathematician has a variety of options. A mediocre physicist competes with trained engineers to become engineers or with trained mathematicians to become mathematicians. In either case, it makes more sense to pick a path that is viable from the start.

That is why I left physics to become an engineer…I never would have gotten a permanent position in physics (I later became a lawyer out of public interest.) I suspect that type of concern deflects others from studying physics.

The question shouldn't be how to excite people to study physics…it is intrinsically exciting enough to anyone likely to invest their life in the field. The question is how to make the field relevant enough to others in a practical sense so that they take more than an introductory course to satisfy another major's requirements, or to justify the public spending billions of dollars on research. And I don't think that science porn will do that.

39. **Professor R**
February 14, 2008

hi Peter, I too noticed the read the Hanlon article, but i disagree with both him and you…
It is not Big Science, or a few theorists, who are peddling sceince pornography – it is NS themselves.
The theorists didn't ask to be the cover story, that's the magazine's choice. Some theories will be more speculative than others, its more a question of balanced reporting, surely.

Bit coy of Hanlon not to mention this (he could do, as he is not their employee)…Cormac

40. **woit**
February 14, 2008

Cormac,

I agree with you that New Scientist has a lot to answer for, but still think they're not the only ones. Scientists can't change the fact that popular media want to make their stories as sexy as possible, but they can take responsibility for what they do and say when they are speaking publicly, and when they are contacted by journalists.

41. **Professor R**
February 15, 2008

Peter – I think you're right, there is also the onus on the scientist to make clear where in the spectrum this particular hypothesis lies…

that said, someone should suggest to NS that they have a special category headed "speculative science"- that way they could indulge their whims without damaging the credibility of science

42. **Vigesh**
February 16, 2008

Yeah 3 weeks… but then if they invent time machine… talking about when they did is irrelevant as the existence of time machine will be(I guess) the (least) time where(/when) they traveled.

Quantum Field Theory, As Seen By Mathematicians

February 11, 2008
Categories: Favorite Old Posts, Uncategorized

In recent years, interest in quantum field theory among mathematicians has gone through ups and downs, in a sub-field dependent manner, as ideas rooted in quantum field theory have turned out to be mathematically useful in a variety of contexts. At Berkeley, it appears that there's now more interest in quantum field theory in the math department than in the physics department, so much so that last fall three senior faculty (Nicolai Reshetikhin, Peter Teichner and Richard Borcherds) offered courses on various QFT topics. Luckily, Berkeley graduate students seem to be very industrious, and they have accumulated quite a few tex-ed lecture notes from these and other courses, gathering together the QFT ones here and here.

Another popular topic at Berkeley has been geometric Langlands, a subject where Witten's QFT approach has intrigued many mathematicians. Witten has a new preprint aimed at mathematicians promoting the QFT point of view, and he explains in more detail claims he made in talks last fall that the use of 4d QFT corresponds in a sense to the use by mathematicians of "stacks". Stacks are a mathematical device useful for handling non-free quotients, situations where one wants to keep track not just of the quotient space (which is often singular), but of more structure, for instance the varying stabilizer groups at different points of the quotient. Witten notes that if one just uses mirror symmetry of the Hitchin moduli space to study Langlands duality, one doesn't know how to handle various singularities. Mathematicians have dealt with these singularities by invoking stacks, Witten instead argues that one should use a 4d gauge theory QFT perspective to see how to study the issue in a way that does not involve these singularities (they only appear when you dimensionally reduce and work with the 2d topological sigma models).

Last week Witten gave a talk to the mathematicians at the IAS on "Duality from Six Dimensions", which is to be continued this week. He explained how the existence of a 6d superconformal theory implies SL(2,Z) symmetry and thus duality (Montonen-Olive duality) in the 4d N=4 supersymmetric topological gauge theory he uses in his approach to geometric Langlands. This is an old story by now, from the mid-nineties duality days, and Witten wrote up some of it here, for his contribution to the proceedings of the conference in honor of Graeme Segal's sixtieth birthday back in 2002. David Ben-Zvi was at the talk taking notes, and I hope he'll be adding to his extensive collection of on-line notes this semester since he'll be at the Institute attending this year's program there.

Note added: David has started posting his notes, the notes from the Witten talk are here.

At MIT this semester there's a "pre-Talbot" seminar being run that will lead up to a Talbot workshop in March. The topic is something that might be called "quantum geometric Langlands", involving not Witten's QFT ideas, but a version of geometric Langlands that uses quantum groups due to Dennis Gaitsgory and Jacob Lurie. Scott Carnahan discusses this at Secret Blogging Seminar, and has notes from his overview talk available.

In March Lurie will be giving the Marston Morse lectures at the IAS, on the topic of "Topological Quantum Field Theories in Low Dimensions".

Comments

1. **David Ben-Zvi**
   February 11, 2008

   Hi Peter — yes I'm taking notes and will start posting them
   very soon (under a heading as notes from
   this semester's activities)

   On another note the quantum geometric Langlands
   program fits very nicely with the Kapustin-Witten
   TFT point of view — the "quantum" parameter
   here is exactly the parameter Psi that appears
   in the 4d TFT (which is a combination of the gauge
   coupling of N=4 superYangMills and the parameter
   that's used in defining the topological twist).
   The idea has been around on the math side
   for a while but Dennis and Jacob have formulated it much
   more precisely (and given a "local" version), and are
   explaining its relation to quantum groups.. it's worth pointing out
   that the same parameter appears as the level of a Kac-Moody
   algebra or (when a positive integer) as the level in
   Chern-Simons theory or (when exponentiated) as the q in
   quantum groups..

2. **A.J.**
   February 11, 2008

   Also worth noting: Peter Teichner is running another Hot Topics course this semester, this time on the work of Freed, Hopkins, & Teleman. I'm not sure if anyone is publishing notes this time, but I'll definitely be blogging about the course from time to time.

3. **David Ben-Zvi**
   February 12, 2008

   Here's the link to the IAS term notes (I'll add to it
   as the term progresses):

   http://www.math.utexas.edu/users/benzvi/GRASP/lectures/IASterm.html

4. **Peter Woit**
   February 12, 2008

   Thanks David, both for the great public service of providing the notes, as well as for the indications of the the frightening degree to which these ideas are all interconnected…

5. **Voltberg**
   February 13, 2008

QFT must be more important for mathematicians than it is now, especially for those in small departments, because it touches so many areas of mathematics. That forces to learn many developments in unconected areas.

6. **Florian**
   February 18, 2008

   Peter, thank you for this very informative post!

Late Night HEP TV

February 13, 2008
Categories: Uncategorized

Particle physics is enjoying a wave of popularity on the late night talk shows this week. On Friday, MIT experimentalist Peter Fisher appeared on the Conan O'Brien show, helping O'Brien see how long he could keep his wedding ring spinning on his desk.

Last night it was a theorist's turn, with Lisa Randall appearing on the Colbert Report, promoting the idea of extra dimensions.

   February 13, 2008

   Conan's on on Saturdays now?

2. **woit**
   February 13, 2008

   Analyzer,

   My bad, it was Friday night. Shows how well informed I am about popular culture. Fixed.

3. **Luzo**
   February 13, 2008

   The movies of Conan's show are down so maybe you can include this link.

   http://www.youtube.com/watch?v=371D99KpVZ4

4. **anon.**
   February 14, 2008

   I watched the video link of 'Colbert Report: Lisa Randall'. I didn't find it funny. String theorists will go to any lengths to hype the claim that string theory is checkable and predicts the weakness of gravity, without making any solid calculations. It's just pseudoscience. Colbert should have asked for the alleged (non-existent) formula for the weakness of gravity and if something was supplied off-the-cuff on the back of an envelope, he should probed how it was derived. Everything Colbert did say was purely pro-nonsense, just giving more airing to vacuous hype. Extra dimensional hype was funny for a day sometime around 1985, but the joke is wearing a bit thin nowadays.

5. **Tom Whicker**
   February 14, 2008

   I actually think Colbert did a great job. In a four minute interview he got to some essential questions: Colbert, "This is all very fancy, but is there any way to make a buck off this?", and next " Is this just theoretical math, or is there some experiment you can do?"
   He also suggested it was similar to looking for "angels or god".

6. **Eric**
   February 14, 2008

   Anon,
   Lisa Randall is not a string theorist and was not discussing string theory on the show. As for the testability of large extra dimensional theories, this is clearly possible at LHC.

7. **IMHO**
   February 14, 2008

   The Colbert with Lisa Randall was brutal…

   There are better representives than her…she's not the only good looking Theoretical Physicist.

8. **Luiz**
   February 14, 2008

   IMHO,

   Yeah, right. Do you care to name a few?

9. **lostsoul Ph. D.**
   February 14, 2008

   Luiz

   Britney, and the girl out of the Wonder Years – get serious. Professor Randall did a good job, given the circumstances. At last she's not a politician.

10. **anon.**
    February 14, 2008

    Eric: yes, Lisa does work on some alternative extra dimensional ideas to mainstream string, but it seems that such ideas are string theories; at least, they are Kaluza-Klein theories with extra spatial dimensions.

    Remember, it's widely claimed that not all dimensions were necessarily compactified to unobservable size in the landscape of 10^500 variants of the Calabi-Yau are supposed to have become unravelled into vast cosmic strings that astronomers should be able to see (when they point their telescopes in the right direction, and remove the lens cover).

Lisa's idea is that gravitons, unlike electromagnetic gauge bosons, are free to propagate in an extra spatial dimension, and this dilutes the gravitational interaction relative to electromagnetism, whose photons can only move in observable spacetime dimensions.

M-theory in fact has 11 dimensions, with 10 dimensional superstring resting like a (mem)brane or a surface structure on an 11-dimensional complete 'bulk'.

Lisa's idea would suggest that in M-theory photons are confined to the 10 dimensional brane (3+1 spacetime dimensions + 6 compactified spatial dimensions), but gravitons can also travel through the 11 dimensional bulk.

Because the gravitons have one extra dimension to travel in, they appear to us in 3+1 spacetime dimensions to give rise to a gravitational coupling constant weaker than electromagnetism, because gravitons spend less time on the brane than photons do.

Photons are a bit like a film of oil floating on the surface of a bulk of water, very concentrated (giving strong electromagnetism), whereas gravitons are like dye thrown into the bulk of the water, which dilutes them throughout the entire volume not just the surface (brane). *C'est magnifique, mais ce n'est pas la science*.

11. **woit**
February 14, 2008

Please, direct discussions of Lisa Randall's appearance to Tommaso Dorigo's blog…

As for whether she's a string theorist, here's what she has to say on the topic, from

http://www.sciencewatch.com/july-aug2001/sw_july-aug2001_page4.htm

"Do you consider yourself a string theorist?"

"I just don't like labels in general, but I certainly don't object to being called a string theorist if it's said in a nice way."

12. **Eric**
February 14, 2008

Dear anon,
You are confusing extra dimensional brane-world theories and string theory. While it's true that string theory gives a concrete realization of brane-worlds with extra dimensions, they are not necessarily the same thing as Professor Randall herself would emphatically tell you.

13. **Fru**
February 15, 2008

As for Lisa Randall's preference for being called string theorist or not, reading her response from the link that Peter provided I wouldn't conclude that she is since, after saying what Peter reported, she adds
"Basically, I'm just a theoretical physicist who, like all the rest of us, would like to figure out how the world works. If that involves some string theory, great, but ultimately I think we should be able to connect it to what we see in the world and be able to test it. I'm just trying to put those things together."
which seems to expose a different attitude compared to the pure abstractism that people don't like (for those who don't of course) about string theory.

14. **Uncle Enzo**
February 15, 2008

Who cares if Lisa Randall is a "string theorist" or not. She's a theoretical physicist working on stuff that interests her. Also, Stephen Colbert is a comedian, not Barbara Walters, and The Colbert Report is supposed to be funny, not serious. If you watch the show, you'll realize that those interviews aren't supposed to be all that serious, as evidenced by Colbert's behavior. Remember, the show is on Comedy Central.

Anon: "Colbert should have asked for the alleged (non-existent) formula for the weakness of gravity and if something was supplied off-the-cuff on the back of an envelope, he should probed how it was derived."
If he asked those types of questions, nobody would laugh. The show is a comedy. None of his interviews are designed to be serious.

15. **wb**
February 15, 2008

Not only was the spot with Conan and Fisher more entertaining, but also Peter demonstrated something very important to the public. Physicists can figure out things that we all can we.

16. **a quantum diaries survivor**
February 16, 2008

Damnit, Peter!!! 🙂

…Ok, I'll admit it – if mine could be a good gossip blog I'd take the traffic and say thanks. But I will never be a good host for gossip. I suck – my interest in the human nature is quite limited (say, to one particular gender and one particular age range).

So people, if you want to discuss the appearance of Lisa Randall forget Peter's advice – he was being facetious – and rather go to Cosmic Variance. There you'll find people really willing to take you on that.

Cheers,
T.

17. **martin**
February 16, 2008

If anyone really wants to discuss Lisas ideas, come over here 😉 (I welcome any scientific chat about randall-sundrum apart from pseudo philosophic branish discussions…)

On-topic. Is it just me or does conan appear kind of disrespectful? I don´t know his usual attitude, but he tries to turn everything in the conversation into (mostly lame) jokes.
And besides that prof. Fischer did a good job, in my opinion.

18. **Tom Whicker**
    February 17, 2008

    Lisa Randall gave a much longer and more serious TV interview with
    Charlie Rose on December 12, 2006. You can google it or get the entire 40 minutes on YouTube. Here is a transcript from about 11 minutes in, where she explains her ideas on extra dimensions. I think the transcription is close to word accurate, but please view the video as it is probably a bit unfair to make opinions based on text versions of live, off-the-cuff discussions.

    Lisa Randall to Charlie Rose, Dec 12, 2006:

    "The idea of extra dimensions has been around for a long time. I mean Abbott wrote his book in the late 19th century, and Einstein completed his theory of relativity in 1915, general relativity, and
    only a few years later somebody named Theodor Kalusa proposed the idea of an extra dimension.

    "So why is it that physicists today are thinking about extra dimensions? Well, one of the reasons is that we think it might actually have something to do with our universe, I mean that's for me I think the most important reason.

    "But another reason is in fact string theory; it has introduced the idea that maybe those dimensions are really there because that's the only way the theory makes sense.

    "But string theory has also introduced something else, in the 1990s the physicist Joe Polchinski realized there were these other objects in the context of string theory called branes…they're named
    branes now..that word is sort of related to membrane…
    and the idea is that there could be, even if you have higher dimensions, even if you have a fifth spacial dimension or a fourth spacial dimension out there, there could be objects in the universe called branes that don't spread throughout the entire universe, and maybe stuff is stuck on those lower dimensional surfaces, so here we have an analogy [points to sketch of a shower curtain] just to give you the general idea, I mean you might have a three dimensional room but in that room there might be a shower curtain and on that curtain there could be water droplets, and those water droplets are only on the two dimensional surface of the curtain. They're not going out throughout the three dimensional room; they're really stuck there. And in the same way [refers to another sketch] it could be that we and the stuff of which we are
    made could really be stuck to a brane… so this brane…although it's drawn as two dimensional, think of it as a three dimensional surface…so if you have this three dimensional brane and the stuff was stuck there, it would look just as if the universe was three dimensional and if..everything..if.. if for example photons and electromagnetism could only travel in the three dimensions of the brane, well that would explain why things look as if they're three dimensional. After all, light doesn't get outside the brane. So it could be that some of it is actually still stuck in three dimensions even though another dimension is out there.

    "What makes it interesting though, from the point of view of physicists ..I mean if everything was stuck in the three dimensions on the brane, who cares if there are other dimensions? We'd never interact with them.. But it is ALWAYS true that gravity goes out in those dimensions and so those squiggly lines in that figure
    represent the fact that gravity always interacts with the other dimensions; gravity will never be stuck on this brane. And that's what's so interesting with these branes..you can get the geometry of space-time….we're used to thinking..we physicists at least.. are used to thinking of space as the same everywhere, as far as we know the laws of physics are the same throughout the three dimensional universe..but it could be that in these extra dimensions and because of the existence of these branes and energy throughout the universe, spacetime can be warped, I mean even in OUR universe it is warped to some extent; that's why there's interesting cosmology. But with this other dimension it could be very dramatically warped and it's THAT that can explain the properties of gravity that we see in our universe, because gravity IS spreading out in those dimensions and so it could be that gravity isn't just spreading out evenly everywhere; it could be highly concentrated for example in the region of a brane, and that's one idea that we got very excited about."

19. **Eric H**
    February 18, 2008

    Ms. Randall is much more specific in the Rose interview than what she seems to be saying recently. I'm beginning to wonder if the reason there is less specificity and more hype in "all" recent public discussions is because physicists are wary in being specific because they themselves now see the contradictions.

    For instance, when Kalusa proposed an extra dimension is was a dimension that circled back on itself, like a circle. Well, it just so happens, (not that we all don't already know it), that there is a particle physics analogue which is spin. So, at least physics had a physically observable behavior to attach to the math. I just don't see anything similarly concrete to attach to additional mathematical dimensions. The same with branes. Is it just me or does it seem like a lot of this later stuff some how got detached and isolated from experimental physics and split off like a bubble. It seems to me that a lot of this work may be intrinsically interesting but it is pure b.s. to try to make the case that this higher dimensional math is attached to physics.

20. **Eric H**
    February 18, 2008

    "I'm beginning to wonder if the reason there is less specificity and more hype in "all" recent public discussions is because physicists are wary in being specific because they themselves now see the contradictions."

    Make that "string theory physicists" as I didn't mean it to come out as a pejorative generalization.

21. **Martin Bauer**
    February 18, 2008

    I think you should not take the extradimensions "too serious". It might be that you get measurable predictions by extra dimensional theories but that doesnt mean that you will ever be able to travel in an additional direction. It should be understood like complex numbers. A mathematical tool which could help us out of the actual misery.

    But nevertheless I agree that (probably because the people which work on these problems today are so familiar with pure mathematics) the temptation to cross the line and think beyond to actually contribute something is huge.

    Not much to falsify at the moment. Sometimes you got the feeling el. particle physics devides into Maths and Names nowadays.

LHC Startup News

February 18, 2008
Categories: Experimental HEP News

I'm a bit confused about the situation with the LHC start-up schedule, maybe someone well-informed can help. Here's what I've seen recently:

At the AAAS meeting last Friday, there was a session on "Big Science", which included discussion of the LHC with Robert Aymar, the CERN director general. Alan Boyle, at MSNBC, reports:

> June was the time frame Aymar had in mind when he was asked about the start-up schedule during a Friday session on large-scale science project. But during a follow-up chat, he pointed out that you can't just press a big red button one day and expect each of the collider's beams to hit full power of 7 trillion electron volts immediately…
>
> Aymar said that buildup could still start around May 21 or 22, with tests continuing for weeks after that. His aim is to have the collider conducting scientific experiments this summer.

One thing that is definite about the schedule is that there will be a ceremonial inauguration of the machine on October 21, with a wide variety of dignitaries present, include French president Sarkozy.

It's not clear what phase of the start-up Aymar had in mind when he was referring to June, and the idea that the machine will be doing physics this summer seems hard to reconcile with information available publicly about how the things are progressing. For an official schedule from last August, see here. The current one, from October, is available here. Both schedules have beam commissioning beginning May 15, and taking about two months, so physics in July.

The LHC is divided into 8 sectors, and each sector must go through a process of flushing, cooling down to 1.8 K (which takes a month and a half), and powering tests of the magnets. The powering tests are crucial to make sure that the magnets can quench safely, dissipating the energy contained in a magnet that leaves the superconducting state unexpectedly. According to the schedules, the powering tests should take 2-3 months, and can start only once the magnets are cool. So, from beginning of cooldown to the point that a sector is ready to try and use should be a process of about 4 months or so. So, for mid-May beam commissioning, all sectors should be cool by around now and starting powering tests soon.

One can follow the actual state of affairs here. One sector (45) is cool and undergoing powering tests, but this sector still has not had its inner triplet magnets fixed, and the plan is to warm it back up before doing this, after which it will need to be cooled down again. Cooling of 3 other sectors has begun, but has been stopped in two of these to make repairs, with cooldown to resume in week 9 of the year for one sector, week 11 for another. Of the four other sectors, cooldown is supposed to start in one of them during week 15 (mid-April), dates are not given for the others. With respect to last August's schedule, the current situation is roughly 4-5 months behind where it is supposed to be. This would suggest that, if all goes well from now on, beam commissioning would begin mid-September. Perhaps there was some slack in that schedule, and things could happen faster than planned, but I'm just not seeing how physics this summer is in the cards for the LHC. Most likely scenario seems to be a big push to get some a beam of some sort stored in the machine in time for October 21 and the big ceremony.

Comments

1. **DB**
   February 19, 2008

   One thing is sure, Aymar is proof that humans exhibit the intrinsic property of spin. Dorigo, for example, doesn't expect the LHC to begin running until the end of the year, and then only at very low luminosities, and no-one really knows how long it will take to ramp the beam up to useful luminosities.

2. **caesar**
   February 20, 2008

   I doubt dorigo can be trusted on these matters. For what I understand from his blog, he basically extrapolates from his past experience with Run I and Run II at the Tevatron, rather than relying on hard information he does not really seem to have access to. He might still be right, though.

   However there is one important thing that is often overlooked. It is easy to understand the problems with cooling down the LHC components, with getting a stable beam, with fixing occasional incidents. But once those are straightened out, there is one major additional hindrance: even if LHC starts producing large numbers of collisions, the two detectors will have to figure out how to best trigger on them. Sure, at the very low initial luminosity a beam clock may be enough to rely upon for a complete readout of the detector. But still, getting good, meaningful data to tape is not a trivial task. If all we care is satisfy our curiosity on whether the LHC creates a black hole that eats out Geneva overnight we may be satisfied from day one, otherwise it will be very, very slow and painful.

US HEP Demography

February 18, 2008
Categories: Uncategorized

Late last week there was a meeting of HEPAP in Washington, presentations available here. Several dealt with the current budget situation, which is basically that the current FY2008 budget is a disaster, and the Bush administration has proposed huge compensatory increases for FY2009. No one seems to have any idea what Congress will do or when, so the future for US government support of HEP is completely unclear not only for the long-term, but even for the next fiscal year, which starts in a few months.

The NSF presentation noted that NSF funding for particle physics theory was down 4% in FY2008, to about $14 million, of which roughly $1.5 million goes to the KITP at Santa Barbara. The critical issues for the NSF particle theory program were listed as:

- Need to involve more people in LHC-related physics.
- Need new hires in phenomenology.
- Traditional funding sources for students (being TAs) is becoming problematic. (need more funding for students)

You can see why string theorists these days are pushing the idea of "string phenomenology" and claims that somehow string theory is relevant to the LHC.

At the DOE, funding for theoretical particle physics was flat for FY2008, at $60 million, with a proposed 5% increase for FY2009.

There was also an interesting presentation about an on-going project to gather demographic information on the people working in particle physics. I was surprised to see that statistics show significant recent increases at all levels in the numbers of people working in particle physics. From 2003-2007 the number of graduate students went from 1129 to 1335 (making one wonder why the NSF is worried about not supporting enough graduate students…), postdocs and untenured research staff from 1331 to 1406, untenured faculty from 228 to 284, and tenured faculty or staff from 1343 to 1355. In particle theory, the total number of people went from 1292 to 1414, so this increase in numbers was not all in experiment.

Also worth reading is a presentation from Robert Sugar about the present state of Lattice QCD calculations.

Comments

1. **Mike**
   February 19, 2008

   Gee, flat funding year after year and the number of people in the field keeps going up. Maybe Congress must know a good deal when it sees it!

2. **Peter Orland**
   February 21, 2008

   Academic employment is determined by more than
   simply the amount of generally available external funding.

   Theoretical particle physicists may have trouble bringing in
   money to universities, but they also cost those universities very little. Hence they don't entail much risk. Though particle theorists obtain smaller (and fewer) grants, they don't have expensive demands, hence universities get to keep much of the overhead. Of course, other theorists are even better in this respect – but unlike particle theorists, they sometimes can't thrive without experimentalists in the same department.

   Despite the last decade's funding difficulties, particle experimentalists
   could be considered a worthwhile risk – when they are funded, the
   university hauls in a bundle. A risk-benefit analysis may suggest
   particle experimentalists aren't a good gamble, but universities
   usually ignore such analyses (a good example is football. Football
   teams are a money sink-hole in most universities. They are kept on because the teams which pay off, pay off big).

3. **Peter Orland**
   February 22, 2008

   P.S. It's interesting that "Late-Night HEP TV" has many more comments than this topic does.

Quick Links

February 22, 2008
Categories: Uncategorized

There seems to be a political scandal going on in Italy revolving around the GIM mechanism, with Antonino Zichichi somehow involved. Definitely a higher level of scandal than we have here in the US.

An Oral History Project at Princeton involving interviews with people associated with the Math department during the 1930s is here, and includes the following exchange with Wigner, who evidently wasn't so happy with Weyl:

> **Interviewer**: We haven't mentioned Hermann Weyl yet. Can you tell me something about your relations with him? When did you first get to know him?
>
> **Wigner**: When he came to Princeton I knew about his work, and I quoted it also. You know he was interested in group theory. But in Princeton we were really strangers to each other. He never mentioned my work in his book on the application of group theory to quantum mechanics, even though practically all that is in the book was contained in publications by me and in joint publications by Johnny von Neumann and me. I resented that because I needed a job then.

The TLS has a review of The Trouble With Physics.

For the latest from the frontiers of physics, see this at the KITP, and this at the arXiv.

There's a P5 meeting going on at SLAC, talks here.

Bert Kostant of MIT gave a talk at UC Riverside entitled On Some Mathematics in Garrett Lisi's 'E8 Theory of Everything', and as part of the festivities John Baez gave an elementary introduction to E8. There's some discussion of this at his blog. It seems that the initial reaction from some string theorists that this material is so easy that undergraduates shouldn't have too much trouble with it may have changed a bit. For a comment on the attitudes involved, see here.

Update: To try and make up for the high-level of snarkiness of this posting, here's something else. This month's National Geographic has an excellent big article about the LHC, with the usual National Geo impressive photography. No hype about extra dimensions, etc., just a serious explanation of what the LHC is all about and what physicists are trying to do, ending with the following wonderful quote:

> …I asked George Smoot, a Nobel laureate physicist, if he thinks our most basic questions will ever be answered.
>
> "It depends on how I'm feeling on any particular day," he said. "But every day I go to work I'm making a bet that the universe is simple, symmetric, and aesthetically pleasing—a universe that we humans, with our limited perspective, will someday understand."

Update: Two more

- FQXI has Phantasms of Infinity, an article on the Boltzmann Brains/counting universes hot topic among theorists. It includes an actual picture of a Boltzmann Brain, as well as a quote from Vitaly Vanchurin, who works in this area:

> Without a way of calculating probabilities, cosmology is a dead science, it doesn't exist.

I think this will be news to most cosmologists, who are happily ignoring the problem of how to count universes in the multiverse. More accurate would be "Without a way of calculating probabilities, multiverse studies is a dead science, it doesn't exist", which is pretty much the situation now and for the forseeable future.

- New Scientist has a reasonably good cover story on cosmic strings. It ends with

> Discovering them would be really big news. String theory has often been criticised as a theorists' plaything, a pretty piece of mathematics unable to make any testable predictions. That perception would change pretty fast if we were to find a host of giant superstrings crisscrossing the skies.

This is an accurate summary of the situation, although it might be worth pointing out that not only is there no evidence for cosmic strings, but there's not even anything ever observed that cosmic strings provide a compelling explanation of. At the moment they're just a pretty pure example of wishful thinking. Sure tomorrow someone may find a "host of giant superstrings crisscrossing the skies". It's also true that tomorrow aliens may land and explain to us how to compute the Standard Model parameters from superstring theory.

   February 22, 2008

   Hm. A small tossoff near the beginning of the TLS Trouble with Physics review states: "He accuses string theorists of racism, sexism, arrogance, ignorance, messianism and, worst of all, of wasting their time on a theory that hasn't delivered." It was awhile back I read Trouble with Physics, but I don't remember– did in fact Smolin accuse string theorists of racism and sexism?! I do remember a section wherein Smolin argued for greater inclusion of women etc in physics, but this was *not* as I recall specifically directed at string theorists, but rather one of several generalized criticisms of the sociology of modern science in the closing sections.

2. **DB**
   February 22, 2008

   Check pages 280 and 320 of Weyl's: The Theory of Groups and Quantum Mechanics, 2nd Edition, November 1930 which was the edition first translated into English in 1931.
   P.280: "P.Jordan and E. Wigner have given a very elegant group-theoretic proof that there exists but one irreducible matrix solution of equations (14.10)" [derivation of the irreducible Abelian group of unitary ray rotations in system space]
   P.320: "The significance of our results for quantum mechanics [symmetric group and equivalence degeneracy in quantum mechanics] as first recognized by Wigner, is the following"

   Weyl cites the source papers in his bibliography, and includes a comprehensive selection from Wigner's and Von Neumann's giving meticulous credit to their contributions.

As for “practically all that is in the book was contained in publications by me and in joint publications by Johnny von Neumann and me” well, even a cursory examination of Weyl’s bibliography gives the lie to that egotistical hype. For more details see
http://www-groups.dcs.st-and.ac.uk/~history/Biographies/Wigner.html
where it is clear that Wigner resented Weyl’s priority in this area. Wigner published his own book on the subject in 1931.
As Abraham Pais has shown, Wigner has some history of inaccurate claims.

3. **Eric**
February 22, 2008

It should be Antonino Zichichi not Antonio.

4. **woit**
February 22, 2008

Thanks Eric, fixed.

5. **anon.**
February 22, 2008

“For the latest from the frontiers of physics, see this at the KITP”

Or, you *could* look at any of the other recent talks at the KITP on heavy-ion physics or LHC physics. What is your point, anyway? One snicker-worthy talk out of many isn’t a sign of anything, no matter how much you want it to be.

6. **Peter Woit**
February 23, 2008

anon,

Well, the topic of the talk was that of the last major story in the New York Times about the latest developments in theoretical physics, and one that has been heavily promoted on certain blogs and discussed here. It seems to be considered by some to be one of the hot areas in the subject, and the audience asked lots of questions and was quite involved. So, that’s why I thought it was worthy of comment.

It’s harder to justify paying any attention to the arXiv posting I mentioned…

7. **censored out**
February 23, 2008

Thanks for the link to the recent entertaining review of Smolin’s 2006 book by the *Times Literary Supplement:*

“… Smolin has launched a controversial attack on those working on the dominant model in theoretical physics. He accuses string theorists of racism, sexism, arrogance, ignorance, messianism and, worst of all, of wasting their time on a theory that hasn’t delivered. …

“Smolin has little new to say about how the institutions of science are undermined by personal ambition, internal politics and bureaucratic overload – as he himself admits.”

– http://tls.timesonline.co.uk/article/0,,25372-2650590_1,00.html

Is it just me, or does the second sentence just quoted contradict the first one, about the excesses of some string theorists and their wasting of time on failed theories? Surely, at least by giving the example of messianism in science institutions, Smolin is saying something “new” about how scientific institutions are undermined by personal ambition, internal politics and bureaucratic overload?

Regarding the denial of credit to Wigner for his work, Wigner’s 1992 autobiography also expresses annoyance toward Fermi for Fermi-Dirac statistics. Wigner was using Fermi-Dirac statistics long before Fermi started doing so, and he suggests that Fermi should instead be given credit for beta decay theory, not Fermi-Dirac statistics.

8. **Professor R**
February 23, 2008

hi Peter,
interesting blog as always. I have two queries/comments:

1. I can’t make head or tail of that Nielsen abstract on ArXiv. Were you being sarcastic? It’s not clear to me at all what their central thesis is – certainly an example of abstract that seems designed to confuse the reader (or is it just me…..)

2. I enjoyed the TLS review of Smolin’s book, thanks for pointing it out. What surprises me is that none of these reviews ever refer to Smolin’s previous book (‘Three Roads to Quantum Gravity’); the latter is a very good book, and probably a more damning criticism of string theory because it is written in a much more objective and technical style….it’s interesting that the ‘The Trouble With Physics’ is selling far better, although less objective and a lot less concise (in my opinion)
Cormac

9. **Peter Woit**
February 23, 2008

Professor R,

Yes, I was being sarcastic. Actually that’s the third paper by these authors on this subject, and the sensible thing to do would be to just ignore them. The fact that serious physicists are engaging in this kind of thing might be of some sociological interest, and some people with a warped sense of humor might find this entertaining…

10. **Professor R**
February 23, 2008

Ah….I wonder about that abstract. Could it be something else?
I wonder if Nielsen and co. are serious physicists who are attempting to highlight the downside of the ArXiv system in today’s world of lazy journalism…
Perhaps they’re waiting for New Scientist to pick one of their papers as a cover article….at which point they’ll come clean and declare it to be complete gobbledygook!

11. **oeL**

poor ellis

12. **Roger**
February 24, 2008

Totally off-topic (and to be deleted) – more a note to Peter for a future blog entry.

There is quite a fierce campaign going on in the UK regarding the recent funding cuts, including the ILC decision.

The story is summarised rather well in http://www.hep.ucl.ac.uk/~markl/pp/

13. **Peter Woit**
February 24, 2008

Roger,

Thanks. Unfortunately I don't think I'm well enough informed about what is going on in the UK to write a useful posting about it, but I'll leave your comment there and advise people to follow the link to learn more about this.

14. **Amos**
February 25, 2008

I read (but hardly understood) the Distler criticisms of Lisi. Is Lisi's E8 theory dead now?

15. **Peter Woit**
February 25, 2008

Amos,

Probably best if you ask this question at the place I linked to, where there are experts on this. I haven't followed it carefully.

16. **A Quantum Diaries Survivor**
February 26, 2008

Hi Peter,

thank you for linking my post on the Glashow-Carlucci querelle – it got visited by a large audience in the last few days. Yes, it is a scandal and no, it is not. Yes, because to us it is indeed a scandal that a politician with no understanding whatsoever of the physics takes the liberty to insult esteemed physicists by pretending to argue on the scientific merit of this or that paper. No, because for many in Italy scientists are perceived as a bunch of snobs who pretend they cannot be criticized, and so to their eyes Carlucci's allegations are perfectly sensible.

Cheers,
T.

17. **Amos**
February 27, 2008

Peter, I find your comments on these issues generally less partisan and more reasoned than those of others on the 'net, so hoped to get your opinion. But thanks.

Peter Goddard on the Birth of String Theory

February 25, 2008
Categories: Uncategorized

Last spring there was a conference held in Florence which brought together many of those who worked on dual models and string theory during the late sixties and early seventies. Slides from the talks are here, and many of the speakers have written up contributions that have been posted on the arXiv. The latest of these is From Dual Models to String Theory, by Peter Goddard, who now is the director of the IAS in Princeton. It contains a detailed description of what he remembers of those early days when people were trying to sort out the significance of the Veneziano amplitudes and how to consistently quantize the string. Goddard also has some interesting remarks on the rapid changes in fashion during those years, and some excerpts follow.

On his student days at Cambridge working under Polkinghorne during the late sixties:

> I, and nearly all my fellow research students, worked on strong interaction physics. (One of us was trying to work out the correct Feynman rules for gauge field theories, but this tended to be regarded as a rather recondite or eccentric enterprise.)

At a summer conference in 1971:

> For me, it was a memorable meeting and one particular vignette has stuck in my mind as an illustration of the prevailing attitude towards the use of modern mathematics in theoretical high energy physics. A senior and warmly admired physicist gave some lectures on the Regge theory of high energy processes. With great technical mastery, he was covering the board with special functions, doing manipulations that I knew from my studies with Alan White (who was also at the School) could be handled efficiently and elegantly using harmonic analysis on noncompact groups. Just as I was wondering whether it might be too impertinent to make a remark to this effect, the lecturer turned to the audience and said, "They tell me that you can do this all more easily if you use group theory, but I tell you that, if you are strong, you do not need group theory."

About his years (1970-72) at CERN:

> The two years I had spent in CERN had built up to an crescendo of intellectual excitement and, though I have found much of my subsequent research work gripping and often extremely satisfying (when teaching duties and the largely self-inflicted wounds of administration have permitted), nothing has quite matched this period. In particular, I had the privilege of working closely for seven or eight months with Charles Thorn, whose combination of deep perception and formidable calculational power had provided the basis of what we managed to do. And, the exhilarating combination of the open and cooperative atmosphere that prevailed amongst (almost all) those working on dual models in CERN, the relative youth of most of those involved, the sense of elucidating a theory that was radically different, even the frisson of excitement that came from doing something that was regarded by some of those in power as wicked, because it might have nothing directly to do with the real world – this cocktail would never be offered to me again.

About the situation in 1973-4 , after the discovery of asymptotic freedom:

> By the end of 1973, as the fascination of dual models or string theory remained undimmed, though with ever increasing technical demands, the interest of many was shifting elsewhere. On 21 December, David Olive wrote to me, "Very few people are now interested in dual theories here in CERN. Amati and Fubini independently made statements to the effect that dual theory is now the most exciting theory that they have seen but that it is too difficult for them to work with. The main excitement the renormalization group and asymptotic freedom, which are indeed interesting."
> …
>
> In Berkeley , I wrote a largely cathartic paper on supersymmetry, which probably helped no one's understanding, except marginally my own. It had one memorable effect: namely, that when I reached Princeton I was invited to give a general seminar on supersymmetry, which most people did not know much about then. When I said I would rather talk about string theory, my offer was politely declined on the grounds that no one in Princeton was
> interested, a situation that has changed in the intervening years. Somewhat put out by this response, I did not give a seminar at all.

About his decision in 1975-6 to work on gauge theory rather than strings:

> I started to realize that following my interests in strings or dual models might be a fine indulgence for me, but it was not going to help my students get jobs. (One of the great attractions of Cambridge at the time was that chances for promotion were so slim – Jeffrey Goldstone was still a Lecturer – that one did not need to be distracted by the prospects for advancement: they seemed negligible.)

Comments

1. **Chris Oakley**
   February 25, 2008

   Peter Goddard – I remember him from Cambridge, c. 1981. He taught us "Advanced Quantum Field Theory" for the Part 3 Mathematics course which, at the time, mostly meant gauge theories and the Higgs mechanism. Mild-mannered, with the obligatory shabby donnish jacket, and hair that looked like it had been cut by his wife or daughter. Great lecture notes, though – legible handwriting and a half-decent job done of explaining things (not that I accepted the Higgs mechanism – even then – of course, but …)

2. **S-P Chan**
   February 25, 2008

   -similar story-as an undergrad at St John's College Cambridge early 80's I was supervised by Peter Goddard in Quantum Mechanics and other sundry applied math courses.

   He was the archetypal professor-type, very gentle (re my crappy undergrad tutorial work) and helpful.

3. **csrster**
   February 26, 2008

   Yes, I remember him lecturing me on something-way-over-my-head during a brief foray into mathematical physics in 1986. I may not have learned much in Part III Maths but at least I got to add some A-list names to my "tried to teach me to think" list – Gary Gibbons, Martin Rees, George Efstathiou, Don Lynden-Bell …

4. **Sandro**
   February 26, 2008

"I started to realize that following my interests in strings or dual models might be a fine indulgence for me, but it was not going to help my students get jobs"
I find this utterly remarkable: the number of Ph.D. supervisors willing to do this nowadays is really close to, if not, 0. Seriously.

5. **Peter Woit**
February 26, 2008

Sandro,

There's a big difference: in the mid-seventies, strings were out of fashion, now they are in fashion.

Goddard is right when he points out that one consequence of working on something unfashionable is that it is hard for one's students to get jobs. But of course there are others. He notes that one won't get promoted to higher positions, and that's why he explains that promotion at Cambridge was so unlikely that this wasn't much of a concern. Other serious consequences are that one is likely to essentially become a nobody in one's community, not invited to conferences, etc., etc. See his story about how people at Princeton wouldn't let him talk about what he was working on, but did want him to talk about the trendy idea (34 years ago and counting…) of supersymmetry even though he didn't know much about it and wasn't very interested.

Back in 1973-75, gauge theories were fashionable, but for extremely good reasons. The Standard model had just been born and revolutionized physics, and gauge theories were not well-understood at all. The revolution had opened a whole new area of theoretical physics, full of new things to do, and deeply grounded in and vindicated by experiment. To ignore this and continue to work on string theory, which was going nowhere and had failed in what it was supposed to do (explain the strong interactions) was to make a decision that most of one's colleagues would see as perverse, motivated purely by an unwillingness to learn anything new, and insistence on sticking to doing the same thing one had been doing since graduate school.

For nearly a quarter-century now, the shoe has been on the other foot, with string theory the fashion, and work on gauge theories unfashionable (acceptable only if it at least involves supersymmetry…). The common opinion has been that those who don't work on string theory just can't cut it as serious theorists. The sociology may be similar to the reverse situation of the 1970s, but scientifically there is a huge difference: gauge theories worked and were a huge success, string theories have been a huge failure. Despite this the political situation remains the same. Any theorist who decides to work on something unfashionable is going to have trouble getting jobs for his or her students, and get told by people at Princeton that they don't want to hear about it….

6. **Sandro**
February 26, 2008

Peter,

you are right, but I think I had something different in mind.
I was referring to the attitude towards students as to "people that have got to get a job in the next future", and not as to "people which are carrying on curiosities that I'd personally like to solve but I've got no time to".(At least that's how I read it.)
This is something I think few supervisors do, whatever their discipline is, and yes, they are not obliged to, but..

7. **csrster**
February 27, 2008

I wonder if there's just something different in the air in Cambridge – or perhaps everywhere in Europe – that makes it easier for individuals to work on their own "interesting" ideas away from the dominant paradigm? I can't imagine an external speaker being turned away by Cambridge just because they're working a little outside the box. (I _can_ imagine them being given a very rough ride if they haven't thought through what they're talking about.)

8. **censored out**
February 27, 2008

csrster, it's just money. Cambridge is the richest university. You used to be able to walk from Cambridge to Oxford without stepping off land owned by Cambridge University. It can still afford to find highly speculative research, e.g. Josephson's 'Mind-Matter Unification Project', http://www.tcm.phy.cam.ac.uk/~bdj10/

9. **csrster**
February 27, 2008

Isn't that Oxford-Cambridge thing just one of those urban legends? And are you saying that Princeton is poor 🙂 ?

As for Josephson, I suspect that the reason behind that is the Nobel Effect – ie once you've got a Nobel Prize you can get away with anything (with the possible exception of outright racism).

10. **MathPhys**
February 27, 2008

Peter Goddard is a very good lecturer and an excellent supervisor. Back in the 70's, 80's and 90's, his students learnt a lot, graduated and many of them got academic jobs. I know. I'm not so sure if he still teaches and supervises students at IAS.

11. **Professor R**
March 4, 2008

hi Peter,
I thought you might be interested to know that one of the excerpts above from Peter Goddard's excellent talk pretty much mirror my Dad's experience. In the period 1974-75, Lochlainn was invited to tour several US universities in the US, in order to give talks on the emerging theory known as super gauge symmetry (a much better name in my opinion!).

As a result, Dad had to furiously brush up on the work of Wess, Zumino et al (although he had worked quite closely with Wess before). Just like Goddard, Dad then felt the need to formally put down what he had learnt on his return, resulting in Lecture Notes on Supersymmetry (published by the Dublin Institute of Advanced Studies in 1975). I've been wondering if this is the world's first formal series of lecture notes on the topic..

Before and after, I think Lochlainn's interest remained in the general area of gauge theory (or the application of group theory to gauge theories)….not in the specific area of string theory. He would not have been pleased with a dominance of string theorists over others in hiring practice – however, it seems this is much more of an issue in the US and the UK, than in continental Europe or Japan.
Cormac

12. **Ben**

March 4, 2008

MathPhys-
There are no students to be taught or advised at IAS. I'm 26, and suspect I'm the youngest person here. You can, in theory, adopt students from Princeton, but this is relatively rare, and I doubt Goddard has time for it, being director and all.

Simons Center for Geometry and Physics at Stony Brook

February 27, 2008
Categories: Uncategorized

Today here in New York City there will be a formal announcement by governor Eliot Spitzer of a gift by Jim Simons of $60 million dollars to fund a new research center at SUNY Stony Brook, to be called the Simons Center for Geometry and Physics at Stony Brook. Simons already made a donation of $25 million dollars to Stony Brook back in 2006 to support math and physics, with the idea of getting such a center off the ground. People there had told me last year that they were expecting Simons to fully fund an expensive new center with a new building once they had managed to find a suitable director, and recently I had heard that string theorist Michael Douglas had accepted the director's position.

This is the largest gift ever made not only to Stony Brook, but to any of the institutions in the SUNY system. Besides the building and the position for Douglas, it is supposed to fund 30 visiting positions and presumably a sizable number of permanent positions in mathematics and physics (the 2006 gift also is supposed to pay for such positions). The scale of this should make the Simons Center among the best funded institutions in this field. Job prospects for string theorists have just improved significantly…

For more details see stories from the [New York Times](), [Newsday](), and [Crain's Business Report]().

Update: More [here]().

Update: More in the New York Times [here](). The $60 million includes the previously announced $25 million, and will pay for a new building as well as an endowment of $40-45 million. The endowment will fund the director's position, 6 more permanent positions, and 30 postdocs and visiting positions.

Comments

1. **Chris Oakley**
   February 27, 2008

   Just to say how delighted I am to hear that despite minor teething problems (lack of a theory, lack of ability to make predictions, etc.) String Theory is considered to be alive and well by scientifically literate billionaires.

2. **Stephen J. Summers**
   February 27, 2008

   Are we to understand that "mathematics + physics = string theory"
   alone? Or even that "geometry + physics = string theory" alone?
   I get this impression from reading the mentioned sites. What a waste such a center would be if it is run with that credo. Does anyone know if the new director is a string theory ideologue,
   or does he recognize that there are other realms in mathematical
   physics which are of physical relevance?

3. **Peter Woit**
   February 27, 2008

   Stephen,

   I suspect that hiring decisions will be made by a group of people from both mathematics and physics, with the mathematicians interested in hiring mathematicians in a range different fields that touch on physics in one way or another. I don't know what the physicists will do: in recent years there has been an unfortunate prejudice in physics departments to identify string theory with the mathematical end of physics. I also don't know to what extent Douglas is a "string ideologue", but given his background and that of some of the other people involved with this, I predict that a lot of string theorists will get hired at the Simons Center.

   Many years ago when I was a postdoc at Stony Brook, even then the math and ITP groups had a pretty close relationship. But when grant money appeared to support math-physics, from what I remember they pretty much split it down the middle, with mathematicians hiring mathematicians not necessarily so interested in physics, and physicists hiring physicists not necessarily so interested in math. This Center is operating on a very different scale and these are very different times, it will be interesting to see how they deal with this.

   In his comments about the gift, Simons specifically refers to the mathematical significance of quantum field theory as well as string theory, so perhaps this will be reflected in who they hire. These days though, I can think of few physics departments interested in hiring mathematically oriented quantum field theorists who are doing things completely unrelated to string theory. Maybe Stony Brook will be different…

   One other problem is that if you try and look for young people trained in physics departments who are working on mathematically sophisticated approaches to QFT, but not string theory, your hiring pool is pretty small and consists solely of the professionally suicidal.

4. **layman**
   February 29, 2008

   Very interesting post. I was a grad student in ITP in the 80s. So, this new center will be a different building from ITP. With Micheal douglas as the new, improved, C.N. Yang?

   Does the 60 billion really fund a new building or will those guys be given offices in ITP?

5. **Peter Woit**
   February 29, 2008

   layman,

   Unfortunately, it's 60 million, not billion…

   My understanding is that the Simons Center will not replace the YITP but be a separate entity, with the YITP continuing as before. There definitely will be a new building, or at least an addition to the current one, I'm not sure which. The current math/YITP building actually has one blank side, since the original plan was to build farther in that direction, but they stopped due to not enough money. I’m not sure if this was during the era of Simons as dept. chair. It would be funny if the building project he could not complete as chair now gets done with his personal money.

Rock Guitars Could Hold Secret to Universe

February 27, 2008
Categories: This Week's Hype

From the Bolton News:

> ROCK guitars could hold the key to the origins of the universe, hundreds of young science pupils were told.
>
> The Institute of Physics held a lecture in Bolton entitled "Rock in 11 dimensions: where physics and guitars collide".
>
> And acoustics physicist Dr Mark Lewney told more than 600 youngsters who attended that the vibration of guitar strings may answer unsolved questions about the Big Bang.

This event is just one of a year-long lecture series promoting string theory at schools throughout Great Britain. According to the promotional material the LHC will help verify string theory experimentally (and it will start up in May….).

Comments

1. **Thomas Love**
   February 27, 2008

   They're starting the brainwashing early. Let's just wait and see what the LHC produces. But the presenter has done "years of research into guitar physics at Cardiff University" which of course makes him an expert on string theory and elementary particles. That's as logical as anything I've read in a book on string theory.

2. **nigel cook**
   February 28, 2008

   String theory and rock have much in common: intoxication, many groupies, and putting vibrating strings to a use that makes a few people very rich and famous. String theory as a rock culture makes sense. One reason to go to rock concerts is socialising. People investigating string theory may likewise do it to fit into physics culture and to get funding, just as venues hire and promote popular rock groups. Others study string theory because they really believe it's the best thing on sale, similar to arguments for liking a particular rock group or even a political party or religion.

3. **csrster**
   February 28, 2008

   Why "Rock" guitars? Don't other types of guitar have vibrating strings? Or does the universe also have twin Floyd Rose humbucker pickups, a scooped fretboard, and a Jackson custom knife-edge tremolo arm?

4. **Steve Myers**
   February 28, 2008

   What amps is he using? How many watts? Is it 5 or 10 strings? Or 10^500?

5. **Eric**
   February 28, 2008

   Well, actually surfing holds the key to the universe. Just ask the 'next Einstein'.

6. **Professor R**
   February 28, 2008

   Surprise!
   I actually heard this talk when Mark Lewney came to our college last year. The surprise is that the talk was very very good (as talks for schoolkids go), a real performance…

   The title is misleading – the talk was mainly a first introduction to particle physics, with emphasis on the forthcoming LHC experiments – what it is for, what it might detect. Mark used the guitar to great effect – more as a prop/gimmick/musical interlude than anything to do with string theory (hard to explain uness you were there). In addition, the guitar was used for several analogies, not least in describing bound states …

   Re string theory, the theory was only mentioned towards the end of the talk, and Mark was v careful to stress that it lies in the speculative area of physics…

   All in all I amazed by this lively talk, and so were the students – you can see reviews from other physicists (favourable) on the IoP website…..Cormac

7. **Sultan**
   February 28, 2008

   Sounds like that line from Spinal Tap: It goes to 11.

8. **Ken Muldrew**
   February 28, 2008

   Didn't Pythagoras already try this tactic (but with a lyre instead of a guitar)?

9. **jpd**
   February 28, 2008

   Re: Erics surfing comment. The rest of the world may think surfing is strange,
   but growing up in California, its not extraordinary at all. Its like being surprised if someone from Switzerland skis. They have mountains, we have an ocean, get over it.

10. **otto schtirlitz**

February 28, 2008

Peter,
What do you think about this article?

http://discovermagazine.com/2008/mar/13-e-nste-n/

Great PR work by Lee Smolin and a sad state of affairs for science is all I can say. Poor Ed, I hope he's got a good sense of humor and is not embarrased by this stuff.

11. **woit**
February 28, 2008

"otto schtirlitz"

This isn't exactly on-topic and your question already came up a couple weeks ago:

http://www.math.columbia.edu/~woit/wordpress/?p=651#comment-34790

I gather that Lubos is pretty upset about this and sees it as somehow the work of that "hostile imbecile" Peter Woit, and evidence of the decline of Western Civilization.

No, I had nothing to do with it and Lee Smolin's list of "new Einsteins" would not be mine. Two problems with even thinking about such a list are that:

1. No physicists have made much progress at all in fundamental theory, so calling anyone a "new Einstein" is pretty silly.

2. Witten's achievements are so off-scale that if your list is longer than one, it's going to include people who are not in his league.

I strongly suspect Ed is not too traumatized by finding out that Lee considers him a new Einstein and has included him in a list of others with much lesser achievements.

12. **Observer**
February 28, 2008

Sadly this is another shoot on the foot for string theory.

13. **Dr Lewney**
February 29, 2008

Christ it's chilly in here. There's enough negative energy to make a bleedin wormhole.

Mea culpa for the poster and press releases. I'm afraid such painful oversimplification of an hour's lecture into a few soundbites which are suitable for a local paper and which stand a chance of getting kids to come to the frigging lecture is sadly necessary in today's competitive educational climate.

But thanks to Professor R, the only one here who has actually seen it, for the kudos. I state explicitly that String Theory might be a load of bollocks, and endeavour to be even-handed in explaining the issues. No, I'm not a particle physicist, but I had to submit the script to four UK experts and their reviews were very positive. And I'm not even that arsed if it is a "shoot on the foot" (irony? nah) – if it increases the uptake of physics A level amongst the audience even slightly, I'll be chuffed.

Cheers

Mark

14. **Professor R**
February 29, 2008

hey Mark, great to see your post!
You should know they're still talking about your lecture here (an obscure country college in Waterford, Ireland). Myself, I think it was a very good example of performance, and I try to incorporate some of your tricks into BB talks I give to local schools. Sadly, most lecturers don't think in these terms when they mount the podium, (including this year's Tyndall lecture, no comparison).

In fairness to Peter, I think his bailiwick is not string theory, or string theorists, but the constant over-emphasis of this area of physics in the media (and in the jobs market). A lot of theoreticians would agree with this, including some prominent sting theorists who were cronies of my Dad.

My own view is that if there's something about strings that grabs the public imagination (more than quarks, for example), I too am happy to use it as a 'hook' to reel in young people to the wonderful world of physics….indeed I suspect an emphasis on the world of the imagination is no harm at all when dealing with young people.
I remember you were careful in your lecture to present the theory as speculative, and the kids they liked that even more… well done again! Cormac O' Raifeartaigh

15. **Dr Lewney**
February 29, 2008

Thanks Cormac – I enjoyed my tour of Ireland immensely, and indeed it was the Irish IoP's recommendation which helped me land this full UK tour.

Of course some people love a good sneer and I can quite understand how some might consider my poster/press to embody all that IS wrong about String Theory, media hype-wise.

But ultimately, I think I'm actually doing Peter Woit's campaign a lot of good. So he's concerned about String Theory's monopoly in recruiting maths and theoretical physics graduates, such that other theories lose out in the competition for such precious resources – yeah yeah, big deal.

I'm concerned about recruiting physics and maths graduates full stop. I'm competing with medicine, law, economics, biochemistry and all kinds of other subjects which a bright kid might gravitate towards. And if I can convince some, jackpot! There's more chance of there being enough graduates to allow other theories to be explored AS WELL AS String Theory.

Of course, the fact that the very superficiality and glitziness of String Theory that Peter complains about is ultimately being used to acheive his goals might stick in his craw a bit. But he should be used to that – after all, if it weren't for String Theory, few people would ever have heard of him!

Cheers

Mark

16. **haha**
February 29, 2008

Don't worry, Mark. Some of us have noticed for a while that Peter has gone over the deep end. Its just that any comment to that effect gets immediately deleted. Lets see if this one survives.

This blog started out moderate enough, but now it is a parody on itself. Anything and everything is slowly becoming the fault of the string theory monster.

17. **Peter Woit**
February 29, 2008

Mark,

I'm glad that Cormac wrote in to tell about what your lecture was actually like. I'd suspected it was likely to be much better than the promotional materials would indicate. Best wishes for the project of getting young people interested in physics. Even if it does involve invocation of string theory hype, at least these days a more skeptical take on this is getting plenty of attention. Hopefully the fact that there's a lively controversy over the subject will have the effect of getting some people interested in the whole thing.

haha,

Actually on any given day I typically delete one or more comments attacking string theory and string theorists, on the grounds that they're just hostile and content-free. There probably are a bunch of comments on this posting that I should have done the same thing to. It is a much rarer event that I delete similarly hostile and content-free comments from anonymous string theory partisans, but when I do it is generally because they generate lots of hostile comments in response, and I have to delete the whole thread.

As for your characterization of this blog, I'll let what I write speak for itself. My name is on it, and I take responsibility for it.

18. **DaveF**
March 1, 2008

[vibration of guitar strings may answer unsolved questions about the Big Bang]

Ask a dumb question, get a dumb answer.

19. **Josh Carmine**
March 1, 2008

"I'm competing with medicine, law, economics, biochemistry and all kinds of other subjects which a bright kid might gravitate towards."

Let's face it. Kids even seriously considering medicine, law or economics over Physics should probably not go into Physics at all. Some years ago when they might not have had any contact with Physics it wasn't so, but nowadays it's almost impossible. So those kids have had contact with Physics and still think about law or economics as an alternative life path?!

Please, let them go. If they come to the field they will do nothing but pollute it.

If this is the lecturer's objective (to "recruit" these kids) then he is doing a disservice to physics.

20. **Dr Lewney**
March 1, 2008

Peter,

Many thanks for your encouragement. Whenever reasonable, sociable people get to present their positions to each other directly, it usually becomes clear that their differences are less significant than what they agree on. I guess it's inevitable that this place also attracts mindblind loners looking for something to hate.

And I'm sure you of all people understand how, despite one's best efforts, what actually ends up getting presented in the media is always a distinctly lossy compression! If you're ever over in the UK, or if I ever get booked in your area, it would be an honour to have you in attendance.

Josh Carmine,

"So those kids have had contact with Physics and still think about law or economics as an alternative life path?! Please, let them go. If they come to the field they will do nothing but pollute it. If this is the lecturer's objective (to "recruit" these kids) then he is doing a disservice to physics."

This is the sadly typical exclusivist snobbery which is causing physics departments to close for want of students. There is, if anything, far LESS physics in the UK curriculum for 14-16 year olds than there was a decade or more ago – I think that my shows might well be the first exposure to what I'd call 'proper' physics (with, you know, maths and everything) that some of these kids receive. And the mere consideration of another subject at FOURTEEN YEARS OLD immediately disqualifies you from a physics career for life and renders you a "pollutant"? I don't think such a position can be reasonably argued with, so I'm not going to bother.

I'm actually very open to ideas as to how best to communicate physics to schoolkids. If any of you here could direct me to recordings of your own efforts to do so, or even to upcoming shows I could attend, I'd be very grateful. Armchair advice not so welcome, thanks.

Cheers

Mark

March 1, 2008

haha,

I just checked the file I keep of deleted comments, and could only identify one that came from you. You were using the pseudonym "string-dude", and your comment had not the slightest thing to do with the posting, but was an attack on Chris Oakley, explaining to him in detail about how he needed to read a textbook on quantum field theory (Weinberg's).

Sorry, but off-topic, content-free, hostile comments from people who think it's a good idea to hide behind juvenile pseudonyms are definitely the sort of thing I delete and will continue to do so. The only reason I can see to allow such things is to try and make string theorists look bad, and I think I'll resist that temptation. If you want to continue to post hostile comments insulting me, at least start putting your name on them.

22. **Chris Oakley**
March 1, 2008

To be fair to "ha ha"/"string-dude" I have only studied volume 1 of Weinberg in any detail. Battling anonymous foes, though, is like punching air. Why are these people so keen not to be identified?

New LHC Schedule

February 27, 2008
Categories: Experimental HEP News

This week is a "CMS week" at CERN, and talks are available here. The plenary talk discussing the LHC status has:

> If all goes well the machine should be cold by 1 June, and protons could be injected by mid-June. Use this information for laying out our schedule…

Poking around the LHC website, lots of other information is available. A draft general schedule from last week can be found here. It has cooldown of the last sector (4-5) ending in mid-June, and powering tests on-going at several sectors until mid-August. Plans from last year for commissioning the beam envision 30 days with beam to go from first injection to usable 7 TeV beams, with an estimate that this would take 60 calendar days. So, most optimistically, it looks like mid-late October is the earliest that 7 TeV collisions could be happening, right around the date of the official inauguration: October 21. More realistically, this may very well take until early 2009.

Fleinhardt Hits a Roadblock

February 28, 2008
Categories: Uncategorized

Larry Fleinhardt, the fictional Caltech string theorist in the TV show Numb3rs, has decided to give up on string theory for now and become a phenomenologist. According to the show's co-writer Nick Falacci:

> Like real-life physicists, Fleinhardt hit a roadblock trying to create an 11-dimensional supergravity theory.

So, he will be joining the DZero collaboration at the Tevatron and work on the search for the Higgs. According to Fermilab Today, an office for Fleinhardt at Fermilab has already been created.

It's not clear if Ed Witten or his brother Matt had anything to do with this…

Comments

1. **Chris Oakley**
   February 29, 2008

   I am still trying to figure out the connection between a TV crime drama and the search for a Higgs boson.

   It could be something like this:

   JUDGE

   Dr. Fleinhardt, I cannot see what relevance this – what did you call it? – bubble chamber photograph? has to the case

   FLEINHARDT

   Your honor, it has everything to do with the case. Those charmed mesons being produced are extremely energetic. They are neutral, and can only decay weakly, and hence the gap between the primary and secondary tracks. An antiproton produced by meson decay could have an energy of up to 1 TeV, and would cause a lot of damage to biological organisms.

   JUDGE

   Enough to kill a man?

   FLEINHARDT

   Indeed, your honor. That could be enough to kill a man.

   JUDGE

   Fleinhardt, these attempts to make particle physics look "cool", in hopes of getting funding, are not going to fool anyone.

2. **Bee**
   February 29, 2008

   How boring. What did 'fiction' come to? They should have let him discover a theory of everything. How come fiction tries to be real, whereas reality becomes more and more fictitious?

3. **A Quantum Diaries Survivor**
   February 29, 2008

   Dear Bee,

   reality beats fiction all the time – and poor fiction gets the worse of it only more quickly. It is the effect of our failing imagination. Look at the LHC startup: today, I heard Joe Incandela at a plenary talk in the main auditorium at CERN saying that these are great times for experimentalists, since the field is all for them: theorists have no clue of what is beyond the standard model.

   I think Joe is right. The poor string theorist in Numb3rs only got the wrong plane ticket – he should've gotten one for Geneva. Dzero will not break new ground, nor will unfortunately do CDF.

   Cheers,
   T.

4. **Coin**
   March 1, 2008

   "I expect it will make more people aware of the work that we do and (if the plot develops) how we actually learn about particle physics," said DZero spokesman Darien Wood. "The characters on the show speak with great excitement and reverence about the search for the Higgs boson at DZero, and I think it captures some of the passion that we real particle physicists have for our work."

   That's… actually kind of an interesting thing for a tv show to try to do.

   And Bee: I don't watch the show, but isn't Larry kind of a secondary character? It seems like letting him discover the Theory of Everything would be inflating his subplot a little too much. What we should really be hoping for is for Charlie to finally succeed in proving P < NP*…

   * Clearly if they don't have the budget to present scenes at the LHC in Geneva, then they don't have the budget either to successfully portray the massive societal breakdown that would occur were someone to prove P = NP

5. **passerby**
   March 4, 2008

   nothing on Darren Crowdy, anybody?

6. **srp**
   March 4, 2008

   Basic rule of series cop shows: All plots end in “order restored.” At the end of the show the universe has been (at least partially) glued back together–injustices have been righted, dangers put back in their place, etc. Part and parcel of that is that the events of the plot, especially by the heroes, can’t change the world too much. We need a stable setting for the next episode and an emotionally satisfying restoration of order by the heroes (for the typical audience member).

   Science fiction plots, on the other hand, are often (although certainly not always) about precisely that–heroes changing the world. That’s one reason the audience is smaller and it’s harder to do episodic forms in that genre. Superhero comic books awkwardly straddle the two approaches; lately they’ve been moving more toward the science-fiction pole of hero-induced change (e.g. Marvel’s Civil Wars), but the comforting adventure-of-the-month against a stable background model will probably never go away entirely.

7. **passerby**
   March 5, 2008

   I did receive the Schwarz-Christoffel paper, jake. thank you. it is old.

This Week’s Hype

March 9, 2008
Categories: This Week's Hype

Today’s Newsday has a long article by Michael Guillen about the significance of the new Simons Center at Stony Brook. Guillen is a theoretical physicist who was the science editor at ABC-TV for fourteen years, and now is the host of “Where Did it Come From?” a science and technology show on the History Channel. According to Guillen:

> Once upon a time, physics likened the tiniest imaginable whit of matter to a geometrical point that, strange as it sounds, theoretically has no dimension: no width, length or depth. But experimental research into protons, neutrons and other elementary particles led physicists in the late 1960s to argue that a subatomic particle behaves not like a point, but a string – a geometrical line segment, with length but no width or depth.
>
> This stupendous hypothesis was followed by another in the 1990s, when physicists discerned in string theory resemblances to an 11-dimensional version of Einstein’s hallowed theory of gravity.
>
> All of this and more has left scientists deliriously optimistic that in string theory – the latest, greatest offspring of geometry and physics – lies the makings of the long sought-after “theory of everything.”

Besides promoting the current delirious optimism about string theory among physicists, Guillen also makes a living as a motivational speaker and promoter of religious faith. His most recent book, Can a Smart Person Believe in God? tell us that

> After the recent, unexpected appearance of something called string theory, science appears to be in the midst of changing its mind yet again. It’s not proposing we live in a universe that has ten or more dimensions!…
>
> As we’ve seen, all the evidence indicates that science is not converging smoothly and consensually upon one firm, reliable understanding of the way our world began or how it operates.

As a guest on the 700 Club, Guillen explained that one of the three things that led him to his religious faith was

> 2. That if a person can believe in black holes and multiple universes, then it would be no big deal to believe in God.

Comments

1. **Big Vlad**
   March 9, 2008

   This is utterly depressing.

2. **nigel cook**
   March 9, 2008

   Guillen’s claim that the widespread belief in multiple universes justifies religion is one that Leonard Susskind intelligently tried to forestall by attacking religion, as indicated by the title of Susskind’s book: *The Cosmic Landscape: String Theory and the Illusion of Intelligent Design*. Susskind argues that string theory is justified because the string theory landscape of 10^500 metastable vacua explains the surprising features of our particular world by using the anthropic selection principle, and this theory is totally incompatible with that of intelligent design by God.

   Susskind’s use of string theory against religion should be one of the major selling points for string theory, and it makes intelligent design skeptics like Richard Dawkins pay close attention to the use of the stringy cosmic landscape as being ‘scientific evidence’ that intelligent design is junk. An early Dawkin argument (that the accuracy of quantum theory is evidence for multiple universes) is on video: http://www.ted.com/index.php/talks/view/id/98

   The real question is whether there is any way of getting proof for the existence of a string landscape so that it can disprove religion?

3. **mike harney**
   March 9, 2008

   I think that although Susskind draws more attention to the argument (which may or may not be helpful), he doesn’t give strong evidence for his claim based on the landscape model. With little or no predictive capabilities, the current string landscape model is likely to be compared more and more to mystical concepts like the multiverse, which climbed into science fiction many decades ago, before this debate is over. Sadly, the public yearns for this fantasy as well so the tide is not likely to turn soon.

4. **Val Wanginstein**
   March 10, 2008

   How could anyone who went through UCLA, Cornell and ended up teaching at Harvard (according to his personal website, no 2nd. ref.), going through grad. level quantum mechanics, grad. level classical mechanics, and undergrad. labs, and then a Ph.D thesis defense, mix “belief” into science? (“That if a person can believe in black holes and multiple universes, then it would be no big deal to believe in God.”)

   It is a big deal. What does faith or some subset of supernatural tales about old dead Jewish men factor into, say, solving a dispersion relation and testing its predictions?

   At the very least, I’m glad that, from a quick xxx.lanl.gov and google lookup, Guillen hasn’t really contributed much to science or shown himself to be a competent scientist, other than passing his classes. Otherwise, my world would be shaken.

5. **srp**
   March 15, 2008

   It’s only fair to point out that many of the greatest physicists of the Scientific Revolution were partly motivated by discovering “the mind of God.” There is a school of historical thought that argues one reason British science was so empirically minded was because their theology was more voluntaristic, i.e. they thought God was not constrained by logic and could therefore have put things together any way he wanted, unlike the French, who tried to reason things out more from first principles.

HEP and Politics News

March 9, 2008
Categories: Experimental HEP News

In perhaps the most important development for the future of HEP in the US in quite a while, yesterday Bill Foster, an HEP experimentalist who worked on CDF and the Recycler at Fermilab, won a race to fill the congressional seat being vacated by Dennis Hastert. This is the congressional district that includes Fermilab, and one of the main reasons for the disastrous budget cuts affecting Fermilab this year seems to have been the fact that the congressional representative for its district not only was no longer Speaker of the House, but had retired.

Foster managed to win as a Democrat in a district that has been a safe one for the Republicans, but he will be up for reelection in November, facing the same opponent. The House Democratic leadership will likely be doing whatever it can to support Foster, and this could very well involve changing its stance from cutting Fermilab's budget to restoring it for next year, FY2009. This should hold true at least through the first week of November, although chances of a budget being passed by then don't seem very high.

I'm still rather confused by news about how the LHC is progressing. A new schedule has appeared, but unlike previous versions, it just shows plans for cooling down the machine, with no information about plans for what happens after that. Earlier versions of the schedule included a period of 2-3 months of powering tests for each sector after it is cool, followed by a month for machine checkout, and two months for beam commissioning before collisions at 7 TeV.

The new schedule has most of the machine cool by the end of May, except for sector 4-5, which is now being warmed up for the repairs on inner triplet magnets, with powering tests already having been performed. This last sector is supposed to be cool again in mid-June. A review of the powering tests is here, from which I gather that discussions are underway about possible ways of speeding up the process for the other sectors, including the possibility of running the machine at 5 TeV rather than 7 TeV during its first year. This would evidently allow a quicker commissioning, avoiding time-consuming quenchings of the magnets that are part of testing them at the highest currents. The Resonaances blog has a report of a talk by Lyn Evans at Moriond this past week, where he describes the possibility of running at lower energy as the currently preferred option, and states that the current plan is for first collisions by the end of August.

For news about recent experimental HEP results, I'm afraid I can't do better than refer you to Tommaso Dorigo for coverage and excellent discussions of a new, more accurate top mass measurement, reports of not very convincing deviations from the Standard model in B-mixing and charm decays, and stringent new limits on WIMPs that make SUSY more unlikely.

For other news about particle detectors, it appears that perhaps at some point in the future, one will be built into every memory chip made, to guard against errors caused by cosmic rays.

Update: For a KITP talk on the current state of the LHC and prospects for the next year or so, by Michael Barnett of ATLAS, see here.

Comments

1. **Alejandro Rivero**
   March 9, 2008

   My understanding is that most of the errors blamed on cosmic rays are really instantaneus lack of power. An ingeneer from west europe, working in my group time ago, was phanatic about putting an extra condensator for each chip in the board.

2. **Hans**
   March 11, 2008

   After you posted aboutthe first schedule, I asked someone i know who was at cern these days. The answer was, that at least cms people told, their estimation would be for cms to give reasonable output data at first in 2010. The one who visited the site, also thought that there is still su much to do, that it won't get ready this year. After pointing the old schedule to him, he asked some cern people and their answer was, that one needs a new schedule.
   This might be the one you are now linking to. They did not give an answer when first collisions will happen. It seems, that there are too many unknowns to put out a reasonable schedule…

The Landscape and the Emperor's New Clothes

March 9, 2008
Categories: Uncategorized

The String Vacuum Project, described as "a large, multi-institution, interdisciplinary collaboration", that has been established over the last few years, is having its Kick-Off Meeting next month at the University of Arizona. This group had submitted grant proposals to the NSF for funding of such a project in the past, but I don't know if they ever managed to get NSF or other funding. They motivate the project by claiming that

> Given that relatively large numbers of string vacua exist, it is imperative that string phenomenologists confront this issue head-on…

In this context "relatively large" involves numbers like 10^{500}, 10^{1500}, etc.

Bert Schellekens has a web-site devoted to promoting the Anthropic Landscape, where he argues that

> The String Theory Landscape is one of the most important and least appreciated discoveries of the last decades.

Besides the web-site, he has slides from two general talks on-line (here and here). In the talks he compares string theorists to the famous Emperor parading in no clothes, except what he is criticizing is those string theorists who have been unwilling to acknowledge the existence and importance of the anthropic landscape. He's critical in particular of

> those people claiming that they have always known that String Theory would never predict the standard model uniquely, but that they did not think this point was worth mentioning.

His modernized version of the fable of the Emperor goes as follows:

> Many years ago, there lived some physicists who cared much about the uniqueness of their theories. One day they heard from two swindlers that they could make the finest theory which was absolutely unique. This uniqueness, they said, also had the special capability that it was invisible to anyone who was stupid enough to accept anthropic thinking.
>
> Of course, all the townspeople wildly praised the magnificent unique theory, afraid to admit that anthropic thoughts were inevitable, until Lenny Susskind shouted:
>
> "String theory has an anthropic landscape"

It's not clear who he would identify as the "two swindlers"….

According to Schellekens, the "string vacuum revolution" is on a par with the other string theory revolutions, but most people prefer to overlook it, since it has been a "slow revolution", taking from 1986-2006. The earliest indications he finds is in Andy Strominger's 1986 paper "Calabi-Yau manifolds with Torsion", where he writes:

> All predictive power seems to have been lost.

and in one of his own papers from 1986 where the existence of 10^{1500} different compactifications is pointed out.

Schellekens claims that "string theory has never looked better", but he completely ignores the main question here, the one identified by Strominger in 1986 right at the beginning. If all predictive power is lost, your theory is worthless and no longer science. What anthropic landscape proponents like him need to do is to show that Strominger was wrong; that while string theory seems to have lost all predictive power, this is a mistake and there really is some way to calculate something that will give a solid, testable prediction of the theory. The String Vacuum Project is an attempt to do this, but there is no evidence beyond wishful thinking that it can lead to a real prediction. Schellekens has worked on producing lots of vacua and describing them in a "String Vacuum Markup Language", and in his slides describes one construction that involves 45761187347637742772 possibilities. These possibilities can be analyzed to see if they contain the SM gauge groups and known particle representations, but this is a small number of discrete constraints and there is no problem to satisfy them. The problem is that one typically gets lots and lots of other stuff, and while one would like to use this to predict beyond-the-SM phenomena, there is no way to do this due to the astronomically large number of possibilities.

He lists goals for the future ("Explore unknown regions of the landscape", "Establish the likelihood of SM features", "Convince ourselves that the standard model is a plausible vacuum"), but none of these constitutes anything like a conventional scientific prediction that would allow one to test to see if what one is doing has any relation to reality. In the end, he comes up with the only real argument for the String Vacuum Project and other landscape research, that of wishful thinking:

> … and maybe we get lucky.

Update: There's a story about the String Vacuum Project in this week's Nature by Geoff Brumfiel. It includes skeptical comments from Seiberg and yours truly, as well as Gordon Kane's claim that:

> evidence supporting string theory could emerge "within a few weeks" of the 's start-up.

Update: At the blog Evolving Thoughts, there's a discussion of whether theoretical physicists have now taken up a "stamp-collecting" model of how to do science. I point out that this is stamp-collecting done by people who don't have any stamps, just some very speculative ideas about what stamps might look like.

Comments

1. **Eric**
   March 9, 2008

   The point has been made many times already, but I guess it has to made again that even with the vast landscape of vacua in string theory, this does not mean that all predictive power is lost. All one has to do is find the particular vacuum which describes our universe, and it will allow an understanding of all phenomena that we can observe. I might add that this is the end-goal of the string vacuum project.

2. **Tim**
   March 9, 2008

   Please: at least with 10^500 possible vacua we have some multiple of 10^500 new SF stories, some of which may win prizes!

3. **Eric**

March 9, 2008

Tim,
At least 99% of the 10^500 possible vacua are complete garbage and can be ruled out easily. Thus, the regions of the landscape for which realistic vacua may arise is limited. If string theory is the right theory, then at least one of these vacua is our universe and it can be found with a focused effort.

4. **Peter Woit**
March 9, 2008

Eric,

Strominger's point back in 1986 was that predictivity is lost because, at the accuracy to which you can calculate anything, finding a vacuum state that agrees with the SM is useless for predictions since there will be lots of them. You can't use any of them to make real predictions of new phenomena, because if experiment disagrees with your "prediction" of something new, you just pick a different state.

If you think Strominger is wrong, you need to come up with a well-defined proposal about how you are going to make a real, testable, convincing prediction. No one has done that because it can't be done. The argument being made by the SVP people seems to essentially be: let's just compute lots of stuff, and maybe a miracle will happen, something will pop out that looks just like new things we see at the LHC. There's no way to prove this is impossible, but it's pure wishful thinking, not science.

5. **Peter Woit**
March 9, 2008

Eric,

Once you rule out the 99% garbage, you're left with 10^498 vacua to study….

6. **Eric**
March 9, 2008

Peter,
This may have been the situation back in 1986. However, today we have better calculational tools and we have a much better understanding of how to calculate gauge couplings, Yukawa couplings and so on. Central to this issue is moduli stabilization which had not even been addressed in 1986. The requirement that all moduli be stabilized is actually quite difficult to achieve. However, if someone constructed a model with the standard model in the low energy limit with absolutely all moduli stabilized then one would have to take it very seriously. Indeed, if all moduli are stabilized then the values of all couplings are fixed and can be compared with experiment.

7. **Peter Woit**
March 9, 2008

Eric,

The fact of the matter is that you couldn't calculate Yukawas reliably in a realistic model back in 1986, you still can't, and there is no realistic prospect of being able to do so in the forseeable future, or ever for that matter. The calculations the SVP people are doing are of things like the gauge groups and representations of low-lying states. Here's a recent quote from Mike Douglas:

"none of us believe we will be able to compute these masses from first principles in any model anytime soon"

see the first page of

http://www.physics.rutgers.edu/~mrd/svp-mar07.ps

8. **Eric**
March 9, 2008

Peter,
Regarding your statement about the Yukawas, I beg to differ. We most certainly know how to calculate them in Type II compactifications. For example, see hep-th/0302105. Again, the problem is uniqueness which brings us back to the moduli stabilization issue.

9. **Jean-Paul**
March 9, 2008

The number of string vacua most commonly quoted is 10^500, so Bert's 10^1500 was wrong by 1000 orders of magnitude. No doubt, it secures him a place in the history of physics.
It is really unbelivable that anybody can take SVML or the idea of "classifying" or "studying" all these vacua seriously. Just wait and see who shows up in Tucson…

10. **Peter Woit**
March 9, 2008

Eric,

I think Mike Douglas actually does know what he is talking about on this issue. Perhaps you can try arguing this with him and let us know the results.

The paper you point to gives nothing like a realistic model in which the low-energy Yukawa terms that determine particle masses can be calculated reliably, to an accuracy that would allow confrontation with experiment. This was the case for the compactifications and attempts to compute Yukawas considered back in 1986, and this hasn't changed.

11. **Eric**
March 10, 2008

Peter,
Douglas's statement about not being able to calculate masses from first principles is not exactly equivalent to saying once cannot calculate Yukawa couplings. I agree that it's unlikely that we'll be able to calculate the exact number for the mass of the electron anytime soon. However, we can calculate the ratio of the masses of the elementary particles to each other.

12. **Shantanu**

March 10, 2008

Peter, here is a link to 2 recent public talks on string theory at
here

13. **Thomas Larsson**
March 10, 2008

Maybe this quote from Polchinski can give us a hint who the two swindlers might be:

"In fact in string theory there is a cult of `monovacuism,' whose prophet resides in New Jersey (or possibly in the office below mine), "

14. **Chris Oakley**
March 10, 2008

OK – so either you believe in String Theory with an Anthropic Landscape or you believe in String Theory with a unique vacuum. I think that covers the universe of possibilities.

15. **Tony Smith**
March 10, 2008

Peter said that he does not "… know if they [String Vacuum Project] ever managed to get NSF or other funding …".

The web site for the SVP "… Kick-Off Meeting … at the University of Arizona …" says in part:
"… Some NSF support is available for participants … This meeting is supported in part by the US National Science Foundation …"
so
it seems that the NSF indeed has deemed SVP to be worthy of funding, and has awarded funds.
That should not be surprising, considering that the three "Meeting Organizers" are listed on that site as
"Keith R. Dienes, University of Arizona
Gordy Kane, University of Michigan
Stuart Raby, Ohio State University"
all of whom are very prominent members of the USA theoretical physics establishment.

Tony Smith

16. **Peter Woit**
March 10, 2008

Tony,

What's not clear to me is whether the NSF funding for this conference is new funding specifically for the SVP, and that's what the "kickoff" is about, or whether this is just being funded out of an older grant of one of the organizers.

17. **King Ray**
March 10, 2008

String theory needs to be taken off life support. Does it have a living will?

18. **Another Anon**
March 10, 2008

Hi Eric,

My understanding was that it's slightly misleading to claim that Yukawa couplings can be calculated, at least in traditional heterotic compactifications – because although one can evaluate the integrals on particular (very symmetric) Calabi-Yaus, to compare with experiment one needs to do a field redefinition so that the kinetic terms are canonical, which one cannot do without knowing the metric on the Kahler moduli space. And the latter is not protected by supersymemtry. As far as I understand not so much is known about these metrics, except that in certain cases they must be quaternion-Kahler, and that various people are working on ways to calculate the quantum corrections more efficiently (Rocek for example).

So it seems that even in the best cases where the CY is symmetric enough to calculate some Yukawas (or at least show that lots vanish), one can't calculate particle masses or ratios thereof.

Am I wrong about this?

19. **Coin**
March 10, 2008

So Eric, I am just trying to understand– when Schellekens says on his website that the String Theory landscape "implies a fundamental non-uniqueness of the gauge theory underlying the Standard Model", do you disagree with this statement?

20. **Eric**
March 10, 2008

Another Anon,
I'm not that familiar with Yukawa couplings in heterotic models. However, from hep-th/0601204 it does appear that one may calculate them. In the case of type IIA compactifications, there is certainly no difficulty in calculating them, at least for toroidal orientifolds.

Coin,
At present, the SM gauge group does not appear to be uniquely singled out. It is actually quite possible that the physics of our universe was by random choice, but at this point nobody really knows. I don't think string theory in it's current form can answer this question.

21. **Trent**
March 10, 2008

Peter,

Somebody above referred to this message from Polchinski http://groups.google.com/group/sci.physics.strings/msg/4c20c2a7d88d6e21 but left out the final sentence:

"I would like this [a unique vacuum] to be true, but scientists are supposed to be immune to believing something just because it makes them happy."

In other words, your insistence on a unique vacuum, or theory of everything with a unique solution is, well, wishful thinking. For this to note we don't need Polchinski but I find it amusing that he points it out so clearly.

Now that we are at it, what are your reasons for believing in a unique theory with a possibly unique solution as the right description of our world other than wishful thinking? Nothing short of knowing the future will make your arguments anything else than wishful thinking.

22. **Peter Woit**
March 10, 2008

Trent,

I have no idea whether an ultimately successful unified theory will have a unique vacuum or not. But I do know that a successful scientific theory will make distinctive testable predictions that will allow us to figure out whether it is right.

My only claim is that the multiverse, string anthropic landscape, etc. is not science but nothing more than an excuse for failure. It predicts nothing, and inherently can predict nothing. This is a conventional way in which speculative ideas fail, the only unconventional thing here is that the people involved refuse to admit what has happened.

23. **Trent**
March 10, 2008

Peter,

I do make an effort to understand you, but I really can't.

On the one hand you say that it's wishful thinking to hope that the string guys will find a vacuum that contains the SM at low energies and on the other hand you say that the whole approach is meaningless because it's not predictive.

Make up your mind! Is it just difficult to study all string vacua? Or it's not science because it's not predictive? These two things are not the same and you keep jumping between the two back and forth as you see fit.

24. **Another Anon**
March 10, 2008

Hi Eric,

From the end of the Braun, He, Ovrut paper you refer to:
"Of course, to explicitly compute the quark/lepton masses one needs, in addition, the Kahler potential, which determines the correct normalization of the fields."
Sure – you can compute on tori, and orbifolds. I guess maybe you can also calculate normalized Yukawa couplings on families CY 3-folds where there is a Gepner point, which gives you an exact solution to normalize the fields.

You agree that these are very special cases though – right?

March 11, 2008

Trent,

First of all, I don't know at what level to try and discuss this with you. What exactly is your background in this subject?

You keep ascribing arguments to me that I don't make, and ignoring the ones I do make. Please read what I actually write and make an honest attempt to understand it.

No, I've never argued that the string guys will not find a vacuum that contains the SM. What I have repeatedly argued is that attempts to construct vacua that reproduce even the gross features of the SM lead to such complicated constructions that you lose all predictivity.

It is both difficult to study "string vacua" since they are so complex (by construction, the simple ones disagree with experiment), and studying them is not science since there is no reasonable hope of ever getting a prediction out of them. They are the end point of a 25 year old research program which found that simple versions of the idea don't work, so you have to go to more and more complicated ones, never actually getting any closer to a real scientific prediction. At the end point you have a complicated and useless mess. This is often what happens when you pursue wrong ideas, there is nothing unusual about reaching such an endpoint when you pursue a wrong idea, all that is unusual is the refusal to admit failure.

26. **Chris Austin**
March 11, 2008

Hi Peter,

As a regular reader of your blog, which I find very useful for the information content, (from your blog I learned about Resonaances, from where I learned about the CERN BSM Institute, which enabled me to visit CERN for a week last summer), I have to say that I understand Trent's point of view.

I am sure you will agree with me that whatever the true fundamental theory of physics is, it must lead to an extraordinarily rich range of phenomena, from simple and economical foundations. And M-theory has done exactly that, to a degree that is unprecedented and completely unrivalled, and indeed was previously unimagined. Moreover, arguments have been put forward that somewhere among the vast number of effectively isolated vacua in the "landscape", there will be some that match the physical world we live in.

If, in fact, we do live in one such effectively isolated M-theory vacuum, then our task must be to find out which of these vacua we live in, starting with coarse characterizations, such as, does it have TeV-scale gravity or not? Is it based on Horava-Witten theory or type IIB or type IIA? Is the compact six-manifold Calabi-Yau, or is it some other type of compact spin six-manifold? Answering these questions, by means of input from both theory and experiment, and pinning down further details of the vacuum we live in, might then help us to answer questions of fundamental practical significance. For example, will it ever be possible and practical to build a space vehicle that can accelerate to about ten percent of the speed of light over the course of a year, travel to the nearest star outside the Solar System over the course of about fifty years, and decelerate at the other end over the course of another year, without consuming a significant fraction of the material in the Solar System as fuel in the process? And if so, how large will such a vehicle be, and what will it be like?

One of the organizers of the Tucson meeting is Keith R. Dienes, who in his paper arXiv:hep-th/0602286 dealt a major blow to the expectation that the existence of a very large number of vacua means that some of them will have a very small cosmological constant. Among the 10^5 vacua studied in this paper, Dienes found a large degeneracy among the different models with regard to the value of the cosmological constant, so that only relatively few different values of the cosmological constant were realized. Both positive and negative values of the cosmological constant were found, but none of the models had zero cosmological constant, and the smallest magnitude cosmological constant found was about 0.02.

If the type of cosmological constant degeneracy identified by Dienes occurs among other types of M-theory vacua, then even the existence of 10^500 vacua would not be sufficient to guarantee that some of the vacua have cosmological constant around 10^-120, so it would seem to be important and useful to investigate this question for the various types of M-theory vacua.

Some of the different types of M-theory vacua have implications for the LHC. In particular, those with TeV-scale gravity certainly do, and there are a number of different realizations of TeV-scale gravity in M-theory, not just RS versus ADD, since there are a number of qualitively very different realizations of ADD in M-theory, with distinct signatures for the LHC. Comparing the predictions of as many different such models as possible, with the LHC data, should help to point in the direction of the correct vacuum.

Best regards,
Chris

27. **Chris Oakley**
March 11, 2008

Hi Chris A,

You forgot to insert the qualifier “if one believes in String Theory” at about six different points in your comment above.

28. **chris**
March 11, 2008

Hi Chris A,

just one question: could you please point me to one reference that defines what M-theory actually is?

thanks.

29. **Peter Woit**
March 11, 2008

Chris A.,

Thanks for writing, although I disagree with you strongly on several points.

1. We don’t actually know what “M-theory” is, all we know is that there probably is some interesting structure that plays the role of such a theory. The underlying structure may not be either simple or useful for unifying physics using extra dimensions.

2. It’s fine to make the hypothesis that we live in a string vacuum and investigate its implications. But thousands of people have been doing this for nearly a quarter century and the results are in. Simple constructions of such vacua don’t look at all like the real world. To get something closer and closer to the real world, you have to invoke more and more complicated constructions, at no point ever finding something constrained enough to convincingly explain the origin of any features of the SM we don’t understand. This is just a classic example of what happens when you follow a failed speculative idea. Instead of acknowledging this failure, people are promoting a research program based purely on wishful thinking that something unexpected is going to turn up, even though the whole thing looks hopeless.

3. Even if you could show that known vacua can’t possibly give a small enough CC (and I don’t for a minute believe this is possible), this would not cause people to give up on M-theory, just to say that more vacua must be found and investigated.

4. If you want to argue that we need more new ideas about signatures for the LHC to look for, I’d agree. I just don’t see the kind of constructions the SVP is promoting as giving anything new here. I don’t at all buy your idea that the agenda for particle physics in the next few years will be to compare LHC data to complicated string vacua constructions. The hope that the LHC is going to produce lots of deviations from the SM that correspond to characteristics of string vacua showing up all of a sudden at the TeV scale seems to me pure fantasy and wishful thinking.

30. **Urs Schreiber**
March 11, 2008

> could you please point me to one reference that defines what M-theory actually is?

Perturbative string theory is the investigation of the implication of replacing in the perturbative expansion of quantum field theory the Feynman diagrams, which are correlators of a 1-dimensional QFT, by correlators of a 2-dimensional QFT.

It turns out that many 2-dimensional QFTs have a close “holographic” relation to 3-dimensional QFTs (the most famous example being the relation between 2-dimensional WZW theory with 3-dimensional Chern-Simons theory).

Generally speaking, “M-theory” is the name given to a hypothetical theory which people seem to keep finding indications for, and which is supposed to be to String theory roughly like these 3-dimensional QFTs are to the 2-dimensional QFTs.

More strictly speaking, whenever you see people actually doing something in what they address as “M-theory”, they are studying the action functional of 11-dimensional supergravity subject to a couple of constraints which generalize the old Dirac quantization constraint of electric and magnetic charges.

Also, whenever you see somebody talk about “M-theory vacua”, he or she is talking about this concrete issue: 11d sugra + quantum constraints.

Possibly the best text on 11d SUGRA is the old textbook by Castellani, D’Auria and Fre, “Supergravity and Superstrings: A geometric perspective”.

The possibly best discussion of those “quantum constraints” is due to Freed, Hopkins, Singer et al.

D. Freed Dirac Charge Quantization and Generalized Differential Cohomology

M. Hopkins, I. Singer Quadratic functions in geometry, topology,and M-theory

There is of course (as always) much more that people are considering. But if you know 11d sugra + Dirac quantization as in the above sources, you have a pretty good idea of what most of the stuff referred to as “M-theory” is about.

31. **Kea**
March 11, 2008

Urs, surely by now it has occurred to you that many of the anti M Theory comments on this blog are rather tongue-in-cheek, and one should probably not assume that the writer, whose comments above suggest at least a little familiarity with the literature, is ignorant of the oft used meaning of the term *M Theory* as a theory in 11 classical dimensions, a theory which in itself does not satisfy the criteria of the real M Theory.

32. **Chris Austin**
March 13, 2008

Hi chris and Peter,

Sorry for the delay in responding. On the definition of M-theory, I pointed out in the introduction and subsection 2.3.3 of arXiv:0704.1476 that the simplest and most economical hypothesis, namely that on a smooth uncompactified background, M-theory and d = 11 supergravity are the same thing, is consistent with all results in the literature, and moreover appears to be required by the apparent absence from the supermembrane mass spectrum of any states other than the single particle and multi-particle states of supergravity, (section 12 of de Wit, arXiv:hep-th/9902051).

This working hypothesis states that on a smooth uncompactified background, the predictions of M-theory are to be calculated from the CJS theory of d = 11 supergravity in the framework of effective field theory, (which in this case simply means BPHZ renormalization, since there are no massive states to integrate out), and that this will lead to unambiguous results, with all finite counterterms fixed uniquely by Slavnov-Taylor-Zinn-Justin identities, (and thus no undetermined parameters connected with the short distance completion of the theory). The content of this hypothesis, which is consistent with all results in the literature, is thus that the CJS theory does not admit any non-trivial locally supersymmetric higher derivative local deformations.

Deser and Seminara, in arXiv:hep-th/9812136 and arXiv:hep-th/0002241, and Metsaev, in arXiv:hep-th/0410239, constructed a family of \partial^{2n} R^4 linearized on-shell invariants, which if they could be extended to fully non-linear on-shell invariants, would invalidate the above working hypothesis. In d = 4, it was found that such linearized invariants could always be extended to fully non-linear invariants by the Noether procedure, but the existence of the auxiliary field formalisms in d = 4 implies that this must necessarily be so. In d = 11 there is no analogous auxiliary field formalism, (Rivelles and Taylor, Phys. Lett. B121, 37-42, 1983), and the Noether procedure is known to fail if one tries to use a six-form gauge field instead of a three-form, (Nicolai, Townsend, and van Nieuwenhuizen, Lett. Nuovo Cim. 30, 315, 1981). The Deser-Seminara-Metsaev linearized invariants have not yet been completed to fully non-linear on-shell invariants, although partial completions exist, and the above working hypothesis implies that there will be an obstruction to full completion.

Superspace counterterms have been constructed in standard d = 11 superspace by Duff and Toms (in Ellis and Ferrara, eds., 1983, see SPIRES), and Howe and Tsimpis (in arXiv:hep-th/0305129), and if the gauge completion mapping that matches the geometrical transformations in superspace to the CJS supersymmetry variations could be completed up to the necessary power of \theta, which in the Duff and Toms case is \theta^{32}, for a general solution of the CJS field equations, then these superspace counterterms would give fully non-linear on-shell higher derivative invariants for the CJS theory, and thus invalidate the above working hypothesis. However the gauge completion mapping is only known for a general solution of the CJS field equations at first order in \theta, (Cremmer and Ferrara, Phys. Lett. B91, 61, 1980), and partly at second order in \theta, (de Wit, Peeters, and Plefka, arXiv:hep-th/9803209). I suggested in the introduction to arXiv:0704.1476 that an obstruction might exist that prevents the geometrical transformations in superspace from matching the CJS supersymmetry variations for a general solution of the CJS field equations beyond a certain power of \theta. This would mean that the superspace counterterms do not result in locally supersymmetric deformations of the CJS theory, and would thus be consistent with the above working hypothesis. There is already a partial proof of the existence of such an obstruction to gauge completion, in the shape of a discrepancy between a component framework calculation of Hyakutake and Ogushi, arXiv:hep-th/0601092, and the superspace construction of Howe and Tsimpis. Howe and Tsimpis found that there should be an independent on-shell superinvariant for each independent Chern-Simons term, of which there are two at dimension 8, namely C \wedge tr(R \wedge R \wedge R \wedge R), and C \wedge tr(R \wedge R) \wedge tr(R \wedge R), but Hyakutake and Ogushi found that only one linear combination of these two terms might occur in a superinvariant, namely the combination which occurs in the bulk Green-Schwarz term. However, there are gaps in this proof, because Hyakutake and Ogushi omitted some possibly relevant terms from their ansatz, namely the third type of term in their equation (4.3), and Howe and Tsimpis have not published the full details of their argument, and it is not clear how firm their claims are. If these gaps could be closed, the existence of an obstruction to gauge completion would be proved.

The way in which the Green-Schwarz action for the type IIA superstring arises from the solitonic membrane of d = 11 supergravity was described by Horvava and Witten in subsection 2 (iii) of arXiv:hep-th/9510209, and I reviewed this argument, with some details added, in subsection 2.3.3 of arXiv:0704.1476. That there is no place for a fundamental supermembrane in d = 11, separate from the solitonic membrane, was already shown by Hull and Townsend in section 7 of arXiv:hep-th/9410167. The supermembrane action instead arises from d = 11 supergravity, as the worldbrane effective action of the solitonic membrane, in the double dimensional reduction from which the Green-Schwarz action for the superstring arises.

The above working hypothesis places the type IIA superstring in a classic strong / weak coupling duality relationship with a known, but very special, quantum field theory in eleven dimensions, namely the CJS theory. On ten extended dimensions times a circle of large radius L, the dimensionless gravitational coupling associated with the circle, namely \kappa^{2/9} / L, is weak, the solitonic membrane is dynamically unimportant, the superstring coupling constant, namely L^{3/2} / \kappa^{1/3}, is large, and the dynamics is most conveniently described by the CJS theory, but when L shrinks to become small compared to \kappa^{2/9}, the situation is reversed.

For M-theory on a non-smooth background, the most interesting case is Horava-Witten theory, and here we can again adopt a working hypothesis that the predictions of the theory are to be calculated from the Horava-Witten action in the framework of effective field theory, with the resistance to deformation of the CJS action preventing the occurrence of undetermined parameters connected with the short-distance completion of the theory. The \delta(0) terms in the action and transformation rules found by Horava and Witten have been avoided in the improved form of Horava-Witten theory proposed by Moss in arXiv:hep-th/0308159, arXiv:hep-th/0403106, and arXiv:hep-th/0508227. A critical test, directly relevant to the LHC, will be to check that the masses of U(1) gauge bosons resulting from Witten’s Higgs mechanism, (Witten, Phys. Lett. B149, 351-356, 1984), work out to be finite and nonzero, since these masses initially appear to be infinite in Horava-Witten theory, as explained near the beginning of section 5 of arXiv:0704.1476.

Some of the above points were made in my talk at CERN on 28 August last year, see pages 16 – 20 and 12 – 13 of the slides, from
http://indico.cern.ch/conferenceDisplay.py?confId=19188

Best regards,
Chris

33. **Henry**
March 13, 2008

Chris A, thanks a lot for your comment and these references!

34. **Coin**
March 13, 2008

Hi Urs/Chris A.,

Not knowing as much about string theory as some of the other commenters here, I am curious. In your posts, you describe M-Theory as simply the study of 11-D SUGRA. This is an interesting way of looking at things, but there is one point that confuses me. Other descriptions of M-Theory that I have seen, and my observations of M-Theory when I hear about people researching it in practice, indicate that much of the actual study of M-Theory is concerned with n-dimensional vibrating objects, where these objects are called "strings" if n=1 and "branes" if n>1.

I can understand why one would choose to use strings if one's goal is the study of 11D Sugra– since the graviton can be viewed as a string excitation mode, etc– but, if M-theory is as you say just the study of 11D Sugra, then I am confused where the branes come from. In what way do (n>1)-branes follow from this depiction of M-theory as in some way derived from 11D Sugra?

(Also Eric, thanks for your clarification above.)

35. **Urs Schreiber**
March 13, 2008

> In what way do (n>1)-branes follow from this depiction of M-theory as in some way derived from 11D Sugra?

Chris Austin briefly mentioned it above: the 11-dimensional theory automatically contains

2-branes

and their magnetic duals, which are

(11-(2+2))-2 = 5-branes .

These are called the

M2-brane

and the

M5-brane.

The 10-dimensional backgrounds for string theory are obtained roughly by shrinking one of the 11 dimensions away.

Those M2-branes which didn't "wrap" the compactified dimension remain 2-branes this way. They are called

D2-branes

then.

M5-branes that don't wrap remain 5-branes and are called

D5-branes

then.

M2-branes that did wrap the compactified dimension become effectively 1-branes and are called

F1-branes

now, also know as

the fundamental string.

(That THE string, yes.)

M5-branes that wrap become D4-branes.

This way (and by some further mechanism) all the brane content of the 10-dimensional theory arises from the 11-dimensional theory.

36. **Urs Schreiber**
March 13, 2008

Sorry, the "D5-brane" should have been the NS 5-brane.

37. **Peter Woit**
March 13, 2008

Chris et. al.,

As far as I can tell, Chris is proposing a series of unconventional ideas about M-theory. This topic doesn't have anything to do with the topic of the posting, I'm no expert on this, and this is not a general physics discussion board. Please, if you want to discuss Chris's ideas about M-theory with him, contact him directly.

38. **dan**
March 13, 2008

Peter,

in response to #2 " It's fine to make the hypothesis that we live in a string vacuum and investigate its implications. But thousands of people have been doing this for nearly a quarter century and the results are in. Simple constructions of such vacua don't look at all like the real world. To get something closer and closer to the real world, you have to invoke more and more complicated constructions, at no point ever finding something constrained enough to convincingly explain the origin of any features of the SM we don't understand. This is just a classic example of what happens when you follow a failed speculative idea. Instead of acknowledging this failure, people are promoting a research program based purely on wishful thinking that something unexpected is going to turn up, even though the whole thing looks hopeless."

Couldn't nature though really be like this? Perhaps nature itself really is the result of one form of string, theory, one choice of string vacua, one compactification among 10^500, one scale of SUSY breaking, and is simply not fundamentally possible for physics to do any better, and is inherently unpredictable.

Regards,
Dan

39. **woit**
March 13, 2008

Dan,

Sure, it's logically possible that nature is like this. It's also possible things are fundamentally just random choices of some Supreme Being. While these hypotheses are logically possible, they're not scientific hypotheses, because they are inherently untestable. The problem with the landscape is not that it's logically impossible, but that it appears to be impossible to ever use the idea to make testable predictions. The people who argue for the Landscape seem to me to just be hoping a miracle will happen and somehow a testable prediction will emerge, despite all the accumulated evidence that there is no sign of such a possibility. If your speculative idea not only make no predictions, but you can't even come up with a plausible scenario of how further work on it will lead to predictions, it's just not science.

40. **Marty Tysanner**
March 14, 2008

Dan,

Although I agree with what Peter wrote, I think there is an additional way that you can look at anthropic considerations as a selection principle. Take, for example, quantum electrodynamics. In QED it is impossible to predict an actual number for either the electromagnetic coupling strength or the electron mass; these are "inputs" to QED. Unfortunately, their prediction is made impossible due to renormalization, a procedure that is used to cancel infinities that arise when one wants to do more accurate calculations in the theory. If one took the point of view that QED is a truly fundamental theory, then one would be forced to say that there is no *a priori* choice of the two parameters, and look for other explanations for why they have the values they do.

You could propose that the explanation for the values of the electromagnetic coupling constant and electron mass could be anthropic, that only certain values would allow us as observers to exist and ask questions and develop QED. You could then quantitatively analyze all possible choices of these two parameters, and probably find out that only certain ranges of values would be compatible with us existing and developing QED. That might give you confidence that you are on the right track, and you might consider your analysis to be evidence that these parameters really are random variables. Then you could end your search for explanations, and just accept that some critical quantities are inherently unpredictable in the final theory, i.e.: that's the way it is, and you just have to deal with it.

However, you could take an entirely different position. You could adopt the view that QED is *not* a fundamental theory, and so the appearance that the coupling constant and electron mass are free parameters is just a reflection that there are crucial ingredients that are missing from the theory, that QED is an incomplete and non-fundamental theory. Then you would keep searching for a better theory with the expectation that QED would emerge as a limiting case of the theory, but that the coupling constant and mass would emerge as predictions of the more fundamental theory.

Comparing these two points of view, there is no way to distinguish which one is correct, given that we don't currently have a theory that predicts the coupling constant or electron mass. All of the anthropic arguments that might look like successes are nothing more than constraints you put on QED; they reflect *observations* about the world that cannot be incompatible with the theory, but a more predictive theory would need to abide by those same observational constraints (or else it is wrong). The fact that we haven't yet found a more predictive theory means nothing more than such a theory is not easy to find from our current vantage point (e.g., we may be unwittingly over-constraining the form that we allow a fundamental theory to take, making it essentially impossible to find that theory while remaining compatible with observation).

In my view at least, anthropic arguments are only worthwhile if they reduce the number of possibilities to a finite and small number of possible solutions, *and* you do not assume that your theory is fundamental. Then you have an interim theory with only a few viable solutions, and you can use it to make predictions that you can subsequently test; the testability makes it science. However, you can't use anthropic arguments as evidence that your theory is fundamental, since the alternative explanation that you haven't yet found the more predictive theory still remains.

41. **dan**
March 16, 2008

Peter, Marty Tysanner,

re: "…..because they are inherently untestable…."

re: "…Take, for example, quantum electrodynamics. In QED it is impossible to predict an actual number for either the electromagnetic coupling strength or the electron mass; these are "inputs" to QED…."

If it were possible somehow to experimentally determine both the scale, mechanism and nature of SUSY-breaking and the specific parameters of the moduli of the calabi-yau manifold of our universe, given these experimentally derived and observed numbers, could they then be used as input for a string theory to see if its "output" (i.e the MSSSM +GR, plus novel predictions or postdictions) be testable and falsifiable. The landscape may well be "inherently untestable", but perhaps the only way to get "predictions" out of string theory is to accept that the specific parameters of higher dimensional space can only be experimentally observed.

42. **Marty Tysanner**
March 17, 2008

Hi Dan,

First your last comment:

> … perhaps the only way to get "predictions" out of string theory is to accept that the specific parameters of higher dimensional space can only be experimentally observed.

This doesn't sound much different in principle than the approach that is used for established theories today, e.g., the standard model of particle physics. The standard model has approximately 20 parameters which are measured (the electron mass and electromagnetic coupling are two of them); once measured, the SM is extremely predictive and very much in agreement with a vast number of experiments, as you already know.

However, taking the widely held view that the standard model is an *effective* theory, not a truly fundamental one, there is no need to explain why its parameters have the values they do; ideally, that would be the job of a more fundamental theory. Depending on your tastes, you could take the view that there is no fundamental theory and the parameters are random variables, or you could assume that a more predictive theory is possible but we haven't found it yet. Both possibilities are logically possible, and as I mentioned before, failure to find that more predictive theory says nothing about whether it is there to be found.

None of this has anything to do with SUSY or compactification of higher dimensions, which you mentioned:

> If it were possible somehow to experimentally determine both the scale, mechanism and nature of SUSY-breaking and the specific parameters of the moduli of the calabi-yau manifold of our universe […]

Certainly, observations by themselves are little more than a collection of literal numbers, pictures, etc. which must organized and interpreted before they carry meaning. For the kinds of experiments you seem to be thinking of, theories play the key role in providing a framework for organizing and interpreting the data. The more "flexible" the theory (i.e., the less predictive it is), the easier it will be to find a way to fit the data, and the less rigid the conclusions you can draw from the fit; this is true in general, not at all specific to the string theory landscape idea.

Assume that a supersymmetric string theory is what you will use to organize and interpret your data, and let's say that it predicts the MSSM plus GR as you said. (In my view, prediction of gravity is not exactly a prediction; the presence of something that looks like gravity was a crucial reason for taking string theory seriously as a "theory of everything" in the first place.) Now you do a number of experiments. If your theory is predictive in the meaningful sense, it should uniquely (i.e., without flexibility) and correctly determine many more experimental values than you used to construct your theory. That is, you want to get more out of the theory than you put into it. Failing that, the theory basically just re-parameterizes what you already know, which is not very impressive.

Nonetheless, even if you have a relatively unique theory that has made robust predictions that were experimentally confirmed (which would be real progress), you still have a lot of unexplained parameters. At this point you are back to the same questions of how to explain them. You still can't scientifically distinguish between the possibility that the parameters are fundamental random variables (i.e., your predictive string theory *is* fundamental), versus the possibility that a more fundamental theory can be found that predicts those parameters uniquely (i.e., your predictive string theory is *not* fundamental), so the arguments in my previous post still apply. You still can't use anthropic arguments to decide whether your theory is fundamental…

43. **dan**
March 17, 2008

Hello, "Marty Tysanner"

I've agreed with what you said. While there would be many unexplained parameters, it could explain what is unexplained in the SM and GR.

While such a theory may not be "fundamental" if we could observe the parameters of the moduli of the 6-dimensional space (or if we live in a large dimensional braneworld) experimentally/observationally and use that data as input and then put them in with the current superstring theories, and we don't get the MSSM + GR, wouldn't this "falsify" string theory, thus making it science?

44. **Coin**
March 17, 2008

if we could observe the parameters of the moduli of the 6-dimensional space… experimentally/observationally and use that data as input…

If we could do this, I think many or most of the people currently complaining that string theory is not science would fall silent, or at least find something else about String Theory to complain about. In fact as near as I can gather, it is specifically *because* no one can observe the parameters of string theory (and even *constraining* those parameters, such as the String Vacuum Project types wish to do, seems to be a great difficulty) that people have started accusing it of being nonscience in the first place.

45. **Marty Tysanner**
March 17, 2008

Hi Dan,

I'm not sure I have correctly interpreted your question, so what follows may not be very helpful.

You mentioned

> While there would be many unexplained parameters, it could explain what is unexplained in the SM and GR.

Sometimes a new theory or perspective can clarify what we know and don't know, but I don't think that is the case here. The parameters of the SM and GR are very specific, and given those parameters the range of those theories is well known. If for some ranges of those parameters the SM or GR break down, that would be extremely interesting and exciting and would probably give clues about a more fundamental theory. But you need experiments to tell you where (or if) the SM and GR have limits of applicability. Theories are generalizations, extrapolations, or interpolations of what we can observe, so beyond requirements of mathematical/logical and empirical consistency you can't use a new theory to tell you that the SM or GR will break down in some regime; you must qualify it with, "If the new theory is true, then…"

I am even less sure I have understood your next paragraph. For example, I don't think anyone would argue that you can observe the moduli; they parameterize the Calabi-Yau manifold, but couldn't themselves be observed or measured because you couldn't step outside our four dimensional spacetime and perform the necessary experiments. Hence you could make only indirect inferences by noting that certain ranges of the parameters are compatible with observations and others aren't; anthropic reasoning would be included here.

> … use that data as input and then put them in with the current superstring theories, and we don't get the MSSM + GR, wouldn't this "falsify" string theory, thus making it science?

First, the MSSM is just one possible extension of the SM. There are no experiments yet which imply that the MSSM (or supersymmetry in general) is part of nature, so it is on a very different footing than general relativity. Assuming you know this, I think you are asking whether everything we have observed experimentally is sufficient in principle to constrain the string theory landscape enough to uniquely predict something new that we can experimentally test. That is where the controversy lies. Peter has argued that if you have an unimaginably large number of valid choices (e.g., 10^500) then, unless you have some way to *a priori* prune that huge number down to a small number, you could have a huge number of theories (i.e., vacua) that each fits all experimentally known (and knowable) values within the limits of experimental precision: your theory ceases to make unique predictions and thus is not testable in the conventional sense. Jacques Distler, on the other hand, has made a fairly specific argument in a spirited discussion on Cosmicvariance that the situation may not be nearly that bad; I think his argument is also reasonable and shouldn't be dismissed, but you should refer to that discussion for some details (the link should be to comment #233, but the complete discussion had more than 500 comments!).

46. **dan**
March 17, 2008

Marty Tysanner,

Coin actually states my intention — would string theory be "predictive" and "falsifiable" if it were possible to observe, experimentally, the values of the moduli? I understand that Peter argues there are an unimaginably large number of possible choices for the vacuum configuration are possible in theory, but if nature is really 11D and SUSY, it has chosen one specific set of values that could, if the technology existed, be observed and measured and recorded. I recognize that it is not evidentially possible to deduce the parameters of these hidden dimensions, even consistency with the SM, MSSM, and GR in the low energy LHC & TEV range does not constrain the theory enough. But if there could be observational/experimental measurements, I understand that "no one can observe the parameters of string theory" but is it less science if the technology does not exist to access and measure the parameters of these hidden dimensions?

47. **Anonymous**
March 18, 2008

"I understand that "no one can observe the parameters of string theory" but is it less science if the technology does not exist to access and measure the parameters of these hidden dimensions?"

Do these parameters make their presence felt in string-scattering amplitudes?

48. **Peter Woit**
March 20, 2008

dan/Anonymous,

The problem is that no one is able to, for any even slightly realistic string theory models, compute the relation between observable quantities (eg masses and mixing angles) and things like moduli parameters that specify the model. This has been the case since string theory became popular, there is no reason to believe it is going to change.

49. **Dan**
March 20, 2008

re:Peter,

Well if that's true, and if it will remain true in the foreseeable future, string theory is indeed "NEW".

Regards,
Dan

50. **hv**
March 21, 2008

The Monster group has nearly 10^54 elements. Creating a multiplication table for the Monster would describe it completely. Such a table would have nearly 10^108 entries, however. Nonetheless, Griess showed *by hand* that the Monster, in fact, is the automorphism group of a 196884-dimensional commutative nonassociative algebra, and many important discoveries involving the Monster followed, despite it's size. So, who can really say that understanding the Landscape fully will be forever out of reach? It might just need a simple genius move, and if numerical analysis helps finding patterns in the Landscape, let them do it! I attended some seminars on numerical landscape analysis, and the results seem quite nice and sometimes intriguing. And what I've understood is that most of the vacua can be easily ruled out and that it seems that only very few Calabi-Yau possess interesting properties (low Betti numbers, etc) to make them good candidates for describing Standard Model.

51. **Peter Woit**
March 21, 2008

hv,

One of many problems with your analogy is that the set of elements of the Monster form a finite, simple group, which is an extremely special mathematical structure of a highly symmetric sort. There is simply zero reason other than wishful thinking to believe that anything like this is true of the set of "string vacua".

52. **Urs Schreiber**
March 22, 2008

The monster as well as string vacua share the property that they both are part of the theory of the "space" of 2-dimensional (rational) conformal field theories. There is every reason to believe that this space is a rich and beautiful mathematical entity in its own right.

The main problem about this space is that it is so very little understood that it seems to be just premature to try to do things like statistics over it. Let alone trying to predict particle masses from it.

53. **Peter Woit**
March 22, 2008

Urs,

Besides not knowing what the "space" of 2d CFTs is, the lack of a non-perturbative formulation of string theory means you wouldn't be able to extract physics from it, even if you knew what it was.

54. **Urs Schreiber**
March 22, 2008

I wouldn't mind, if I knew what it was.

Part of the beauty of string theory is that it builds on the notion of 2D CFT, which is a mathematical structure of the kind mathemticians get in love with (like the monster) but bigger. And less well understood. (Well, actually for non-super and *rational* 2-D CFT people have understood a whole lot meanwhile.)

If everybody would just stop worrying about cranking out numbers where no numbers can be cranked out and concentrated again on investigating the basics we'd be in much better shape.

55. **Thomas Larsson**
March 23, 2008

The basics of CFT is well understood; there is no more low-hanging fruit to pick. Moreover, beautiful as this mathematical structure may be, it is not the only conceivable mathematical structure.

Cranking out numbers is important to figure out if it is CFT or some other structure that governs the laws of the universe. The simplest numbers are indeed easy enough to crank out, and they disagree with experiment – spacetime does not have 26 or 10 dimensions, and there are not 496 different gauge bosons. CFT number fit perfectly into 2D statmech, but this only shows its limitations. Whereas one may argue about CFTs beauty in hep, in statphys there is no doubt that it only applies to toy models in 2D, and not to the physically important systems in 3D.

One can learn one thing from these toy models, though. Universality in 2D is explained by CFT, i.e. by the Virasoro algebra. Universality is an empirical fact also in 3D. Therefore, one may suspect that 3D universality has a similar explanation as 2D universality.

56. **curious**
March 23, 2008

Thomas Larsson what do you mean by "universality" in your last comment? What does it mean that universality is explained by CFT in 2D and is an empirical fact in 3D?

57. **Thomas Larsson**
March 23, 2008

Universality in statphys means that similar systems do not just have similar, but identical (or completely different) critical exponents. This is explained in CFT because there is only a discrete set of universality classes (unitary Virasoro representations) in the simplest cases. That universality holds also in 3D is standard lore and has been confirmed by experiments (real and numerical) and various theoretical arguments (epsilon expansion and others).

58. **curious**
March 24, 2008

Thanks, but I guess it was too technical for me. Now I don't know what you mean by systems and their critical exponents.

I guess I want to know what aspect of physical reality "universality" refers to. What kind of experiment could confirm or refute it.

59. **Daniel de França MTd2**
March 24, 2008

It seems LQG people also becoming fond of landscape-like ideas:
http://arxiv.org/abs/0803.2926

Some coments on this paper:

http://www.physicsforums.com/showthread.php?t=223450

60. **Peter Shor**
March 24, 2008

Chris A,

Dienes' paper implies nothing about the existence of small cosmological constants. Anybody who tries to use samples from a probability distribution to estimate its behavior in the low-probability tail is, as von Neumann would say, living in a state of sin. The only way to learn anything about the low probability tail is either to generate an astronomical number of samples or to use theory, both utterly hopeless at this state of the game.

61. **Anonymous**
March 24, 2008

curious, see this:
http://en.wikipedia.org/wiki/Critical_exponent

62. **curious**
March 25, 2008

Thanks, I've got it now. I was aware of various other meanings of the word "universality", but not of this particular meaning until now.

63. **Urs Schreiber**
March 25, 2008

Thomas Larsson wrote:

> The basics of CFT is well understood; there is no more low-hanging fruit to pick.

Right, we are certainly not talking about low-hanging fruit here.

And the space of 2d CFTs is not low hanging fruit and not well understood. Even the more easily accessible subspaces have only been understood rather recently.

One problem is that what many people call CFT is only half of the story: namely "chiral CFT". This is given, equivalently, by

– a vertex operator algebra and its representation category

– a conformal net of local algebras on the line and its representation category .

All things Virasoro live here. But that's not yet a CFT, it just encodes the local symmetry properties of a CFT. In particular, there may be none, one or several non-equivalent full CFTs associated with a given vertex operator algebra.

A full CFT is a representation of the category of conformal 2-dimensional cobordisms such that the infinitesimal neighbourhood of the length 0 cylinder reproduces the given chiral CFT.

In the case that the chiral CFT part is *rational* in that the representation category has finitely many isomorphism classes of simple objects ("primary fields") the "space" of all corresponding full CFTs is essentially understood: there is one equivalence class of such CFTs per Morita class of special symmetric Frobenius algebra objects internal to the representation category.

One may think of that results as “completely solving rational 2d CFT”. But even in that case a problem remains: to connected the Frobenius algebra object with the chiral vertex operator algebra requires a choice of isomorphisms between the vector spaces associated by the Reshitikhin-Turaev functor to given surfaces and the space of conformal blocks of that surface given by the VOA.

That isomorphism is explicitly known only in a few simple cases.

But already at this point, lots of nice structure appears. Practitioners I know think of rational 2d CFT as a generalization of group representation theory.

And the structure of the proof for the result of the rational case indicates what one should expect more generally. So now the question is how to generalize the proof to

– non-rational

and to

– supersymmetric

2dCFTs. It is clear that we expect to see again that these are given by certain Frobenius algebra objects in certain VOA representation categories. But now there are technical details to deal with, since in lots of places where we have finite sums appearing in the rational case, the non-rational case, naively, leads to infinite sums. (Not those kind of infinite sums one sees in perturbative QFT, though.)

64. **Urs Schreiber**
March 25, 2008

Thomas Larsson wrote:

> spacetime does not have 26 or 10 dimensions,

Bosonic 2d CFTs of central charge 26 correspond to effective target spaces which are 26-dimensional manifolds only in a tiny subset of the space of all such CFTs, namely those that are entirely of the naive sigma-model type with large flat dimensions.

Supersymmetric 2d CFTs of central charge 15 correspond to effective target spaces which are 10-dimensional manifolds only in a tiny subset of the space of all such CFTs, namely those that are entirely of the naive sigma-model type with large flat dimensions.

That there is and has been so much focus on such utterly over-simplistic CFTs as string backgrounds is the problem whose very point we are discussing: the space of all CFTs is little understood and everybody has been searching the key under the lamppost which illuminates only the most elementary examples.

Not that it is guaranteed that the key actually is somewhere else in the currently dark realms of CFT-land, but it is certainly premature to make statements about the shape of the key from what we can find under this tiny spotlight.

To appreciate the situation, it may help to simplify it drastically and marvel at how complicated it still is:

As Roggenkamp and Wendland show, and especially Yan Soibelman describes in a big (unfortunately not yet published) opus, a 2dCFT encodes a categorification (2-dimensional version) of a Connes spectral triple. The effective target space described by the CFT regarded as a string background is the spectral geometry encoded by the point particle limit of that spectral triple. So when we are talking about string backgrounds, we are talking about a vast generalization of ordinary spectral (“noncommutative”) geometry, which itself is a vast generalization of ordinary geometry.

Alain Connes picks a certain spectral triple that encodes a target space which is a weird non-commutative space and argues that it comes close to encoding the standard model. Nobody complains that he picks that spectral triple from a huge “landscape”, namely from the space of *all* spectral triples. Remarkably, his spectral triple has K-theoretic dimension 10. Suppose this arises as the point-particle limit of a 2-spectral triple a la Soibelman, i.e. from a 2dSCFT of central charge 15. Then, clearly, this won’t be of sigma-model type and will not describe an effective target which is a 10-dimensional manifold.

All this mostly shows one thing: we know so shockingly little about the space of all 2dCFTs and yet are used to hearing so shockingly many claims about what it looks like.

So perturbative string theory does not predict that spacetime is 10-dimensional. What it does predict (essentially as its fundamental hypothesis!) is that spacetime is the effective target geometry of a 2dSCFT of central charge 15. That’s all.

10-dimensional manifolds appear here only in the most simple minded examples. Claiming that string theory predicts 10-dimensional spacetime is exactly like claiming that general relativity predicts flat empty Minkowski spacetime. No, it does not. This just happens to be the most simple solution that comes to mind.

Precisely similar comments apply to heterotic models which predict 496 gauge bosons.

65. **Daniel de França MTd2**
March 25, 2008

“10-dimensional manifolds appear here only in the most simple minded examples.” But those are the models that are uniquely said to be truely superstrings. Or at least that is what seems but taking a daily look at hep-th. Some trolle people even troll to say that those are uniquely the true ones. I mean, that’s the impression I take by looking everywhere…

66. **Thomas Larsson**
March 27, 2008

If some structure is physically relevant, it is usually the simplest examples that are the easiest to see in nature. In the application of CFT to 2D statphys, the simplest examples are things like the Ising and Potts models. One could in principle construct systems with arbitrary multicritical behaviour (e.g. RSOS models), but it is almost impossible to realize such systems experimentally when multi >= 6 or so. Similar comments apply to spin (reps of SO(3)) and to the gauge groups in the SM.

Since the simplest CFTs applied to gravity give completely wrong answers, it is a very clear indication that the basic idea is just wrong. But my opinion is of course colored by the fact that I have successfully unified the symmetry principles underlying gravity (4-diffemorphisms) and QM (lowest-energy reps). The resulting theory does not look anything like string theory.

That mathematicians fall in love with some mathematical structure has historically not been a good indicator of the structure’s physical value. Ptolemy and Lorentz (and definitely Poincare) were good mathematicians by the standards of their time, and they may have fallen in love with circles and classical field theory, respectively. This neither proved epicycles nor ether theory, it only made it take longer before people accepted the experimental verdict.

67. **Urs Schreiber**
March 29, 2008

Replies to Daniel de Franca's comment are given here.

68. **nbutsomebody**
March 30, 2008

well, It is not clear why string land scape should be predictive anyway. The best alternative we have to string landscape is a QFT like Standrad model or some extension of it where parameters are anyway put by hand. String theory should be thought as a method of including gravity above the framework of quantum field theory.

But the important problem with String theory is that we have not yet derived Standard Model from string theory and it is not even sure that whether it can at all be done. One may argue that the problem is too easy !!!, as there are many vacuas (may be 10^O(100)), many of them should reproduce the standard model as we know. However, one should keep in mind that in standard model we have a many parameters (about 20?, can't remember now) and most of which is known up to many decimal place. It naively seems that we know standard model also in a very huge accuracy. May be number of string vacuas are much more, but reproducing Standard Model will still be an interesting and significant achievement.

Peter said
"The problem is that no one is able to, for any even slightly realistic string theory models, compute the relation between observable quantities (eg masses and mixing angles) and things like moduli parameters that specify the model. This has been the case since string theory became popular, there is no reason to believe it is going to change."

Can somebody kindly enlight me about the exact reason why mass and mixing angles are not calculable from moduli parameters? May be they can be done numerically with recent advances in numerical constructions of Ricci-flat metric in 3-folds.

2008 Templeton Prize

March 12, 2008
Categories: Uncategorized

The 2008 Templeton Prize was announced today. It goes to Michael Heller, a Polish cosmologist, philosopher and Catholic priest, for "sharply focused and strikingly original concepts on the origin and cause of the universe." The full name of the Templeton Prize is the "Templeton Prize for Progress Toward Research or Discoveries About Spiritual Realities" Its goal is to promote bringing science and religion together by awarding a prize of 820,000 pounds sterling, the single largest award given to an individual. Prince Philip somehow gets into the picture too, since he will be presenting the prize to Heller in a private ceremony at Buckingham Palace in early May.

In recent years Heller has been interested in non-commutative geometry as way to study quantum gravity and cosmology. According to Heller, the crucial question of cosmology is "Can the Universe Explain Itself?", and associated with the awarding of this prize, the Templeton Foundation will be hosting a discussion of the associated question "Does the Universe Need to Have a Cause?".

The Templeton press materials describe Heller as "initiating what can be justly termed the 'theology of science.'" His nomination for the prize says that:

> It is evident that for him the mathematical nature of the world and its comprehensibility by humans constitute the circumstantial evidence of the existence of God.

I'm rather dubious about the way Heller mixes theology, philosophy and cosmology, but, unlike much harder-nosed physicists these days, at least he seems to recognize the problems with the Multiverse.

Heller intends to use the prize money to create a Copernicus Center in Cracow to further research and education in science and theology.

Comments

   March 12, 2008

   Don't forget that the Big Bang Theory was formulated by Abbe George Lemaitre, a Belgian priest and mathematician. So there has been a mix since the beginning.

2. **Steven H. Cullinane**
   March 12, 2008

   According to the New York Times, it's Prince Philip, not Prince Charles, who will do the awarding.

3. **Peter Woit**
   March 12, 2008

   Thanks Steven, fixed.

4. **!?!**
   March 13, 2008

   820,000 pounds? Now I understand the meaning of papers like:

   Does God so love the multiverse? arXiv:0801.0246

5. **chris**
   March 13, 2008

   actually, the paper you refer to makes a lot of sense to me. and i don't find any metaphysical speculations there.

   it's actually kind of funny that these days physicists construct wild untestable speculations about the universe and have to be reminded about the empirical basis by theologists. well, philosophers at least.

   actually, thinking twice, this is rather depressive than funny.

6. **Yatima**
   March 13, 2008

   Not directly related, but in the department of dubious claims we have this:

   Physicists Make Artificial Black Hole Using Optical Fiber

   I can imagine that the mathematical description of an electromagnetic wave in fiber may have some analogue to the equations of a GR static black hole, but still it is *not* a GR black hole.

   "It is much easier to use these objects for observations instead of their astronomical counterparts," says Grigori Volovik of Helsinki University of Technology, in Finland, who has found other analogues of cosmological phenomena in laboratory condensed-matter physics.

   Mistaking the map for the terrain I would say.

7. **anonymous**
   March 14, 2008

   Peter,

   can I just say that as a long time reader of this blog who is familiar with your frustrations, I admire the fairness and restraint that you showed in this post when you wrote:

   "I'm rather dubious about the way Heller mixes theology, philosophy and cosmology, but, unlike much harder-nosed physicists these days, at least he seems to recognize the problems with the Multiverse."

8. **also anonymous**
March 14, 2008

If any of you commenting/blogging had a look at Heller's publication list (or better still, spared a moment to find some of his recent physics publications on arxiv) he would notice M.H. does not "mix" physics and theology – at least in what he himself put in section "physics" – he does both physics and theology. And that is a big difference. The word 'frustration' is quite appropriate in context of this posting, I'm afraid…

9. **Peter Woit**
March 14, 2008

AA,

The writings of Heller linked to from the Templeton web-site very explicitly are a mixture of theology and physics. I doubt that he would object to this kind of characterization, based on his own comments about his intellectual history and interests. I see no evidence at all that he sees theology and science as two completely separate things.

10. **Andy**
March 15, 2008

Anonymous — I don't see any postings of M. Heller on the arXiv. There are a large number of papers by Urs M. Heller, but he is a different person (his institutional affiliation is the American Physical Society in New York).

I must say, however, that M. Heller's critique of the multiverse displayed a rather good understanding of the philosophy of science and of the underlying scientific issues. Certainly he is no Fritjof Capra or Gary Zukav!

11. **Peter Woit**
March 15, 2008

Andy,

There are quite a few papers by Michael Heller on the arXiv, see

http://arxiv.org/find/gr-qc/1/au:+Heller_M/0/1/0/all/0/1

It's true that these papers have no theological component, also true that he has written many other papers explaining how he sees his scientific work as inspired and related to his theology.

12. **Angel**
March 15, 2008

@ all,
The extent to which Heller 'mixes' science and theology is described in detail in his forthcoming book 'A Comprehensible Universe'
See: http://www.springer.com/philosophy/philosophy+of+sciences/book/978-3-540-77624-6

13. **alex**
April 8, 2008

Don't forget that the Big Bang Theory was formulated by Abbe George Lemaitre, a Belgian priest and mathematician. So there has been a mix since the beginning.

Electric-Magnetic Duality on a Half-Space

March 13, 2008
Categories: Uncategorized

The past few weeks I've often been going down to the IAS in Princeton on Thursdays to hear talks given as part of the special program there this semester in mathematics. These talks included a series of five talks by Witten; notes from David Ben-Zvi and Sergei Gukov are available here.

The first three talks concentrated on the existence of a very special superconformal six-dimensional QFT, and information that could be derived from what is known of its properties. Such a theory is an inherently quantum object, lacking a usual sort of classical limit or Lagrangian formulation. Witten compares it to the holomorphic conformal field theory that appear as "square roots" of the WZW model. These field theories are closely related to the representation theory of loop groups and at the core of a several important mathematical developments of the last couple of decades. The mathematical significance of the six-dimensional theory remains much more mysterious, and Witten argues that understanding this mystery is a very worth goal for both mathematicians and physicists. . For more about this, see the article Conformal Field Theory in Four and Six Dimensions, based on his lecture at the Oxford conference in honor of Graeme Segal's 60th birthday back in 2002. Taking the six dimensions to be the product of a torus and a four dimensional space, the existence of such a superconformal six dimensional theory implies an SL(2,Z) symmetry of N=4 Super-Yang-Mills on the four dimensional space. This includes the famous Olive-Montonen non-abelian electric-magnetic symmetry that is responsible for Langlands duality in Witten's 4d QFT approach to Geometric Langlands.

The last two talks of the series dealt with a different topic, boundary conditions in N=4 SYM. Taking this theory on the half-space with boundary conditions, one can ask about the implications of non-Abelian electric-magnetic duality for these boundary conditions. Witten has recently been working on this subject with Davide Gaiotto, he'll be talking about it later this month at a Stony Brook symposium in honor of C. N. Yang and Jim Simons, and I assume a paper will appear sooner or later. In his IAS lectures Witten was talking to mathematicians and arguing that "universal" operations (ones that can be done uniformly for all Riemann surfaces) in geometric Langlands should all come from the properties of these boundary conditions. Note that in this work what appears is the full N=4 SYM theory, not just the topological twisted version. This theory plays a central role in AdS/CFT, so if new information about its physics arises from this study, this should be directly interesting for physics, although Witten did not discuss this in his talks.

The two sorts of boundary conditions that get related by duality are analogs of Neumann and Dirichlet boundary conditions. The Neumann boundary conditions involve superconformal 3d QFTs, examples of which were studied by Intriligator and Seiberg in their 1996 paper Mirror Symmetry in Three Dimensions. Witten has previously worked on this kind of thing in the Abelian case, see here.

During these visits to the IAS I got the chance to meet Meng-Chwan Tan, who is there in the Physics group this year. He has been working on a different QFT approach to geometric Langlands, one that is purely two-dimensional and based in conformal field theory, using (0,2) sigma models on flag manifolds, and has just posted a the revised for publication version of his paper on the subject here. This is much closer to the approach to geometric Langlands via conformal field theory that Edward Frenkel has described here.

In other geometric Langlands news, there was a workshop on Homological Mirror Symmetry recently in Miami, with notes from many of the talks available here (and a blog posting by Joel Kamnitzer here). And there's another one (notes here from David Ben-Zvi) going on this week at the IAS. I better stop now, go and get some sleep so I can head down there tomorrow morning to catch the last day of it.

   March 16, 2008

   Hi Peter,

   I wanted to mention that as a math grad student who is getting interested in geometric representation theory and related topics, I find your posts on Geometric Langlands to be very informative. I hope you continue to post more on the subject. It is a shame that entries such as this one typically don't generate as many comments as the ones about string theory.

Media Events in Paris

March 15, 2008
Categories: Uncategorized

Tomorrow I'll be in Las Vegas, on my way to southern Utah, so will miss a couple of math-physics media events taking place in Paris. At 2pm on Sunday, Lubos Motl will be appearing at the France Television booth at the Salon du Livre, together with the Bogdanov brothers, to sign copies of his new book L'equation Bogdanov: Le secret de l'origine de l'Univers?. In other Lubos news, I recently heard a rumor that he is now the scientific advisor to the president of the Czech republic.

On Monday, a day-long symposium on the topic of how mathematics and physics are covered in the press will be held at the Institut Henri Poincare. One focus of the symposium is the celebrity exceptional Lie group E8, which last year kicked up media-storms for both the classification of unitary representations of its split real form, and for Garrett Lisi's attempt to use it for unification. Jean Iliopoulos will be speaking on the topic of the hopes and controversies surrounding string theory, and I'd be curious to find out what he has to say about this.

Update: More information about the E8 talks here, Lubos's impressions of Paris here.

Comments

   March 15, 2008

   Czech prez Klaus is an ex-prime minister. He does not make policy decision (including decisions about science) anymore, as a prez he is just a titulary head of state that talks to other dignitaries and gives speeches.

   He is quite an ideologue who derives much of his recognition from his outspoken opposition to EU bureaucracy, socialist state and enviroactivism. Klaus is economist by training so he could use some help with preparing his anti-global-warming arguments. It has been a love fest between him and Lumo for quite some time.

2. **theoreticalminimum**
   March 16, 2008

   Peter,

   Have you, or are you planning to, read Motl's book?

   I have read a review written by a French guy named Christophe de Dinechin, who writes the blog "Grenouille Bouillie". As one can read, he points out many expository and factual shortcomings of the book.

3. **Lubos fan**
   March 16, 2008

   Chapter 1 (*Le grand mystère de l'Origine*) of *L'equation Bogdanov* by Lubos Motl is freely available from the publisher in PDF format: http://www.presses-renaissance.fr/extraits/9782750903862.pdf

4. **MathPhys**
   March 16, 2008

   The backcover says that Motl is the author of a fundamental paper on string theory. Really?

5. **Robert**
   March 16, 2008

   I find it surprisingly well written, the first chapter of Motl's book, and quite entertaining.

6. **Jos**
   March 16, 2008

   Well, in page 4 of the pdf. it says "le temps de Planck" = 0,1 sg. I thought it was smaller 🙂

7. **Rien**
   March 16, 2008

   Enjoy southern Utah, that's one of the most beautiful and bizarre places on Earth.

   The Czech president supposedly has the same mistaken view of global warming as Lubos. But anyway, did Lubos write the book in French or is it translated?

8. **chris**
   March 17, 2008

   oh my god, i thought this was a joke first. really interesting though, that someone knowledgeable can hype the bogdanov brothers while dismissing people like smolin as crackpots. what has the world come to…

9. **MathPhys**
   March 17, 2008

   I'm confused. What is Motl's position of the B Brothers?

10. **Chris Oakley**
    March 17, 2008

    Hi MathPhys,

My understanding of the situation is something like this: The Bogdanov brothers, though well-known in France as TV science presenters, crave legitimate academic credentials. So they write theses & publish papers on quantum gravity that, though containing a lot of buzzwords, are generally regarded as having negligible scientific content. Peter W (and John Baez, and many others) say so publicly. Lubos then, on the basis that anyone who Peter thinks is charlatan must have something going for him, then takes the brothers' side, writing a book that is vaguely supportive, but mostly just a platform for his own opinionated ramblings. Because of the Bogdanov's celebrity status, the book gets published, and Lubos gets on French TV.

Or have I missed something here?

As for the Scientific Advisor to the Czech government job, if this rumour is true, then I can only assume that is because they want a climate change sceptic on their books. I wonder if he has told them that climate change is something that he only does as a hobby? Probably not.

11. **Mondrian**
March 17, 2008

Just found this:

http://www.xkcd.org/397/

cheers

12. **Fabien Besnard**
March 17, 2008

Concerning Motl's book, I wrote a short review here (in french).

13. **anon.**
March 17, 2008

Fabien's review translated into English by Babelfish.

14. **Chris Oakley**
March 17, 2008

Hi Fabien,

Even with my poor French, I like your review. Any chance of an English translation here? (Babelfish is, I am afraid, not really up to it).

15. **Gilbert**
March 17, 2008

Well, here's one. I hope Fabien doesn't mind:

The "science" section of large bookstores, jammed between "esoterica" and "personnel development" was already chalk full of "Canada dry" physics, courtesy of the Bogdanov brothers, when an ex-Harvard professor (so it says on the cover), known for a highly nuanced internet site, jumped in to offer his support (The Bogdanov Equation, the Secret to the Origin of the Universe? Lubos Motl, Presses de la Renaissance, 2008, 240 pages, 19 €). The reason, if "reason" is really the appropriate term here, is easily summed up: only theories involving strings make any sense (p.199), all those who think otherwise are idiots (cf. p. 105 where the author modestly explains that he has become a sort of messiah for having proved a conjecture in a competing theory). As the first critics to point out the absurdities in the articles of the Bogdanov brothers were not string theorists, the Bogdanovs deserved support. In short, the enemies of my enemies are my friends. That's all that was needed for Professor Motl (have I mentioned he used to teach at Harvard?) to sign a book to the greater glory of the twins. The author's style, which one could compare to that of a Japanese tourist guide (to your left Galileo's telescope, to your right Newton's apple), with a dash of self importance thrown in, is often very bogdanovien, especially during the introduction, in pomposity ("The Ultimate Secrets of the Universe") and blunders ("Alexander Euler"). But enough suspense: nowhere in this book will you find even a hint of the Bogdanov equation. But by the time you put it down, you will have solved the Motl equation.

16. **Chris Oakley**
March 17, 2008

Excellent!

Oh – and did you mention that Lubos used to teach at Harvard?

I assume "Canada Dry" one translates as "Mickey Mouse" (unless it's a reference to those crackpot not-totally-convinced-by-string-theory lunatics at PI).

17. **Coin**
March 17, 2008

I recently heard a rumor that he is now the scientific advisor to the president of the Czech republic.

It seems like this is the kind of thing that it would be in principle possible to get a definitive answer on one way or the other rather than having to reply on rumors.

18. **Fred**
March 17, 2008

So this book is pretty funny. It has absolutely nothing to do with the BD brothers (who *are* cranks any way you slice it) or their physics and everything to do with LM managing to weasel his way into getting a book published without undue expense and hassle.

Consequently the physics enclosed is pretty solid (despite the usual hysterics Motl injects in his discussions) and if you like the style of his website, sort of funny. On the other hand it is indeed a little bit *too* opinionated and does read a bit like some sort of glorified advertisement for LM's views on physics

19. **Fabien Besnard**
March 17, 2008

Gilbert, thanks a lot for your translation. It is much better than anything I could have written myself. As for Canada Dry, I'm not sure it is known in the US : this is a beverage that is supposed to "taste like alcohol, but is not alcohol.", as the commercials put it.

20. **Gilbert**
March 17, 2008

Hi Fabian, Chris,

My pleasure. I had been wondering about the Canada Dry reference myself. I couldn't translate it as it was already in English, and wasn't sure what to make of it. Back in the day, right around the first superstring revolution, the ads for it made a point about how it was "not too sweet", which left me scratching my head. Thanks for clearing up that it's meant to be something like "looks like physics, sounds like physics, but tastes like…. Well, not physics."

21. **ad**
March 17, 2008

Canada Dry is dry ginger ale. It's used as a mixer, eg. brandy 'n' dry. Clayton's I always thought was the 'drink you have when you're not having a drink'.

22. **Professor R**
March 18, 2008

Hi Peter,
interesting thread as always.It reminds me of a query I had about your book.

If I remember correctly, you had a whole chapter on the Bogdanov Affair – it made for v interesting reading, but I remember being a bit puzzled about the connection to string theory (and more so when I looked up the papers). Their work certainly seemed to be a fairly typical example of meaningless hyperbole, but not particulaly in the area of ST – was your point that this stuff is facilitated by the vageness of the whole string theory edifice?

Apologies if I've misremembered – I don't have your book to hand as I'm on holiday….regards Cormac

23. **Urs Schreiber**
March 20, 2008

> Their work certainly seemed to be a fairly typical example of meaningless hyperbole, but not particulaly in the area of ST

There is a general point to be made that part of current "formal high energy theoretical physics" has become a rather complicated mess which, while doing very fine in the hands of some, has gotten rather out of control here and there, being neither math nor experimental science. Which is the reason why way back when the Bogd.-brother's thing came out, there was for a short while the suspicion that maybe they were intentionally playing a game with the theoreticl physicis community, the way Alan Sokal did to the Social Sciences back when, which suffered from similar disease of partial degeneration.

String theoretically motivated work and quantum gravity research in general has its grand share in the part of theoretical physics that would admit Sokalification, but it's not restricted to that. Ironically, in an age where, due to plenty of new experimental data, *cosmology* has become a fruitful exact science, much of what is being done in "theoretical cosmology" is little more than story telling.

24. **MathPhys**
March 20, 2008

Urs,
Are you saying that the B Brothers were serious? I thought it's now accepted that they were not.

25. **chris**
March 20, 2008

it's now accepted, but there was the suspicion for a short while that they were.

26. **anonymous**
March 20, 2008

Have you seen this one?

http://xkcd.com/397/

27. **Peter Woit**
March 20, 2008

Cormac,

In the book I wrote about the Bogdanov story mainly because I thought it raised important questions about how this kind of speculative research gets evaluated in an environment where speculation has gotten out of control and the standards that keep it in check have broken down. This wasn't specifically about string theory, and some people gave me grief claiming it was an unfair hit on string theorists.

In retrospect though, I think it was not unfair, that the problems raised by the Bogdanov affair have become much worse in recent years. Almost all of the book was written before the Landscape nonsense got going. Part of the reason the Bogdanov papers are obviously over the edge is that they go on about "before the Big Bang" in a hyper-speculative mode. At the time, this was fairly unusual behavior, now it's mainstream cosmology, at least as practiced by string theorists.

Another reason for including the Bogdanov story was that I couldn't resist including a quote from an e-mail written by someone who observed the response of some members of the string theory group at Harvard, who seemed to be having trouble recognizing obvious nonsense. Again I was criticized for this as an unfair characterization of some string theorists. Now we have one of those string theorists writing a book promoting the work of the Bogdanovs. I rest my case on this one…

Finally, I think the Bogdanov story was important because it clearly demonstrated that the refereeing system in theoretical physics has broken down, as they were able to get nonsense papers published in several reputable journals. The response to this, and the latest plagiarism scandal, where journal editors have decided to either ignore or defend plagiarism, shows that the situation here has gone from bad to worse.

28. **milkshake**
March 20, 2008

when Bogdanovs affair came up Lubos claimed that Harvard string theorists discussed Bogdanovs – and they concluded that the Bogdanov brothers made a valid (if dim) effort and the main reason why ST community did not object to those papers was that they were just little below the average so no-one really cared, etc.

29. **Urs Schreiber**
March 20, 2008

“MathPhys” and “Chris”,

not sure what you are referring to. By their own account, their work was not *meant* as a joke.

Imagine how immensely famous and reputed they could have become by instead claiming afterwards that the papers they managed to publish in journals *were* meant as a joke.

30. **chris**
March 20, 2008

Urs,

this is from your perspective. i.e., they would have risen in the eyes of hephysicists. but they only care about their public image because this makes them the money. and they needed a ph.d. for that.

i think it is just so plain simple.

31. **Chris Oakley**
March 20, 2008

It may just be that the Bogdanovs are choosing their moment. They may yet do a “special” on French TV going through the whole story of their PhDs and papers, explaining how the whole thing was devised simply to demonstrate to the world just how stupid and gullible the so-called “smart” people are.

They just want to snare a few String Theorists first and probably would have done the expose already but for Lubos’s book.

32. **YBM**
March 20, 2008

” …that they go on about “before the Big Bang” in a hyper-speculative mode. At the time, this was fairly unusual behavior, now it’s mainstream cosmology, at least as practiced by string theorists. “

Beware Peter ! This kind of sentence, with a bit of magic in the translation process, could likely be quoted in the next B&B’s book…

33. **Urs Schreiber**
March 21, 2008

Theoretical cosmology is and has been overly speculative even if it didn’t come, as they say, “string inspired”. “String cosmology” proper does not really exist, in the absence of anything but a perturbative formulation.

The power of Einstein’s insight allows people to write down a simple ordinary differential equation in one or two variables, point to it and translate it into fantastic stories about the origin of the universe. While nice, this has lead to strange outgrowth.

I’d dare say that the problem one sees in theoretical cosmology is to a large degree also a result of activities of the school of Hawking et al.

34. **MathPhys**
March 21, 2008

Does Lubos say that the B Brothers are serious scientists? I find this hard to believe.

35. **MathPhys**
March 21, 2008

I have just read this

http://en.wikipedia.org/wiki/Bogdanov_Affair

and it contains the whole strory. I now know that Motl actually defends them.

36. **Hans de Vries**
March 21, 2008

You can search the book, and yes…. it has three entries for Woit and four for Smolin.
In the introductions Lubos “reveals” a private email of Woit to the
brothers where Peter says that the brothers may certainly
have found new and interesting results but the problem is that to be able to readily understand the significance of what they have written requires an expertise held by only a handful of people in the world…..
He goes on to claim that Smolin also isn’t capable of understanding
the mathematics used by the Brothers. Next in line is Franz Wilczek.

Regards, Hans

37. **Thomas Love**
March 24, 2008

Peter, According to

http://www.nndb.com/people/195/000165697/

you are a string theorist! Rather funny considering that they mention NEW!

Will Physicists Find God?

March 25, 2008
Categories: Uncategorized

Today's second most viewed article in Newsweek is an interview with Steven Weinberg about what we'll learn at the LHC. Unfortunately it almost immediately turns into a discussion about religion and is linked to on the Newsweek site as Will Physicists Find God? The interviewer wants to know whether the Nobelist will be willing to reconsider his well-known atheism based on what is found at the LHC. Weinberg does a good job of answering these questions politely and sensibly. He gets a bit into philosophy of science, noting that the hypothesis of the existence of God is testable (in the same sense that string theory is testable), since thunderbolts coming out of the sky and striking atheists dead would give strong evidence that He (or She) exists.

Sean Carroll, quoting from a book by David Deutsch on parallel universes, attacks Weinberg as not understanding how science works in a blog posting about Science and Unobservable Things, and in a discussion with John Horgan at Bloggingheads entitled Cosmic Bull Session. He specifically is critical of a claim by Weinberg that "the important thing is to be able to make predictions", arguing that such a statement is "going a bit too far."

This month's Discover magazine has a cover story on theories of what happened before the Big Bang. The article begins with St. Augustine speculating on what God was doing before the first day of creation, then moves to discuss the work of several modern "cosmology heretics". The discussion doesn't include the work of the Bogdanovs, but does cover three such theories, from Steinhardt and Turok, Carroll and Chen, and Barbour, ending up with a discussion of the crucial problem of testability of such theories. Steinhardt and Turok are rather concerned about this, and point to one negative prediction (shared by many cosmological models) that they can make: effects of gravitational waves will not be seen in the CMB polarization. Carroll and Barbour on the other hand don't seem to have a problem with not being able to predict anything, with Barbour described explicitly as having "no way to test his concept of Platonia."

For more recent research on the multiverse, see philosopher Klaas Kraay's Theism and the Multiverse, where he argues that:

> theists should maintain that the world God selects is a multiverse. In particular, I claim that this multiverse includes all and only those universes which are worth creating and sustaining. I further argue that this multiverse is the unique best of all divinely-actualizable worlds.

Comments

1. **Michael Bacon**
   March 25, 2008

   Peter,

   You said that Carroll ". . . specifically is critical of a claim by Weinberg that 'the important thing is to be able to make predictions', arguing that such a statement is 'going a bit too far.'"

   Not exactly, the quote says just a bit more. Deutsch is apparently critical of the following quote from Weinberg:

   "The important thing is to be able to make predictions about images on the astronomers' photographic plates, frequencies of spectral lines, and so on, and it simply doesn't matter whether we ascribe these predictions to the physical effects of gravitational fields on the motion of planets and photons or to a curvature of space and time."

   Of course it "does matter" whether or not an eclipse is predicted by Ptolemy's geocentric theory of the solar system — wasn't this really the point that Deutsch and Carroll were trying to make?

   Of course, you're trying to make a broader point, but . . . . .

2. **Peter Woit**
   March 25, 2008

   Michael,

   After quoting the longer passage, Sean later pulls the part that I quoted out of it and refers to this specific part, in the way that I indicated.

   The full Weinberg quote makes perfect sense. Weinberg understands the scientific method well, and is expressing himself accurately and carefully. He's not discussing eclipses and Ptolemaic theory, and what he writes is not "crazy", as Sean describes it. Both Sean and Deutsch are wilfully misinterpreting Weinberg's words and setting up a silly straw man to knock down. I get a lot of this, but it being done to Weinberg.

3. **Shantanu**
   March 25, 2008

   Peter have you seen D. Gross's talk on status of string theory at IPMU
   opening symposium. It can be found here
   The video is also apparently online, though I cannot find the link.

4. **Michael Bacon**
   March 25, 2008

   Peter,

   You said " [a]fter quoting the longer passage, Sean later pulls the part that I quoted out of it and refers to this specific part, in the way that I indicated."

   Actually, immediately following the quote from Weinberg, Sean says "[t]hat's crazy, of course — the dynamics through which we derive those predictions matters enormously. (I suspect that Weinberg was trying to emphasize that there may be formulations of the same underlying theory that look different but are actually equivalent; then the distinction truly wouldn't matter, but saying "the important thing is to make predictions" is going a bit too far.)"

   Perhaps not quite as clear as it could be, but not really " . . . wilfully misinterpreting Weinberg's words and setting up a silly straw man to knock down . . " either, is it?

   As for your statement that Deutsch is willfully misinterpreting Weinberg's words, what exactly do you base that on? I have an old copy of the book around somewhere and I guess I could pull it out, but it seems like a lot of effort for the issue involved. I suspect it was part of a much longer and detailed argument by Deutsch that the purpose of science is more than making predictions — it's explaining how the world works. You may not agree with that emphasis, but I think Deutsch is usually careful and sincere in this regard.

Anyway, I do enjoy your blogging even if I don't always agree — keep it up.

5. **Peter Woit**
   March 25, 2008

   Shantanu,

   Thanks for the link. It looks like Gross's talk was much the same as other ones that I've discussed here in recent years, urging string theorists to not give up the search for a new formulation of string theory that would have a unique vacuum and make predictions. Also, the talk was at the opening of the new IPMU in Tokyo, which I should have written about.

   Michael,

   I still don't get the "that's crazy, of course" bit (and you're right, that's Sean, not Deutsch). There's nothing crazy at all about what Weinberg writes, unless you misinterpret it.

   I took a more careful look at the original source from Deutsch. He's trying to use the Weinberg quote to set up a contrast between "predictive" and "explanatory" power of a theory, but both sides of this are slippery. The problems with defining a "prediction" are well known, and an "explanation" is even trickier to define. We want not just an "explanation", but a "scientific explanation", and to me such an explanation inherently comes with some way that you can test it by observation of the real world, i.e. it makes predictions. Sure, you can come up with constructions of a theory with predictive, but not explanatory power, and that would be an unsatisfactory theory. But there really is no such thing as a scientific theory with explanatory power, but no predictive power, and unfortunately that's what some string theorists and multiverse proponents are trying to sell to the public these days.

6. **Kris Krogh**
   March 26, 2008

   The original Weinberg quote is one I'm fond of, from page 147 of his text *Gravitation and Cosmology*. He was making the point that we are not necessarily bound by experimental facts to Einstein's geometric interpretation of gravity:

   …Einstein and his successors have regarded the effects of a gravitational field as producing a change in the geometry of space and time. At one time it was even hoped that the rest of physics could be brought into a geometric formulation, but this hope has met with disappointment, and the geometric interpretation of the theory of gravitation has dwindled to a mere analogy, which lingers in our language in terms like "metric," "affine connection," and "curvature," but is not otherwise very useful. The important thing is to be able to make predictions about images on the astronomers' photographic plates, frequencies of spectral lines, and so on, and it simply doesn't matter whether we ascribe these predictions to the physical effect of gravitational fields on the motion of planets and photons or to a curvature of space and time. (The reader should be warned that these views are heterodox and would meet with objections from many general relativists.)

   I.e., there is more than one way to skin a cat.

7. **chris**
   March 26, 2008

   michael,

   actually, ptolemy's theory was discarded not by its metaphysical implications but by its inability to accurately describe planetary orbits, in particular that of mars. it is simply a false statement regarding a crucial point in science history that the ptolemaic system was obsoleted by its dynamical content or anything the like.

   actually (in one of these truly unscientific what if statements) i would argue that had the ptolemaic system described planetary and lunar orbits just a tad better (so that naked eye observations would not reveal inconsistencies), people at the time would have probably tried harder and harder to mate it to aristotelian dynamics.

   but fortunately, at this juncture, observational data were good enough to guide the way. if you just recapitulate, keplers milestone achievements were based on tychos and his own data, that were orders of magnitude better than previous ones. in fact, the very new ingredient of observing planetary positions out of opposition could be viewed as a major experimental breakthrough that allowed kepler to derive the elliptical form of the orbit.

   this particular episode is very general to scientific advancements i think. and i challenge you to give me one single instance of advancements in fundamental physics that were not based on solid experimental (including of course observational) data.

8. **anon.**
   March 26, 2008

   'actually, ptolemy's theory was discarded not by its metaphysical implications but by its inability to accurately describe planetary orbits, in particular that of mars. it is simply a false statement regarding a crucial point in science history that the ptolemaic system was obsoleted by its dynamical content or anything the like.' – chris

   Chris, you are completely wrong, please see the Java animation which compares the motion of Mars predicted by both theories:

   http://www.jimloy.com/cindy/ptolemy.htm

   '… Mars' retrograde motion, the way it appears to go backward in the sky. This happens because the faster Earth passes the slower outer planet (in the left part of the diagram). And on the right, we have Ptolemy's attempt to explain retrograde motion with a fixed Earth, using epicycles. Both ideas (Copernicus' Sun-centered system, and Ptolemy's Earth-centered system) seem to work well. But the Sun-centered system is the true situation.'

   The point is, you could endlessly add epicycles to Ptolemy's model to 'correct' imperfections. Ptolemy's model made anthropic predictions because the exact version of the infinite landscape of possible epicycles was selected specifically to match known features of the observer's universe, including the motion of Mars.

   If you then make a prediction of something new but the prediction fails, the temptation is to announce the discovery of a new epicycle to 'correct' the model, to claim you are doing science, not to announce that you've discovered you're wrong. So every problem with the theory is hyped as being 'scientific evidence of the need for more complexity in nature': see e.g. *The Crime of Claudius Ptolemy* by Robert R. Newton (John Hopkins University Press, London, 1977). The ptolemaic system was obsoleted by its vast dynamical content of epicycles, compared to the simplicity of Newton's three laws of motion.

9. **Michael Bacon**
   March 26, 2008

Peter,

You said "... there really is no such thing as a scientific theory with explanatory power, but no predictive power. . ."

Yes, and as anon's post implies above, if you have a theory that seems to have predictive power it may in fact not have explanatory power and thus not be a true scientific theory. I agree that any true "scientific theory" should both make predictions and explain how the world really works.

I still have a bit of a problem with '. . . it simply doesn't matter whether we ascribe these predictions to the physical effect of gravitational fields on the motion of planets and photons or to a curvature of space and time." I think in the end it does "matter." However, the full quote from Weinberg provided by Khris shows that the ideas were part of a broader and more complicated argument — something that's not always conveyed in the 25 word or less quote — whether the quote is taken from Weinberg, Carroll, Deutsch or you.

Thanks again for such an interesting blog.

10. **jurisper**
March 26, 2008

Going the other way, the Economist has a long piece on various projects to find scientific explanations for religion: http://www.economist.co.uk/science/displaystory.cfm?story_id=10875666

11. **Peter Woit**
March 26, 2008

Kris and Michael,

All Weinberg is doing is making the point that what is experimentally known about the gravitational force is consistent with either a theory based on Riemannian geometry, or with one that has a massless spin-two particle to provide the gravitational force. In the latter case, geometry may be "emergent", only an aspect of a low-energy approximation. The idea that some (unknown) more fundamental non-perturbative version of string/M-theory might have this feature is what Gross is talking about in the lecture linked above. I'm still not getting why Sean thinks this is "crazy".

12. **chris**
March 26, 2008

hi anon,

i am very sorry, but i have to accuse you of ignorance in this topic. of course retrograde motions are possible in ptolemys astronomy. and of course you could add an arbitrary number of epicycles to match the observed position of each planet but the historic fact is, that the breakthrough of copernican astronomy happened precisely with the establishment of the elliptical orbits around the true (and not the average) position of the sun. and even before that, copernicus-based planetary tables were more precise than the preceeding alphonsine tables which was percieved at their times as the major advantage.

it's easy in retrospect to fall into the trap of believing that observational methods back then were so poor that everyone would be content with vaguely qualitative statements like the one you quoted. they were not. similarly, it is only in retrospect that the infinite addition of epicycles is a good argument. for people of the day (without a firm grasp of the concept of series limit e.g.) the complication of one additional epicycle in terms of real work was quite noticeable and models that simplified were quite welcome.

let me finally add, that perhaps the final irony in this discussion is the arguments brought against the copernican system. if one discounts all the preoccupied 'it must not be so it can not be' type, the one main scientific argument against copernicus was metaphysical in nature: if earth would rotate, the missing observed parallaxe on the fixed stars implied their distance to be way beyond contemporary belief about the size of the universe (mainly influenced by aristotelian metaphysics). that was the most serious argument *against* heliocentrism.

in conclusion, i think this little piece of science history highlights very nicely the forward power of painstaking observation-phenomenology-modelbuilding as compared to the manifest backward trend inherent in metaphysical speculation.

13. **Bee**
March 26, 2008

Hi Peter,

Reading your post, I have to wonder whether the question should have been 'Will physicists search for God'.

The Discover article is actually nicely written.

As an aside, there is this annoying 'null-physics' ad in the middle of the page. I first noticed that while reading an article about Einstein's family, and the ad said 'null physics – bring the science back into physics' or something like this. I wrote an email to the magazine, complaining the whole advertisement is an insult to every physicist reading it (no matter what it actually advertises), and got the expected reply saying we have to get the money in etc. I don't know whether there is a causal relation, but at least the slogan of that ad has changed into something less offensive. (I am occasionally convinced advertisements are the source of all evil in the world.)

Either way, to come back to the question of making predictions vs. offering explanations. There has been a decade or so where PREDICTIONS, testability, and falsifiable were the keywords. Now I have to wonder whether at some point people will just turn around, drop these efforts and say, no, we don't need predictions, stop whining. It's a bit scary to think about what this would do to science, starting from theoretical physics which is especially vulnerable in this regard, but when I read your blog it doesn't seem impossible to happen.

Best,

B.

14. **Michael Bacon**
March 26, 2008

Chris,

You said "... this little piece of science history highlights very nicely the forward power of painstaking observation-phenomenology-modelbuilding . . ."

It's true that Ptolemy's theory was discarded for its metaphysical implications and for it's inability to accurately describe planetary orbits, particularly as new observations were made.

I certainly didn't mean to imply that an incorrect scientific (i.e. falsifiable) theory wouldn't inevitably be proven wrong by further observation and discovery. In fact, that's the notion I'd hoped to reinforce by mentioning how one such theory — which held sway with quite a few people for a good period of time — ultimately neither correctly predicted natural phenomena or explained the true nature of world, and was discarded.

In any event, a scientific theory has to make testable predictions. Carroll speculated that Weinberg might have been getting at this idea: "there may be formulations of the same underlying theory that look different but are actually equivalent; then the distinction truly wouldn't matter." Peter filled in the blanks saying "[a]ll Weinberg is doing is making the point that what is experimentally known about the gravitational force is consistent with either a theory based on Riemannian geometry, or with one that has a massless spin-two particle to provide the gravitational force."

It's easy to distinguish between theories that make different predictions that can be tested. But perhaps in the "hard" cases, it's OK to lean a little toward the view that "explanatory" power takes on a bit more importance.

15. **Peter Woit**
March 26, 2008

Bee,

I definitely find the "we don't need predictions, stop whining" arguments being made worrisome, but don't think this is a big problem for science in general. It is a big problem for certain subfields of theoretical physics though, where the people pushing these arguments have influence. What is happening is that these arguments are being used to justify an unwillingness to drop research programs that have shown themselves to be inherently unpredictive. This behavior stops the field from moving forward, and destroys its credibility among potential young theorists, other physicists, granting agencies, other scientists, and the general public. I think the fall-out from this is already becoming visible.

16. **andy**
March 26, 2008

I'm sorry, Peter, but could you explain why you said this:

"we don't need predictions, stop whining" arguments being made worrisome, but don't think this is a big problem for science in general.

Why isn't lack of predictability "a big problem for science"?

17. **andy**
March 26, 2008

Or perhaps you meant this in the context of, e.g., evolutionary biology, where we can't "predict" the next species to evolve, but we do know that "something" will?

18. **Michael Bacon**
March 26, 2008

Andy,

I thought Peter meant only that the attitude wasn't as prevelant in most areas of science but is a growing problem in subfields of theoretical physics, but maybe I missed the point.

19. **Thomas Love**
March 26, 2008

On page 24 of his talk, Gross says: "We are not sure what the final theory is and what the rules of the game are."

Then on page 25, he says "The Strategy

Calculate

Calculate

Calculate & observe.

Well, if one does not know the rules of the game, one does not know the rules for calculation, which means the calculations are meaningless. All too often physicists substitute calculations for understanding.

20. **fritz**
March 26, 2008

> and i challenge you to give me one single instance of advancements in fundamental physics that were not based on solid experimental (including of course observational) data.

General relativity, and the prediction of the existence of antimatter (Einstein and Dirac, resp.) are the only two examples I know of. Both revolutionized their respective fields, and were not based on previous experimental/observational data.

21. **Peter Woit**
March 26, 2008

andy,

Yes, Michael is right. What I meant is just that I don't see this as having any effect on scientists outside of string theory and associated areas in cosmology. It's not changing their views on the necessity of coming up with ideas that have predictive power if they want to do science.

22. **Peter Woit**
March 26, 2008

fritz,

GR did make distinctive predictions (precession of perihelion of Mercury, bending of light). It's an interesting question how seriously it would have been taken if there were no such predictions. Absent such testable predictions I doubt many people would have considered it as revolutionizing the field.

The Dirac equation makes all sorts of testable predictions, antimatter was just one more.

23. **Peter Woit**
March 26, 2008

Thomas,

Gross has a point that the thing to do when you don't know how to make progress is to calculate what you can and see what it teaches you. But if as you do more and more of these calculations you just find more and more evidence that the framework you are working in can't do what you want, at some point you should stop and calculate in some other framework. I don't see the relevance of "observe" to string theory at the moment.

24. **Kris Krogh**
March 26, 2008

Peter,

I think Sean's point was the same one Feynman made with Mayan astronomers. They could predict eclipses, using a system of beans, without understanding the solar system. Plenty of physicists today seem to feel calculations are the only things that matter, but the irony is that Weinberg has spoken out against that positivist viewpoint. In saying it doesn't matter whether the underlying theory of gravity involves curved space-time, I'm sure he was only referring to the current experimental evidence.

New experimental evidence exists now, a rough measurement of frame dragging by Gravity Probe B, but it isn't clear when we will be allowed to see it. Data collection finished two and a half years ago, but it was announced yesterday the program has been extended again — at least to the end of the year, and possibly to the year 2010. I wouldn't bet the farm that general relativity has been confirmed.

25. **Chris**
March 26, 2008

Hi Peter,

One interesting irony in all this is that Weinberg is in some sense the father of the landscape. I think it is his work (http://prola.aps.org/pdf/RMP/v61/i1/p1_1) on using a landscape to solve the cosmological constant problem that provides the most compelling justification for considering the landscape.

26. **Henry**
March 26, 2008

Peter,

"All Weinberg is doing is making the point that what is experimentally known about the gravitational force is consistent with either a theory based on Riemannian geometry, or with one that has a massless spin-two particle to provide the gravitational force."

My two bits: In the context of the G&C textbook quote, I believe the point was not that there are two competing theories, one based on Riemannian geometry and one based on the massless spin two particle. Instead, there are two ways of looking at the same theory (GR), and one may compute the same answers for the same observables from either perspective. The issue is not that the experimental data is yet insufficient to distinguish between two theories, but that there is really only one theory. This situation can be contrasted with the case of say, GR vs. Brans-Dicke, where one is actually dealing with different theories that lead to different predictions.

27. **Kris Krogh**
March 26, 2008

Hi Henry,

You're right. Weinberg's approach to gravity is considered equivalent to GR, and has not provided any different predictions. (Though I wonder a little whether they are really 100% the same.) Some other non-geometric alternatives to GR do make different predictions for Gravity Probe B.

28. **fritz**
March 26, 2008

Peter, I absolutely agree with you. Chris' challenge was to mention a fundamental advance not directly based on solid experimental data (like the BCS theory depended a lot on the discovery of the isotopic effect, and Hubble's law was basically a fit to data (a fit of sorts, though…)).

As far as I know there are just those two examples. Both were experimentally confirmed about a year after being published, as you say.

29. **Anonymous**
March 26, 2008

There is already an assumption that getting beyond the Standard Model will give us the "final theory" – see Gross's comment cited above.

30. **Michael Bacon**
March 26, 2008

"Sean's point was the same one Feynman made with Mayan astronomers. They could predict eclipses, using a system of beans, without understanding the solar system.

And that was the point I was trying to make referring to Ptolemy . . . . but I like this one better.

31. **Peter Woit**
March 26, 2008

All,

Please stick to the topic, I'm deleting various excursions into the history of physics which don't add anything to the discussion.

32. **Brett**
March 26, 2008

There are plenty more examples of important work that was done without any experimental basis. There's Chandrasekhar's calculation of the maximum white dwarf mass and the subsequent predictions about compact objects. Einstein's prediction of the relative rates of spontaneous emission, stimulated emission, and absorption was done before same could be measured.

Lots of important theoretical work on the foundations and structure of quantum mechanics was done without any experimental input. For example, there's the Aharonov-Bohm effect and Bell's inequalities, both of which introduced highly unexpected phenomena. In the latter case, experimental confirmation didn't arrive until years after the prediction.

33. **mike harney**
March 26, 2008

Peter,

Do you think there is a sociological reason for the association of God in science with various theories like multiverse that fall into the category of "hard to falsify"? It seems to me that there is a common element of mysticism to both areas that allows for common ground to be woven. How do scientists turn the tide back to "predictability" and putting the focus on experimental evidence? Is it a lack or redefinition of what is being taught in schools about the scientific method, or is it just a periodic dark age that we just have to suffer through?

34. **woit**
March 27, 2008

Mike,

The problem here is localized to certain subfields in physics, more particularly to some specific people in these subfields. There's no dark age, the rest of physics and science in general is doing just fine, and I assume that virtually all school teachers continue to teach their students what the scientific method is, recognizing the string theory anthropic multiverse nonsense for what it is and ignoring it.

35. **Anon**
March 28, 2008

I am not quite sure what you understand by the word "testable", but I was a little misled by it, and had to read the original to confirm that Weinberg had not lost his marbles. Weinberg does not use that word, and in fact explicitly states that asserting the existence of a deity is not a falsifiable statement, which to me means prceisely that it is /not/ experimentally testable. So "testable in the sense of string theory" means "not testable", correct?

36. **anon.**
March 28, 2008

'Weinberg [notes that the] hypothesis of the existence of God is testable (in the same sense that string theory is testable), since thunderbolts coming out of the sky and striking atheists dead would give strong evidence that He (or She) exists.' – Woit.

Actually, anyone who looks at all the suffering and tragedy in the world can see that if God exists, then She/He either has better things to do than to monitor (or respond to) serious human problems, let alone to get in a huff about claptrap from atheists like Weinberg. It's a big multiverse, so maybe God's presence is seen elsewhere. Maybe He/She resides only in higher dimensions…

37. **mclaren**
April 6, 2008

Andy asked:

> *"we don't need predictions, stop whining" arguments being made worrisome, but don't think this is a big problem for science in general.*
>
> Why isn't lack of predictability "a big problem for science"?

This is an important point and seems worth discussing briefly. All mathematical models have boundary conditions, and when you push the models close to or beyond those conditions, the models start to break down. A good example would be very high Reynolds numbers in the Navier-Stokes equation. NS predicts fluid dynamics very well until you get into the regime of turbulence (high Reynolds number). Then everything becomes increasingly non-linear and eventually chaotic. That doesn't make the Navier-Stokes equation useless in dealing with fluid dyamics, but does impose limits on how much we can predict and how far into the future underconditions of extreme turbulence. In particular, when the equations become usfficiently sensitive to intial conditions, predictability vanishes.

We see the same situation with weather prediction, protein folding, and so on. Weather prediction works well locally a few days into the future. Globally and years into the future, it works less well. This doesn't invalidate climatology or fluid dynamics as valid sciences: it does place limits on our ability to make predictions far into the future under extreme conditions, given the current state of mathematics.

The hope is that eventually some better mathematical methods will be developed for dealing with highly-nonlinear regimes of dynamical systems, viz., turbulent fluid flow, protein folding, and so on. Work continues in an effort to develop new mathematical methods to tackle these challenging problems. In the meantime, most of these disciplines, like fluid dynamics, give excellent predictions for regimes outside of extreme conditions.

I believe Dr. Woit's point is that this is an **entirely different situation** from a "theory" which cannot be disproven by any possible observations, such as the idle speculations about 10^500 vacua.

2008 Abel Prize

March 26, 2008
Categories: Uncategorized

The winner of this year's Abel prize, a prize of over $1 million set up back in 2001 to provide an equivalent of a Nobel prize in mathematics, is…

Actually, I have no idea. If you know who it is, feel free to break any vows of confidentiality in the comment section here. Otherwise we have to wait until 7am EDT tomorrow morning, when the answer will be revealed here.

Update: The prize goes to John Thompson and Jacques Tits, for their work on finite groups. More details here, including the citations for Thompson and Tits.

Comments

1. **MathPhys**
   March 26, 2008

   I nominate A Grothendieck, who will be 80 this year, and lives in the south of France.

2. **Peter Woit**
   March 26, 2008

   MathPhys,

   A good nomination, but I don't think it will be him. The Scandinavians already once tried to give him a prize carrying a lot of money (the Crafoord) back in 1988, and look what he did then…

3. **Melvin Eloy**
   March 26, 2008

   Incidentally, Grothendieck's birthday is on this Friday, 03/28.

   Hamilton perhaps?

4. **A.J.**
   March 26, 2008

   I'm betting on Israel Gelfand.

5. **Phil G**
   March 26, 2008

   The announcment page says that Marcus du Sautoy will give a popular talk on the subject. Could that be a clue? Marcus has worked on finite groups and zeta functions so it could be someone in that area, maybe.

6. **fp**
   March 26, 2008

   I guess it would be John Tate or (and) Robert Langlands since Du Sautois speaks after the annoucement.

7. **Voltberg**
   March 26, 2008

   Zelmanov and Dusa McDuff are on the committee. Maybe M. Gromov?

8. **Harry**
   March 27, 2008

   My bet is someone who, at least, attached his name to a well-known program: Pr. R. Langland or Pr. R.S. Hamilton ..

9. **MathPhys**
   March 27, 2008

   Gelfand would be a very, very good choice. Besides, he's well over 90 years old, so it's about time.

10. **Abel Prize**
    March 27, 2008

    Abel Prize to Thompson and Jacques Tits!

    Surprizes all round

11. **theoreticalminimum**
    March 27, 2008

    John Griggs Thompson and *Jacques Tits* have been awarded the prize for their contributions to group theory.

12. **Thomas Love**
    March 27, 2008

    Thanks for this link Peter! Normally I visit your site to find links to research articles for me to read. I just sent out an email to my Abstract Algebra class with a link to the

Abel Prize site and instructions to read the articles on group theory, the history of groups and the group theory of the Rubik's cube. That should make for an interesting class next week.

13. **Peter Shor**
March 27, 2008

    Are there any Norwegians who want to translate the jokes in the citations?

14. **Professor R**
March 27, 2008

    Hi Peter, interesting post.
    This is obviously a very prestigious prize – great to see it going to group theory.
    By the way, I guess there's a difference between pure group theory and group theory applied to physics?
    I ask because most of the names listed in the posts above are not familiar to me – also, although there is a specialist physics prize for "outstanding contributions to the understanding of physics through Group Theory" (the Wigner medal), it has not been won by any of the names above, or by Thompson or Tits..

15. **Professor R**
March 27, 2008

    I sometimes think it's a pity these prizes are only awarded to the living. If that sounds daft, there are actually two good reasons for posthumous awards
    (i) the work of these good mathematician/scientists lives on long after them…and often the true value of the work becomes even more apparent after their death
    (ii) while the scientists themselves won't benefit from posthmous awards, their students, their institutions, and even their countries might benefit, inspiring others to similar feats

    For example, should evidence of supersymmetry be glimpsed at LHC, almost none of the pioneers will be alive to see it – so there wil be no public recognition of their long toil in the sixties and seventies. Here in Ireland, I have huge problems convincing people that Dad's work was important, and am continually confonted with books about Irish scientists that ignore his contribution – a few prizes would help!
    Regards
    Cormac O' Raifeartaigh

16. **Chris Hillman**
March 27, 2008

    For those who don't know much about the work of Thompson or Tits, I am cautiously optimistic that master expositor John Baez (who has discussed finite simple groups, buildings, and other highly relevant topics in past postings) will rise to the occasion.

    Would it be imprudent for me to hazard the guess that the award to Tits in particular reflects a resurgent appreciation of the legacy of Klein?

17. **Jakob**
March 28, 2008

    The joke: 604800 equals the number of seconds in a week

18. **Felipe Zaldivar**
March 28, 2008

    Group theory had many origins: the problem of solving polynomial equations via the work of Lagrange, Viete, Cauchy and Galois relating the original problem to the permutations of the roots of the equation, and giving rise to the group concept requiring that the set of permutations must be closed under the product of any two such transformations. This same idea originated in geometry with Klein's idea that a geometry is determined by the rigid transformations of space that leave invariant the objects of that geometry. There is a third source of the group concept, that goes back to Gauss, Kronecker and Dedekind, and is related to number theory, where a new idea comes into the field, that is studiying a commutative group via its characters, i.e., functions from the given group to the multiplicative group of nonzero complex numbers. And there is a fourth line if we consider Sophus Lie idea to create a "Galois Theory" of differential equations in analogy to the Galois theory of number theory and algebra that studies the symmetries coming from the permutations of roots of polynomials. Lie's ideas are the ones any Physicist recognizes immediately, all of them quite familiar with differential equations and Noether's theorem. At the end of the XIX century, Frobenius in Berlin, his student Schur, and Burnside in England introduced the idea of studying an abstract group by replacing its abstract elements with concrete objects, namely, invertible (complex) matrices. Initially they applied this new tool (called the representation of the abstract group) to study the structure of finite groups, but soon they were also considering representations of infinite groups and also of Lie groups, and later on Weyl enters the picture and representation theory (mainly of Lie groups) becomes part of the toolbox of a theoretical physicist. Gelfand, Naimark, Wigner, Bargmann, and many others are associated to the study of representations an characters of Lie groups that are of interest to physicists.
    To end this too long comment, what physists call "group theory" usually means "representation theory of Lie Groups", and the relevance of the abstract representation theory of finite groups is that sometimes it provide methods that may be useful for representation theory in general.

19. **Professor R**
March 29, 2008

    Thanks Felipe, great post

20. **theoreticalminimum**
April 2, 2008

    Something completely off-topic here, but I was just wondering if this paper by Prof Ngô Bao Châu (Université Paris-Sud, Orsay) has come to the attention of those concerned. It is written in French, so I don't think many will be able to understand it, but the abstract is rather interesting.

21. **Peter Woit**
April 2, 2008

    theoreticalminimum,

    Ngo's work on the fundamental lemma has attracted a lot of attention from experts in that area. I wrote a little bit about it here:

    http://www.math.columbia.edu/~woit/wordpress/?p=18

    I'd write more about this and about more recent developments like the paper you mention if I actually understood more about it…

Off-topic

March 27, 2008
Categories: Uncategorized

I usually try hard to avoid writing here about anything not directly related to mathematics and physics, but on rare occasions I can't resist. Many readers may want to skip this posting as unserious, but maybe some will find it entertaining.

My travels last week took me to Las Vegas, where I stayed overnight with my old housemate John Chang and his family. During my graduate student days at Princeton, one year I lived with two fellow physics graduate students who were part of a card-counting team which had started up to take advantage of the recent opening of casinos in Atlantic City. Many of the other members of the team were based at MIT, and my roommates often mentioned one of them, "John". A few years later I was looking for a place to live in Cambridge, answered an ad, and ended up going to meet the owner of a house who was looking for a housemate. After we talked for a while, I realized that he was the "John" my Princeton roommates had been telling me about.

Anyway, you can read more about John in a story just put up at the Xconomy web-site. He's the model for the character "Mickey Rosa" in the book "Bringing Down the House", which has just been made into the movie "21", opening this weekend (Kevin Spacey plays "Mickey Rosa"). I'm looking forward to seeing the movie on Saturday.

Update: For more about John and the card-counting business, see this article in Men's Vogue.

Update: If you're interested in this, you should definitely check out John's blog, which he has started updating again with new postings.

Comments

1. **Chris Oakley**
   March 27, 2008

   This would be great jump-off point for "The String Kings". The String Theorists start out as card counters at Atlantic City, but are kicked out once the management realises what they are up to. Unperturbed, the String Theorists hire their own muscle, forcing the casinos to readmit them, and the cycle of supersymmetric, eleven-dimensional violence starts …

2. **stevem**
   March 27, 2008

   Gambling theory and "statistical logic" are among my interests. The optimum strategy for blackjack was worked out analytically and verified on computer sims as far back as the late 50s and published in American statistical journals. It minimises the house edge but can't overcome it. MIT math professsor Ed Thorpe worked out that the player can gain a 1% edge by counting cards so you can estimate how rich the deck is in aces and tens. There are some amusing stories about him liked how in Las Vegas he doubled $10,000 of mobster money. Thorpe went into finance and later used his abilities to exploit statistical anomalies in various types of securities and make a lot of money. I think he now runs a hedge fund.

   However, according to blackjack folklore card counting was actually worked out first by a character in Las Vegas called "Greasy John", an obese and somewhat obnoxious individual who always had a large basket of fried chicken. But when he played blackjack he won regularly. He seemed to know exactly when to up his bets. However, he took his secret with him since he died of a massive heart attack while playing, but Ed Thorpe gets the credit. There are also various amusing BJ stories like people playing with computers strapped to their backs under their clothes. Card counting is banned in Vegas now I think or else security "asks you to leave". They also introduced multiple-deck games and other distractions. I also heard some of the MIT team got seriously physically threatened in Europe.

   When casinos opened in Atlantic City in the late 70s they did so with a unique rule for BJ–early surrender–which actually gave BJ players an advantage over the house. However, the New Jersey Casino Control Commission who mandated the rule did'nt actually know the math and by the time they got rid of it about a year later a lot of "college kids" and pros had already milked it for millions.

   As author of "String Kings", I do recall they had set up rigged slot machines with only a 1 in 10^500 chance of paying out;) I suppose they could also introduce "supersymmetric 11-dimensional quantum blackjack".

3. **tomj**
   March 28, 2008

   On what planet can a player gain an advantage over the house in blackjack? John Scarne has debunked this idea many years ago.

   But let's review a critical fact: the house advantage in blackjack is based 100% (as a minimum) on the way the game is played. The advantage is due to the fact that players go first, and that ties don't pay off. Any player going over 21 instantly loses. Also, after the first two cards are dealt, if the dealer gets 21, players either lose, or 'tie'.

   Just these rules give the house a 8.27% advantage, but the payoff when a player wins with a 21, which pays 3 to 2, reduces this to 5.9%.

   Card counting is useless in blackjack as long as the last 1/5 or so of the cards are discarded. With 208 cards, at least 40 are never played.

   Certain other rules can bring down the house advantage, maybe to 1-2%, but it is impossible to overcome the advantage the house has from playing last.

   The main advantage that players have is knowing the dealers up card, and also knowing that the hole card can't add up to 21.

   Maybe the best proof is that the MIT group supposedly made $10 million, but John was still seeking a roommate.

4. **Chris Oakley**
   March 28, 2008

   stevem,

   I am not sure quite how one classifies the skill of being able to write insightful reviews of non-existent films, but whatever it is, you clearly have it in spades. My suggestion was actually for the prequel, as some kind of explanation is required as to how a bunch of Princetonian rough-diamonds with bad hearts end up ruling the clubs.

5. **Chris W.**
   March 28, 2008

   Bob Mondello reviewed '21' this evening on NPR's *All Things Considered*. He wasn't especially complimentary:

   > But because the director knows there's a limit to how exciting he can make the sight of cards being turned over, most of the film is taken up with explaining what's happening, or is going to happen, or has just happened. Which may be enough to keep audiences from heading for the nearest slot machine, but at best, 21 is a sort of collegiate *Ocean's 16* — with dimmer stars and less oomph.

   (Actually, he covered two films in one review—usually not a good sign.)

6. **Peter Woit**
   March 28, 2008

   tomj,

   The information stevem gives agrees exactly with what I remember from my days hanging out with card counters, at least one of whom was an extremely talented physicist, expert in the field of Monte-Carlo calculations, which he performed not just on physics problems.

   When I was living with John, he was still in his twenties, had only been doing this for a few years. At the time he definitely didn't have $10 million, but he did own the Cambridge house we were living in ….

7. **tomj**
   March 28, 2008

   Peter,

   I read the thesis of your friend. Compared to the analysis of Scarne, who never even graduated high school, your friend is an idiot. I'm not even sure that your friend understands basic probability theory.

   For instance, your friend assumes an 'infinite deck'. That means that each card always has 1/52 change to be dealt.

   But the theory of counting cards assumes some non-normal distribution of cards. It is obvious that if you could detect a non-regular distribution of cards, you could gain an advantage, on average, how big is this advantage?

   If there was not a huge structural advantage from going last, the game of blackjack would not exist. This is the secret of gambling: somehow promote the idea that more work, more analysis will overcome the structural deficit.

   It isn't going to happen. This is the huge con. The idea is that you can beat the house. You just need to memorize some tables, memorize some exceptions.

   Maybe you have some additional information, but what I have read is that you have attested to _missing_ money, not actual money.

   I think it is important. Someone who wishes to make money via gambling, and, maybe worse, by organizing a gang of gamblers, just to eek out a 1-2% advantage (at most), who would do this? I mean, we are talking about commodities trading. Only an MIT geek would think this is something worth reporting.

   This is pretty close to the string theory bs. Some moron over-exaggerating, and all his friends being amazed. It is just bs.

8. **John Chang**
   March 29, 2008

   tomj is correct that the house edge arises from the double bust probability, less the 3:2 blackjack payoff to the player. But he seems not to realize that the house has a fixed strategy, whereas the player has the option to double, split, hit, stand, or even surrender. Depending on the exact rules and number of decks, proper play reduces the house edge to a small amount, generally around 1/2%.

   Ed Thorp published the first counting system in 1961. He determined the effect of removing one card of each denomination on the expectation of the game. The sum of the effects is close to linear. It turns out that an excess of small cards are bad for the player, or conversely, an excess of tens and aces helps the player. This makes intuitive sense, since more tens and aces increases the probability of blackjack, which pays 3:2 to the player; it increases the chance the dealer will bust with a small card showing; and it helps the player with his doubles.

   Anyway, if you can determine there is an excess of 10s and Aces, you can also determine when you have a positive expectation bet. Depending on exactly how many cards are dealt, the rules, how much you bet at various "counts" and so forth, your average expectation is generally 1-2% of the money bet.

   As for Scarne, he was no mathematician. He was a great sleight-of-hand magician, but his blackjack writings have long been debunked.

   And as for making money, if your average bet is $1000 a round, you will bet about $1 million in a weekend of play. At an advantage of 1-2%, your expectation would be $10-20K. Of course, winning is by no means guaranteed, but that's why you form a team, to allow the law of large numbers to work. Even going on one trip a month, 10-20K is a nice income for a hobby.

   The method is simple, but the discipline to carry it out is uncommon. As for being a moron, I guess that depends on what company you keep.

   Perhaps the best proof of the profitability of blackjack is that casinos bars counters. And have you ever had 80K in cash to misplace?

9. **Brett**
   March 29, 2008

   First, the notion that there is no winning strategy for counting cards in blackjack is ridiculous. If the deck is rich enough in ten cards and aces, the gave favors the player. If reserved almost all your betting until that happens, you will expect to win. That may not be a realistic or interesting strategy, but it works.

   Also, the attitude of casinos towards card counters varies a great deal by place and, more importantly, how much money is involved. Back in the 1960s, my dad and two other MIT students took a trip to the Bahamas, and they spent an evening counting cards in a casino. They weren't very professional about it. One guy counted the ten cards, my dad counted the total number of cards, and the third guy actually played. They did this quite openly, and the casino didn't care, because they were playing at a $5 table. They won less than $100 total. I've heard similar things from other people about more recent trips to Vegas and Atlantic City. If you're playing for peanuts, (some) casinos really don't care if you count.

10. **stevem**
March 29, 2008

Tomj, everything John says makes perfect sense but I don't get your reasoning. It is mathematically very well established that card counting works, although putting it into into practice is difficult and hard work. It is also intuitively obvious that tracking the fluctuations in the composition of the deck(s), and varying the wagers accordingly, is advantagous to the player. The player's edge comes from the increased probability of blackjack and the ability to perform operations like doubling and splitting that are not available to the dealer/house. It does'nt matter that the player "goes first".

My own experience of blackjack is limited to the online game where the cards are "electronically shuffled" after each hand so card counting is useless. An interesting question therefore–and one that remains unanswered as far as I can tell–is whether an edge could be gained in the computer-generated online version of the game. That is, is the online game perhaps more "pseudo-random" than random? Could one data mine a large statistical sample of computer-generated hands and look for repetitive patterns, trends, predictive signals, correlations–kind of like what Jim Simons does with financial data–and make bets or alter the magnitude of the wager in accordance? For example, could you reasonably predict when the negative fluctuations or variance/volatility is going to hit at which point you would start betting small? It is pretty much an open problem in cryptography as to whether one can effectively distinguish between a large sample of purely random objects and a large sample of pseudo-random objects. Some modern rngs are pretty sophisticated however, but computers still essentially remain deterministic machines and must generate random objects (card hands, dice throws) from a formula or iteration algorithm. However, in the online game successive bets can be laid down very fast and even with a slight edge the law of large numbers would quickly do the rest if one could even get a small edge. The hassle associated with real casinos is avoided and you can play anywhere at anytime. Sorry to rant on but I've never had a response to this query;)

Chris, as a spinoff or prequel to "String Kings", one could perhaps base it on Scorcese's film "Casino": string mobsters set up a casino in Vegas called "The Only Game in Town" (with flashing neon) and featuring rows and rows of the 1-in-10^500-payout slot machines, skimming the profits for the bosses back east in Princeton and Harvard; and with a "bagman" taking the cash back east on regular trips. (Guess who?;)). I can imagine a lot of violence though with cheaters and counters being taken to a back room and getting their hands and heads busted with heavy bound archival copies of Nuclear Physics B.

11. **woit**
March 29, 2008

stevem,

I have no idea how good the random number generators being used are. If you did manage to figure out how to take advantage of their pseudo-randomness, presumably whoever operates them would notice this and change to a different one.

Card counters over the years have put a lot of effort into trying to exploit non-randomness in casino shuffles. I don't know what the current state of this is, although I did hear that at least one casino hired mathematician Persi Diaconis to check out their shuffle.

It's not against the law to do what card-counters do, although casinos (at least in Las Vegas) can kick you out if they think you are doing this too well. Using a hidden computer to play in a Las Vegas casino is now against the law there, and you could end up in jail if you do this. Most card-counters are careful to not do anything illegal, so this is not one of their tactics in Las Vegas.

tomj,

Please stop insulting people. I should have deleted your comment when first posted, will just leave it because of the informative response from John that it generated.

12. **Deane**
March 30, 2008

So how did you like the movie? Lauren and I went on Friday night. The theater was completely full. But we were quite unimpressed by the movie. And its depiction of math was awful. It was fun to see MIT and Cambridge in a movie, though.

13. **Peter Woit**
March 30, 2008

Deane,

I thought the movie was kind of a disappointment. Not that good (especially the performance of the lead actor, who was vapid), and it could have been a lot better. Having so much of it set in Planet Hollywood was both ridiculous and boring, and the movie was too full of product placement and a bit too much of a bland product itself. But it was entertaining enough, and I just read that it's number one at the box office this weekend, so the filmmaker is doing something right, at least as far as making a product with as wide appeal as possible.

Check out John's blog for his take on it, which is interesting.

14. **Anders**
April 3, 2008

stevem,

I had not thought about the psedo randomness of the cards in online Black Jack before, but if you know what generator is being used and if you could find the seed value used the game would become totally deterministic. However as far as I know it is extremely difficult (if at all possible) to determine the seed value from observing the random numbers (and you cannot really observe the numbers only the cards) even if you know what random number generator is being used.

If the casino uses an old generator with a short period then eventually you will get the same sequences of cards again, but a modern generator such as the "Kiss-Monster" repeats itself after 10^8859 numbers so then you will have to play for awhile 🙂

15. **Shantanu**
April 3, 2008

Peter have you seen the talks at Lindefest (which has talks on string theory and anthropics)

16. **woit**
April 4, 2008

Thanks Shantanu,

I hadn't seen that. Especially glad to see the notes from Witten's lecture, which was the same one I saw at Stony Brook last week and hope to get a chance to write about.

17. **Shantanu**
April 4, 2008

No problem, Peter. Also for some reason my post about Coleman's 1975 lectures
and a very interesting paper by Carlip is no longer there. I was hoping you would
blog about it (since both of these are related indirectly to string theory)
Did you take the same class by Coleman at Harvard?
Thanks

18. **Peter Woit**
April 4, 2008

Shantanu,

As the comment policy says "off-topic comments better be interesting…" otherwise I'll delete them. I wasn't much interested in the Carlip paper, just because my interest in that kind of debate about quantizing gravity is limited. There are lots of things worth reading on the arXiv that aren't discussed here.

As for the Coleman lectures, this was mentioned on several other blogs already and I think I've written about Coleman and his QFT course here in the past. I actually attended two quantum field theory courses at Harvard, and during the first, which wasn't taught by Coleman, I watched some of those lectures on videotape in the science center. The second time around I took the course from him. He was a great teacher and it was a great course. But trying to follow a course of blackboard lectures by watching low resolution video on the internet seems to me to be a painful idea.

19. **Chris Oakley**
April 6, 2008

I just got home after seeing "21".

My idea (doing the movie as a prequel to "String Kings") is better.

In particular, I'd like to have a scene where the young String Kings abduct a security guard from an Atlantic City casino who has previously thrown them out for card counting, dragging him to basement and tying him to a chair.

THE KID

How many space-time dimensions are there, punk?

SECURITY GUARD

Three space, one time.

THE KID (punching him in the face)

Wrong, totally moronic crackpot! The answer is TEN space, one time! Let's try again, shall we? How many spacetime dimensions are there?

SECURITY GUARD

Three space … one time.

THE PLUMBER (A string theorist)

WRONG! Get this wrong one more time and you're going to go glub, glub, glub to the bottom of the sea.

Etc.

20. **Steve Caudill**
April 16, 2008

On the topic of gambling and card counting in the movies, I was reminded of "Rain Man," where Tom Cruise's character takes Rain Man to a casino and has him count the cards at blackjack.
There was a famous poker champion named Stu Unger, who had a total-recall memory and could memorize every card in a 6 deck blackjack shoe, yet Unger's game was poker and he supposedly won over $30 million in poker tournaments. For more info see:
http://en.wikipedia.org/wiki/Stu_Ungar

Another excellent gambling movie is "Rounders," starring Matt Damon as a poker player.
As for me, I like all of the casino games, and the only counting I do is my money, Rule number 1 of my 'winning formula' is to quit after winning 10 percent of what I came in with; Rule number 2 is don't bring an ATM card; Rule number 3 (of 3 Rules) is don't be a gambling addict.

21. **Bill**
May 20, 2008

Just a quick one to throw into the pot, which involves adding a few variables other than the numbers themselves into the equation for beating house edge

To really beat house edge, you have to think outside the box. That is, you have to think of gaining benefits other than the montry win itself from your play. This means factoring in comps

The easiest way to do this is to play slots and the first thing to do is find a slot that pays 99% or over. Slot play now attracts the best perks in casinos. Better still, combine this with entering a slot tournament where you can get free rooms in hotels when you enter and will often get a free lunch too. In doing this you automatically have an edge worth hundreds of dollars. Now, when playing the machine, you must use your points card in the machine. This will monitor your play and you will then begin to acquire morefreebies such as complimentary meals, rooms, shows, limos etc

Of course, the edge you get is only of value if you actually desire these freebies and you will never get rich on them…

Similar edges can be gained on blackjack. If you are good enough at blackjack and can get the floor house edge down to less than 1%, that is a good start. You must then get your play ‘rated’ by the floor manager. He can then pass that info along to the casino system and you can then accumulate comps in the same way that will be greater than the 1% you have been losing on blackjack over time.

Krauss on Boltzmann Brains

March 27, 2008
Categories: Multiverse Mania

Lawrence Krauss has a piece this week in New Scientist about the latest hot topic in theoretical physics, Boltzmann brains. It's entitled String Theory's Latest Folly, and starts off:

> THOMAS AQUINAS may never have actually wondered how many angels can dance on the head of a pin, but his tortured musings about metaphysical issues associated with the non-corporeality of angels (and the related issue of whether there is excrement in heaven) stretched the limits of reasonable rational inquiry so far that later scholars invented the phrase to mock him.
>
> My thoughts turned to Aquinas last week as I sat through a lengthy seminar on the subject of Boltzmann brains. The speaker decided his ruminations were so important that he needed 90 minutes rather than the customary hour. To my surprise, many in the room seemed to agree with him.

He goes on to explain what this is all about:

> The problem is that statistical arguments suggest that in long-lived universes, far more Boltzmann-brain consciousnesses will develop than intelligences like our own, which have evolved over billions of years. That would mean we are far from typical, so anthropic explanations of our universe fall by the wayside.
>
> Some theorists have therefore tried to develop constraints that would force all inflating universes like our own to decay well before Boltzmann brains can infect them. The bad news here is that in this case our universe must be unstable, and heading for a catastrophic end. But at least anthropic arguments from string theory would not be undermined. You can decide for yourself which you would prefer.

and to conclude:

> If debating angels dancing on pins marked the intellectual low point of medieval theology, then we may similarly question the merits of debating problems that require hand-waving arguments involving unknown quantities that differ by billions and billions of orders of magnitude. Let's focus on other issues, at least until better theories come along.

Update: At Lubos Motl's blog, there's a comment from Krauss noting that the title was chosen by an editor, not by him, and that he agreed that it was misleading, since the piece was not specifically about string theory.

Comments

1. **Tim R. Mortiss**
   March 28, 2008

   From the article: "If debating angels dancing on pins marked the intellectual low point of medieval theology".

   I thought that was a later invention, used to smear scholasticism. If not, I would actually like to read that discussion!

2. **M**
   March 28, 2008

   maybe this "String Theory's Latest Folly" can be interpreted as evidence for the prediction of String Anthropic Cosmology: Boltzmann brains are among us, and they will dominate the Universe

3. **DB**
   March 28, 2008

   Have you read Krauss' latest book? It looks like he's taking a leaf out of Smolin and yours:

   http://www.slate.com/id/2131014/

4. **fh**
   March 28, 2008

   I thought the idea of the debate was that a) if a theory predicts Boltzmann Brains we are misapplying it and its wrong (that is its origin, right? it meant that Boltzmanns idea about the universe as a statistical fluctuation was wrong because it predicted Boltzmann Brains) and b) it's actually a subtle question that teaches us something about the proper use of statistics to investigate whether it does.

5. **Xerxes**
   March 28, 2008

   While I think contemplation of Boltzmann Brains is probably philosophy and not physics, I really don't see what is so bad about thinking about them or (to flip the argument around) what is to be gained by purposefully not thinking about them. The argument starts from assumptions that virtually every physicist would agree with and uses a pretty straightforward argument to come to a paradox. Clearly, there's something that we don't understand here, and resolving it might teach us something interesting. I'd consider it at least as interesting as, say, the Fermi paradox. Perhaps someday, we'll consider it more like the Olbers paradox, where the resolution follows from a critical property of the universe.

6. **oohay**
   March 28, 2008

   [text of comment anonymously attacking Krauss deleted. Please don't do this here, take it to one of the blogs that encourages anonymous attacks on others.]

7. **Moshe**
   March 28, 2008

   Funny piece, full of rhetorical flourishes, as usual with Krauss. The timing is puzzling though, Krauss must have been sitting in this kind of talks, given by his fellow cosmologists, for about 25 years. Why complain now?

Oh, just saw the title, got it.

8. **Yatima**
March 28, 2008

It's Friday afternoon:

[Botanist sues to stop CERN hurling Earth into parallel universe](http://)
A colourful American botanist, teacher, former biologist and sometime physicist says (in outline) that the LHC may rip a hole in the fabric of the space-time continuum and so destroy the Earth. He wants the US government to act now and delay the LHC's startup while a new safety review is carried out.

These 14 TeV are gonna burn, man.

9. **Coin**
March 28, 2008

A little confused here since as far as I'm aware Boltzmann Brains aren't an originally or specifically String-Theory-related idea.

Since I can't read the article itself, I just want to be sure: Would I be correct in interpreting that Krauss is *not* saying that Boltzmann Brains are "String Theory's Latest Folly", but rather that the "folly" is that string theorists have backed themselves into a corner via anthropic arguments such that they now feel compelled to seriously attempt to refute the Boltzmann Brains idea for fear it would pose a threat to string ideas if allowed to stand?

10. **Peter Woit**
March 28, 2008

Moshe and Coin,

I think that Krauss is just properly laying at string theory's door the phenomenon of serious physicists giving research talks devoted to anthropic computations of numbers of universes. Before the anthropic string theory landscape nonsense started up a few years ago, despite what Moshe seems to think, this wasn't the kind of thing cosmologists gave talks about, at least not if they hoped their talk not to be drowned out by snickering from the audience. Now instead this kind of thing is covered in the New York Times and many talks about it are scheduled, given, and, amazingly enough, taken seriously.

11. **Moshe**
March 28, 2008

Oh, there were plenty of talks counting universes, comparing probabilities, talking about the proper measure etc. etc., I sat through some of them as a grad student in the mid-1990s, and it was already a mature subject by then. There is also a paper trail- for an entry point to this vast literature just look at the early papers of any of the main actors in this research area (quite a distinguished list of cosmologists). They start around the early 1980s, when people realized there are new and fascinating issues eternal inflation forces upon us. Even if Krauss gets his "better theories", those would have to deal with precisely the same issues.

12. **Greg Egan**
March 28, 2008

I'm largely persuaded by the paper by Hartle and Srednicki, Are We Typical?, which concludes (roughly speaking) that we have no grounds for discriminating between cosmological theories on the basis of the *proportion* of conscious entities in the history of spacetime that human beings happen to comprise.

We really can't choose values for the cosmological constant, etc., on the basis that a "bad" choice would allow 10^10^10 Boltzmann brains to come into existence at some time in the future, thereby making us atypical observers. If we're atypical, we're atypical; Copernicus won't really spin in his grave, and it won't be the end of science. Nobody had to pull us out of a barrel containing all observers before we were allowed to make an observation.

13. **Zathras**
March 29, 2008

OT, but this article blew my mind in terms of the journalist's sensationalism. It deals with a lawsuit to close the LHC because it will create black holes that will devour everything. The journalist made it look at least very possible

http://www.nytimes.com/2008/03/29/science/29collider.html?_r=1&hp&oref=slogin

14. **Peter Woit**
March 29, 2008

Moshe,

Sure, eternal inflation and discussion of what its significance is have been around for a while, including a certain level of anthropic nonsense. As far as I remember though, the anthropic nonsense only started getting widespread and infecting other areas of physics with Susskind et.al. The attention being paid to the Boltzmann brain silliness is definitely a recent development.

Xerxes and fh,

Despite what you might read on certain well-known blogs, the notion that one can sensibly assign probabilities to different universes and then use this to make scientific predictions is not one shared by most theorists. This is exactly what Krauss is objecting to.

15. **Moshe**
March 29, 2008

Peter, as a matter of personal choice of research direction, I'd probably agree with everything Krauss says in the piece, including his summary – I don't think we have enough knowledge of quantum gravity at the moment to ask the questions raised by eternal inflation, and attempts to proceed anyhow result in low signal to noise ratio. One interesting line of research is then to develop the tools needed, and lots of smart people are thinking about it, not likely to make it to the New Scientist pages anytime soon.

However, Krauss' choice of venue for this message, and timing, and emphasis, and tone, are all in things I disagree with. Oh well…

16. **Randal**
April 5, 2008

If it’s your time and your mind, I guess you can spend it thinking about anything you want, but I think Krauss is essentially right: this is unlikely to prove a fruitful line of reasoning – much like Acquinas’ pin head. Future generations will likely view them similarly. Speculation makes better press than developing real understanding because it’s more fun.

I understood the “latest folly” of the string theorists to be introducing the notion of universe decay as a constraint on the propagation of brains throughout their models; they sacrifice the stability of our universe to save their theories from this absurdity. (Some here don’t seem to like the tone, but I thought this was funny.)

LHC Startup at 10 TeV

March 29, 2008
Categories: Experimental HEP News

Robert Aymar, the Director General of CERN, has announced that the LHC will operate when it starts up this year at an energy of 5 TeV per beam (10 TeV total center of mass energy), rather than the design energy of 7 TeV per beam. To operate the LHC magnets at the highest current and get to 7 TeV requires a time-consuming sequence of powering tests and quenches, so the decision was made to put this off until the winter shutdown. With this decision, the process of beam commissioning can start soon after all sectors have been cooled down, and this is now scheduled for mid-June. Beam commissioning should take two months, with first physics collisions thus scheduled for late summer.

It remains possible that problems will be found during or after cooldown that will require warming back up one or more sectors, and this would lead to a delay of a couple months or so. The last sector scheduled to be cooled down is 4-5, which is now warm to allow repair of the defective triplet magnets. Whenever a sector is warmed up, a major problem is damage to defective PIMs which then need to be replaced. If there are too many of these, a delay in the cooldown is possible. The search for damaged PIMs relies on a “sputnik” tennis-ball-like sensor sent through the beam-pipe. Latest news is that 4 damaged PIMS have been found so far.

Update: I’d been wondering how much extra work this change in energy would cause for the experimentalists, just saw a posting about this by Gordon Watts, entitled Start Your Monte-Carlo Engines!

Comments

1. **D R Lunsford**
   March 29, 2008

   Whoa there. This is a matter for the courts, Peter.

   http://www.nytimes.com/2008/03/29/science/29collider.html

   The laws of physics. PN injunction!

   -drl

2. **Peter Woit**
   March 29, 2008

   I did see the NYT story about the lawsuit this morning, and half a dozen blogs already have postings about it. As far as I can tell, no court is going to take this seriously, so it’s unclear why this story deserves any attention, much less ending up on the front page of the Times.

3. **Domenic**
   March 29, 2008

   Hey Peter,

   As an undergrad, this is the first time in my life I’ve watched a new particle accelerator go through the birthing process. My impression is that the LHC is kinda sucking at it—lots of delays, problems, subpar results, etc. But, I have no basis for comparison, so I thought I’d ask someone who’s been around long enough to know: is this typical?

   Thanks :).

4. **Peter Woit**
   March 29, 2008

   Domenic,

   I don’t think the LHC problems and delays have been at all unusual for a project of this magnitude. For a comparison you’d have to go back to the early 80s (Tevatron) or late 80s (LEP), to see how those projects went as they approached beam commissioning. But the LHC is a more ambitious endeavor than either of those, and it is receiving a lot more attention.

   The crucial period will probably be this summer and fall when they start trying to store a beam in the machine and get a useful luminosity. If this goes smoothly, the thing will be quite a big technical success, even though it would end up being a couple years behind early optimistic schedules.

5. **Domenic**
   March 29, 2008

   Thanks Peter, I thought that might be the case. Well then, here’s hoping! It’d be pretty amazing to go into grad school (2.5 years from now) with some LHC data to guide me.

6. **milkshake**
   March 29, 2008

   About that lawsuit: Here is a photo of a black drainhole at Monticello. (Coming soon to Lake Geneva):

   http://pixdaus.com/single.php?id=30364

7. **wb**
   March 30, 2008

   Peter,

   Not to find fault with the LHC progress but rather to give some additional perspective, I would point out that the PEP-II and KEK-B B-factories were commissioned extremely rapidly. Rapid commissioning is also commonplace these days with synchrotron light sources. RHIC also went fairly smoothly. Regarding LHC one must keep in mind that this is by far the most difficult and largest collider ever built. Moreover it has a enormous stored energy in the beam, the magnets and the fluid systems.

While we all would have liked to see collisions earlier, the LHC team must be applauded for their steady and systematic progress. Likewise the decision to begin collisions at 10 TeV is a prudent one. There is great physics awaiting us.

As for the law suit… the less said the better.

8. **YBM**
   March 30, 2008

   Dear Peter,

   this is related only by Motl adding this postscript to a post of him on the LHC :

   > P.S.: Let me say something about the titles. Of course, I do know that the title is routinely chosen by the editor or the publisher. That was the case of "The Bogdanov Equation", too. On the other hand, I am convinced that the author always has to approve it. Although it was a bit of a shock to see the cover of the book for the first time, I of course fully confess that I approved it after a little thought accompanied by mixed feelings even though this title is arguably not the most accurate description of the content of the book. Whether someone including myself likes it or not, I am responsible for the title. In the very same way, I am convinced that the titles such as "The Trouble With Physics" and "String Theory's Latest Folly" were approved by the authors, too. Trying to get rid of the responsibility – whenever the title becomes inconvenient – is an unfair game.

   Do you know of any reason or event making Lubos to regret his french book ? Apart of him getting miracously some kind of intellectual honesty (which I doubt)…

9. **Peter Woit**
   March 30, 2008

   YBM,

   That comment of Lubos's was in response to Krauss writing in to say that he was not responsible for the headline put on his article in New Scientist. Lubos seems not to understand the difference between a book (where the author definitely has a say about the title) and a magazine article (where the author doesn't). The way he writes about this, one gets the impression that the title was chosen by someone else. It's definitely a curious book, quite possibly there were other hands at work creating the thing than just its official author….

10. **Harry**
    April 1, 2008

    Anyway (and off-topic, sorry),

    "the Bogdanov Equation" is a phenomenal success in France : it just took the record of the best-selling book for its first month (this record was previously hold by "Harry Potter and the Deathly Hallows")

    Unbelievable !

11. **Hans**
    April 1, 2008

    @ Harry

    according to which source?
    The book doesent even figure in the FNAC top 100 and holds place 19 on the FNAC science and culture list. On amazon.fr it has the rank 2,059 (thought #1 in Physics). Sure, this is not bad, but not exactly Harry Potter. ..

12. **Peter Woit**
    April 1, 2008

    Hans,

    I had assumed that Harry's comment was an attempt at April 1 humor.

    Actually, if I had first heard of the Lubos-Bogdanov book on April 1, I would have been 100% convinced the whole idea was an April Fool's joke.

13. **Harry**
    April 2, 2008

    Yes, it was indeed an attempt of April Fool's joke 🙂
    (Sorry, I could not resist.)

14. **Hans**
    April 2, 2008

    Ok, I got fooled!
    And i actually spent 10 minutes checking the sources!

15. **piscator**
    April 3, 2008

    hey peter,

    back to the topic of the post: any idea what is happening with the LHC? In the last day and a half or so all the sectors that were previously being cooled down now all seem to be being warmed up…..

    piscator

16. **Peter Woit**
    April 3, 2008

piscator,

Maybe this has something to do with “Open Days”. On the 5th and 6th they’ll be opening the lab up for visitors, may be that the cooldown is being stopped during that period.

I haven’t heard of any problems, and don’t see anything unusual at their web-site. They finished warming back up one of the sectors (4-5) a while ago, now are looking there for defective PIMS, have found 9. Supposedly more than 24 will be a problem. They just started cooling down 6-7, three other sectors are being cooled down now. Maybe they’re stopping this for a few days…

Short Items

April 4, 2008
Categories: Uncategorized

The Tevatron has been performing well, producing record-high weekly luminosities. Fermilab director Oddone has announced that plans to shut-down the accelerator complex for yearly maintenance work are being canceled this year, instead the plan is to run the Tevatron straight through the year, with a shutdown not until spring 2009. The current proposal to DOE is to run through FY 2010 (i.e. until September 2010), by which time the expectation is that integrated luminosity would be more than double the current value of nearly 4 fb^{-1}.

The budget situation for US and British HEP continues to look rather grim. Durbin and several other senators sent a letter to the Senate Appropriations Committee requesting that supplemental funds for FY2008 be found to stop lay-offs at Fermilab. Senators Clinton and Obama did not sign the letter, which seems especially remarkable in the case of Obama, since Fermilab is in the state he represents. For the latest in the sad story of UK physics funding cuts, see here.

As far as FY2009 goes, Congress is on more or less exactly the same path as last year. Attempts to rein in earmarking were defeated, and committee hearings, including those on the science budget, show no signs of interest in making any tough decisions (to cut military/Iraq war spending, domestic spending, raise revenues) now. See some commentary here. Presumably decisions will ultimately get made by the same mysterious staffers in the same mysterious way as last year. This year the betting is that there actually won't be a budget until deep into the fiscal year, with Congress waiting for a new president rather than negotiate with Bush. This will leave US science programs operating under a continuing resolution, financed at FY 2008 levels into FY 2009.

The P5 committee is meeting in Washington today to put together recommendations for how US HEP should proceed, under various possible funding scenarios over the next few years. For more about their deliberations, see their web-site here. The last public meeting of the group was at Brookhaven, talks there are available here.

Some other recent or upcoming conferences include one at ICTP, one at Warwick on TQFT and string theory (see Marcos Marino's notes here), and the Linde-fest at Stanford.

Talks at the Linde-fest included many serious and informative ones about current cosmology research, together with a large helping of Multiverse madness, since Stanford is ground-zero for this phenomenon. The string cosmology talks were mostly devoted to showing that some string compactification or other can reproduce any conceivable experimental result. Several speakers discussed Boltzmann brains, perhaps one of them was the one who so annoyed Lawrence Krauss recently. Max Tegmark promoted future measurements of the 21cm hydrogen line as being very promising for cosmology, the same point was made here by Scott Dodelson. Lance Dixon gave a talk on the finiteness of N=8 supergravity. He describes conversations with string theorists who would like to interpret this result as indicating that string theory would still be necessary to deal with the asymptotic nature of the perturbation series (not clear why the same problem in string theory doesn't bother them). One problem with this is that string theory doesn't have the same symmetries as N=8 supergravity. Witten gave a talk on his recent work, much the same as one he gave at Stony Brook last week. I hope to write about that in my next posting.

See here for an interesting talk at the KITP in Santa Barbara from Albert de Roeck about what to expect from the early stages of the physics run at the LHC.

Michio Kaku's new book The Physics of the Impossible is getting some attention, especially in the UK. A Fox News story headed Physicist Says Time Travel Is Not Only Possible, but Likely claims that:

> … in Blighty , Kaku's being treated as if he's Doctor Who informing dim-witted humans about the wonders of the Universe, with front-page treatment Wednesday in both the Daily Telegraph and the Guardian. Even the normally staid Economist is chiming in.

while, in the US:

> … outlandish claims in books are recognized as, well, a good way to sell books.

Here in New York, my colleague Brian Greene's World Science Festival is getting off the ground, with a press conference held this week described here.

Sabine Hossenfelder, Michael Nielsen and Lee Smolin are organizing a conference at Perimeter this semester on Science in the 21st Century.

   April 4, 2008

   Thanks for mentioning our conference!

2. **Flip**
   April 4, 2008

   Thanks for another set of great updates.

3. **Lloyd**
   April 4, 2008

   Hi Peter,

   I recall some time ago you announced that you are about to write down some of your original research in a research paper. If I remember correctly the topic was representation theory and quantum field theory or some such.

   How is that going?

   Best wishes,
   Lloyd

4. **Peter Woit**
   April 4, 2008

   Lloyd,

I'm working on some new ideas (involving representation theory) about the mathematics behind the BRST formalism and how to handle gauge symmetries. I have a partially written paper now, hope to get something finished and done this summer. I probably should be spending less time on the blog….

5. **Steve Caudill**
   April 4, 2008

   I'd like to nominate Peter Woit as the initiator of the "Third Superstring Revolution"!!!!

   The Third Superstring Revolution will brand as a 'NON-SCIENCE' string theory, superstring theory, brane theory, M-theory, (or whatever alias the subject goes by.) As a result, American academia, the U.S. government, and publishers of popular science physics books (as well as New Age-related books) will see the need to provide equal support to all valid theories which attempt to find a theory of quantum gravity or a theory of 'Everything'.

   Well, thanks in part to Woit's book, this month instead of buying a book on superstrings from the Scientific American Book Club, I think I'll order "Discarded Science: Ideas That Seemed Good at the Time," by John Grant.

6. **Peter Woit**
   April 4, 2008

   Steve,

   Thanks, but I think the "Third Superstring Revolution" has been the anthropic landscape/multiverse, as popularized by Susskind in his book, and promoted by a growing number of theorists. This is what is behind the increasingly widely held opinion that string theory has degenerated into non-science. Compared to this, the role played by my book was relatively minor.

7. **Copy editor**
   April 4, 2008

   Typo in link to Tegmark talk slides: try this.

8. **milkshake**
   April 5, 2008

   You know Big Sur is a very scenical place and not too far from Stanford – maybe they could organize a joint Multiverse workshop at the Esalen Institute…

9. **Peter Woit**
   April 5, 2008

   Thanks Copy Editor, fixed.

10. **I say**
    April 5, 2008

    There's always a Multiverse workshop happening somewhere. Perhaps even infinitely many. So they say.

11. **Chris Oakley**
    April 5, 2008

    Susskind proselytising the Anthropic Landscape may not in itself demonstrate that the subject has gone into a tailspin, but the fact that the media and conference organisers give him a platform does.

    "I say",

    You don't know that. It could be that in the other Multiverses they speculate about the possibility of their own universe being the only one.

12. **anon.**
    April 6, 2008

    Chris, the multiverse is the most impressive prediction of string theory. What's interesting about multiverse 'physics' is the way it debunks Mach's insistence that physics should deal with what we can potentially observe. The multiverse is the exact opposite of Occam's razor, the principle of economy in speculations. It's a great advance because it makes physics interesting to those greats who would otherwise devote their lives to philosophy.

13. **DB**
    April 7, 2008

    Obama's silence is in no way surprising and is quite characteristic. He is no supporter of large government sponsored research. For example, he plans to "delay" NASA's constellation program in order to fund an early education plan. The implications are discussed further here:

    http://www.thespacereview.com/article/1100/1

    I would predict that with the support available from the likes of Obama, Fermilab's future as the last major outpost of US HEP research is bleak.

14. **chris**
    April 7, 2008

    about obaba and hep funding: i think the us hep community put itself into a political position. essentially, the hep budget is treated like an appendix to the huge defense budget and for better or worse, it is now linked to it politically. that was a relatively easy game under neocon political leadership, but it will bite certainly be very bad if the political course changes to deemphasize military expenses. kind of like a pact with the devil..

15. **Shantanu**
    April 8, 2008

    Peter, the video of David Gross' talk at the IPMU is now online and there was some discussion of anthropic principle and Boltzmann brains
    here

16. **Peter Woit**
April 8, 2008

Thanks Shantanu,

It seems that Gross and I may have some disagreements about string theory, but we agree about "Boltzmann Brain" papers (which he characterizes as "totally preposterous", saying that people work on this "to my regret"). Maybe he can have a talk with Sean Carroll and convince him to stop promoting this stuff…

17. **Hendrik**
April 9, 2008

Michio Kaku's book just had a scathing review at
http://newhumanist.org.uk/1747

18. **nigel cook**
April 10, 2008

That's a worthless book review because it doesn't address the main issue. It's like an *ad hominem* attack, trying to debunk one thing by attacking something else. The alleged trivial errors aren't necessarily a sign that the big arguments are wrong, and I think the reviewer is incompetent to review the book because he ignores the main arguments altogether.

It's simply not good enough to spot a few trivial errors in a book and then try to discredit the main message as suspect. The amount of polishing and error checking of a book written by a very busy author is mainly down to the publisher's editor, not the author. I read a couple of earlier popular books by Professor Kaku, and found them to be well written. The fact that he writes a lot about non-speculative (non-predictive) stuff like string theory is the reason why he is so popular. Fiction outsells fact, and you can't debunk it. If fiction sells, someone will write and publish it.

19. **Shantanu**
April 13, 2008

Peter probably you have seen , but see the talk by Roberto trotta
at PI (last year) arguing against anthropic pinciple.
here
Towards the end of talk (after about 1:00 hr) there is interesting discussion between Moffat and Susskind (I think at least from the voice)

Stony Brook Dialogues in Mathematics and Physics

April 5, 2008
Categories: Uncategorized

Last week I spent a day out at Stony Brook, attending the second day of a two-day symposium devoted to mathematics and physics, held in honor of C. N. Yang and Jim Simons. Peter Steinberg was there for the first day, and has a report about this on his blog. The symposium was in many ways also a celebration of the new Simons Center for Geometry and Physics, which is just getting off the ground with a $60 million donation from Simons. A new building will be constructed over the next couple years, and already one permanent member (Michael Douglas, who will not be the Director, as mistakenly reported in some press accounts and here) has been hired. In an era when string theory has caused a backlash against mathematical and formal research at many physics departments, the Simons Center may be one of very few places where a physicist working at the boundary of mathematics and physics will be able to find employment. To get some idea of how dramatic the situation is this year, with only "phenomenologists" and "cosmologists" getting hired into tenure-track positions, take a look at the Theoretical Particle Physics Rumor Mill.

Stony Brook played a very important role in the interaction of mathematicians and physicists around the topic of gauge theory, and many of the speakers at the symposium discussed this. Since his early work on Yang-Mills, Yang had been intrigued by the similarities between gauge theory and the Riemannian geometry of GR. He built up the ITP at Stony Brook, in the same building and at the same time as a great mathematics department focused on geometry was being built up by Simons. He discussed these similarities with Simons, who told him that gauge theory must be related to connections on fiber bundles and pointed him to *Steenrod's The Topology of Fibre Bundles*. Yang didn't get much out of that (not surprising, since Steenrod is purely topological, with nothing about connections and curvature), leading him to make the statement:

> There exist only two kinds of modern mathematics books: ones which you cannot read beyond the first page and ones which you cannot read beyond the first sentence.

In early 1975 Simons gave a series of lectures to the physicists on differential forms, geometry and bundles, and some real communication between the two camps began. This led to Yang writing a paper that year with Wu, *Concept of Nonintegrable Phase Factors and Global Formulation of Gauge Fields*, Phys. Rev. D12, 3845, that included the famous "Wu-Yang dictionary" explaining how to translate back and forth between mathematician's and physicist's language. The crucial example was the Dirac monopole, where the bundle (for a sphere enclosing the monopole) is what a mathematician would call the Hopf fibration. This was already becoming a hot topic among physicists, with the 't Hooft-Polyakov monopole having been discovered in 1974.

Is Singer visited Stony Brook in the summer of 1976 and talked to the physicists about gauge theories and geometry. In early 1977 he traveled to Oxford, where he, Atiyah and Hitchin began working on instantons, i.e. solutions of the self-dual Yang-Mills equations. Again the physicists had started this, with the discovery of the BPST (Belavin, Schwarz, Polyakov and Tyupkin) solution in 1975, followed by its use by 't Hooft, Polyakov, Jackiw, Rebbi, Callan, Dashen, Gross and others soon thereafter. In his 1977 Erice lectures on The Uses of Instantons, Sidney Coleman refers to the "classic part of the theory":

> "Classic", in this context, means work done more than six months ago.

Atiyah and collaborators were to devote much of the next decade to work on gauge theories. In 1977 he also met Witten, and this began a long and fruitful collaboration. During the years after 1977 Witten would become by far the dominant figure in the subject.

At Stony Brook last Friday, I arrived just in time to catch a morning talk by Dennis Sullivan about the classification of 3-manifolds (he was speaking in place of Iz Singer, who wasn't able to come due to a respiratory infection, but an e-mail from him was read to the audience). Yang made some short comments about a problem in condensed-matter physics. The afternoon featured three hour-long talks. The first, by Dijkgraaf on *The Unreasonable Effectiveness of Physics in Mathematics* was a talk for a general audience advertising some of the high points of how ideas originating in string theory have had influence in mathematics. The main example was the computation of the number of rational curves on a quintic. The talk was extremely polished, featuring very impressive graphics. He described the current situation of string theorists as being very enthusiastic about "emergent geometry", but struggling for the right mathematical language to express these ideas. This is an interesting research program, but as far as I can tell it is one that has to some extent ground to a halt, with little progress in recent years, and Dijkgraaf's talk being essentially the same one he has given on other occasions during the last 5-6 years.

Michael Douglas, who is joining Stony Brook next year as the first permanent member of the Simons Center, spoke on *Physics and Geometry: past, present and future*. He emphasized ideas about "branes" and non-commutative geometry that have been popular since the late 1990s, like Dijkgraaf giving a take on the question of what new sort of geometry string theory might be pointing to. He ended his talk with a sentiment that I would heartily agree with, that he thought the time had come for a deeper investigation into quantum field theory. Unfortunately it was in a context I find not so promising: he has been thinking about how to count quantum field theories as part of anthropic landscape research, and has realized that this is a pretty ill-defined question. His final remarks seemed to be designed to answer skeptics who have noticed that string theory has stopped making progress, noting that physicists like himself are always moving on to something new, and this something new might soon not be string theory. In answer to a question from the audience about what the LHC might tell us about string theory, he gave a defensive set of remarks about the testability of string theory.

The last talk of the symposium was Witten on the topic of *Electric-magnetic duality on a half-space*, and this was a breath of fresh air and an extremely impressive performance. He was discussing joint work with Davide Gaiotto that I wrote a bit about here, based on his recent series of lectures at the IAS, which you can follow in lecture notes from David Ben-Zvi and Sergei Gukov here. The Stony Brook talk was an extended version of one he gave recently at the Linde-fest, available here.

The talk began with a motivational example from d=2, with a 1-d boundary, of a duality in the QFT of real scalars, taking Dirichlet boundary conditions on one side of the duality to Neumann boundary conditions on the other. The next example was 4d U(1) gauge theory, with its electro-magnetic duality, again relating by duality Dirichlet boundary conditions and Neumann boundary conditions for the field-strength F at the boundary. Most of the talk was about his new work on the surprising ways in which duality is reflected in choices of boundary conditions in N=4 super Yang-Mills. He claimed this to be a physicist's way of understanding geometric Langlands and its duality between D-modules and coherent sheaves, but ended after an hour without having much to say about these mathematical implications, (although he jokingly threatened to go on for another hour on this topic if people were willing to stay).

In response to a question, he noted that unfortunately there seemed to be no useful relation between this S-duality and the AdS/CFT duality of the theory that is the reason for its central importance in modern string theory and particle theory.

Witten's talk ended the symposium on a high note. This summer he'll be temporarily moving to CERN as a visitor for the next academic year, so he may be on-site there as, if all goes well, the first results come in from experiments at the LHC.

Comments

1. **nbutsomebody**
   April 6, 2008

   Peter,
   Thanks for pointing out that string theorists are not getting faculty jobs. I think it is almost impossible to judge between important work and junk in string theory, as there

is no objective criterion (no experiment) of doing so. Hence it is not easy to decide who should be offered a job and only choice left is to not offer jobs to string theorists. I guess it is wise too.

2. **Brett**
   April 7, 2008

   Gian-Carlo Rota, a mathematician himself, described algebraic topology books thusly, "There are two kinds of books on algebraic topology: those that end with the Klein bottle and those that are written in the form of a personal letter to Norman Steenrod."

3. **Thomas Love**
   April 7, 2008

   Peter, You quoted Yang:
   "There exist only two kinds of modern mathematics books: ones which you cannot read beyond the first page and ones which you cannot read beyond the first sentence."

   What is the source of this quote?

   IMHO, the statement is a synopsis of the problems with modern physics. The physicists really don't understand the math they are trying to use.

4. **Peter Woit**
   April 7, 2008

   nbutsomebody,

   I think the hiring situation in physics departments is disturbing, with my concern not about string theorists losing out to non-string theorists, but about "formal theory" losing out to "phenomenology". The reason string-based unification failed was not that it was insufficiently concerned about connection to experiment, but that it was a wrong idea. Unfortunately string theorists have been unwilling to admit this, and many of them have tried to turn themselves in "string phenomenologists", claiming often bogus connections to LHC physics or cosmology.

   My own view is that there is still a huge amount we don't understand about quantum field theory itself, that new tools and deeper understanding are needed to make any real progress, and that one way to get to this is through better understanding of the relation of QFT to important ideas in mathematics. Quite a few string theorists in the past have actually been working on this, or on related issues, but research in this direction is now being killed off in physics departments, all in the name of a rush to do often bogus "phenomenological" work. This is a real shame, leaving the only hope for progress in this area increasingly in mathematics departments, but these are typically very ill-equipped to train people or support this kind of research, emphasizing only certain areas that have to do with traditionally popular areas of math research.

5. **Peter Woit**
   April 7, 2008

   Thomas,

   A couple people told me that Yang had repeated this in his remarks on the first day of the conference, which I missed. He also talks about this in his interview in the Mathematical Intelligencer (volume 15, no. 4 Fall 1993, 13-21).

   I don't think it's surprising that physicists have trouble with Steenrod and similar algebraic topology books. Both the language and issues these books are concerned with are quite different than what physicists care about. One excellent book about topology that is more appropriate for physicists is Bott and Tu. These days there are many more readable modern math textbooks than there used to be, mathematicians have moved away from the Bourbaki style of exposition (which was never intended to be a way to teach people anything). But, a lot remains to be done in terms of writing expositions of modern mathematics that can be read by even mathematicians in other fields, much less physicists.

6. **Thomas Love**
   April 7, 2008

   Thanks for the reference Peter. According to Yang, his joke goes back to 1983. From the Mathematical Intelligencer interview:

   Yang: I can tell you a relevant story. About 10 years ago, I gave a talk on physics in Seoul, South Korea. I joked, "There exist only two kinds of modern mathematics books: one which you cannot read beyond the first page and one which you cannot read beyond the first sentence." The Mathematical Intelligencer later reprinted this joke of mine. But I suspect many mathematicians themselves agree with me.

   It has happened to me, I once read an sentence in a math book which I didn't understand. I had to read another book to get the background to read the background to continue.

7. **nbutsomedy**
   April 7, 2008

   Peter said,
   "My own view is that there is still a huge amount we don't understand about quantum field theory itself, that new tools and deeper understanding are needed to make any real progress, and that one way to get to this is through better understanding of the relation of QFT to important ideas in mathematics."

   Your views may be true but I think a lot of theoretical physicists will disagree with such a view. I personally partially agree with what you are saying, but it should also be remembered that too much formalism makes main questions obscure and people have a tendency to do a lot of fancy stuffs (but solvable) without much real progress. In such a point thinks become exactly like string theory. The questions become community driven and which is important becomes completely a question of who thinks it is important. In short objectivity is completely lost.

   Frankly speaking how much the so called "important areas in mathematics" has helped us to gain a better understanding of the physical world is something waiting for a judgement. It may even be more misguided than the string landscape.

8. **nbutsomedy**
   April 7, 2008

   peter,
   Having said what I have written before, I should mention that I agree to completely with your concern about bogus "phenomenology". Especially "string inspired" cosmology and phenomenology. It almost seems like a disease and most of the researches are irrelevant at the best.

The New Math

April 7, 2008
Categories: Uncategorized

Via Steve Hsu, I ran across the cover article from Alpha magazine, a magazine for the hedge fund industry, entitled The New Math. It describes the role physicists are playing in several hedge funds, developing sophisticated trading strategies. One of the best known of the organizations doing this is Renaissance Capital run by Jim Simons, and its success is now responsible for funding the new Simons Center at Stony Brook.

Two of the theoretical physicists featured in the article were fellow graduate students at Princeton while I was there. One of them, Marek Fludzinski (who was a couple years ahead of me), quickly left academia and went on to a career in finance, ending up founding the Thales hedge fund, which he still runs. The other, John Moody (more about him here), was in my class and so I got to know him quite well, but I had lost track of him in recent years. He worked with Frank Wilczek on axions and left Princeton for Santa Barbara after Wilczek went there to the ITP.

In recent years quite a few mathematics Ph.D.s and a very large number of particle theory Ph.D.s have ended up in the finance industry, and the article describes the kinds of things that they are doing. The impact of the recent melt-down in the credit markets remains to be seen: maybe there will be fewer jobs available in this field, or maybe demand will increase for people with this kind of technical background as companies pursue ever more sophisticated strategies.

Comments

1. **TomW**
   April 7, 2008

   Unfortunately, the most likely outcome is that the "eggheads" will serve as convenient scapegoats for the fact that banks had no idea what kind of debt they owned or whether it was any good or not. Cue backlash in three, two, …

2. **Chris W.**
   April 7, 2008

   The last thing they need is more sophisticated strategies. It's funny how so-called financial engineers never seem to have heard of the old engineering **KISS** principle, much less thought paid close attention to the hard lessons software engineers and computer scientists have been learning about building complicated systems for the past 5 decades. And then there is the natural invitation to fraud offered by debt securitization…

   Of course, they've had to deal with clueless executives and investors breathing down their necks, looking for ever higher returns. That certainly doesn't help in learning and sustaining good engineering judgment.

   Sorry; the rant is over.

3. **D.**
   April 7, 2008

   There is always room at the top, if I may steal that paraphrase, but in my experience there exists a fairly high washout rate among the physicists, less from aptitude than boredom or culture shock.
   However, once you've developed your toolbox and demonstrated good results, you'll basically never want for a job again; the unemployment rate among good quants has been about zed for at least two decades, being more a factor of liquidity than anything else.

4. **Deane**
   April 7, 2008

   In business section of last Sunday's Times, there is a review of a book called "The Trillion Dollar Meltdown". It quotes the author as saying, "As a general rule, only the very smartest people can make truly catastrophic mistakes".

   I think Chris W. has it right.

5. **mathjunkie**
   April 8, 2008

   It is not new that banks or financial institutes look for quants who have PhD degrees in physics. Back in year 2000, the physics professor I worked with asked me if I was interested in working in some banks as a quant as they needed such people to do very difficult maths. As my maths was really not good, I refused the offers.

6. **Allan**
   April 8, 2008

   It will be interesting to see how many of the Masters programs in financial math/ risk engineering / whatever will survive the current meltdown. And what will happen to the unemployment rate for new Ph.D.s in both math and physics if this alternative career is no longer readily available.

7. **Mathew Crawford**
   April 8, 2008

   This article should get play higher up the media chain. Off Wall Street, industries should recognize what geeks bring to the table in terms of strategic sophistication. Many do, but many don't. The number of math jobs (including those going to the physicists) will increase, not decline.

   Chris W.,

   I don't think the current financial meltdown and the sophistication of hedge fund strategies are linked in a particularly meaningful way. The mortgage system that failed us was in place before hedge funds became what they are today — a field of giants in the financial industry. Hedge funds didn't pressure anyone to make an industry out of sub-prime loans. (And hedge funds have been complaining about Bear for a long time.)

   Hedge fund traders have been talking about how scary the leverage at Fannie Mae and Freddie Mac have been for over a decade, but could do nothing about it but talk.

Deane,

As for the smartest people making catastrophic mistakes, that may often be true. But most generally, it's the people with the most power who make the biggest mistakes. This is just the common investor effect, and sometimes the power holder is not the smartest person in the room.

8. **Chris W.**
April 8, 2008

See this interview with Robert Merton in *Technology Review*.

I'm not buyin' it…

Matt: Major players in the financial services industry facilitated and encouraged the growth of the sub-prime mortgage industry, and disseminated securities based on these sketchy loans. They can say that nobody had to invest in these things, but that's disingenuous; they were *marketing* them, and they were fully intent on succeeding in those marketing efforts. Clearly there was a lot of fraud and stupidity among subprime lenders, but they've paid the price; they're out of business or shadows of their former selves. The borrowers are hardly getting a free ride either.

The whole "investors and borrowers were stupid, and have themselves to blame" argument is at about the same moral level as a drug dealer who ridicules his junkie customers for buying the product.

Perhaps the only reality check (if not a solution) is extreme skepticism, shading into paranoia, and willingness to look under the hood by anyone who relies in some way on the machinations of this industry. If that smacks of saying screw the banks and hiding one's savings in a mattress, so be it. Fortunately there are quite a few financial institutions that managed to maintain some detachment from the whole debacle.

[Sorry, Peter.]

9. **Deane**
April 8, 2008

I maintain that the most powerful person in the world (say, George W. Bush) is able to make a catastrophic mistake only with a lot of help from extremely smart people. The point is that smart people are able to magnify or leverage a small or diffuse effect into much bigger or more concentrated one.

10. **Michael Bacon**
April 8, 2008

"The point is that smart people are able to magnify or leverage a small or diffuse effect into much bigger or more concentrated one."

Yes, but there's a bit of cancellation going on at the same time. Probably stable overall, but subject to big fluctuations that could have really bad effects.

11. **DB**
April 9, 2008

I think you need to distinguish two categories of math jobs, those related to creating quantitative trading strategies and those used for the securitization of mortgages into what are known as Collateralized Debt Obligations (CDOs).
The former will continue to prosper, but the latter is essentially dead in the water, because it is a major factor in the credit crisis. Enormously complex mechanisms were used to package suspect loans in order to obfuscate the true risk in the underlying securities – essentially nobody understood how dodgy these vehicles were because they were deliberately packaged so as to frustrate any attempt to understand them according to standard financial principles.
Mortgage securitization will recover and continue, but this industry is experiencing a "flight to simplicity", transparency will be everything so there will be no place for complex and concealing math.

12. **Chris Oakley**
April 9, 2008

DB –

The most common use for math/science PhDs in finance that I am aware of is in developing derivative pricing models, of which CDOs are but one strand … I do not see this going away any time soon – although the appetite for derivatives is greater in a bull market it does not go away completely in a bear market, especially as existing portfolios still need to be managed.

13. **Deane**
April 9, 2008

Re: DB's comment

"Flight to simplicity" is a good thing, and I hope it continues.

And indeed this will probably lead to reduced demand for quants and less blind acceptance of sophisticated models. But that does not mean that mathematical finance will go away. It will definitely continue to play a significant role in finance, including securitization of mortgages and other assets. However, both quants and their overseers need to be both more honest and outspoken about the limits of what mathematical finance can do.

I believe a lot of quants understand the pitfalls of their models but have been unwilling or unable to express these issues effectively to others.

14. **Tim Jones**
April 9, 2008

An early example of the particle theory to finance transition is eloquently described in Emanuel Derman's autobiography "My life as a quant". I should declare an interest: we worked together on early electroweak models in 1973, and this is discussed briefly in the book. (Page 73!).

15. **stevem**
April 9, 2008

In the (rather good) textbook “Statistical Mechanics of Financial Markets” one chapter discusses potential uses of earthquake prediction theory and a “Richter scale for market crashes”, as well as ideas of scaling, turbulence theory and so on; so all sorts of ideas are being considered. Getting some real idea of when things are about to go seriously awry is the real trick in this game, and that’s where LTCM in particular failed disasterously. It has clearly been demonstrated that these trading strategies can work effectively if they are not pushed too hard; then steps can be taken if there is a nasty change in market dynamics. But LTCM in particular was massively overleveraged and got immobilized by its sheer mass. The problem is that some managers and investors are always going to want to always push the models and push boundaries to try and create bigger returns, or to outdo each other. The state of the art seems to be getting very advanced now though albeit not infallable. The stuff on genetic algorithms, machine learning and neural nets discussed in the linked article is pretty interesting though.

Another problem is when you have more and more people chasing the same money and opportunities in the markets, using the same strategies. I wonder how much of the financial engineering literature is worth reading since all the best stuff will no doubt be kept very secret. Also, it could be all too tempting and convenient for traditional manages, traders and Wall street types to blame the current mess (or future crises) on the “eggheads” or “rocket science”, especially if things get worse. Some traditional Wall Street types and traders also no doubt feel resentment towards hedge fund managers who make much more than them and of the widening gap between “the haves” and the “have mores”.

The fact that there were a number of well-documented high-profile disasters in the 90s directly due to “eggheads” does not help either:LTCM of course, as well as Joseph Jett and Kidder Peabody, and the Orange County derivatives mess, also due to a theoretical physicist I believe. However, the steady, consistent and sober performance of Renaissance Technologies for example has also given a lot of credence and respect to what responsible quantitative finance or financial engineering can actually do. So I would say it is an open question for now as to whether the current situation will see an increase in demand for physicists and mathematicians or a decrease. I’m skeptical though as to whether aspects of human behavior and psychology can be factored into models. When he lost £20,000 in the South Sea Bubble Newton supposedy said: “I can compute the motion of heavenly bodies but not the madness of people”.

16. **Chris Oakley**
April 9, 2008

Dr. Oakley’s Lessons To Be Learned From Past Financial Disasters

Orange County: Some derivatives salesmen are really good.

Joe Jett, Nick Leeson & Jerome Kerviel: When large amounts are involved, make sure that at least one person in the organisation outside the trader’s bonus pool knows and understands fully what is going on.

LTCM: PhDs in Mathematics sometimes do really stupid things.

17. **Sven**
April 9, 2008

When you think about it, what is the common thread between the following?

String Theory
LQG
LTCM
Subprime Hedge Funds

18. **locrian**
April 9, 2008

> And what will happen to the unemployment rate for new Ph.D.s in both math and physics if this alternative career is no longer readily available.

Unaffected. Financial engineering is a fairly small (in the scheme of physics) area that only a very few PhD’s from the very top schools tend to go into. If it disappeared entirely I doubt it would have any dramatic affect on physics employment rates. The idea that Wall Street is scouring physics departments is largely a myth these days; what might be more accurate is that there area couple of physics departments and a few MFE departments they look to.

Personally I see physicists as being eliminated from that area entirely over the next quarter century as students with more formal training replaces them.

19. **Teacher of Quants**
April 9, 2008

It’s unlikely that “students with more formal training [will] replace” physicists and mathematicians. Despite the availability and employment advantages of specialized MFE and PhD programs in quantitative finance, there is still a wide gap in capability between the students on that bandwagon, and the theoretical math/physics types.

20. **locrian**
April 10, 2008

I agree that there is a wide gap in capability between students in MFE programs and theoretical physicists – the MFE peeps are much better at quantitative finance, at least for some significant initial period of time.

21. **Teacher of Quants**
April 11, 2008

Unless you mean “MFE peeps” who already have a solid math/physics background (such as academia opt-outs grabbing a remunerable credential), the physicists leave them in the dust sooner rather than later. For a physicist to replicate the MFE skillset is much easier than the reverse.

22. **Chris Oakley**
April 12, 2008

I have to agree with ToQ here: I mentored a PhD in Aeronautical Engineering who had no previous finance experience. In less than three months he was able to write code to calculate cross-currency asset swap spreads from first principles. OTOH others I worked with in the investment banking business, some of whom had taught Finance at university level, but had no specific math or “hard science” background did not, IMHO, even understand what a yield curve was.

23. **Haelfix**
April 12, 2008

Everyone knew the housing bubble was going to burst, but actually some of the largest money to be made is right at the tail end of a bubble, which is why you see all these people staying in the game years after they first calculate the impending doom.

The whole art is knowing when to get out in time. To that end, many quant derived highly adaptive and sophisticated computer models were made that were very sensitive to the relevant indicators that should predict how and when that would take place.

The catastrophe occured when every indicator failed at the exact same time. There was no provision for that, and thus the models failed.

Its a good example of when and how computer simulations can go awry.

24. **dave tweed**
April 12, 2008

It does strike me as unfortunate that a high proportion of the people who get these sort of finance jobs are theoretical physicists rather than population biologists, computer network designers or others who work with mathematical models in science. By its nature, physics tends to deal with situations where you can make accurate measurements of variables and where there's no collusion between states, so they really don't have an intuitive feel for when they don't hold, but neither are particularly true in finance. On the other hand they're dealt with everyday in other fields. I wonder if there is any reason beyond economists physics-envy and the inherent self-promoting bombast of physicists why they're the primary group recruited into mathematical finance? Is it an apostolic-succession situation?

Physicists are hired for marketing reasons…."Look how smart our people are"

Physicists On Tape

April 12, 2008
Categories: Uncategorized

Over at the Center for Science Writings, John Horgan has started an interesting project of posting copies of taped interviews with scientists that he has accumulated over the years, starting with an interview with Chandrashekar. In a blog entry about this, he points to a piece entitled Revenge of the Science Writer from 2001 by Robert Crease, a historian of science and co-author of what I think is the best history of the development of the Standard Model: *The Second Creation: Makers of the Revolution in Twentieth Century Physics*. Crease describes Horgan as "a man who does not destroy his tapes", and tells the following story:

> I once interviewed a well known European physicist whom I had arranged to meet at a table in the noisy lunchroom at the Brookhaven National Laboratory. I pulled out a tape recorder and asked him about one of his experiments. The scientist could barely disguise his impatience. After five minutes we had a slight misunderstanding about where a certain event took place. I corrected him; he thought I hadn't been listening.
>
> "That's it!" he fairly roared as he abruptly stood up, his chair shooting backwards. The background hubbub in the lunchroom suddenly plummeted and everyone turned to stare. He strode away, shouting, "This is a total waste of time! You're an imbecile!" Or at least I think that's what he shouted. I can't be sure, because I destroyed the tape. I was too embarrassed to consider replaying it, or risk having others know my humiliation.

One tape I wonder if Horgan still has is that of his interview with Witten back in the mid-nineties. His chapter on string theory in *The End of Science* included a rather harsh portrayal of Witten, some of which I remember as being quite unfair. It's also true that Horgan's aggressive skepticism about the claims being made at the time for string theory has stood up very well in light of what has happened in the intervening fifteen years or so.

3. **Michael**
   April 14, 2008

   I know many writers and artists that have the same reaction to interviewers, this is from Sally Mann:

   "Over the years I've learned not to talk about my work, taking to heart the Robert Doisneau quote that goes something like this: "If you make pictures, don't speak, don't write, don't analyze yourself and don't answer any questions." I would amend that by adding, "And don't read any critical comments, either." People always seem to freight the work so heavily with meanings that were not in any way intended or even subconscious. "

4. **Wavefunction**

   Crease's book is indeed excellent.

Dark Matter

April 13, 2008
Categories: Film Reviews

Yesterday evening I went to see the new film Dark Matter, which opened here in New York this weekend. In many ways, it's very good, much better than I was expecting.

The plot is loosely based upon the story behind the 1991 shootings at the University of Iowa physics and astronomy department. Gang Lu, a Chinese graduate student who had recently defended his Ph.D. but was having trouble finding a job, shot and killed five people, including his advisor, and severely wounded a sixth person. One unfortunate aspect of the movie is that it rewrites this true story to make the killer much more sympathetic, while making some of the people who were murdered much less so than they seem to have been in real life. The families and friends of the victims may be justly outraged by this. There's more about the film and the controversy over its relation to the Gang Lu story here.

In the movie the real life space physics at Iowa has been transposed to cosmology at a university in Utah. It remains set in the early 1990s, with protagonist Liu Xing recently arrived in the US from mainland China. His advisor, Jacob Reiser, is a cosmologist with a model called the "Reiser model" which is based on cosmic strings. Liu Xing comes up with what he considers a breakthrough, a new model based on using superstrings to explain dark matter. This doesn't meet with Reiser's approval, and he is failed at his dissertation defence for a bogus reason (this is one of the ways the movie sadly departs from a realistic plot or the true story). The scientific advisor for the movie was David H. Weinberg, a cosmologist at Ohio State, and Lee Smolin is thanked among many others in the credits.

The strongest point of the movie is its portrayal of the lives of the graduate students, mostly Chinese, who are struggling to adapt in an alien environment, some of them consumed with a passion to make breakthroughs in science, others already trying to figure out what to do about their not-so-great academic job prospects. The director, Chen Shi-Zheng, emigrated to the US about the same time as Gang Lu, 1987, and so starts from a deep understanding of what the experience of Chinese students arriving in the US at that time must have been like.

Back in the real world, David Harris is reporting from the big April APS meeting on the new Symmetry Magazine blog Symmetry Breaking. In a blog entry entitled Dark Matter Discovered? he reports a rumor that the DAMA collaboration will report on Wednesday that they have detected dark matter in the latest run of their experiment. This story just appears on Slashdot, "slashdotting" whatever unfortunate web-server is running the Symmetry Breaking blog, so it is inaccessible for the moment .

Update: For more about the DAMA rumor from science writers at the APS meeting, see this blog entry from JR Minkel, and a characteristically detailed and informative posting from Jennifer Ouellette.

Update: There are now reports from the talk by Tommaso Dorigo and Alexey Petrov, and the slides are here. Sounds like this experiment is definitely seeing a signal with yearly variation, but it's controversial whether this is due to dark matter or something else much less interesting.

Update: Yet more from the New York Times and Tommaso on this topic.

Update: Yet more skeptical commentary about DAMA here.

Comments

1. **Thaddeus**
   April 13, 2008

   Come on Peter, it's fiction. Artistic license is not only permissible, it's desirable.

2. **DB**
   April 14, 2008

   The Dama collaboration will have a job on their hands to convince sceptics after they cried wolf in 2000. The latest PDG review states:

   "The DAMA experiment operating 100 kg of NaI(Tl) in Gran Sasso has observed, with a statistical significance of 6.3 σ, an annually modulated signal with the expected phase, over a period of 7 years with a total exposure of around 100 000 kg·d, in the 2 to 6 keV (eee) energy interval [33]. This effect is attributed to a WIMP signal by the authors. If interpreted within the standard halo model described above, it would require a WIMP with mχ □ 50 GeV and σχp □ 7 · 10–6 pb (central values). This interpretation has, however, several unaddressed implications. In particular, the expected nuclear recoil rate from WIMPs should be of the order of 50% of the total measured rate in the 2–3 keV (eee) bin and 7% in the 4–6 keV (eee) bin. The rather large WIMP signal should be detectable by the pulse shape analysis. Moreover, the remaining, presumably
   e/γ-induced, background would have to rise with energy; no explanation for this is given by the authors. The extended version of DAMA, LIBRA, is now taking data with 250 kg of NaI(Tl) in Gran Sasso; results are scheduled to be published in 2008."

3. **Coin**
   April 14, 2008

   Artistic license is not only permissible, it's desirable.

   Couldn't we object on purely artistic grounds? It seems to me that storytelling is much less interesting when you try to sugarcoat everything.

4. **Mike**
   April 15, 2008

   The link to Jennifer Ouellette is broken. You are missing the "t" from "twisted".

5. **Peter Woit**
   April 15, 2008

   Mike,

   Thanks, now fixed.

6. **axel.**
   April 15, 2008

I agree with Coin: turning a tragedy caused by an (apparently) personal crisis into one caused by politics is not a very artistic way of looking at things, is it? but i haven't seen it yet, only the trailer, and of course the infos on wikipedia are not really "first hand", either.

7. **luny**
   April 15, 2008

   I read about this episode in the book Disciplined Minds.
   The account given there was very sympathetic to the student and unsymphathetic to the advisor.

John Wheeler 1911-2008

April 14, 2008
Categories: Obituaries

News of the death of John Wheeler came yesterday, and many people have already written detailed, touching and informative pieces about the man, his life and scientific achievements. See for example here, here, and here. With Wheeler gone, physics loses one of its very few living contacts with the early days of quantum mechanics, since his career reached back to the early thirties when he went to study with Bohr.

My most extensive contact with Wheeler was surely through learning GR from the marvelous textbook he co-authored on the subject. By the time I got to Princeton as a student, he had recently left for the University of Texas, in order to evade Princeton's mandatory retirement age policy. He still was a presence in the department though, returning to give talks (I remember one that was an advertisement for the importance of the notion of a complex: "the boundary of a boundary is zero!" was the slogan). My only conversation with him was at a meeting organized between graduate students and a visiting committee of people evaluating the department. I recall a very friendly older man who came up to talk to me, and listened attentively to my going on for quite a while about how things could be improved. Only after we had finished speaking and he had left did I realize who I had been talking to. My overwhelming feeling immediately was that if I had realized this earlier I'd have much more enjoyed keeping quiet and getting the chance to ask him a few questions.

Update: See here for another article about Wheeler, from the University of Texas. It includes the claim that "Wheeler was the first person to emphasize the importance of string theory", which, as far as I know, has nothing to do with reality.

Update: For more about Wheeler, see this interview just put on-line, and this discussion at Bloggingheads.

Comments

1. **Thomas Love**
   April 14, 2008

   Way back in 1973 I was a pilot in the USAF, thinking about graduate school. I wrote a handwritten letter to Wheeler. In response I received a 5 page handwritten letter from him with very good advice (including advertisements for his books). I only know him through his books and articles, but he had a profound effect on me and my work.

2. **Matti Pitkänen**
   April 15, 2008

   Wheeler-Thorne-Misner was also for me a very stimulating book, in particular his topological ideas were very inspiring. I remember also Boulder lectures. Without Wheeler's very positive and detailed hand written summary about the article representing the first version of Topological Geometrodynamics it would have been probably very difficult to publish it. The attribute "Topological" was added to "Geometrodynamics" as the title of article for obvious reasons: I do not remember whether it was Wheeler or David Finkdelstein who proposed this. I am really proud of having had this contact.

3. **MathPhys**
   April 15, 2008

   Misner, Thorne and Wheeler is on the bookshelves of almost every person I know who trained and/or aspired to be a scientist in the 70's.

4. **Dr. E**
   April 15, 2008

   John A. Wheeler was my advisor for my junior projects at Princeton.

   He was a "professor emeritus," with an office on the third floor of Jadwin Hall.

   The first junior paper was on GR, and the second was on the EPR effect & quantum paradoxes.

   I had first come across Wheeler's work my freshman year in the awesome book: Quantum Theory and Measurement (Princeton Series in Physics) by John Archibald Wheeler and Wojciech Hubert Zurek.

   There was a copy in my freshman dorm's library–it was the only physics book in the rather small collection.

   I remember one autumn day, in his office in Jadwin Hall, he clenched his fist lightly and said that today's culture lacks the noble. And he looked at me and said it was our generation's duty to bring it back.

   This was around 1990; and think of all that we have seen in the past twenty years or so, in physics, politics, Wall Street, and beyond. It seems we have some work to do….

   Wheeler had walked with Einstein at Princeton and mentored Feynman. He came of age in an era when debates, as manifested by that by the Bohr Einstein dialogues, were marked by an exalted respect–both for one another and for Physical Reality. And he embodied that refined respect; with a humility matching his intellect and monumental accomplishments.

   He said that freshmen ought begin research right away, when he adressed the freshman class of physics majors; and he told us that while the grad students knew a few things, the professors knew even less. He said this with a wink and smile.

   He was a cordial friend to all; and always lent everyone his ear. He was most generous with his time; and his enthusiasm to "know what the show is all about, before its out," was contagious. He was one of those rare intellectual leaders who inspired the better angels of our nature.

   Well, we will all miss him. And we ought do our best to thank him, by embodying his principles in our daily actions and contemplations–in our pursuit of physical reality's fundamental nature.

5. **Ali**
   April 15, 2008

Hi Peter,
What is this Princeton’s mandatory retirement age? This is the first time I am hearing of this type of practice in USA.

6. **Peter Woit**
April 15, 2008

Ali,

Many universities in the US used to have mandatory retirement ages for tenured faculty, typically age 70. This was made illegal in 1994.

7. **nontrad**
April 15, 2008

True, the UT article seems to suggest a quote by Unruh that relates Wheeler to ST. That’s strange, at least to me, since I can’t think of significant contributions to ST made by Unruh or Wheeler. But, I’m probably myopic and mistaken. The mix of folks and folklore and word of mouth can be hard to follow.

That said, the UT article seems to reiterate a consistent point in the various tributes to Wheeler seen since his NYT obit: He advocated for physic’s future in general; and the younger generations in particular.

A man who truly made difference.

8. **nbutsomebody**
April 16, 2008

I regret that I did not have the opportunity to meet the last of the giants.

9. **Thomas Love**
April 16, 2008

Peter, This is the only comment by Wheeler on strings that I have found so far:

“Space and time are not things, but orders of things. If these words of old call to a new and deeper conception of space and time than Einstein’s publications give us, then in what direction are we to look? For a reply, many today would point to string theory or other new and exotic developments. But if we are not yet ready to accept them, with all of their new elements, then where can we look?”

—Daniel H. Wesley and John A. Wheeler, “Towards an Action-at-a-Distance Concept of Spacetime”, in A. Ashtekar et al (eds.), “Revisiting the Foundations of Relativistic Physics”, pp. 421-436, Kluwer Academic Publishers, 2003

That doesn’t sound like a supporter of string theory.

10. **Peter Woit**
April 16, 2008

My best guess would be that the claims about Wheeler and string theory are based on someone mistaking the S-matrix for string theory. The recognition of the importance of the S-matrix is often attributed to Wheeler, back in 1937.

11. **rob**
April 16, 2008

The statement about string theory is bizarre indeed. My guess is along the same lines as Peter’s: Bill Unruh probably said Wheeler was one of the first people to think about quantum gravity. The reporter probably confused quantum gravity with string theory, as so many people do.

12. **Luiz**
April 16, 2008

Ali and Peter,

Sorry for the off-topic but maybe this “mandatory retirement age” wasn’t such a bad idea after all.
http://www.phdcomics.com/comics/archive.php?comicid=912

Cheers.

13. **Professor R**
April 17, 2008

Hi Peter,
your tribute ‘my most extensive contact with Wheeler was surely through learning GR from the marvelous textbook he co-authored on the subject’ is very fine, and probably the sort of tribute Wheeler would have appreciated most.
I suspect the passing on of knowledge becomes very important to the giants of science as they get older, jst as it does for musicians etc. It must be fantastic to see one’s students and grand-students making progress in theoretical physics – but a good textbook can reach a much larger audience!

14. **Jimbo**
April 18, 2008

Much continues to be said about Johnny Wheeler, but if you’d like to watch him describe his remarkable life, here is a link to a series of in-depth video interviews he gave just a few years ago.

http://www.peoplesarchive.com/browse/movies/2359/

15. **Daniel Wesley**
April 20, 2008

remember that John Wheeler he occasionally expressed a desire to learn more about string theory. He wasn’t overly critical of, but he certainly never tried to sell me on it. To that extent I think it is probably not accurate to describe him as a strong supporter of string theory. I think it would be just as inaccurate to describe him as a foe.

To extrapolate from my own experience, I think the issues that string theory has been successful in addressing are not necessarily the ones that he was most interested in: things like the nature of (space) time, the connection between physics and information ("it from bit"), why quantum mechanics is so strange, and so on. I think he believed that the big advance in quantum gravity would come from a conceptual breakthrough (a la Einstein) rather than a technical one. He believed that once we had the right answer we'd be able to explain it easily to "the man on the street," and I don't think any of the ideas we've come up with so far pass this test!

I was very sorry to hear about John's passing. He was a great inspiration to me, and I cherish the lessons I learned from him. I've met very few scientists of his stature who were so generous with their time and energy. He had a sign in his office, which said "Encourage! Encourage! Encourage!" and he lived that motto in an exemplary way.

16. **Eric H**
April 23, 2008

From the comments I'm reading I believe Mr Wheeler was a compassionate person and a scientifically great man in the technical sense. The only thing that bothers me about his legacy is that he seems to have given so much credence to bad ideas, such as "delayed choice", "quantum fluctuations" in the absense of describable forces, etc. While he understood that great ideas have an intuitive aspect to them the ideas he ended up being famous for were exactly the opposite of that realization. Its really unfortunate that good people can end up being the promulgators of these types of ideas.

Because he seems to have been a kind and encouraging person many of these ideas that have led to a dead end in quantum physics have been promulgated by his students. Now, if he had had a nasty temperament I'm sure this wouldn't have been the case. How many times through history has the sociological aspect of the teacher/student relationship had an impact on what gets taught rather than the quality of the ideas?

17. **Eric H**
April 24, 2008

At the risk inflaming feelings and becoming a scapegoat I will add one further observation about John Wheeler. His attitude about quantum mechanics was summarized in this quote:

"To Wheeler, quantum mechanics was a "great smoky dragon," particularly with respect to the bizarre behavior of the electron, which defied classification as a wave or a particle. It could be anywhere, everywhere or nowhere, depending on the observer.

This led him to the conclusion that reality, as we know it, comes into existence only because we are here to see it and bring it to life. "

I believe this conclusion that he came to that there is no external reality apart from our observation is the single most deluded and erroneous conclusion about quantum mechanics that has ever been foisted on the scientific community and the public at large. This is what allows scientists to speculate about alternate universes being created when a quantum choice is initiated. Because all possibilities are simultaneous realities then there "must" be an alternate universe created whenever a quantum choice is made.

To me it is incredible how scientists just go along like sheep with such ideas because the scientist making them, John Wheeler, is well regarded in other aspects of physics. It just shows how stupid physicists can be and how they can be led astray even more than the general public on these types of things. Poor William of Occam would shudder at the ineconomy of having to create an entire universe out of whole cloth every time a decision is made.

18. **Peter Woit**
April 24, 2008

Eric,

I don't think you can blame Wheeler for multiple universes. The recent interest in them comes from a very different direction.

Actually, just about all physicists not only don't follow Wheeler like sheep, but happily ignore his idiosyncratic views about quantum mechanics. Even among those who are more interested and would pay some attention to his views, I don't know of anyone who would follow them because of their source. More typically, such people have their own idiosyncratic views…

19. **Eric H**
April 24, 2008

Peter,
I hope you're right about independent thought. I used to believe in it much more than I do now. There seems to be unconscious processes that go on in all of us that make us want to fit in with the herd. I don't think it is a very attractive characteristic – especially so in the different fields of science. I sincerely wish I was wrong but I don't see evidence of it.

Multimedia and the Journal of Number Theory

April 16, 2008
Categories: Uncategorized

I recently heard from David Goss, editor-in-chief of the Journal of Number Theory, that the journal is planning on introducing video abstracts for papers that they publish. Here's his e-mail explaining this:

> Dear Colleagues:
>
> By now I believe that all of us have had the pleasure of watching a famous scientist or mathematician discuss their work on internet video. I have certainly done so myself and learned much. Indeed I can readily give a long list of mathematicians who I would very much like to view presenting the ideas behind their great works.
>
> For example, it would be fabulous to watch a young Serre discussing the ideas behind FAC or GAGA; or a young Faltings discussing his solution on the Mordell Conjecture etc. I am sure that each of you can compile your own long list (and obviously not just papers on number theory!).
>
> It is in this spirit that I suggested to Elsevier that all JNT authors be allowed to present a short (4 minutes max) "video abstract" of their accepted manuscript. Elsevier has kindly accepted this idea and is now quite excited about it.
>
> The idea is very simple: When a paper is *finally accepted* for JNT, the author will be notified and given the option of putting up a video abstract — THIS IS ONLY FOR ACCEPTED PAPERS! The video will be watched to check for professionalism etc., and those videos deemed offensive will not be used (and the author sanctioned!). The video will then be linked next to the paper on the JNT website. Information on how to upload files, etc., will be on the JNT website by April 23, 2008.
>
> Videoing virtually anything is now deeply a part of our culture as witness the rise of YouTube. In fact, we will be using YouTube itself temporarily until Science Direct is augmented to handle flash files (which I hope will be within a few months). The url is:
>
> http://www.youtube.com/user/JournalNumberTheory
>
> where there is a short video about these multimedia abstracts!
>
> I expect the video to be very low key like the one on the above url. I also think that, frankly, it will be a fun thing to do after all the hard work producing an accepted manuscript! Certainly the technology to produce such videos is now ubiquitous worldwide.
>
> It is important to note that ALL such videos will be archived by Elsevier and thus will be available for future scholars and mathematicians.
>
> With a little thought one can see vast possibilities here: For instance a paper on the topology of elliptic curves could be proceeded by a short video of computer graphics narrated by the author etc.

Comments

1. **Jason Starr**
   April 16, 2008

   Why do we need Elsevier for this? Anybody can post video to YouTube, and no university libraries need be bankrupted in the process.

2. **Arun M T**
   April 17, 2008

   An open repository would be truly great. `You Tube' wouldn't be a bad idea.

3. **tom**
   April 17, 2008

   I agree that libraries don't need an extra Elsevier charge for this and that anybody can post on youtube.

   On the other hand since the aim is really to talk only about accepted papers, all such videos posted to the youtube group of the journal should have both comments and ratings disabled since any youtube user (think laymen, children and anonymous colleagues) can comment and rate any youtube videos that allows it. In fact I'm not sure that ratings can be disabled in youtube, which would be a problem.

4. **Klaus Korak**
   April 17, 2008

   Hi, I am a co-founder of the Journal of Visualized Experiments in Cambridge, MA.

   Please visit our site at http://www.jove.com.

   we would be very happy to support this effort!

5. **Bee**
   April 17, 2008

   I can only say about this what I said previously: the quality of a video and how well one can sell oneself or the topic does greatly depend on professional support. If the journal doesn't provide a service that ensures videos can be produced with roughly equal quality, this will just widen the gap between the scientists in institution where there is such a support (e.g. by the public outreach department or by a hired contractor) and where there isn't. When I read a sentence like 'videoing virtually anything is now deeply a part of our culture', I have to ask myself exactly whose culture is meant here? (I certainly don't see it as part of my 'culture'.) As much as I like watching videos myself, I am afraid this can bias people's opinions towards those who have the possibilities to come up with great videos. Yes, I would expect that the first some videos are low key, but if this becomes an established procedure and gains in importance, researchers and their institutions will try to produce the most convincing videos they can possibly come up with. The analogy to commercials and their influence on the 'free marketplace' lies at hand.

6. **Alejandro Rivero**

April 17, 2008

It is important that youtube (and, I expect, other storage sites in the future) provides now a "chromeless player" which allows full control of video, jumping to specific positions, sinchro with slides or other videos, all from javascript.

7. **Steve Myers**
April 17, 2008

At first it seems like a good idea, but I think it would also cause fear & trembling to run through math depts. The few times I've been forced to "present" it is usually a disater with an hour lecture condensed to 5 minutes of quick explanations & scribbled derivations & questions answered by pointing to an equation. And it could easily start the wrong kind of competition (American math idol?).

8. **Thomas Love**
April 17, 2008

The five minute limit seems rather strange, who can say anything worthwhile in that time? It would be better to have each author post a video presentation of a full hour lecture.

9. **Coin**
April 17, 2008

Alejandro: Lee Smolin has been posting a lecture series this past semester on the nature of time, and he is using some interesting flash player that shows a video of Smolin giving the talk in one corner of the window and the current page of Smolin's slides in the rest of the window. It would be interesting to see this concept used more often (and especially interesting if it could be extended such that the table of contents for the slides could be used to jump to that point in the lecture!).

10. **dave tweed**
April 17, 2008

Since Arun talked about an open archive, let me point out that another issue is storing the video in an open format. YouTube relies on Adobe Flash, and my understanding is that whilst Adobe releases a specification of the format their licence disallows using it to implement a player, so "officially" you are restricted to hoping adobe release a player for the computer system you use. (It may be that this clause in their licence is invalid; I'm not a lawyer.) Even if Adobe do release a version for your system, I've had bad experiences with their installer software on minority systems like Linux, where it makes some big assumptions that are sometimes wrong. So picking a format where legally only one company can make the software presents problems that could be avoided by picking a format that's intended to be free for anyone who wants to to implement.

11. **Jeff McGowan**
April 18, 2008

I don't get the point of this at all. I had a paper (joint with E. Makover) in JNT in 2006, 5 pages long, I could explain the proof to a good high school student. Even with an unusual paper like that, I can't see what this would add. I could pretty much read the main part of the paper in 5 minutes, but to explain it well takes about an hour. And I don't want to sit through 5 minutes for each paper to try and figure out if I'm interested, I want to scan though my most recent email from arxiv with a short paragraph about papers in fields I might be interested in, and figure out quickly which ones are worth putting more time into

I'm guessing they were thinking "well, it's great when one of your colleagues stops you in the hall and spends 5 minutes telling you about their latest result" but that is a completely different thing.

While I'm here, hi Peter, long time. Remember getting pulled over at UCLA with Huntley. I tell that story all the time 🙂

12. **Maynard Handley**
April 18, 2008

WTF is this being done using streaming technology?
There is NOTHING streaming can do that cannot be done better with downloaded files. A downloaded file can be played on a media player away from your desktop, can be played at greater or slower than 1x, can be substantially more easily and smoothly scrubbed.

If you want to see how to do this sort of thing properly, go to the KITP web site (http://online.kitp.ucsb.edu/online) instead of reinventing the wheel and doing so badly.

13. **Peter Woit**
April 18, 2008

Hi Jeff,

Nice to hear from you!

From what I remember of the incident Jeff is referring to, we were stopped by UCLA campus police, presumably on the grounds that no person with any legitimate business on campus would be driving there at night in the kind of car I owned at the time (an ancient Chrysler New Yorker, on its last legs, that I had bought for some ridiculously small amount of money from Peter Orland). It took some effort to convince the cops that we were reputable mathematicians there for a conference, with the behavior of one of our number in the back seat not helping matters… But it's been a long time, I probably am misremembering this.

14. **Jeff McGowan**
April 19, 2008

Peter,

That's it, more or less as I remember. My only misbehavior in the back seat was not having my hands in view, which annoyed the officer with the gun behind the car. I seem to remember Huntley being quite loud, which is no surprise, and of course all three of us had pony tails. Ah, I miss my hair….

btw, love checking in on the blog. I ended up interested in the whole string theory thing since I kept bumping into it at conferences (my first memory is some talk on Riemann surfaces where the number 26 popped up and someone asked "is that the 26 from string theory dimensions"), and now I'm actually doing a lot of stuff on RS and trying to learn Grothendieck's stuff. I really enjoyed your book, and Smolin's (I never met Lee, but always felt a connection since he was the physics student at Hampshire before me, and there weren't many of us).

15. **John R Ramsden**

April 20, 2008

From David Goss's email:
>
> The video will be watched to check for professionalism etc., and those videos deemed offensive will not be used (and the author sanctioned!).

Chortle. How in the world could a 4-minute abstract on a number theory paper conceivably be offensive? Are there number theorists with Tourette's syndrome, or those who tend to flash their audience without warning?! Those number theory seminars must be more interesting than I thought 😉

16. **Peter Orland**
April 20, 2008

Well, to be precise, it was a Ford LTD, with a police-car engine.

At Fermilab the Tevatron is producing record amounts of luminosity, see here for a story about a celebration of this. Things also appear to be going well at the LHC, as the cooldown remains on schedule, and only a tolerable number (12) of PIMs needed to be replaced in the sector recently warmed back up. See here and here for some discussion of current planning for the next year. The machine should be cool and ready for beam commissioning in late June, and if all goes well, by September an initial physics run with 5 TeV beams at relatively low luminosity may begin. At these luminosities and energies, the stored energy in the LHC beam will be no greater than at the Tevatron (although the important number for physics, the per-particle collision energy, will be 5 times higher). The plan is to run until December, with a heavy-ion run at the end, then shutdown until April 2009. During the shutdown the magnets will be trained, allowing beams at the full energy of 7 TeV during the 2009 run.

Particle theory, especially string theory, is not doing as well. Data recently compiled about top-cited particle physics papers from 2007 shows only one theory paper from this century making the list of 51 most heavily cited papers, and that was the KKLT paper which is referenced by all "landscape" and "multiverse" studies. The sad state of string theory has even made it deep into the popular consciousness. Last week's episode of "The Big Bang" featured a brilliant young prodigy explaining to the particle theorist character that his work on string theory was a "dead-end", due to the landscape problem. Even economists are dissing the subject:

> Modern financial theory as applied ranks with string theory in physics as one of the greatest intellectual frauds of our time. Whereas the vacuous pretensions of string theory have finally been exposed (we now know that the theory never generated a single falsifiable prediction), those of "financial engineering" are just beginning to be exposed both in the press and in lawsuits alike.

At Santa Barbara, Jennifer Ouellette reports on a workshop about "how to come off better during TV appearances":

> Joe Polchinski (inventor of D branes in string theory, and one of the few permanent members at KITP) also agreed to be mock-interviewed, revealing a sly sense of humor in the process. For instance, asked if there was any controversy about string theory, he deadpanned, "Oh no. Everybody agrees that string theory is correct." It cracked up the room.

This workshop unfortunately didn't seem to include the advice to just say no when asked by TV producers to participate in a short stupid comedy skit making fun of science and scientists. See here, here and here, for reports on Wednesday's "Root of All Evil" show from Comedy Central, which featured a mercifully short segment making fun of scientists as incomprehensible geeks. Participating in things like this does about as much to help the image of science and scientists as appearing on a Spike TV segment about the use of physics to determine whether women can crush beer cans with their breasts.

Given that things are going very well with the LHC, and badly with string theory, string theorists are doing the logical thing: advertising their activities with graphics of strings superimposed on a picture of the LHC. See here and here.

Update: Minutes from the LHC Installation and Commissioning Committee April 11 meeting are here. They include the exchange:

> L.Evans asked if the cryogenics teams are still on track for having the whole machine at operating temperature in mid-June. S.Claudet replied that taking the figure of 6 weeks from room temperature to 2K, and allowing 2 weeks of cryo tuning, sector 45 would be ready for hardware commissioning in the first half of July.

This indicates that beam commissioning is likely to begin in July, not June.

Also discussed was what to do about possible stray plastic parts in the beam tube:

> Any pieces of plastic would be vaporised by the beam so we should not delay start-up to search for these.

Update: Commentary on this posting from Lubos here, including

> I am amazed by the people who deliberately keep on opening the pile of manure called Not Even Wrong – it must be due to a really nasty deviation of theirs that dwarves pedophilia.

Comments

1. **Ethan Siegel**
   April 18, 2008

   Peter,

   Thanks for an interesting post today! I'm trying to figure out whether there are any definitive tests one can do to either validate or falsify string theory, and the overwhelming large parameter space the landscape provides seems to make this impossible.

   I've written a little bit about it on my website here and here, but haven't gotten any responses that explain whether string theory is, even in principle, testable at this point. What are your thoughts on it?

   Best,
   Ethan

2. **dan**
   April 18, 2008

   Dear Peter,
   I understand that luminosity is related to the number of particle events, a certain large number of which is required for the statistical probability of interesting rare events like the production of Higgs and/or SUSY-partners.

   I understand for a given collision energy, a non-detection of an increased luminosity beam rules out the existence of Higgs and/or SUSY-partners at that energy (i.e Higgs does not have a mass below 130GEV with 2-sigma 95% before the luminosity upgrade, increasing to 3-sigma 99.7% with the luminosity upgrade)

   I understand that Tevatron has had a "300x" increase in luminosity with a 100x increase in data, but how does this affect string theory? Neither string theory nor SM is committed to a specific value for the Higgs and/or SUSY partner masses, although it is obvious the increased luminosity constrains it. How does an increase in luminosity for TEV spell things going badly for string theory (unless you feel that TEV's non-observation contrains what LHC might see)?

3. **piscator**
April 18, 2008

If particle experiment does well particle theory does well. The entirely correct model of TeV-scale physics may already be written down, published, on the arxiv – and attracting five citations a year.
Experiment alone will separate the wheat from the chaff.

The logic of counting citations to measure success says that particle theory is only doing well when there is a bandwagon that is acting as a paper factory. If (God help us) there were three hundred papers on unparticles this year would that really make 2008 a great year for particle theory? There is lots of interesting work around, but it is no bad thing if there is not so much ambulance-chasing.

4. **Jacob**

Seems like someone is a bit jealous he wasn't asked to be on "Root of all Evil" instead………

5. **big vlad**
April 18, 2008

I feel I must point out that just because string theory is in a parlous state, doesn't mean the rest of particle theory is. In particular, phenomenology is in a great state. There is more work in this area than there are people to do it, and career prospects are bright for young researchers entering the field.

6. **Peter Woit**
April 18, 2008

Ethan,

String theory is simply not testable, by any conventional understanding of what it means to have a scientifically testable theory. I've spent much time here going over the arguments about this, I suppose I should spend some more and get them put together in some place I could easily point to. A FAQ, if you will…

dan,

The fact that the Tevatron and LHC are doing well has no correlation with the fact that string theory is doing badly. String theory has zero to say about what either machine will see.

piscator,

I just disagree with your statement that "there is lots of interesting work around", but for some mysterious reason, almost everyone is ignoring it. If you have some data that backs up this point of view, I'd be interested to hear about it.

Jacob,

I suppose there's a long list of things in life that other people but not me are invited to do and I'm jealous of this. Appearing on "The Root of All Evil" isn't one of them…

7. **Coin**
April 19, 2008

we now know that the theory never generated a single falsifiable prediction

Maybe OT, but I am fascinated by the way this is phrased. "We now know"? It is as if this was only discovered in retrospect. "In 2006 a theorem was published which proved that no one had published a paper between 1986 and 2006 containing a distinct predictive model of M theory…"

8. **Sara**
April 19, 2008

At this moment, the motto of String Theorists seems to be: "If the mountain won't come to Muhammad, Muhammad must go to the mountain".

9. **dan**
April 19, 2008

Dear Peter

"dan,

The fact that the Tevatron and LHC are doing well has no correlation with the fact that string theory is doing badly. String theory has zero to say about what either machine will see."

String theory may have "zero" to say but what about SUSY-quantum field theory? Since string theory would probably go into decline if LHC-TEV does not see SUSY, and continue to flourish if it does see SUSY,

If SUSY does stabilize the EW scale, and some form of SUSY-field theory is used as a basis of some sort of prediction based on this, what does the current non-observation of a light higgs and other SUSY-partners at TEV's increased luminosity imply with the likelihood LHC will see SUSY when the TEV currently has not, with its much increased luminosity.

10. **IMHO**
April 19, 2008

> Peter Said:This workshop unfortunately didn't seem to include the advice to just say no when asked by TV producers to participate in a short stupid comedy skit making fun of science and scientists. Participating in things like this does about as much to help the image of science and scientists as appearing on a Spike TV segment about the use of physics to determine whether women can crush beer cans with their breasts.

Hi Peter,

I don't think that's even close to accurate. In fact, I think it shows a severe misunderstanding of popular culture, social interaction, and human nature in general.

It's pretty basic…

An incomprehensibly opaque field populated with unaccessible inhuman humorless people who don't act "normally" like the rest of us……that's scary and scary things are burned at the stake.

Those smart guys who talk all that incomprehensible smart stuff, but they're pretty funny and just regular people like the rest of us….If tv says they're important, then I guess it's ok to support them.

To see that this is true, just look at every government that has ever existed in the history of the universe. There is an entire political appatatus as a buffer between serious policy and the lay public….think of that skit as the incipient physics political arm.

Bad publicity is something like: Those smart guys think we're stupid, and they're trying to trick us.

A FAQ would be an excellent idea.

12. **Peter Woit**
April 19, 2008

dan,

As the Tevatron gets more data, they presumably can push up a bit the bounds on SUSY, and there is a range of possible SUSY parameters that the Tevatron can't exclude, and that the LHC could observe. But string theory has nothing to say about the values of these parameters, even about whether anything will show up in the LHC range.

13. **just a graduate student**
April 19, 2008

I'm starting my phd on quantum gravity and already got sick about the existent situation. I'm tired of watching consecutive attacks against string theory (ST). ST did this, ST can't do that, ST is the atomic bomb.

All we have in quantum gravity is 5-6 theories that did simply nothing for physics. No predictions, no experiments, nothing at all. Still, everyone still fights for the best theory to survive the game. "MY theory has unification!" yeah, but "MY theory is background indipendent, yours is not!" etc etc etc.

oh dear lord, why quantum gravity is so appealing to me instead of condensed matter physics, or photonics?

why?

14. **tommaso dorigo**
April 19, 2008

Dan: *"I understand that Tevatron has had a "300x" increase in luminosity with a 100x increase in data,"*

Sorry for nit-picking, but it takes so little additional effort to be accurate… It bothers me when numbers fly loosely in a scientific argument.

The Tevatron had a x15 increase in the record instantaneous luminosity in Run II over Run I. The integrated luminosity in Run II is now 30x larger than in Run I, not x300. And that means a similar factor in the increased statistics for rare processes with high trigger and collection efficiency, say for instance top quark pairs; save a small (30%) additional increase due to the larger energy of the beams in Run II vs Run I (980 vs 900 GeV per beam).
Instead, the total bounty of data has not increased by x30 WRT run I, but just by about x10. That number is almost meaningless, however, since it is only connected to the data aquisition capabilities of the system, and has nothing to do with the size of "discovery" datasets (which have increased by about x30x1.3=x40, as I said above).

Cheers,
T.

15. **Steve Caudill**
April 20, 2008

Interesting that there is a workshop on how to look better on TV!

As a government scientist (U.S. Nuclear Regulatory Commission nuke inspector), I've had to go through about 6 week-long training courses over the past 17 years, in which we were videotaped and our taped performances critiqued, etc. One such course dealt specifically with how to handle interviews by the media, which was taught by ex-media personnel.

Now I'm just waiting to get on TV!!! (but not as a result of a nuke accident of course!!)

16. **chethan krishnan**
April 20, 2008

> All we have in quantum gravity is 5-6 theories
> that did simply nothing for physics.

This is a bit of a murky area. Because science is not JUST about predictions, but also about understanding. Epicycles could make excellent predictions for planetray motion, but understanding came only with Newton.

String theory does give you its share of Aha! moments. I will just mention one that I haven't seen mentioned much to the general public: Mathur's fuzzball proposal for black holes. It is very hard to believe that we do not understand the essential mechanism of black holes after you read, say, hep-th/0502050. Of course it is possible that "real" black holes don't fit with the plan, etc. etc., but thats mostly because everything is possible.

The basic point is that string theory seems like a good theory of some quantum gravity – but not manifestly ours. I think this is reason enough to work on it.

> No predictions, no experiments, nothing at all.

Yes, expriments are hard to come by in this day and age. But should we shut down speculative theory because of that? Heck, thats all we got! The other option seems like throwing the baby out with the bathwater to me.

17. **Bee**
April 20, 2008

Given that things are going very well with the LHC, and badly with string theory, string theorists are doing the logical thing: advertising their activities with graphics of strings superimposed on a picture of the LHC. See here and here.

At least the first graphic I am sure I've seen before, I think on a workshop called 'Strings at CERN' in 2004 or so.

18. **jpd**
April 20, 2008

re chethan krishnan:
i think the gist of the opposing argument is that the
bath water is cold. take the baby out , dump the water
and get some more hot water.

19. **chethan krishnan**
April 20, 2008

> i think the gist of the opposing argument is that
> the bath water is cold. take the baby out , dump
> the water and get some more hot water.

I am glad you got the maximum mileage out of that bit. 🙂

If there is a new theory that is more promising than string theory, by all means I am for it. I am just not happy with the sitting around and waiting for it part. In the meantime, exploring string theory seems like the most useful thing to do to get some insights into quantum gravity. The fact that it might even be right, adds to the attraction.

Also, the inherent difficulty of testing quantum gravity at low energies makes me suspect that speculating will be inevitable to get a glimpse of the truth. Which is why I find arguments against speculative theories not so compelling. My claim is that even though the issue is often portrayed as string theory vs. something else, it really reduces to theorizing vs. no theorizing.

Over and out.

20. **Peter Orland**
April 20, 2008

>chethan krishnan Says:

>If there is a new theory that is more promising than
>string theory, by all My claim is that even though the
>issue is often portrayed as string theory vs. something else, it really > reduces to theorizing vs. no theorizing.

Chethan,

I think you are right, if there are only certain problems you want
to theorize about. But there are other things besides gravity
and unification to theorize about. Your view is the mainstream
one in theoretical high-energy physics, of course.

Personally, I don't think quantum gravity is an important science question, though it is certainly a fun and interesting question. I would write a paper about it (and have once or twice), if I had an idea concerning it I liked; but it just doesn't interest me as much as other problems. The Planck mass just can't be studied with experiments. Quantum gravity may be fun, but it also seems like a distraction from serious physics. People who hold this view aren't loved by their colleagues (I don't think we are disliked either, just ignored), but there it is…

21. **anon.**
April 20, 2008

'… the inherent difficulty of testing quantum gravity at low energies makes me suspect that speculating will be inevitable to get a glimpse of the truth. …'

You're judging alternative theories by the criteria of string theory. In string theory, quantum gravity effects are important only at unobservably high energy scales.

Take a look at all the loose ends in classical gravity at present (dark energy, dark matter, etc.) which quantum gravity should say something about at low energy where general relativity is a classical approximation to quantum gravity.

An alternative to string theory may predict the amount of dark energy, i.e. the lambda term in the classical general relativity solution which will emerge as an approximation for low energy.

That would be a checkable prediction. String theory can't do it because of the landscape problem, but some alternative quantum gravity theory might be able to predict lambda. Just because string theory is a failure, doesn't mean to say that all other ideas will be a failure, too. They just haven't had the concentrated attention and effort devoted to them yet, that string theory has received for ages.

22. **Peter Woit**
April 20, 2008

chetnan,

The only people I see suggesting "sitting around and waiting" as a research strategy these days are string theorists, who are unwilling to give up on a failed theory, and instead advocate waiting for LHC results that will "narrow the parameter space" of possible string theory vacua to be investigated, or produce some unexpected result which will fuel the next theory bandwagon for them to hop on to.

The only way a new, more promising theory will come about will be from people working on trying new things, not from sticking to tired, familiar ideas that they are comfortable with even though they don't work (for by now well-understood reasons). If you don't want to try to find something new, why bother spending your life working in this area? The world is full of all sorts of interesting things to do and to think about, devoting yourself to a failed idea because it pays the rent isn't much of a way to spend one's life.

23. **Aaron Bergman**
April 20, 2008

But there are other things besides gravity
and unification to theorize about. Your view is the mainstream
one in theoretical high-energy physics, of course.

Judging by where the money's going, I don't think that's an accurate assessment anymore.

To anon: If you happen to have a theory of quantum gravity, or really anything at all, that has something useful to say about the cosmological constant, I think you'd find that people will start studying it very quickly.

24. **One of 10,000 Monkeys**
April 20, 2008

"who are unwilling to give up on a failed theory, and instead advocate waiting for LHC results that will "narrow the parameter space""

You seem to think that unless a theory can uniquely predict everything that will be seen at LHC from first principles, then the theory must be no good. I'd like to ask, when has such a thing ever happened? The Standard Model was produced with the guidance of experimental results, not deduced beforehand. You're like some guy around 1960 going around complaining about how Yang-Mills theory is a total failure and waste of time because it can't predict anything.

Really, you're just the equivalent of a Rush Limbaugh for science. All one has to do is replace 'string theory' with 'liberalism' in your diatribes and it's a one-to-one mapping. Indeed, you were probably the main source for articles such as

http://www.conservapedia.com/String_theory

People who read such articles and take them seriously are your intellectual brothers.

25. **Peter Woit**
April 20, 2008

"You seem to think that unless a theory can uniquely predict everything that will be seen at LHC from first principles, then the theory must be no good."

Monkey,

For the 10,000th time, the problem with string theory is not that it doesn't "uniquely predict everything" that the LHC will see, but that it predicts absolutely nothing at all about this (or anything else for that matter…).

Thanks for the link to "Conservapedia" where the entry for string theory states "As of today, string theory has been a total failure." That's not a web-site I would normally ever consult, interesting to see that the "string theory has failed" meme is even showing up there. Someone should tell Lubos.

Seeing all the bad press string theory is getting some days makes me feel sorry for string theorists. I tend to get over this pretty quickly though when I see how they are reacting to it, e.g. by making bogus claims about testability and the LHC.

26. **Aaron Bergman**
April 20, 2008

Just as a random note, why is it that falsificationism and positivism seem to be conflated so often? (Conservapedia, admittedly not a source known for its accuracy, is just the latest I've seen.) As I recall, Popper came up with falsificationism as an explicit reaction against positivism which was more concerned with making meaningful statements (a sort of verificationism).

27. **One of 10,000 Monkeys**
April 20, 2008

"the problem with string theory is not that it doesn't "uniquely predict everything" that the LHC will see, but that it predicts absolutely nothing at all about this (or anything else for that matter…)."

Exactly the same thing could have been said about Yang-Mills theory in the fifties and sixties. Yet, the Standard Model turned out to be a Yang-Mills theory. In reality, string theory is presently in the same place today as the quantum theory was from the period 1905-1925, before the formulation of quantum mechanics.

28. **Peter Woit**
April 20, 2008

"string theory is presently in the same place today as the quantum theory was from the period 1905-1925"

Monkey,

If you want to get some idea of the broad range of convincing experimental tests passed by the old quantum theory, you might want to look up the Nobel citations for Planck (1918), Einstein (1921) and Bohr (1922). These were not people who spent their time making up absurd excuses for not having a testable theory, and the Nobel committee didn't give them Nobel prizes based on such excuses.

29. **One of 10,000 Monkeys**
April 20, 2008

Peter,

Please explain to me how the photoelectric effect and the emission spectra from the hydrogen atom were tests of the quantum theory (using the criteria you apply to string theory)? Both of these phenomena were well-known before either Einstein's or Bohr's models, so I don't think you can claim that the quantum theory of this time made any testable predictions. Indeed, the Bohr model is in fact not correct. Rather, the quantum theory itself was pieced together bit by bit using these experimental data as guidance.

As a counter example, I can construct string models with three generations of chiral fermions which transform as representations of the SM gauge group, just as Bohr used the quantum theory to construct models of the hydrogen atom. In neither case, do we make any new predictions. However, the models themselves may lead us to a deeper understanding.

30. **Peter Woit**
April 20, 2008

Monkey,

It's just simply not true that all Bohr did was "construct models of the hydrogen atom" that predicted nothing.

31. **David Nataf**
April 20, 2008

Peter, is it really true that string theory failed to make any predictions, did they predict a cosmological constant would have to be negative in the 1990s?

10, 000 monkeys, the Bohr model of the hydrogen atom was able to explain things that nobody else was able to explain – the emission lines of hydrogen. The theories available at the time predicted the electron should crash into the proton… whereas the standard model has a solid grip on particle results. Does ST have such a result? Einstein got a value for h in his photoelectric experiments that matched the h that popped out of Planck's equations for the blackbody spectrum. That's pretty good.

They worked off not understood anomolies such as atomic spectra. We've now had equally not-understood anomolies such as dark matter for thirty years, and dark energy for ten. We have a curiously flat and uniform universe. There's a lot that no one understands, as much as there was in 1905.

32. **dan**
April 20, 2008

Hey Peter, have you seen this article, string theorists weigh in on what they think the LHC will see, and how it affects string theory

http://www.telegraph.co.uk/earth/main.jhtml?xml=/earth/2008/03/25/scibigbang125.xml
http://www.telegraph.co.uk/earth/main.jhtml?xml=/earth/2008/03/25/scicomments125.xml

For copyright reasons I won't reproduce what they say here except this:

MARTIN VELTMAN "As for string theory, it's all mumbo jumbo, with no connection with experiment.' I wonder if he came to this conclusion on his own or as a result of reading your work and the controversy it has inspired

NIMA ARKANI-HAMED "My hunch is that there's a better than evens chance that supersymmetry will show up at the LHC"

EVA SILVERSTEIN "I'd be extremely puzzled if they don't find the Higgs, but wouldn't be devastated if they didn't come up with evidence for supersymmetry.

'Some of my intuition comes from string theory, an appealing candidate for a theory of all the forces of nature. According to many – perhaps most – versions of string theory, supersymmetry does not hold good at the energies probed by the LHC, so its discovery might require further explanation from this point of view."

PW, Eva's statement comes as news to me, is there any reason why Eva (and some of the other string theorists interviewed) are backpeddling from seeing SUSY at LHC energies, given the 'hierarchy" argument for SUSY in the EW-scale? Eva is now claiming that string theory SUSY probably won't show up at LHC energies, but that if SUSy does show up, string theory would need further explanation.

If LHC does not see SUSY, could SUSY still be (experimentally speaking) the explanation for hierarchy argument (if the SUSY-breaking scale is above what LHC can produce/detect) which is what Eva seems to be saying.

33. **Peter Woit**
April 20, 2008

David,

There never were serious claims that string theory "predicts" a non-positive CC, although as late as 2001 Witten was writing that he knew of no "clearcut way" of getting a positive CC out of string theory.

If you look at the Einstein Nobel citation you'll see that it explicitly refers to detailed tests of the photo-electric effect performed after Einstein's proposal that tested and confirmed his predictions.

dan,

Thanks for pointing those out, I hadn't seen those quotes. The Silverstein quote that

"According to many – perhaps most – versions of string theory, supersymmetry does not hold good at the energies probed by the LHC"

is a bit striking, given that many string theorists in the past have claimed low-energy supersymmetry as a "prediction" of string theory, and that if it does show up, they certainly will claim it as evidence for string theory.

I think what she is referring to is the idea that one can show that there are more string vacua with SUSY breaking at high energy than at low. If SUSY doesn't show up at the LHC, Arkani-Hamed and others will claim this as evidence for the landscape, on the grounds that the only possible explanation for the hierarchy is an anthropic landscape.

Veltman has always been a string theory skeptic, he didn't get that from me…

34. **One of 10,000 Monkeys**
April 20, 2008

David,
The Bohr atom didn't explain anything, it merely fit the data that was available namely, the Balmer series. As for the stability of the atom, Bohr only gave an ad hoc rule for this, which was to say by decree that orbits satisfying the angular momentum quantization rule (which was again ad hoc) were stable. This is not an explanation, merely a phenomenological model. Even though the Bohr model was almost completely wrong in almost every respect, it was still useful, mostly because it led to the deBroglie wave/particle duality. This of course, then led to the Schrodinger equation.

Regarding the Silverstein statements regarding not being upset about the prospect of not seeing supersymmetry at LHC, Peter is correct. I've heard this from Kachru himself, who made the accompanying statment that 'Natural is whatever nature does', to justify why the anthropic arguments to solve the hierarchy problem are no more unnatural than supersymmetry.

35. **dan**
April 20, 2008

Peter,
I thought Eva's guess was based on the fact that the light higgs, higgs, and SUSY has not been seen at TEV, which constrains and decreases the likelihood low energy hierarchy-solving SUSY will be observed at LHC, or 50-50 as NIMA ARKANI-HAMED quantifies it.

Eva's argument seems specious to me since even if most vacua imply a high-scale susy-breaking than is unattainable at LHC, I would use the anthropic principle to argue that we happen to live in a universe where the SUSY-breaking scale is close to the EW breaking scale (within LHC energies) so as to solve the hierarchy problem. In a multiverse, we would not exist in a universe with a high energy SUSy breaking, as it would allow the Higgs boson through radiative quantum contributions to pull up to the GUT or planck scale.

If LHC doesn't see SUSY, then evidently SUSY isn't the correct explanation for the hierarchy problem, is there any experimental or observational reason to think SUSY is a true but broken symmetry of nature besides the running coupling constants?

36. **chris**
April 21, 2008

dan,

if you ever heard veltman talk on anything, you would have instantly recognized that he is a critic of everything except feynman diagrams. i am not sure he even takes local QFT as well established fact.

monkey,
i encourage you to stop embarrassing yourself and do as peter suggested: read up the nobel citation for bohr.

37. **Bee**
April 21, 2008

Monkey,

Your reasoning is completely confused, read your own comments. You've eventually come to claim the thing to do is making 'phenomenological models' that are 'useful' because they can lead to further insight. I couldn't agree more! Just that you started up claiming essentially the opposite, namely that theories do not need to give rise to models that make predictions that test the theory. I think you have somewhat of a confusion about models and theories (recommended reading). Best,

B.

38. **One of 10,000 Monkeys**
April 21, 2008

Dear Bee,
I'm not sure where I claimed that theories do not need to give rise to models that make predictions that test a theory. I certainly hold no such opinion. However, you must first get to the point where your theory is understood well enough to do this, and generally you need to be able to construct specific models. In the previous example I gave regarding Yang-Mills, there is absolutely no chance that the Standard Model can be derived directly from YM. Indeed, the SM is but one of a vast landscape of possible Yang-Mills theories. To discover which one describes our universe, we construct models that describe the known data and try to fill in the gaps. Once the model is sufficiently developed, then testable predictions can be made. This is how science works.

39. **Brett**
April 21, 2008

The Bohr model made several crucial predictions. It predicted the existence of new lines in the hydrogen spectrum, although this probably could have been done using numerology alone. Much more important, it predicted that the quantized nature of the spectrum was related both to the quantization of light as photons and the quantization of the energy levels of atoms. The former form of quantization was still gaining acceptance, although its utility in explaining physical phenomena was already demonstrated. That the atomic levels of hydrogen (and by extension, all atoms) were quantized was completely new. This property of the Bohr model made many strong predictions, such as the outcome of the Frank-Hertz experiment.

40. **One of 10,000 Monkeys**
April 21, 2008

Brett,
The Bohr model did not predict any new lines in the hydrogen atom. At best, it merely gives the Rydberg formula. As far as the quantization of energy levels is concerned, this is a postulate of the model, not a prediction. For all practical purposes, it was a lucky guess. Don't get me wrong, I am not puttying Bohr down. He was a first class phenomenologist and philosphopher.

41. **jpd**
April 21, 2008

its amazing how many geniuses come up with lucky guesses.

42. **Peter Woit**
April 21, 2008

"For all practical purposes, it was a lucky guess."

I see, the only difference between string theorists and Planck, Einstein, Bohr is that they haven't been as lucky…

The argument that Monkey is making I think is based upon a somewhat different argument that David Gross is fond of, that, at the conceptual level, one should think of the present state of string theory as analogous to that of the old quantum theory, a patchwork of ideas that indicates the existence of a still unknown underlying well-defined theory.

I always thought it was a bad idea for Gross to promote this analogy, since there were obvious huge problems with it, especially problematic being that the old quantum theory had a huge amount of experimental backing, while string theory has none. Monkey's comments indicate that my concern was justified.

43. **One of 10,000 Monkeys**
April 21, 2008

Are you guys that are so fond of the 'genius' Bohr aware that he advocated giving up the principle of energy conservation?

At any rate, I put Bohr's model on the same level as the deBroglie wave hypothesis. Both ideas were brilliant and lead us to the correct theory, quantum mechanics, but the ideas in themselves are not completely correct. This is the essence of bottom-up phenomenology, as opposed to the top-down approach.

44. **chethan krishnan**
April 21, 2008

>The only way a new, more promising theory will come about
> will be from people working on trying new things, not from
> sticking to tired, familiar ideas that they are comfortable with

Not sure there is a recipe for scientific revolutions. One thing I am fairly certain of is that pushing the current ideas to their limits is probably going to be essential to see beyond them. In the case of quantum gravity, string theory is certainly a way to gain such insight, whatever its ultimate use.

> even though they don't work (for by now well-understood
> reasons).

:).. Right.

> If you don't want to try to find something new, why bother
> spending your life working in this area?

Not wanting to try something new? Try what? The only way to come up with something new that is non-crackpot is to understand the existing ideas well enough to know their holes.

Besides, we are all clutching for straws here! It is easy to sit there, play critic, condescend, etc.

> The world is full of all
> sorts of interesting things to do and to think about, devoting
> yourself to a failed idea because it pays the rent isn't much of a
> way to spend one's life.

Thanks for the career advice. I guess! 🙂

Its amazing the bitter resentment here, even when we are just trying to have a conversation.

45. **proofreader**
April 21, 2008

chethan krishnan Says: "…Besides, we are all clutching for st**rings** here!…"

You had a typo. I've fixed it for you.

46. **Peter Woit**
April 21, 2008

chethan,

No, there's no "bitter resentment" here. I'm quite happy with my life and things I'm working on. Life is good. I happen to think that the decision by much of the particle theory community to keep pursuing string-theory based unification despite the increasingly obvious failure of the idea is a mistake, and this is worth pointing out. The argument that "let's keep doing this, maybe something will turn up" has been made for many years now, and has just led to the field working itself farther and farther down a blind alley. Sooner or later this will have to be acknowledged. Sooner would be better.

47. **nbutsomebody**
April 21, 2008

Monkey,
I understand your point that Bohr model did not predict anything new, it has just explained something already known. Ok, let me agree (even if it may not be true). Let us forget about predictions altogether.

Just explain, no need to predict. I am placing a lower acceptance criterion than Peter usually put on string theory. Just give me a model, which has standard model gauge group, three generations, all moduli stabilized and with reasonable cosmological constant and particle mass. Do not even bother about whether it is unique and stuffs like that. Just give me one. Do not say that there are so many string models in the landscape one will certainly match with Standard Model. Give me an example. Just one…. Please…

48. **dan**
April 21, 2008

PW,
playing DA here, "especially problematic being that the old quantum theory had a huge amount of experimental backing, while string theory has none."

the LHC isn't online yet. If, hypothetically speaking, SUSY does show up at LHC, this would be a reason theorists to claim string theory has experimental backing.

49. **milkshake**
April 21, 2008

that offhand remark about no need for searching after hapless things that may stray into the beam path (for they shall be vaporised in instant)…..”At last, we have ways to make you pay attention. New physics is not here to be posessed by the faint-hearted theorists!”

50. **One of 10,000 Monkeys**
April 21, 2008

nbutsomebody,
There are such models in the literature which closely resemble the MSSM, and where all moduli may be stabilized. However, at this point I don't want to say more for fear of being accused of self-promotion.

51. **Peter Woit**
April 21, 2008

dan,

The problem with the idea that the LHC will provide experimental backing for string theory is that string theory doesn't predict anything at all about what the LHC will see.

52. **Coin**
April 21, 2008

However, at this point I don't want to say more for fear of being accused of self-promotion.

Erm, we don't know who you are so we wouldn't have known it was self-promotion unless you'd said that, now would we have?

nbutsomebody, you can find models purporting to be of the exact type you're requesting by typing variations on “mssm string” into Google. Here's one, title “The Exact MSSM Spectrum from String Theory”, abstract starts with “We show the existence of realistic vacua in string theory whose observable sector has exactly the matter content of the MSSM…”. I am not qualified to evaluate whether these models deliver on their claims.

53. **dan**
April 22, 2008

Hello PW,
I guess it's an issue of semantics

you are obviously right that some string theorists from Michio Kaku and Lubos Motl are betting that string theory implies LHC-accessible SUSY partners to show up, with others like Eva Silverstein saying it won't show up (but still working on string theory nonetheless)

so string theory as you say doesn't make a prediction about whether SUSY shows up in the LHC,

but as far as prediction goes
1- all susy string theoris predict SUSY. it does not offer any details about the nature of SUSY that can be predicted a priori. So while string theory cannot predict whether SUSY will show up in LHC, or any of its values, if SUSY does show up at LHC, it would be evidence consistent with susy-string theory.

The semantic issue is this: string theorists say some models of string theory predicts susy at LHC energies, the LHC finds susy, a prediction is verified. If LHC does not find SUSY, some classes of string theory are falsified. So string theory does make predictions (or some classes do)

If LHC were to see SUSY, string theorists will continue its dominance of HEP and QG for decades on end. I do wonder what will happen if LHC does not find SUSY — Eva Silverstein clearly feels this is likely.

If Eva Silverstein is right and that string theory predicts SUSY will not be seen at LHC energies, but the higgs is, what then stabilizes it from quantum corrections, if it is not SUSY?

I take it from what you described that we're looking at 2010 for quality large data sets to come out to show higgs and other exotics from LHC?

54. **A.J.**
April 22, 2008

If Eva Silverstein is right and that string theory predicts SUSY will not be seen at LHC energies, but the higgs is, what then stabilizes it from quantum corrections, if it is not SUSY?

Fine tuning?

55. **nbutsomebody**
April 22, 2008

monkey,
It does not matter who is the author. A objective truth is a scientific progress, and there is no self-promotion involved. I just like to learn. If you are an honest scientist, please give the arxiv number. Well, I am not an expert in compactification, but I would very much like to discuss the work with somebody who knows more.

56. **chethan krishnan**
April 22, 2008

> “…Besides, we are all clutching for strINGS here!…”
>
> You had a typo. I've fixed it for you.

Very cute. Now run along and bother mommy.

To Peter:
I wasn't implying that YOU are a bitter person. I meant that I came here expecting disagreement with string theory, but what I also find is a lot of bitter hostility towards string theorists. The former of course I might debate with, but the latter seems a little …

In any event, about the scientific issue: I think it is fair to take a moderate stand about string theory, but I simply disagree with your implication that string theory is almost provably useless in our quest for quantum gravity.

57. **nbutsomebody**
April 22, 2008

Coin,

Many thanks. I am not also qualified enough to judge these models, but it seems they do not talk much about moduli stabilization and particle mass and cosmological constant. Getting the gauge group is not enough, one has to get the Higgs and/or sponteneous symmetry breaking. (That is a tough job considering our inability calculate particle masses.)
Unfortunately just now I do not have access to guys who work on string compactification.
I really like to interview somebody like Kachru, Douglus etc., and put up a faq on what is known and not known about landscape and compactification.

58. **nbutsomebody**
April 22, 2008

chetan wrote,
"…but what I also find is a lot of bitter hostility towards string theorists."
It is true that some people are to some extent hostile to string theorists. Even considering the fact that the string theorists have a rare trait of perceiving hostility when people are simply differing in their opinion, there are still some who really are hostile. The reason is simple. People are pissed off by the extreme stupidity and stubbornness of seemingly intelligent string advocates.

When a bunch of religious fundamentalists make bogus claims, people may forgive and overlook them as mere idiots. When a bunch of iv-league faculties does the same, people kick b*tt.

Peter, extremely sorry for being rude…..

59. **Duncan MacGregor**
April 22, 2008

So the LHC can vaporise plastic but (remembering an old news story about the LEP) how would it do against beer bottles?

60. **Peter Woit**
April 22, 2008

chethan,

My claims that string theory has failed has to do with the idea of using it to do particle physics. If you want to use it purely to do quantum gravity, the problem is that it's unclear what "success" would actually look like. You're not going to get anything you can test experimentally, and thus get stuck in the situation an earlier commenter referred to of near religious warfare between competing "quantum gravities", with no good way of distinguishing which is "better" than the other.

As for the hostility towards string theory, some of it is, well, hostile people, or those who are hostile to things they don't understand. But a great deal of it is coming from the behavior of string theorists. The amount of unprofessional behavior, conviction that anyone who disagrees with you is an idiot, unwillingness to admit a mistake or that things are going badly, etc. that has been on display over the last few years coming from the string theory community has been shocking.

61. **PN**
April 22, 2008

>Particle theory, especially string theory, is not doing as well. Data recently >compiled about top-cited particle physics papers from 2007 shows only one >theory paper from this century making the list of 51 most heavily cited papers, and >that was the KKLT paper which is referenced by all "landscape" and "multiverse" >studies.

Hmm… Particle phenomenology papers (#27 and 31) are not counted to be THEORY anymore?

62. **nbutsomebody**
April 22, 2008

Peter said,
"the problem is that it's unclear what " success" would actually look like. You're not going to get anything you can test experimentally, and thus get stuck in the situation an earlier commenter referred to of near religious warfare between competing "quantum gravities", with no good way of distinguishing which is "better" than the other."

The comment is not entirely correct in my opinion. A quantum theory of gravity should have the following properties, which put strong restrictions of them. At the primary
level this conditions can be used to distinguishing which is "better" than the other.

1) As a quantum theory of GRAVITY, it should at least reproduce general relativity at low energy.

2) It should have a meaning full perturbative expansion.

3) It should reproduce the formula of black hole entropy calculated by Hawking in 1972.

4) It should say something about what happens near the initial singularities like big bang.

Once more than one theories at least satisfy first three of the four criterion, then only one has the luxary of a "religious warfare" between competing "quantum gravities". As far as I know String theories are the only one to fullfill (partially) these criterion ,

1) What we get from a naive low energy limit of String theory is Dilaton gravity in 10D. It is not exactly GR in 4 dim but it is certainly GR+other fields in 10dim.
It is possible that there are compactifications exists for string theory which gives 4dim GR. That will bring us to the controversial arena of landscape.

2) It seems that a finite perturbation series exists, but yet to be demonstrated.

3) Using AdS/CFT black hole entropy has been successfully calculated in various cases. Even for some non-supersymmetric black holes.

4) There are some preliminary result.

At least it seems to me that string theory is partially successful as a MODEL theory of quantum gravity. There may be other theories which are equally consistent and it may be possible that in time experiment will prove some of them to be correct.

63. **DB**
April 22, 2008

The blurb for the upcoming Kalvi conference "Anticipating physics at the LHC " is remarkably free of explicit string theory tie-in or the usual hype, considering the number of string theorists slated to appear:

http://www.kitp.ucsb.edu/activities/auto/?id=916

David Gross will open the conference.

Is this (along with Strings 2008 at CERN, and Witten spending next year on sabattical at CERN) part of a strategy to try to bring string theorists into closer contact with their experimental colleagues?

While it's difficult to see how string theory can effectively interface with the LHC, bringing both communities together seems like a good idea.

64. **Peter Woit**
April 22, 2008

PN,

Oops, sorry I missed those two papers. Still, the latest of these is from more than 6 years ago…

DB,

I don't actually see many string theorists listed as talking at that conference. While paying attention to what experimentalists are doing should be encouraged among all theorists, I don't think that string theorists claiming to be "string phenomenologists" is such a great idea, although it may work for them as a career move. Witten is an interesting case. I believe he's intensely interested in what is going on experimentally, and that's one motivation to visit CERN, but his own research remains more mathematical, presumably since that's where he sees a way to make progress absent new hints from experiment.

nbutsomebody,

Surely you've seen a similar list from Lee Smolin about the state of quantum gravity, in which LQG comes off better than string theory. I don't want to get into that argument. I'll just point out that this shows there is an obvious problem with such lists and the attached claims about how one's favorite theory is doing better than someone else's. One common problem with claims about string theory is that they neglect to mention that they've solved a problem in the wrong number of dimensions.

65. **nbutsomebody**
April 22, 2008

Peter,
Thanks.

"Surely you've seen a similar list from Lee Smolin about the state of quantum gravity, in which LQG comes off better than string theory."

Sorry I do not, but will try to find the reference,,,

"One common problem with claims about string theory is that they neglect to mention that they've solved a problem in the wrong number of dimensions."

Certainly , that is what I mentioned too.

66. **Peter Woit**
April 22, 2008

The Smolin article I was thinking of is:

http://arxiv.org/abs/hep-th/0303185

67. **high school physics teacher**
April 22, 2008

Might I offer into this discussion of Bohr's contribution my own first hand account of Dirac's position on the issue? In the 1982 conference at Loyola New Orleans, on the occasion of his 80th birthday, Dirac was asked from the audience if it was possible for him to name one name whose contribution to the development of QT was most important. Dirac's answer, "Bohr."

68. **Chris Oakley**
April 22, 2008

nbutsomebody,

The only property that a quantum theory of gravity *must* have is your #1, i.e. that it must reproduce GR in the classical limit. The rest … maybe … maybe not.

(That's why I never got interested in the subject).

69. **sanity**
April 22, 2008

Quantum field theory as a whole makes no
phenomenological predictions,
until you specify the content and couplings of the theory.

String models are in an early stage, but have already led to predictivity (in the same sense as QFT, namely after specifying a controlled and stabilized corner of string theory with specific field content) in inflation, a subject which is sensitive to quantum gravity effects and requires "top town" constructions. Upcoming data will falsify a subset of the known mechanisms.

Although there is a large landscape, there are many criteria that must be satisfied by a theoretically and observationally viable model, and it is not yet known which of these effects wins and whether string theory can or cannot be as predictive as QFT, correlating signatures with features of the internal dimensions. This will simply take more time to determine, and there will be important interplay between experiment (LHC and CMB) and theory. The reason no one makes a prediction one way or the other regarding low energy SUSY (the comments of Silverstein and others that you quote were essentially vacuous on this point, not committing to a prediction pro or con) is that there is no such sweeping prediction to make and they are trying to be conservative.

70. **Peter Woit**
April 22, 2008

"sanity",

I suppose I really should get around to writing that FAQ, including the answer I've given here many times to the claim that "string theory is just as predictive as QFT" (the short version is that what is predictive is gauge theory, it is predictive because the simplest gauge theories agree with a huge number of different observations, make huge numbers of testable and verified predictions. In string theory on the other hand, simple backgrounds disagree with experiment, so people end up choosing more and more complicated backgrounds until they can evade confrontation with experiment. Sure, you could make QFT unpredictive my constructing more and more complicated and ugly QFTs designed to not actually say anything about physics you can observe. But you don't do this. You do do it in string theory).

One reason I haven't gotten around to this is that I have a hard time believing that anyone is making this argument seriously. On the one hand you have the most successful scientific theory ever developed, one that makes an infinity of highly specific and testable predictions, thousands of which have been verified to high precision. On the other hand you have a theory that predicts absolutely nothing, is completely untestable and designed to remain so indefinitely. You want to argue these are "the same". Why should I bother to take the time to answer such an argument? It's obvious sophistry on its face.

And your claims that string theories make "predictions" about inflation are every bit as much nonsense as claims that they make "predictions" about particle physics at LHC energies.

71. **Peter Woit**
April 22, 2008

"sanity"

Oh, and doing this anonymously doesn't help. It indicates that you have so little faith in your own arguments that you are not willing to put your name to them.

72. **nbutsomebody**
April 22, 2008

Chris Oakley,
I agree to you partially.

No. 2) of my point is what is meant by a quantum theory of gravity. However I do agree that even if there is no perturbative expansion the theory may be defined non-perturbatively. But one has to conclusively answer such question in his/her theory of quantum gravity.

No 3) Yeah, There is a possible that the black hole entropy calculated by Quantum theory of gravity may not match with Hawkings result. But one need such a calculation in ones theory.

73. **nbutsomebody**
April 22, 2008

Peter,

oh thanks!, I read the article when it came out. Anyway I do not agree with it completely. Primarily for the reason I do not think GR at low energy has not come out of LQG yet. Plese see http://arxiv.org/abs/hep-th/0501114.

Also the AdS/CFT is making steady progress and people are now even calculating entropy of Non-SUSY black holes. That does NOT prove the correctness of string theory in four space time dimension, but shows it to be a consistent quantization of some extension of GR .

74. **anon.**
April 22, 2008

John March-Russell's answer in that Telegraph article — new particles with technological benefits for energy production — is the weirdest LHC prediction I've ever seen. (OK, maybe not weirder than Nielsen/Ninomiya's….)

75. **chris**
April 23, 2008

>Oh, and doing this anonymously doesn't help. It indicates that you have so >little faith in your own arguments that you are not willing to put your name to >them.

no, it probably just means he doesn't have tenure. it's a sad world.

76. **Christine**
April 23, 2008

Indeed, the Bohr model is in fact not correct. Rather, the quantum theory itself was pieced together bit by bit using these experimental data as guidance.

Just one more observation concerning Bohr, if I may.

"Two important heuristic principles have guided quantum physicists during the period 1913-1925, viz. Ehrenfest's Adiabatic Hypothesis [term due to Einstein] and Bohr's Principle of Correspondence". (…) "The research work during the years 1919-1925 that finally led to Quantum Mechanics may be described by systematic guessing, guided by the Principle of Correspondence". B. L. van der Waerden (Sources of Quantum Mechanics).

Bohr's contribution was fundamental from that alone, in the case one has some reservations towards statements of the sort: "the synthesis of the Rutherford's atom model with Planck's quantum hypothesis was [his] great achievement" (ibid).

One can also consider Bohr's [and Kramers'] ideas on the statistical conservation of energy and momentum and the statistical independence of the processes of emission and absorption in distant atoms (described in the paper by Bohr, Kramers and Slater), which turned out to be wrong (as already proved by experiments by Geiger and Bothe in 1924; Slater, the third author, was actually against those ideas and his contribution to that paper was more on the idea of 'virtual radiation field'). Those concepts were sources of great debates, I mean, productive debates in physics, and were tightly connected with what one could test experimentally.

We are at different times.

Christine

77. **Peter Shor**
April 23, 2008

As far as I can tell, string theory as a model of quantum gravity has so far not produced a complete resolution to the black hole information paradox: that is, nobody has explained exactly how information gets out of a black hole convincingly enough to be widely believed. What is more disturbing, some string theorists say they consider this problem to be "solved."

78. **David B.**
April 23, 2008

Dear Peter (Shor):

The most conservative claim in string theory is that there are examples, like in the AdS/CFT correspondence, where the complete non-perturbative definition of quantum gravity (realized as a string theory) on some spacetime is equivalent as a quantum system to a dual unitary quantum field theory without gravity on the asymptotic boundary of the spacetime. The claim is then that unitarity
is preserved in the full dual theory and therefore the information gets out of the black hole, somehow. In these examples the information presumably gets so scrambled by interactions that it becomes a complicated dynamical problem to see how much information one can extract about the initial state from a few obersvations after a small black hole has evaporated. This problem is not too different from burning a piece of paper with some writing on it, and reconstructing the writing from the smoke that one collects afterwards.

In the end, no one has a proof for the general case. But in essence the problem is solved in examples in the same sense that an abstract proof of existence of some mathematical object gives you very litttle information as to what the object actually can look like: it is a non-constructive proof that information gets out. I think everyone agrees that it would be a lot nicer if one could understand the same problem by solving the dynamics.

79. **Coin**
April 23, 2008

This indicates that beam commissioning is likely to begin in July, not June.

If this is true then when are we looking at for first collisions?

80. **Peter Woit**
April 23, 2008

Coin,

Their nominal beam commissioning plan refers to taking 30 days of work on the beam to get ready for physics, with likely down-time meaning it would take on average two calendar days for each day of work. So, this puts them with a physics run starting in September. Maybe it will go more quickly, maybe they'll run into problems, we'll see.

81. **nbutsomebody**
April 23, 2008

David B. and Peter Shor,
It is true that AdS/CFT provided a way to understand information paradox, but we certainly need to have a better understanding of the information paradox in the gravity itself. Like what is really happening in a AdS black hole?. Gauge theory should guide us in this manner. But the whole picture is not yet clear.

82. **Moshe**
April 23, 2008

Peter Shor, in addition to what David is saying, let me ask you a question, which I ask everyone skeptical of claims regarding the information paradox. Suppose we accept for the moment the picture of black hole evaporation suggested by AdS/CFT. In that picture the process is no more mysterious, but no less complicated, than any detailed dynamical process in strongly coupled many-body system. Under these circumstances, what kind of result or argument would you consider to be a satisfactory solution to the information paradox?

83. **oohay**
April 23, 2008

Moshe, Prof Shor's observation has two parts. Your point addresses the first part very well indeed; but it only makes his second point all the stronger:

“What is more disturbing, some string theorists say they consider this problem to be “solved.””

The point is that the AdS/CFT resolution of the problem relies completely on the structure of AdS, which is an utterly unrealistic background. In fact, it would be quite reasonable to guess that, since the asymptotic structure of the *real* world is nothing like that of AdS, string theory probably *does not* solve the information problem in the real world! That is, the dependence of the string-theoretic explanation on the specific structure of AdS is both a plus and a minus. Now actually I myself don’t believe that this guess is right. A fair assessment is that there are promising signs but that we are still far, far, far away from solving the problem for black holes on realistic backgrounds. [Of course work has been done, but the problem with it is precisely that it does not rely on AdS/CFT !]

84. **Aaron Bergman**
April 23, 2008

It all depends on what question you are asking. If the question is, does black hole evaporation violate unitarity, string theory tells you that the answer is no. Ergo, no paradox. However, if you ask exactly where the semi-classical intuition breaks down and where the information is encoded, then string theory has not yet produced a definite answer. However, there do exist proposals (note 2 links).

85. **Moshe**
April 23, 2008

I was not making a point, I was asking a question. I think a person with experience dealing with quantum information may come up with an answer to my question I may not anticipate as a high energy theorist, so I thought I’d ask…

86. **nbutsomebody**
April 24, 2008

oohay,
Questions like black hole entropy and Hawking radiation is probably a local property of the black hole and does not in essence depend on the asymptotic geometry. I may be mistaken but I would suggest that you consult Hawking’s original papers and recent reviews.

Aaron Bergman,
Exactly!

87. **Dan**
April 24, 2008

PW,

Quick question — based on what you’ve read and your experience, when do you think LHC will be ready to start collecting quality data, which should shed light on EW breaking, SUSY, condensates etc.

thanks
Regards,
Dan

88. **Peter Woit**
April 24, 2008

Dan,

For a more informed opinion about this, see

http://online.kitp.ucsb.edu/online/lhc08/huston/

My understanding is that the easiest thing to see is colored superpartners, since they are strongly interacting, and if these exist within the LHC reach, they should be found quickly, even in data from the hoped-for 2008 first physics run. As an uninformed guess, if there is significant data in 2008, sometime in 2009 the experiments would be ready to announce such a discovery.

I hear the Higgs is much harder, requiring a lot of luminosity and good understanding of backgrounds. If it’s there and the LHC works well in 2009, maybe there would be a discovery announcement in 2010.

If there is no Higgs, but something else is going on, unless there’s a dramatic signal, I’d also guess it wouldn’t be until at least 2010 before something was announced.

But I’m no expert on this, would prefer to hear from one…

89. **piscator**
April 24, 2008

I’m no expert either, but I have heard it said that the missing energy trigger, which is crucial in many of the standard susy searches (as to cut the SM background you trigger on the large missing E_T carried off by the stable LSPs), will take a long time (maybe a year) to commission. This is because at first lots of detector bugs, such as a malfunctioning calorimeter, will look like missing E_T.

I recall being in a talk where someone gave the timescale from when the Tevatron run II started to when they first published data using a missing E_T trigger. I forget the exact timescale but seem to recall it as being 18-24 months.

So even if susy is present, and even if it is light, and even if it is on the SPS point 1A slope, it doesn’t mean that it will be discovered through the first three months of data taking. And of course: `LHC discovers new coloured stuff’ is not the same as `LHC discovers susy’.

90. **Peter Shor**
April 24, 2008

Aaron – many thanks for the excellent clarification.

Moshe – if you take an ordinary dynamical process (burning an encyclopedia, say), there is no discrepancy depending on which reference frame you are in. If you consider the viewpoint somebody falling into a black hole, what they experience (nothing, when they pass the horizon) seems at odds with what is experienced by an observer outside the black hole (the information contained in the object falling in is somehow transferred to the Hawking radiation that is exiting). There are a number fo proposals about how to reconcile these viewpoints, but (a) they seem contradictory and (b) as far as I can tell, the community hasn't really accepted any of them.

91. **chethan krishnan**
April 24, 2008

Dear Peter Shor,

Here is an approximate answer to precisely your question:

http://arxiv.org/abs/0705.3828

I am not very sure how the community views this, but it seems pretty reasonable so I think it is not too controversial.

Chethan.

92. **Moshe**
April 24, 2008

Hi Peter, as Aaron says it depends what you call the information paradox, and I thought "breakdown of predictability in gravitational collapse" pretty much sums it up. In that case AdS/CFT suggests there is no such breakdown for an outside observer, though maybe it is interesting to make the case (that the information is fully contained in the Hawking radiation) more explicit.

The view of an in-falling observer is indeed much less clear, but I am wondering what is the precise problem implicit in "discrepancy" (beyond just seeking a convenient mental image, aka a classical limit). In any event, I am not sure any such issues are conventionally referred to as the information paradox. Maybe I'm wrong, it's just semantics anyhow.

(As a side comment, Mathur's proposals are of course fascinating, but in my mind have not reached the point of being uncontroversial).

93. **Peter Shor**
April 24, 2008

The question is: how does the information get transfered from the infalling object to the Hawking radiation when, in the semiclassical view, in the infalling objects' reference frame, it never actually interacts with the outgoing Hawking radiation? Obviously, if string theory is a consistent theory of quantum gravity, something must be wrong with the semiclassical view (or else something much more mysterious is going on, which is what Leonard Susskind seems to believe). But exactly what?

94. **Moshe**
April 24, 2008

Thanks Peter. Yeah, that is a good question, wish I knew the answer…

95. **Thomas Larsson**
April 25, 2008

One thing about observers and black holes which has bothered me for a long time is this. Hawking says that area and entropy are the same. However, area depends continuously on the observer since it undergoes length contraction, whereas entropy is the discrete number of state which presumably is the same from every observer's point of view. So, in which reference frame is the black hole's area equal to its entropy?

96. **nbutsomebody**
April 25, 2008

Thomas Larsson,
Good question. Continuity of area may really be due to semiclassical approximation and in a quantum theory of gravity area may be discrete. That is what one gets from LQG.

There are other issues also. e.g. entropy is a discrete quantity only when one using micro-canonical ensemble to calculate it, whereas an entropy calculated from a canonical ensemble is a continuous quantity. They agree for a large system but may differ for smaller ones. Hence it is a question of what ensemble one should use to get a matching with the area law. This is not really settled yet. However it does not matter for a large black hole anyway.

97. **Moshe**
April 25, 2008

Thomas: stationary observer far away from the black hole sees the entropy proportional to the black hole horizon's area. Both quantities transform under the asymptotic Lorentz transformations.

The entropy is a logarithm of an integer, and the area is the leading approximation to that entropy for large black holes. Subleading terms in this asymptotic expansion (in black hole inverse mass) are known geometric quantities (due to work of Wald and collaborators). In string theory this expansion is calculated in various cases, where comparison to exact formulas gives precise agreement. The subject is pretty recent and goes under the name of precision counting.

98. **Sidious Lord**
April 26, 2008

Thomas and Moshe: I don't think the area of the horizon transforms under asymptotic Lorentz transformations and under diffeomorphisms. The entropy does not transform either, so I don't think there's any issue of observer dependence here.

99. **Haelfix**
April 27, 2008

Assume that quantum gravity in reality is governed by a renormalizable Yang Mills theory. Lets say someone stumbled upon it by chance and showed a correct GR limit and so forth with only minor, unobservable corrections (so not quite Einstein-Hilbert but something close). This is at first glance, a perfectly plausible possibility (forget for a moment that such a thing probably does not exist).

The situation would be no different for predictivity, since you would still need to input some couplings into the theory, taken from experiment. So we would never know if it was or was not true, but just that it was minimal, nice and made good sense.

The only difference between that hypothetical and where ST is currently is that physicists already know the mathematics of YM is correct and that it has in the past described real natural processes.

But, if string theory can be independantly shown to be correct in different contexts (implying that the math is at least consistent), I fail to see the problem. Take AdS/QCD as a motivating example.

Point being, the QFT analogy is pretty good.

100. **anon.**
April 27, 2008

Haelfix, a Yang-Mills quantum gravity theory which 'showed a correct GR limit and so forth with only minor, unobservable corrections' might have similar lack of falsifiable predictions to string theory. I don't see the point of the analogy.

The critics of 'not even wrong' ideas aren't irrationally singling out string theory for criticism just because it is called string theory, but because it's become a massive public relations exercise that eclipses other ideas which contain fewer unobserved extra dimensions.

For you to invent a failure of an imaginary Yang-Mills quantum gravity to make falsifiable predictions, and to imply that this makes criticisms of string theory bogus because the failure of string theory is no more serious than the failure of the imaginary QFT you wish to use for comparison, seems specious.

It just seems a lame excuse for string theory to say that certain other theories may be failures too when it comes to experimental verification. (Otherwise, the courts would need to excuse people of misdemeanours which have also been committed by other people, on the basis that only unique crimes deserve punishment!)

101. **oohay**
April 27, 2008

Summary of the black hole discussion:
[1] There are very good reasons to believe that the evaporation of a black hole in AdS is a unitary process.
[2] Exactly how this happens is not understood, but work proceeds.
[3] We have no clue as to whether the evaporation of a realistic black hole is unitary. All we can say is [a] well, realistic black holes are still *black holes*, and if some black holes evaporate in a unitary way, well, maybe they all do, and [right out on the lunatic fringe now] [b] after all, AdS with small curvature is not so different from de Sitter spacetime; I mean, apart from the different causal structure, the fact that one has a timelike Killing vector and the other does not, and that they have totally different topologies, they are almost the same thing. Just drop the anti. *Therefore* the evaporation of a real black hole must be unitary, right? At least in certain extremely boosted Reference Frames.

102. **woit**
April 27, 2008

Haelfix,

Sure, there may be QFT theories of quantum gravity that are just as untestable or unpredictive as string theory. The reason so many physicists got interested in string theory was that it is supposed to explain something observable: particle physics. It is as a unified theory of particle physics that string theory has turned out to be a failure. It is the claims people are making comparing this failed theory of particle physics to the successful QFT approach that are ludicrous sophistry.

103. **Vince Velocci**
April 27, 2008

I'm not sure if this comment is relevant to this discussion, but I will submit it anyway. I'm not really surprised that a proposed unified theory of particle physics and gravity (string theory) isn't a UNIQUE theory of particle physics, allowing us to derive the masses of particles and the couplings of forces. I mean, why should we believe that a mathematical theory will logically and necessarily imply our universe and all its gory details? It makes sense that this theory can describe many many universes because I don't see why our universe is a logical necessity, following from some mathematical theory us humans have cooked up. I don't think pure mathematics will ever lead, uniquely, to our universe. Things have to be put in. Plus, I don't think our minds our perfect, so whatever kind of model we cook up will always be an approximation to the truth and only observation will enable us to come up with better and better models. But just as our minds are imperfect, so will our models be.
Maybe I don't really understand things all too well, but I just don't see how mathematics can uniquely imply our universe with all its constants.

104. **Eric**
April 27, 2008

"It is the claims people are making this failed theory of particle physics to the successful QFT approach that are ludicrous sophistry."

It seems to me that QFT and string theory are actually two sides of the same coin, and are essentially equivalent. Is this not what Ads/CFT teaches us? QFT and string theory are essentially dual descriptions.

The bottom line is that one can easily construct QFT's from string theory, so what goes for one also goes from the other. The only thing lacking at present is the particular construction from string theory which gives us the QFT that we observe, the standard model.

105. **Peter Woit**
April 27, 2008

Vince,

Again, the problem with string theory is not that it can't predict things uniquely. It's that it can't predict anything at all.

Eric,

According to your argument, the weakly coupled electroweak theory is a string theory since AdS/CFT says it is dual to strongly coupled string theory. But what is strongly coupled string theory? Well, the only answer to that is to apply AdS/CFT again and you have just shown that weakly coupled QFT is weakly coupled QFT…

106. **Eric**
April 27, 2008

"Again, the problem with string theory is not that it can't predict things uniquely. It's that it can't predict anything at all."

One only needs to find the particular string vacuum which describes our universe in detail. Once one has such a construction in hand, and all moduli are stabilized, then one can predict the values of all couplings, such as gauge couplings and Yukawa couplings. Also, it should also be possible to address the issue of supersymmetry breaking within such a construction, and describe any new physics.

In regards to cosmology, string theory can essentially make a predicton in regards to inflation: no tensor modes.

107. **woit**
April 27, 2008

Eric,

You're not keeping up with the latest string cosmology research. See for instance

http://arxiv.org/abs/0803.3085

where Silverstein and Westphal discuss string cosmology models with observable tensor modes.

"One only needs to find the particular string vacuum which describes our universe in detail"

You're ignoring the minor problem that you don't know how to calculate in detail the predictions of realistic string vacua, and that there are 10^{500} of these calculations you don't know how to do…

108. **Eric**
April 27, 2008

Peter,
Yes, I'm aware of the Silverstein-Westphal paper. However, this paper is still a little controversial.

"You're ignoring the minor problem that you don't know how to calculate in detail the predictions of realistic string vacua, and that there are 10^500 of these calculations you don't know how to do.."

Actually, we do know how to calculate in detail many predictions for a wide class of vacua. This is where the moduli stabilization issue comes into play. As I stated earlier, once this is done, all quantities such as the Kaeler potential and gauge kinetic function can be uniquely calculated. What is still needed is an example of a fully realistic example. Finding such an example might be closer than you realize. To be honest, your knowledge on this is about 20 years out of date.

109. **Peter Woit**
April 27, 2008

Eric,

Instead of just insulting me as ignorant, please provide me with a reference to a paper which gives a string theory background with fully stabilized moduli and a reliable calculation of Yukawa and gauge couplings, accurate enough to be compared to experiment. One of the easiest things to compute in such a background should be ground state energy, so tell me what the result of that calculation is.

110. **Eric**
April 27, 2008

Peter,
At present, there are several examples of semi-realistic vacua in the literature where many of these calculations can be performed, which I encourage you to study. As I stated previously, a particular vacuum where it can be claimed to be fully realistic has yet to be found. However, there has been a lot of progress and I don't think that it will be too long before this happens.

I should emphasize that the problem is not in calculating couplings. The issue is in finding a particular vacuum which 1) has exactly a three-generation standard model in its low-energy limit and nothing else, 2) satisfies all consistency conditions, 3) all Yukawa couplings are allowed by selection rules, and 4) all moduli may be stabilized, so that the values of all couplings may be calculated. The problem is that perhaps 3 out of 4 of these conditions may be satisfied for a particular construction, but so far not all.

111. **Peter Woit**
April 27, 2008

Eric,

I've looked at many papers of the kind you describe. From what I've seen, generically the kind of constructions you describe have vacuum energies that are wrong by a hundred orders of magnitude or more, and no hope of calculating Yukawas in a reliable manner that could be compared to experiment. If you claim otherwise, give a reference, not just over-hyped claims about what can be done, when it really can't.

112. **piscator**
April 27, 2008

Peter, seriously, if your complaint is really that there is no remotely plausible way of constructing vacua which looks like the Standard Model and where the vacuum energy can be computed to agree with experiment, then it's not just string theory you're giving up on but particle theory in its entirety. No-one knows a good solution to the cc problem. The only halfway reasonable `solution' is anthropica, and that approach (what a climbdown from the high points of particle theory) is nothing to boast about.

113. **Peter Woit**
April 27, 2008

piscator,

My point is just that the CC is the easiest thing to compute in these vacua, and as far as I can tell, you can't even calculate that in such a way that you could compare it to experiment. The state of the art seems to be that people are trying to see whether or not they can find an argument that would show existence in principle of a vacuum with small enough CC, even though it couldn't actually be constructed.

As for the rest of the continuous parameters of the standard model, e.g. Yukawas, every paper I've looked at seems to involve some kind of extremely crude approximation or other, with no reliable calculation of these numbers. I'd really like to get a reference from Eric or anyone else to a reliable calculation of Yukawas in a fully-stabilized string vacuum. People talk as if such things exist, but I haven't seen such a thing.

Seriously, I'd like to see references to somewhere such a calculation is done, or at least to somewhere which explains in detail what is needed to do such a calculation, e.g. what technical or conceptual problems still need to be solved before it is possible.

114. **dan**
April 27, 2008

Thanks for the reference, PW,

quick question — If SUSY is broken at TEV scale, thus stabilizing the EW, and providing a solution to the hierarchy problem, should the Tevatron, with its luminosity and intensity, have the energy to see some of the lighter SUSY-partners/higgs?

115. **Peter Woit**
April 27, 2008

dan,

Many people expected evidence for supersymmetry to show up at the Tevatron if it really was at low enough energy to solve the hierarchy problem. The fact that this hasn't happened is one piece of evidence against supersymmetry. As far as I know, the increases to come in Tevatron luminosity won't change much the bounds on superpartners, progress on this will have to come from the LHC.

116. **Ethan Siegel**
April 28, 2008

Funny thing; Lubos came to my site a week or two ago and left a comment there when I commented on yours. I have analytic software installed, which tells me where he came from.

And it was your site. Funny, but I think he might be one of your number one readers!

117. **woit**
April 28, 2008

Ethan,

I'm well aware that Lubos is one of my most loyal and attentive readers. Very often after I write about something here, a long denunciatory post about the issue at hand appears frighteningly quickly at his blog. It's scary how fast the guy can write huge long postings. One example is the latest one about Connes, which, while containing lots of nonsense, does contain some material worth reading, largely because Lubos is writing about something he actually has some experience of, growing up under the Soviet system as implemented in Eastern Europe.

118. **piscator**
April 28, 2008

Hi Peter,

Well, I think the cc can be computed quite easily in all the moduli stabilised backgrounds, it just that it tends to be at the natural scale you would expect based on supergravity, which depending on how you break supersymmetry is somewhere between (1 TeV)^4 and (10^7 TeV)^4. And effective field theory suggests that this is the answer you expect whatever high scale theory you are working with, as the Standard Model is valid up to a scale of a TeV. So either you need something very new and very smart, or you run away to anthropica and rely on a massive and uncalculable cancellation.

As for Yukawas: a full calculation would require knowledge of the Kahler metrics for the matter fields. This is non-holomorphic, and therefore in general very hard to compute. Fully explicit formulae exist on tori, so how to compute Yukawas is in principle something that people know how to do, but there is (IMO) no background where you have controlled moduli stabilisation and a Standard Model sector, so it's not clear comparing Yukawas with experiment is where progress lies right now.

119. **Peter Woit**
April 28, 2008

piscator,

Thanks, that's very helpful. From what I understand, except on tori you don't have explicit Calabi-Yau metrics, would need to get them numerically and this is very challenging. Can you get fully-stabilized moduli on a torus or do you need some other Calabi-Yau?

120. **piscator**
April 28, 2008

Hi Peter,

You may be able to get fully stabilised moduli on a torus, but I don't know of any schemes there that really look plausible for breaking supersymmetry at a hierarchically low scale. Straight flux models with no non-perturbative effects may be able to stabilise everything on a torus, but then there is no obvious small parameter and the flux stabilisation will likely give you a gravitino mass (and thus susy breaking) around the GUT scale or so.

On a Calabi-Yau, it may be possible to be fully explicit for local models, such as branes at singularities or resolutions thereof. Metrics are in some cases known there, and at the orbifold limit the string can be quantised. That said, I do not believe that full string calculations for the Kahler metrics have been carried out there, but it may be possible.

For traditional vanilla global compactifications, such as the E_8 x E_8 heterotic string on a Calabi-Yau, then I would have expected that computing the full expression for the Kahler metric of chiral matter fields would be of the same order of difficulty as computing the Calabi-Yau metric itself.

The superpotential is of course more tractable, and so some progress can be made purely through selection rules – if a Yukawa vanishes, it still vanishes whatever the normalisation is. Likewise if there are gauge symmetries and Froggatt-Nielsen type attempts at flavour are possible, assuming that all normalisation terms are O(1).

121. **Peter Woit**

April 28, 2008

Thanks again piscator, that's very helpful. I've periodically tried to understand a bit about what the problems are in these kinds of calculations, your summary made the situation much clearer.

122. **dan**
April 29, 2008

Dear PW,

Sticking back to the topic 'My understanding is that the easiest thing to see is colored superpartners, since they are strongly interacting, and if these exist within the LHC reach, they should be found quickly, even in data from the hoped-for 2008 first physics run."

so by the end of this year, 2008, around Nov election time, if there are colored superpartners (superpartners of colored quarks I take it?) the LHC could see evidence of SUSY (which string theorists would take as proof of the correctness of String's foundation)

Anything else in the first hoped for 2008 run?

123. **Peter Woit**
April 29, 2008

dan,

Even if something like colored superpartners are there in the 2008 data, it may take quite a while for the experiments to properly analyze this data, and have enough confidence that they are seeing something like this to make an announcement.

124. **Dan**
April 29, 2008

PW,
Okay, thanks. When you write "and if these exist within the LHC reach, they should be found quickly" is there any reason to suspect that if SUSY does stablize EW scale, the LHC does not have enough energy to produce such strongly interacting colored susy-partners?

If you don't believe in SUSY as the explanation for hierarchy (and neither, presumably, does Eva Silverstein, with other string theorists offering LHC-accessible SUSy a 50-50%), how do you (they) propose the EW-higgs is stabilized? curious
dan

125. **David B.**
April 29, 2008

Dear Dan:

Alternatyive B to a technically natural explanation of the hierarchy problem is that the EW scale is stabilized because it is finely tuned. This means, no real explantion. This is a possibility that can not be discarded, although there is quite a bit of theoretical prejudice against it.

Various people have used landscape-based arguments to say that this is indeed the case, because in the landscape sense, fine tunings can be accidental environmental parameters.

This will be settled one way or another by the LHC, as it is the first machine that has been built that can reach and explore the EW symmetry breaking scale.

126. **milkshake**
April 29, 2008

I was reading the Lubos rant about Connes and even the part when he supposedly "knows what he is writting about" is full of it, as always, when he explained why soviet physics was not affected.

Turns out Soviet physic was very nearly wiped out and replaced by "research on ether" the same way the biology and was replaced by teachings of Lysenko. There was actually a congress organised by soviet acad sci establishment, in 1946 I think, to purge soviet science of burgeois theories like relativity and uncertainity, and to put the young generation in line with the Party line on science – all scripted out, all denunciations prepared in advance – and it was called off just few weeks before it was when it became clear this would interfere with soviet bomb effort. "We can always shoot them later" was the Stalins comment on his decision to call it off.

127. **dan**
April 29, 2008

Thanks Dave B.

I take it we're looking 2010 at the earliest then for LHC to provide the requisite data & analysis?

128. **innocentbystander**
April 30, 2008

Eric,

I wish I could share your optimism regarding general predictions
from string theory. You mention two general
predictions: 4d SUSY (which you tacitly
assume in describing the problem in terms of a Kahler potential)
and absence of tensor modes. Please indicate
how you would establish either of these predictions.
Finding *a* vacuum with the right properties obviously
is not sufficient, since there may be many more
which match current data but differ in other ways.
And as Peter said, on tensor modes there is now a class
of inflation models, which is at least as concrete as any

other known class, in which a specific
chaotic inflation type potential and prediction of of tensor modes drops out. How can you possibly exclude this possibility on general grounds?

129. **Eric**
April 30, 2008

Dear Innocentbystander,
First, 4D supersymmetry may be established by the detection of superpartners at LHC. Second, finding a vacuum which reproduces the SM plus new physics that is later observed would establish the model.

Examples of new physics might include the superpartner spectrum and extra matter which may arise from a hidden sector. Once a fully realistic model is constructed, the issue of supersymmetry breaking should be able to be addressed and it should be possible to calculate the soft-terms and therefore the low-energy superpartner spectrum.

As far as your question regarding the uniqueness of such a vacuum, nobody knows at this point. At present, there is not even one such model which can be claimed to be fully realistic, so the claim that there will be multiple vacua which reproduce the SM in detail is
insupportable.

Regarding the tensor modes, all I can say is that the paper which Peter referred to is currently being studied. It has not yet been accepted as valid. Many people who work on this topic are presently trying to find a problem with it, which is how the scientific process works.

130. **innocentbystander**
April 30, 2008

Dear Eric,

Sure, what you say makes sense, and applies
to all string cosmology models. As such, at
present there
is not a general prediction from theory regarding tensor modes.
(This would be the case even
if there were not a candidate mechanism for
tensor modes in the literature.)
Different mechanisms make different predictions, and
those which appear in advance of the next round of
observations in fact provide cosmological
examples along the lines you suggest for
particle physics (that is, examples of models
which are currently viable, and can be observationally tested in
the foreseeable future).
As with SUSY, the experiments will decide this question.

131. **dan**
April 30, 2008

Dear Eric,
"First, 4D supersymmetry may be established by the detection of superpartners at LHC."

As string theorist Eva Silverstein pointed out, she and other string theorists think there's a good chance LHC won't find any evidence of SUSY. While it's understandable that Tevatron may not have enough energies to explore EW scale, what will become of string theory/M-theory in the event of an LHC SUSY-null result? (i.e finding a single higgs and nothing else). Does Eva and other statements reflect this possibility, and hedging the bets of the future of string community?

132. **Eric**
April 30, 2008

Hi Dan,
I don't think that most string theorists believe that LHC won't find any evidence for SUSY. Only those who've become enamored of fine-tuning think this way. For the most part, Silverstein, Kachru, etc., I think prefer this over supersymmetry because they didn't invent supersymmetry. On the contrary, they invented fine-tuned models such as KKLT, and because they have so much confidence in themselves, believe these ideas must be right.

133. **dan**
April 30, 2008

Hi Eric,

well NIMA ARKANI-HAMED "My hunch is that there's a better than evens chance that supersymmetry will show up at the LHC"

I've heard quotes from some Tevatron experimentalist the odds of finding SUSY are more like 5%. Could it be Eva invented such models to provide string theorists a way out should LHC provide a null SUSY result?

If LHC does provide a null SUSY result, and finds only a single higgs plus SM only, how will affect the future prospects of string theory research program? What would it mean to both education and string theory research to say that for every fermion in the SM, there is a SUSYpartner boson, not seen even by LHC energies. What does string theory community have as an alternative in the event of this experimental result?

134. **Eric**
May 1, 2008

Dan,
Arkani-Hamed has his own favorite alternative to low-energy supersymetry, namely split supersymmetry with large extra dimensions. It's not surprising that he wants his own model to be true rather than low-energy supersymmetry.

As far as the 5% figure you are quoting, I believe that may be the odds for discovery at the Tevatron. At LHC,I would put the odds at at least 50%. If low-energy supersymmetry is not discovered at LHC, then it is not the solution to the hierarchy problem. In this case, one may expect one of the alternatives to show up, either large extra dimensions or technicolor. A very, very small chance that only the SM Higgs and nothing else is found.

At this point, all signs point towards low-energy SUSY.

135. **anon.**
May 1, 2008

Eric said:

split supersymmetry with large extra dimensions.

Huh? Those are two completely different and unrelated things, and there's no good reason to put them together. Are you referring to an actual paper, or just combining buzzwords?

Also, KKLT isn't inconsistent with TeV-scale supersymmetry. The fine-tuning is in the cosmological constant; no one has yet figured out an alternative solution to that one….

You seem strangely eager to assign suspect motivations to perfectly respectable physicists.

136. **Eric**
May 1, 2008

Anon,
Sorry, I meant to say split susy or large extra dimensions, both ideas of which AH has contributed. Regarding KKLT, the point I was trying to make is that KKLT is a fine-tuned solution to the cc problem, and if you believe this is how nature works, then you are free to believe that the electroweak scale is fine-tuned.

As far as my eagerness to assign suspect motivations, please calm down. We know how people are and how the real world works. As far as the public statements of the aforementioned persons regarding supersymmetry, my opinion is that they are simply pushing their own ideas and dissing the main competition.

137. **dan**
May 1, 2008

Eric
"At this point, all signs point towards low-energy SUSY."

What signs do you refer to? g2 muon magnetic dipole moment, or something else (or more)

138. **anonymous**
May 2, 2008

Regarding the public statements on SUSY: this part of
the discussion
started with a quote that Silverstein "would not be
devastated if SUSY is not found". The end of her quote
in the telegraph article is something like "On the other hand, supersymmetry fits well with some existing
observations, and it will be
spectacular to finally learn whether it arises." How do you
go from this "not devastated" statement
to claiming she (or anyone else) is making
a prediction of no SUSY, based on ill motivations to boot?
I have heard Eva
emphasize in talks that SUSY requires rather special choices of
compactification manifold, etc., and that there are
arguments going both ways in terms of which is
easier to construct from string theory and so on;
she also writes papers on
SUSY model building some of the time, citing the usual
motivations. Anyway we need the LHC to tell us.

139. **Eric**
May 3, 2008

Anonymous,
I don't assign any ill motivations to Eva or Nima, only that they, like most people, have a built-in bias towards their own favorite ideas. It's obvious to anyone who reads between the lines that they prefer one of the alternatives to low-energy supersymmetry to be discovered at LHC. This is not to say that they are trying to mislead anyone. It is in fact possible that one of these alternatives will turn out to be right. However, one shouldn't read these statements as if they know something about the prospects for finding supersymmetry that the rest of us don't.

In any case, their 'insight' is most likely based on their current knowledge of the landscape of flux compactifications, where it's quite easy to find vacua with a low string scale (the large volume models) or where supersymmetry is broken at a very high scale. However, there are no fully realistic models where this occurs, so noone should take these ideas too seriously. Indeed, until there is a completely worked out example or examples of the low-energy physics we observe, it's simply impossible to make any judgments at all. To do so puts too much faith in our current understanding of string theory, which is far from complete.

Dan,
There are lots of hints that low-energy supersymmetry exist. Gauge coupling unification, g-2 for the muon, and so on are some of these hints. However, I think the indications from experiment of where to expect the Higgs mass are the biggest hints that the MSSM is the correct model.

140. **Urs Schreiber**
May 4, 2008

> g-2 for the muon

What is the latest state of affairs concerning this? In

http://arxiv.org/abs/hep-ph/0703125

I see that a deviation of by now 3.2 sigma has been reached. At the time of the writing of the review

http://arxiv.org/abs/hep-ph/0609168

of Muon g-2 implications on susy physics just a few months earlier, it was still reported as being 2 sigma.

So I suppose it is clear by now that there is a real beyond-SM effect seen in Brookhaven?

What's the implication for the susy parameter space as searchable by LHC?

This and That

April 27, 2008
Categories: Uncategorized

The interactions.org web-site has a new useful feature, Interactions Blog Watch, which aggregates links to recent physics-related blog entries. One of the older such aggregators I know of is Mixed States, but it seems to have stopped on March 15. There's also Jacques Distler's Planet Musings, where he continues his efforts to pretend "Not Even Wrong" doesn't exist.

Vanity Fair seems to think that the right person to review a book about Isaac Newton is Christopher Hitchens. Hitchens devotes much of the piece to condemning Newton as "a crank and a recluse and a religious bigot" who "spent much of his time dwelling in a self-generated fog of superstition and crankery." He feels the same way about most scientists before the modern era, noting that:

> It may not be until we get to Albert Einstein that we find a true scientist who is also a sane and lucid person with a genial humanism as part of his world outlook—and even Einstein was soft on Stalin and the Soviet Union.

He ends the piece by accusing Newton of doing everything he could to keep people from understanding the universe, and claiming that this was typical of physicists until recently, when physics began to become indistinguishable from the humanities:

> Newton was a friend of all mysticism and a lover of the occult who desired at all costs to keep the secrets of the temple and to prevent the universe from becoming a known quantity. For all that, he did generate a great deal more light than he had intended, and the day is not far off when we will be able to contemplate physics as another department—perhaps the most dynamic department—of the humanities. I would never have believed this when I first despairingly tried to lap the water of Cambridge, but that was before Carl Sagan and Lawrence Krauss and Steven Weinberg and Stephen Hawking fused language and science (and humor) and clambered up to stand, as Newton himself once phrased it, "on the shoulders of giants."

Hitchens doesn't mention Michio Kaku, who has a new book out The Physics of the Impossible, which is on the New York Times bestseller list with the blurb:

> A theoretical physicist who is one of the founders of string theory discusses the possibility of phenomena like force fields, teleportation and time travel.

The notion that Kaku is a "founder of string theory" seems to be becoming very widespread in the media.

Over at Cosmic Variance, Sean Carroll and various of his anonymous commenters are upset that Lee Smolin made it onto a list of Top 100 Public Intellectuals, with some suggesting that Kaku deserves to be there instead.

Finally, the latest Newsletter of the European Mathematical Society has the second part of an interview with Alain Connes, who has many interesting things to say:

> they work in huge groups and the amount of time they spend on a given topic is quite short. At a given time t, most of them are going to be working on the same problem, and the preprints which will appear on the web are going to have more or less the same introduction. There is a given theme, and a large number of articles are variations on that theme, but it does not last long…
>
> The sociology of science was deeply traumatized by the disappearance of the Soviet Union and of the scientific counterweight that it created with respect to the overwhelming power of the US. What I have observed during the last two decades since the fall of the USSR and the emigration of their scientific elite to the States is that there is no longer a counterweight. At this point, if you take young physicists in the US, they know that, at some point, they will need a recommendation written by one of the big shots in the country, and this means that if one of them wants to work outside string theory he (or she) won't find a job. In this way there is just one dominant theory and it attracts all the best students.
>
> I heard some string theorists say: "if some other theory works we will call it string theory", which shows they have won the sociological war. The ridiculous recent episode of the "exceptionally simple theory of everything" has shown that there is no credibility in the opponents of string theory in the US. Earlier with the Soviet Union, there was resistance. If Europe were stronger, it could resist. Unfortunately there is a latent herd instinct of Europeans, particularly in theoretical physics. Many European universities, at least in France or England, instead of developing original domains as opposed to those dominant in the United States, simply want to follow and call the big shots in the US to decide whom to hire…
>
> I don't think that we see similar things in mathematics, so there is a fundamental sociological difference between mathematics and physics. Mathematicians seem very resistant to losing their identity and following fashion…
>
> In physics I adore reading; I spent about fifteen years studying the book of Schwinger, *Selected Papers on Quantum Electrodynamics*. He collected all the crucial articles, by Dirac, Feynman, Schwinger himself, Bethe, Lamb, Fermi, all the fundamental papers on quantum field theory, those of Heisenberg too, of course. This has been my bedside book for years and years. Because I have always been fascinated by the subject and I wanted to understand it. And that took a very long time to understand.

Comments

1. **Bee**
   April 27, 2008

   Hi Peter,

   Thanks for the Connes quote, that is interesting. Regarding his assertion

   "Unfortunately there is a latent herd instinct of Europeans, particularly in theoretical physics. Many European universities, at least in France or England, instead of developing original domains as opposed to those dominant in the United States, simply want to follow and call the big shots in the US to decide whom to hire…"

   I can't quite agree on that for Germany. Yes, there is definitely that trend that Germans should do what the Americans do because they are just so cool, but at least in academia this isn't such a pronounced influence and as far as I can tell it's been getting weaker lately. The reason I guess is mostly that Germans are (in my impression, on the average, apologies to every exception) rather conservative, cautios and suspicious when it comes to 'new' ideas. It's for that reason I believe that many young researchers have left Germany for North America where research is more progressive, and the academic system not as conservative. These 'fashion' trends are considerably more pronounced in the USA – and that not only in research, it's a far more general sociological phenomenon that I believe just reflects in the scientific community. I don't generally think it is bad to have these trends. It is a good idea to have some established stuff, but also to have some topics of the months to try out new things. But I think the balance is somewhat off here (that being related to the short-time funding I believe).

But anyway, the problem that one needs to have letters and to produce papers isn't related to these fashion trends, and exists independent of that. Best,

B.

2. **Peter Woit**
April 27, 2008

Hi Bee,

I think that the remarks by Connes about US theory faddishness are a bit out of date, since the subject seems to have gone into a funk around 2000, and since then fads have been having trouble getting off the ground. Crudely, the problem is that string theory has become too moribund to generate an idea interesting enough to create a fad, but the fad-generating powers-that-be refuse to give up on string theory and try other things.

As for his comments about Europe, note that he refers especially to England and France, perhaps well aware that things have been different in Germany. When I was in Italy last year and talked to quite a few Italian physicists, their attitude seemed to be that the string theory hype was an American phenomenon, that Italy had never had the over-hyped fad problem with the subject that the US had.

Even here in the US, I think that in the past year or two, attitudes have changed dramatically, with string theory starting to become quite unpopular among most physics departments. It will be interesting to see how this plays out. It is definitely becoming true that someone most concerned about their career prospects is going to be thinking twice before promoting themselves purely as a string theorist.

3. **Peter Woit**
April 27, 2008

Bee,

One other comment. I increasingly find it odd to see string theory set up as a progressive "new idea", contrasted to conservative "old ideas". It has dominated the subject in the US now for nearly 24 years, since before most of our graduate students were even born, and the physicists who started string theory research almost 40 years ago are now pretty much all old enough to be collecting Social Security. How old does an idea about physics have to get before it no longer is a "new idea"?

4. **Bee**
April 27, 2008

Hi Peter,

I wasn't referring to string theory in particular, but to fashionable topics more generally (the extra dimensional stuff e.g. or the unparticles, both of which originate in the USA and seem to abundantly happen there). I noticed Connes was speaking about France and England, that's why I meant to add this isn't all of Europe. From the German perspective I too would have said the string theory hype is an American phenomenon (anybody knows a hype which isn't?). I also didn't call string theory a 'new' idea, though it was 'new' at some point and in my impressions the Germans where considerably slower jumping on the train than the Americans. I guess an idea stops being 'new' when you find it in the obituaries 😉 Best,

B.

5. **Bee**
April 27, 2008

PS: *"It is definitely becoming true that someone most concerned about their career prospects is going to be thinking twice before promoting themselves purely as a string theorist."*

Indeed, I too noticed a certain change in attitude (people assuring they are no string theorists/don't want to become string theorists). I am not sure though whether this is desirable, or where it will go. It might just backlash – the public sympathy is often with those in the defensive.

6. **JC**
April 27, 2008

Bee,

Were there any supergravity and/or string theorists appointed to German professorships before the Berlin Wall came down and German reunification? From what I can recall, I don't really remember many German university professors doing string theory before 1989-1990. (At least nobody who was famous).

7. **Allan**
April 27, 2008

The article by Hitchens is useful
at least for its first paragraph
where Hitchens admits that he is stupid,
something many of us have suspected for some time.

8. **Joseph Triscari**
April 27, 2008

Connes's belief that the Soviet Union was some sort of moderating counterweight to American science is downright silly. I was a genetics major in the 80's and it was widely understood that genetics from behind the iron curtain had not yet recovered from Lysenko. I vaguely recall there being resistance to the Big Bang Theory in the Soviet Union because it smacked too much of a Creation which might be interpreted incorrectly as confirming religion.

I don't have a list of Soviet silliness but, I really doubt the Soviet Union was influencing science in a positive manner because of its existence as a super-power.

I think his belief that mathematicians are above fads is just as wrong. The history of math is filled with times where some areas are neglected to the benefit of others. Math has the advantage of being able to generate ideas by axiomatic proof which makes the damage less when the fad ends. I doubt very much fad mentality is correlated to which department you find yourself in.

The problem with quantum gravity – as I believe has been said repeatedly by others – is that experiment is not supporting theory as well as it has in the past. Math doesn't have this problem and other areas in physics and science don't have this problem (they have others).

9. **dan**
April 27, 2008

Dear PW

"The ridiculous recent episode of the "exceptionally simple theory of everything" has shown that there is no credibility in the opponents of string theory in the US."

What did Connes find "ridiculous" over Lisi's ESTOE and how does this show "there is no credibility in the opponents of string theory in the US"?

10. **Peter Woit**
April 27, 2008

dan,

Interesting question. I don't know what Connes thinks of the Lisi story, or what he means by that comment.

Joseph,

In many areas of science, I don't think the former Soviet Union was of much influence. But in theoretical physics and mathematics, they had a very strong presence, with a large number of very good people, working to some extent isolated from the West, and within a different tradition and environment. It really was in many ways a separate, strong culture, and its existence was significant for how math and physics developed. With the fall of the Soviet Union and the emigration of many of its best people, this changed dramatically.

11. **Eric**
April 27, 2008

"From the German perspective I too would have said the string theory hype is an American phenomenon (anybody knows a hype which isn't?)."

And yet, I know of several German string theorists, two of whom are coauthors of a string theory textbook.

12. **anonmo**
April 28, 2008

Unless I missed it, Sean Carroll didn't seem to be complaining about Smolin being on the list. In fact he compliments him in the comment thread.

13. **Joseph Triscari**
April 28, 2008

Peter,

I don't disagree with a word you said. Let me emphasize: Some scientists (mathematicians and physicists in particular) in the Soviet Union did tremendous work with the resources they had available. Their contributions are all the more heroic given conditions under which these contributions were generated. That's a far cry from saying science (or math or physics) was "traumatized" by the loss of the Soviet Union.

The Soviet Union's contributions to math were, in my opinion, greater than their contributions to physics but we're not dealing with the same problem in the math community. If the loss of the Soviet Union, meant that a "counterweight" to wrong headed thinking disappeared, we'd have the same problems in the math community as the physics community – possibly worse. Connes seems to recognize this and tries to inoculate his argument by saying mathematicians have a higher resistance to fads. As I've said, I doubt that such a resistance exists and history doesn't seem support that belief.

Connes seems to be saying that, with the Soviet Union present, we wouldn't be enduring this current string theory fad. Maybe. Maybe we'd have two silly fads to deal with – one based on correct communist thinking. Maybe more. Who can say? What I do know is that the loss of the Soviet Union was not a "trauma" to science or math or physics but a relief. Science was not stifled by the loss of the Soviet Union. It was enriched.

I cannot see how the existence of the Soviet Union would have prevented the current string theory fad except in some random future time-line way. I cannot see a plausible mechanism by which young physicists would be able to pursue interests in quantum gravity outside string theory even if the Soviet Union were present pursuing something else – even if that something else was the objectively correct theory. Would they be getting grants from the Soviet Union? Would the move to to the Soviet Union to pursue their interests? What experiments would be supporting that theory?

If the problem is that European funding doesn't come without implicit approval of one super power or another, then that's a problem that can and should be solved without enslaving thousands of scientists.

14. **chris**
April 28, 2008

spinning?

This is what sean carroll said:

Speaking only for myself, I don't think that I "give Lee Smolin s**t." I disagree with him strongly on certain matters of substance, and I don't think that his presentation of the state of play in modern theoretical physics is especially accurate. But I applaud him very sincerely for his efforts to talk to a wider audience — I very much wish that others would also do so.

doesn't soound hostile to me, now does it? and in fact, one may really wonder why Lee Smolin is more of a public intelectual than Stephen Hawking, no?

15. **simple z**
April 28, 2008

Thanks for the quotes!
I remember Hawking doing the very same thing to Newton:
making him appear like a complete monster.

(think this was in "A Brief History of Time")

16. **MathPhys**

April 28, 2008

I recently saw a full page interview with M Kaku in a local newspaper so I suspect similar articles have appeard all over the world. His claims are very carefully worded.

Roughly speaking, he refers to himself as "One of the pioneers of string theory". I took that to refer to the papers of Kaku and Yu from the early 70's on loop calculations. They were not bad papers, but they were not pioneering either. They followed other people's works.

He also refers to hismelf as "one of the founders of string FIELD theory". The emphasis here is on FIELD. I take that to refer to a couple of papers that he wrote on the subject. Siegel and Witten were the true pioneers, but the subject didn't get very far anyway.

He also talks about pioneering a different theory and later on to realize that "his theory" coincides with strings. I take that to be a reference to his on conformal supergravity. Here too, the real pioneers are the supergravity people.

His statements are so carefully worded to give the layman a certain impression, but in such a way that an expert cannot say that he's making things up. He's just very misleading.

Very interestingly, the interviewer asks him if his very frequent public appearances and commercial book writing (he must have written half a dozen by now) aren't taking too much time that could be devoted to scientific research. He "gently smiles" and reminds us that Einstein played the violin.

If statements like that aren't misleading, what is?

17. **Peter Woit**
April 28, 2008

Eric,

The two physicists you have in mind may be German, but they are pursuing their careers in the US.

anonomo and Chris,

The first comment in the thread is a nasty anonymous one unfairly attacking Smolin (many respectable people agree with him, and he has published many peer-reviewed papers):

Smolin… so "top public intellectual" can mean "one who disagrees with nearly every respectable person in his field, and instead of persuading others through peer-reviewed literature, appeals to the general public for support"?

Sean's response is not to defend Smolin, but to agree with the anonymous attacker, complaining only that people haven't disagreed with Smolin more vigorously.

If the "respectable" people can't be bothered to explain themselves compellingly to the general public — then, yeah.

18. **Bee**
April 28, 2008

Hi Eric, Peter,

Of course there are string theorists in Germany (e.g. Lüst, Nilles, Louis, etc), and also Germans in the US. I said I think the Germans were slower jumping on the topic than the Americans, and I can't say I've noticed much of a hype.

Hi JC,

I honestly don't know. I was 13 then, and I wasn't particularly interested in string theory.

Best,

B.

19. **Eric**
April 28, 2008

Peter,
Yes, but non-string theorists such as Sabine Hossenfelder are also pursuing a career in North America. So, maybe there is some conservatism in Germany, but it isn't restricted to string theory. From other conversations I've had, the real issue is that proferships in Germany tend to be given to old men who've been at it a while, whereas in the US/Canada, it's possible for younger people with new ideas to receive advancement.

20. **Bee**
April 28, 2008

Btw, regarding this comment section over at CV, I find this pretty much disgusting. Once again, I can't understand why Sean just lets people (even anonymously) bash others for no good reason whatsoever. This list isn't a list with scientists who've made a good deal publicizing their work, and it also isn't a list of the most influential researchers in the respective field. Lee isn't on that list because he's "manufactured" a "public controversy", as another anonymous commenter found it necessary to proclaim. Didn't anybody actually read his books? Or the articles that one finds online, the stuff on the website etc? Doesn't anybody realize that a discussion about which environment scientific research needs to function best is necessary, overdue, and should have been lead probably a decade ago? Doesn't anybody see how this polarization into the string-haters and string-lovers completely distracts from the actual problem that is the circumstances under which scientists do their research? And how Sean promotes this? Can't all these people just please look somewhat farther than the tip of their own nose?

21. **Bee**
April 28, 2008

Hi Eric,

Yes, that's what I meant to say. In my perception Germans are more conservative than Americans (again, restrictions apply, exceptions exist). And yes, the reason why I moved to the USA was that I couldn't find a place to fit in. The German academic system has several problems, some of which are different from those in the USA, some are similar. E.g. there is the usual problem of networking, if you have connections, know the right people (preferably those in the hiring committee), have been in the right places, you have a much easier time getting a job. That I believe is quite similar to the USA. One thing that's different is that there is no tenure track, so people hang in thin air until they eventually make it on a professorship which is a livetime position (you can't be fired). I don't think though Germany has a specific problem with women. The reason why I think there are little female professors is what I just said: you have no secure position possibly until your late thirties. Everybody who wants family must be appalled by this idea. Another thing that's different is that a professorship in Germany requires an additional academic degree called habilitation. They are trying to change this, but this discussion goes back a long time and hasn't been very fruitful so far. Best,

B.

22. **Bee**
April 28, 2008

Err, I mean 'few female professors'

23. **David Nataf**
April 28, 2008

Bee,

Late thirties doesn't sound too different from North America.

Say one finishes graduate school at 27, and then does two postdocs for six years (both optimistic assumptions), one will then get an assistant professorship at 33 and get tenure (if things work out) at 43.

Between undergrad through professorship that implies a minimum of five different locations to live in. Hardly the optimal situation in which to raise a family… and now as more and more scientists date other scientists, two-body problems will become more frequent.

24. **Professor R**
April 28, 2008

Hi Peter, slightly off-topic for discussion above, but on-topic for your original post.
I've finally got around to starting a physics blog (mainly concerned with cosmology and particle physics at an introductory level). I've listed NEW as a link I use myself if that's ok. Have a look at

http://coraifeartaigh.wordpress.com/

would appreciate any comments/tips.
Regards Cormac

25. **chris**
April 28, 2008

hi Bee,

seems you are away from germany for quite a while now. there is tenure track now – just starting but many positions are out there already. and from a family point of view – i am not too excited about the prospects of financing 3 children until grad school in the us on a mere academic salary or two. germany is way more attractive from this point of view. what is really true is the networking however. smaller countries have less people so inevitably there will be more room for this kind of stuff.

and on a very different note, i find it amusing how harsh you and peter woit are with cosmic variance. sean has not said one bad word about lee smolin there. there is a certain tendency of course, but come on, if you read this blog and don't see a certain tendency here either then i don't know who can't see beyond the tip of their nose. there are people out there – smart people – with a very different mindset and that's just it. i must say that compared to your comments, sean was very civil towards lee smolin, really. and it is a very good practice in my opinion not to censor except obviously illegal or spamy content

26. **chris**
April 28, 2008

Dear Peter Woit,

note the quotes around "respectable"? i am not an english native speaker, but for me sean carolls statement clearly meant that he does not agree with the previous asessment. furthermore, he says that if these "respectable" people don't raise their voice they will certainly not be heard. i don't see anything wrong with that.

27. **Bee**
April 28, 2008

Hi Chris,
Yes, I've heard the Germans are experimenting with tenure, and I think it's a good thing. Reread what I said, I didn't say the system in the states is better, I said they are both different, and tenure is one of the differences. You misunderstand my problem with CV. I have nothing against Sean. I just very much dislike his attitude to let commenters insult others, even anonymously. It doesn't matter to me whether he just doesn't read it (as I think he said somewhere), or whether he doesn't care – it's his blog and it's his responsibility. I've said repeatedly previously that I think tolerating such 'discussion' corrupts the values of our society, and I still think so. I want to see one of these commenters stand up in public and say openly I don't think so-and-so belongs on this list because (upon which it would probably turn out they don't know why person x is on a list with public intellectuals, or what a criterion could be for a public intellectual to begin with, just that they maybe don't like person x). What do they do instead? They anonymously make fun of those who have the courage to stand to their opinion publicly. I think this is disgusting, full stop. I have the impression that many people do that kind of thing or like to read it because they find it entertaining (thus your suggestion not to delete it, thus I think the reason Sean doesn't delete it, because it attracts readers like shit attracts flies.) I also have occasionally had the strong impression that a large part of the blogosphere just sits there and waits for some 'scandal', some physicists arguing publicly, things get personal, somebody get called names. What do you think why Lubos' blog has attracted so much attention? Certainly not because he has such a great writing style. No, because he's provided exactly that, and I believe people read it with some disgusted fascination, and then pass it on (have you seen, did you read, he said WHAT?). However, one has to give it to Lubos that he's always signed with his own name, so at least he's not a coward. Hope that clarifies my disliking. Best,

B.

April 28, 2008

The decline in the Big Physics (and related engeneering) project budgets on USA is clear with the period in which soviet union declined (ending of the 70´s and one) and even worsened after its ending. If it was a coincidence or not, I cannot say for sure. But if I could bet, I would say it had a negative influence on US, because the output of experiments do have political consequence when it comes to claim a superior technological level.

But given the information revolution happening, i'd say that the overall situation, in other fields, specially the nanotech field, everything got much better, there are much more brains and information sharing problems and information and brains.

29. **Peter Woit**
April 28, 2008

Chris,

Sean's reaction to the fact that someone had anonymously submitted a comment to his blog attacking Lee Smolin in a quite unfair way was not to delete it, not to ignore it, but instead immediately add his own comment elaborating on the original comment, and ending with "yeah". In English, this unambigously means that you agree with the original statement, given the elaboration (which in no way indicated any problem with the nasty characterization of Smolin).

As Bee notes, Sean has somewhat of a history of this, not only allowing the comment section of his blog to be used for nasty, unfair anonymous attacks on people (including Smolin), but responding in an insulting manner to complaints about this practice.

30. **Jeff McGowan**
April 28, 2008

MathPhys,

I saw Kaku give a talk a while back (pre the "string theory wars," or at least the public ones) at the CUNY GC. The talk was for a general audience (not a general scientific audience, just a general one). He mentioned string theory a number of times, and even put up a slide with an integral, I can't remember but I assume one of the loop calculations you mention, and commented something along the lines that this was the first real string theory calculation. In any case it was clear he was claiming to be one of the "founders" of string theory. I was sitting next to my thesis advisor and turned to him and said I thought he was angling for a Nobel (not that they would give one for that).

In any case it struck me that back then at least, when string theory was riding high, he was positioning himself very carefully.

31. **Christine**
April 28, 2008

I will never understand people's behavior. If someone is in some list made by someone, so what? I really don't care. I would care, of course, if the existence of the list would somehow harm me or my family/friends in a very direct and personal way. What is the harm of X being in the list and Y or Z being not? It is a list made by someone (or by a group of people), right? What is the intrinsic value of this list? If Y or Z feel it is not just, it's their problem. It's just a list. People care too much about unimportant things. Or maybe this is just a reflection of the fact that they themselves don't have more important things to do with their lives.

32. **jhk**
April 28, 2008

Kaku started out describing himself as one of the founders of "string field theory", which was technically sort of defensible, but over time the word "field" was put in smaller and smaller font until finally it has disappeared completely. Or perhaps it's still there just not visible to the naked eye.

I'd love to see him debate Susskind in public over the paternity of string theory.

33. **Professor R**
April 28, 2008

Re annonymity, I think Bee is absolutely right.

Just today I had the rather unpleasant experience of discovering an enitre thread on a politics blog

http://www.politics.ie/viewtopic.php?f=2&t=34334&p=1135958#p1135958

concerning a letter I had published in a newpaper.
(In the letter I was simply making the point that Ireland's non-membership of CERN has decimated Irish research in particle physics).
On the blog the letter have been attacked by all sorts of people who know nothing of physics, or CERN, and who hide behind silly names…annoying.
I think I will restrict comments on my own blog to people who declare themselves, at least to me!
Cormac O' Raifeartaigh

34. **woit**
April 28, 2008

Hi Cormac,

Good luck with the new blog, I'll look forward to following it. Figuring out what to do about comments can be tricky, although if you avoid the controversy over string theory the comments you get are likely to be few and relatively polite.

35. **Shantanu**
April 28, 2008

Bee, the idea of branes were discussed initialy by C. Wetterich and he mentioned
this in one of his talks at PI.
Does anyone know how well was the theory of inflation (in early 80's) received
in Soviet Union? I do know that Ginzburg was not a big fan of it.

36. **Changcho**
April 28, 2008

"and now as more and more scientists date other scientists, two-body problems will become more frequent."
And sometimes, eventually the two-body problems evolve into three and more body problems, and as is well know, there are no anaytical solutions to the N body problem with N>2 (i.e., it may get more complicated!)

I agree with commenter Allan on Hitchens…what makes people still think that Hitchens has anything worthy to say anymore?

37. **David Nataf**
April 28, 2008

Changcho,

Hitchens' popularity arises from his mastery of the English language and his bold approach to controversial social issues such as atheism. There's a general theme of people being fatigued by nuance and articial centrism, and that explains the popularity of George Monbiot, Ann Coulter and everyone in between.

Was your joke referring to love polygons or children?

I do think it's a serious issue however. There's a risk three or four postdocs might become the expectation. I've heard of one individual doing five postdocs.

38. **DB**
April 28, 2008

Cormac,

The thread you point to is a good example of the level of public understanding of HEP and the LHC. And it's not hard to see why. Back in the fifties people could understand the potential benefits of nuclear physics – it won the Pacific war and promised electricity "too cheap to meter". And its dangers. They could visualize the splitting of the atom and could marvel at the recreation of the sun's furnace on earth. Most importantly, they could translate this wonder into perceived benefits in their daily lives. It turns out that the hype didn't live up to reality. Yes, they got the Standard Model. But they also got Chernobyl.

Since the fifties, HEP has become terribly remote from the ordinary individual whose taxes fund it. While they understand very little, they doubt that it is likely to be of any real benefit to them, the lumpen proletariat, in the foreseeable future. They also know it is far too complicated for all but a very talented minority to properly grasp so that any understanding gained will be reserved for a tiny elite. And if that's all they get in return for their taxes they are likely to say, thanks, but we have more pressing priorities.

Which is precisely why James Orbach felt obliged to tell his Fermilab audience last week: "You scientists must make the case". It was a very salient warning.

Europe is currently revelling in its leadership position but I suspect it is just at an earlier stage of the US learning curve. US politicians have "been there, done that" and they appear to be fast losing faith with expensive fundamental science. I don't believe the average European voter is all that different to his American counterpart.

Without a much more successful outreach effort from the HEP community the outlook is not great, post-LHC.

39. **Eric H**
April 28, 2008

I agree very strongly with Alain Conne's, (Connes'?) comment about the traumatizing influence of the fall of the Soviet Union. Much of the work they did that was important related to extentions of Einstein's original geometric approach. That is, instead of making the huge jump to 10 and 11 dimensions, they used the conservative approach of investigating the connection between spin and the 5-d approach in Kaluza-Klein theory.

In the West the KK idea is treated as a toy construct that can't be taken seriously. The provisional reason for doing this is that spin isn't inelastic but can "break" in a sense and this negates KK. However, a proton's quarks really can be seen in a sense as having an inelastic bond – > 10^32 years and counting – they still haven't found a limit.

I think the real reason KK was thrown out prematurely is that Einstein used the KK ideas in constructing his unified field and by that time quantum mechanics occupied all the energy and time of physicists. It's sad really. How many people actually know the details of Einstein's theory but have only been told that he wasted his life on it. It's also sad because gravity emerges naturally in KK theory. While it may be too low-brow for some around here check out the English Wiki site on "zero point field" that I did a lot of editing of. Andrei Sakharov was a real pioneer.

40. **Professor R**
April 28, 2008

DB, you're absolutely right.
I thnk the statement 'Europe is currently revelling in its leadership position but I suspect it is just at an earlier stage of the US learning curve' is all too correct. I'm afraid where the US goes today, we generally follow tomorrow (with Ireland leading the way).

The terrible irony is that CERN has saved Euroean a fortune – by centralizing mst of the accelerator build in one location, individual nations saved millions and avoided duplication.

My own viewpoint is Tim BL and Cern missed a trick – while I am very glad he (and not a commercial firm) put the web together, there should be a permanent reminder that this came from CERN research – everytime you open a browser in fact. If they had done that, no-one would need to argue the case for CERN …Cormac

41. **Changcho**
April 28, 2008

D. Nataf – actually, the joke referred to children…In matters of atheism, I'd turn to Dawkins, not Hitchens. The latter may have a mastery of the English language, but little else imho ; regards.

42. **Michael Bacon**
April 28, 2008

"While they understand very little, they doubt that it is likely to be of any real benefit to them, the lumpen proletariat, in the foreseeable future."

Db,

Lumpen proletariat? Really? What an odd way to describe people in this day and age.

43. **anonymous**
April 28, 2008

Bee, you are annoyed that Sean Carroll lets anonymous commenters insult people … well, so does Peter Woit, as you'll notice by reading the comments about Christopher Hitchens in this thread (I count a first name with no link as anonymous, since it effectively is).

44. **DB**
April 29, 2008

Cormac wrote:
"My own viewpoint is Tim BL and Cern missed a trick – while I am very glad he (and not a commercial firm) put the web together, there should be a permanent reminder that this came from CERN research – everytime you open a browser in fact. If they had done that, no-one would need to argue the case for CERN "

Yes, CERN invented the World Wide Web, but the US made best use of that invention and paid nothing for the rights. A similar attitude seems to have emerged in the US with regard to ITER, i.e., "Let the others pay for the fundamental research, we'll clean up on the commercial side".
Had CERN licenced that invention, it would probably never have to raise a cent from governments again.

Michael,
My use of the phrase was a poor attempt at irony. But I do think that is how they view themselves when it comes to subjects such as HEP.

45. **anon.**
April 29, 2008

Having left the anonymous comment at CV, maybe I should have picked someone other than Smolin, since people seem upset about that and don't notice that he's not the only person I singled out. Lomborg is the worst, being a fraudulent hack who is actively hurting the entire world with his efforts to delay action on climate change. (His pose as an 'environmentalist' makes it all the worse.) There were other people on the list who are similar, but outside the sciences — Kagan, for one, surely takes part of the blame for a great deal of human suffering. Arguments within theoretical physics are, ultimately, utterly insignificant compared to these things, so probably my complaint should have focused on that, but since I was commenting on a physics blog I mentioned Smolin. He isn't really hurting anyone, of course, but he's someone who is taken far more seriously in the press than by other physicists.

46. **Peter Woit**
April 29, 2008

anonymous,

My objection is specifically to the use of blogs by scientists to anonymously attack their colleagues in unfair ways. I wish people would not post comments anonymously like the ones about Hitchens, but I don't find it so objectionable that I delete them.

More problematic actually were the comments about Kaku, which I did seriously consider deleting. I left them because I thought that the question they addressed of claims being made that he is a "founder of string theory" is a valid one, and they did not treat it unfairly. But I encourage people to not post anonymously, and if they do feel it necessary to do so, they should bend over backwards to be polite and fair to anyone they have a critical comment about.

47. **Bee**
April 29, 2008

"Bee, you are annoyed that Sean Carroll lets anonymous commenters insult people … well, so does Peter Woit"

So what? I'm not the insult-police of the blogosphere and I actually don't read Peter's blog very closely (or any other blog for that matter, not even my own), and I have no idea what Peter did or didn't do elsewhere.

But since you bring it up, you are trying to excuse behaviour by saying others do the same. This is exactly the reason why I think one should not tolerate insults in discussions. This isn't something specific to CV, NEW or TRF, you find this in almost every more or less public comment section (just pick a random blog-section of a newspaper or magazine). Can't you see how this is pushing the boundaries farther and farther aways from what the average human would consider a civilized communication? I mean, come on, it is well known that humans test the boundaries that are being set to their behavior all the time, may that be laws, morals or ethics. It will get worse until they perceive they've reached that boundary, but where is it supposed to come from if not from us?

Thanks for your explanation why you don't want to see some people on that list. It sounds very similar to what I guessed above doesn't it? I don't like that person or his opinion, and soandso is taken more seriously by the press than by his community. What has this to do with anything?

Anyway, I actually agree with Christine's comment above that it's more or less irrelevant who appears on what lists of which magazine, that wasn't the reason why I brought it up (and given that I don't know most of the names on that list, I see no point in discussing it.) My problem is just, one again, how it comes close to impossible having a sensible exchange on the blogosphere.

Best,

B.

48. **Professor R**
April 29, 2008

Bee and JC, in response to disscussion at top

'Were there any supergravity and/or string theorists appointed to German professorships before the Berlin Wall came down….'

I was sorry to see Julius Wess didn't rate a mention (a pioneer of supersymmetry, he and Zumino pactically invented supergravity). Julius had a very big group in Munich and was a great collaborator
with my Dad's group at th Dublin IAS. I think they were fairly typical of the continental European school – rather than get hung up on string theory itself, they were much more interested in the mathematics of supersymmetry and other gauge symmetries.

In fact I would argue that while Peter's quote from Connes is interesting, it pretty much ignores the whole field of gauge symmetry…Cormac

49. **Professor R**
April 29, 2008

P.S. Julius passed away last summer, but you can find his bio on wiki (http://en.wikipedia.org/wiki/Julius_Wess) or his famous book at
http://www.amazon.com/Supersymmetry-Supergravity-Julius-Wess/dp/0691025304

50. **Bee**
April 29, 2008

Hi Professor, JC,

Yes, I'm sorry. I wasn't an attempt to give an exhaustive list of Germans who've worked on st or related things, just the first three names that came into my mind. Best,

B.

51. **anonymous**
April 29, 2008

Vanity Fair seems to think that the right person to review a book about Isaac Newton is Christopher Hitchens.

Exactly who at Vanity Fair do you think is the right person, Peter? The people profiling Miley Cyrus?

In any case, I read Hitchens' article, and I think the passages you quote are somewhat unfairly taken out of context.

52. **anonymous**
April 29, 2008

Bee, you said, in response to my comment: "But since you bring it up, you are trying to excuse behaviour by saying others do the same. "

No, I'm not, I only pointed out that other people do the same as Sean Carroll. I didn't make any comment one way or the other about the acceptability of this style of comment moderation.

You also wrote:

"I'm not the insult-police of the blogosphere and I actually don't read Peter's blog very closely (or any other blog for that matter, not even my own)""

To which I have to say: couldn't Sean Carroll say _exactly_ the same thing in his own defense? So why criticize him?

53. **Bee**
April 30, 2008

Anonymous, I do read the comments at my blog, in case that's what you mean, and either I or my husband deletes the inappropriate ones (though there aren't many, I guess people get the message). I occasionally admittedly don't very closely read Stefan's posts (since he usually only writes when I am really busy anyhow), but hey, I'm married to that guy so I trust him to not publish anything outright offensive while I'm not looking. My remark was a reply to yours "you are annoyed that Sean Carroll lets anonymous commenters insult people … well, so does Peter Woit, as you'll notice by reading the comments about", which I interpreted as: "you either are annoyed by both, or by none", to which my reply is, what I don't read doesn't annoy me, and I still don't know why it is relevant whether I might not have noticed what happend in Peter's comment section in the year 10 BC or whatever. Besides this, it isn't hard to figure out that it annoys me far more if insults go against people I know, and who I know don't deserve being insulted. Either way, this exchange is basically content free. I've said what I had to say. Best,

B.

54. **CV**
April 30, 2008

«In any case, I read Hitchens' article, and I think the passages you quote are somewhat unfairly taken out of context.»

Maybe you can explain us how writting

« the day is not far off when we will be able to contemplate physics as another department—perhaps the most dynamic department—of the humanities.»

can be placed in a context where it doesn't sound like an insulting piece of pseudo-intelectual trash.

55. **Arun**
April 30, 2008

« the day is not far off when we will be able to contemplate physics as another department—perhaps the most dynamic department—of the humanities.»

Obviously, Hitchens thinks that the future of physics is entirely string theory.

56. **anonymous**
April 30, 2008

CV, if you deigned to pull your head out of the sand, you would realize that Hitchens has the utmost respect for science, and is expressing the hope that it will come to be more widely appreciated by people in the humanities.

There's nothing wrong with that sentence (which, by the way, begins with "For all that, he did generate a great deal more light than he had intended", praising Newton's achievement). Do you mean to tell me that it's "insulting" to contemplate the prospect of a rapprochement between the so-called humanities and the sciences? I think it's badly needed.

57. **CV**
May 2, 2008

Your interpretation is completely off the mark.
By writing "For all that, he did generate a great deal more light than he had intended" he is for all effects stating that Newton did his work by chance and that his main objective was keeping people ignorant.

As for : *Do you mean to tell me that it's "insulting" to contemplate the prospect of a rapprochement between the so-called humanities and the sciences?*

In the way Hitchens is implying yes I do. It's extremely insulting.
Rapprochement like that if it occurs should come from the humanities resembling proper sciences and not by making physics into a pseudo-intellectual endeavour where the only metric is the capacity to impress other people by gluing words with no final meaning.

Hitchens showed with this piece that he has no idea what science is about and thus can't have any respect for it.

58. **John R Ramsden**

> of discovering an enitre thread on a politics blog

That site http://www.politics.ie/ is a forum rather than a blog, the difference being that discussions in a blog can be started only by its "owners" (possibly, in fact usually, one individual) whereas any registered user can start a forum thread as well as replying.

Forums can be bear gardens, even where moderators are vigilant (don't get me started on spam-ridden unmoderated usenet groups!). So one must get used to that.

I was shocked that a self-proclaimed *physicist* of all people in that discussion you referred to agreed with the unfathomable decision of the Irish Government not to join CERN for such a modest fee.

Doesn't this muppet realise how diverse and speculative today's leading-edge physics theories are, and the importance of the LHC in whittling down the contenders and perhaps providing vital clues and new insights (which will quite likely refine low-energy physics too in due course).

Also, you only have to look at the Atlas detector to realize what a massive boost the whole thing must be to high-tech manufacturing industries, which God knows the West needs when practically everything is made in third-world countries these days.

59. **Chris W.**
May 3, 2008

Speaking of that "ridiculous recent episode of the 'exceptionally simple theory of everything'" (Connes' words), the May issue of Outside Magazine has a rather long profile of Garrett Lisi. Needless to say, one won't learn much about his research from the article, although Glashow and Wilczek are quoted.

Creutz On Rooting

April 28, 2008
Categories: Uncategorized

Michael Creutz has a remarkable new preprint out this evening, entitled [The Saga of Rooted Staggered Quarks](). It explains what has been going on in a rather bitter controversy within the lattice gauge theory community over the last few years.

While lattice gauge theory provides a quite beautiful way of discretizing gauge fields, preserving their geometric significance, fermions have always been much more problematic. Here the geometry is spin geometry, which doesn't appear to have a natural formulation on a lattice. What does have a natural formulation is not a spinor field S, but End(S), the linear maps from S to itself, which can be identified with the exterior algebra, and naturally put on the lattice by assigning degrees of freedom to points, 1-simplices, 2-simplices, etc. The problem is that if you do this, you don't get a theory of a single fermionic field, but instead multiple copies. This geometrical argument is just one aspect of the problem, which appears in other more convincing ways, but this all adds up to making chiral symmetry especially problematic on the lattice.

There are many possible ways of dealing with this, but one popular one has been "rooting" some of the fermionic degrees of freedom that have been staggered on neighboring vertices of the lattice. One ends up with four copies of what one wants, so the argument has been that the thing to do is to take the fourth root of this to get a calculation that tells one about a single fermion. The problem is that this is a quite non-analytic thing to do, and it is not clear that it gives one something sensible. A debate between Creutz and people using this method has raged for the last few years, with Creutz claiming that the rooting procedure gives the wrong answer, while proponents of rooting argue that the problems involved will go away in the continuum limit.

Creutz's preprint describes the conclusion he has been led to about this, and his problems getting some of them published:

> This led me to question whether there was some physical measurement one could make to determine if a quark mass was indeed zero. I could think of none, and proposed that a single vanishing quark mass might not be a physical concept. This paper was submitted to Physical Review D.
>
> This is where the shit started hitting the fan. There was a common lore that if the up quark mass were to vanish, then the problem of why theta appeared to be phenomenologically very small would be solved. I was saying that this lore might be wrong. This drove the referees nuts, with statements like "I am somewhat concerned that the errors are so obvious." After numerous similar scathing remarks the paper went to a divisional editor for PRD, who upheld their opinion. On rejection I took the paper and split it into two parts, one on the phase diagram and the second on the vanishing mass issue. These both appeared in Physical Review Letters, Phys.Rev.Lett.92:201601,2004 (hep-lat/0312018) and Phys.Rev.Lett.92:162003,2004 (hep-ph/0312225). I do derive some visceral pleasure from having turned a rejected PRD paper into two PRL's…
>
> Eventually the claims of the staggered advocates became so outrageous that I felt I had to be more aggressive. I was pushed further by statements that if someone had issues with staggered quarks, they needed to write them up. At the time I was too naive to appreciate how the stubborn nature of some personalities involved would mean that these arguments would be dismissed without serious discussion. As with the up quark mass issue, this is one of those situations where a person without tenure would be ill advised to challenge conventional lore.
>
> So I submitted a paper (hep-lat/0603020) pointing out the inconsistencies between rooting and the expected chiral behavior. This was quickly rejected by PRL which has a policy of not publishing interesting and controversial papers. After transferring it to PRD, things got stuck, with numerous referees simply refusing to respond. After about a year and eight referee reports, some positive and some negative, PRD decided that they don't publish interesting and controversial papers either. I did not take this delay kindly and rewrote the paper with the provocative title "The evil that is rooting." This was fairly quickly accepted by Physics Letters (Phys.Lett.B649:230-234,2007; hep-lat/0701018), although the title was mollified at the editor's suggestion…
>
> The staggered community has continued to ignore these problems. I feel their stranglehold on the US lattice effort approaches scientific dishonesty. As an example of the prevailing vindictiveness, a recent paper of mine on a completely different topic was rejected from a prominent US journal on the basis of a single negative referee report stating that "It is puzzling that the author ignores all these highly relevant lessons that have been learned long ago in the context of the staggered fermion formalism." It was overlooked because I wanted to avoid the ongoing controversy, of which the referee was certainly aware. After I did add remarks on the comparison with staggered, the paper was rejected without further review by a divisional associate editor representing the staggered community. He raised some symmetry issues based on comments by the Maryland group, to which I was never given a chance to respond. This paper was then submitted to a European journal where I hoped for a more equitable treatment. There it was quickly published.
>
> Beyond the international ridicule this this controversy brings on the USQCD community, other aspects are particularly upsetting from a scientific point of view. First, enormous amounts of computer time continue to be wasted on generating lattice configurations from which any non-perturbative information will be questionable. About 38 percent of the current computer time allocated by the USQCD collaboration is going to continue these efforts. Second, young people associated with this project are taught to repeat, without question, the party line that all will be okay in the continuum limit. Third, the practitioners are such a powerful force that most outsiders are unwilling to look into the problems despite the fact that the underlying physics is so fascinating. And finally, I find it extremely unsettling that some physicists widely regarded as experts in chiral symmetry and lattice gauge theory can so casually and thoroughly delude themselves with bad science.
>
> In short, the lattice has been very good to me. It is extremely painful to see it abused so blatantly

One would like to think that this issue will get sorted out over time as more work makes it clear whether or not rooting is as serious a problem as Creutz thinks it is. But the progress of science is not always smooth…

Comments

1. **Peter Orland**
   April 29, 2008

   One way to settle the controversy would be to carefully formulate order-by-order renormalization (of physical operators) with rooted fermions. Has anyone studied this?

2. **Peter Orland**
   April 29, 2008

   P.S. It clearly isn't easy, since there doesn't seem to be a local (within a small number of lattice spacings) Lagrangian. So I guess I am asking if rooted Fermions can be formulated (in some complicated way) so that there is manifest locality.

3. **nbutsomebody**
   April 29, 2008

Whether Creutz is right or wrong and whether there is bad scientific practice, one good point about hep-ph and hep-lat community is that they still debate, whereas in String theory nobody argues.

4. **Sandro**
   April 29, 2008

   "Whether Creutz is right or wrong and whether there is bad scientific practice, one good point about hep-ph and hep-lat community is that they still debate, whereas in String theory nobody argues."

   I don't think that "It is puzzling that the author ignores all these highly relevant lessons that have been learned long ago in the context of the staggered fermion formalism." can be considered as a healthy debate situation, and yes, it is a journal context, but I don't think the arxiv one goes much better. All this only reminds me of an african animation movie in which a young child asks his mom "Mom, why is the Sorceress so evil?", and the mom replies "She's not more evil than others: she just has more power."

5. **Arun**
   April 29, 2008

   I reformulated my arguments in terms of the 't Hooft vertex, something crucial to the understanding of how the theta dependence of QCD works. While previously I had not claimed to have a proof, here I showed specific non-perturbative effects that must come out wrong, even in the continuum limit. This proof appears in the proceedings. A more extensive discussion of the issues appears in Annals.

   How difficult is it to assign a couple of graduate students to check this proof?

6. **Peter Woit**
   April 29, 2008

   Arun,

   The problem with physics "proofs" is that they typically involve lots of assumptions, often not made explicit. I don't know anything about the argument Creutz is referring to, but I'd guess that it evaluating possible objections to it would require quite a lot of expertise, not the sort of thing a typical graduate student has the background for.

7. **An anonymous lattice**
   April 29, 2008

   In Europe, our community no longer debates Creutz's 'proof' because it is known to be incorrect.

   For the most recent paper debunking the criticism, see Kronfeld [2007] http://arxiv.org/abs/0711.0699 that also agrees with previous points by Bernard and his collaborators [2006] http://arxiv.org/abs/hep-lat/0603027

   These papers do not quite prove that rooting works perfectly, as indicated by formal manipulations and by the numerical data. But they show that Creutz's arguments are incorrect. For instance, the Kronfeld paper has a section dedicated to each aspect of Creutz's criticism (cutoffs, ranks of groups, and so on). I am slightly worried that the new Creutz's preprint, submitted as HTML, won't be enough to convince me or my German and other European colleagues.

8. **Brett**
   April 29, 2008

   There are actually two distinct but seldom disentangled issues related to rooting. The same two issues arise with many respect to many of the techniques used in lattice calculations. The issue is whether what you're calculating approaches continuum QCD in the right limit. The second is whether the technique gives useful/accurate results at the physical lattice spacing you are using.

   It's not clear whether the first issue is a problem with rooting. Neither side has produced a definitive argument. If I had to guess, I'd bet that the continuum theory is not QCD, but that's just a guess. What gets obscured in this debate over rooting is that there things done in lattice calculations that we know for sure do not lead to the right limiting theory. For example, lattice calculations are now done using an irreversible Markov chain. (Lattice people would refer to this as "not actually using the Metropolis alogrithm.") In this case, the continuum limit of any calculation cannot even be defined, because the calculation does not, in principle, converge.

   But that's only in principle. We know that practically, the improved, non-Metropolis algorithms do converge (faster even!), so the problem is not worth worrying about. This brings us to the second issue. The lack of Markov reversibility does not introduce any meaningful errors at the level of accuracy of current calculations. Indeed, it improves the accuracy. Coming back to rooting, while whether it is formally valid is an open question, whether it is practically useful is not. Rooting does an excellent job of dealing with low-mass dynamical quarks at the present time. Maybe it will need to be re-evaluated when calculations get a lot more precise, but all indications are that the lattice community will keep an eye on this matter.

9. **milkshake**
   April 29, 2008

   Brett, this is way too technical for me – but I wonder if the current argument about rooting is analogous to the old debates about validity of renormalization ("sweeping the problem under carpet" etc), a suspect calculation trick that worked, for reasons that were understood only afterwards

10. **Peter Orland**
    April 29, 2008

    Milkshake,

    There were no debates about renormalization. It took people a while to realize that it was deeper than just "sweeping…", but few competent people doubted it was valid, even in the the late 40's. The reason was that it gave stunningly good results for measurable quantities in atomic physics.

    The argument about rooting is different. I was asking above if a rooted lattice theory might have an (albeit complicated) local formulation. If so, it probably can be renormalized, and therefore should be standard QCD. If not, it isn't so clear.

11. **milkshake**
    April 29, 2008

    but Brett claims that "rooting does excellent job" – and if this is so, does this make the observable things come out better? And how much hand-adjusting is done in these calculations to make things come out right? Also, the most authoritative people at any given time in science history are not always the most competent ones in hindsight. So if Creutz claims he has been unfairly censored, is it because he is crackpotty – or did he become unpopular for repeating a valid complaint that no-one wants to hear?

12. **Peter Woit**
April 29, 2008

milkshake,

I don't see Creutz complaining of censorship. He's a leading figure in the field, and his problems with referees haven't kept his papers from being published. The scientific issues he is concerned about are getting a full airing, while, as is often the case in science, the way the debate is taking place may be less than the fully rational process one would hope for.

13. **Chris Oakley**
April 30, 2008

Brett,

> What gets obscured in this debate over rooting is that there things done in lattice calculations that we know for sure do not lead to the right limiting theory.
> For example, lattice calculations are now done using an irreversible Markov chain. (Lattice people would refer to this as "not actually using the Metropolis alogrithm.") In this case, the continuum limit of any calculation cannot even be defined, because the calculation does not, in principle, converge.
> But that's only in principle. We know that practically, the improved, non-Metropolis algorithms do converge (faster even!), so the problem is not worth worrying about.

In my experience (limited to solving PDEs for derivatives pricing), if you do not have a handle on errors/convergence properties you might as well not bother … better to use the same computer power for playing "Doom" instead – at least you know what is going on there. So I guess, to use Susskind's terminology, I would never have "made it" as a Lattice Gauge Theorist.

Peter O,

I agree with you about renormalization. After 1950 only retards like Landau, Feynman and Dirac ever expressed doubts.

14. **chris**
April 30, 2008

hi peter orland,

yes, locality is the crucial issue.it has been proven, that a) at m=0 there is no local formulation b) that at m>0 there is no local formulation, but the nonlocality is a cutoff effect, so it vanisches in the continuum limit. so at m=0 rooted staggered fermions are in the wrong universality class (which is easily seen by the fact that the symmetry content is wrong). but outside m=0 the topic is quite subtle if you reflect a bit about what it means that you have a nonlocality that is a cutoff effect. there is the issue of the order in which you take the three limits (m->0, cutoff->00, V->00).

in fact, order by order in PT it has been proven that things are fine, but this is not enough. also there is strong numerical evidence that supports the view that everything is ok if you stay in the correct regime, but a full analytical proof is somethig that the whole community tried to hunt for at least half a decade and it is not in sight.

15. **Peter Orland**
April 30, 2008

chris –

Thanks for the information. It's clearly worth looking into!

Chris O.

>I agree with you about renormalization. After 1950
>only retards like Landau, Feynman and Dirac ever
>expressed doubts.

They doubted the interpretation of renormalization. They weren't sure whether the idea was really right at a deeper level (in the meantime, nonperturbative techniques have shown that it is). I heard Feynman express these misgivings (he was teaching QED and QCD in 1977-78). But he and others never doubted its validity for leading orders of QED.

Mike Creutz is not expressing only misgivings, but openly claiming rooting is valueless.

16. **Coin**
April 30, 2008

In the continuum limit, staggered fermions yield four species, called tastes. To reduce the number of tastes to one (per flavor)…

Holy crud! Terry Pratchett was right all along!

So, I have what I hope is not a stupid question:

Here the geometry is spin geometry, which doesn't appear to have a natural formulation on a lattice. What does have a natural formulation is not a spinor field S, but End(S), the linear maps from S to itself

What I am immediately curious here about is, is there a reason the spin networks incidentally used in LQG cannot be made use of here? They aren't lattices, but they are a method of discretizing space, and at least in their original pre-lqg formulation they by design affixed a spin to each spacetime "point". Looking up spin geometry online however (which if I'm understanding this right is basically just the study of spinor bundles?), I don't see anything at all indicating people have even tried to link that subject with spin networks. Is there some obvious reason I'm missing why it would not be natural to try to do spin geometry with spinnets?

Or, put another way: Is it known whether some of the advantages with lattice gauge theory (like computability) can be retained if one moves to some other discrete structure which doesn't have the problem with accommodating fermions?

Only adding to my confusion, the wikipedia article for "Lattice Gauge Theory" tosses off this cryptic factoid:

> Lattice gauge theory has been shown to be exactly dual to spin foam models provided that the only Wilson loops appearing in the action are over plaquettes.

17. **wolfgang**
May 1, 2008

> wikipedia … tosses off this cryptic factoid:

Has anyone asked the Aussie LQCD community for their opinion on rooting.

19. **Wombat**
May 10, 2008

"Has anyone asked the Aussie LQCD community for their opinion on rooting."

Do they disapprove of rooting?

Do they refrain from engaging in rooting?

20. **lattice observer**
May 23, 2008

hi all,

some answers to Peter Osland's technical points — plus a humble opinion.

———————————————————————————————————————

Peter Orland Says:

One way to settle the controversy would be to carefully formulate order-by-order renormalization (of physical operators) with rooted fermions. Has anyone studied this?

P.S. It clearly isn't easy, since there doesn't seem to be a local (within a small number of lattice spacings) Lagrangian. So I guess I am asking if rooted Fermions can be formulated (in some complicated way) so that there is manifest locality.

———————————————————————————————————————

there has been some work along this direction, interested readers may look for papers by Joel Giedt and David H. Adams in SPIRES. the problem is, in perturbation theory the rooting procedure is essentially ok, precisely because PT fails to tackle long-distance couplings at any given order, and non-locality would have a non-perturbative origin. indeeed, as observed by Creutz, even the theorists supporting the rooted staggered approach do currently think that there is no local formulation of the regularised theory; needless to say, this makes it very hard to understand how to take a continuum limit that defines QCD consistently. (cf. work by Bernard, Golterman, Shamir, Sharpe.)

on the other hand, as an Anonymous lattice points out, Creutz's argument is widely regarded as insufficient ("incorrect" is maybe too precise a word in this context) to show that rooted staggered quarks do not lead to QCD in the continuum limit. yet, the overwhelming majority of the community still thinks that the rooted staggered approach is at best controversial, and at worst just an elaborated model that cannot be plausibly claimed to produce first-principles results. the rift between the two fields is deep indeed…

Anonymity at Cosmic Variance

May 1, 2008
Categories: Uncategorized

Over at Cosmic Variance, anonymous comments personally attacking me have been posted recently by someone who identifies themselves only as "string theorist". I've complained to Sean Carroll and his colleagues about their policy of allowing the comment section of their blog to be used for anonymous ad hominem attacks by physicists who are unhappy with Lee Smolin and me because of our criticism of string theory. If someone wants to argue not about science, but to complain about my behavior, I'm perfectly willing to engage in such a discussion, as long as it's with someone who is willing to take responsibility for their own behavior.

Here's the response I received from Sean:

> Personally, I could not care less whether a comment is anonymous or signed. It just makes no difference to me. I understand that you feel otherwise, as you have said so over and over and over again. I will delete comments if they are vulgar or overly obnoxious, but anonymity is completely beside the point. If my co-bloggers feel differently, they are welcome to overrule me.

So, I guess if you want to anonymously attack, insult or slander people you disagree with about a scientific issue, Cosmic Variance is open for business.

Comments

1. **anonymous**
   May 2, 2008

   Of course if you want to anonymously attack non-scientists like Christopher Hitchens, feel free to do so here. Remember, anonymous attacks are only bad if they are directed at scientists …. right?

2. **Yzer**
   May 2, 2008

   Peter, I'm a big fan of yours, so I mean no insult by this, but is it not possible simply to ignore such nonsense, be the bigger man, and rise above it? You only call greater attention to their immaturity when you single them out for a tongue-lashing. Let them fade into the anonymous obscurity whence they came. Your good name has more to lose from your response to them than from anything they say about you.

3. **Anonymous**
   May 2, 2008

   It is a common stratagem to reject as cowardly criticisms leveled anonymously. However, such a rejection neither rebuts the criticisms, nor has much merit, at least if the criticisms are dispassionately formulated and substantial (and if they are not, they should simply be ignored).

   There are many reasons to remain anonymous – among which perhaps the most responsible is the desire not to draw attention to oneself, or even to disassociate what one says from who one is. If Famous Man X says something openly it will be ignored by his haters and repeated by his lovers, regardless of its merits, and knowing this Famous Man X may decide to say something anonymously; there is a long tradition of this in the world (pseudonyms). (Compare this to Famous Man Y, who glowingly trumpets his identity even when farting; he is no coward, I guess, but nor is he responsible). If Unknown Man X says something openly, it will be ignored by almost everyone, because he is Unknown Man X and, being unknown, can have nothing interesting to say, so perhaps by saying it anonymously, and thereby raising the possibility that he is Famous Man X in disguise, he will actually be heard. Other motivations abound – fear of reprisal is one, and to call such cowardly is simply to have never lived in fear of a beating. Among these motivations is surely the cowardly desire to hit from behind, it is not the only one.

   The most basic such motivation, is – it does not matter who I am; in any case the audience does not know who I am, and knowing so would not change the content of what I say, so what is to be gained by advertising who I am? There is of course something to be lost – one's dignity.

4. **Another grad student**
   May 2, 2008

   Hi Peter,

   You may remember me from a discussion (a.k.a. cat and dog fight) in 2006 on Clifford's blog, where I defended your reluctance to continue a somewhat hostile discussion with Clifford and someone whose writing style bears some resemblance to that of the poster you felt was attacking you very recently on cosmicvariance. It wouldn't surprise me if you also noticed the similarity in style.

   I defended you then for several reasons. Most importantly, I felt you were being subjected to unnecessarily personal and condescending attacks because you promoted a point of view your antagonists strongly disagreed with; their "debating" style was offensive to me because of the degree of disrespect and unwillingness to acknowledge that there might be some validity or forethought in your point of view. Another reason was that in following your blog (and Usenet posts before you had a blog), you seemed to be sincere in your intentions (not a publicity hound as some people assumed), and willing to acknowledge your mistakes. I still believe you are sincere in your intentions, not just trying to stir up trouble because you are bitter or whatever, but over the last year or two I have also perceived (rightly or wrongly) certain changes in your style that I wish I didn't see. This post of yours seems like an appropriate place to mention them; you won't have to suffer hearing them from me again.

   Before you responded to ST on cosmicvariance, I saw his/her comment. My initial thought was that ST was being somewhat presumptuous to think that you had so much power over Sean that he would consider taking a break from blogging due to anything you might say. Sean strikes me as having some pretty strong opinions, and is willing to freely write about them (which is fine, since a reader can always skip over whatever is annoying to read); I could be wrong but I don't think he would be beaten down by you expressing your points of view. I didn't know you would respond, but it seemed like if you *did* want to say something the perfect response would be to make a joke about the power you hold over Sean, and generally dismiss ST's concern. That would have fit very nicely with the generally congenial tone of the comment section up until ST chimed in, and you would have come across as disarming and friendly. Instead, your response seemed like a very jarring attack on ST, well beyond what I would have thought was needed to make your point. An image that came to mind was of a social gathering where people are chatting amicably, and then someone makes an unkind remark; the recipient reacts with such rage that he startles the other guests, and then he accuses the host of the party of behaving inappropriately for not throwing the guest out for making the unkind remark.

   Perhaps this mental image of mine is overly harsh, but I expect that many people seeing your reaction to a comment in cosmicvariance or elsewhere don't know about your history of having to deal with repeated unwarranted personal attacks on you, much less the specific personalities involved. Those people would probably just see a very strong (over)reaction to some throw-away snide remark from someone else they don't know, and the impression would not be good; if anything, I think they would look at your comment as confirming the negative remarks by, e.g., ST, with the net result that someone who had no opinion about you now has a negative one. If you had responded with humor, I think that ST would more likely come across to that person as overstating things and you would look fine. Someone who did know something about you at least would have seen a pleasant side of you that didn't reinforce their earlier perceptions.

I remember a comment by Chris Oakley sometime ago where he essentially said that he thought it was counterproductive to get into pissing contests with string theorists, and I completely agree. I also agree with others who think you shouldn't try to doggedly and publicly shame other blog owners into treating certain kinds of comments the way you would like; it seems fine to complain once, but after that it can come across to others that you have appointed yourself to a role they aren't willing to give you.

Anyway, that's my two cents and it may not even be worth that. I hate writing critical comments like this, and I hope you will see it as an attempt to be constructive.

5. **Another grad student**
   May 2, 2008

   Grrr… One sentence didn't come out quite the way I intended. The end of the fourth paragraph should have been:

   Someone who had already formed an unfavorable impression of you at least would have seen a pleasant side of you that didn't reinforce their earlier perceptions.

   Sorry about that.

6. **rh**
   May 2, 2008

   First they ignore you, then they laugh at you, then they fight you, and then you win … I entirely agree with Yzer. Best, R

7. **nbutsomebody**
   May 2, 2008

   There is no way to verify identity in a blog. Hence anybody can take any identity, even false identity. I do not see any simple way to stop anonymous comments. If one stops anonymous comment, people will just use false identity or some strange nick names like me.

8. **John Wheeler**
   May 2, 2008

   No way to verify identity, really ? Never a clue ? 🙂

9. **AT-S**
   May 2, 2008

   I agree with Yzer and "Another Grad Student": best to ignore the pot-shots.

   Remember the adage: "The dogs may bark, but the caravan moves on."

   Keep up the good work.

10. **Arun**
    May 2, 2008

    Another grad student, that is good advise for everyone.

11. **Peter Woit**
    May 2, 2008

    Thanks all,

    The advice to ignore this and/or treat it with humor is excellent. It's my intention to waste as little time and energy on it as possible, but I confess that I'm not amused at all about this situation. The point of this posting was just to make clear what is going on:

    I'll respond seriously to any complaints about my behavior from people who are willing to take responsibility for their own. When I have responded to anonymous insulting comments at CV by telling the commenter what I think of their behavior, my response has been deleted by Sean as "vulgar or overly obnoxious". I suppose perhaps he has been doing me a favor, but his views on censorship are rather one-sided.

    I continue to find it truly remarkable that some professional scientists find it acceptable to anonymously post personal attacks on people they disagree with about scientific issues, and that others endorse and enable this behavior.

    Now, on to trying to ignore this and develop a sense of humor about it….

12. **Maya Incaand**
    May 2, 2008

    Sticks and stones……

13. **Bee**
    May 2, 2008

    "Sticks and stones may break my bones, but words will make me go in a corner and cry by myself for hours."

    ~ Eric Idle

14. **Bee**
    May 2, 2008

    Well, I've commented on that previously, but since it's on the table again. I find it very inappropriate to tolerate anonymously made insults. I don't care very much who believes who 'set a tone' or whatever, and I do indeed agree that Peter too sometimes hasn't been holding back, but I don't want to make this a discussion of a particular person.

Anonymity is certainly necessary in some cases to protect a person, but in almost all cases on the internet it is completely unnecessary and only used out of cowardice, because one can't be held responsible for what has been said and doesn't have to fear a lack of reputation. I guess I don't have to tell you what the result is of that, just go look into any comment section for some newspaper column or whatever. One of the problem with anonymous insults is that the anonymous insulter deserves to be insulted even in the opinion of the more polite commenters, which will make matters worse. I therefore think such comments should be deleted asap. This has nothing to do with freedom of expression. Say what you want, just sign with your name.

What I find especially upsetting in this case is the following comment by Jennifer West "This is what the internets is all about people. If you cannot take the heat, get out of the kitchen." or generally the often made recommendation to 'just ignore'. A recommendation usually made by people who hardly ever are subject to such insults.

If anonymous insults is what the internet is all about – and yes, one could indeed sometimes have that impression! – then it's about time to change it. To what level do we want interhuman communication to drop, huh?

To repeat something else that I've said before: I think one of the reason why some people don't want to delete such comments is that many readers, including the blog owners, find it entertaining to see how others are insulted, and then the attacked persons subsequently defend themselves. I even sometimes have the suspicion that some commenters only post insults to 'stir things up' a bit and have fun. Such things increase the number of comments and attracts visitors like shit attracts flies. I seriously can't see any other reason to willingly support such a disgusting level of discussion than the wish to entertain readers on the cost of the person attacked. The wish to avoid this has nothing to do with 'high' ethic standards. It is simply the desire to have the same standards that we have in normal life. At least where I grew up, the tone has been somewhat more respectful than it is on the average in the 'hot kitchen' of the internet.

In this regard, it is interesting to read these two pieces on the Edge:

Cyber Disinhibition

and

More Anonymity is Good

15. **Yatima**
May 2, 2008

16. **Peter Woit**
May 2, 2008

Over at CV, "anonymous" is on the anonymous attack:

http://cosmicvariance.com/2008/04/28/vacation-2/#comment-315873

I wrote a response there, which didn't appear. Maybe it was caught by their spam filter, maybe I'm persona non grata. Anyway, for those following both threads, here's a copy:

"The comment that "anonymous" is complaining was censored by me was posted here:

http://www.math.columbia.edu/~woit/wordpress/?p=681#comment-37499

and my response to it is here:

http://www.math.columbia.edu/~woit/wordpress/?p=681#comment-37524

What happened in this case was that the comment was initially identified by the WordPress spam filter as spam, so not immediately posted. When I checked the spam queue that day and found it, I dug it out, posted it and responded to it. It seems that "anonymous" couldn't even be bothered to actually read the comment thread in question before posting accusations attacking me here. If "anonymous" were using their real name, they might find this embarrassing and it might do some damage to their reputation. But, hey, when you"re "anonymous", that's something you never have to worry about!"

17. **anonymous**
May 2, 2008

Peter,

the comment that was censored was posted to this thread, last night, and would have been the first comment on this thread if it hadn't been censored. As for my anonymity, it's because I'm actually an "anonymous" nobody, an undergraduate student whose name doesn't show up in a google search. I post comments anonymously because I don't want to make it possible for a google search to reveal my blog reading habits.

best,

-anonymous

18. **milkshake**
May 2, 2008

I hate trolls who change their name frequently, whenever they write ad hominem insults. But if someone decides to create a web persona for himself and is consistent in using it and his critical arguments are of substance, there is no reason why he shouldn't remain anonymous if he has chosen so.

One thing that is pretty funny though is an morally-outraged anonymus commenter.

A problem with having a "serious" web presence – with a web page where people can comment – is that one feels a compulsive urge to see who is commenting and why, by tracking those IP addresses and by answering every comment…

19. **woit**
May 2, 2008

"anonymous"

If you bothered to look, you would notice that the comment in question was not "censored", but is there at the top of this comment thread. This is the second comment from you anonymously attacking me over the Christopher Hitchens issue. Both ended up for unknown reasons in the spam queue, both were retrieved by me from there and posted (on two different days). You have now posted 5 anonymous comments here on this topic, from two different IP addresses, using two different fake e-mail addresses. Please grow up. If you want to start behaving like an adult, please write to Sean Carroll and request that he remove the inaccurate comment you posted on CV.

20. **DB**
May 2, 2008

Peter, I think it's perfectly reasonable to take the stand you take. Not that it's not fine to take the alternative viewpoint of simply ignoring them. Given the diversity of human response, your forthright approach can strike some as being "oversensitive" while a passive, indulgent policy could give others the impression of timidity, appeasement, and unwillingness to defend one's views.
In such situations one should just go with one's instincts. What is not acceptable is to operate an internet blog where anonymous commentators are shepharded by a blog moderator in order to develop a coherent attack on an individual so as to chase them from the scene. That's nothing less than bullying, and bullies should never be appeased.

However, there is a rational utilitarian approach to selecting the optimum strategy:
Because the jury remains out on string theory, and is likely to do so for the foreseeable future, the debate will remain highly politicised. And while this is a scientific debate and not a political campaign, the lack of any prospect of a decisive resolution of the issues means that it takes on many undesireable features associated with political debates. In this respect, packs of attack dogs in the guise of hostile anonymous commentators represent a form of "negative campaigning", and in such situations, a robust confrontational approach is preferred because it communicates the strength of your convictions while providing additional opportunities to publicly target the weakness of an opponent's position. Look where a passive strategy landed Mike Dukakis.

From this perspective, the choice of approach to be used against trolls would ideally depend on the degree of politicisation of the debate, which is why I think you should stick to your guns, metaphorically speaking.

21. **Julianne**
May 2, 2008

Peter — Your comment was indeed hiding in our spam filter, which has been a tad overagressive of late. Whenever someone puts html in the comment, there's a much higher chance of it winding up with an erroneous spam classification. I've rescued it from the filter.

22. **Peter Woit**
May 2, 2008

Thanks Julianne.

Thanks DB. I think your analysis of the situation is spot on.

23. **anonymous**
May 2, 2008

Peter,

I did indeed bother to look. That comment wasn't posted there until just now. I checked before I wrote anything at CV. Lots of comment appeared before mine, and mine was the first to submitted last night. You can see how I thought you were censoring it. I don't have a blog so I'm not familiar with spam filters etc. Also, you see two IP addresses because I posted comments from two different computers, since I don't have a computer of my own. And as for the fake email accounts, an email is required, and — you guessed it — I don't have an email account.

Milkshake: why can't an anonymous commenter feel moral outrage? What's wrong with being anonymous? I don't get it.

-anonymous

24. **anonymous anti-string-theorist**
May 2, 2008

So, I guess if you want to anonymously attack, insult or slander people you disagree with about a scientific issue, Cosmic Variance is open for business.

God, I never realized [*deleted*] was such a total wanker!!!

[*As far as total wankers go, the author of this comment knows a lot about the subject. He repeatedly posts juvenile comments like this one here, from the IAS in Princeton (IP number 192.16.204.77). The last one I didn't delete was this:*

]

25. **Noah**
May 3, 2008

Sticks and stones can break your bones, but anonymous ad hominem attacks in the comment section of blogs really can't hurt you.

The "Internet" is where a lot of people come to blow off steam, overstate their case, and act like jerks. They're stressed out from spending most of their day quietly putting up with the trials and tribulations of life, and they feel like they need to be a jerk somewhere, to someone, just to keep their sanity.

I know it, because I've been there. When I was seventeen I used to go into Christian Singles Chat and talk like a caveman (trust me, it was funnier than it sounds). Then I used to anonymously email married men who posted personal ads looking for affairs, and tell them they had small penises. I'm not especially proud of this behavior, but all in all, there are plenty more harmful ways I could have released my pent-up frustrations.

So Peter, I like what you write, but here's a bit of friendly advice: Try to empathize with the trolls. And if you can't, at least grow a thick skin, because this is The Internet, the last wild frontier, and the trolls will never ever be stopped.

26. **milkshake**
May 3, 2008

Anonymous moral outrage: When I was kid in Prague in 80s we got a visit from State Security and they gave us a lecture on fortitude and moral fibre. I stil remember the officer explaining: “They say snitch or grass – but I prefer to call them advisor. Please advise us the very moment you notice some wrongdoing, advise us even anonymously”

27. **Anonymous (OH NO!)**
May 3, 2008

Its not my intention to spread hostility, but to be blunt and concise- Who cares if some random dude is talking shit about you on CV. I don’t think it merits your attention, or the attention of your blog-readers. I read all the linked postings you made there, and it was a huge waste of time, i’m sorry to say. Seriously, I come here to read about a bunch of physics and math that I don’t understand, and instead, i’m greeted with something I know all too well- DRAMA. Lame! Bring back the science already.
PS I won’t be offended if you delete this, ‘cus who cares!!!

– dude that doesn’t hate your blog

28. **Professor R**
May 3, 2008

Hi Peter, it’s a pity to see you and Sean C at loggerheads, as Not Even Wrong and Cosmic Variance are the only two blogs I find myself reading regularly (they’re also the only physics blogs I recommend on my own humble effort at http://www.coraifeartaigh.wordpress.com).

I think overall you’re right, though, and would like to add my own tuppence-worth; there is already far too much space taken up by random opinion on blogs – personal attacks, especially annoymous attacks, is simply a waste of space and everybody’s time…
Regards, Cormac

29. **Eric**
May 3, 2008

Peter,
Why not just admit that making a big issue about anonymous posters who attack you is really just a strawman argument that you use as a diversion whenever someone makes a point that you don’t like? This seems especially to be the case when you are losing a debate.

30. **Peter Woit**
May 3, 2008

Eric,

The recent anonymous attacks Sean is hosting aren’t about scientific issues, but are purely ad hominem. I think you’re right that this phenomenon has to do with someone losing a debate, but it isn’t me….

31. **anonymous**
May 3, 2008

Milkshake,

That has nothing to do with this situation, as far as I can see. You’re overgeneralizing from your experience. Like people who’ve had a bad experience with a cop who then decide that all cops are bad. Anonymous blog comments are not the same as informing on people. Compare the consequences of each. It’s a difference of kind, not of degree.

32. **tommaso dorigo**
May 3, 2008

my very own two pence: following o.wilde, it is not important what they say, but it is always a good sign if they talk about you.

Peter, for good or worse, has become a flag of the resistence to stringdom. And it shows…

cheers,
t.

33. **George**
May 3, 2008

People are constantly hurling anonymous abuse at each other on the internet, especially on blogs. The fact that some anonymous “string theorist” is hurling abuse at you should be taken in the context that it’s an anonymous comment on a blog with numerous anonymous comments. i.e. give it the extremely minimal consideration it merits. Maybe you can decide that after every n=5 idiotic anonymous comments, you write a short response explaining why you feel the comments are idiotic. If it were me though I wouldn’t even bother, as the effort expended in getting riled up is not worth it. But I’m not a “blog person” so what do I know.

34. **Arun**
May 3, 2008

Anonymous insults hurled around on a blog rate slightly less relevant than string theory.

35. **Observer**
May 4, 2008

Be a bigger man and ignore those anoymous insults, most probably came from someone who was “working” in “new directions” and “noble ideas” and was uncovered and sacked by his/her department chair, obviously is no longer a happy string theory camper if ever was.

36. **Ellipsis**
May 4, 2008

IMHO, if I made the rules, moderation of blog comments should be based purely on whether the content is clearly profane, libel by a strict U.S. legal definition, or commercial spam — not adjusted based on whether the commenter is anonymous or not. Otherwise, don’t worry at all, some people will be jerks but that’s life, people will see them for the jerks they are. I think people should probably have the right to comment anonymously (note, I may be biased!). Sometimes that results in some asinine comments, but other times it helps the truth to come out.

37. **Peter Woit**
May 4, 2008

Many commenters here are (anonymously) making the point that anonymous insults and personal attacks are just part of how blogs work, so one should accept this and get used to it. While this is an accurate description of the way things mostly are in the physics blogosphere, I think this is an unfortunate situation, one that could be changed.

If you want to see how things can be different, go take a look at some of the excellent blogs run by research mathematicians, e.g. sbseminar.wordpress.com. Almost all comments are polite, professional and come with a name attached. This situation encourages participation by serious people, and the quality of this is very high.

Physics blogs by contrast are overrun by anonymous commenters, with a significant fraction of irresponsible ones. I delete many such comments, probably should delete more. Once you allow anonymous insults and attacks, you drive the level of discussion down to that of the overall blogsophere. This drives up the number of comments, but ensures that very few serious professionals are going to want to participate.

One possibility would be for me to take some commenters advice and embrace the way things are. In that case, the way to deal with my disagreement with Sean on this issue would be to anonymously post comments here, on his and on other blogs attacking him. According to what he wrote to me, he himself would have no problem with this, so why shouldn't I do it? To me, the reason seems obvious: does one want to make the world a worse or better place?

Please, I encourage everyone who posts comments here to avoid doing so anonymously unless they have a good reason, in which case they should take extra care to behave responsibly. I remain convinced that it is possible to raise the level of discussion in physics blogs to something closer to that of mathematics blogs.

38. **João Carlos**
May 4, 2008

Your conclusion about the way to deal about your disagreement with Sean is a complete *non-sequitur*… Sorry to say that, but he's right and, this time, you're "not even wrong".

39. **Peter Woit**
May 4, 2008

Joao Carlos,

You don't exactly make much of a substantive argument in response to what I write, you could at least point out explicitly the non sequitur in what I write. Again:

Sean claims:

"Personally, I could not care less whether a comment is anonymous or signed. It just makes no difference to me."

Actually I think this is obviously an untruth: if someone wrote in a comment to his blog attacking him, whether it was signed and by whom would actually make a difference to him. But taking this at face value, if I'm annoyed at him, and want to get some choice comments about him and his behavior out before a large audience, should I do this and should I put my name on these or not? Commenters here urge me to just accept that anonymous attacks are a normal part of the physics blogosphere, and Sean has no problem with them, so why shouldn't I go ahead? Obviously I think this would be a bad idea, and I've explained why I think so.

40. **anonymous**
May 4, 2008

Peter,

I for one promise to never post anonymously here again, even though I don't see a problem with it … it's your blog after all, so I will respect your opinion on this issue. I think I have a good enough reason to want to remain anonymous as I've already explained, but clearly my anonymous comments have not been welcome here so I'll be signing off.

Respectfully,

-anonymous.

41. **John R Ramsden**
May 4, 2008

I'm ashamed to say I find these controversies hilariously funny, although I suspect I'm far from alone in that. I do see the serious side though, where people think their reputations may be threatened; but those fears are probably greatly exaggerated.

My only slight objection to posts by "anonymous", aside from the obvious potential for unaccountable innuendo, invective, or defamation etc, is that they can't be put in context of other opinions expressed by the same individual.

That's often fine, in a "res ipse loquitur" sense, where "anonymous" chips in with indisputable facts for example. But in a long discussion someone who consistently uses a unique nickname is still anonymous but establishes a context, for good or ill. In other words, regular readers recognising the nickname know where that poster is likely to be coming from.

It also avoids confusion where there's more than one "anonymous" in the same discussion – I've seen that happen, and the result can be surreal!

42. **João Carlos**
May 4, 2008

Professor Woit,

Prof. Carrol says **he** doesn't care. The reason **you** should not do this is because **you care**. You can't have it both ways.

If you think that it's – at least – a lack of good manners (and I fully agree), it's a *non-sequitur* if you propose anything otherwise.

And, by the way, everyone knows the one behind those "anonymous" posts. So, as Prof. Carrol says, "why bother?" If you don't want to get mad, get even. Reply anonymously… if you really think those *ad hominem* comments deserve a reply, other than a significant lack of response.

May I remember you of the old saying: "Don't feed the Troll…"?

43. **Peter Woit**
May 4, 2008

Joao Carlos,

Actually I don't know who is behind these anonymous posts. If you do, please tell, and explain how you know this.

And no, if there's an anonymous response to these posts, it won't be coming from me.

44. **geometer**
May 4, 2008

Not sure whether WordPress allows this, but some other blog providers offer a number of privacy option including disallowing all anonymous posts. It should not be hard to make posting password protected. Perhaps this is what you need for your own blog. As for other people's blogs, I think the best attitude is to never worry about things beyond your control.

45. **Ellipsis**
May 4, 2008

I like your blog very much and do think attacks on you and Lee Smolin are often unfair — and that indeed tends to be biased toward the anonymous ones.

But the reason I, and I think a good set of others, happen to be anonymous is, I think, a basically reasonable one: if my colleagues see me commenting in a lot of physics blogs, they will know that I'm not doing "real work" and I think my professional reputation will slightly suffer. One's definition of what "real work" is can most certainly vary, and I do think people should certainly not be penalized for this sort of thing, but things are what they are in a lot of the physics world, and if one bans anonymous commenting, one can often throw out a few decent babies with bath water. Unless we can somehow single-handedly change this view among many people of what "real work" is in physics, then if you happen to want this set of opinions, for what they are worth, I would vote that you please don't uniformly insist on people using their names.

46. **Peter Woit**
May 4, 2008

geometer and ellipsis,

Technically it would be possible to enforce non-anonymity in a blog comment section. I have no intention of doing this, but do think it's a good idea to encourage people to use their names. I do understand why many people prefer not to use their names, for several legitimate reasons including the one given by Ellipsis.

I suspect one of the main reasons people are reluctant to use their names on physics blogs has to do with the unfortunate politicization of discussions involving string theory. Saying something even tangentially related to one of the hot-button topics surrounding the theory, or posting a comment on a blog identified with one side of the controversy can all too easily get one on someone's enemies list (or subject one to personal attacks on blogs, whether nonanonymous, eg. Lubos, or anonymous). This is really a shame, but I guess until it changes many sensible people will not want their names to appear on blogs.

47. **Me**
May 5, 2008

You can make people sign-in with openid/typepad and while they would still be anonymous, no one would be able to impersonate someone else.

48. **Thomas R Love**
May 5, 2008

Peter, You should be proud that people are attacking you. That means your work is influential and your attacks on string theory are spot on. If you were wrong, the critics would offer something proving string theory. They can't , so they attack you. The problem is when people ignore your work. So, I offer my congratulations to you! Keep up the good work. When can we expect the sequel to NEW?

49. **Peter Woit**
May 5, 2008

Thanks Thomas,

To write a sequel to Not Even Wrong, there would have to be some new developments to write about, and remarkably little has changed since the book was written back in 2002. So, no plans for a sequel any time within the next few years, maybe never. I do joke sometimes that my next book may be a comic novel created by cutting and pasting things from blog entries and my e-mail. But one problem with that is that readers probably would find the whole thing implausible…

50. **Gil Kalai**
May 5, 2008

Ethics of blog discussions is an interesting topic. I can understand Sean's position that vulgar or abnoxious comments will be deleted whether they are anonymous or not, and I also understand the point of view that anonymous commentators should be more restrained in their behavior.

Perhaps one thing we can agree on is that invented names who are themselves insulting should not be permitted. I remember in the earlier days of NEW a commentator whose nickname was of the form "X makes me puke" being permitted to comment. Perhaps a little consensus we can reach is not to allow insulting nick-names in the future.

(We also have to be careful about ethics which is sensitive to personal attacks but is tolerant to attacks against a large group of people.)

51. **Amos**
May 5, 2008

If you don't want people making anyonmous derogatory comments about you and your work than you should not have published a book or started a blog. It comes with the territory.

I guess I think this whole issue is odd. Its like when Lubos banned all links from this blog to his. What's the point?

Considering the two issues, it reminds me of what Kissinger said: Academic disputes are so bitter because the stakes are so small.

52. **anonymous**
May 6, 2008

I think anonymous is a scoundrel!

anonymous

🙂

53. **Anonymous Hater of Peter Orland**
May 6, 2008

That S.O.B., Peter Orland would probably tell you to just ignore anonymous insults at other blogs, because they are beyond your control, and you can't be liked by everybody. But hey, he'sjust a stupid jerk.

P.S. He's ugly too.

54. **Jack Lothian**
May 6, 2008

I think that people who throw insults & hide behind "anonymous" are persons of low ethics and morality but trying to enforce this morality on the web is a challenge. Creating fake identities is not hard and the sheer volume of this nonsense can be overwhelming sometimes. If I ran CV and had the time, I would delete such responses but I do not know their circumstances so I say it is their call. My recommendation is enforce this policy on your blog if you have the time & ignore these gadflies on other blogs. Everyone who counts will ignore them so why not join the crowd.

55. **Juan R.**
May 9, 2008

Peter, anonymous attacks on the Internet are the rule. I recommend you to follow guidelines when dealing with internet critics. I recommend you specially the guideline: *do not respond to obvious flame bait and red-herring arguments*

> It is a pointless waste of time, energy, bandwidth, and disk space to respond to these insults. Flames and red-herring are intended to confuse the reader or divert attention away from the subject.
>
> Some people are masters of changing the subject. This even includes the subject title. Flames often are attempts to hide the poster's ignorance on some topic by inciting a series of angry responses. Ignore this nonsense.

I personally attach guidelines

guidelines for online scientific discussion

to my postings on several online services, including Usenet sci.physics.research and sci.physics.foundations.

Regards.

“So what will you do if string theory is wrong?”

May 5, 2008
Categories: Uncategorized

In a new preprint of an article entitled “So what will you do if string theory is wrong?”, to appear in the American Journal of Physics, string theorist Moataz Emam gives a striking answer to the question of the title. He envisions a future in which it has been shown that the string theory landscape can’t describe the universe, but string theorists continue to explore it anyway, breaking off from physics departments to found new string theory departments:

> So even if someone shows that the universe cannot be based on string theory, I suspect that people will continue to work on it. It might no longer be considered physics, nor will mathematicians consider it to be pure mathematics. I can imagine that string theory in that case may become its own new discipline; that is, a mathematical science that is devoted to the study of the structure of physical theory and the development of computational tools to be used in the real world. The theory would be studied by physicists and mathematicians who might no longer consider themselves either. They will continue to derive beautiful mathematical formulas and feed them to the mathematicians next door. They also might, every once in a while, point out interesting and important properties concerning the nature of a physical theory which might guide the physicists exploring the actual theory of everything over in the next building.
>
> Whether or not string theory describes nature, there is no doubt that we have stumbled upon an exceptionally huge and elegant structure which might be very difficult to abandon. The formation of a new science or discipline is something that happens continually. For example, most statisticians do not consider themselves mathematicians. In many academic institutions departments of mathematics now call themselves “mathematics and statistics.” Some have already detached into separate departments of statistics. Perhaps the future holds a similar fate for the unphysical as well as not-so-purely-mathematical new science of string theory.

This kind of argument may convince physics departments that string theorists don’t belong there, while at the same time not convincing university administrations to start a separate string theory department. Already this spring the news from the Theoretical Particle Physics Rumor Mill is pretty grim for string theorists, with virtually all tenure-track positions going to phenomenologists.

I have some sympathy for the argument that there are mathematically interesting aspects of string theory (these don’t include the string theory landscape), but the way for people to pursue such topics is to get some serious mathematical training and go to work in a math department.

The argument Emam is making reflects in somewhat extreme form a prevalent opinion among string theorists, that the failure of hopes for the theory, even if real, is not something that requires them to change what they are doing. This attitude is all too likely to lead to disaster.

Update: A colleague pointed out this graphic from Wired magazine. Note the lower right-hand corner…

Update: Over at Dmitry Podolsky’s blog, in the context of a discussion of how Lubos’s blog makes much more sense than this one, Jacques Distler explains what it’s like for string theorists these days trying to recruit students:

> Unfortunately, I’ve seen a number of prospective graduate students, who spent their undergraduate days as avid readers of Woit’s blog, and whose perspective on high energy physics is now so hopelessly divorced from reality that the best one can do is smile and nod one’s head pleasantly and say, “I hear the condensed matter group has openings.”

Comments

1. **anon.**
   May 5, 2008

   I have some sympathy for the argument that there are mathematically interesting aspects of string theory (these don’t include the string theory landscape)

   The string theory landscape (i.e., the space of string vacua) is, from another point of view, a space of 2d CFTs. Why isn’t that an interesting mathematical object?

2. **Peter Woit**
   May 5, 2008

   anon,

   Maybe there’s some interesting global structure to the space of all 2d CFTs, but people have been looking for such a thing for years and I don’t see any progress. In any case, that’s not what people working on the landscape are doing, instead they’re looking at specific points or neighborhoods in this space, and these are typically not mathematically very interesting.

3. **Jonathan Dursi**
   May 5, 2008

   Somehow I have a hard time seeing grad students and undergraduates beating down the door of admissions clamouring to be part of a program in this new department of not-physics-not-math.

4. **weichi**
   May 6, 2008

   hmm, a new department claiming to have insight into the nature of reality, but not mathematics, not physics … does he really think the philosophers are going to let them horn in on their territory like this?

5. **Chris Oakley**
   May 6, 2008

   I am having a big problem with this:

   > So even if someone shows that the universe cannot be based on string theory, I suspect that people will continue to work on it. It might no longer be considered physics, nor will mathematicians consider it to be pure mathematics. I can imagine that string theory in that case may become its own new discipline …

   … if a mission that you have been embarked on for over thirty years turns out to be futile then dumping it is not only sensible – it is a *moral obligation*.

6. **Urs Schreiber**
May 6, 2008

> that's not what people working on the landscape are doing

But maybe it's what they should be doing. (Well, some do, but not those in the string theory departments.)

A theory is independent of what people do about it. If all present attempts to address open question X are inadequate, it doesn't necessarily imply that question X is uninteresting.

7. **Bee**
May 6, 2008

Hey! Adrian is going back to NY!

Reg the question what would the string theorists do in case. Well, one couldn't just fire all these string theorists, what were they supposed to do? If they were able to, they might change fields, but we all know this isn't easy especially if the education has been narrow and one has passed the fifty or so. Maybe one should offer a re-education program or something. There is without doubt a strong specialization going on in the community. Many of these people are extremely smart and could make contributions to many other fields, but who is going to hire somebody who has worked 10 years on string theory for, say, an astrophysics position?

That being said, I too would guess that those who couldn't jump off the field but could keep their job would just continue working on it. Well, you know what they say, progress isn't made from conference to conference, but from funeral to funeral. Maybe string theory would become an art form, or a branch of philosophy? Who knows.

8. **Christine**
May 6, 2008

Well, astrology has been proved to be wrong, but I'd say there are more astrologers out there than astronomers, and for certain they are making more money than the latter, so I'd not be surprised.

Now, seriously, if string theory turns out to be proven wrong, I hope people who devoted they careers to it are reasonable enough to pursue other lines of research, or at least admit that string theory is pure mathematics and treat it as such.

9. **piscator**
May 6, 2008

I think an equally appropriate question Peter is what would you do if string theory is shown to be correct? 😉

10. **Peter Woit**
May 6, 2008

piscator,

Doesn't seem to be going that way, does it? But if it does, probably I'd keep working on the same things I've been working on for years. Maybe I'll pay less attention to gauge groups and more to Diff (S^1)….

11. **Daniel de França MTd2**
May 6, 2008

Poor Witten.

12. **Maarten Bergvelt**
May 6, 2008

Peter wrote:
> Maybe there's some interesting global structure to
> the space of all 2d CFTs, but people have
> been looking for such a thing for years and
> I don't seen any progress.

Isn't the space of superconformal field theories
supposed to be the topological modular form spectrum? Work of Hopkins, Lurie, Teichner and Stolz etc. Maybe not of physical interest but algebraic topologists are very excited about this, I think.

13. **blop**
May 6, 2008

It sounds like Clinton: I lost but I stay…

🙂

14. **Peter Woit**
May 6, 2008

Maarten,

Sure, if you look at special classes of 2d CFTs, you get extremely interesting mathematics, one example is the one you mention. The problem is that the class of CFTs the landscape people are interested in because it is supposed to unify physics doesn't seem to be a mathematically interesting one.

This has always been the problem with string theory: some parts of it lead to deep and wonderful mathematics, but those have always turned out to be orthogonal to the parts of string theory you get into when you try and use it to unify 4d gravity and the standard model.

15. **Shantanu**
May 6, 2008

Peter, have you looked at Witten's talk at the ongoing Dark energy symposium at
STSCI

16. **Ethan Siegel**
May 6, 2008

Is there really anything wrong with that?

"Well, we had an interesting idea, and gave it a go, but it doesn't look like it panned out. Still, this is a fun system to play with, and we think that we'll keep playing with it, even if it doesn't have any relation to physical reality."

Of course they're going to have to stop calling it physics, which they've agreed to. But how is this less "valid" than, say, searching for all of the Mersenne primes? Or, for a physics analogy, solving mathematically interesting cosmologies that simply don't happen to be ours?

17. **Peter Woit**
May 6, 2008

Thanks Shantanu, very interesting. Maybe I should write a blog entry about that…

Ethan,

Sure, anybody whose research program fails is welcome to decide that he or she wants to keep going anyway. The problem I'm trying to point out is that it is unlikely that either the physics or math communities are going to support this. So, unless you've got tenure and don't care whether you have a grant and graduate students, you'll probably find that you can do this but no one is going to pay you to do it, or hire any students who work with you on it.

18. **estraven**
May 6, 2008

I have seen some string theory physicists do exactly that: study maths, become mathematicians, and keep working on problems they find interesting for physical reasons. They have the bonus advantage of being able to speak (or at least read) "physiquese", something most pure mathematicians (like me) usually can't do and occasionally is useful.

19. **Thomas R Love**
May 6, 2008

The big question is: "When string theory is proven not to correspond to physical reality, will any journals publish research on string theory?"

20. **Benni**
May 6, 2008

I think string theory is still an excellent topic for graduate students at this time.

Since string theory contains both QFT and GR, and also some math, one can switch to these three fields later on.

If the LHC finds a simple higgs-sector, which will be theoretically explored in relatively short time, phenomenologists will have problems, because there won't be many problems left to solve..

I dont think that a phenomenologist can become a mathematician, or a researcher on pure quantum gravity.

Where as i think it is sure, that it can be expected from a string theorist, he can switch to mathematics, phenomenology, pure quantum gravity, or genral relativity.

21. **RK**
May 6, 2008

http://xkcd.com/171/ !

22. **Thomas Larsson**
May 6, 2008

"Well, we had an interesting idea, and gave it a go, but it doesn't look like it panned out. "

Well, this is pretty much what we wanted Witten and others say for a decade. With the notable exception of Dan Friedan, no string theorist has been willing to say it, though.

23. **Peter Orland**
May 6, 2008

>Benni Says:

>I think string theory is still an excellent topic for graduate students at this time.

>Since string theory contains both QFT and GR, and also some math, one
>can switch to these three fields later on.

It isn't easy or practical for some people to switch academic fields without some kind of temporary position, such as a postdoc in the meantime. If string theorists don't get postdocs, they usually have to leave academia fairly.

> I dont think that a phenomenologist can become a mathematician, or > a researcher on pure quantum gravity.

Though I am not a phenomenologist, I know that some of them certainly could make such a move.

24. **Peter Orland**
May 6, 2008

Fairly quickly, I meant.

25. **big vlad**
May 6, 2008

“Where as i think it is sure, that it can be expected from a string theorist, he can switch to mathematics, phenomenology, pure quantum gravity, or genral relativity.”

that’s like saying a 100m sprinter could switch to american football, or rugby.

26. **Bjoern**
May 6, 2008

Today, Alvarez Gomé gave a talk in Munich about the riddles in fundamental physics. He tried to make of the “self-righteous popperazzi”; but in fact he seemed very hurt by the critics of string theory, including Peter, whom he mentioned at the beginning of his talk, together with Lee Smolin.

He also made an interesting and strong statement that was new to me: only string theory can explain gauge theory. Asked why, he stated that string splitting/breaking is equivalent to a gauge theory.

In the introduction to the talk, Dieter Lüst explained that a new faculty position on “higher dimensions” is available in Munich. A faculty position on something unobserved. Times are bizarre …

27. **Peter Woit**
May 6, 2008

Bjoern,

When I was in Lisbon last fall I had the chance to talk to both Lust and Alvarez-Gaume, and we had some interesting and worthwhile discussions, which were polite but sometimes forceful. Alvarez-Gaume is certainly not happy with all the criticism that string theory has been getting. As a leader of the CERN theory division and a string theorist, I’d guess the public criticism and change in attitude has made his job significantly harder and put him on the defensive.

Unfortunately, I think this has made him focus on some of the unfair criticism string theory has gotten, and upon making a forceful defense, instead of acknowledging that there is a legitimate problem to be discussed. I don’t know exactly what claim he was making, but the statement that “only string theory can explain gauge theory” is simply not true. Going too far in its defense is not going to be helpful to the interests of either string theory or of particle theory in general.

28. **Joseph Triscari**
May 6, 2008

I’ll update the old joke:

The dean of the school of science was scolding the chairman of the physics department:

“Why,” he asks, “does it cost so much money to run your department? Why must you purchase all this equipment?

“Why can’t you be more like the math department. They only need pencils, paper and garbage cans. Or better yet, like the string theory department! They only need pencils and paper…

29. **Eric**
May 6, 2008

In the words of Einstein, “I would be sorry for the dear Lord. The theory is not wrong!”.

30. **JC**
May 6, 2008

Thomas R Love,

If mainstream particle theory journals ever ceased to publish string theory papers, then most likely the remaining string theorists will start their own “peer reviewed” journal dedicated to string theory.

31. **Gil Kalai**
May 7, 2008

It is nice to see scientists writing papers on philosophical or foundational issues and in this respect Emam paper is quite welcomed. As for the content, I did not find the paper very convincing. At present, both a success of string theory or its failure are well beyond the horizon. A failure will most likely not be of the form of a single bit of information coming from the sky, but probably will be related to major other developments, theoretical or empirical, and thus will probably give people in the field a lot to work on.

32. **Bjoern**
May 7, 2008

Peter,

indeed, your description of Alvarez-Gaumé’s feelings is precisely the same that I got in his talk. My opinion is that there is a huge difference between saying “string theory is useless because it makes no predictions” (as you do) and attacking string theorists personally (AG mentioned a ferocious literary critic called “Steiner” which must have offended him in a public meeting recently).

It is important for one’s personal image and also for one’s personal well-being to keep and upheld this difference.

AG was also annoyed by the statement “the end of science is there” (citing John Horgan explicitly) and explained how many open problems there are in biology, chemistry etc.

I looked again into my notes. I did not copy the exact statement from his slide, but he really made the statement that no other theory except string theory explains gauge theory from a more basic point of view. The question that was asked only asked how string theory deduces gauge theory. Why no other theory does so was not addressed.

Nevertheless, Alvarez-Gaume was well-balanced, and I am sure that one can have interesting professional discussions with him.

Bjoern

P.S. In my first post, the sentence should have read: “He tried to make fun of the …”.

33. **Peter Woit**
May 7, 2008

Bjoern,

The conference in Lisbon I was referring to was organized by George Steiner, and John Horgan also spoke. Both had quite critical things to say about string theory, but neither is a physicist (Steiner is a literary critic, although somewhat of a polymath).

34. **Peter Shor**
May 7, 2008

Bee says “Reg the question what would the string theorists do in case. Well, one couldn’t just fire all these string theorists, what were they supposed to do?”

Well, you certainly can’t fire a lot of them … they have tenure. I believe that pretty much the only way to fire tenured faculty (if they aren’t guilty of gross misconduct) is to dissolve the department they are in. So if Moataz Emam gets what he is wishing for, and university adminstrators start creating Departments of String Theory, I would say this would be very bad news indeed for string theorists.

35. **Gil Kalai**
May 7, 2008

yes, yes and just imagine what will happen to mathematics departments if a contradiction in mathematics will be found.. and if the view regarding the “end of science” will previal we will have to rename “science faculties” to “post-end science faculties”…

Seriously, I am skeptical if this type of fantasies are the right avenue for skepticism in science, which shoud be welcomed.

36. **Coin**
May 7, 2008

yes, yes and just imagine what will happen to mathematics departments if a contradiction in mathematics will be found..

Indeed… who could imagine how mathematics departments would cope if such a strange, unheard-of thing were to happen?

I think the thing to keep in mind here is, mathematics disciplines can validly motivate themselves entirely on internal metrics of progress. You can have subjects in mathematics putter along happily for years in the complete absence of any practical application, and no one really minds. If you’re going to describe yourself as *physics*, though, it’s not enough to be internally consistent. You also have to coincide with what is true in the real world. And the real world simply happening, coincidentally, to not be the same as some theory or other is a real, constantly looming possibility which needs to be taken seriously for all physics theories– even established ones, I think.

(I personally would find string theory a lot more interesting if it did jump ship and decide to become a mathematics discipline rather than a physics one. As Woit notes above there are some rather interesting bits of math in string theory but they get overshadowed if you think about string theory as a way of unifying physics. Like, I want to know more about these “fractal string” things. And isn’t it true that even if String Theory is “proven wrong” as a physics unification theory, AdS/CFT will continue to be a relevant mathematical tool in physics?)

and if the view regarding the “end of science” will previal we will have to rename “science faculties” to “post-end science faculties”…

Heh, this is a fun point though. I wonder if Post-Science is similar to post-modernism or post-rock.

37. **Thomas R Love**
May 8, 2008

I found this quote:

I can now rejoice even in the falsification of a cherished theory because even this is a scientific success

—John Carew Eccles

Rejoice!

38. **Dmitry Podolsky**
May 9, 2008

Dear Peter

I’ve got an impression that the question “what will you do if string theory is wrong” as you presented it actually sounds empty. To define whether string theory gives the wrong answer to the question you ask, you first need to ask the question.

If your question is “does landscape have anything to do with objective reality”, then the answer could be very well “no” (although it could very well be “yes”).

If your question is “does string theory have anything to do with strongly coupled regime of gauge theories or, say, 3D Ising model”, then, I guess, the answer should be already known to people around.

I think, if landscapism will eventually die out, string theorists will start working on problems requiring string theory to solve them such as strongly coupled YM.

Cheers

39. **Peter Woit**
May 9, 2008

Dmitry,

I’m not the one going on about “string theory is wrong”, what I was doing in this posting was linking to an article by a string theorist on this topic. “String theory” now refers to a huge array of different kinds of things, from the quite interesting to the nonsensical. The statement “string theory is wrong” is meaningless, and not one that I make.

To respond here to the posting on your blog, I'd like to point out that your characterization of what I wrote here as: "String theory is wrong, all string theorists should be immediately fired" has nothing to do with what I actually wrote or what I think. At least you're not referring to me as "Peter Whore" or calling for my death, but you are adopting Lubos's tactic of drastically misrepresenting the arguments of other people.

The gist of my comment on the article here was that the idea that string theorists should give up on being part of physics departments and start their own separate departments is unrealistic, since virtually no university is going to fund this. The comment that this year in the US virtually all tenure track theory jobs are going to phenomenologists, not string theorists, is simply factual and not made as a value judgment. The kind of work that I think needs to be done, deeper formal investigations of quantum field theory, is every bit as unpopular as string theory, and tenure-track jobs are not going to people doing this either.

40. **Thomas Larsson**
May 9, 2008

If your question is "does string theory have anything to do with strongly coupled regime of gauge theories or, say, 3D Ising model", then, I guess, the answer should be already known to people around.

Does string theory have anything to do with the 3D Ising model? If so, what? Can you use it to extract some numbers exactly? If so, which numbers and what are their values?

CFT has of course a lot to do with 2D Ising, but that is an almost trivial toy model in comparison.

41. **Peter Woit**
May 9, 2008

Dmitry,

Rereading your blog posting, I see that you are also completely misrepresenting Peter Shor's comment. He was not regretting that string theorists cannot be fired "because they are on a tenure track". He was pointing out that separate string theory departments would be dangerous for string theorists, since essentially the only way US universities can (and do) fire tenured people is by closing down their department. If string theorists had 20 years ago organized themselves into new separate departments, there would be a danger now that universities would start closing these.

And, just being "on a tenure track" does not at all make it difficult to fire someone, they need to actually have been tenured.

42. **Eric**
May 9, 2008

Peter,
Regarding the issue of faculty hires this year, don't you suppose that the reason phenomenologists have been hired has something to do with the fact that LHC is about to turn on for the first time? It seems a little dishonest to me to intimate as you do that this is a sign that string theorists are falling out of favor. Once the results from LHC are in, then we should probably expect more string theory hires if all goes as expected.

43. **Dmitry Podolsky**
May 9, 2008

Peter

If I misitepreted your or Peter Shor's words, I apologize. Nevertheless, your post left me with a particular impression (and I have to confess that it did not dissolve), and that was the reason why I wrote what I wrote.

Thomas

For 2D Ising, there are two equivalent formulations of the theory: in terms of spin variables \sigma and in terms of disorder variables \mu (the ends of dislocation lines). Although \sigma and \mu satisfy rather complicated equations, their product satisfies linear equation; that fact allowed Onsager to find exact solution of the 2D Ising model.

For 3D Ising dislocation lines become dislocation surfaces, boundary of such surface is the variable on which disorder variable \mu depends. One hope to find simple equations describing 3D Ising is to construct product of \mu (C) and \prod \sigma (x_i) where x_i are points close to the loop C. The first impression was that such a loop C together with "spin" variables – vectors normal to loop and connecting it with points x_i – is NSR string, and the equation describing its dynamics is linear in the space of loops.

One person who tried to pursue this program was Polyakov. As far as I know, he got stuck since it was hard to write equations in loop space for renormalized variables.

44. **Peter Orland**
May 9, 2008

Thomas,

This is off topic and Peter may want to delete your comment and mine – well not SO off topic. You were asking about the application of string theory to field theory/stat. mech. problems. I have worked on this sort of thing on and off for a long time. It may not be much off the main topic, because it does touch on the justification for continuing to do string theory, should the subject fail to unify forces or give definite results in quantum gravity.

There was a program initiated by many people – Nambu, Weingarten, Hasslacher and Corrigan, Makeenko and Migdal, Polyakov … the list goes on – that gauge systems like QCD and the 3D Ising model (which is dual to the Z_{2} gauge theory) could be solved using string-theoretic ideas. There are exact representations of the 3D Ising model as random surfaces with a certain action.

This program only seems to an unqualified success for N=4 susy YM. It has not yet panned out for pure Yang-Mills (which one wants to solve at weak bare coupling, near the RG fixed point, not strong bare coupling) or finding exact results for 3D stat. mech. systems. If you want critical exponents for statistical models in 3D, epsilon and 1/N expansions are still your best bet.

In fact, it is much easier to obtain string-like excitations from field theory than the other way around. The examples are strongly-coupled lattice theories, Higgs theories with vortex strings, compact QED in 2+1 dimensions and recently SU(N) gauge theories with two small couplings (sorry to advertise my own work Peter). These string-like excitations have not been shown to have any connection to standard string theory. When actions can be written down, they contain extrinsic-curvature-dependent terms, and are not local on the world sheet.

Maybe someday some of these long-standing problems will be solved using standard string-model ideas. Personally, I hope so. But maybe not.

45. **Moshe**
May 9, 2008

Peter Orland, I have zero interest in the "justification" issue. Just wanted to comment that there are new ideas on the market relating various 3dim systems to string theory, via the gauge-gravity duality. These may or may not pan out, but they are different from the set of ideas you refer to (more to do with perturbative ST). For an entry point to the literature you can look at recent papers of the nuclear theorist D.T. Son.

46. **Peter Orland**
May 9, 2008

Hi Moshe,

Yes, I have seen this stuff – but these systems are interesting because of their connection to string theory. I am not convinced they have any application to nature (I know people are trying to make such a connection).

Regards,
Peter

47. **Peter Orland**
May 9, 2008

P.S. The effective string excitations, which arise in field theories, also
have no obvious connection with perturbative string theory.

48. **Moshe**
May 9, 2008

Not sure I agree this is the only interest in these systems, but in any event there is currently a new set of ideas of dealing with strongly interacting systems. It may be of some interest for people with experience dealing with such systems to explore these ideas and discover what they are good for.

49. **Peter Woit**
May 9, 2008

Eric,

The problem with the argument that physics departments have only stopped hiring string theorists this spring is because of the LHC is that the LHC turn-on has been imminent for quite a few years, and departments that wanted to move in that direction have been doing so for quite a while.

However, it is only this spring that string theorists have started posting articles on the arXiv about what they plan to do once it is shown that string theory is wrong…

50. **Peter Orland**
May 9, 2008

Sure, new things need to be explored. The ideas you mentioned aren't being neglected, while there are other approaches to strongly-interacting problems which have excited less interest, possibly because they don't start from string theory (using exact form factors is one of those of which I am familiar).

51. **Peter Orland**
May 9, 2008

Moshe – If you are interested, the form factor program is reviewed in
an excellent article by Essler and Konik.

52. **Moshe**
May 9, 2008

Thanks Peter O., I'll take a look.

53. **Eric**
May 9, 2008

Peter,
I don't think you can claim that physics departments have stopped hiring string theorists. For example, Hawaii has just made an offer to a string theorist, and I'm sure others will be forthcoming.

54. **Eric**
May 9, 2008

Again, what about Lehman College, CUNY? Can we not consider Dan Kabat a string theorist?

55. **Peter Woit**
May 9, 2008

Eric,

I'm not claiming that no physics department is hiring any string theorists, just that dramatically fewer are getting tenure-track jobs this spring than was typical in recent hiring seasons. I've given you my source for this information: the rumor-mill web-site. Go check it for yourself.

56. **Eric**
May 9, 2008

Peter,
Perhaps you should have a closer look at the rumour mill site yourself, as the information I was just giving you came directly from there. Even if there are fewer string

theorists hired this spring, I don't think this would be that unusual, as these things are cyclic.

57. **Coin**
May 9, 2008

Sorry if this is kind of a dumb question, but this is something I've been a bit confused about for a while: What exactly is the difference between a "Phenomenologist" and an "Experimentalist"?

58. **Peter Woit**
May 9, 2008

Coin,

Experimentalists design, build, operate experiments and analyze the data from them. Deciding which theorists are "phenomenologists" is not so clear, the term covers a wide range of activity. But in general the idea is that they are theorists working not on theoretical or mathematical foundations, not on models far from reality, but on better understanding and extracting predictions from testable models that can be compared with experiment. At one end of the subject, their activities probably become indistinguishable from some of the activities engaged in by experimentalists as part of their data analysis.

59. **Peter Shor**
May 10, 2008

Peter Woit is right; I certainly wasn't calling for all string theorists to be fired. I was trying to point out that Moataz Emam's call for string theorists to form their own departments (and I don't quite know how seriously to take him on this) was not only completely implausible, but it also wasn't even in the best interest of the string theorists. If anybody tries to form a separate Department of String Theory, I would expect and hope that most of the physicists (string theorists and others alike) in the affected Department of Physics would resist.

60. **Thomas Larsson**
May 10, 2008

Dimitry and Peter O.

I am well aware that the 3D Ising model is Kramers-Wannier dual to the 3D Ising gauge model and admits a random surface representation. Even better, one can write down a funny O(N) or U(N) lattice gauge model on a 3D brick lattice, with a log action, that can be exactly mapped onto a model of self-avoiding random surfaces; the weight of each graph equals N^chi u^A, where chi is the Euler characteristic, u is related to the coupling constant, and A the surface area.

Does this construction solve U(N) gauge theory, or make me into a string theorist? Hardly. Just because I have mapped one untractable model into another does not mean that I have solved it. If anything, this shows that perturbative string theory is inadequate for this problem because steric repulsion is crucial here (self-avoiding surfaces do not self-intersect!).

A method has only really contributed to our understanding of a model if it helps to extract some kind of quantitative information about it, not necessarily critical exponents and not necessarily exactly. The methods that Peter O. mentioned do that, as do high- and low-temperature expansions, real-space RG and computer simulations. However, AFAIK no quantitative results about 3D Ising have come out of string theory.

61. **Peter Orland**
May 10, 2008

Thomas,

As you can see from my earlier comment, I largely agree with your sentiment that string/random surface approaches to field theory/stat mech problems have not been successful. In fact, as I said, it has been much easier to obtain string excitations from field theory than the other way around (except in AdS/CFT approaches, which have not yet made a connection with real physics problems. Maybe the work Moshe referred to will change the situation). I must admit, however, that I still have some fondness for this approach, in spite of its lack of success, since it captured my imagination in grad school. It was a very daring suggestion, which, unfortunately, may not lead anywhere.

62. **Jonathan Vos Post**
May 10, 2008

As someone with credentials as a scientist and as a writer, I see the argument for splitting String Theory Departments away from Physics Department, to allow Physics Departments to return to the "Real World" and to allow the String Theorists to pursue their quest; as analogous to an argument that Critical Theory Departments split away from English Literature Departments, to allow Eng Lit to focus again on poems, stories, and novels, and be free from Deconstructionism, Feminism, Pan-Africanism, Asian Pacific Islandism, Gay Theory, Postcolonialism, and the like, while the Critical Theory professors and grad students and postdocs explore a rich sociocultural and semiotic landscape unfettered by having to read and explain prose and poetry that naive millions of readers actually enjoy buying and reading.

63. **JC**
May 10, 2008

Is that quote on Podolsky's blog really by Jacques Distler himself? Or is that quote just somebody else posting under Distler's name, trying to make him look bad?

(Offhand, I can't really tell either way).

64. **Peter Woit**
May 10, 2008

JC,

If it's not Jacques, it's someone doing a pitch-perfect impersonation….

65. **Gil Kalai**
May 11, 2008

Peter, this thread shows the difficulty in discussing hypothetical scenarios. Emam referred to a hypothetical situation that "someone shows that the universe cannot be based on string theory" so he was certainly not calling to form separate departments now.

Overall, Enam's analysis is not convincing. I think he is simply wrong in his assumption that if someone shows that the universe cannot be based on string theory many string theorist will continue to do what they do. Showing that the universe cannot be based on string theory (if this will be the way things will go) will represent a major breakthrough which is one of the potential fruits of string theory research. Probably such a (hypothetical) development will cause most string theory to work on something else (that can still be called "string theory"). Those who will continue to work on string theory (or "old-fashioned string theory") will have a place in physics department just like many other theoretical physicists who work on models which while not describing the universe, still give important physics insights and develop important mathematical physics. Also Emam's comparison with statistics does not make sense.

Here is an analogy from mathematics. For many centuries algebraists tried to find formulas for solving polynomial equations. If somebody had come say in 1600 and said: "guys in view of the many years of failure, try to think about the possibility that such formulas are impossibles" this could be a little useful. If the same guy had said "algebraists have failed and they should be fired" (opening the door to more astrologists and alchemists), then this could be a little harmful. But what was really needed is an understanding why there are no formulas to solve polynomial equations and not just vague speculations and meditations.
Once this was understood nobody continued the old algebra endeavor but there was plenty of work left for algebraists, in fact, this was the beginning of modern algebra.

The turning point and the beginning of modern algebra was not just the "gut feeling" that the old endeavor might have failed but the detailed technical understanding why it cannot succeed.

66. **Peter Woit**
May 11, 2008

Gil,

String theory, as an idea about unification, is not in danger of failing because of mathematical contradiction. It is failing because it is becoming clear that, as an idea about unification, it is essentially vacuous. The reasons for this are well understood (e.g. the landscape). I don't think the author of this article or anyone else envisions string theory being shown to be mathematically wrong, or being falsified by showing that it predicts something that disagrees with experiment. What is happening is that conviction within the physics community is growing that there is no hope to get a real prediction out of string theory, thus the failure. Die-hards will keep claiming that hope remains, but there will be fewer and fewer of them, and at some point the consensus of the community will be that the cause is hopeless.

Right now, I think many of the leaders of the subject are well aware of how bad the problems are, but are holding out from giving up on the theory, waiting to see what the LHC says, hoping that LHC results will change the current picture. If the LHC doesn't come up with something that somehow gives new hope to the string theory unification program, I think it will be conclusively dead, although some people will insist on pursuing it. I would guess that it is exactly this all too possible situation that Emam is thinking about when he brings up the possibility of string theory being shown to be "wrong".

67. **Gil Kalai**
May 11, 2008

Dear Peter,

It is entirely rational to wait to the LHC outcomes and I think most people interested in the scientific endeavor are hoping that it will give new data and lead to important new insights. I have noticed that your opinion on string theory is negative, but your description of the convictions within the physics and string theory communities may very well be biased by your own personal position. At least your description differs from the convictions I sense when talking to many colleagues in these areas. (My little comment to Peter (Shor) was that Enam does not call string theorists to form independent departments but rather discusses a scenario which is hypothetical from his point of view.)

68. **Kea**
May 12, 2008

Gil

It is not at all reasonable to *wait and see* what happens at the LHC. Any responsible tax funded theoretician should be working their ass off to come up with quantitative predictions *before* 2009.

69. **Thomas Larsson**
May 12, 2008

Peter O,

I am sorry if my post came across as more negative than it was meant to be. The random surface approach also captured my attention a few years after it captured yours (when *I* was in grad school), and I find it frustrating that it has not panned out. When I now think about the problem again after many years, it seems like the obstacle is the self-avoidance constraint, which induces an interaction which is very non-local on the worldsheet, although it is local in the ambient space.

70. **Gil Kalai**
May 12, 2008

Peter, of course the nature of scientific proofs is different in different disciplines so mathematical proofs just appeared in my analogy since the analogy was drawn from the area of mathematics.

Ahh, I think I see a serious difficulty with your approach. You cannot imagine a way that string theory will be definitely proved to be wrong by physicists and therefore you assume that its weaknesses already suffice. (But just like the case of solving polynomial equations, in view of the prominence and successes of string theory much stronger scientific arguments will be needed.)

Similarly, you cannot imagine how string theory can prevail as a viable physics theory and therefore you conclude that it failed. But string theory can win in ways we cannot imagine at present and can also fail in ways we cannot imagine at present.

71. **anon.**
May 12, 2008

'But string theory can win in ways we cannot imagine at present and can also fail in ways we cannot imagine at present.'

This kind of statement is what you expect to find in a religious tract. It's not really scientific, but is more in the category of belief systems/cults/wishful thinking/crackpotism. If string theory 'wins' or is falsified, then it will be deserving of a media mention. Until then, it's not a scientific theory.

Feynman told a story of 'Cargo Cult Science'. During WWII, South Sea islands were used as military airports, and the islanders had business. After the war ended, some islanders tried to attract business by encouraging passing planes to come down to land by building improvised runways with control towers.

Their efforts looked professional from a distance, but up close they were fake. It's the same with string theory. The mathematics and alleged physical successes make it superficially look like a scientific discipline, but it isn't because it can't predict anything checkable.

72. **Zathras**
May 12, 2008

I've seen a number of prospective graduate students, who spent their undergraduate days as avid readers of Woit's blog, and whose perspective on high energy physics is now so hopelessly divorced from reality that the best one can do is smile and nod one's head pleasantly and say, "I hear the condensed matter group has openings."

That this blog has steered young students away from string theory is the best endorsement of any blog ever. Sounds like a clear charge of you're corrupting the youth.

73. **Mitch Miller**
May 12, 2008

Peter Woit Wrote:
"Right now, I think many of the leaders of the subject are well aware of how bad the problems are, but are holding out from giving up on the theory, waiting to see what the LHC says, hoping that LHC results will change the current picture. If the LHC doesn't come up with something that somehow gives new hope to the string theory unification program, I think it will be conclusively dead, although some people will insist on pursuing it."

Wow, that is not the impression I get at all. Everybody seems to already know what the LHC will find (Higgs for sure, maybe Susy and small chance of extra dimensions and even smaller chance of something crazy and non standard model). i don't see how anything bad for string theory can come out of the LHC. If extra dimensions are found, it will be great, if not its no big deal as the lower bound for these effects (or anything else related to string theory) to be measureable is not even close to being reached by the LHC. If something truely unexpected is found, everybody will be scrambling to explain it, not just string theorists. As a young grad student that is what I'm routing for, unlikely as it is 🙂

74. **Gil**
May 13, 2008

Dear Anon, please note that the statement you quote and criticize

"String theory can win in ways we cannot imagine at present and can also fail in ways we cannot imagine at present."

is not a statement **within** a scientific theory, but a statement **about** scientific theories. As such, I think it is perfectly fine and can be supported by examples.

75. **anon.**
May 13, 2008

Gil, string 'theory' is a misnomer. Stringy ideas are an empty framework which fits 10^500 theories. To get a specific string theory, you need to specify all of the moduli of the Calabi-Yau manifold of 6 compactified dimensions. If there was a string theory then your position would be sensible (and this blog wouldn't exist).

76. **Kris Krogh**
May 13, 2008

Gil,

It's true something unimaginable may save string theory. Would you like to invest in Company XYZ? The stock is performing terribly, but something unimaginable may save it.

77. **Gil Kalai**
May 13, 2008

If this looks more accurate to you, anon, replace "string theory" by 'the string framework'.

It is possibe that the 'string framework' will lead to a definite win (and thus perhaps to a 'string theory') in ways we cannot expect, and it is also possible that it will be definitely shown, in unexpected manners, that the 'string framework' is inedequate for its (ultimate) purposes.

There are also various possible forms of partial victory for 'the string framework', in terms of new insights and horizons in mathematics and physics which come short of a definite 'theory' to your taste. Some of these partial victories are already in place.

78. **Peter Woit**
May 13, 2008

The debate about string theory on this thread has become more or less completely content-free. Enough.

My apologies for not providing fresh material for discussion. I'm busy with other things, and there has been remarkably little news on the math-physics front.

79. **nbutsomedy**
May 13, 2008

"I've seen a number of prospective graduate students, who spent their undergraduate days as avid readers of Woit's blog, and whose perspective on high energy physics is now so hopelessly divorced from reality that the best one can do is smile and nod one's head pleasantly and say, "I hear the condensed matter group has openings."

Thank God (anyway, not a believer) !!!! A wise step for the students. Both monetary and scientifically.

80. **TCO**
May 25, 2008

Why the disdain for condensed matter from the first poster at the other site? Look at what Feynman did with helium. What Einstein did with thermoelectric effect. BCS theory. Fermi-Dirac. Bose-Einstein. How about figuring out cuprate superconductors, studs? Come on smarties. Direct your theory to something physically tangible.

-solid state chemist

81. **Jonathan Vos Post**
June 4, 2008

A deep statement by Atiyah, discussed by Gowers, recently in turn referenced by Terry Tao, explains why it might be a bad idea for String Theory (if "proven wrong") reconsolidate itself as distinct departments away from Physics.

Tao: "In fields such as nonlinear PDE (which Perelman's result can broadly be included in), individual theorems tend not to be directly applicable much beyond their original intended use, but general ideas, strategies, tricks, and paradigms are often far broader. A similar point (using combinatorics as the primary example) is discussed in Gowers' 'two cultures' paper

http://www.dpmms.cam.ac.uk/~wtg10/2cultures.pdf

Gowers citing Atiyah:

"The ultimate justification for doing Mathematics is intimately related to its overall unity. If we grant that, on purely utilitarian grounds, mathematics justifies itself by some of its applications, then the whole of mathematics acquires a rationale provided it remains a connected whole. Any part that drifts away from the main body of the field has then to justify itself in a more direct fashion."

If String Theory has drifted away from the main body of Physics, or Mathematics, then (however beautiful it may be) it is sociologically subject to a demand for direct justification.

82. **S Halayka**
June 11, 2008

For what it's worth, this paper seems to highlight the possibility of experimental verifiability at a scale of around 20 orders of magnitude larger than the Planck scale:

http://arxiv.org/abs/0806.1431

83. **S Halayka**
June 11, 2008

The paper mentioned above has been criticized to death by a trusted string researcher. My apologies for jumping the gun.

Witten on Dark Energy

May 6, 2008
Categories: Uncategorized

Commenter Shantanu pointed to a web-site with talks available on-line from a symposium about Dark Energy now going on at the Space Telescope Science Institute. Yesterday Witten gave a talk entitled “Models of Dark Energy”, where he lays out very clearly the conventional wisdom of the string theory community about the dark energy problem and its implications for string theory.

Witten describes how the problem of a huge number of possible vacua has always been an embarrassment for string theory. Until about 10 years ago his attitude towards most constructions of string vacua was “who needs this mess”, thinking that once one figured out the vacuum energy problem, such constructions would all go away. He explains how the discovery of a small positive CC has changed his attitude, that he’s no longer sure that one can find a distinguished vacuum state, and thus maybe the anthropic landscape/multiverse crowd is right. He describes this possibility as involving both good news and bad news:

> The good news (such as it is) then is that if we are really living in a “multiverse”, it may be that the theory as we know it is pretty close to the truth.
>
> But there’s a hefty dose of bad news… If the vacuum of the real world is really a needle in a haystack, it is hard to see how we are supposed to be able to understand it. In other words, if an unimaginably large number of approximate “vacuum” states are realized in different parts of the Universe, none of them with any special meaning, and with the details of particle physics depending on where one happens to live, then what sort of understanding of particle physics can we hope to get? I don’t have an answer to this question, although we might learn something from the LHC that will help…

The crucial point of course is this last one: how can you ever test these ideas, making them real science and not metaphysics? At the end of his talk, Rachel Bean tried to pin him down on this question, leading to this exchange:

> Bean: “If we have this landscape, this multiverse, … can we learn nothing, or is there some hope, do you have some hope, that if you were to find a universe that had remarkably small CC you could also make some allusion to the other properties of that universe for example the fine structure constant, or are we saying that all of these things are random variables, uncorrelated and we’ll never get an insight.”
>
> Witten: “Well, I don’t know of course, I’m hoping that we’ll learn more, perhaps the LHC will discover supersymmetry and maybe other unexpected discoveries will change the picture. I wasn’t meaning to advocate anything.”
>
> Bean: “I’m asking your opinion.”
>
> Witten (after a silence): “I don’t really know what to think has got to be the answer…”

Besides the landscape problem, Witten also described attempts to model dark energy as an aspect of some differerent sort of physical field, saying that he has been working on this with a student, but that the problem is the strong experimental bounds on the existence of light fields coupling to ordinary matter.

   May 6, 2008

   I believe Witten was referring to his previous work with Peter Svrcek who graduated a few years ago.

2. **Peter Woit**
   May 6, 2008

   Thanks Aaron,

   I think you’re right, he seemed to be referring to work with Svrcek, although that paper didn’t seem to mention anything about the dark energy problem, which was what Witten’s talk was about.

3. **Ethan Siegel**
   May 6, 2008

   At the very least, I’ve always found Witten to be remarkably balanced on the utility of string theory for the real world. This points towards that as well.

   He recognizes the limitations and pitfalls of the idea, as well as the difficulties inherent in attempting to find what we can learn from string theory if the models are non-predictive. I think that’s a very reasonable answer to Rachel’s question.

4. **Bill**
   May 6, 2008

   At the risk of embarrassing myself I have to admit that my knowledge of string theory is about at the level of that discussed in Zwiebach’s introductory book, so I’m an idiot. But the site’s mention of Witten and Moataz Emam’s proposed “future” of a failed string theory motivates this layperson’s following questions: One, if by adding a single dimension Witten can collapse five theories into one, can we not just add lots more dimensions to eliminate all the other inconsistencies (like the 10^500 vacuua) in the theory? (Of course, I’m thinking about von Neumann’s reputed curve-fitting comment regarding squeezing an elephant into some given model, and of course I’m also being facetious.) Two, if no one other than a post-doc math major can possibly appreciate this stuff, what good is it (recall Eddington’s comment about the dozen or so people who could understand general relativity at the time), particularly if it doesn’t deliver? And three, what right has the legitimate physics community to even consider taking a falsified or failed theory and turning it into another “discipline” (read: “religion”) on the sole basis that it is too beautiful to ignore (or, much worse, because so much time and effort has already been expended that we have to press on regardless)? This is the very definition of fanaticism.

5. **Kea**
   May 7, 2008

   Witten’s talk was clear, and surprisingly noncommittal regarding the existence of Λ, but I preferred Steinhardt’s talk, which discusses the need for a range of complementary tests and possible JDEM exclusions of large numbers of models, both stringy and not. As Witten also stressed, more accurate measurements of w will be important in ruling out classes of model, especially Λ varying ones.

6. **Chris W.**
May 7, 2008

Kea (and anyone else who is interested):

The HTML character entity for **Λ** is **Λ**.

The HTML character entity for **λ** is **λ**.

(Note the variation is case of the mnemonic, ie, the *entity* name.)

For greek letters (and other characters) see this reference or Wikipedia, among others.

7. **Chris W.**
May 7, 2008

From Peter: “The crucial point of course is this last one: how can you ever test these ideas, making them real science and not metaphysics?”

In the preceding paragraph (within the quote) Witten asks “then what sort of *understanding* of particle physics can we hope to get?”

Note the implicit identification of *understanding* and *testable explanation*. It seems that those who are attracted to the idea of a multiverse—in the form Witten has in mind—have effectively endorsed breaking down this identification, while continuing to assert that such an explanation could be scientific. What Witten is acknowledging is the untenability, even incoherence, of this assertion.

Untestable explanations may fulfill a desire for a putative understanding of the world that can assume various cultural roles, but in science they are at best *preludes* to the development of an explanation that can be tested, and stands up under testing. It does not seem that the multiverse can be such a prelude, except as part of an attempt that is frankly admitted to be a failure and thereby helps point the way to crucial insights. Of course for now, as Witten is also acknowledging, the way forward remains shrouded in obscurity.

8. **mike harney**
May 7, 2008

I like Witten’s coments that the LHC might give some clues – at least he is in touch with experimental reality.

9. **Arun**
May 7, 2008

In fact .. I think he’s going to be at CERN on a sabbatical when the machine turns on 🙂

10. **Shantanu**
May 8, 2008

Hi,
Peter and others,
Mario Livio’s talk was also very good and worth a look
and discusses anthropic principle.
right now John Peacock is giving a talk (which can be viewed live)

11. **egbert**
May 12, 2008

There’s talk on CNN about the LHC “test” of string theory being a religious experience for Nina Arkani-Hamed.

When I signed up to be a scientist, religion was considered a negative influence on science. How times change.

12. **Chris Oakley**
May 12, 2008

My favourite quote from the CNN article:

> “From the point of view of the big experiments at the LHC, there is no amount of money or craftsmanship that would produce the kind of insight that comes from sharing LHC data with a true visionary like Nima Arkani-Hamed,” Tully said.

13. **fh**
May 12, 2008

egbert:

Ludwig Boltzmann, quoting Goethe on Maxwells equations:

“War es ein Gott, der diese Zeichen schrieb?”
(Was it a God that penned these signs?)

A religious experience does not a religion make and in many forms it has a long and positive tradition in fundamental science.

14. **D R Lunsford**
May 12, 2008

fh,

He was paraphrasing – no, QUOTING – Goethe. You can find it for yourself.

Ok, I give in – it’s in the movie “Faust Times at Egmont High”.

-drl

15. **Peter Woit**
May 12, 2008

    egbert,

    I think he was just referring to visiting the LHC as a “religious experience”. The claims made in the article that the LHC may see strings and test string theory involve a different and more dubious sort of religious belief….

16. **chimpanzee (aka "joe")**
May 13, 2008

    I read an LA Times article about the passing of Robert Wilson (1st director of Fermilab). He was a sculptor, & desired an aesthetic looking building for Fermilab. Something to the effect of a cathedral, where physicists would try to unlock the secrets of the atom.

    “It [theoretical physics] is very religious”
    — xx, Caltech CS professor

    My take on HEP & cosmology is that of ill-conditioned problem: insufficient data.

    “Insufficient facts always invite danger.”
    — Spock, Space Seed, Stardate 3141.9, Episode

17. **Ethan Siegel**
May 14, 2008

    Peter,

    I’m sure you’ve seen this posting today:

    http://xxx.lanl.gov/pdf/0805.1911

    But I’m really curious as to your take on it; especially on sections 5 and 6. Does he get it right?

    Ethan

18. **Jonathan Vos Post**
May 14, 2008

    Besides his scientific achievements, Dr. Wilson was known for the environment he created at the Fermilab site, with hundreds of acres of restored prairie, a herd of bison, fishing holes, abstract sculpture and a central building modeled, in spirit at least, on the Beauvais Cathedral in France.”

Do We Need to Change the Definition of Science?

May 15, 2008
Categories: Multiverse Mania

Media hype about how the LHC is going to test string theory continues: see Will String Theory Be Proven and here:

> String theory has come under attack because some say it can never be tested; the strings are supposed to be smaller than any particle ever detected, after all. But Arkani-Hamed says the Large Hadron Collider could lead to the direct observation of strings, or at least indirect evidence of their existence.

A recent New York Times article ends with another Arkani-Hamed quote about what to expect at the LHC:

> He pointed out that because of the dice-throwing nature of quantum physics, there was some probability of almost anything happening. There is some minuscule probability, he said, "the Large Hadron Collider might make dragons that might eat us up."

Obviously I'm being unfair to put these two quotes together, but they both raise a basic question about the philosophy of science. When can we legitimately say that a theory is testable and makes a scientific prediction? The most straightforward examples of scientific predictions are cases where we have high confidence that a certain experimental result has to happen if a theory is right: such a theory satisfies Popper's falsifiability criterion. But many theoretical ideas are not so tightly constrained, and compatible with a range of possibilities. This range generally comes with some notion of probability: certain experimental results are more likely to come out of the given theory, others less likely. This may allow you to gain confidence in a theory even if it is not falsifiable, by seeing things that the theory says are more likely, not seeing the things it says are unlikely. The problem with the idea that the LHC is going to test string theory by seeing strings is that according to the standard framework of string theory, this is just very unlikely. Saying that an experiment is going to test your theory when it is extremely unlikely that it will provide any evidence for it or against it is highly misleading. You're always free to say "this experiment is unlikely to test my theory, but who knows, I may get incredibly lucky and something unexpected will come out of it that will vindicate me". But that's not really a "test" of your theory, that's wishful thinking.

There's a new article in New Scientist closely related to this by Robert Matthews entitled Do we need to change the definition of science?. It's about claims being made that multiverse studies show that we need to re-examine conventional ideas about what is science and what isn't. I'm quoted saying the sort of thing that you might expect:

> I never would have believed that serious scientists would consider making the kinds of pseudoscientific claims now being made…
>
> an outrageous way of refusing to admit failure…
>
> The basic problem with the multiverse is not only that it makes no falsifiable predictions, but that all proposals for extracting predictions from it involve massive amounts of wishful thinking.

Max Tegmark argues against a straw man:

> Some people say that the multiverse concept isn't falsifiable because it's unobservable – but that's a fallacy

noting that just because some implications of a theory aren't directly observable doesn't mean the theory is untestable. If a theory passes many convincing tests involving things we can observe, and the theoretical structure is tight enough, then we have good evidence about what is likely to be going on with phenomena we can't observe. This is certainly true: if the string theory landscape made lots of testable predictions so that we had good reason to believe in it, and the same structure implied a multiverse, that would be good reason to believe in the multiverse. The problem is that the landscape makes no predictions and we have no reason to believe in it. It's not a real testable scientific theory, rather an untestable endpoint of a failed theory. As such it implies nothing one way or another about the existence of a multiverse.

Matthews quotes various people arguing for a "Bayesian" view of science, that what is going on is that experimental observations probabilistically provide evidence for and against theories, with the falsifiability case of probability zero or one not usually occurring. This may be a good way of thinking about how science actually works. But by this criterion, string theory unification and the multiverse remain pseudo-scientific, as no one has been able to come up with proposed experimental tests that have a significant chance of providing such evidence for or against these theories.

   May 15, 2008

   "Matthews quotes various people arguing for a "Bayesian" view of science, that what is going on is that experimental observations probabilistically provide evidence for and against theories, with the falsifiability case of probability zero or one not usually occurring."

   The big problem with this is called the "Paradox of the Ravens" and is due to the philosopher Hempel. If my hypothesis is "All Ravens are Black", then whenever I see something that isn't black and isn't a raven, whatever it may be, whether a nugget of gold or a horse, that has counted as an "experiment" which "confirms" my hypothesis.

   People have been trying to change the definition of science throughout the 20th century.

2. **anon.**
   May 15, 2008

   "This is certainly true: if the string theory landscape made lots of testable predictions so that we had good reason to believe in it, and the same structure implied a multiverse, that would be good reason to believe in the multiverse." – PW

   Even a theory which makes tested predictions isn't necessarily truth, because there might be a another theory which makes all the same predictions plus more. E.g., Ptolemy's excessively complex and fiddled epicycle theory of the Earth-centred universe made many tested predictions about planetary positions, but belief in it led to the censorship of an even better theory of reality.

   Hence, I'd be suspicious of whether the multiverse is the best theory – even if it did have a long list of tested predictions – because there might be some undiscovered alternative theory which is even better. Popper's argument was that scientific theories can never be proved, only falsified. If theories can't be proved, you shouldn't *believe in them* except as useful calculational tools. Mixing beliefs with science quickly makes the fundamental revision of theories a complete heresy. Scientists shouldn't start begin believing that theories are religious creeds.

3. **Icecycle**

May 15, 2008

Not being a scientist I really don't see the need to change the definition of science, however; much of our current knowledge seems to be based on faith.
(I know a swear word; in the first paragraph.)
Why don't we have a little funding for the fanatics out there; you know who you are; and just step into the fringe on occasion.
If there is a multiverse (for instance) it is a black box and has to be investigated as a black box; we would need philosophy to even look at it.
But philosophers (generally) don't know physics (just look at Bertrand Russell's explanation of relativity; I felt really bad for him when I found out he was a mathematician.)

For myself; not being a scientist; I make myself believe a concept absolutely. Then, finding all the proof that fits I make myself believe the same concept is wrong and find all the proof that makes it fail.
Because; like everyone else; I tend to get too much of my personal beliefs into my world view.

As a computer programmer I can't get away with that nonsense.

4. **St. George**
May 16, 2008

Is the probability of getting a fire-breathing dragon out of the LHC more or less than that of directly observing a string?

5. **Peter Erwin**
May 16, 2008

The big problem with this is called the "Paradox of the Ravens" and is due to the philosopher Hempel. If my hypothesis is "All Ravens are Black", then whenever I see something that isn't black and isn't a raven, whatever it may be, whether a nugget of gold or a horse, that has counted as an "experiment" which "confirms" my hypothesis.

Why is this relevant? No real scientist, Bayesian or not, operates that way.

A reasonable Bayesian would argue that the probability of seeing a non-black nugget of gold is *independent of* the hypotheses "All ravens are black" and "Not all ravens are black" [or hypotheses like "No ravens are black", "Half of all ravens are black", etc.]. So actually seeing a non-black nugget of gold does not change the prior probabilities for any of the relevant hypotheses.

Someone taking a non-Bayesian approach (e.g., a naive Popperian, or someone who prefers a "frequentist" approach to probabilities and hypothesis testing) would operate in essentially the same way: scientific hypotheses about the color of ravens make no predictions about the color of gold nuggets, and so observations of nugget colors do not test the raven hypotheses.

6. **Peter Erwin**
May 16, 2008

anon. said:
Popper's argument was that scientific theories can never be proved, only falsified. If theories can't be proved, you shouldn't believe in them except as useful calculational tools. If theories can't be proved, you shouldn't believe in them except as useful calculational tools.

Ironically, that's not unlike what some Jesuit astronomers suggested to Galileo during his trial: go ahead and use the Copernican model if it makes good predictions, but don't claim that it actually describes reality in any fashion — it's just a useful calculational tool!

The point about scientists "believing" in theories is not that they accept them as religious dogma. It's that they're making positive statements about which theories seem to be *better* descriptions of reality, and about the relative amount of observations/experimental support for them.

The problem with Popper's argument is not that it's wrong per se, it's just that it's *incomplete*. It has no way of distinguishing between, say, the heliocentric model of the Solar System (which has successfully passed an enormous array of increasingly stringent tests) and some preliminary hypothesis about the spectrum of density fluctuations in the early universe (which has been tested by the WMAP data, but not by anything else yet). All Popper allows is a passing grade for both ("not yet falsified"). In practice, however, scientists *do* accord more "belief" to the first than they do to the second. That, I think, is what the Bayesian argument is about. (It's also, as Peter Woit notes, about how to accommodate tests that provide statistical limits, rather than idealized "confirm or deny" results.)

7. **Zathras**
May 16, 2008

Peter Erwin,

A reasonable Bayesian could also say that seeing the nugget of gold acts as "confirmation" of the raven hypothesis, but only by raising the probability of the proposition's truth an infinitesimal amount e.

Come to think of it, e might be the same order of magnitude as the possibility of confirming string theory.

8. **weichi**
May 16, 2008

"All Popper allows is a passing grade for both ("not yet falsified")."

It's been a while since I read popper, but I don't think this is correct. He certainly certainly acknowledges that theories can be submitted to more or less severe tests, and I thought that he states that the more severe the tests, the more we should trust the theory (or something along these lines). Am I misremembering this?

9. **Joseph Triscari**
May 17, 2008

Unfortunately I cannot read the whole article because I don't have a subscription to New Scientist.

I wonder if the relevant point about a move to a Bayesian philosophy is not the way evidence is aggregated but the fact that in a Bayesian philosophy the priors are admittedly subjective. In my understanding, this is the central point of a Bayesian. The opposing view – which I think is called Frequentist – requires all inputs to a model to be probabilities that can conceivably be measured.

A Bayesian approach is fine for reasoning under uncertainty because many times, priors *are* subjective and there's nothing to be done. On the other hand, openly subjective priors are a facet of the Bayesian philosophy that can be abused in practice by shifting inputs to fit data (and declaring that it's OK because, after all, they're subjective).

I am curious to know in what way a Bayesian philosophy of probability is being applied to justify ST.

10. **Gil Kalai**
May 17, 2008

Joseph, in The Bayesian approach, initial probabilities are subjective but with more and more evidence the emerging scientific conclusion will be the same regardless of the initial probabilities. In practice, the interpretation of new evidence which is required for updating your initial subjective probabilities, is not entirely objective. Still the Bayesian approach looks to me a more realistic description than the Popperian approach regarding how science is practiced, and both approaches have problems.

11. **Peter Erwin**
May 17, 2008

Joseph Triscari said:
I wonder if the relevant point about a move to a Bayesian philosophy is not the way evidence is aggregated but the fact that in a Bayesian philosophy the priors are admittedly subjective. In my understanding, this is the central point of a Bayesian. The opposing view – which I think is called Frequentist – requires all inputs to a model to be probabilities that can conceivably be measured.

My impression is that prior probabilities are, if anything, better viewed as the Achilles heel of the Bayesian approach: there's no clear, obvious way to decide on what the prior probabilities should be, and this irks a number of people. The usual response by Bayesians is to point out that the choice of the prior ceases to matter once enough relevant observations have been used to update the probabilities. This amounts to admitting that arbitrary or subjective priors are a *problem* (not an advantage), while arguing that in most practical cases it doesn't matter too much.

The real difference between the Bayesian and Frequentist approaches is in the interpretation of "probability" and whether it makes sense to say things like "The probability of rain tomorrow is 90%." See, for example, the posting and comments here.

(There are also practical differences, in that a Bayesian approach arguably provides a more general and direct way of constructing tests of hypotheses, without requiring the assumptions — e.g., a Gaussian distribution for errors — that underlie most traditional frequentist hypothesis tests.)

12. **Peter Woit**
May 17, 2008

Joseph,

The article was more about the multiverse than string theory. The discussion of the problems of falsification and the advantages of Bayesian ideas seemed to me to be a red herring. There just aren't any conventional scientific tests of string theory or multiverse ideas. So arguing about the philosophy of science is irrelevant, unless you are trying to abandon the conventional understanding of what science is. Doing this to avoid confronting the failure of these ideas seems to me to be a big mistake.

13. **Joseph Triscari**
May 17, 2008

I agree with you Peter that it's a mistake not to confront the failure of an unfalsifiable theory. I didn't mean to invite an exploration of the differences between Bayesian and Frequentist theories of probabililty.

The point I was trying to make (and I see I made it poorly) was that if one doesn't wish to confront the failure of a theory, one might try and legitimize the theory using an established philosophy that acknowledges and sometimes encourages subjectivity – such as a Bayesian philosophy of probability.

14. **davetweed**
May 18, 2008

For completeness, I'll point out that Peter Erwin's point about subjectivity being a philosophical problem primarily applies in those cases where one is obtaining more than enough observations to sharply determine the posterior distribution, so that the question "why did you use a personal prior if it doesn't actually matter" comes up. This is generally the case in hard science (although even then…). The advantage of Bayesian model evaluation (to some extent in science and more widely in technology) is strongest when you have relatively few relevant observations (eg, due to medical ethics, response time constraints, etc) so that the prior can make observations which which would be inconclusive under frequentist tests (which often hide a universally held prior in them) more discriminatory when they coincide with various parts of the prior distribution. The personal (what's called "subjective", although I dislike that term because AFAIK you can't have a subjective idea that's wrong, whereas personal ideas can be wrong) nature of the prior is arguably not a problem in this case as long as it is made explicit. It's always struck me as strange that Bayesianism is widely touted for dealing with uncertainty (which I always think of in the sense of randomly inaccurate sensors) rather than for dealing with small numbers of observations.

15. **Peter Shor**
May 18, 2008

Most scientists have never really paid much attention to the definition of science anyway, have they?

16. **Peter Woit**
May 19, 2008

Peter Shor,

I find it very strange to be involved with physicists in discussing what's science and what isn't. It always seemed to me that such discussions were for philosophers or for softer sciences (e.g., is economics a science…), with physics embodying the extreme of a hard science, with everybody on the same page as to what counts as a testable prediction.

Then string theory and the landscape came around….

17. **Peter Erwin**
May 20, 2008

I find it very strange to be involved with physicists in discussing what's science and what isn't. It always seemed to me that such discussions were for philosophers or for softer sciences…

Might one argue that previous debates about "interpretations" of quantum mechanics, what "collapse of the wavefunction" actually means or entails, etc., had at least some “philosophy of science” flavor? That is, physicists ended up disagreeing about whether investigating interpretations was scientifically useful, or whether “interpretation” was even a part of science, and some of this did involve philosophical issues about science.

(I don’t mean that this was the same kind or order of disagreement that may be happening around the landscape — no one, so far as I know, was suggesting that we didn’t need testable predictions or experimental results. Just that this isn’t the first time that physics has been involved in “philosophy of science” territory.)

18. **Peter Shor**
May 20, 2008

I have a sort of ambivalent view of the previous debates on the interpretation of quantum mechanics. On the one hand, as Feynman warned graduate students, most people who started thinking about the interpretation of quantum mechanics and stopped worrying about more mainstream physics never got anywhere, and eventually derailed their careers. On the other hand, thinking about the interpretation of quantum mechanics led David Deutsch to think about quantum computing and from their to the first quantum algorithms.

What, if any, lessons about string theory we should take from this I leave to other readers.

19. **Michael**
May 20, 2008

Peter,

just a little reminder: You are an insufferable fool who shamlessly promotes his anti-science agenda for personal benefit. Shame on you and go to hell!

20. **Chris W.**
May 20, 2008

Philosophical concerns have always been at least a subtext in physics. In fact, I would argue that physics really amounts to an effort to confront what were originally philosophical problems with detailed observation, in such a way that we can actually learn something, ie, discover that some of our preconceptions are wrong. If this sounds strange to most scientists, that’s because they have so little interest in the history of science, and tune much of it out.

The great physicists of the 20th century were all interested in philosophical issues. Efforts to confront current problems in fundamental physics are hamstrung by naive empiricism just as much as by unhinged elaboration of formalism and metaphysics masquerading as physics.

Even Feynman was interested in the philosophical preconceptions of physics and its practice, notwithstanding the fact that he considered overt preoccupation with philosophy to be an early sign of senility.

21. **Peter Woit**
May 20, 2008

My point about physicists and the philosophy of science was restricted to the specific question of the so-called “demarcation problem”. There have always been interesting and real questions in the philosophy of physics, but, until recently the question of whether particle theorists were doing science or pseudo-science was not one that ever came up. You just didn’t see leading figures in the field publicly making bogus claims about what it means to test a scientific theory.

22. **Clark**
May 20, 2008

I think there’s two kinds of philosophy of science – prescriptive and descriptive. The prescriptive folks are effectively telling scientists how they *ought* do science. (I think Popper partially falls into that category) Then there are the descriptive folks who suggest we merely look at what the scientists are doing and excluding to understand what science is. Of course in practice most do a little of both.

The problem is that Popper was hardly the last word in philosophy of science. A lot of people have grave difficulties with his views. So it’s odd that so many scientists – especially physicists – seem to take Popper as if he were telling it like it was. There’s been quite a few decades of thought on things as well as arguments and counterarguments.

Personally I find the demarcation problem largely irrelevant. I don’t think there’s anyway to tell what is or isn’t a science beyond looking at what the community of scientists exclude or include. And that’s good enough for me.

The string issue is interesting since it’s one of the rare cases where agreement breaks down. Given that turning to the philosophers can be helpful (although I don’t think they’ll ultimately be able to resolve the problem either). I suspect what will happen is that research will continue and that if string theory doesn’t make more practical progress scientists will stop working on it. A few decades after it’s ceased to be a concern to any but a few scientists *may* start to think of it as a pseudoscience. But who knows. They may not. It may end up being viewed as science but an example of a dead end and something one shouldn’t emulate.

What I do think is true though is that scientists – especially physicists – would benefit from doing a bit more reading on philosophy. Especially philosophical histories of various ideas in physics. So, for instance, read a little Sklar, Fine, and so forth. Get a Philosophy of Science reader from Amazon. (There are several good ones)

Regardless of what you think of his physics, I think Lee Smolin made a very well thought out appeal a couple of years ago for physicists to engage philosophy more. Normally it doesn’t matter. But I think especially in theoretical physics it can be quite helpful. Despite what Feynman said about physicists and birds.

23. **Arun**
May 21, 2008

What is scientific and not-scientific is not a eternal classification. Democritus, Kannada’s atomic theory, while containing a correct insight and pertaining to reality only became scientific when the technological means to address the theory were developed.

I think the history of science will show that many ideas were kept in limbo for a time because their development was not feasible at the time the idea was generated. (I hesitate to call such ideas theories.) One can easily imagine a plausible alternate history, where General Relativity was developed much earlier than any capability to test it.

24. **Zathras**
May 21, 2008

Those are good points Arun.

In fact, under the lax standards of string theorists, one would consider the mathematical theories of Riemann, Lobachevsky, etc as having “developed [General Relativity] much earlier than any capability to test it."

25. **Christine**
May 21, 2008

PhD means Doctor of Philosophy; we should not forget our roots. The aim of physics is to advance its frontier into metaphysics, trying to make the latter a smaller and smaller territory. For instance, cosmology was in the metaphysics territory before the 19th century, but gradually became a physical science in the 20th. History shows that the advancement of physics proceeds over two pillars: the scientific method *and* philosophy. When doing "standard science" the physicist might disregard the latter and focus on the former, but the *advancement* of scientific knowledge needs both. Philosophy about nature and observations of phenomena trigger the first logical questionings; science is often developed from these prerequisites, it does not develop from itself alone, since it is a process to gain knowledge, not an end per se, otherwise it makes no sense at all.

The relative emphasis on the scientific method and on the philosophical inputs, however, varies from time to time, from person to person, from objects of investigation from objects of investigation. One thing, however, that must be invariant from this relative emphasis is the meaning of science, which must have a clear definition and agreeded among its practitioners. If this meaning is what is being currently debated or revised, then one should ask why, and this is what puzzles me.

26. **Peter Woit**
May 21, 2008

Arun and Zathras,

The issue of when a theory is practically testable is just another red herring in the string theory debate. String theory unification not only makes no predictions that are testable using current technology, it makes no predictions testable at any energy scale using any conceivable technology. That's the problem, not that tests are not currently feasible.

27. **Arun**
May 22, 2008

Peter,
I have no disagreement with you on string unification/theories of everything.

To the extent that we consider as science the elaboration of mathematical formalisms that include models that are scientific (e.g., study of QFTs other than the Standard Model) string theory other than unification has not yet departed from science.

Recognition of the string unification failure also leads to the next puzzle – from which direction is progress likely to come?

28. **Peter Orland**
May 22, 2008

"Recognition of the string unification failure also leads to the next puzzle – from which direction is progress likely to come?"

Arun,

Though it all depends on what you mean by progress, I think the best hope is experiment.

29. **Matt**
May 22, 2008

This is a subject near to my heart, as my own website is named after a quote of Maxwell which some scientists could stand to re-read.

In every branch of knowledge the progress is proportional to the amount of facts on which to build, and therefore to the facility of obtaining data.

If string theory or the multiverse or anything else can't build on facts, it ain't science.

May 15, 2008
Categories: Uncategorized

The speakers for Strings 2008 have been announced. One anomaly is that someone from the LQG camp has finally been invited, Carlo Rovelli. Another anomaly is that Witten won't be speaking.

Remember last November's "unmistakable imprint of another universe" which vindicated string theory? False alarm.

There's a new X-files movie coming out this summer, The X-Files: I Want to Believe, with a plot that revolves around string theory and features Amanda Peet (no, not the string theorist).

Outside magazine has a profile this month of Garrett Lisi, and quotes from various physicists about last year's media storm. I'm pretty much with Frank Wilczek on this, who says:

> To my perception, Lisi hasn't advanced the story. That said, I admire people who think for themselves and dare to take on reality directly rather than writing footnotes to fashionable literature. So I hope he keeps trying and inspires others.

I also hear that the New Yorker will have an article about this, to appear sometime during the next couple weeks.

Bert Schroer has a new version of his paper about String theory and the crisis in particle physics. It contains both sociological observations on the string theory phenomenon, as well as more technical arguments about how to think about a quantum theory of strings. Schroer was involved in endless battles on this blog a couple years ago over an earlier version of this paper. People who want to argue this again are encouraged to first read through the old discussion, and then see if there's something new and interesting to contribute, rather than a rehash of the previous arguments.

Comments

1. **Sara**
   May 15, 2008

   I'm very very happy they have choosen Carlo Rovelli as speaker, but I asked myself why they don't have called Lee Smolin, for example, or somebody else.

2. **Coin**
   May 15, 2008

   Is it known what Rovelli might be talking about?

3. **Sulfur Surfer**
   May 15, 2008

   Schroer's new paper claims that there are technical flaws in the understanding of string theory. However, the entire basis of his argument is incorrect. He begins by asserting that "string theory has no vacuum polarization." He appears to draw this conclusion from the ultraviolet finiteness of the theory, and its S-matrix character, but this is a non sequitur and false besides. For example, the most notable physical consequence of vacuum polarization is the running of couplings; such running is observable in the S-matrix (and this is actually done in accelerator observations). The couplings do indeed run below the string scale in string theory, and exactly as they would in the corresponding effective low energy QFT.

4. **Jean-Paul**
   May 15, 2008

   Surfer — if you are so sure about running couplings, why don't you compute just one on-shell S-matrix element that has "observable" running. You will see that all on-shell S-matrix elements are infrared divergent in D=4, already at the one loop level.

5. **Sulfur Surfer**
   May 15, 2008

   Jean-Paul — Sure, but the meaning of these divergences is taught in every QFT course, as is the cure – what particle physicists actually observe, and calculate, are IR finite cross sections with the detector resolution taken into account. You can substitute that long phrase for `S matrix', but I don't think that this was Schroer's point.

6. **Trent**
   May 16, 2008

   Peter,

   "….. see if there's something new and interesting to contribute, rather than a rehash of the previous arguments."

   Do you ever come up with new arguments? It seems to me you constantly are rehashing your old arguments. Or did I miss something? Do you actually have new arguments?

   Best,
   Trent

7. **Professor R**
   May 16, 2008

   Hi Peter, thanks for the reference to the Garrett Lisi article in Outside Magazine, it's a good article once you get past the initial bombast. Given his lifestyle, I imagine Garret probably enjoyed this article more than any of the others!

   I didn't know what to think about the Lisi story when it broke, but I'm glad this story is resurfacing, it's a bit of light relief in our dull lives. ..

   While the Wilczek quote probably summs it up for most of us, there are a few points I'd like to make

1. Every time journos draw a comparison with Einstein, Lisi patiently points out that the tenure issue is the only similarity – so it's not his fault they keep making this comparison

2. I don't see the problem with the surfer angle – surely it makes a welcome change from the usual media view of scientists

3. I'm delighted to see group theory get some attention – few outside the particle physics field have the slightest idea of the importance of group theory in this field…and even if the whole E8xE8 thing turns out to be a fairly trivial classification, so what? It's very nice to be reminded of the eigthfold way, no harm at all

I think we physicists are inclined to react strongly against media attention, especially if we feel there are more deserving cases. It's a pity, because such stories probably do far more for the public perception of physics than any number of well-intentioned school visits! Cormac

8. **D R Lunsford**
May 16, 2008

Schroer makes a chilling point in his paper, one that I've often worried about – apart from derailing progress in science, the current environment is utterly corrosive of the collective understanding of known results – so the old theorists are something like stone masons without apprentices and with no more cathedrals to build, and as they pass on, they take their hard won knowledge and experience with them. I know in my own area, completely separate from QFT, I find a shocking ignorance of basic things among my juniors. Of course the knowledge is still there, on the books that no one reads, in the history that is ignored. It does no good if someone does not own it. This to me is a tragedy beyond expression.

-drl

9. **David Nataf**
May 16, 2008

Am I the only one who found the profile of Garrett Lisi offensive? The article refers to him as a "hobo" and a "surfer bum".

10. **MIchael**
May 16, 2008

Trent wrote:

"Peter, … Do you ever come up with new arguments? It seems to me you constantly are rehashing your old arguments. Or did I miss something?"

The argument "String theory does not make predictions" is so strong that it does not need new ones. String theorists should take it as a challenge. The fact that they don't is telling.

11. **Mitch Miller**
May 16, 2008

David,

Do you find it offensive to Lisi or Bums?

(Not a dig at Lisi, as I think he used those terms to refer to himself so I don't see how it could be offensive to the former)

12. **David Nataf**
May 16, 2008

I think the term "hobo" is very derogatory of the homeless and should not appear in a respectable publication, with the exception of paraphrasing. Language is very important.

13. **Professor R**
May 17, 2008

P.S. Thanks for the listing on the website Peter, I hadn't noticed it!

Re Schroer paper, I'm still wading through it. Broadly speaking, I find myself in agreement with most of his points. However, it seems to me that one big point is conspicuous in its absence (so far). ..

Nobody asked nature to get more complicated mathematically, the more we probe the world of the sub-atomic, and attempt to describe it. That just seems to be the way the cookie crumbles, so far. Of course, this may well be an indication that the entire ST program is simply barking up the wrong tree… but isn't there another possibility?

Namely, that we simply haven't developed the appropriate mathematical framework yet..perhaps the breakthrough is just around the corner..

After all, E. was lucky Riemann had already deveopled non-Euclidean geometry, when general relativity came along. If Riemann hadn't, and GR involved harder maths, it's possible physicists might have missed the whole GR thing for quite a while, instead starting with something vague and ambiguous before we narrowing it down…

or is that simply a naive view of the experimentalist?
Regards, Cormac

14. **D R Lunsford**
May 17, 2008

Prof R,

Your point about the mathematical description being more complex is, I think, a little off. In fact most theories become more coherent as they get closer to nature – and this shows up in the mathematical expression. A sure way to know that something is probably on the wrong track is that is lacks tightness and economy of expression. Compare, for instance, the Lorentz deformable electron with Maxwell-Lorentz relativistic dynamics.

-drl

15. **Walt**
May 17, 2008

Trent, I suggest you scroll up to the masthead, and look where you're commenting. This is Peter's blog. If you find his posts repetitive, I suggest you look for something more appealing to you. There are many recipe blogs, for example.

16. **Jason**
May 18, 2008

Hobo is not an offensive term. Hobos call themselves hobos. Hobos are often homeless, but hobo is not synonymous with homeless person. A hobo is simply one who adopts a wandering way of life, traveling by hitching rides on freight trains. There is a hobo convention every August in Britt, Iowa; and a hobo king and queen are cononated there.

17. **AnonLQG**
May 18, 2008

Sara, because Carlo Rovelli rather then Lee Smolin is at the heart of the current developments in Spinfoams/Lattice Gravity/LQG. Smolins latest works are viewed with tremendous skepticism in the community and the general feeling is that he has vastly oversold them. Many are quite unhappy with the fact that he is seen as representing the community.

18. **Professor R**
May 18, 2008

DR, of course I agree with your point " most theories become more coherent as they get closer to nature – and this shows up in the mathematical expression".

But my point is, could it not be that ST simply hasn't reached this stage yet? Many theories are far too general, and non-specific, in the early stages of development. Perhaps, if the math is difficult enough, a theory could get stuck in this phase for decades before the key breakthroughs occur (if ever)? Just a thought…Cormac

19. **Sara**
May 18, 2008

AnonLQG,
can you indicate me any papers in which Carlo Rovelli discuss this subject?
Thank you.

20. **AnonLQG**
May 18, 2008

Which subject?

21. **Arun**
May 18, 2008

One anomaly is that someone from the LQG camp has finally been invited, Carlo Rovelli.

Don't worry, string anomaly cancellation will be found in dimensions that do not admit Rovelli.

22. **AnonLQG**
May 19, 2008

is that in and only in? Because as Rovelli is an empirical fact that would mean that anomaly cancellation can not occur for physical systems….

23. **Clark**
May 22, 2008

For a persuasive account of the seminal opposition between Planck and Mach on the core of scientific understanding :

[SEP_on_Ernst_Mach]

One side of the dialectic, in the span of a few generations detached from its founder's restrained values and amplified to an extreme, inevitably spawns nonsense such as theories of everything.

24. **Yok**
May 26, 2008

> can you indicate me any papers in which Carlo Rovelli discuss this subject?

"Flipped spinfoam vertex and loop gravity." Nucl.Phys.B798:251-290,2008. arXiv:0708.1236

"LQG vertex with finite Immirzi parameter." Nucl.Phys.B799:136-149,2008. arXiv:0711.0146

25. **Sara**
May 27, 2008

Thank you very much Yok, I'm going to read them with great interest.

26. **Ervin Goldfain**
May 27, 2008

A recent paper by Hashimoto et al. published in Phys Rev D 77, 086001 (2008) claims (what appears to be) the first experimental evidence for brane theory. Here is the abstract:

"Using holographic QCD based on D4-branes and 8-anti-D8-branes, we have computed couplings of glueballs to light mesons. We describe glueball decay by explicitly calculating its decay widths and branching ratios. Interestingly, while glueballs remain less well understood both theoretically and experimentally, our results are found to be consistent with the experimental data for the scalar glueball candidate f0□1500□. More generally, holographic QCD predicts that decay of any glueball to 4□0 i is suppressed, and that mixing of the lightest glueball with q □ q mesons is small.
DOI: 10.1103/PhysRevD.77.086001 PACS numbers: 11.25.Tq, 12.39.Mk"

I invite comments on the validity of these claims.

27. **Peter Woit**
May 27, 2008

Ervin,

This has nothing at all to do with the debate over the testability of string theory, which is about whether one can test the idea of string theory as a fundamental theory.

We have very good evidence for what the theory governing strongly interacting particles is: QCD. Many people are working on trying to find string theories that would give approximate calculational methods in QCD valid at strong coupling, and this is one such attempt. If the "predictions" come out right, all that is being tested is the validity of the approximation method.

Bryce DeWitt on Quantum Gravity and String Theory

May 21, 2008
Categories: Uncategorized

Last night a preprint appeared on the arXiv from beyond the grave, an undated manuscript entitled Quantum Gravity, Yesterday and Today, found without any indication of its purpose in the files of Bryce DeWitt, who passed away in 2004.

DeWitt devoted much of his career to the question of how to quantize the gravitational field, beginning back in 1948 when he was a student of Julian Schwinger. He has some interesting comments about the dramatic changes over the years in popularity of research work on GR and quantum gravity:

> Most of you can have no idea how hostile the physics community was, in those days, to persons who studied general relativity. It was worse than the hostility emanating from some quarters today toward the string-theory community. In the mid fifties Sam Goudsmidt, then Editor-in-Chief of the Physical Review, let it be known that an editorial would soon appear saying that the Physical Review and Physical Review Letters would no longer accept "papers on gravitation or other fundamental theory." That this editorial did not appear was due to the behind-the-scenes efforts of John Wheeler.

DeWitt gives some history of his important work on the quantization of gauge theories, which culminated in working out a functional integral method to handle to all orders the ghost terms that Feynman had shown to be necessary. He describes a 1955 offer from the Glenn L. Martin Aircraft Company to fund his research in hopes that it would lead to an antigravity device, one that he didn't accept. Instead, the Air Force supported his research during the period he was unraveling the story of ghosts, support that ended in 1966 when they finally realized that gravity research was not going to lead to magical results. With the termination of his grant, he could no longer pay page charges to the Physical Review, delaying the publication of one of his papers by a year.

He also has some interesting comments about the DeWitt-Wheeler equation:

> … intensive work was carried out in those years on canonical quantum gravity, culminating in an equation that bears my name along with that of John Wheeler who was the real driving force. Research on the consequences of this equation continues to this day, stimulated by work of Abhay Ashtekar, and some of it is quite elegant. But apart from some apparently important results on so-called "spin foams" I tend to regard the work as misplaced. Although WKB approximations to solutions of the equation may legitimately be used for such purposes as calculating quantum fluctuations in the early universe, and although the equation forces physicists to think about a wave function for the whole universe and to confront Everett's manyworld view of quantum mechanics, the equation, at least in its original form, cannot serve as the definition of quantum gravity. Aside from the fact that it violates the very spirit of general relativity by singling out spacelike hypersurfaces for special treatment, it can be shown not to be derivable, except approximately, from a functional integral. For me the functional integral must be the starting point.

He ends the paper with positive comments on string theory:

> In viewing string theory one is struck by how completely the tables have been turned in fifty years. Gravity was once viewed as a kind of innocuous background, certainly irrelevant to quantum field theory. Today gravity plays a central role. Its existence justifies string theory! There is a saying in English: "You can't make a silk purse out of a sow's ear." In the early seventies string theory was a sow's ear. Nobody took it seriously as a fundamental theory. Then it was discovered that strings carry massless spin-two modes. So, in the early eighties, the picture was turned upside down. String theory suddenly needed gravity, as well as a host of other things that may or may not be there. Seen from this point of view string theory is a silk purse. I shall end my talk by mentioning just two things that, from a nonspecialist's point of view, make it look rather pretty.

The two things he has in mind are the ability of a single string diagram to sum up a lot of Feynman diagrams, and the use of orbifolds to make possible topology-changing transitions.

Comments

1. **Shantanu**
   May 21, 2008

   Hi,
   Peter,
   This is interesting. Were you planning to attend the emergent gravity workshop at MIT in August?
   also did not know that Olaf Dreyer(who primarily works in LQG) is now at MIT.

2. **Brandon DiNunno**
   May 21, 2008

   If you found this particular article to be interesting, you should see all of the amazing things in Bryce's documents. Hopefully Cecile and I will be able to get a few more out to the public very soon.

3. **Marcus**
   May 21, 2008

   on internal evidence I would date the manuscript roughly around 1995. it refers to something "forty years ago" and cites a 1955 publication. Can someone more knowledgeable say whether circa 1995 makes sense?

4. **Professor R**
   May 21, 2008

   "Most of you can have no idea how hostile the physics community was, in those days, to persons who studied general relativity."

   Peter: coming from such a reputable source, that's an astonishing statement. It makes me wonder whether it really is true that the American schools are more suceptible to trends that their European counterparts…

   For example, I do know that at the Dublin IAS in the fifties and sixties, all the quantum hotshots started their careers with serious research in GR as a matter of course (not least due to the presence of Synge). For example Dad's first book was on GR, not QFT (see General Relativity; Papers in Honour of JL Synge, ed O'Raifeartaigh OUP 1972).

   Actually, if you don't know this collection, you might find it a treat – it has papers by Lanczos, Sciama, Penrose, Chandrasekhar and Israel, among others!

5. **Robert**
May 21, 2008

Thank you for the link to this first-hand view, by one of the founders, on the history of quantum gravity.

6. **Peter Woit**
May 21, 2008

Brandon,

Thanks, will look forward to more. Maybe you can set up a web-site…

Shantanu,

Thanks for the info, but my interest in quantum gravity is limited enough that I wouldn't travel to such a conference.

Cormac,

At least in the US, I think GR was considered somewhat of a backwater, with the leading institutions and physicists pretty focussed on the particle physics that was coming out of dramatic amounts of accelerator data. Much of the fundamental work on gauge theory ended up being done in Europe and the Soviet Union, with DeWitt one of the few doing this in the US. As he notes, it's funny that the US during the late 80s and 90s then swung to the other extreme and became completely focussed on (one idea about) quantum gravity.

7. **Dr. E**
May 22, 2008

I recall Wheeler characterizing the heavy focus on particle physics as "ino-itis."

8. **Indrajeet**
May 22, 2008

Hi Peter,
This is just to draw to your notice that Willis Lamb has passed away on 21st. More here:
http://edition.cnn.com/2008/TECH/science/05/20/obit.lamb.ap/index.html

9. **RZ**
May 22, 2008

"Given the fact that the vertex function in diagram 1 contains over 175 terms and that the vertex functions in the remaining diagrams each contain 11 terms, leading to over 500 terms in all[…]"
I suspect that there is a typo there, and there actually were 110 terms.

10. **wb**
May 22, 2008

"Most of you can have no idea how hostile the physics community was, in those days, to persons who studied general relativity."

I can certainly confirm that in the '60's Chandrasekhar warned prospective students. "GR is outside the mainstream of physics. That is okay for people at my stage of a career. But as a young person you need to consider whether you want to work outside the mainstream."

11. **Shantanu**
May 22, 2008

Peter and wb, I thought that 60s and 70s were the golden age of black hole physics. I did not know that GR was outside the mainstream.
Shantanu

Does Time Run Backward in Other Universes?

May 22, 2008
Categories: Multiverse Mania

Scientific American in recent years seems to be quite fond of parallel universes, with major articles promoting the multiverse here, here and here (commentary on this blog here and here). Their latest issue continues in this vein with an article by Sean Carroll entitled Does Time Run Backward in Other Universes?, which advertises his 2004 work with Jennifer Chen claiming that the multiverse explains the arrow of time. For new blog entries about this, see here for something from Sean, here for a Lubos rant.

As with all claims about the multiverse, the problem is whether they are even in principle scientifically testable or not. If they're not, they're not science and promoting them to the public is a bad idea. The only thing I can find in the Scientific American article that addresses the testability issue at all is the following:

> As of right now, the jury is out on our model. Cosmologists have contemplated the idea of baby universes for many years, but we do not understand the birthing process. If quantum fluctuations could create new universes, they could also create many other things—for example, an entire galaxy. For a scenario like ours to explain the universe we see, it has to predict that most galaxies arise in the aftermath of big bang–like events and not as lonely fluctuations in an otherwise empty universe. If not, our universe would seem highly unnatural.

This doesn't seem to have anything to do specifically with the Carroll/Chen claims about the arrow of time, but rather is just a restatement of one of the desired properties of multiverse models, that they don't lead to "Boltzmann Brains".

Comments

1. **Ethan Siegel**
   May 22, 2008

   Peter,

   Surely this is a question that we don't take seriously anymore. It isn't that the laws of physics aren't time-reversal invariant, it's that quantum mechanics and "probabilities" have a preferred arrow.

   If I take a free neutron and it decays into a proton, electron, and antineutrino, well, sure, if I took the proton, electron, and antineutrino and fired them at one another with the same momenta the neutron emitted them at, they could re-form into a neutron. But if I run time forwards, the neutron will decay again; if I run time backwards, the neutron will never decay.

   Or, in simpler terms, I can't un-fry an egg. With a view of this, why is it even interesting to think about the arrow of time?

   Ethan

2. **Peter Woit**
   May 22, 2008

   Ethan,

   If you want to discuss this kind of question about the arrow of time, best to do it over at Sean's blog. The topic here is what if anything this has to do with the multiverse.

3. **Kris Krogh**
   May 22, 2008

   The time issue has also been a topic at Backreaction, with a poll taken: here

4. **DB**
   May 23, 2008

   There is a long tradition behind the cosmological arrow of time, going back to Boltzmann, and the question which Sean and his colleague attempt to address directly, namely, why did the universe start from such a low-entropy state really does go to the heart of the issue.

   The modern history of this subject dates from the Cornell 1963 conference (described in T. Gold The Nature of Time, 1967). This meeting is remembered for the presence of a Mr.X who, according to Hawking "felt the proceedings were so worthless that he didn't want his name associated with them. It was an open secret that Mr.X was Richard Feynman" (cf. S.Hawking in "Physical Origins of Time Asymmetry, eds J.J.Halliwell, J.Perez-Mercader, W.H. Zurek" (1993), p.346). In my mischievous way I bring it up because Sean is fond of reminding us that he sits at Dick Feynman's desk at Caltech:) This latter reference documents the second major conference on the subject in Mazagon, Spain in 1991. It's an interesting read, with contributions from Wheeler, Gell-Mann and Hartle, Hawking, Zureck, DeWitt and Griffiths (of consistent histories fame) and others, along with a record of post-talk debates. But, as before, it's very philosophical and I couldn't extract any evidence that anyone was in the business of making scientific predictions. Instead, they appeared to spend a fair of time arguing over semantics, e.g. decoherence, consistent histories, what is "reality" etc..

   Sean's paper is very much in the tradition and style of such contributions, but I liked it because unlike many others it really tries to home in on the core issue – why the initial low entropy.

   Ultimately however, most of this quantum cosmological palaver relies on Everett's many-worlds interpretation of quantum mechanics and the multiverse which flows from that.

   But as we know, there is no credible experimental mechanism to tell us whether the Copenhagen interpretation should be favoured over the Many-Worlds one (or any of the other stabs at this topic). David Deutsch, who filled in the gaps in Everett's original arguments claims there is (Int. J. Theor. Phys. 1985), but other dispute this.

   All I ask is, show me a reasonable experiment capable of telling us which interpretation (if any) is favoured by nature. Until then, it's just philosophy with a high-tech veneer.

5. **Peter Woit**
   May 23, 2008

DB,

My problem is not with the discussion of the entropy problem of early cosmology, but with the idea of writing articles for a major US popular science magazine promoting the multiverse and Boltzmann brain argumentation. This gives people the idea that this kind of empty speculation is what science is, impressing those who can't tell the difference between science and science fiction, and turning off those who can.

6. **Professor R**
May 23, 2008

I'm reading through Sean's article on my lunchour. It's a very good artilce, highly informative. But the context worries me too. I feel that most science magazines make very little distinction btween theories that are grounded in experiment, and theories which are promising.

It must be very confusing for the reader – in fact, I know it is. Every time I refer to say, GR, in a public lecture, it's clear most have no idea of the supporting evidence. It all gets lumped in with 'all those other theories', from string theory to the multiverse.

I sometimes wonder if magazines should have a special section marked 'speculative' – articles on topics that are a long way from experimental verification….Cormac

7. **DB**
May 23, 2008

I completely agree, Peter. My comments were directed at his paper with Chen.

8. **D R Lunsford**
May 23, 2008

I just had an example of this last night. I ran into a friend at a tavern, and he excitedly told me how he learned from "Discover Magazine" that a new accelerator was going to test string theory. He's a smart person but has no training in math or science. Who could blame him for believing what he reads? The editors of these publications do not care what the content is, as long as it sells. Even "Sky and Telescope" is guilty of hyping pseudo-science to generate sales.

-drl

9. **Peter Woit**
May 23, 2008

drl,

I don't think this is the fault of the editors of these magazines, they are just printing what prominent string theorists are saying. Quite a few of these are out there promoting the idea that "the LHC will test string theory", with the great majority of physicists who know better keeping quiet.

I suppose after all one should perhaps encourage this nonsense. If you could get everyone to believe that the "LHC will test string theory", and as expected no evidence for string theory shows up there, maybe everyone would then accept that string theory had failed and move on.

May 23, 2008

I have co-authored and published a couple of papers, in the Physics track of international conferences, on the Arrow of Time which deal with the putative Multiverse, including this one, which grapples with the specfic paper of Carroll and Chen:

Title: Comparative Quantum Cosmology: Causality, Singularity, and Boundary Conditions
Authors: Philip V. Fellman, Jonathan Vos Post, Christine M. Carmichael, Andrew Carmichael Post
Comments: 17 pages, 2 figures. 7th International Conference on Complex Systems
Subjects: General Relativity and Quantum Cosmology (gr-qc)

(Submitted on 26 Oct 2007)

Abstract: In this review article we compare the recent work of Peter Lynds, "On a finite universe with no beginning or end", with that of Stephen Hawking, primarily "Quantum Cosmology, M-Theory, and the Anthropic Principle", and two foundational works by Sean M. Carroll and Jennifer Chen, "Does Inflation Provide Natural Conditions for the Universe" and "Spontaneous Inflation and the Origin of the Arrow of Time", in order to evaluate their comparative treatments of the nature and role of causality, time ordering, thermodynamic reversibility, singularities and boundary conditions in the formation of the early universe. We briefly reference Smolin and Kauffman's recent arguments with respect to possible processes of "evolutionary selection" in early universe formation as an alternative explanation to key elements of Hawking's earlier "M-Theory", and its attendant anthropic principle. We also briefly excerpt a short section of Smolin's recent work on topology in quantum loop gravity, simply as an illustrative example of the type of complex quantum topological transformation which he offers as a theoretical alternative to string theory in quantum cosmology.

Peter, re
"I don't think this is the fault of the editors of these magazines, they are just printing what prominent string theorists are saying"

I think that's we disagree. Granted, one can't expect science journos and their editors to have a good knowledge of every part of science. But they are surely aware that each branch tends to overemphasise its own importance, and overlook its flaws.

In other words, they shouldn't be just printing what prominent string theorists are saying. Surely it's the job of a good editor to play devil's advocate to some degree, and bring the article back down to earth. To me, it seems that this professional skepticism has gone missing in today's science journalism…Cormac

12. **Kris Krogh**
May 23, 2008

Scientific American used to have the brilliant, independent-minded physicist Philip Morrison, who helped keep things grounded in reality. Unfortunately, he passed away several years ago.

13. **Thomas Larsson**
May 24, 2008

I suppose after all one should perhaps encourage this nonsense. If you could get everyone to believe that the "LHC will test string theory", and as expected no evidence for string theory shows up there, maybe everyone would then accept that string theory had failed and move on.

Larsson's theorem uses string theory to make a falsifiable prediction about the LHC. I am particularly proud that I already in 2007 could correctly predict that poor Lubos would lose his experimental-susy-by-2006 bet.

Of course, if the LHC does find sparticles I will be proven wrong. It is in the nature of falsifiable predictions that they are, well, falsifiable.

14. **mike harney**
May 24, 2008

Does anybody know if we are spending government money on multiverse theories? If so, I would like to put in a grant of my own for some untested, highly unrealistic notions.

15. **Haelfix**
May 24, 2008

So I gather you don't like the idea of eternal inflation either. A lot of people don't, but you must admit its a logical possibility (if you have inflation at one place, what stops you from having inflation somewhere else).

It *is* testable to a certain degree, though we need to have better resolution of gaussian profiles and presumably gravity wave detectors to really distinguish between the class of models

16. **Haelfix**
May 24, 2008

Replace eternal with chaotic for the post to make sense.

17. **Peter Woit**
May 24, 2008

Mike Harney,

To the extent government grant money is being spent on multiverse models, I think the amounts are quite small. Actually, I'm quite curious how multiverse grant proposals are doing before NSF and DOE panels. Searching on "multiverse" in the NSF database of funded proposals turns up nothing. Getting popular science magazines to promote ones multiverse research is one thing, getting other physicists to give it the kind of uniformly high marks needed to get a grant funded is something different.

Haelfix,

My comments were about Sean's multiverse/arrow of time proposal, which as far as I can tell is completely empty of any predictive power or any sort of testability. Different inflationary models have different degrees to which they make distinctive predictions, but at least in those cases there is something to discuss.

18. **Smedley**
May 25, 2008

Point of interest: you ought probably no longer link to anything on Lubos Motl's blog, as he has set it up so that any visitors with your blog as their referred are redirected to this (rather unfortunate and vitriolic) page: http://lubos.motl.googlepages.com/crackpot-not-even-wrong.html

Stay classy, Motl.

19. **Arun**

'tis why physicists find second careers on Wall Street – they excel in speculation.

News From CERN and Fermilab

May 23, 2008
Categories: Experimental HEP News

Things have been going quite well recently at the LHC, with cooldown beginning now for the last two sectors of the ring, three sectors cool, and three cooling. The latest cooldown schedule is here, a report yesterday on progress here. Sometime in July the beam commissioning process should begin, with the current plan to inject first particles in late July. About 2 months should be needed to get to first collisions at 10 TeV and the possibility of starting to take some data. The LHC has to have a winter shutdown so that the residents of Geneva don't freeze to death, and that will start in late November. Estimates are that the fall 10 TeV run will produce total luminosity of "tens of pb^{-1}". Tommaso Dorigo predicts 40 pb^{-1}, see more here. Also, don't miss his series of recent posts from PPC 2008 giving the best blogging from a conference I've ever seen… The plan for 2009 is to run at 14 TeV, with perhaps 2.5 fb^{-1}.

The situation at Fermilab is extremely unclear. The final plan for layoffs there has 140 people losing their jobs, presumably starting next week. This week, Congress is facing down the president, putting together bills to fund the war in Iraq that also contain large amounts of new domestic spending, something Bush has promised to veto. The Senate version of this bill contains $45 million for DOE HEP research, which presumably would be enough to stop the Fermilab layoffs. It passed yesterday with a veto-proof majority of 75-22. The House bill has no such provisions, and now the two bills need to be reconciled, and either passed over Bush's veto or somehow made acceptable to him. More about this here. Remember that is we're already two-thirds of the way through FY2008, with US HEP labs unsure (by a huge amount) of what their budget for the year will end up being. What a way to run a government…

Director Oddone has scheduled two all-hands meetings today, one for half the lab's divisions at 11:30, another for the other half at 1pm.

Update: The University of Chicago today announced an anonymous $5 million donation from a family that will go towards funding some of the programs at Fermilab that have suffered from this year's budget cuts. This will allow Fermilab to stop the forced furlough program it has been operating under at the end of this month. The prospect of layoffs at the lab continues.

Comments

   May 23, 2008

   This is a very short review of '*Même pas fausse ! La physique renvoyée… dans ses cordes*', but I thought you might want to read it.

2. **Peter Woit**
   May 23, 2008

   theoreticalminimum,

   Thanks, it seems to be hard to get a link to that review but I did find it. It's a fair and sensible review of the book.

3. **JTankers**
   May 24, 2008

   Congress authorized $100 million by a veto proof majority. The jobs are safe. Now lets focus on the safety of the planet.

   A new site was created to detail the FACTS at LHCFacts.org, and allow honest feed back and counter arguments.

   Review the issues for your self to determine who is honest about the risks and how large those risks might surprisingly be… (Some evidence indicates that real risk may be 100%, but science is unable to determine risks accurately at this time. That is not a time to say "no proof of reasonable risk, launch!"

   Dr. Raj Baldev, Director of the Indira Gandhi Center for Atomic Research. Dr. Baldev says the following " But the scientists are fully aware that it is not a project without a grave risk to the life of the Earth."

   JTankers
   LHCFacts.org

4. **wilbur**
   May 24, 2008

   JTanker, nothing will happen at the LHC that does not happen everyday in the upper atmosphere with cosmic rays… except that at the LHC there will be a lot of people watching the show with huge detectors…

5. **Peter Woit**
   May 24, 2008

   Please, if anyone wants to discuss JTankers arguments, do it as his website.

6. **DB**
   May 25, 2008

   Oddone revealed that an anonymous Chicago family has donated $5m to Fermilab so the furloughs no longer need to go ahead.

   As to the House of Representatives going along with the Senate proposal, that's considered unlikely:

   http://www.symmetrymagazine.org/breaking/2008/05/23/5-million-donation-relieves-fermilab-of-furloughs/

7. **Professor R**
   May 25, 2008

   To European eyes, it is incredible to see Fermilab with such funding worries, given its record of achievement, and current success…

Just how dumb are your leaders in the White House? Do they not have science advisors with any intelligence ?

Here in Ireland, a similar situation prevails. Ireland is the only country in the EU that is not a member of CERN, and we have been trying to persuade the governmnet to rectify this shameful situation for years.

But that level of ignorance in a small country on the edge of europe is one thing – it is quite another in the worlds permier superpower..
Cormac

8. **Visitor**
   May 25, 2008

   "Just how dumb are your leaders in the White House?"
   Not as dumb as you think; the White House wants to fund FermiLab, it is the Democrats who have cut their appropriations specifically because Bush wants to protect them. You, along with some other people here, need to rethink your stereotypes. (Of course, that's not very likely, is it?)
   (There have already been a few threads here about the situation.)
   Incidentally, if Obama is elected, I would expect that the situation for science funding will get worse…

9. **Coin**
   May 25, 2008

   Do they not have science advisors with any intelligence ?

   I don't think you need those last three words there, really, at this point.

10. **Professor R**
    May 26, 2008

    Coin: I see what you mean!

    To European eyes, it seems incredible that Fermilab funding is being cut at this point (irrespective of who is doing the cutting), given its current beam efficiency, and the fact that LHC will not start delivering for some months yet.

    Cost effective? Any experimentalist will tell you that cost-effectiveness is about grabbing as much data once the thing's working smoothly!

11. **wb**
    May 27, 2008

    I accept the argument that once a machine is running you take as much data as you possibly can. Nonetheless if one uses the old guideline that a "factor of two in energy is worth a factor of ten in luminosity with a hadron collider, the prospect of 40 inverse picobarns at LHC by years end is becoming a scene stealer.

12. **Professor R**
    May 28, 2008

    Agreed, wb – but that's at year's end, not now!

Train of Thought

May 23, 2008
Categories: Uncategorized

For the last 15 years the New York City subway has featured “Poetry in Motion”, which places extracts of poetry in subway cars. Starting next month this program will be expanded, joined by Train of Thought, which will add “short quotations in history, philosophy, literature, and science chosen by Columbia University’s Graduate School of Arts and Sciences.” I gather that my colleague Henry Pinkham, a mathematician now dean of the Graduate School, is responsible for this. Of the first two quotations to go up next month, one is dear to my heart, from Galileo:

The book of nature is written in the language of mathematics. Its symbols are triangles, circles, and other geometric figures, without which it is impossible to understand a single word; without which there is only a vain wandering through a dark labyrinth.

   May 23, 2008

   > La filosofia è scritta in questo grandissimo libro che continuamente ci sta aperto innanzi a gli occhi (io dico l’universo), ma non si può intendere se prima non s’impara a intender la lingua, e conoscer i caratteri, ne’quali è scritto. Egli è scritto in lingua matematica, e i caratteri sono triangoli, cerchi, ed altre figure geometriche, senza i quali mezi è impossibile a intenderne umanamente parola; senza questi è un aggirarsi vanamente per un’oscuro laberinto.
   >
   > Galileo Galilei, “Il Saggiatore,” (1623).

2. **Ken Muldrew**
   May 23, 2008

   Here is a quote from Feynman that is also in the genre of refutations for the trope about being able to explain your theory to your grandmother:

   “… it is impossible to explain honestly the beauties of the laws of nature in a way that people can feel, without their having some deep understanding of mathematics. I am sorry, but this seems to be the case.”

3. **exanto**
   May 24, 2008

   This is actually a great idea. My personal favourite from Galileo:

   > Man kann einen Menschen nichts lehren, man kann ihm nur helfen, es in sich selbst zu entdecken.

   or in english (freely translated):

   > One cannot teach a human anything, you can only help him to discover it on his own.

4. **Paul Jackson**
   May 24, 2008

   Galileo is of course right. But those who overindulge in mathematical ratiocination (like string theorists) should remember the more sceptical view of Mark Twain:

   “There is something fascinating about science. One gets such wholesale returns of conjecture out of such a trifling investment in fact.”

   Life on the Mississippi

5. **Dorian Allworthy**
   May 24, 2008

   Men can do nothing without the make believe of a beginning. Even science, the strict measurer, is obliged to start with a make-believe unit and must fix on a point in the stars’ unceasing journey when his sidereal clock shall pretend that time is at Nought. His less accurate grandmother Poetry has always been understood to start in the middle; but on reflection it appears that her proceeding is not very different from his;since Science, too, reckons backward as well as forward, divides his unit into billions, and with his clock finger at Nought really sets off in Medias res.
   George Eliot

INSPIRE

May 28, 2008
Categories: Uncategorized

Since 1968 SLAC has been maintaining a database of HEP documents called SPIRES, and this has become one of the main tools used by anybody searching the HEP literature. In recent years CERN has developed a much more modern document management system known as CDS Invenio. The two projects are now being brought together into something to be called INSPIRE, which will combine the best of both, in particular making the SPIRES data available through the more modern Invenio software.

There's a press release from DESY about this here, and an alpha version is up and running here. The current state of the project is that most of the SPIRES functionality has been reproduced, and they are working on getting a beta version ready of a complete replacement of SPIRES.

Last week at DESY a workshop was held about this, announced as an HEP Information Resource Summit, talks are available here. There were presentations from other HEP information providers, including the APS, commercial publishers and the arXiv. The arXiv presentation discussed their desire to better support blogging, and the role of the blogosphere, including the fact that Garrett Lisi's paper was the most downloaded article on the arXiv. The current trackback system provides links to 21 discussions of the paper, but due to the Distler/arXiv policy of censoring links to this blog, one that is missing is the discussion here. More and more very worthwhile content is appearing on blogs, so the question of how to make this readily available in a useful form will become an increasingly important one.

Unfortunately, while the arXiv does a good job of bringing together mathematics and physics, there seems to be no discussion of the role of the mathematics literature in the new INSPIRE system. Besides the arXiv, the main database used by mathematicians is the excellent MathSciNet developed by the AMS.

Update: Travis Brooks of SPIRES has a posting about this here.

Comments

   May 28, 2008

   Thanks for the ArXiv presentation Peter, interesting reading.
   On the 'like least ' slide, do you know what is meant by the three categories GUI, coverage, basic arXiv?

   I think it's great to see Garrett's paper riding so high – if nothing else, it's nice to remind the wider physics community of the role of group theory in today's particle physics!

2. **Professor R**
   May 28, 2008

   P.S. It seems strange that ArXiv have omited a trackback to the Lisi discussion on NEW. After all, Garrett himself contributed quite a bit to the discussion, as I recall – which is more than can be said for several of the discussions listed…Cormac

3. **Peter Woit**
   May 28, 2008

   Cormac,

   If you want to read up on "Trackback-gate" from a couple years ago, see for instance:

   http://www.math.columbia.edu/~woit/wordpress/?p=357

   and follow the links. The bottom line there is that Distler is unhappy with any mention of my criticisms of string theory appearing anywhere he controls (he is involved in running the hep-th part of the arXiv), and some other well-known multiverse-promoting physicists are unhappy with the idea of links to my criticisms of this as pseudo-science appearing on the arXiv. So, links to my blog are banned on hep-th. A dishonest excuse that only blogs run by reputable "active researchers" are allowed to have links was made, you can look through the trackbacks to the Lisi article to see if that's really the policy.

4. **Alejandro Rivero**
   May 28, 2008

   My experience with the people of SPIRES has always been better than with the arxiv. Of course, SPIRES do not need to censor papers. But I can cite two cases: when old physcomments needed to check for author data, Arxiv cut the access and SPIRES allowed it (and then Arxiv admins were paranoid because they thought I was hacking some of their mirrors). And when I worked out the genealogy of theoretical physicists, SPIRES people was kind enough to create a new "tree" output in HEPNAMES. But all of this was old history, before of the Arxiv API. So perhaps it could be interesting to give the guys some new credit!

   The social network think is an interesting idea. Perhaps they could provide an opensocial REST API interface, with "friends" akin to "coworkers", and "activity" equal to "publication" or update of a preprint. Then standard Opensocial gadgets could work as extensions of the Arxiv.

5. **Professor R**
   May 28, 2008

   Thanks Peter, enjoyed that link, especially Smolin's comment.

   I think the situation on the Lisi paper today points up the situation even more – if Garrett is happy to discuss his paper on your weblog, it seems absurd that ArXiv not link to the discussion in their list…

   Re ArXiv discussion of weblogs, I wonder did the criterion 'usefulness' get a mention – I find the links at NW v useful, which is why I keep coming back…Cormac

6. **somebody**
   May 28, 2008

   Distler is one of those guys who has to get off his throne. If he did not try to look so condescending, string theory would not have looked so pathetic, even despite your attacks. I say this as a string theorist, because he and Lubos do more to damage the credibility of string theorits than any single thing you have ever written. I have to say that I disagree with your views, but these guys do so much to help you!! Of late you are kind of extreme, but in the beginning at least, you were moderate, and some of us "string theorists" would have actuatlly agreed with you!

Good work, Peter, because a bit of disagreement is always good!

7. **dragon**
May 28, 2008

I note that there are no trackbacks from L Motl to any of Lee Smolin's papers since September 2006. It seems hard to believe that this is a case of voluntary restraint, so could it be that LM has been quietly banned from making trackbacks? That would be good news indeed.

8. **dragon**
May 28, 2008

By the way, I met someone at a conference who works in a field where people are regularly subjected to abuse by Motl and others. She said that she fears the trackback system — even if the attack is garbage, who can say whether a referee might be influenced by it? There's no point in saying that everyone knows that LM is full of it — the usual formulation is that he may be a lunatic, but he really knows his physics. Even Distler seems to subscribe to this strange notion, which is actually very debatable indeed outside a small area; in some cases his views on *physics* have bordered on [or gone beyond the border of] crackpottery. So the danger of referees being influenced in a malign way is not negligible.

So I strongly believe that the trackback system should be heavily moderated; only strictly technical discussions should be allowed, no attacks whether personal or otherwise, and no philosophical stuff [because that all too easily turns into abuse or something indistinguishable from it]. If the arxiv people aren't willing to do that —- which would be a pity, because some trackbacks are actually very useful —- they should scrap the whole thing.

9. **anon.**
May 29, 2008

'I note that there are no trackbacks from L Motl to any of Lee Smolin's papers since September 2006 … so could it be that LM has been quietly banned from making trackbacks? …' – dragon

See the second trackback (dated 7 Nov 2007) on the list http://arxiv.org/tb/0711.0770

arxiv censorship isn't entirely automated. For example I updated a paper some years ago and it was given a number but then deleted within the time taken to refresh the browser (a few seconds). They rely on their genius at spotting errors in papers based on the author's level of prestige and the title of the paper, not on reading and checking the actual content. So it is rather arbitrary. There are people there, making quick decisions based on gut feelings.

10. **Peter Woit**
May 29, 2008

somebody,

I agree that Jacques and Lubos have done far more damage to the interests of the string theory community than critics like me. They represent only one rather pathological wing of this community, and it's unfortunate that they have been the most vocal part of it in the blogosphere. I'm glad to hear that you appreciate what I've been up to here, even if you often disagree with it. You may be right that I've become more immoderate in recent times, perhaps driven to madness by the whole multiverse business…

dragon,

As anon points out, the arXiv hasn't stopped trackbacks to Lubos's blog, since there is one for Garrett's article. At one point I was paying attention to which trackbacks were appearing there, trying to figure out what their policy was, but I gave up on that long ago, unable to make much sense of it.

In general, I think the only way to provide a high quality source of information on the web is to have sensible people doing some degree of moderation of the content. This can't be automated, and there's no single right way to do it, with difficult choices having to be made. In general I think the arXiv does a good job, under difficult circumstances, but in this case I think they made an error in judgment, allowing decisions to be governed by someone seriously lacking in good sense. Distler's conviction that anyone who disagrees with him about string theory must be incompetent, coupled with his belief that personal insult is the way to carry on scientific discussion make him an inappropriate person to be making decisions about moderation.

As for the problem of links to Lubos's blog postings swaying referees, I guess I think that if you have as a referee someone who takes Lubos seriously, you've already got a big problem, whether Lubos has a posting on the article or not.

11. **Daniel de França MTd2**
May 29, 2008

I dont know exactly how much, who or why, etc… the damage someone did to the string theory image. But, I know that at least someone is doing a great job in promoting string theory, and that person in Urs, from n-cafe category. He is extremely helpful guy, always talks with formulas and try to work out ideas, even if those that re from non string framework, and is always motivated to promote string theory, even if it is in terms of just using its mathematics machinary.

Sorry for the eulogizing here, it's just that he is one of the people that made me start studying physics again after years of general deception with academia, and I wouldn't like people cursing string theorists as they were all leading to failure. Maybe, at least some of the mathematical framework motivated by it, will be used in a future QG theory…

12. **Marcus**
May 29, 2008

Daniel, I think you mean
"after years of general disappointment with academia,"

decu, in French, translates to disappointed, in English (not to deceived).

I share your high regard for Urs Schreiber and moreover do not consider him to be limited to string theory exclusively. He seems to have shifted successfully into mathematics, and have a wider scope now than he did a few years ago.

13. **Daniel de França MTd2**
May 29, 2008

Sure Marcus, thanks. But my mother language is Portuguese, not French :). But since they are closely related languages, I can see that the correction would likely have the same result anyway. 🙂

Even if I don't not understanding everything, Urs always posts great tutorials so that we end up learning a lot. In this aspect, John Baez is great too.

PS.: That word "de França" is in fact the first of my surnames, and the one I like best. I write "MTd2" just so that people can indentify my real name with the one I post on forums.

14. **Peter Orland**
June 1, 2008

I have been playing with the trial version of INSPIRE. Even the advanced search doesn't seem as versatile as SPIRES. I hope that the beta version is better.

15. **Shantanu**
June 1, 2008

Btw ADS has papers going back to the 11th century !!. I wish there was a similar database of
all GR papers.

P5 Report

May 29, 2008
Categories: Experimental HEP News

A new P5 report is out, and being discussed at the HEPAP meeting in Washington today. The charge to P5 was to develop tentative 10 year plans for US HEP, under 3 scenarios:

- Scenario A: funding at the current post-budget cut level of $688 million for the DOE.
- Scenario B: funding at the pre-budget cut (2007) level of $752 million for the DOE.
- Scenario C: a doubling of the budget over 10 years, starting from the 2007 level.

This report updates earlier ones and the EPP2010 report in light of new realities, specifically acknowledgement that the cost of the ILC means it's not happening anytime soon, and the grim budget situation caused by the recent budget cuts for this year. To be honest, it's very unclear to me how anyone can sensibly carry through this kind of exercise right now. With the supplemental appropriation still up in the air at the House and the Senate, it's hard to know what the US HEP budget will be next month, much less next year, or over 10 years. The LHC startup is only months away, and how long that takes and what the LHC shows are crucial things for any future planning.

In the report, the field is broken into three parts:

- The Energy Frontier: experiments at the highest possible CM energies. This is the Tevatron now, the LHC soon, and a possible electron collider later.
- The Luminosity Frontier: experiments at the highest possible event rates. This include neutrino experiments and searches for rare decays. The proposed "Project X" at Fermilab is the main possible new machine here.
- The Cosmic Frontier: astro-particle physics studies of dark energy and dark matter, study of astrophysical sources of high energy particles and neutrinos.

One crucial decision that will need to be made soon is how long to run the Tevatron. The report says to continue support "for the next one to two years", with two only in the optimistic scenario C. On the question of the ILC, the report describes "a wide range of opinion" in the HEP community and on the panel. Opinions about both of these may very well change over the next year depending on what happens at the LHC.

In both scenarios A and B, the report envisages cutting staff at the national labs, in favor of preserving support for research based at universities.

Other blogs posting about this here and here.

Update: Science magazine this week has two excellent articles by Adrian Cho, about the problems facing Fermilab, and the ILC.

Update: The final P5 report is here.

Comments

1. **wb**
   May 30, 2008

   RE: "The Energy Frontier: … a possible electron collider later."

   While the VGs of the report maintain a possibility for an ILC, they do by implication raise the distinct probability that the energy of the ILC is wrong and therefore the technology is wrong. If that is so one of the justifications for Project X as so late a date (compared with J-PARC) is cut away. Hence, it would have been helpful if the report specifically stated that research should be increased to determine if a consistent end-to-end concept for a muon collider is possible. Instead we have in Scenario C, "If another lepton collider technology is found to be preferable, its R&D would be advanced." One can certainly read support for muon collider R&D that into the words, but not necessarily. The words could just mean CLIC – no sure thing as a concept. In recommendations more explicit language would have been preferable.

   The report seems to make the future of Fermilab – as a single purpose HEP accelerator lab – contingent on a vigorous program at DUSEL. Otherwise and for the most part Fermilab seems to be reduced to playing a supporting role in HEP. Ah, yes, but it is the leading supporting role in the US. Perhaps that is what "maintain a leadership role in world-wide particle physics" means."

   The report of the report cannot be considered an endorsement of the strategic plan for Fermilab presented at the last HEPAP meeting. Particularly for Scenario A: "Constant level of effort at FY2008" the panel sidesteps the obvious but crucial question, "at that funding level does the US need a single purpose HEP laboratory?" I admit that were I on the panel I would also have ducked the question. Especially since the Panel admits that Scenario A "would sharply diminish the US capability in particle physics from its present leadership role;" the most likely scenario next year is inconsistent with the panel's primary recommendation, "maintain a leadership role in world-wide particle physics."

   To be sure one must wait to read the entire report before one understands all the implications. It is easy to be critical and not so easy to be constructive in so highly constrained a situation. The Panel was dealt a poor hand to play.

   My bottom line is that we need to make every effort to get results out of LHC as early as possible. Only compelling results from LHC are going to change a grim picture for accelerator based HEP.

2. **Peter Shor**
   May 30, 2008

   I don't believe the scientists looking at data from the LHC are going to rush things to try to get the next generation of particle accelerators scheduled sooner, nor do I believe that this is a particularly good idea. We'll just have to wait and see what these results are, and try somehow not to lose expertise in buliding particle accelerators in the meantime.

3. **wb**
   May 30, 2008

   My point about LHC was not about "rushing to Judgment" at the LHC, but about the 1) importance of a very strong US commitment to the LHC physics program, 2) the value of a faster rather than slower sociological process in the ATLAS and CMS collaborations. Investment choices may well have to be made on far less than discovery-level data for a vigorous accelerator-based program beyond LHC-1. Even preliminary hints as to energy scales is critical to decisions over the next 3 – 4 years concerning the suitability of the technology choice for a linear collider.

   There is no question that Europe and Asia will maintain a high level of expertise in accelerator science and technology throughout the next decade. The prospects for the

US in general and Fermilab in particular are not so sanguine.

4. **srp**
   May 31, 2008

   Relatively small amounts of money (but a multiple of what is spent today) could be allocated to advanced accelerator concepts to determine whether they were feasible. Before deciding about next-generation accelerators of conventional design (and hence no improvement in energy), common sense suggests first spending a little bit of money to determine if advanced machines could/should be built instead.

   If the answer from such investigations were yes, then it would be much easier to get the money for an operational machine because the jump in energy would at least offer the potential for fundamentally new results. Exciting new technology that opens up new frontiers is much more likely to attract support than giant installations that don't move the needle very much.

   If the answer about advanced concepts were no, then the sorts of incremental but hugely expensive projects currently under discussion could be put forward. I wouldn't be optimistic in this latter case, but at least the alternatives would have been explored and ruled out.

   The stubbornness (or lack of vision) of the community in obstinately putting forward these high cost/benefit incremental accelerator concepts, without seriously trying to get out of today's energy dead end, is very disappointing. It's almost as though people are more concerned with a steady flow of jobs than with maximizing the rate of discovery. But the public and its representatives are not likely to fund these conventional concepts–the scientific return per dollar invested just seems too low. Any new accelerator is going to have to make a compelling case that it can do much more than the LHC.

5. **Peter Shor**
   June 2, 2008

   If high-energy physicists try to make a snap decision on the energy level and usefulness of a followup to the LHC, spend a large amount of money on this followup, and then are proved to be wrong by further analysis of data from the LHC, I strongly suspect the damage to physics will be far greater than that incurred by waiting until definitive results are out from the LHC.

   I have no objections to spending relatively small amounts of money in a planning phase for the next accelerator.

World Science Festival

May 30, 2008
Categories: Uncategorized

Most of the time the attention paid here to efforts to popularize physics is restricted to grumpy complaints about the hype surrounding string theory as well as the more general dubious phenomenon of scientists promoting things that are more science fiction than science. Today I'm in a much more positive mood, and thought I'd take the opportunity to make some unusually sunny comments for a change.

One reason for this is that I attended the opening party for my colleague Brian Greene's World Science Festival Wednesday night at the American Museum of Natural History, and several people have told me about the enthusiastic reception the festival events have been getting. I was hoping to attend one of the events, but it was already sold out.

Things started off during the day Thursday with a World Science Summit here at Columbia featuring a speech by Mayor Bloomberg, and award of the new Kavli prizes. That evening, at the museum event, Brian, Fred Kavli and Senator Schumer all spoke, and the crowd was entertained by the choir of the Abyssinian Baptist Church.

Among the people I got a chance to talk to at the event were several string theorists. One of these was Jim Gates, who I had the pleasure of first meeting last year down in Orlando. He was there with his wife, just back from South Africa where he is involved with the African Institute for Mathematical Sciences.

Gates told me that his collection of video lectures with impressive graphics explaining quantum mechanics, general relativity and superstring theory called Superstring Theory: The DNA of Reality has been selling well, generating over a million dollars in sales, despite not being able to get it reviewed in major publications. Strong evidence of its popularity comes from the fact that if you google "The DNA of Reality" you get an impressive variety of sources for pirated versions. Evidently he has done an excellent job of reaching a wide audience with this material. From conversations with him I know that we're in closer agreement than you would guess, sharing an interest in the mathematics behind supersymmetry and a skepticism about extra dimensions.

I have mixed feelings about the highly enthusiastic promotion of certain speculative ideas about physics involved both here and in some of the World Science Festival events, but it's undeniable that these are reaching a lot of people and getting them excited about science. Perhaps I can convince Jim to market what could be the ideal package: his videos to get people excited and enthusiastic about the open problems in physics, and my book to give them some skepticism about the solutions now being promoted…

Update: For an article describing what happened at the World Science Festival program about unification and string theory, see here.

Comments

1. **The Vlad**
   May 30, 2008

   Dear Peter,

   An excellent attempt at a sunny disposition, though perhaps not an entirely successful one 🙂

   Your post leads me to ask the following question: Do you think that your critical viewpoint has acted to promote the profile of physics in the public eye?

   I am not a physicist by training, and although I cannot follow many of the more technical discussions here, I would say that I have certainly learned much from your posts and the discussions in the comments sections. Thus, to the extent that your blog has educational value to the layperson, I would suggest that you are doing physics a promotional service. Skepticism of extant viewpoints, even dogmatically asserted ones lacking experimental support, is not necessarily bad from a public-relations angle.

   Which brings me to a second question: When does 'healthy skepticism' cross the line into 'irresponsible criticality'?

   A senior colleague of mine recently suggested to me that another senior colleague, whose reputation for skepticism borders on the extreme, was irresponsible and therefore lacked 'leadership qualities'. Yet to my view, failing to speak out against false or misleading scientific claims is also an act of irresponsibility (by omission).

   I would love to your view and those of your readers.

   The Vlad

2. **Changcho**
   May 30, 2008

   With regards to doing Physics (or science in general): one needs to find the right balance between 'wonder' and 'skepticism', as Sagan often wrote. I suppose the right allocation between the two would be different for different fields, or even different problems in the same field.

3. **Peter Woit**
   May 30, 2008

   Vlad,

   I don't really think that "the profile of physics in the public eye" is something particularly well-defined or of a simple signficance. There's lots of different kinds of physics, "the public" is all sorts of different people, and what is ultimately desirable is not that all people have a high opinion of everything physicists are doing. What's important is that some talented people get seriously enough interested in it to pursue it as a career, that lots of people get some appreciation for what we know about the physical world, and that there's sufficient support among the public for good physics research.

   It matters a great deal which research areas get into the public eye and thus are more likely to get public support. As an example, if the campaign to promote multiverse studies is successful, there's a danger that real science will get crowded out, both in terms of funding and attracting good young people. Physicists need to promote their science, but they need to do so honestly, and also to do what they can to stop misleading and self-interested promotion of unsuccessful research programs.

   As far as the whole string theory controversy of recent years goes, I think string theorists have made huge mistakes in how they have dealt with it, and this has seriously damaged both their standing in the physics community and the public perception of their field. The smart thing to do would have been to acknowledge the existence of the serious problems being pointed out by their critics and to make the case to the public that this kind of very real scientific controversy is a healthy part of science, evidence of how little we know about some topics, and a good reason for young people to go into the subject, since some of it is still wide-open. Instead the typical attitude has been to remain quiet, trying to ignore criticism in the hope that it will go away, leaving the public response to extremists who do a very poor job of representing them.

4. **Bill**
May 31, 2008

Now this is hilarious Peter!

You want to ride the coattail of a string theorist promoting science including string theory to sell more of your books and thus generate more revenue. Truly bizarre.

Best,
Bill

5. **Peter Woit**
June 1, 2008

Bill,

The comment about packaging my book with the videos was a joke, actually. Believe it or not, the book was not written to make money. It was written to explain a different point of view on the currrent state of particle physics. I'm rather proud of it, and, yes, like the idea of more people reading it.

Besides yours, this posting also generated other anonymous comments of pure personal abuse from string theory partisans, which I've deleted. Weird that the most nastiness I've had to contend with in a while was triggered by my saying something positive about the efforts of some string theorists.

6. **Bill**
June 1, 2008

Peter,

Make no mistake, the "nastiness" was not triggered by your saying something positive about the efforts of some string theorists. Rather, the observation was made that you intend to sell more books not by convincing people that your book is worth reading but by packaging it together with a book/video/lecture/etc of a string theorist. Joke, or not, this is truly bizarre.

Why? Because one of your main issues is the public perception of string theory and the "hype" that surrounds it. This "hype" is not a scientific statement, it's related to it's public perception. Which is fine, you don't have to have a scientific point, you can be a popular science journalist and you can criticize issues from that perspective. But then coming along with a "joke" that you think it would be useful to package your book with a hugely successful string theory "hype" publication makes one wonder that it's really no surprise people don't take you seriously.

Bill
(Just to avoid confusion, I'm a nuclear physicist, and yes, I'm tenured and yes, I have over 1500 citations. All of this is completely irrelevant, however, you like to picture any critique of yours as "string theory partisan".)

7. **Peter Woit**
June 1, 2008

Bill,

My criticisms of string theory hype have always been from the point of view of a scientist, addressed to the ways that science is being misused and misrepresented and I intend to keep on pursuing those. But I think it's also important to recognize that many of the people writing enthusiastically about string theory are doing so in the larger context of an attempt to get the public interested in and excited about modern physics. This ends up producing what seems to me a mixed bag, and I've often criticized the problematic parts of it, but there are also valuable parts, and I wanted to acknowledge those. Lots of people have gotten interested in physics and learned something about it from Brian and Jim's efforts. Many may also have acquired an unreasonably optimistic view of string theory, but the other side of the coin has also been getting quite a bit of attention recently.

It was definitely a joke to suggest a joint marketing effort; given the hostility of the "string wars" I found the notion amusing although many may not share my sense of humor. The serious part of the suggestion was that I think that it wouldn't be a bad thing at all for people to be exposed to both a pro-string effort and my book. This has nothing to do with a desire to make money selling books (the book was intended to be published by a university press and addressed to a relatively narrow audience, I don't need the money).

8. **curious one**
June 1, 2008

"I think that it wouldn't be a bad thing at all for people to be exposed to both a pro-string effort and my book…." – Peter Woit

Yes, if people actually remember to read it.

9. **somebody**
June 1, 2008

Frank said:

>I'm a QCD person, not a 'string partisan', and it is hard to

>people consider Peter a parasite.
>
>In the 'mixed bag' of the 'hype', what are the 'problematic
>parts'? Let me guess. They're the parts that don't allow Peter
>to feel important and to earn a few bucks.

Being a string theorist, I have found a lot of people who are in the hate-string-THEORY camp because of the string THEORISTS' arrogance or know-it-all attitude. I have found VERY few critics of string theory whose views have not been corrupted by this aspect. Incidentally, I think that this arrogance is a very real phenomenon, even if I believe it is beside the scientific issue. I would have given you the benefit of the doubt if you said Peter was one of them who hated string theory because of the string theorists, even though I have no idea whether it is true.

But to say that he is after money, seems ridiculous to me. I think a real and honest critic of science should really walk the middle ground and we should congratulate Peter for making such an effort in this post. I personally would find a post like this far more refreshing than an unqualified rant.

10. **Matthew Putman**
June 1, 2008

peter,

I am a patron of the festival, so am a bit biased as to its merits. Still the entire thing went even better than i had imagined. i am both a scientist and involved in the arts, and while in sciencific circles we tend to debate the merits of theories, outside of science the worlds of art and science dont really know how to communicate at all with each other. This event gave me hope in a different way than an invidual project would give me, and instead gave me a chance to be myself in art and science. I give Brian and Tracy a lot of credit for this, but also you, and others who have differed in regards to string theory, for attending, and embracing the romantic notion of an event like this. This is one of the reasonsons it worked so well.

Matthew Putman

11. **Peter Woit**
June 1, 2008

My apologies to the string theory partisans of the world for making unfair accusations…

Matthew,

Glad to hear you also found the festival to be a success!

somebody,

Thanks for your comments. My problems with string theory don't have much to do with string theorists personally. Some of my best friends are string theorists… and the theorist I have the highest opinion of professionally and personally (Witten) is also probably the one most responsible for promoting the subject to his colleagues. One interesting thing I learned after getting involved in this controversy is that the sheer complexity and difficulty of string theory is a large part of the story. That has made it very hard for people to sensibly evaluate it, and that's behind some of the bizarre behavior surrounding the "string wars".

12. **somebody**
June 2, 2008

> the 'arrogance' accusations are frequently raised against all
> of science, not just string theory, by those who don't
> understand it.

I was saying that against string theory there is certainly anatgonism of this kind even within the scientific community. Here is a view from the other side:

http://cosmicvariance.com/2005/11/18/a-particle-physicists-perspective/

I think her claim that string theorists are arrogant is true. But I also think she is upset only because she is at the receving end of it. I am pretty sure that she seems equally arrogant to somebody doing plasma numerics. There is, and has always been, a heirarchy of "fundamentalness" in physics. The reason why string theory is strange is because it claims to be the most fundamental thing, stakes a claim on all the glory, while not (yet) producing a single new experimental test. We string theorists claim that it is because quantum gravity is inherently difficult to test, and that we need more time, but that hasn't stopped people from getting pissed.

Please note that I am not endorsing the arrogance of string theorists – but I feel that this specific piece of sociology has been a huge reason why the anti-string wave has been so powerful. I think the scientific case is much weaker than the popular reaction, Peter of course might disagree.

> the 'arrogance' accusations are frequently raised against all
> of science, not just string theory, by those who don't
> understand it.
>If there is a difference, could you please
> enlighten me about this difference?

As has been already pointed out by others, string theory is perhaps more complicated than other subjects. At the very least it is certainly BIGGER than the other subjects.

But I think the real reason for the arrogance is that string theory forces you to know both QFT and general relativity really well, and between the two it exhausts most of the juicier aspects of theoretical physics – from critical phenomena to particle physics to the big bang and black holes. Then there is the fact that string theory has a lot of geometric tools usually unncessary in other physics. There is a very real sense in which a COMPETENT string theorist has to be a jack of all trades.

Arrogance or the perception of arrogance happens when you can understand THEM relatively quickly, while they need lot of new tools to undertstand YOU. Once again, I am not trying to defend the phenomenon, just trying to explain it.

Of course, there is also a kind of arrogance that comes from being associated to a field of work where you are basking in the reflected glory of people like Witten, but I think this applies mostly only to the not-so-competent string theorists. I was talking about the more serious kind of arrogance, the one that stems from true vanity. I also want to emphasize that I have known some exceptionally brilliant and creative guys in this field who are also extremely modest. The ratio of the jerks to the nice guys is probably the same in string theory as it is in any field.

13. **Peter Orland**
June 2, 2008

This thread seems off-topic, but after Somebody's last comment, I feel I have to say something.

"But I think the real reason for the arrogance is that string theory forces you to know both QFT and general relativity really well, and between the two it exhausts most of the juicier aspects of theoretical physics – from critical phenomena to particle physics to the big bang and black holes. Then there is the fact that string theory has a lot of geometric tools usually unncessary in other physics. There is a very real sense in which a COMPETENT string theorist has to be a jack of all trades."

Actually, any good theoretical physicist should try to know at least a little about all these things! Add the Hubbard model, superconductivity, integrability,…. It is important to keep learning things.

I have never been frustrated by anybody's arrogance. Arrogance is par for the course. What bothers me is that so many people are working on problems where there is no specific goal in mind. You've solved a problem at three loops, so do four. You have one formulation of something, so find another. Much of this activity is pure mountain climbing and teaches us nothing. This is very different from finding a new way to understand a well-formulated problem, even if it is only a toy model (like N=4 Yang-Mills or 1+1-dimensional theories). For the past several years, almost every seminar speaker I see doesn't really have anything to say. I want to stress that it isn't only string theorists who are guilty of this.

For some reason, people feel they can get away with solving problems with no motivation other than someone else is doing it. It's important to have a message in your work.

If you don't like what I've said, call me arrogant.

14. **Peter Orland**
June 2, 2008

I should correct my next-to-last paragraph. It should read:

For some reason, people feel they can get away with formal things with no motivation other than someone else is doing them. It's important to have a message in your work.

15. **somebody**
June 2, 2008

> I have never been frustrated by anybody's arrogance. Arrogance is par for
> the course.

It is precisely attitudes like this that has left the string theory community with few friends these days. Instead of recognizing arrogance as a form of insecurity, there is a certain glorification of it in the community. Now it has come back to bite us in the behind. It is one thing to be vehement and passionate about what you think, and that can sometimes come across as arrogant. I must admit that sometimes I am massively guilty of that myself. But some of the more visible string theory blogs are very clearly conscious attempts at shushing the opposition through condescension and disrespect.

The collateral damage is that now we are slowly left with no friends and no funding. You just need to take a look at the hiring patterns last year to see the truth of this statement. You cannot treat everybody else like cattle and then expect them to see how good string theory is.

16. **Peter Shor**
June 2, 2008

Peter Orland says "Much of this activity is pure mountain climbing and teaches us nothing. … For some reason, people feel they can get away with formal things with no motivation other than someone else is doing them. It's important to have a message in your work."

This is, of course, what all of mathematics looks like, at least at first glance. After you learn more about a specific mathematical field, you realize that many of the better mathematicians in it are actually pursuing some kind of directed program that is moving forward, while others are just solving random problems and accumulating publications.

String theorists have now lost the guidance of experiment, so they are doing something much closer to pure mathematics without having been exposed much to the mathematical culture. I can't say for sure whether this culture helps mathematicians make progress in such a vague and fuzzy environment, but I suspect that it does.

17. **Peter Woit**
June 2, 2008

This thread has wandered from the topic, partly due to the anonymous insulting comments from "Frank". I've deleted those comments, but mostly left those responding to him.

If people want to continue this discussion, that's fine, but keep in mind that posting insulting comments anonymously is out of bounds here. Don't do this and don't respond to those who do.

Note: The original version of this comment mentioned that I suspected that "Frank" was someone who used to post here as "amused". He assures me that this was not the case, so the comment has been edited, with my apologies to him.

18. **somebody**
June 2, 2008

> This is, of course, what all of mathematics looks like, at least at first glance.
> After you learn more about a specific mathematical field, you realize that many
> of the better mathematicians in it are actually pursuing some kind of directed
> program that is moving forward, …

This I think is an excellent characterization of the situation in string theory. All the fad, for example, are about minor breakthroughs that take us a tiny bit closer to a better understanding/control of the theory – even if they seem pointless to an outsider. In some grandiose sense, they are indeed pointless, because they are minor stepping stones. But we cannot do without (most of) these stepping stones on our way. Most serious people do understand the mission statement, and even though progress is slow, it has direction. Unfortunately, it really does seem that even though the physical picture has a lot of coherence to it, the technical and conceptual problems that need to be solved before we can wield string theory with sufficient comfort (so as to be useful for making predictions for low energy physics) are many and difficult. The hope is that they would not turn out to be insurmountable, and that they would not lead to an asymptotic slowdown of the field. I am not worried about the latter yet because we have been making progress in fits and starts so far (even though these last couple of years were admittedly a bit dull).

19. **Peter Orland**
June 2, 2008

Somebody,

I'm not a total outsider, so that's not why these activities seem pointless, at least not to me. I know enough string theory to see that most of what string theorists are doing really doesn't have a point (and this is also true in other areas of physics, as I said above).

Most people are just refining calculations of models or playing with formalism. They are doing technical things with no motivation for what they are doing. I'm absolutely sure of this, because I sometimes ask WHY THE HELL ARE YOU DOING THIS? (but more quietly and politely) and get no answer.

So what should they do? Well, this works for me: when I can't get further with some line of research, I'll usually work on something else for a while.

20. **somebody**

June 2, 2008

> I know enough string theory to see that most of what string theorists are
> doing really doesn't have a point (and this is also true in other areas of
> physics, as I said above).

So you are essentially saying that most of the scientific research that goes on in most fields is pointless. I agree that bad research is FAR more common than good research. But that said, I still don't see your point. I think your view amounts to looking at the bad research going on in string theory and related fields and vaguely IMPLYING that that is essentially ALL that is going on. If thats the case, I disagree.

Even today on the hep-th arXiv, there are some interesting papers. Lets look at the first two papers. I would say they are immediately interesting to any theoretical physicist. I find it interesting that there is a dual gravitational description for the quantum hall effect. The second paper talks about the emergence of geometry from doing matrix model quantum field theory. I think these are interesting results, even if they are not making predictions about low energy physics. I think an understanding of the relations between the mathematical structures in theoretical physics is essential to see beyond the technical complexities, so even if not immediately, these papers are useful to my mind. They are not revolutionary, but they are certainly doing good science – which is to push forward during the interval between two successive revolutions.

If these works seem pointless to you, I don't know what wouldn't. In fact, at the risk of sounding arrogant, it would make me suspect your competence in string theory. Because the only systematic thing we know in science is to push forward. Paradigm shifts do not appear on demand.

If you were saying that MANY of the papers that appeared on the arXIv today are crap, I would agree with you. But I would still think that you are missing the point. I have looked occasionally at research in condensed matter, astrophysics/cosmology and quantum computing, and I have never felt that the ratio of quality papers is significantly less in string theory. I HAVE felt that the progress in string theory could be a little faster, but thats because I know exactly what I would LIKE to do with string theory if I had all the necessary tools, whereas in other fields the future is much more open.

21. **Peter Woit**
June 2, 2008

somebody,

My problem with string theory boils down to the ongoing problem of a refusal to evaluate what has failed and what still has promise. Sure, as in the examples you give, string theory provides interesting models for strongly coupled QFTs, and for quantum gravitational effects, and these are, among many other possible things to work on, worth looking at. But the idea of a 10/11d superstring as a model of particle physics has failed miserably, and the unwillingness to acknowledge this has created huge problems for the field, including sending parts of it down the multiverse blind alley. It increasingly seems like a waste of breath to keep pointing this out, as most have decided to ignore the problem in hopes that the LHC will make it go away. We'll see over the next few years…

I very much agree with Peter Shor that physicists should look carefully at the culture in mathematics and try and understand how it has continued to allow progress, in a context of no experiments to decide things, and of ideas that are often so abstract, demanding and understood by very few people as to make string theory look easy. It's a fascinating and not well-understood question how this culture has done as well as it has.

22. **somebody**
June 2, 2008

"But the idea of a 10/11d superstring as a model of particle physics has failed miserably, and the unwillingness to acknowledge this has created huge problems for the field, including sending parts of it down the multiverse blind alley. It increasingly seems like a waste of breath to keep pointing this out, as most have decided to ignore the problem in hopes that the LHC will make it go away. We'll see over the next few years…"

Peter, You have discussed these things many times here, so I will not start with the rehashing of what I believe are the counter-arguments. Lets just agree to disagree.

23. **Peter Orland**
June 2, 2008

I am not complaining about bad research per se. Nor am I complaing about string theory specifically (though people don't always agree as to what string theory is. At Perimeter, a talk I gave was a String Theory talk. At Brookhaven the same talk was a Nuclear Physics seminar). What I am complaining about a lack of direction, the absence of passion. People are giving talks and writing papers, but all they care about is getting their work cited. The content seems secondary.

Passion is important. Give me a bad paper, in which the author tries to solve a real problem, over a pointless correct paper any day. At least I might learn something by reading it.

Next time you are in a seminar, ask yourself what you are getting from it. Is the speaker telling you something really new about Nature/the model/the concept? Is a number calculated? Is there some new intuition about some field? Or maybe the speaker tells you that his/her research program will do one of the above? Well, in ninety percent of the talks I have been to, for more than a few years, the answer is NO.

I suppose I have now alienated everybody and destroyed my chances of future funding and invitations to speak. I better get used to my new status as a pariah. I don't know if it was worth it.

24. **Peter Woit**
June 2, 2008

"amused" requests that I add a new comment here pointing to the note I added to this comment

http://www.math.columbia.edu/~woit/wordpress/?p=696#comment-38786

to the effect that the anonymous commenter "Frank" was not him. I'm happy to oblige.

25. **Eric H**
June 3, 2008

I think its great to encourage more people to get involved in science professions and especially in the physics profession. But my personal experience, which may be unique for all I know, is that physics is very myopic in its criteria for selecting people to encourage. People like me, who are very visually oriented, can tell in a minute that a dimension you can't visualize has no meaning. Symbolic meaning in the absence of a physical correlation seems just silly to many of us. But we get discouraged from even entering the physics field because of our unexceptional mathematical ability. People that have brains that are more visually oriented can be very useful in physics.

I would say that Einstein's greatest gift was in his visual acuity and intuition and certainly not his mathematical ability. But he was very unusual in that he had "sufficient" mathematical ability to translate his visual approach into mathematics. That is very rare. People like me who feel we have something to contribute will still be shunted aside. So what is the point of putting on the World Science Festival to get people interested if the sorting method for encourageing people doesn't change to become more inclusive?

26. **Ethan Siegel**
    June 5, 2008

    An inspiring read from your colleague Brian Greene made it into the New York Times this past week…

    …and it's about the power of Science to inspire. How do we manage, while still keeping everyone in the scientific community honest about what we know, what we think we know, and what's still speculative, to be unified in our approach to raising awareness of this beautiful enterprise?

27. **Bruce Bartlett**
    June 9, 2008

    Hooray for the African Institute for Mathematical Sciences! It's great to see it make an appearance on this blog. Along with the Stellenbosch Institute for Advanced Study, there are some interesting things going on in theoretical physics in Southern Africa. In fact, blogs are the great leveller – they give an opportunity for those who have traditionally been on the sidelines to become a part of the exciting day-to-day issues and debates.

Experimental Predictions From F-Theory

I've been known to claim that string theory makes no experimental predictions, so this evening thought I better take a look at a preprint that just appeared entitled [GUTs and Exceptional Branes in F-theory – II: Experimental Predictions](). The abstract claims that to have found "a surprisingly predictive framework".

This paper is 200 pages long, and a companion to part I, which was 121 pages. For part I, there's a [posting by Jacques Distler]() that explains a bit of the very complicated algebraic geometry going on. Making one's way carefully through the entire 200 pages of the new paper looks like a very time-consuming project, so I thought I better start by identifying what the experimental predictions are. These days, one expects experimental predictions to say something about LHC physics, but I don't see anything about that in the paper. Perhaps this is because, except for some comments in section 16, it appears that the authors are studying a model with exact supersymmetry.

Looking at the introduction and conclusion sections of the paper, the only predictions I can see are for neutrino masses, and there are two of them. Either $.5 \times 10^{-2 \pm .5}$ eV or $2 \times 10^{-1 \pm 1.5}$ eV is given for the neutrino mass, with the error bars just those due to an unknown value of one of the geometrical parameters involved. There's no mention of which neutrino is being discussed, and as far as I can tell this is just an order of magnitude estimate of the neutrino mass scale, one which the author's describe as "somewhat naive", noting that "factors of 2 and π are typically beyond the level of precision which we can reliably estimate". It's unclear to me whether or not other mechanisms giving quite different neutrino masses would also fit into the author's model.

Maybe I'm missing something and an expert can help me out, but I'm not seeing anything here of the sort one would normally describe as an experimental prediction. There's certainly nothing falsifiable at all about the model, since one knows from limits on neutrino masses and measurements of oscillations that the neutrino mass scale has to very roughly be in this kind of range. Furthermore, again maybe I'm missing something, but I don't see any way in which more detailed calculation in this framework can make it any more predictive.

Update: Lubos has a detailed [posting]() about this, and from reading it, it doesn't appear that the paper has experimental predictions that I missed. I do wonder what a "musculus maximus" is…

Update: For more about this, see presentations at PASCOS 08 [here]() and [here](). The first describes this as "a modest step" in the direction of predictions, the second doesn't mention predictions at all.

Comments

1. **GR**
   June 2, 2008

   I'm a physics undergraduate who's interested in this sort of thingl… if I wanted to decide things for myself, where could I start?

   Obviously it takes many years of hard work to develop the math skills (not to mention vocabulary), but is there a reasonable introduction so I can start to understand the crazy things people talk about these days in HEP theory?

2. **GR**
   June 2, 2008

   Also, and hopefully not as off-topic as the above, the old joke comes to mind:

   Engineers are happy to get an answer to a few decimal points.
   Physicists are happy to get an answer to an order of magnitude.
   Astrophysicists are happy to get an answer to an order of magnitude in the exponent…

   Can we substitute string theorists into the punchline now?

3. **Peter Woit**
   June 2, 2008

   GR,

   Well, I wrote a whole book aimed at you, and it contains lots of recommendations for further reading.

   I don't recommend trying to understand what is going on in this kind of paper. It involves a huge amount of technical background, in both math and physics, and by the time you would be able to absorb it, LHC results almost certainly will have made it irrelevant. Study quantum field theory. It's a huge subject, and will be there in the future no matter what.

4. **Luboš Motl**
   June 3, 2008

   Dear GR, a standard textbook that introduces students to modern geometry, algebraic geometry, and similar subjects that are needed in the F-theory model building is one by Nakahara.

   Click my name, go to my blog, and a link to the amazon.com page of the book is included in the article.

   Unless you want to become a complete idiot, I recommend you to pay no attention to Peter Woit and his blog. He is just an aggressive crackpot who tries to revenge to physics for the fact that he is unable to do it himself.

5. **Gil Kalai**
   June 3, 2008

   Hi Peter, this post is related to quite a basic question in the evaluation of scientific theories, (and also related to basic issues in statistics.) According to all major philosophy of science theories, e.g., both the Popperian falsification approach and the Bayesian verification point of view, scientific theories should be judged based on their ability to predict and not based on their ability to explain known observations. Still in reality, most scientific theories were created in order to explain known observations. Predictions as well as empirical proofs based on fresh observations came much later. Trying to connect a theory to what "one already knows" while falling short of an “experimental prediction” can be of interest.

6. **Sara**
June 3, 2008

“a complete idiot”? Luckily you are an intelligent person and a very very well-brought-up man.

7. **Peter Woit**
June 3, 2008

Gil,

Sure. I’m just trying to figure out why the authors put “experimental predictions” in the title of this paper.

8. **M**
June 3, 2008

do they predict that neutrino masses are of Majorana or of Dirac type?

9. **Peter Woit**
June 3, 2008

M,

As far as I can tell they predict both, with one of their mass ranges a Dirac prediction the other Majorana.

10. **Mark**
June 3, 2008

A somewhat related thought: In the mathematics literature if you want to find out more about what the main results of a paper are you can try its mathscinet review.

Is there any kind of broad (online) database for what various physics papers predict from the outcome of proposed, as yet unconducted, experiments?

(Perhaps I should have posted this in the comments for the INSPIRE post?)

11. **Garrett**
June 3, 2008

Hi Peter,
I’ve been sitting in on some of the PASCOS 08 talks here at the Perimeter Institute this week. Cumrun Vafa gave a talk yesterday, which Perimeter already has up here:

http://www.pirsa.org/08060030/

12. **Peter Woit**
June 3, 2008

Thanks Garrett,

I see that in slides introducing his talk, Vafa agrees that string theory does not make “a verifiable quantitative prediction for the real world”, and that this work is only “a modest step in that direction.”

13. **Garbage**
June 3, 2008

I haven’t read the paper, but for one thing…it is a hep-th

Regarding SUSY, they say in the abstract:

“Communicating supersymmetry breaking to the MSSM can be elegantly realized through gauge mediation. In one scenario, the same repulsion mechanism also leads to messenger masses which are naturally much lighter than the GUT scale.”

So they do address SUSY breaking…

14. **Peter Woit**
June 3, 2008

Garbage,

If you do take a look at the paper, you’ll see that my remark that only in one section (16) do they address supersymmetry breaking, and then basically just to say that they could break supersymmetry if they wanted to.

So, I guess the idea is that on hep-th, the term “experimental prediction” means something different than elsewhere?

15. **Sanjay**
June 3, 2008

Dear GR,

In addition to Nakahara’s book, I would also recommend Tu’s Introduction to Manifolds followed by Bott and Tu’s Differential Forms in Algebraic Topology. All three are excellent and Nakahara gives a very physical picture of the mathematics. As for QFT, there is a whole range of books, but for a solid introduction look at both Zee’s Quantum Field Theory in a nutshell and Srednicki’s new QFT book. Also, Tom Banks’ new QFT book should be coming out soon.

http://www.cambridge.org/uk/catalogue/catalogue.asp?isbn=9780521850827

Good luck with your studies!

16. **Alex Mikunov**
June 3, 2008

Lubos has to stop creating paradoxes (e.g. "…I recommend you to pay no attention to Peter Woit and his blog…" while posting on the P.W.'s blog 🙂 and get back to M-theory (or whatever currently its name is). Otherwise he's really boring

17. **Peter Orland**
June 4, 2008

Dear GR,

I fear you are being led down the garden path (or whatever the hell the metaphor is) by my esteemed friends and colleagues.

If you really want to learn about theoretical particle physics (or theoretical condensed matter physics), learn quantum field theory. This means functional methods, scattering amplitudes, renormalization
and critical phenomena.

You will have to read and understand a good graduate text on quantum mechanics first. General relativity (your initials) is also useful and much easier to learn than QFT. Algebraic geometry, algebraic topology, differential topology, …. are nice, and some advanced concepts in QFT, require knowing these subjects. But they are just pleasant diversions until you know basic QFT.

18. **somebody**
June 4, 2008

While we are all giving advice: I would second Peter O.'s recommendation. Don't focus on the math. The math will come, when you need it. Same is true about GR. Learn QFT. By that I mean know everything inside Srednicki's book. Which in my opinion is the best book out there. Don't get distracted by too many books if you can help it, but this is not always easy. If you can work through Srednicki cover to cover, you are already pretty powerful. By the time you finish that, hopefully you will know what to do next yourself.

19. **Sam**
June 4, 2008

Peter, you will be pleased to learn that musculus maximus is defined at:

http://cancerweb.ncl.ac.uk/cgi-bin/omd?musculus+gluteus+maximus

I'm sure you're not shocked… 😉

20. **Aki**
June 6, 2008

"I do wonder what a "musculus maximus " is…"

Supersymmetry in human body, i guess 😉

21. **Indrajeet**
June 10, 2008

You have not written anything about the recent work of Sunil Mukhi and co. from TIFR which has "led to a mini-revolution in the theory of membranes".

22. **Brini**
June 11, 2008

Indrajeet,

this is not too much of a surprise. Woit, who hastened to write after attending a talk by Berkovits, that

"it would be pretty damn funny if it turns out that multi-loop superstring amplitudes aren't finite"

and who started an infinite blogwar against Distler on string perturbation theory a couple of years ago, has completely overlooked the recent papers by Grushevsky, Cacciatori et al on genus 4 amplitudes. He probably hasn't found them "funny" enough 🙂

Personally, I just find it more and more difficult to consider fair such a blind, biased and emotional criticism of string theory, let alone to see its scientific foundations – if any.

23. **Thomas Larsson**
June 11, 2008

Indrajeet,
You might want to have alook at this and that posts by Jacques Distler. Punchline: "That was fun while it lasted".

The Nambu bracket is a kind of Jacobiator. I don't associate with Jacobiators.

24. **Urs Schreiber**
June 11, 2008

> The Nambu bracket is a kind of Jacobiator.

I tried to make sense of a statement along these lines but was not really happy with what I got. Do you know more? I'd be interested.

25. **Peter Woit**
June 11, 2008

Indrajeet and Brini,

I keep a list on my desk of topics I'd like to write about, but haven't gotten around to for one reason or another.

One item on the list is the activity surrounding the so-called Bagger-Lampert model, a new 3d superconformal model. I haven't written about this because I don't know much about it. I haven't spent time learning more partly because I recently asked an extremely distinguished expert on the topic about what one could do with it, and he told me he wasn't aware of any really significant implications. Maybe I misunderstood him and am misrepresenting his views, but this seemed like a good time to wait a bit and see what emerges from all the current activity. Thomas's link to the latest Distler posting shows why following one piece of this, the Mukhi et. al. work, might not have been worth the time. For now, I think I'll stick to my decision to wait and see what comes out of this, if there is something really significant, many review articles will be appearing later this year. I'd of course be happy to hear from anyone who can explain more about the significance of Bagger-Lampert.

The work of Grushevsky et. al on multi-loop amplitudes is also on the list, awaiting my finding time to consult with experts and better understand its significance. My understanding right now is that a conjectured form for 3 and 4 loop amplitudes has been found that satisfies the various stringent consistency conditions one expects, but that this is not an actual derivation from the definition, but I may have this wrong.

Previous arguments on this blog were about the question of whether a proof of finiteness of super-string theory amplitudes exists. I've always said that the situation is that it is likely that these amplitudes are finite to all loops, but that this remains to be shown. People are still working on the Berkovits pure-spinor formalism, but as far as I'm aware, it still does not give a proof at higher loops. The work of Grushevsky et. al. certainly pushes the subject forward and removes some possible places a problem could turn up, but as far as I know, it also does not provide a finiteness proof.

26. **Thomas Larsson**
June 11, 2008

According to the appendix of arXiv:0712.3738v2, Andreas Gustafsson has shown that a 3-algebra is almost equivalent to a Z_2-graded Lie algebra (not a superalgebra). However, not quite, because the odd-odd-odd Jacobi identity is replaced by the "associative condition", which says that the sum of two of the terms in the Jacobi equals zero. The tri-linear product is then the third term in the would-be Jacobi identity, and thus a Jacobiator.

Hm. Or so I thought. Looking at eqns (47) and (49) again, it looks like I got some signs wrong.

Sorry if this comment strays too far from the topic of the post.

27. **Urs Schreiber**
June 11, 2008

> Looking at eqns (47) and (49)

I read (48) as saying that the Jacobi identity holds everywhere except when you feed in three elements of curly A. On them it just plain fails. Not up to some Jacobiator.

28. **Observer**
June 16, 2008

Peter,

The only reliable data on neutrino masses are the mass squared differences for solar and atmospheric neutrinos. Does the prediction of F-theory match these measurements?

29. **Peter Woit**
June 16, 2008

Observer,

I don't see a real prediction in the paper, and the authors don't compare the numbers they quote to experiment, possibly since there is no way to do this. The vague neutrino mass scale in the paper is not inconsistent with what is known about neutrinos (e.g. mass differences), if it were the authors wouldn't have pursued this.

Two Unrelated Topics

June 3, 2008
Categories: Multiverse Mania

I was planning on writing something about the field with one element, but Lieven Le Bruyn has done a better job of it than I would have, linking to all of the recent news on this subject I was aware of, and more.

Today's New York Times has an article entitled Dark, Perhaps Forever, which is summarized as "Scientists are beginning to despair of explaining the universe". It is about the recent dark energy symposium in Baltimore, and focuses on Witten's talk, which was discussed previously here. To an account of the talk itself, it adds this quote from Witten:

> As for how I feel personally, I am not sure what to say… I wasn't terribly enthusiastic the first, or even second, time I heard the proposal of a multiverse. But none of us were consulted when the universe was created.

There's no mention of the crucial issue that Rachel Bean implicitly confronted Witten with in a question at the end of his talk: if the landscape inherently can give no testable insight into physics, why should a scientist bother with it?

Other speakers at the symposium discussed possible future experiments to measure dark energy and their funding prospects. One worry is that such experiments may do little more than give a somewhat more accurate dark energy number, providing no further insight into the problem of its origin.

Comments

1. **Ethan Siegel**
   June 3, 2008

   > One worry is that such experiments may do little more than give a somewhat more accurate dark energy number, providing no further insight into the problem of its origin.

   Why do you say this is a worry? Unless they find strong evidence that dark energy is inconsistent with a cosmological constant, this is a *given*. NASA's upcoming joint dark energy mission (either SNAP, DESTINY, or ADEPT) is banking on finding something interesting, where interesting means the equation of state (w) can be determined to be something other than a cosmological constant (w=-1, with no change in w over time). It's terribly boring, but there's really no other option other than to look for this.

   Either way, we still have no idea how to account for either a cosmological constant or something different from a cosmological constant.

2. **Peter Woit**
   June 3, 2008

   Ethan,

   I was just summarizing the remarks of Steinhardt and Krauss at the end of the article. In any case, everyone agrees that there's not much to do except go do the experiment and see.

3. **John**
   June 3, 2008

   Wiltshire proposes an alternative to dark energy in arxiv.org/abs/0712.3984 , namely the interpretation that it is a measurment artefact due to the inhomogeneity of the universe. When integrated over 13700 million years, the inhomogeneity yields acceleration and all other modern observations. What has to be thought about this sort of work?

   John

4. **John Baez**
   June 4, 2008

   I wish more people understood math. Then they'd realize what the really cool part of this blog entry was!

   Thanks for the link, Peter – I hadn't seen it.

5. **Herman**
   June 4, 2008

   350 scientific instruments now on line:
   http://instrumentenzaal.teylersmuseum.nl/

6. **Peter Woit**
   June 4, 2008

   Following up on John's comment, I should mention that one of the best links to follow from Lieven's posting is this one:

   http://math.ucr.edu/home/baez/week259.html

7. **Professor R**
   June 4, 2008

   Hi Peter, this is off-topic but relevant to your campaign against hype in general, you might consider a post on it.

   The word over here in Europe is that the cold fusion controversy is back – yet more headlines on the fantastic promise of cheap energy, this time backed by an experiment at Osaka University.

   I have a posting on my blog, or you can red the original story at http://physicsworld.com/blog/2008/05/coldfusion_demonstration_a_suc.html

Cormac

8. **Peter Woit**
June 4, 2008

Cormac,

On the list of things I would like to ignore, and definitely don't want to start a discussion about here, cold fusion is right up there…

9. **Professor R**
June 4, 2008

Oops, sorry! Just wondered if you guys had heard..

10. **Ed N**
June 4, 2008

>Wiltshire proposes an alternative to dark energy in
>arxiv.org/abs/0712.3984 , namely the interpretation that it is a
>measurment artefact due to the inhomogeneity of the universe.

Edward "Rocky" Kolb of Fermilab made a similiar proposal in 2005.

http://arxiv.org/abs/astro-ph/0506534

11. **Shantanu**
June 4, 2008

Peter what do you think of Susskind's talk at the PASCOS meeting?
There area also some other string theory related talks.

12. **Peter Woit**
June 5, 2008

Shantanu,

I took a look at the Susskind slides. I still don't see any predictions of anything coming out of the multiverse scenario he is promoting.

13. **vicar**
June 5, 2008

"if the landscape inherently can give no testable insight into physics, why should a scientist bother with it?"

It is not true that the landscape "inherently can give no testable insight". cf the work of Anthony Aguirre, Matthew Kleban, and many others on the possibility of collisions of universes in the multiverse. You have had this pointed out to you *many* times. Readers can draw their own conclusions.

14. **Peter Woit**
June 5, 2008

vicar,

I have many times pointed out that, yes, it is in principle possible to construct multiverse models in which there are observable effects on our universe, for example the kind of thing that the people you mention are trying to do. There's a huge difference though between showing that one can construct such models, and showing that they have something to do with our universe.

The models typically being studied by the string theory landscape people don't have observable effects due to other universes, and it was those that Rachel Bean was asking Witten about in the question I referred to.

15. **Peter Woit**
June 5, 2008

I should also point out that the context of the quote is about the question of whether the multiverse can provide insight into why we live in one "string vacuum" rather than another, and thus explain something about particle physics. The models you refer to don't provide any such insight or explanation.

16. **somebody**
June 6, 2008

Peter, Lets assume the very real possibility that that there are indeed many ways (which cannot be resolved at current energies) to UV complete our familiar low energy physics and gravity. Is there ANY way of doing physics in that context which will keep you happy?

The way I would do physics in that context is to construct models that contain well-known low energy physics (with extra stuff at higher energies that I might or might not add depending on my prejudices), and wait for the next round of experiments. Modulo the (very important) fact that our tools are not sharp enough to give us the full control we would like to have, this is precisely what the string phenomenologists are trying. I don't understand what is the issue of PRINCIPLE that you seem to be arguing against.

There is a huge distinction to be made between understanding the multiverse, which presumably tells us about string theory, and understanding specific vacua, which could potentially tell us about OUR universe. Landscape statistics, measure issues etc. belong firmly in the first category. But model-building sits squarely in the second. The word anthropic makes some people turn to violence, but for me it is the same as fixing the vacuum from experimental input, which is what we have ALWAYS done in physics! There is nothing I understand in string theory which tells me that this is in principle impossible. The real problem is actually technical control, but stabilized string vacua are only a few years old, so its not hopeless yet.

17. **somebody**
June 6, 2008

Peter says:
"if the landscape inherently can give no testable insight into physics, why should a scientist bother with it?"

It is not the landscape that gives us predictivity, it is the individual vacua.

18. **somebody**
June 6, 2008

Let me emphasize this once more: if there are many UV completions consistent with low energy physics, then it would be inherently impossible to offer a single "prediction" for future experiments. The best one can do is to offer classes of predictions. You will need future (LHC?) experiments to pin them down further.

This is for example essentially what Vafa and collaborators did in the paper that you talked about couple of days ago, which you were unhappy with because it did not make "a" prediction.

19. **Peter Orland**
June 6, 2008

How can a vacuum be a theory? It's a solution, with some parameters. If you call it a theory, you're admitting that there is no criterion for these to be the right parameters. All you have then is a fit. Are we seriously going to call a parameter fit a theory of nature?

If it is true that fits are physics, I propose (take a moment to pause in childlike awe of Nature's works!) the Standard Lagrange Model of the universe. Give me any set of data points, I will use Lagrange's method to find a smooth function fitting those points. How beautiful that everything in the world is reduced to simple algebra. And by these ingenious method we require no more parameters than numbers to fit (in this respect it is better than some approaches). Now we finally understand how everything works.

OK, forgive my sarcasm. But seriously folks, if you want a UV completion of the Standard Model without experiments, you need a good reason to chose this completion. Renormalizability tells you that any completion is equally good – and no completion is necessary! QUALIFICATION: well the Higgs needs fine tuning and most likely has a trivial S-matrix near the Planck scale, but we'll probably never do experiments there.

20. **somebody**
June 6, 2008

>All you have then is a fit. Are we seriously going to call a parameter fit a theory
>of nature?

The difference is that for a fully stabilized vacuum to qualify as our Universe, it has to accommodate not just the finitely many experiments that have to be done in order to determine the vacuum, but also the infinitely many experiments that CAN be done afterwards. Thats how we know that we are not merely fitting curves. Incidentally, the standard model is fixed exactly in this way – except that fortunately this could be done already at currently accessible energies.

There are many crucial questions. Here is one: can we fix a vacuum in string theory by doing finitely many sub-Planckian measurements? Or do we need Planck-scale measurements? These and other questions have to be answered to make string theory useful, and string theorists are trying (or should try) to answer them. But these are serious questions and real work will be necessary to see how useful or not string theory ultimately is.

My point is that the mere existence of the landscape or multiverse or whatever you want to call it, does NOT make the theory unpredictive. That is merely a strawman argument that gets a lot of knee-jerk reactions. Almost all theories have landscapes.The weird thing is not that string theory has a landscape, but that string theorists were hoping against all reasonable hope for tens of years that there would be a unique vacuum.

>if you want a UV completion of the Standard Model without experiments,
>you need a good reason to chose this completion. Renormalizability tells
>you that any completion is equally good – and no completion is necessary!

The problem is we have something other than standard model at low energies: gravity. And string theory provides the UV completion there, but also tells us that there could be many ways to do it.

21. **Eric**
June 6, 2008

Peter O,
In a particular vacuum with all moduli stabilized , all parameters such as gauge, Yukawa couplings are fixed as these depend on the moduli. In addition, it is not possible to just construct any model you want as there are usually a host of consistency conditions that must be satisfied that strongly constrain the models. Thus, if one can find a model which describes exactly the SM in detail in its low-energy limit, then this would be a very significant discovery.

22. **Peter Orland**
June 6, 2008

Somebody,

I'm probably not going to convince you of anything in my rebuttal below. But I hope you will feel it is worth knowing that there is a rebuttal.

1. "There are many crucial questions. Here is one: can we fix a vacuum in string theory by doing finitely many sub-Planckian measurements? Or do we need Planck-scale measurements?"

Suppose you could do this. Isn't this just a parametrization consistent with string theory? And if so, how does it prove anything? I like my Lagrange Standard Model (above) better. The nation that controls Lagrange polynomials controls the universe!

2. "The weird thing is not that string theory has a landscape, but that string theorists were hoping against all reasonable hope for tens of years that there would be a unique vacuum."

I'm with David Gross on this one. Abandoning this hope means that you no longer have a theory.

3. "The problem is we have something other than standard model at low energies: gravity. And string theory provides the UV completion there, but also tells us that there could be many ways to do it."

No, it doesn't provide THE UV completion. It provides a UV completion. I happen to think (as I'm sure you do) that it is an interesting completion, but it's definitely not the only possible completion. For example, instead of a string tension as a cut-off, we could use a lattice spacing (like Regge calculus) as a completion. I am certainly not claiming that this is right, but a Regge-type lattice with lots of other fields (and Wilson terms to remove Fermion doublers) is something you can't rule out, any more than you can rule out string theory. So there are even MORE ways to do the completion.

My own view on string theory is similar to what some people said about N=8 supergravity when I was a student: String theory is worth learning because it's interesting, not because it's right.

23. **Peter Orland**
June 6, 2008

Eric,

"In a particular vacuum with all moduli stabilized , all parameters such as gauge, Yukawa couplings are fixed as these depend on the moduli. In addition, it is not possible to just construct any model you want as there are usually a host of consistency conditions that must be satisfied that strongly constrain the models. Thus, if one can find a model which describes exactly the SM in detail in its low-energy limit, then this would be a very significant discovery."

Well, there are a host of consistency conditions on any model you use to fit data. As I said to Somebody, let's all finally admit that the world is just a Lagrange polynomials. Sorry, but fits are not physics.

24. **Peter Woit**
June 6, 2008

somebody, etc…

I don't think it's possible to have a sensible discussion about this, except by looking carefully at actual attempts to construct string theory vacua. This is why I wrote the earlier posting about the claims to get predictions out of an F-theory construction. My argument is not that having lots of string theory vacua inherently makes it impossible to test, but that you have to examine what these vacua look like and see what can be gotten out of them.

Sure, it's possible to imagine a string theory vacuum construction that, given some experimental input, is predictive and testable. Problem is, people have been trying to do this for almost 25 years, and have gotten nowhere. Take a look at the F-theory paper. Taking as input everything we know about particle physics, and engaging in 300 + pages of complex constructions, the end result is a vague claim about the neutrino mass scale, that it is more or less where we already know it is. 25 years of this kind of thing is exactly what you would predict would happen if people pursue a wrong idea and refuse to stop.

Similarly, going on about how string theory completely stabilizes all moduli, making, for each vacuum state, precise testable predictions about SM parameters is just pure hype. That's a dream about what some people would like to be true, not the current state of string theory. If people want to pursue that dream, fine, but they should acknowledge that they are nowhere near this, and that the current state of the subject gives no reason to believe that even if you could do such calculations, they would turn out to be predictive and explain anything about particle physics.

25. **Eric**
June 6, 2008

"Similarly, going on about how string theory completely stabilizes all moduli, making, for each vacuum state, precise testable predictions about SM parameters is just pure hype. That's a dream about what some people would like to be true, not the current state of string theory."

Actually, this isn't hype, this is in fact the current state of string theory, as moduli stabilization has been a very important area of research for the last 10 years or so. It is really only a matter of time before a specific model is found which completely describes the SM and for which all moduli are stabilized. Progress in physics goes on despite the Woit's of the world.

26. **Peter Orland**
June 6, 2008

Eric,

"Actually, this isn't hype, this is in fact the current state of string theory, as moduli stabilization has been a very important area of research for the last 10 years or so. It is really only a matter of time before a specific model is found which completely describes the SM and for which all moduli are stabilized. Progress in physics goes on despite the Woit's of the world."

In other words, it is only a matter of time before string theorists find a fit. See my remarks above.

27. **Eric**
June 6, 2008

Peter O.,
No, once the moduli are stabilized there no free parameters. Thus, all physical parameters are determined dynamically. This is quite different than just finding a fit.

28. **somebody**
June 6, 2008

> In other words, it is only a matter of time before string
> theorists find a fit. See my remarks above.

I explained to you very clearly why it is not just a "fit". Because once you fit a vacuum every new experiment is a prediction. Why do you not acknowledge this issue and keep repeating your original, misinformed statements again and again?

What I find strange is that the critics are NOT attacking the weaknesses of string theory, which are real!!! There are two issues here. One is the construction of standard model-like vacua, which as Eric emphasized to you is a difficult problem, which has not yet been fully solved. The second is the issue of the landscape (which was what I was talking about), which is that we expect that there will be many vacua which can reproduce the standard model, once we construct ONE. Can you see all the leaps of faith employed by the string partisans here? Why are you not attacking those (relevant) issues?

Frustratingly, you seem to be not getting any of these subtleties and just keep repeating your irrelevant soundbites again and again. I apologize to Peter (Woit) if I sound a bit harsh.

29. **Peter Orland**
June 6, 2008

Sorry Eric. I don't get it.

You need to chose moduli, i.e. a vacuum. This is designed to fit your data. Then you want to use this vacuum to make predictions. If there is a unique choice of moduli (this strikes me as unlikely), you are fixing these moduli as parameters. If the choice of moduli isn't unique, you will simply have more parameters than you need (but okay, maybe there are some unique predictions within this parameter set).

Here is my question. How is this better than using any method to fit data by some function. My joke about the Lagrange Standard Model aside, any fitting method will make predictions. Don't say it's because it comes from string theory. You have to do better than that.

30. **Peter Orland**
June 6, 2008

Somebody,

"I explained to you very clearly why it is not just a "fit". Because once you fit a vacuum every new experiment is a prediction. Why do you not acknowledge this issue and keep repeating your original, misinformed statements again and again?"

This is why we fit data by functions. Experimentalists do it all the time. Once this is done we can make predictions. For example, we might try to fit some data by a straight line using a chi-squared fit, or we fit data by a Lagrange polynomial fit. But it doesn't mean we have a correct theory. I asked Eric above why choosing moduli to fit data is better. If the answer is "because we like this way of doing things, since it comes from string theory", it just isn't good enough.

31. **Peter Orland**
June 6, 2008

Let me put it another way. You fit data by a string vacuum. I fit it by Lagrange polynomials. We can both make predictions, and since we have both parametrized the data by smooth functions, they won't differ very much. Why is your method better?

32. **Eric**
June 6, 2008

Peter O,
The moduli are not 'chosen', they are determined dynamically by a potential which is generated by turning on fluxes or other non-perturbative effects. For a particular construction, the fluxes are generally tightly constrained by consistency conditions. For example, in Type II vacua the flux is constrained by tadpole equations as well as supersymmetry conditions.

33. **somebody**
June 6, 2008

> This is why we fit data by functions. Experimentalists do it all the
> time. Once this is done we can make predictions. For example, we
> might try to fit some data by a straight line using a chi-squared
> fit, or we fit data by a Lagrange polynomial fit. But it doesn't
> mean we have a correct theory.

Of course it does! If the next experiment tells you that the data lies on the same straight line, your straight line theory was correct! The only difference in high energy physics is that the fit that you are trying to make is so involved that there is a whole subculture called "theory" that is devoted to it. This is ALL there is to theory. You might want something more grandiose, but there isn't anything more grandiose.

The real subtlety is that the thing that you are trying to fit is NOT always a straightline. There are many comlicated things that you are trying to fit at the same time. But apart from that "technical" issue, the analogy works.

34. **Peter Orland**
June 6, 2008

"The moduli are not 'chosen', they are determined dynamically by a potential which is generated by turning on fluxes or other non-perturbative effects."

Wait a minute, the moduli are determined?…this negates the whole idea of the landscape…

But I think you mean that there are consistency conditions on the choice of moduli, which have to do with things like p-form fluxes. Just as a Lagrange polynomial used to to fit data is constrained by the assumption that it IS a polynomial. Any method used to parametrize data will have its own idiosyncracies. But the results will only be a little different, assuming Nature likes smooth functions. So I ask again: why is your method better?

35. **somebody**
June 6, 2008

> You fit data by a string vacuum. I fit it by Lagrange polynomials.

I would like to see you fit all the high energy experiments for for example the standard model, by a spline fit. Its not one set of data that you have to fit, but every possible sets of data.

36. **Peter Orland**
June 6, 2008

"If the next experiment tells you that the data lies on the same straight line, your straight line theory was correct!"

No! A straight line is not a theory. It is just a fit (NOW am I getting through?).

"The real subtlety is that the thing that you are trying to fit is NOT always a straightline. There are many comlicated things that you are trying to fit at the same time. But apart from that "technical" issue, the analogy works."

OK, so don't fit with a straight line. Use a Lagrange polynomial. You can fit anything this way. Why is your way better?

37. **Peter Orland**
June 6, 2008

"I would like to see you fit all the high energy experiments for for example the standard model, by a spline fit. Its not one set of data that you have to fit, but every possible sets of data."

I'm sorry, but I can fit anything with a Lagrange polynomial, no matter how much data you give me (assuming I was a good enough programmer). Why are the moduli (constrained by whatever nonperturbative effects you want) better than the coefficients of this polynomial?

38. **somebody**
June 6, 2008

Peter O., a theory is useful because it can fit all data. If there is a finite number of experiments you can do and then predict EVERY single new experiment in our Universe, you will have the final theory. If you can some up with it, by curve-fitting if you will, thats all you need. In any event, this discussion is beyond ridiculous now and Peter (W.) is probably going to get upset, so unless there is something new you have to say…

39. **Peter Orland**
June 6, 2008

No, no, I said what I have to say. I am happier than a pig in &^%&%&^$# that you finally agree that what people are doing with the landscape is curve fitting. What we disagree about is whether that constitutes a physical theory. I say it doesn't.

40. **Peter Woit**
June 6, 2008

Ummm, maybe enough about this particular point, OK?

What I've found in discussions here is that abstract arguments tend to degenerate, because string theory advocates point to the most optimistically possible situation that doesn't completely violate the rules of logic, and, by this measure, sure you can't rule out string vacua scenarios. That's not the measure usually used to evaluate a research program though, which is results achieved so far, and ones which seem plausibly achievable considering how things have been going recently.

41. **Peter Orland**
June 6, 2008

Sorry to let this argument continue for so long Peter. I believe, however, that is goes to the very core of the value of the landscape and that somebody, Eric and I performed a useful service is illuminating the issue.

42. **Eric**
June 6, 2008

"Wait a minute, the moduli are determined?…this negates the whole idea of the landscape…"

No, the landscape emerges because there are many different models with differerent gauge groups and matter content for which the moduli may be stabilized rather than just a single model which is unique.

43. **anon.**
June 6, 2008

Eric, that's exactly the same thing as saying that moduli can't be determined. I.e. the reason you can't determine string theory moduli (to allow checkable predictions to be made from string theory) using the 19 empirical standard model parameters is precisely because string 'theory' isn't a unique theory, but is instead a collection of a vast number of different models. So the inability to determine moduli is the same thing as having a landscape. Any theory with a collection of parameters that can be empirically constrained to no less than 10^500 possibilities, then that's identical to having a landscape size of that magnitude.

44. **Peter Orland**
June 6, 2008

Er, Peter is going to mad at me. But Eric, so what? The acceptable moduli are discrete rather than continuous. But there are so many choices that they might as well be continuous. Just curve-fitting.

OK, this is my last word. Eric, blast away in my absence.

45. **Peter Woit**
June 6, 2008

Sorry folks, anything else on this point will have to be insightful and brilliant beyond words for me to not delete it.

46. **Andrew Mayo**
June 29, 2008

If you will pardon this interjection from a purely lay perspective, and focussing for a moment on the New York Times article, then is Witten's perspective – or indeed, that of physicists collectively – really one of 'despair'.

In reading Peter's brilliant book, Witten comes across as a rare figure in the modern landscape; a man with an eclectically wide range of interests who uses these to synthesise new viewpoints.

In many ways this seems to me to be similar to Einstein's world view; he considered the physical world from many disparate viewpoints in order to construct a new understanding of space and time.

If eminent figures such as Witten are now starting to consider the physical landscape from an anthropic perspective – and just setting aside for a moment the instinctive revulsion many people have towards this approach – isn't this simply a sign of a brilliant mind exploring a different perspective simply to see if it yields results, rather than an abandonment of the scientific principle?. Certainly this doesn't seem like an act of despair.

Although Peter Woit has – quite understandably – expressed negativity regarding this approach – it does, after all, smack of some kind of recursive navel-gazing – it does seem to lead to some interesting lines of inquiry.

Most obviously, we can take the 20-something arbitrary parameters of the standard model and adjust each one by a small amount to see what the outcome is with regard to the evolution of the universe (e.g nucleosynthesis etc). Some parameters will presumably be more sensitive than others. Suppose it turns out there are some fantastically huge number of possible universes, say, with no matter as we understand it at all, only photons, some lesser number with – perhaps – photons and leptons – a smaller number again with fermions as well. And so on down to the universe containing only hydrogen, etc. etc. (or must all possible universes contain all the fundamental families of particle in the standard model, an interesting question in its own right, I'd have thought).

Then – and I think this is the spirit in which Witten is proceeding – let's assume our observable universe is potentially a 'bubble' evolving from some alternate universe in which the laws of physics differ. We assume some probable alternative configuration based on our adjustment of the standard model parameters and then we calculate, for example, how our universe might evolve and expand from its parent. (would it, for instance, be possible to show that such expansion would accelerate and if so under what circumstances?).

Now this could be dismissed as crackpot science but there are testable hypotheses here, are they not, so it sounds to me like science. Certainly it involves entertaining some rather speculative hypotheses as a starting point, but how is this different from Einstein imagining what an observer 'sitting on a photon' would see, which appears to be his starting point for his exploration of relativity. At the time, there must have been many of his fellow physicists who at first thought his views untenable.

Hints of ‘time before Big Bang’

June 8, 2008
Categories: Multiverse Mania

The BBC is running a story entitled Hints of ‘time before Big Bang’ based on Sean Carroll’s latest efforts to promote the multiverse. The writer attended Sean’s talk at the recent AAS meeting and presumably also read Sean’s new Scientific American article, and here’s what he got out of them:

> A team of physicists has claimed that our view of the early Universe may contain the signature of a time before the Big Bang…
>
> Their model may help explain why we experience time moving in a straight line from yesterday into tomorrow…
>
> Their model suggests that new universes could be created spontaneously from apparently empty space. From inside the parent universe, the event would be surprisingly unspectacular.
>
> Describing the team’s work at a meeting of the American Astronomical Society (AAS) in St Louis, Missouri, co-author Professor Sean Carroll explained that “a universe could form inside this room and we’d never know”.
>
> The inspiration for their theory isn’t just an explanation for the Big Bang our Universe experienced 13.7 billion years ago, but lies in an attempt to explain one of the largest mysteries in physics – why time seems to move in one direction…
>
> “Every time you break an egg or spill a glass of water you’re learning about the Big Bang,” Professor Carroll explained…
>
> If the Caltech team’s work is correct, we may already have the first information about what came before our own Universe.

Besides the “Does Time Run Backwards in Other Universes?” material from his paper with Jennifer Chen discussed in Scientific American, what’s new here is his recent paper with two Caltech collaborators about the possibility of explaining an asymmetry of marginal statistical significance observed in the CMB by invoking a more complicated version of inflation, adding a “curvaton” field to the usual inflaton. In their model, this asymmetry comes from a perturbation to the curvaton field of size larger than the horizon. Such a thing could in principle make testable predictions, but doesn’t necessarily come from the existence of a multiverse or tell us anything about it. The authors throw in one clause of a sentence about how it might occur as

> a remnant of the pre-inflationary epoch or as a signature of superhorizon curvaton-web structures.

and that’s the basis of the BBC article. I have no idea what’s going on with the business about universes forming inside of rooms and us not knowing anything about this.

Sean gives more details about this in a new blog posting.

Update: The author of the piece, Chris Lintott, has a blog, and a posting about the article, where he writes:

> What made me want to write the story in the first place, though, was exactly what Sean said above – to an outsider to the field the idea that it is even imaginable that we might be able to make concrete predictions from ideas about multiverses which have haunted the pages of New Scientist and its ilk for decades is stunning. That’s what I wanted to get across.

He doesn’t seem to realize that there’s nothing here different than the things he’s thinking of that “have haunted the pages of New Scientist and its ilk for decades.”

Update: This story is getting the full media treatment, including haunting the pages of New Scientist, which has the sense to strip out the nonsense and hype about the multiverse and the arrow of time. Slashdot emphasizes the part about:

> Describing the team’s work at a meeting of the American Astronomical Society (AAS) in St Louis, Missouri, co-author Professor Sean Carroll explained that ‘a universe could form inside this room and we’d never know.'”

Comments

1. **anon.**
   June 9, 2008

   ‘I have no idea what’s going on with the business about universes forming inside of rooms and us not knowing anything about this.’

   If time is going backwards in the universes that form in your room, they will instantly disappear into the past, so you can’t see them.

2. **Peter Woit**
   June 9, 2008

   anon.

   Thanks, I was having trouble figuring that one out.

3. **hmmm**
   June 9, 2008

   I wonder how many unobservable universes will be produced at CERN.

4. **Chris**
   June 9, 2008

   Thanks for the link. Sean in his talk made a possible connection between pre-inflationary structure and the observations contained in the paper. As you say

   “Such a thing could in principle make testable predictions, but doesn’t necessarily come from the existence of a multiverse or tell us anything about it.”

   The ‘could in principle’ was new to me as an astronomer, not a cosmologist, and I thought that was worth writing about. Perhaps these ideas have been floating for a while, but it was the first time I’ve heard a talk that directly suggested we could – even in principle – hope to probe pre-inflationary structure. That’s a better and more interesting story than the classic multiverse with no observable consequences which I was unfairly throwing at New Scientist.

If that’s common knowledge among those who work in this field, then you should all shout louder.

5. **Jayvee**
June 9, 2008

    According to this week’s New Scientist, Benjamin Wandelt has discovered the non-gaussianities that Sean is looking for in the cosmic microwave background.

6. **Peter Shor**
June 9, 2008

    anon says “If time is going backwards in the universes that form in your room, they will instantly disappear into the past, so you can’t see them.”

    I don’t understand. If there are backwards-going universes that are currently forming in my room, won’t I remember them having been there yesterday?

7. **wolfgang**
June 9, 2008

    > If there are backwards-going universes that are currently forming in my room, won’t I remember them having been there yesterday?

    No. you would remember that they have been there tomorrow 😎

8. **jpd**
June 10, 2008

    i think the tense you want is “will have been”

9. **Christine**
June 10, 2008

    Meanwhile…

10. **Thor**
June 10, 2008

    Perhaps there are many universes, each with it’s own point of origin or big bang like expanding soap bubbles. And spots inbetween where matter from different big bangs gather in massive black holes. Then when each of those black holes reaches some critical point or some other criteria it explodes with a big bang, forming a new universe. That’s my theory at lest.
    Note that scientists can only inspect the universe to the degree their equipment allows, and the universe is hugenormous.

11. **Amos**
June 10, 2008

    “If time is going backwards in the universes that form in your room, they will instantly disappear into the past, so you can’t see them.”

    Wouldn’t this violate the conservation of… like everything?

12. **M.Wang**
June 10, 2008

    The host really makes the paper sound like lame beyond belief. Does anyone have a rational retort, i.e. an argument why this line of research should not be dismissed off-hand as meaningless mumble-jumble?

13. **Sakura-chan**

    “Never understimate the power of Human Stupidity in large groups [science challenged journalists]”
    — anonymous

    A good example is a post by Joanne @Cosmicvariance

    > My senior science teacher summed it up best by saying `**What you said was probably correct, but it’s not what you say to a newspaper reporter.’ That’s when I should have learned to be careful with reporters.**
    >
    > Two weeks ago, it happened again. The good folks in the SLAC publicity office are starting a feature where every few weeks a piece of work from the SLAC theory group will be highlighted. Great idea, I thought! I was the first guinea pig and was asked to do an interview for an article on a paper I wrote last Spring. The work was cute, has a catchy title, and is published in Physical Review Letters, but is not going to change life on earth as we know it. The article was to be for the internal SLAC newsletter TIP (The Interaction Point) and would also make a brief appearance on SLAC Today, the daily newsboard for the SLAC community.
    > …
    > Next thing I knew, the headline
    >
    > SLAC Physicists Develop Test for String Theory
    >
    > was emblazened on the main SLAC homepage! Then Peter Woit of Not Even Wrong lashed onto it. Then it was picked up by PhysOrg.com, which was subsequently featured by Slashdot. All with a smiling picture of yours truly, supposedly devising a definitive test for all of string theory. AARGH!!!!
    >
    > **The entire article was misrepresented, blown up out of proportion, and I could not have been more upset. Nothing against the good folks at the**

> **communications office at SLAC – we worked on this together and none of us saw this coming. Nonetheless, I did not have a good week.**
>
> The remedy? We posted comments on all the blogs and revised the article to include the scientific details which then put our work into proper context.

I recall P. Woit & Bee complaining (rightfully) about poor Science coverage in media, e.g. New Scientist.

Why do you keep pandering to these idiots?

The physics blogosphere needs to realize that blogs can be used for Journalism (Content/Distribution model). You no longer have to use a [science-challenged] journalist as an intermediary to the Media (Standard Model of TV, newspaper, etc). You Can Do It Yourself.

It's trivial to setup an RSS feed to iTunes (from WordPress, Blogger blog), & blog with video. There are solutions out there which will automatically set you up with an iTunes video-podcast. Presto..YOU are a scientist reporting the Science News as It Should!! Over the iTunes portal (with its powerful search engine), which has numerous distribution points: iPod/iPhone (mobile media device..over a hundred million units), AppleTV (living room set top box, reaching the public in the comfort of their living room), Internet (embedded Flash or Quicktime videos, i.e. Internet website). See for example:

http://strings07.blogspot.com
[search in iTunes using "physics", "string theory", "lisa randall", etc]

Based on my multimedia project, I've tried to encourage physicists to video-blog, to no avail (here, Backreaction, Arcadian Functor, CV). I know the mentality (since I am guilty of it myself): "It is illogical for Technical types to use an emotional argument".

"Facts Tell, Stories SELL"
— marketing pots&pans, auto-racing, etc

Scientists fall into the trap of using Facts to "sell" to the public, when in fact they should be "telling a story". In a sense, this is what S. Carroll is doing: he's "weaving a [fairy] tale". The G. Lisi publicity (Next Einstein, surfer dude, et al) is the correct strategy..which is widely criticized in the Physics community!! Take the JPL Rover mission, geophysicist Dr. M. Golembeck was considered "the story" (because of his **personality**: boyish looks & enthusiasm).

At least L. Motl/TRF embraces extensive use of Youtube videos in his blogging (Youtube is a video-sharing service).

L. Motl/TRF ("End of Science"):

> **Nevertheless, the author of the stupidity from 1997, after those ten years that have demonstrated that his stupidity is among the greatest stupidities that have ever been pronounced by homo sapiens, has the stomach to come in front of a conference in Portugal and repeat the same stupidity.**
>
> How is it possible? Well, it is because there are almost no people who would be pointing their fingers at this – very politely speaking – intellectual shit that keeps on contaminating the public sphere. That's why the likes of Horgan keep on thriving. If we allow them to thrive, they can indeed force science to end on a sunny day in the future. This is the only way how science could possible end. Let's not allow it.

Lumo is 1 of the few physicists "starring" in their own Youtube productions, a Tom & Jerry rendition (entertainment). Max Tegmark recently did a musical skit for his MIT class.

A) Information
physics, etc

B) Entertainment
"the sizzle sells the steak" as the saying goes. Looks, musical ability, personality (incl strange behavior), etc.

The flawed reasoning by HEP community (which is the cause of the Fiscal 2008 crisis) is that they are selling A), instead of A+B. I.e., they need a mult-dimensional model (call it a "multiverse" of solutions) for marketing to the masses. That's how NASCAR (a geographically niche, gear-head techno thing) made their breakthrough to the masses (leapt past Baseball as the No 2 sport in USA!!??). There are enough physicist baseball fans (Joanne, et al) to understand the enormity of this. Simlarly, Formula 1 (auto racing) is the No 1 watched sport in the World (exceeding Soccer).

"Life's a Stage"
— Shakespeare

S. Carroll/CV understands this, & that is exactly what he's doing: "pulling an act" (marketing his research) for the Media. He had a long post about how to "play the game" in Academia: "suck it up" (Bee & others found it somewhat offensive)

"People don't buy Good Products [research], they buy GOOD MARKETING"
— business saying

Physics is not that different from the Business World. You have a product, you have to sell it, you have to get funding. "You have to learn to sell yourself" (advice given to Bee by her advisor). Here's an example from Caltech/IPAC:

from Kip Thorne's PhD student (who works at IPAC):

1) He who has the Gold..rules
funding issues

2) Schmoozing & Salesmanship are important
marketing/sales, aka "kissing a**" as per M. Franklin/Harvard

3) Dealing with Difficult people
"Suppose you were an idiot, suppose you were a Congressman..but I repeat myself"/Mark Twain

Face it, we live in an Imperfect World. Deal with it (or not).

Guess what? There is a "sleeping giant" & it's Kea..she's the key to a Physics marketing breakthrough. L. Randall is 2nd. Hint: extreme outdoorsmanship & survival. Perfect subject matter for media coverage: TV, movie, etc. I've recently been contacted by National Geographic documentary (I know the chief illustrations editor), chief of ABC prime-time programming, BBC Documentary. Hit them up with proposals.

15. **Eric H**

June 11, 2008

Joe,
Your comments about becoming a better showman put me into a cold sweat. I don't think the answer to the ignoramuses promoting multiverses inside a coffee cup is to fight fire with fire. For one thing, many of the best minds that go into science fields go there because because they have a basically reflective temperament. They don't want to stir up the atmosphere around them so much that they can no longer be objective in their own thinking. This problem always comes with being too publicly pushy in one's ideas. Once your name is firmly established in the public mind with a specific point of view, it is very difficult to unwed yourself from it. People with a more humble and denigrating temperament – i.e. the best people in science – know this. They know that, even with a great preponderance of evidence in their favor, that the future can be somewhat unpenatrable.

The problem is that the worst people in science, and for that matter in general, have no such problem. They go along quite swimmingly with any change that proves they have been alarmingly wrong. And like politicians and neo-conservatives declare that they secretly suspected the new information all along – no shame and no regret to their prior public declarations. Maybe you want to try to compete with those kind of people in that kind of salesmanship but I sure wouldn't attempt it. I'd feel sort of dirty.

16. **ProfM**
June 12, 2008

Peter,

Why do you allow this meaningless, offensive and irrelevant exchange of opinions to take place on your blog? The last two entries are good examples. These pathetic conversations have nothing to do at all with the issue of testability in String Theory!
People enter your blog to be educated but they are turned away by significant loud noise and mumble-jumble.

I know that you are going to delete my message right away. But you cannot hide the truth!

17. **Tony Smith**
June 12, 2008

Adrienne Erickcek, Marc Kamionkowski, and Sean Carroll (all of Caltech)
in arXiv 0806.0377 astro-ph said:
"… there is an anomaly in the CMB: measurements from the Wilkinson Microwave Anisotropy Probe (WMAP) indicate that the temperature-fluctuation amplitude is larger, by roughly 10%, in one hemisphere than in the other. This power asymmetry occurs at the 99% C.L. …
the observed CMB fluctuations … appear to be modulated by a dipole …
More precisely, the fluctuation amplitude in one half of the Universe is higher, by about 10%, than in the other half …
it cannot be attributed to any known astrophysical foreground or experimental artifact.
This asymmetry has gone largely unnoticed
(as opposed to the "axis of evil", an apparent alignment of only the lowest multipole moments) …".

However,
in a 2006 Physics Nobel Prize powerpoint (slide 17) at
http://www.nat.vu.nl/~mulders/Nobelprize-2006.ppt
Piet Mulders said, about the work of Mather and Smoot:

"… COBE and WMAP … A dipole effect corresponding to the motion of Earth with respect to CMB rest frame (about 600 km/s) …".

Is there any reason to reject the explanation of such a dipole asymmetry by "the motion of Earth with respect to the CMB rest frame"?

Tony Smith

18. **Christine**
June 13, 2008

Tony Smith,

I could be mistaken, but Isn't the CMB dipole anisotropy about two orders of magnitude above the other CMB anisotropies? Those authors do not appear to be talking about the amplitude of CMB dipole per se, but a 10% fluctuation of it.

19. **Tony Smith**
June 13, 2008

Christine, thanks for explaining to me that "Those authors … appear to be talking … about a 10% fluctuation of … CMB dipole …".

Does that mean that there are 3 relevant axes ?

dipole axis of amplitude – due to motion with respect to the Cosmic Microwave Background. – according to astro-ph/0302207 (First Year WMAP) "… COBE determined the dipole amplitude is 3.353 +/- 0.024 mK in the direction (l, b) = (264.26 degrees +/- 0.33 degrees, 48.22 degrees +/- 0.13 degrees),
where l is Galactic longitude and b is Galactic latitude …".

dipole axis of fluctuations – according to astro-ph/0701089 (Hemispherical power asymmetry) "… in Bayesian terms, the log-evidence difference is about 1.5 to 1.8, corresponding to odds of one to five or six. … Thus, there is still a chance that the effect may be a fluke, and most likely, this will remain the situation until Planck provides new data in some five years …
The best-fit modulation dipole axis points toward (l, b) = (225 degrees, –27 degrees) …
much effort has been spent by theorists on providing possible
physical explanations …
e.g.,
second order gravitational effects from local inhomogeneities – Tomita 2005;
the presence of local voids – Inoue and Silk 2006 …",

quadrupole/octupole axis (axis of evil) – according to astro-ph/0302496 (cleaned CMB map from WMAP) "… The preferred axes … for the quadrupole and octopole … are … both roughly in the direction of (l, b) = (–110 degrees, 60 degrees) in Virgo …".

So, is it fair to say that:
the dipole axis of fluctuation as of now is hard to distinguish from an irrelevant fluke;

and
even if it might turn out to be real,
it might be explainable in conventional physics terms, including but not necessarily limited to those described by:

Tomita (astro-ph/0505157) "… The present state of our universe is … locally complicated and associated with nonlinear behavior on various scales, and so the observed quantities of CMB anisotropies may include some small effects caused by large-scale local inhomogeneities through nonlinear process. … there is a non-trivial north-south asymmetry in various quantities about CMB anisotropies … based on the relativistic second-order theory of perturbations in nonzero-/\ flat cosmological models … and on the second-order formula of CMB anisotropies … it is found that there is a possibility to explain the small north-south asymmetry of CMB anisotropies …".

Inoue (0710.2404 (astro-ph)) "… various types of anomalies have been reported after the release the WMAP data … an asymmetry in the large-angle power between opposite hemispheres … Inoue and Silk 2006 … explored the possibility that the CMB is affected by a small number
of compensated local dust-filled voids … The Shapley supercluster
(SCC) is near the tangential point of the two local large voids. The mysterious correlation with the ecliptic plane can be explained naturally because the ecliptic plane is by chance tangential to the CMB dipole that originates from a mass concentration around the SCC …".

"… dipole axis of amplitude – due to motion with respect to the Cosmic Microwave Background. – according to astro-ph/0302207 (First Year WMAP) "… COBE determined the dipole amplitude is 3.353 +/- 0.024 mK in the direction …"."

'Dipole axis of amplitude' is a very polite euphemism for this massive +/- 3mK cosine anistrophy in the CBR, compared to the original name given by discoverer R. A. Muller in his Scientific American article (v238, May 1978, pp. 64-74): see http://adsabs.harvard.edu/abs/1978SciAm.238…64M

(If the CMB is used to establish a reference frame for motion, this anistrophy indicates absolute motion with respect to that frame.)

Tony et. al.

Please, a much better place to discuss the technical details of Sean's paper would be at his blog posting on the topic.

22. **Pradeep**
June 14, 2008

"a universe could form inside this room and we'd never know"

I am an engineer by profession and working towards a PhD. My advisor would throw me out if I propose any explanation of any experiment and not substantiate it with numbers/logical arguments/predictions about how to go further about the experiment.

I have an avid interest in the way physics (I don't say "theoretical"..after all, this distinction of subject into theory and experiment is really meaningless…both have to go hand in hand) is going. The way I look at the claims and hype about stuff like multiverse, string theory, brane world and so on… is getting really disgusting.

If I had made a statement as the one quoted above, my advisor would throw me out of PhD programme telling me I am a crackpot.
And string theory and its ilk has continued to occupy center stage for ~30 years without someone calling them crackpots baffles me!

I think Feynman's dictum that the experiment is the only test of theories summarizes all that is wrong with string theory and it's variants.

PS: I was made aware of the "dark side" of string theorists by this blog and I thank Peter for calling spade a spade (or crackpot theory as crackpot theory)!

23. **Christine**
June 14, 2008

"a universe could form inside this room and we'd never know"

When I read this I thought: this only deserves a cartoon. What else?? That's why I draw it in 5 minutes in my paintbrush and posted on my blog as a comedy. Reminds me of when kids swear that they saw things that don't exist. Actually, I was not really very fair to it. My kid asks far more relevant scientific questions than that silly statement.

I don't have the willingness or energy to debate that claim scientifically, even because it's not scientific to start with. It's difficult to understand how a scientist would ever think this is scientific and spend his/her time with it. And having it published, if that is/will be the case, is beyond my comprehension.

I usually am not so harsh and try to have an open mind. But everything has limits and I'm really getting tired of these multiverses & co.

24. **Peter Woit**
June 14, 2008

Pradeep,

"string theory" is a very big subject, and it's extremely unfair to dismiss it all as "crackpot". Unfortunately some parts of string theory (and parts of cosmology having little to do with string theory) have taken a turn towards pseudo-science, but I think the people promoting this are very much a minority in the subject. It would be in the interest of serious physicists working in string theory and cosmology to take a more active role in making it clear to the public what is pseudo-science and what isn't. By not doing this, I think they are damaging the credibility of their field, with the whole thing getting tarred as "crackpot".

25. **Eric H**
June 14, 2008

Peter,

I agree with your assessment of the need for pointing out more publicly what is pseudoscience and what is not. There is a definite need to call out publicly the wackiness of some of these ideas. I hope you and others understand that what I was saying earlier about the problem with public promotion refered to excessive pushing of "one's own theories". I think a lot of the problem with string theory and multiverses originated from that human frailty of need for recognition at the expense of truth and logic. In a way you could say that kind of human sociology produced string theory and the trendiness in physics that went with it, and not the other way around.

26. **somebody**
June 14, 2008

Pradeep says:
"I think Feynman's dictum that the experiment is the only test of theories summarizes all that is wrong with string theory and it's variants."

The tragedy of string theory (and in fact theoretical physics in general today) is that the really interesting questions that we want answers for, are currently way outside our experimental capabilities. To answer essentially all the questions to which we have experimental access, standard model plus Einstein gravity is perfectly enough. But unfortunately(?) human curiosity does not end where our experimental capabilities end. The difficult question is where does the deadly combination of curiosity + lack of experiments turn into mathematical masturbation.

When you attack a caricature of this problem (like "no experiments yet, so kill strings"), it is easy to come up with simple answers to this difficult question like you did. But on the other hand, if we take the hints from particle physics and gravity seriously, we are lead to an enormous and (surprisingly) consistent mathematical structure called string theory. Should we take this structure seriously in the interim, or should we not do anything because we have no experiments (yet)?

Of course, most of the criticisms against string theory come from people like you who are (admittedly) ignorant about these hints. So any debate of this form almost always degenerates to frustration for the defender of string theory. I see no way even in principle to show you my side of the argument. And when I say this, I am called arrogant.

Incidentally, your advisor is perfectly right to kick you out of the department if your model does not tie up with experiments. Because you HAVE experiments. Everything you ever do (if you are anything other than a reactor engineer or something) MUST be prefectly understood within the context of electromagnetism. This does not mean that what you are interested in is useless, but it does mean that what you are interested in is merely a detail from the perspective of someone interested in more fundamental things. But there are people who want to see beyond E&M, the standard model and all the way to gravity. I am sorry to be rough, but I see no way but to point out the difference in perspective when faced with such hostility.

In any event, as everyone knows, we string theorists do face the possibility that we are victims in an unfortunate age trying to delude ourselves. But even then, I see no reason for your hostility. If you do not like what we are trying to do, think of us as something like half-mathematicians. We only take up as much academic resources as them.

The fact of the matter is that string theory IS fascinating. That is the bottomline at the moment.

27. **somebody**
June 14, 2008

Just to point out one historical fact: the whole idea of the multiverse in the sense of eternal inflation has been there long before string theorists stumbled across it via independent arguments. And Sean is a cosmologist.

So even if the idea was flack-worthy, …

28. **Chip Neville**
June 14, 2008

Peter,

You are right when you say in your June 14th reply to Pradeep, "It would be in the interest of serious physicists working in string theory and cosmology to take a more active role in making it clear to the public what is pseudo-science and what isn't", and you are right when you criticize Scientific American and other popular science publications for hyping speculative ideas without warning readers of their speculative nature. But perhaps you will be cheered up by the Letters section of the June issue of Scientific American, the very same one containing Sean's article, where a reader asks: "Are any experiments planned for the LHC that could either support or falsify theory's claims, expectations or predictions?", and Quigg replies: "String theory is not at the point of making specific predictions for the LHC. … The LHC has influenced some prominent string theorists to put the theory aside, for the moment, to concentrate on theoretical problems that promise a more immediate dialogue with LHC experiments."

Do you have any idea to which prominent string theorists Quigg is referring?

29. **Peter Woit**
June 14, 2008

Chip,

Quigg's description of

"a conversation between an experiment and threads in the string theory worldview"

just sounds like obfuscation to me. I don't see why he can't just straightforwardly say that string theory predicts nothing about what the LHC will see, and that the interest in the LHC has to do with physics (electroweak symmetry breaking) which has nothing at all to do with string theory.

I don't know who he is thinking of in claiming string theorists have abandoned string theory for LHC physics. LHC phenomenology is a very different subject than string theory, and few people can move from one to the other. One example might be Arkani-Hamed, but he was never much of a string theorist. Some string theorists have gotten involved in the "LHC Olympics", but it's unclear whether that counts as a change in research direction. There are a few other examples of people doing AdS/CFT stuff that is supposed to be related to the LHC, see, e.g. recent paper by Maldacena.

30. **Thomas Larsson**
June 15, 2008

The tragedy of string theory (and in fact theoretical physics in general today) is that the really interesting questions that we want answers for, are currently way outside our experimental capabilities.

I want to know why m_p/m_e = 1836 or why 1/alpha = 137.036. It seems to me that it is theory rather than experiment that is the problem.

31. **Chris Austin**
June 15, 2008

Hi somebody,

"To answer essentially all the questions to which we have experimental access, standard model plus Einstein gravity is perfectly enough."

Three independent approaches to making sense of the quantization of Einstein gravity in 3 + 1 dimensions have had a substantial amount of success recently:

1) Bennie F. L. Ward's technique of resumming Feynman diagrams, e.g. arXiv:hep-ph/0610232

2) Asymptotic safety, e.g. arXiv:0708.1317, arXiv:gr-qc/0610018

3) Causal dynamical triangulations, e.g. arXiv:0712.2485

All three of these approaches appear to lead to the conclusion that the strong / electroweak Standard Model plus quantum Einstein gravity in 3 + 1 dimensions predict that the universe has a radius of curvature around 10^{-35} metres, i.e. the Planck length, in gross contradiction with observation.

On the other hand, if we choose not to quantize gravity, but accept the existence of gravitational radiation, for which there is experimental evidence from binary pulsar timing studies, see http://nobelprize.org/nobel_prizes/physics/laureates/1993/press.html then we meet the equipartition theorem of classical statistical mechanics, namely that in thermal equilibrium at temperature T, every quadratic degree of freedom has mean energy (1/2)kT, where k is Boltzmann's constant. The gravitational radiation field has an infinite number of quadratic degrees of freedom per unit volume, since the frequency of gravitational radiation can be arbitrarily high, hence we must conclude that the gravitational radiation field is either not in thermal equilibrium, or has exactly zero temperature, or has infinite energy per unit volume. This is precisely analogous to the corresponding paradox for the electromagnetic field, that led Planck to the introduction of quantum theory, so that the equipartition theorem is only valid for frequencies \nu such that h \nu is small compared to kT.

Best regards,
Chris

Somebody says:

"The tragedy of string theory (and in fact theoretical physics in general today) is that the really interesting questions that we want answers for, are currently way outside our experimental capabilities"

Since the complaint is testability of String Theory, I am interested to know if there are any thought-experiments that can reasonably substitute experiments.

33. **Aaron Bergman**
June 16, 2008

Since the complaint is testability of String Theory, I am interested to know if there are any thought-experiments that can reasonably substitute experiments.

Of course not. But, when you don't have any real experiments, you make do with what you have.

34. **Peter Orland**
June 16, 2008

Somebody says:

"The tragedy of string theory (and in fact theoretical physics in general today) is that the really interesting questions that we want answers for, are currently way outside our experimental capabilities"

I don't understand why some people think that the only really interesting questions are quantum gravity and unification.

What about confinement? What about the soft Pomeron in QCD? What about chiral symmetry breaking? What about High-T_{c} superconductivity? What about turbulence? What about the Hubbard model in two or three dimensions? What about dark energy? What about inflation? Etc., etc., etc. All of these questions are related to experiments or observations. The people who work on them have as much talent as anyone (with the exception of yours truly).

35. **Tom W.**
June 16, 2008

Peter, you say:
>Unfortunately some parts of string theory (and parts of cosmology >having little to do with string theory) have taken a turn towards >pseudo-science, but I think the people promoting this are very >much a minority in the subject. It would be in the interest of >serious physicists working in string theory and cosmology to take >a more active role in making it clear to the public what is pseudo->science and what isn't.

Anyone claiming the existence of extra dimensions is talking pseudo-science, so this would seem to include a majority of string theorists. If this is not the case, then can you (as a serious physicist) make it clear to me (the public) where the scientific basis for extra dimensions can be found?

36. **Christine**
June 17, 2008

I philosophically oppose to extra-dimensions and multiverses.

Scientifically, the only way to address them is to experimentally test the various hypotheses for their existence. In this case, extra-dimensions can be scientifically tested, but not multiverses. By definition, the universe is *all* that exists. There is no intrinsic meaning to talk about *other* universes. It is not scientific because to begin with, it has no meaning. I don't understand why people cannot see the logic of this simple argument.

Sometimes I find interesting to read about ideas like the quantum creation of the universe from nothing, like Vilenkin's attempt, but when it comes to other universes, the line between science and pure imagination/illogic is crossed. Since I have a science-fiction vein, these ideas can serve as some inspiration. But even then, since they are already so much explored (and since I dislike them), I avoid them and look for other more interesting ideas that abound in other areas of science.

37. **Peter Woit**
June 17, 2008

Christine and Tom,

I don't think a generalized denunciation of multiverse and extra dimensions research is at all helpful. All it does is convince string theorists that their critics are completely close-minded and don't understand what they are trying to do. You have to look at exactly what the research in these fields is, it's not so easily dismissed without considering exactly what is going on.

In the case of extra dimensions, first of all there are successful uses of the idea (see AdS/CFT). Mostly though, it's not pseudo-science, just unsuccessful science. Multi-dimensional models in principle typically make predictions, the problem is that they don't agree with observation. You end up having to adjust your model so as to not violate known experimental results, making it untestable and not explaining anything.

In the case of the multiverse, one can imagine testable versions of the idea, but one often sees people pushing research programs that all evidence shows are inherently untestable. This deserves to be called pseudo-science.

38. **anon.**
June 17, 2008

"… it's not pseudo-science, just unsuccessful science. …"

It's financially successful in being marketed. So it gets citations and research grants. The number of researchers exceeds the critical mass for a growing discipline: reading, peer-reviewing and citing one another. From these criteria, it is a scientific success.

39. **Christine**
June 17, 2008

Peter Woit,

It may appear to others that my "generalized denunciation" of these issues are closed-minded. Well, I don't care to be judged that way, simply because I know how I am better than anyone else, and I know that I am an open-minded person. I have run and run blogs that widely accept any civilized comments on all these issues, even if I strongly oppose one concept or another.

As I mentioned, I am not philosophically inclined to the extra-dimensional programme, although I was much more interested in the past. And I never said that it cannot be tested. My general remarks about extra dimensions were purely philosophical.

Concerning multiverses, as I wrote, I see it clearly untestable by definition, because by definition there is only one universe, which encompasses all nature. I see no logic in talking about multiverses poping in and out of "existence" "elsewhere". This is my starting point, but it does not mean that I don't want to hear anything about it or that I am not interested in understanding the arguments further.

String theory is testable and should be tested, and it is scientific as far as I understand it. But I presently am interested in other ideas. I don't really care whether other people want to work on this subject as far as they act as honest scientists and face the problems of their discipline with dignity. (I am *not* saying that string theorists are dishonest or lack dignity. This should be applied to any scientist, or any person for that matter).

Yes, I do have a strong philosophical position that multiverses are things of the imagination, and hence one will have to convince me that it is a scientific problem. Since up to this moment I have not seen any convincing argument, I keep my position. If people want to try to convince me, they are invited to post on my blog; I have specific entries on these matters. Search for, e.g., "the universe" and "what is science", etc. But I strongly advise that if you don't have a really sound argument, never mind, I'd rather run a low traffic blog.

40. **Peter Woit**
June 17, 2008

Christine,

I'm sorry if my comment came off as hostile, I'm well aware that you are a quite open-minded person, well-informed about these issues, and that your blog does a good job of reflecting this.

You're right that the overriding problem with the multiverse idea is that the other "universes" are by definition not directly observable to us. So anyone who wants to talk about them has to come up with an explanation of how multiverse research is going to lead to an experimental test. My point is just that multiverse proponents do have answers to this, and one needs to look at them and address them. I think when one does, one finds that they are completely unconvincing. The kinds of answers they have are:

1. A version of string theory will be found that explains the standard model convincingly, while at the same time also implying the existence of other universes corresponding to other states of the the theory. Knowing one ground state of the theory will tell us what the theory is, and indirectly evidence for the other ground states. Problem with this of course is that, after a quarter century string theory has failed completely to explain anything about the standard model.

2. Statistical analysis of string vacua will make testable predictions, again giving indirect evidence that the other states in the statistical ensemble exist. Again, this is a research program that has gone no where, and has zero evidence supporting it, or giving any encouragement that anything can come of it.

3. Construction of models with observable effects of pre-inflationary times. Such models typically are rather contrived, and involve an extremely small amount of information about this pre-inflationary "other universe", such as one number, the only thing surviving from some very complex earlier state. Actually I don't think this really works, since you're talking about the earlier history of this universe, not another one. Again, you can claim that finding evidence of a pre-big-bang state consistent with multiverse ideas of existence of lots of baby universes is indirect evidence for them, but at this point this just seems to me to be wishful thinking.

41. **Chris Austin**
June 17, 2008

Hi Tom W.,

" … can you (as a serious physicist) make it clear to me (the public) where the scientific basis for extra dimensions can be found?"

I hope Peter won't mind if I try.

Experimental evidence has been steadily mounting since 1915, when Einstein proposed his General Theory of Relativity, that gravitational fields are properly described as a curvature of space and time. A logical consequence of this description, already recognized by Theodor Kaluza in 1919, is that there could be extra dimensions of space, curled up too small for us to see them.

To see something small, it is necessary to look at it with something – photons, electrons, neutrons – whose wavelength is smaller than the thing we are trying to look at. From Planck's relation $E = h \nu$, where E means energy, h is Planck's constant, and ν means frequency, and the relation between frequency and wavelength, which for photons, and also for massive particles, when their energy is sufficiently high, is $\nu = c / L$, where c is the speed of light and L means wavelength, it follows that to see very small things we need very high energies.

The Large Hadron Collider, due to start up at CERN in the next few months, will enable us to see smaller things than ever before, down to around 10^{-19} metres, by looking at them with the quarks and gluons in protons colliding at extremely high energy. This does not mean that we will see such small things immediately. Rather it will be like gradually increasing the level of illumination in a room that was initially completely dark: things will gradually appear out of the murk as the accumulated data increases. There is a significant possibility that the LHC will eventually see small extra dimensions of space, curled up to a size of around 10^{-19} metres, that are too small to have been detected up to now, and I will try to explain why this is.

The two most fundamental experimentally established theories of physics that we have at present are the Standard Model of the strong / electroweak interactions, which describes everything that we observe except the gravitational field, and Einstein's theory of gravity, which describes the gravitational field and its interactions with the energy and momentum of matter. As I tried to summarize in my comment above, when we work out the logical consequences of the two theories together, they make a prediction that is disastrously wrong, namely that the universe curls up so that its radius of curvature is around 10^{-35} metres, which is roughly as small in comparison to the smallest specks of dust we can see with the naked eye, as those specks of dust are in comparison to the actual size of the universe. This means that the two established theories must be part of a larger picture, and a very important part of the larger picture is missing.

The reason the two established theories make this wrong prediction, is that the fields associated with the particles of the strong / electroweak Standard Model, in the same way that the electromagnetic field is associated with the photon, have nonvanishing fluctuations even in empty space, and these fluctuations have nonvanishing energy. The energy of these fluctuations acts as a source for the gravitational field in the same way as massive objects do, and this results in the universe curling up to a size around the square root of $G h / c^3$, where G is Newton's constant. This size is around 10^{-35} metres, which is roughly what is known as the Planck length.

For particles like the photon, the W and Z particles that transmit the weak interactions, the gluons that transmit the strong interactions, and the graviton, which are collectively called bosons, the leading contribution to the energy of their fluctuations in empty space is always positive, while for particles like the electron, the muon, neutrinos, and quarks, which are collectively called fermions, the leading contribution is always negative, so there is in principle the possibility of a cancellation between the two, but this does not happen for the strong / electroweak Standard Model, nor for the Standard Model plus gravity. However in 1974, Bruno Zumino demonstrated that in field theories with a special property called supersymmetry, the contributions to the energy of fluctuations in empty space cancelled between bosons and fermions exactly, for the leading contributions, and also for all further contributions from more and more complicated processes. Supersymmetry means that the formula for the energy density of the fields, averaged over space and time, which is called the action, is unchanged when certain small multiples of the fermion fields are added to the boson fields and conversely. Because of Zumino's proof, it seems reasonable to expect that supersymmetry is part of the missing part of the larger picture.

Zumino's proof does not apply, however, to field theories with supersymmetry that involve the graviton, which are called supergravity theories, and with one single exception, whose fluctuations in empty space can only have exactly zero total energy, supergravity theories can have zero *or negative* total energy of their fluctuations in empty space, so that the energy of their empty space fluctuations is not much better controlled than for theories without supersymmetry. The single exception is supergravity in eleven dimensions, that is ten space dimensions and one time dimension, which is the largest number of dimensions in which supergravity can occur. Supergravity cannot occur in more than eleven dimensions, because the number of degrees of freedom of the gravitino, which is the fermion field of which a certain small multiple gets added to the gravitational field in a supersymmetry operation, increases much more rapidly than the number of degrees of freedom of the graviton, as the dimension of spacetime increases. The result of this is that while supergravity in four spacetime dimensions can involve up to eight gravitinos, in ten dimensions it can only involve either one or two gravitinos, in eleven dimensions it involves exactly one gravitino, and in more than eleven dimensions supergravity cannot occur at all, because the gravitino has too many degrees of freedom.

In consequence of being an extreme case, supergravity in eleven dimensions has completely exceptional properties. Its action is unique, and the pieces fit together like a perfect Chinese puzzle. It is the only field theory involving gravity whose fluctuations in empty space necessarily have exactly zero total energy. When one of its ten space dimensions is curled up into a very small circle, and a certain solution of its field equations, which looks like a membrane, is wrapped around this circle, it becomes the type IIA superstring in ten spacetime dimensions, and it can also become each of the other four superstring theories when one or more of its ten space dimensions are curled up or folded in appropriate ways, and certain modifications fixed by self-consistency on any folds are made. Its quantum theory, which is called M-theory, has a vast array of consistent solutions in which seven of the space dimensions are curled or folded up into a very small size, while the remaining three space dimensions and the time dimension are very large and nearly flat, like the familiar dimensions of space and time that we know.

In many of these consistent solutions, there are fermions and bosons on the four large spacetime dimensions that look very similar to those in the strong / electroweak Standard Model, in the sense that exactly the same fields occur as in the Standard Model, and they have exactly the same types of interactions as in the Standard Model, but the masses of the particles, and the strengths of interactions, defined by numbers such as Newton's constant and the fine structure constant, are generally different from those in the Standard Model. However only a tiny fraction of the possible consistent solutions of this type have been examined so far, so it seems reasonable to expect that the larger picture, of which the strong / electroweak Standard Model and Einstein's theory of gravity are the two parts that have been established experimentally up to now, will be a consistent solution of M-theory of this type.

The vast number of consistent solutions of M-theory which, for everything larger than around 10^{-19} metres in size, look similar to the strong / electroweak Standard Model plus Einstein gravity in 3 + 1 dimensions, but differ in detail, have been characterized as a "landscape", and leave us with the practical problem of finding out where in that "landscape" we live. The parts of the "landscape" that have been investigated up to now fall into some ten or so broad families, that differ very greatly from one another for things smaller than around 10^{-19} metres in size. It will thus be possible to distinguish between some of these broad families at the Large Hadron Collider, and exclude some of them in favour of others.

The reason it is certain that the Large Hadron Collider will be able to distinguish between some of the broad families of solutions is that the strong / electroweak Standard Model becomes very stressed at the energies that will be studied at the LHC. One of the particles predicted by the Standard Model, called the Higgs boson, has never been discovered, and the logical consistency of the parts of the Standard Model that have been confirmed experimentally, requires that the Higgs boson, or something more complicated to serve in its place, must be light enough to be discovered at the LHC. Furthermore, the mass of the Higgs boson in the Standard Model is unstable to quantum corrections that tend to increase it greatly, so if the Higgs boson is discovered, then something more complicated must also be discovered that stabilizes its mass.

Whatever more complicated things are discovered, either together with the Higgs boson or in place of it, will distinguish between some of the broad families of solutions. In some of the broad families, the seven extra dimensions are large enough to be seen at the LHC, while in others they are not. In some of the families, there will be string-like excitations similar to the Regge recurrences observed at much lower energies in the strong interactions, while in others there will be none. In some of the families, the size of the extra dimensions is much *larger* than 10^{-19} metres, in fact up to a millimetre, but the Standard Model particles can only move in a small part of them, of size around 10^{-19} metres, which is why the large extra dimensions have not yet been detected, whereas the graviton and gravitino can move in their full extent. This would explain why the force of gravity is so much weaker than the other forces, for example the gravitational attraction between two protons is around 10^{-40} times weaker than the electrostatic repulsion between them, due to the gravitational force being diluted by the larger volume in which the graviton can move. In these families, the strength of the gravitational force increases extremely rapidly with energy as the LHC energy is approached, becoming comparable in strength to the other forces at around the LHC energy, and loss of part of the collision energy due to radiation of gravitons into the large parts of the extra dimensions will be observed at the LHC.

Best regards,
Chris

42. **Christine**
June 17, 2008

Peter Woit,

No, your comment did not came off as hostile, perhaps I was a little too defensive.

I appreciate that you have itemized your main criticisms to the “multiversism”. If I may, I suggest that you produce a FAQ to your arguments. It would avoid that you keep repeating yourself. There is a lot of information in your blog that deserves to be assembled into one place for easy access.

What concerns me is the recent edifice of joining string theory and multiverse scenarios (in addition to the intrusive anthropic arguments). I think this is a major shortcoming, but my discomfort is purely philosophical, because, as I mentioned previously, the multiverse idea does not convince me as scientific to begin with. I wonder whether only a minority of string theorists are willing to embrace such an edifice, or whether in fact this is a major trend.

43. **Eric H**
June 17, 2008

Chris,
Your latest comment explains where you are coming from theoretically. However, it seems to me you are just repeating standard theory from certain books, some of which are right and some of which are probably wrong.

While I agree that supersymmetry explains some things in particle physics it seems to do a lot more damage at theories of large scales, i.e.,gravity. It also must be remembered that general relativity can be considered proven while supersymmetry cannot. This isn’t to say that general relativity won’t probably be eventually enfolded into a larger theory that explains things such as the acceleration due to dark energy, (not to be confused with the vacuum energy or zpf). But my view is that supersymmetry directly contradicts GR and thus can’t enfold GR within it. In this way supersymmetry can be considered a good, but very flawed theory for certain interactions. Let me say it again: supersymmetry has not been proven.

Finally, the basic problem seems to come down to the problem of the universe being nearly “flat” but not quite. Supersymmetry addresses the problem by assuming “anti” particles and forces to everything. That ball got rolling because there actually are anti-particles with the same mass but opposite spin in all their internal components. But you are basically extrapolating an “anti” universe from the tinyest bit of evidence. And even then it doesn’t explain the small bit of “material” remaining that makes the combined positive and negative universes flat. It’s not good science but just a supposition that actually creates more questions than answers. Good science is when after given suffient time what remains in the wake of a new theory are “less” unanswered questions from the original questions, not more.

44. **Eric H**
June 17, 2008

“And even then it doesn’t explain the small bit of “material” remaining that makes the combined positive and negative universes flat.”

make that not quite flat.

45. **Eric**
June 17, 2008

Eric H.,
You apparently have a misunderstanding about what supersymmetry is about. Supersymmetry does not assign an anti-particle to every other particle. Supersymmetry is a symmetry which relates bosons to fermions. Thus, for the case of N=1 supersymmetry every fermion has a scalar partner, while every boson has a fermionic partner. In the case of supergravity, the spin 2 graviton is paired with a spin 1/2 gravitino, and gravity emerges from elevating supersymmetry to a local gauge symmetry. Your statement that supersymmetry contradicts general relativity is completely wrong.

46. **Eric H**
June 17, 2008

Eric,

Have they found any of these superpartners experimentally?

47. **Eric**
June 17, 2008

Give LHC a couple of years….

48. **woit**
June 17, 2008

Enough unenlightening supersymmetry warfare.

Chris laid out some of the standard lines of speculation that lead to the theoretical picture that string theorists are trying to sell today. The problem is that it’s a long line of speculation, which could be wrong at many places, which has never managed to make contact with the real world. There’s no particular reason to believe that extra dimensions explain electroweak symmetry breaking, they don’t explain any of its known features, or predict what the LHC will see.

So, I still maintain that extra dimensions are science, just (scientifically) unsuccessful science. We’ll see what happens at the LHC, I just hope that if extra dimensions or supersymmetry don’t turn up there, we can finally stop having the field of particle theory dominated by these ideas.

49. **Eric**
June 17, 2008

Peter,
I hope that whenever supersymmetry is found at LHC that you will disappear.

50. **Observer**
June 17, 2008

Peter,

In a previous comment you say: "In the case of extra dimensions, first of all there are successful uses of the idea (see AdS/CFT). Mostly though, it's not pseudo-science, just unsuccessful science"

Is there any empirical evidence in support of the AdS/CFT correspondence to promote it at the level of a successful theory?

Best regards,

Observer

51. **Peter Woit**
June 17, 2008

Observer,

AdS/CFT gives a very non-trivial calculational method for dealing with the strong coupling behavior of certain gauge theories, and as such is a success. Whether it can be turned into a reliable method for dealing with the physical case of QCD remains to be seen.

In this case the problem is not finding the right theory that describes the real world, we have strong evidence for QCD. But this still leaves the problem of actually calculating things, and that's also part of physics.

52. **Observer**
June 18, 2008

Peter,

Thanks for the reply.

To my knowledge, the AdS/CFT model applied to QCD goes by the name of holographic QCD. It is claimed to be a computational tool that is superior to Chiral Perturbation Theory when it comes to the strong coupling regime. But, again to my knowledge, holographic QCD has not been proven to yield predictions that are consistent with observations.

Is my understanding correct?

Best regards,

Observer

53. **Peter Orland**
June 18, 2008

Observer,

I'd like to try to answer your question concerning holographic ideas in QCD. I hope you can follow my attempt to give a basic explanation. Perhaps Peter won't mind that this doesn't have anything to do with the big bang (it seems that this comment thread is already very tangled, so I don't think I am messing it up too much).

AdS/QCD or whatever one calls it is essentially a bare-strong-coupling scheme. There is another such scheme, devised a long time ago, which is to do the strong-coupling expansion (NOT Monte-Carlo/numerical methods) on the lattice. Both of these have yielded some insights into quark confinement and chiral-symmetry breaking, and led to interesting lines of inquiry, but both have a serious problem.

In such schemes, there is a dimensionless parameter, called the bare coupling. This is not the same as the physical or effective coupling. To understand how real QCD works, this bare coupling must be taken to zero as an ultraviolet cut-off is removed. Unfortunately, nobody can do this yet.

Here is a semi-technical explanation, which you may want to skip. The reason the bare coupling must be taken to zero has to do with how QCD renormalization works. If we want to keep experimental parameters (like cross sections or masses) fixed as we remove the cut-off, the bare coupling "runs", i.e. becomes a function of the cut-off. It so happens that the bare coupling runs toward zero as the cut-off (in momentum units) diverges. SIDE REMARK: You may already know that the renormalized/effective coupling also runs, as we look at different energy scales (not cut-offs), and it runs in the same way as the bare coupling.

No calculation in the holographic approach to QCD can be taken seriously, unless someone figures out how to deal with arbitrarily small bare coupling (which means large curvature). Real QCD means infinitesimal bare coupling. My impression is that few string theorists (perhaps none) are working on this problem, because it is extremely hard.

In the light of the above, I think AdS/QCD and the older strong-coupling lattice approach should be viewed only as imperfect models of the strong interaction. This does not mean that they are unworthy of study. They are not, however, real QCD.

54. **observer**
June 18, 2008

To Peter Orland,

Thanks for your reply and explanation.

Best regards,

Observer

55. **M.Wang**
June 19, 2008

I am truly curious to see some real debates on the physics related to the direction of time paradox, so pardon me for interrupting your lively discussions about String (an issue that I consider moot).

The central argument in this paradox concerns the entropy of the pre-inflation universe. It is commonly stated (by Penrose, for example) that it has to be even lower than just after inflation ends. The reasoning that leads to this conclusion involves the statement that the pre-inflation universe contains the same number of quantum states as the current universe, because "according the rules of quantum mechanics, the total number of microstates in a system never changes" (a quote from the SciAm article).

But this is very suspect. Quantum mechanics is known to be incompatible with gravity (or, equivalently, dynamic space-time). Trying to trace all microstates backward through inflation is plain nuts. Furthermore, the current universe has undergone 14 billion years worth of quantum de-coherence. Maybe someone has a way of estimating the effect of all the quantum de-coherence on the microstate count, and I sure would love to read it, but I doubt the answer can be as simple as "no effect" because quantum de-coherence is in essence the APPARENT decoupling of entangled states when the particle in question interacts with cold, localized, massive subsystems (yes, like those objects that formed AFTER the inflation). The wave function is truncated in an (albeit extremely accurate) approximation. The new EFFECTIVE quantum description of the system remains valid for all practical purpose, but the number of microstates does not seem to be conserved, or maybe someone can enlighten me otherwise.

Oh, by the way, I am aware of the fact that the universe always has had exactly ONE state. Talking about entropy, however, requires the invocation of ensembles (or something similar, although the multiverse concept may be a step too far). Counting the microstates, therefore, involves solving the effective quantum Hamitonian after de-coherence. Now I really do not see how the count can be possibly conserved.

Even if the microstate count in the pre-inflation universe is indeed high enough, we still cannot safely jump to the conclusion that "among all the different ways the microstates of the universe can arrange themselves, only an incredibly tiny fraction correspond to a smooth configuration of ultradense dark energy packed into a tiny volume" (again, a quote from SciAm). That statement is true if one assumes that there is no interactions among the incredibly dense collection of ultra-heavy particles packed into a universe the size of a penny, but that is such a dumb assumption that I do not presume anyone can seriously make it. In fact, smoothness seem almost inevitable with any meaningful collisions going on, so if anyone understands how that SciAm quote was arrived at, please enlighten me by all means.

56. **Observer**
June 19, 2008

Dear M. Wang,

Extrapolating thermodynamic and quantum concepts all the way to the Universe scale is highly speculative and should not be taken seriously. Likewise, assuming that both statistical and quantum physics continue to be valid in pre-inflationary Universe lacks any foundation.

57. **Christine**
June 19, 2008

The meaning of the word "speculation" appears to have changed in recent times.

Atiyah on Atiyah-Bott

June 11, 2008
Categories: Uncategorized

This week I'm in Montreal attending a [conference in honor of Raoul Bott] (who I wrote about in some detail [here] a couple years ago).

On the first day of the conference, a documentary film about Bott made by his grandaughter Vanessa Scott was shown, and there was a panel discussion about the man and his influence on students and collaborators. Bott was both a wonderful mathematician and human being, and many people at the conference paid tribute to him as someone who encouraged them and taught them beautiful and deep mathematics. Quite a few commented on visits to him and his family at their summer place on Martha's Vineyard. It adjoined a clothing-optional beach frequented by Alan Dershowitz among others, a beach where Bott was supposedly known as the "Mayor".

Bott was very much involved with physics later in his career, and two physicists spoke at the conference: Cumrun Vafa on topological strings and Edward Witten on the 6d QFT point of view on geometric Langlands. I greatly enjoyed both talks, but I suspect they were pretty difficult for the mathematicians in the audience to follow, covering a great sweep of material bringing together new mathematical developments not understood by most mathematicians with QFT and string theory techniques far from their background.

Michael Atiyah gave a truly wonderful talk to open the conference. He described how his friendship with Bott had covered a period of 50 years, from 1955 until Bott's death in 2005. From 1964-1984 they did some of the best work of their careers together, and Atiyah tried to summarize the high points of this, as well as point out problems their work raised that he sees as still open and worthy of investigation by a new generation. Editions of the collected works of both of them are available that include their commentaries on the papers, and these are very much worth reading. Each of them is a masterful expositor, so their joint papers are uniformly models of clarity.

Atiyah broke things up into the following main topics:

- Bott Periodicity

In work with Hirzebruch, Atiyah realized that Grothendieck's construction of K-theory in algebraic geometry could be turned into a generalized cohomology theory in the topological category. To make this work uses Bott periodicity in a crucial way, to show that $K(MxS^2)$ is the tensor product of K(M) and $K(S^2)$ for any compact manifold M. Atiyah realized he didn't know how to prove this, and got Bott to produce an appropriate proof, which appeared in a paper of Bott's in 1959. The paper is written in French, clearly not by Bott, and Atiyah says he still doesn't know who translated it into French for Bott.

Atiyah and Bott worked together on extending the Atiyah-Singer index theorem to the case of manifolds with boundary, where the issue of how to handle the boundary conditions so as to get a good index problem is a subtle one. As part of this, they needed a new, more "elementary" proof of Bott periodicity, finally finding one that "even MIT faculty could understand". This is periodicity for the unitary group and crucially uses Fourier analysis. Atiyah gave as a problem deserving attention that of extending the proof to the case of the orthogonal group, where the use of Fourier series would have to be replaced by the representation theory of O(N). Multiplying Fourier series becomes taking the tensor product of representations, which is much more non-trivial to deal with.

- Heat Equation Proof of the Index Theorem

Using the McKean-Singer formula, one can relate the computation of the index of a differential operator to the asymptotics of a related heat equation. Patodi and Gilkey had carried this through using complex and skillful algebraic calculation, but Atiyah and Bott felt they couldn't understand these proofs, so with Patodi came up with a new proof, one that just used Weyl's invariant theory for the orthogonal group and the Bianchi identities of Riemannian geometry.

As a problem for the future, Atiyah listed finding a better understanding of the relation of the Atiyah-Bott-Patodi argument with the supersymmetric quantum mechanics proof. More explicitly, he conjectures that one should be able to just use invariant theory, but perhaps invariant theory of the infinite dimensional group Diff(M), of a sort advocated by Gelfand.

- Fixed Point Theorems

The Atiyah-Bott fixed point formula computes the Lefschetz number one gets in the context of index theory and a mapping of the manifold to itself (coming for instance from a group action) in terms of data at the fixed points of the mapping. This has many beautiful applications, including a new proof of the Weyl character formula. The formula is sometimes known as the "Woods Hole formula", since Atiyah and Bott conjectured it at a conference at Woods Hole, where certain experts told them it couldn't be true, since they had computed counter-examples. Atiyah didn't name names, but described the experts involved as now claiming to not remember this. "They deny it to a man" he said, but he remembers it distinctly while being in the frustrating position of having nothing written down to provide incontrovertible documentary evidence.

One generalization of the fixed point formula shows that for manifolds with circle action the index is zero, and Atiyah mentioned Witten's extension of this to the case of a loop space, leading to a relation to modular forms and the subject of "elliptic cohomology". This continues to be an active subject, with Mike Hopkins and others developing the theory of "topological modular forms", something that has shows interesting relations to number theory. Atiyah described a "moral bet" between him and Andrew Wiles about whether QFT will ultimately influence number theory. Wiles thinks not, but Atiyah believes it will happen, and hopes to be around long enough to find out if he is right.

- Yang-Mills and Algebraic Curves

Morse theory and equivariant cohomology were two of Bott's favorite tools, and he and Atiyah did some wonderful work applying these to the case of Yang-Mills theory in two dimensions. Here the Yang-Mills functional is a Morse function, the space of connections is a symplectic manifold, and the reduced space for the gauge group action is an important mathematical object that can be thought of as the moduli space of flat connections, or of stable holomorphic bundles on the 2d surface. Their main result, a calculation of the Betti numbers of this space, reproduced earlier results coming from a very different approach, that of using algebraic curves over finite fields and the Weil conjectures.

As a problem for the future, Atiyah asks if there is some infinite-dimensional version of the Weil-conjectures, and some QFT where the Feynman integral is analogous to Tamagawa measure. He says he has been thinking about this off and on for 30 years, hasn't found anything satisfactory, but offers the problem as a gift to younger mathematicians, as long as they let him know if they solve it. For some recent work related to this, see [here].

- Hyperbolic Equations and Lacunae

Atiyah described work of his with Bott on this topic as "performed under a subcontract" with Garding.

Finally, Atiyah commented on how his mathematical style was quite different than Bott's with Bott always advocating an "old-fashioned" way of proceeding, involving concrete formulae, where Atiyah favored "new-fangled" abstraction, only writing down formulae when forced to by Bott (and then discovering that this gave important insight). Later he found himself in the opposite position when working with Graeme Segal, with respect to whom he was the "old-fashioned" one, resisting abstraction. He commented that Bott and Segal had written a paper together, and he was shocked to see that such a thing was possible.

He noted that he had met many fascinating people through Bott, including one of the world's best known mathematicians: Tom Lehrer. Finally, he ended with the comment that, while Bott was no longer here, the great thing about doing math the way he did it is that you become immortal.

   June 12, 2008

   Peter, Do you know if the talks were recorded and/or whether the proceedings will be published?

2. **Peter Woit**
   June 13, 2008

   mathphys,

   The talks weren't recorded as far as I could tell. Don't know if there will be any effort to put some of the slides on-line. There will be a volume of papers at some point.

3. **Fabien Ngo**
   June 16, 2008

   I attented the Bott legacy conference too. I noticed that Professor Woit was on the list of participants but didn't find him unfortunately. Concerning the talks, most of them were very nice and the speakers tried to make them as clear as possible. Vafa's talk was very hard and i wasn't able to understand it. I wanted to ask him question but he disappear imediatly after his talk (So if someone can help me to understand what he talk about that would be nice).

   The conference wasn't recorded but CRM(Centre de recherche mathématique) who organised the conference will publish the proceedings of the conference as soon as possible.

4. **Peter Woit**
   June 16, 2008

   Hi Fabien,

   Sorry I didn't get to meet you at the conference.

   For some fraction of what the Vafa talk was about, one reference with lots of detail at various levels is the book "Mirror Symmetry" from the AMS, edited by him and Zaslow.

5. **Fabien Ngo**
   June 17, 2008

   Thank you very much for the reference. The book is big but i'll try to take a look.

Is the Universe Actually Made of Math?

June 17, 2008
Categories: Uncategorized

The relationship between mathematics and physics is a topic that has always fascinated me, and today I noticed two interesting blog postings related to the topic. The first was Ben Webster's posting inspired by a recent XKCD comic. The discussion in the comment section is well worth reading, especially the contributions from Terry Tao.

Over at Backreaction, Sabine Hossenfelder discusses an interview with Max Tegmark from the latest issue of Discover magazine entitled Is the Universe Actually Made of Math?. Much of the discussion is about Tegmark's comments on how he dealt with the potential danger to his career caused by his unconventional publications on the "Mathematical Universe Hypothesis". This says that

> Our external physical reality is a mathematical structure

I've always had an extreme case of mixed feelings about this, thinking that Tegmark manages to bring together the extremely deep and the extremely dumb. He embeds this as "Level IV", the highest level, of the multiverse, and multiverse mania is one reason he has gotten attention for this and not had it dismissed as crackpotism. The idea he is pursuing is that any mathematical structure can be thought of as a "universe", and we just happen to be in some random one of these. This seems to me to be pretty much content-free, and the attempts to fit it into more conventionally popular multiverse studies don't help.

At the same time, this does get at an incredibly deep problem, that of the relationship between mathematical structures and physical reality. Some of the central mathematical structures that mathematicians have discovered have turned out to be identical to those found by physicists pursuing models of fundamental physics. This has happened in several very striking ways over the years. Thinking of the universe as a mathematical structure has turned out to be extremely fruitful, both for mathematics and for physics.

What is important though is that not all mathematical structures are equally important, central, or interesting, and this is the crucial point that Tegmark seems to me to be missing. Once you learn enough mathematics, you find certain recurring themes and deep structures throughout the subject. What fascinates me is that these often also turn out to be central in theoretical physics. Tegmark just accepts every mathematical structure as equally important, creating a huge undifferentiated multiverse where we occupy some random anthropically acceptable point. But the evidence is that the mathematical structure we inhabit is a very special one, sharing features of the very special structures that mathematicians have found to be at the core of modern mathematics. Why this is remains a great mystery, one well worth pursuing from both the mathematician's and physicist's points of view.

Comments

1. **Frank**
   June 18, 2008

   An acquaintance of mine has a simple but deep criticism of Tegmark's ideas. He says that all mathematical structures are built and based on sets. This is especially the case for all structures looked at by Tegmark. But on the other hand, it is not clear at all whether nature is a set. In fact, there are many reasons that point to the opposite conclusion.

   He says that at high energy, it is not clear that a "set" is the correct description for nature, it rather looks as if it is not. If nature is not a set, Tegmark's ideas lose their base.

2. **Paul Jackson**
   June 18, 2008

   I'm amazed that Max Tegmark seems to entertain the notion that mathematics is constituent of the physical world, somehow waiting to be discovered "out there". Is it not obvious that mathematics is an invented language that we chattering African apes have evolved to describe the mysterious world we find ourselves in? No wonder its structure has evolved to closely resemble that of the physical world.

3. **Fabien Besnard**
   June 18, 2008

   "Is it not obvious that mathematics is an invented language that we chattering African apes have evolved to describe the mysterious world". It is not obvious, to say the least. Whole books have been written about this, and I recommend this one : "Matière à pensée", a dialogue between Alain Connes and the neurologist Jean-Pierre Changeux. I can also point you to Omnès book "Converginf realities".
   I think that when you ask yourself what "real" means, what criterion permits to classify something as real, what comes to mind is logical consistency. Everything else seems to be ill-defined intuitions. I talked about this subject in more length here : http://math-et-physique.over-blog.com/article-1591626.html (in french). I'll try to put a trackback but for some reason it never works…

4. **anon.**
   June 18, 2008

   All applied mathematics for real world physics is only approximate:

   1. Newtonian physics only has exact analytical solutions for two-body interactions, whereas there are many bodies present in the universe. Poincare chaos arises for orbits of more than two bodies, where each affects (alters) the orbit of the other as it moves. There is also a quantum chaos from the random exchange of field quanta that causes the electromagnetic interaction between electrons and protons, which on small scales is random (on big scales the large number of field quanta interaction statistics smooth out to give the deterministic classical Coulomb law). This prevents deterministic calculation of electron orbits inside the atom.

   2. General relativity's stress-energy tensor uses an artificially smoothed distribution of mass and energy instead of representing the real particulate (discontinuous, i.e. atoms and quanta) distribution of matter and energy, to create an equally false smooth source for the Riemann curvature. It just ignores the QFT idea that gravity field quanta (gravitons) are exchanged in discrete interactions, not continuous acceleration (smooth curvature).

   3. Even if you just consider simple addition, counting two electrons, you haven't an exact mathematical model with 1+1=2 for two times the same thing, because the electrons are all slightly different in their motions and by the uncertainty principle in principle you can't ever find their exact positions and momentums. So they will have slightly different velocities and therefore slightly different masses. So you're not adding up exactly the same real thing. To make the point clearer, if you add up apples (or if you count sheep), you are adding up things which are approximately similar, but not exactly the same. Two similar looking items will differ at the atomic scale. So addition is *only ever exactly true* when dealing with tokens like money, an invention due to mathematics.

   It is impossible even in principle to get exactly true input data in the real world from making measurements. Also, it's impossible to make exact predictions, because all applied physics calculations for the real world involve making approximations. So the universe isn't intrinsically mathematical. You can't get completely exact input data, and – even if you did know exact initial conditions – the mathematics used to model real (complex) phenomena is an approximation only.

In order for the universe to be intrinsically mathematical, it would be necessary in principle for there to exist some way of *exactly* representing the real world using mathematics, instead of relying on approximations and statistical wave equations. Mathematics is in principle at best just an approximation to the universe, so the universe can't – even in principle – be intrinsically mathematical in nature.

5. **Fabien Besnard**
   June 18, 2008

   'In order for the universe to be intrinsically mathematical, it would be necessary in principle for there to exist some way of exactly representing the real world using mathematics'.

   Isn't it what physicists are after ?

   Anon, you seem to confuse two kinds of approximations : 1) the fact that our best theories are still approximations 2) the approximation in data. I don't see any relation between point 2 and the issue of the true nature of physical objects. As for 1), what is your argument for saying that there is no such thing as an exact mathematical description ? We do not have such thing at hand right now, but the simplest way to explain the fact that there exist excellent mathematical models of reality is that these models are approximations of a complete mathematical description.

   Finally, I think that one should distinguish between approximation and abstraction. Mathematical concepts are abstracted from 'familiar objects' ('familiar objects' might include other mathematical concepts), in a way I think is akin to chemical purification. Then these concepts are assembled to form a "synthetic product". These synthesis can produce mathematical theories which (perhaps crudely) model parts of the "real world". But both the "real thing" and the mathematical models are of the same nature : there are made of "atoms", which in my metaphor are elementary mathematical concepts.

   I speak about this "chemical metaphor" in the link I gave above.

6. **Christine**
   June 18, 2008

   Apparently, his philosophy is to equate the physical world with mathematics (yes, equate, not a sort of mapping between the two, nor a kind of approximation or representation or abstraction or whatever). If I understand Tegmark's point correctly, in general terms he seem to argue that this direct equality solves the philosophical problem of whether there is an ultimate reality. He says there is one and it is pure mathematics.

   I may have misunderstood it all since I have only read a simplified paper that he published some time ago. In any case, I didn't find any of his arguments brilliant or convincing. Looks like a very bad philosophy to me.

   The fact that we can describe physical phenomena through mathematical *reasoning* (no matter limitations concerning approximation of data, etc) is something much deeper to me and equating both is no solution (again, to me). It's like turning a difficult question into a trivial one as the best way to actually avoid it.

   Why am I being harsh?

   My formative years in astrophysics were the 90's, where I have seen cosmology turn into a real, quantitative science, the beginning of the "precision era" of cosmology. What I see today, however, concerns me deeply. I see well-known cosmologists, Tegmark and Sean Carroll being two examples that come easy to my mind, whose work I came to appreciate for many years, to start drifting into a speculative world, which has nothing to do with cosmology or science.

   Now let me be clear on this. I have a deep passion for philosophy and a great appreciation for the great classical philosophers, and actually I firmly believe that science must go hand in hand with philosophy. So I have nothing *against* a cosmologist or anyone attempting a serious work in philosophy or any other kind of speculative adventure, up to the point that he or she makes that absolutely clear. One should not confuse one thing with the other. Philosophy and science can go hand in hand, but one must be clear of what he/she is talking about, and make no confusion between the two disciplines.

   Concerning "the potential danger to his career caused by his unconventional publications", I take a very pragmatic approach. If a PhD student of mine in cosmology (let us say) started to drift into philosophy to the point of interfering with his/her research, no matter how fascinating his/her ideas were, I would have a conversation with him/her in order to make it clear that he/she would have to make a choice between these fields in that point of their formative years. After his/her PhD, he/she could choose whatever he/she wants to do, it doesn't concern me. I see no point in making so much fuss about this.

   June 18, 2008

   .

   I've always liked a remark that physicist Sir James Jeans made back around 1935: "The more we study it, the more it all looks like a dream."

8. **Richard Oldani**
   June 18, 2008

   What one does not put into the equation will not finally be given by the mathematics. James Franck

   IOW if you begin with math and try to go backwards you end up with nothing.

9. **Joao Leao**
   June 18, 2008

   Peter,

   You make a very crucial observation that deserves serious attention namely that physics appears to select mathematical structures to faithfully represent it that end up being recurrently isomorphic among themselves! This indeed is what makes Tegmark's call for `mathematical democracy of all structures' so totally sterile and silly! The notion of a "universe made of math" is not new: it is an old creed called pythagorianism, sure to be periodically revived by people who lack (better) ideas. Tegmark's profligate version is also not original: it was advocated by the argentinan philosopher Mark Balaguer in his book
   "Platonism and Anti-Platonism in Mathematics" as Full-Bloodied Platonism, though I believe Plato to be a lot less sanguine in his advocacy! You are right that this notion caters to the whole Landscape mentality that anything goes and it is basically a call to abandon all criteria of adequacy of mathematical speculation to empirical evidence, a notably self serving strategy for people who don't care to have their "bright" ideas falsified.

   The issue of whether (logical) self-consistency distinguishes mathematical structures that apply to physics from those that don't has been raised by Hawking, Barrow and others but it seems clear that, if this may (or may not) be a necessary qualification, it surely cannot be sufficient — unless perhaps one revives Hillary Putnam's proposal that logic may be an empirical science! There is indeed a very interesting set of questions surrounding this math-phys interface but the pythagorians seem very much more keen in obfuscating than addressing it…

June 18, 2008

I think its just that what mathematicians work on is inspired by the real world and in the real world you get analogous physical structures at different levels of physical reality.

11. **anon.**
June 18, 2008

'It always bothers me that, according to the laws as we understand them today, it takes a computing machine an infinite number of logical operations to figure out what goes on in no matter how tiny a region of space, and no matter how tiny a region of time. How can all that be going on in that tiny space? Why should it take an infinite amount of logic to figure out what one tiny piece of spacetime is going to do? So I have often made the hypothesis that ultimately physics will not require a mathematical statement, that in the end the machinery will be revealed, and the laws will turn out to be simple, like the chequer board with all its apparent complexities.' – R. P. Feynman, The Character of Physical Law, 1965.

Feyman is not referring to the use of the path integral for summing and weighting all possible interactions in spacetime even for relatively simple interactions, e.g. two electrons. There are an infinite series of increasingly complex Feynman diagrams for even the simplest interaction. The perturbative expansion for the path integral is an infinite series of terms of increasing complexity. The math is summing an infinite number of possibilities for how the field quanta will be exchanged.

This calculus error reminds one of the exponential formula for radioactive decay, a continuous curve which ignores the fact that radioactive decays are discrete events, so that there should really be a step-wise quantized decay line (with quantum drops as individual atoms decay, and horizontal lines in between the decays). The math is a nice approximation when the decay rate is very large, but nature doesn't strictly obey the equation at any time, and after the final atom decays the exponential law is obviously completely false and misleading.

June 18, 2008

Heh, if someon wanted to seek an independent research, I would recomend looking for a job in the federal governament, specialy in something burocratic. I don't know how is it outside Brazil, but generaly here you get a enough free time to study, have some money to subscribe to a decent ISP and buy some books. Maybe sometimes one could travel and attend conferences, during vacations.

13. **Eric**
June 18, 2008

As a physicist, Tegmark's ideas seem completely useless. I wonder if philosophers would find anything interesting. I don't enjoy sounding harsh, but I suspect not. Any philosophers out there?

14. **Marcus**
June 18, 2008

Compare what Tegmark says with pages 42-49 of the July Scientific American, where the question of fundamental constituents of spacetime is answered differently. This site has the complete article free, for online reading:
[url]http://www.scribd.com/doc/3366486/SelfOrganizing-Quantum-Universe-SCIAM-June-08[/url]

They get deSitter space to self-assemble from no prior geometry. Instead of being made of mathematics, their universe is more like a flock of birds.

15. **neo**
June 18, 2008

Is there a connection between Tegmark's "The universe is math" contention and Seth Lloyd's "The universe is computation" contention? I find the computation analogy or mapping more compelling, but I am curious.

16. **Observer**
June 18, 2008

The statement that the Universe is made out of Math first emerged in Plato's philosophy. It is a proposition that is untestable and, as such, it does not belong to science.

17. **ZoloftNotWorking**
June 18, 2008

Don't forget Bee's hilarious posting on Backreaction when Tegmark's book came out.

18. **Tom W.**
June 18, 2008

I think it bears on this topic to mention that the physiology of the brain itself causes an internal creation of complex geometric representations. When deprived of external stimuli the brain can become aware of its own geometric background signal:

http://chronicle.uchicago.edu/010426/visual-cortex.shtml

It's furthur interesting to note that experimental subjects who have these experiences often recall the recognition of these patterns as
extremely important or all encompassing realizations of the universe.

This is not to say that our view of the universe is nothing more than a hallucination, but without doubt human brain function is very geometric at fundamental levels. To this day, one of the classic images we assign to cosmology is that of Kepler's Platonic solid model of the solar system (Mysterium Cosmographicum).

Centuries later String theory seems much more sophisticated, but it remains inseparable from its imbedded geometric allusions.

A big question could be to what extent do we have the freedom or ability to transcend the very limitations of our own mental machinery.

19. **Bourgeois Nerd**
June 18, 2008

Instead of "the universe is math," wouldn't it be more accurate to say that the universe is built on evolvingly complex patterns? We then translate the patterns into the "language" of math.

20. **Ryan Dickherber**
June 19, 2008

He says all mathematical structures are created equal, but I'm pretty sure that 2>1.

21. **Steve Myers**
June 19, 2008

I thought all this stuff was settled long ago — especially by Russell. Anyway, if you want to say something objective about real world relations (or any relations) or describe what's happening you have to use math, since that what math does. And no, it is not a separate language — everything in math can be expressed in English or Russian, etc.

22. **EJN**
June 19, 2008

"Paper in white the floor of the room, and rule it off in one-foot squares. Down on one's hands and knees, write in the first square a set of equations conceived as able to govern the physics of the universe. Think more overnight. Next day put a better set of equations into square two. Invite one's most respected colleagues to contribute to other squares. At the end of these labors, one has worked oneself out into the doorway. Stand up, look back on all those equations, some perhaps more hopeful than others, raise one's finger commandingly, and give the order 'Fly!' Not one of those equations will put on wings, take off, or fly. Yet the universe 'flies'."

John A. Wheeler

23. **Jeremy Bowers**
June 19, 2008

Consider your conscious experience as a trajectory through the n-dimensional space of possible conscious experiences.

It clearly has a certain coherency; the world does not radically change on a Planck-time-by-Planck-time basis.

However, if all possible mathematical structures are equally "true", then for each Planck time, there are an infinite number of discontinuous universes that you *could* suddenly find yourself in that aren't this one, but are otherwise perfectly acceptable. That is, mathematically, despite living in the world you think you've been living in all your life, it is perfectly acceptable mathematically that in the instant after you read this, you'll find yourself on a planet Vulcan, as in, the Star Trek planet. The universe discontinuously shifts around you, but math has no problem with discontinuous shifts.

Therefore, if all possible mathematical structures were equally real, the probability of use experiencing such a clean, ordered universe are infinitesimal. Perhaps we are simply that infinitesimal bit of the mathematical structure that actually, factually experiences such a simple and orderly universe, but it is far more likely that Tegmark is simply wrong, and there really is some sort of mysterious dividing line between "real" and "unreal".

24. **Joel**
June 19, 2008

Has no one thought to look at this using the discipline of cognitive science? I think it could offer some perspective that is lacking within the frameworks of physics and mathematics.

Mathematics is just a practice of studying relationships between patterns. We come across these patterns in individual experiences, and and in human thought.

It is no surprise that patterns in human experience are related to the structure of the universe, or that the mind is structured (both through nature and through nurture) to pay particular attention to patterns that bear upon physical existence. But mathematics is a map, rather than a territory.

25. **Peter Woit**
June 19, 2008

The spam software is having trouble distinguishing between the short, not very informative comments and quotes people are posting here and the ones coming from spambots, and I have to admit I can't completely blame it. Well thought-out comments that add something significant are encouraged, but please resist the temptation to add to the noise level here.

26. **Observer**
June 19, 2008

Unfortunately, the debate about whether or not Math forms the underlying fabric of the Universe leads nowhere. Statements cannot be proven true or false and the discussion is entirely scholastic. Despite what Tegmark advocates, Math is a tool , a rational collection of symbols helping to describe Nature, "a map rather than a territory" to paraphrase Joel.

27. **Jack Lothian**
June 19, 2008

I read the Discover article a month or so ago but if I remember my reaction, it was that the guy over-rates his insight. I didn't think he was out-to-lunch; he was just too full of himself. I kind of find the reaction here to be a bit too much as well. This guy is esoteric but I think he acknowledges that fact which is better than some. One of the things that struck me was his comment about what turned him in his current direction. Something about the wave-function collapsing when a particle is observed & that he felt this was wrong in some sense. My thoughts were much the same in 3rd or 4th year undergraduate physics & I think many other physic students felt the same way. Intuitively the Schrödinger wave function interpretation feels wrong. It works but it seems to imply an underlying unreality that makes me uncomfortable. Interestingly my reaction was to treat it like a math tool that that helps solve physics problems but may or may not be a description of reality. So for me math was always a tool that I could make do what ever I wanted it to do while physics was something real. This guy seems to have gone in the opposite direction embracing the potential unreality. For him math is the reality & physics the abstraction. Strange but if he can get people to pay him to write like this – good luck to him.

28. **kyb**
June 20, 2008

> "I think that when you ask yourself what "real" means, what criterion permits to classify something as real, what comes to mind is logical consistency. Everything else seems to be ill-defined intuitions."

Of course everything else seems to be ill-defined intuitions – it's not consistent, so it's not likely to look good under logical analysis. Which means you're begging the question. The real point is whether or not it is necessary for "real" to be logically consistent, or if that is just a convenient assumption. Since logical consistency is something (in my view) dreamed up by humans, dependant on a number of assumptions, and not an external truth, I see no reason other than that of pragmatism for making such an assumption.

The whole "universe is maths" idea raises as many questions as it answers. For people, maths is a mental activity, where is the unversal mind that thinks the universe? Even if you discount the mental nature of maths, what medium exists to reify the maths? Just because I come up with a mathematical structure in my head, doesn't mean I've created a universe of it that describes all the results of that structure beyond even what I'm able to trace. Or perhaps he wants to go back to platonism and the theory of forms.

We create models of our environment, our models are at most countably infinite (they can be expressed in language, or at least encoded in our brains), but there's no reason to believe that the environment itself (rather than our model of it) does not require uncountably infinite symbols to accurately represent it.

It's much more sensible to say that our maths is at best a model that approximates reality rather than that reality approximates our models.

29. **kyb**
June 20, 2008

Oh and for full accuracy, that "increasing purity" comic, should have had a philosopher to the right of the mathematician, and then a psychologist to the right of that, etcetera, ad infinitum.

30. **Arun**
June 20, 2008

Roger Penrose in The Road to Reality has a triangular diagram, that expresses the idea that some of our mental activity is mathematics; some of mathematics describes physical reality and finally, some of physical reality is our minds.

This diagram illustrates a mystery and it seems to me that Tegmark seeks to banish the mystery by collapsing Penrose's triangle into a point. If the universe is mathematics and mathematics is the universe, then every thought of ours is also mathematics. Our minds are mathematics. Even thinking that Tegmark's idea is absurd is mathematics. Agreeing with him is mathematics, too!

31. **Fabien Besnard**
June 20, 2008

>Even if you discount the mental nature of maths, what medium exists to reify the maths?

What do you mean by "medium" ? In this debate, I noticed that one very often reintroduce in a way or another, under a name or another, the intuitive but rather wrong idea that what is real is made of matter, and matter is made of small hard spheres (made of what ?). I would be very interested if someone could come up with a definition of reality that excludes mathematical structures but not quantum fields, which do not possess any of the macroscopic qualities (such as hardness, localisation, etc…) with which we mentally endow "real things". What is reality is certainly an old metaphysical question. I tend to think that these kind of questions cannot receive an answer as such because their terms are not well-defined. Logical consistency=reality is a definition of reality that has the advantage of not being polluted by our macroscopic prejudices.

>Just because I come up with a mathematical structure in my head, doesn't mean I've created a universe

Certainly not. Mathematical structures do not live in spacetime, so they can't be created. They just are. You can think about one, it does not mean that you have created it (as with everything else you can think about).

32. **Arun**
June 20, 2008

Mathematical structures do not live in spacetime, so they can't be created. They just are. You can think about one, it does not mean that you have created it (as with everything else you can think about).

What determines which mathematical structures "just are" and which "just are not"? E.g., why haven't we seen supersymmetry so far?

33. **kyb**
June 20, 2008

As it happens I'm much closer to a Berkleian idealist than a believer in small hard round spheres.

If you're going to say things like "Maths just exists", perhaps you should give a clear and unambiguous definition of what you actually mean when you say maths. It's quite possible that this is just a difference in use of terminology.

I'm very confused where you get "Logical consistency=reality is a definition of reality that has the advantage of not being polluted by our macroscopic prejudices." from. It seems to me that belief in consistency is one of our biggest macroscopic prejudices.

34. **Chris W.**
June 20, 2008

You seem a little confused there, Arun. As a mathematical construct, supersymmetry has as much claim to exist in a Platonic sense as any other mathematical construct. Whether this construct can be given an *interpretation* that brings it into *successful* confrontation with observation (both passive and active, ie, experimental) is a separate question. So far, the answer seems to be no.

Of course this just indicates the fundamental wrongheadedness of Tegmark's formulation. All sorts of mathematical constructs exist (in an appropriate sense) in our heads, or in objective form (following Karl Popper) in books, journal articles, implementations of algorithms in computer hardware and software, etc. (For all we know they also exist widely among the cultures of sentient beings across our galaxy and beyond.) However, in the empirical sciences we're concerned with inference from certain premises that leads to specific, empirically testable conclusions about the physical world. We generally do this in a conceptual framework that organizes and motivates the inferences, but the relevance of logic and mathematics comes first and foremost from their power in helping us draw those inferences. Admittedly, in physics, various areas of mathematics have also contributed increasingly to the development of the conceptual frameworks, but this is ultimately to serve inference; we hope they can help us draw far-reaching and unambiguous conclusions that we can *test*.

I would suggest that the relevance of mathematics as a source of patterns comes ultimately from the simple fact of some regularity and stability in the world. Patterns are useless in describing experience if their appearances are completely ephemeral. In fact, noticing patterns *in time* is arguably where science begins. The fact that we can reproduce experiences of certain sorts, or merely note their regular repetition, is the starting point for the application of inference, and ultimately mathematical inference, via mediating abstractions (starting with simple idea of number).

One could say that the central mystery in nature is the interplay between pattern and structure on the one hand, and chaos and disorder on the other. It seems to involve a delicate balance; nowhere is this more evident than in quantum mechanics. John Stachel has argued that Einstein's objections to quantum theory were misconstrued. He didn't object to indeterminism itself so much as the lack of any explanation for why just so much, and no more, should be admitted. In other words, if the laws of physics do not fully determine the future from the past, why should they exist at all? Why should there be any structure in the world?

[By the way, your earlier comment—mentioning Penrose's book—reminds me of my first encounter (in my teens) with B. F. Skinner's *Beyond Freedom and Dignity*. I was entranced for a while with the idea that one could give a behaviorist account of the objections to behaviorism. What a great way to make an idea invulnerable to criticism! Over the course of the next year and a half I started to grasp how pernicious and sterile that tactic was. I'll leave it someone to say whether Skinner was actually indulging in it.]

35. **Arun**
June 21, 2008

Thanks, Chris W. You made pretty much the point I was leading up to.

36. **Shaun**
June 21, 2008

For me the universe-as-math question raises 2 primary questions:

1) Questions of the ultimate structure of the universe aside, it seems a tautology that the 'ultimate structure' of the brain must be a subset of the universal one. This imposes limits on what we as a species can perceive or even theorize about.(Tom W. makes this point above, with a link to a very interesting article.)

2) Why then the "unreasonable effectiveness of mathematics" in the natural sciences? – exactly what we're dealing with here.

The shared element that connects these two questions is Logic, and the connection occurs at a fundamental level, pretty mush as deep as it gets. For this reason, I believe there is genuine merit in Hilary Putnam's view of Logic as an empirical science.

Whatever else the universe is, it is an entity that allows Logic, and so far, seems to demand that we completely constrain our thought processes to those which are logical if we wish to model it. This is the origin of Pythagorean mysticism, Plato's idealism and our own personal intuitions regarding the relationship between abstract mathematics and physical science.

Math is built from logic – Russell/Whitehead showed us this, Godelian limitations notwithstanding. When we are marveling over the relationship between math and science, we are really remarking on the fact that nature has, to some significant extent, a logical substructure. This is a lesson we were strongly encouraged to learn, as a species, and taking these lessons to heart our most reliable forms of thought are logical ones.

I think Physics, as a discipline, is approaching the point where it will begin to ask questions like: "what is the nature of the fundamental structure of the universe such that it supports Logic as a mode of computation?".

Or something like that.

37. **Eric H**
June 21, 2008

It seems to me that in all this comment about logical consistancy of math and its relationship to the world individuals have left out the most important relationship of math to the world – and that is the conservation rules. While geometry has its important place in math, it deserves a position one rung lower than conservation laws when it relates to physics. More mathematically oriented physicists seem to continue to forget that.

In the universe geometry is related to the geometry of energy. Energy, as far as we know, is the only substance that always remains and is finite in the universe even as the geometry of its forms change. For some reason which I can't fathom theoretical physicists, as a generalization, seem to be the most likely people to forget it and are the ones who must continually strive to remember it. The relationship of how those forms change geometrically while continuing to conserve energy is where the answers lie in physics. This is not true for math.

38. **woit**
June 21, 2008

Eric H.,

The relation between conservation laws and symmetries is an absolutely fundamental aspect of how physics and math are related. In quantum mechanics this can be identified precisely with the mathematics of the unitary representations of Lie groups. I've gone on in many places about how important I think this is, and it's exactly the sort of thing that I think Tegmark misses (along with people who see this as an issue about logic, or the human brain, or any number of other very different questions).

39. **Jonathan Vos Post**
June 21, 2008

Dr. Woit, can you please elaborate on why Tegmark is wandering in the darkness, despite the illumination of Amalie Emmy Noether, who (as thumbnailed in wikipedia) the German Jewish mathematician [March 23, 1882 – April 14, 1935] known for her seminal contributions to abstract algebra. Often described as the most important woman in the history of mathematics, she revolutionized the theories of rings, fields, and algebras. She is also known for her contributions to modern theoretical physics, especially for the first Noether's theorem which explains the connection between symmetry and conservation laws [Ne'eman, Yuval. "The Impact of Emmy Noether's Theorems on XX1st Century Physics". The Heritage of Emmy Noether. Ed. M. Teicher. Israel Mathematical Conference Proceedings. Bar-Ilan University/American Mathematical Society/Oxford University Press, 1999. OCLC 223099225. ISBN 978-0198510451. pp. 83–101.]?

My bias is that the 2nd most important woman in the history of 20th century mathematics, Olga Taussky Todd [30 August 1906, Olomouc, then Austria-Hungary – 7 October 1995, Pasadena, California] Czech-American Jewish mathematician, gave me her personal and professional take on Emmy, whom she'd met. Similarly, I've heard great talks at symposia in the memory of Emmy Noether and Olga Taussky Todd.

Please, though I agree with you, I'd like your more detailed rationale.

40. **Peter Woit**

June 21, 2008

Jonathan,

I’m talking about symmetries in quantum mechanics, not classical mechanics. See my book for more details.

41. **John Rennie**
June 23, 2008

Suppose it were possible to formulate a theory that was independent of topology and the number of dimensions. Then suppose you could use a procedure analogous to gauge fixing to work out the physical predictions of the theory in 3+1 dimensions and arrive at something that described the world we see. Then what we see as the physical world and it’s contents, including ourselves, is merely a result of a gauge fixing. (You’d have to show that choosing any other gauge i.e. dimensionality and topology produced results that wouldn’t support observers.)

Anyhow the point is that the world you end up describing would necessarily reflect the mathematics used for the “gauge fixing”. Then physics and mathematics would be inextricably linked and Tegmark’s view of mathematics would arise naturally.

42. **Peter Woit**
June 23, 2008

It’s not “gauge-fixing” if physical observables depend on it. All you have done is decided (illegitimately…) to call the mathematical structure of physics “gauge-fixing”, you haven’t addressed at all why it is one structure and not another.

Philosophy of Science on Bloggingheads.tv

June 21, 2008
Categories: Uncategorized

Today's Bloggingheads.tv diavlog features Sean Carroll and philosopher of science David Albert, discussing a variety of issues. Albert tells about his unfortunate experience with the What the Bleep? film, a good example of why it's not always a good idea to get involved with people doing a supposedly science-related media project. He also discusses the hostility towards study of the quantum measurement problem from within the physics community over the years, a situation that has changed recently. The two also had a long discussion concerning Carroll's claims about the arrow of time, about some of which Albert seemed to be rather skeptical.

The discussion of criticisms of string theory were on the whole ill-informed, misleading, and devoted to ferocious attacks on straw men. For some reason, only John Horgan was mentioned, with the existence of trained theoretical physicist critics and two recent books on the topic completely ignored. Albert insisted repeatedly on the idea that Horgan and other critics were not acknowledging the "spectacular predictive success" of string theory. He was referring to claims that string theory "predicts gravity", since it contains a massless spin-two particle (ignoring the fact that it is in the wrong dimension; to quote Lisa Randall "string theory predicts gravity: 10d gravity"). Later on Carroll did explain the problem with this, that string theory seems to allow an infinite variety of ground states with different physics, many of which don't have 4d gravity. Carroll told about having asked various string theorists if they could imagine any kind of experimental result at any energy that would be incompatible with string theory, and getting the answer "No" from at least some of them. This seemed to rather shock Albert.

There was no real discussion of the multiverse, a topic where philosophers of science might be able to perform a public service by taking a serious look at what physicists are up to and analyzing what they learn. Carroll launched the standard attack on string theory critics as having a "sophomore-level" understanding of the philosophy of science, unaware that there is anything to the problem of what is science and what isn't other than Popper's falsifiability criterion. He also claimed that string theory critics have created a "20 year statute of limitations" criterion, that theoretical work must lead to a falsifiable prediction within 20 years or cease to be science, chuckling with Albert about how ignorant people must be who think such a thing. This kind of willful misrepresentation of the views of people you disagree with seems to me to be less than honest. From what I remember of Lee Smolin's book, there's a long section about his engagement with the philosophy of science, and his sympathies are not with Popper, but with Feyerabend's "anarchistic" views on the subject, which are very different. In my book there's an entire chapter devoted to explaining what is wrong with just invoking falsifiability. I assume Carroll has read at least one of the two books, so it's unclear why he thinks it's acceptable to go on like this. He does make one more accurate accusation, that critics of the multiverse are stuck in an out-dated 1960s particle physics paradigm of what it means to test a theory. I suppose this is true enough. Not the first time I've been accused of being stuck in the 60s, which, if one has to be stuck somewhere, doesn't seem like that bad a choice…

Update: Evolving Thoughts has a link to The Ideas of Quine on Youtube, an interview of the philosopher Willard Van Ormond Quine by Brian Magee. The relation of physics and philosophy was one of Quine's main concerns, and one of the main topics of the interview. I suppose that to the extent my own philosophical views could be characterized by picking one philosopher I find most sympathetic, Quine would be a good choice. Perhaps he's responsible for my "sophomore-level" philosophy of science, since I took a course from him as a sophomore.

Comments

1. **Bee**
   June 21, 2008

   Indeed what I don't get is that people don't want to understand it's not a do-or-don't question, but one of balance. Except for the occasional misinformed commenter in the blogosphere I haven't encountered any serious scientists who thinks one should drop string theory, and I too am all for live and let live. The question instead is whether the amount of people working on a research program and the resources invested are appropriate to the promises it holds. This, (as I have said repeatedly, but just to make sure) is not a question constrained to the case of string theory but of a much larger interest: are resources, human and financial, optimally distributed in the academic system? The answer is no, and it seems to me the problem is precisely that today it is not the case that 'anything goes'. Instead, we have a very strong influence on the allegedly 'free' marketplace of ideas that goes back to social phenomena as well as business tactics that are not appropriate to scientific research. (See also my post on The Marketplace of Ideas).

   Btw, Peter, did you see this paper?

   http://arxiv.org/abs/0806.1431

2. **Peter Woit**
   June 21, 2008

   Bee,

   I agree, the crucial question is that of evaluating whether and how the string theory research program is making progress, an evaluation that should then carry implications for how it is pursued. The problem is not that string theory unification makes no predictions, it's that no progress has been made over the last 24 years towards predictions, actually quite the opposite.

   I took a quick look at the paper you mentioned. It seems to make the claim that the low energy modes of a superstring will not look like Dirac particles satisfying the Dirac equation, but instead like Klein-Gordon particles. I don't understand the author's argument for this, I do understand the conventional argument for why you get the Dirac equation (Ramond's work on the superstring uses a Dirac operator on loop space, Fourier modes satisfy a Dirac equation).

3. **Not a string theorist**
   June 21, 2008

   Dear Peter,

   I am a mathematician working in areas adjacent to string theory; I know a little but not a lot about the subject, but more importantly for the purposes of this post, I have no strongly formed opinions about the fundamental philosophical issues it raises.

   I think much criticism of your approach is entirely due to a perceived (whether accurate or not) unwillingness to learn about the frontiers of the subject on your part – even the more mathematical aspects of string theory.

   If you limited your criticism to the poor statistical techniques of the multiverse protagonists you wouldn't really be saying anything outside mainstream string theorist opinion, from what I can gather talking to my stringy colleagues.

   But what seems to rankle is the dismissive tone with which you (do not) properly discuss developments such as the recent Beasley Heckman Vafa paper, together with a lack of technical discussion (200 pages is not really that long if you are prepared to make the effort – an advanced graduate student or postdoc in string theory would expect to read and understand it in a week or so if they wanted to).

What my colleagues (and to some extent, I) take greatest issue with is not the fact of the criticism but the manner of it. They see you talking about Geometric Langlands with great enthusiasm, but without mention of the underlying string theoretic concepts which underlie the calculations – or the fact that such profound understanding depends on string theory in absolutely crucial ways. They see you limit your criticism to the easy targets of the multiverse and Lubos and hubristic paper titles and anthropic stuff and bad journalism and the one-line pithy quotes from prestigious figures therein, and couching your discussion in matters of philosophy and sociology.

Whilst these things are incredibly important, and not to be brushed under the carpet, ultimately, the technical stuff is what counts – and one of the reasons why you are not taken particularly seriously as a critic is that you haven't presented DETAILED criticisms of the latest directions (or even slightly dated directions) in string theory. To illustrate: if you discussed (or even better, found flaws in) Bagger-Lambert theory, or the Sen conjectures, or the ideas of conifold transitions, or dyon partition functions, you would be taken incredibly seriously. But repeating "Sean Carroll is misrepresenting me again" (even if true) will get you little respect.

Your mathematical posts are always interesting, but in my opinion, such as it is worth, your criticism needs to be elevated if you want it to be taken seriously. And at some point, you need to address the question of how to value the astonishing mathematical consistency of string theory (I seriously doubt you can find many practising mathematicians in whose fields conjectures have been raised who do not believe this).

(For what it's worth, my own job does not depend on string theory in any way, but I have had great fun in the past few years proving mathematical conjectures which have partial stringy origins).

Whilst it is of course your own blog and you can do as you see fit, I agree entirely with a comment by John Baez in that I would love to see more equations here and less vitriol.

4. **onlooker**
June 21, 2008

"how to value the astonishing mathematical consistency of string theory" is a question that answers itself. There is a high value of string theory (and related ideas) for mathematics, to the point that the mathematical aspects and connections of string theory will be pursued whether or not the intended physical applications materialize.

The question that I think Woit and others are raising is about the discrepancy between string theory's dominant status as a particle theory research program and it's not-astonishingly-high contribution to observable physics.

5. **Buffon**
June 21, 2008

Dear "Not a string theorist",

You must be new here. All your points are 100% correct and have been explained to Peter a gazillion of times yet he refuses to listen and bring home at least 1% of the arguments made. Hence it's a total waste of time to argue with him which fact is correctly recognized by the particle physics community i.e. nobody takes him seriously.

His blog is still amusing for casual reading 🙂

Best,
Buffon

"Not a String Theorist"

First of all, please think seriously about whether it's a good idea to post this sort of comment anonymously. Because of the nature of this controversy within the physics community, physicists sometimes have a legitimate reason to hide their identity when discussing it. There is no such controversy among mathematicians, everyone (including me) agrees that string theory research has led to all sorts of interesting mathematics. I can't think of any valid reason for you to hide who you are. In addition, it makes it hard to respond intelligently to your criticisms, since all I have to go on about your background is your own admission that you don't know a lot about this subject.

Your attack on me completely ignores that this posting and much of my concerns motivating this blog are about physics and have nothing at all to do with mathematics. As a mathematician, there's no reason you should be concerned about the physics question of evaluating whether string theory, as a physical idea about unification, is a failure or not. My discussion of the Beasley/Heckman/Vafa paper was about this issue, not about the details of their calculations, which quite likely are fine, since these are highly competent people. The issue I was discussing was that of what physical predictions they get out of their model, and I tried to do that carefully.

As for Bagger-Lambert, the Sen conjectures, conifold transitions, dyon partition functions, I haven't posted any criticisms of such work, much less detailed criticisms, and don't intend to, because I'm not critical of such work in any way. I probably think more highly of it than most physicists do. As long as no one is making bogus claims that such ideas solve the problem of making string theory unification predictive and successful, I see nothing to criticize. I'm perfectly happy that some people are working on these topics, they just don't happen to be close enough to my own research interests for me to try and become expert on them and write about them here.

Geometric Langlands is a different story, since it is closely related to my own research, which focuses on the relation of representation theory and QFT. Because of this, I've spent a lot of time learning about Geometric Langlands, and have enthusiastically in some of my blog postings outlined some of what is going on in the subject, while pointing to some of the excellent expostions of this material from people much more expert than me. Witten, David Ben-Zvi, Ed Frenkel and some others are wonderful expositors, and I'm not going to try to compete with them on this. I'm working on some of my own ideas related to the subject, and am in the middle of writing a paper, which I hope to have completed by the end of the summer. The technical details of what I have to say will be in a paper, perhaps with some blog postings giving some general comments and explanations.

As for the relation between string theory and Geometric Langlands, I just don't agree with you that string theory underlies the subject. The relations between Geometric Langlands and physics are almost entirely about QFT, not string theory. This quickly becomes a technical discussion, which isn't worth entering into unless we can agree on what "string theory" is, in particular what the difference is between a string theory and a 2d conformal quantum field theory.

Similarly for the "astonishing mathematical consistency of string theory", to address this, I need to first know precisely what you are talking about. "string theory" is a research program trying to understand a class of physical models, some of which are understood well enough to see that they are likely consistent, but don't work as unified models.

I'm trying here to address your criticisms seriously, if you want me to continue to do so, please use your real name. I've come to intensely dislike trying to have a serious scientific discussion with people not willing to take responsibility for their arguments.

7. **Peter Woit**
June 21, 2008

“buffon”,

As to whether no one takes the kinds of arguments I’m making seriously, you might want to consider whether string theorists from UCSB such as yourself posting stupid anonymous comments on blogs encourages your colleagues to take string theory seriously or not. Are you tenured and thus not worried about this? If not, have you noticed that physics departments have stopped hiring string theorists and asked yourself why this might be?

8. **anon.**
June 22, 2008

‘… [Smolin’s] sympathies are not with Popper, but with Feyerabend’s “anarchistic” views on the subject…’

Popper’s approach that theories must make falsifiable predictions has the problem that it doesn’t include useful ad hoc theories which formulate an equation empirically that summarises existing experiments. If existing experiments already cover the whole range of possibilities, such theories don’t make falsifiable predictions.

E.g., if the deflection of light by the sun’s gravity (and the many other consequences of general relativity) had been observed prior to November 1915, would general relativity have been dismissed for not making falsifiable predictions?

If so, the only reason for dismissing general relativity as unscientific would be the historical accident that observations and experiments happened to discover phenomena before Einstein and Hillbert came up with a theory for it. It’s a paradox if historical accidents determine whether a theory is scientific or not scientific.

So clearly, falsifiability isn’t the key criterion for science.

Feyerabend’s Against Method takes the pragmatic view that there isn’t a scientific method. Whatever theory turns out to be most useful is the most scientific. Because string theory has in the past been the most useful fundamental physics research in helping theorists to get books to sell and to get research grants, it has been the most practical and therefore the most scientific of the various options. Even while it flounders in the landscape problem, because no better theory evident, so string theory remains the leading contender for a scientific theory of everything. [I am not a string supporter; I’m just explaining why string can’t be undone.]

9. **Arun**
June 22, 2008

Whether you go Popperian or Feyerabendian, in both philosophies, science is seen to be dealing with facts, i.e., statements about how the “real world operates” (or “consequences” as anon. at 5:47 AM put it, as in “and the many other consequences of general relativity”). Falsifiability is simply one prescription of the relation between the facts a theory generates and whether the theory is scientific or not. Even with Feyerabend, even if a new theory need not be compatible with all known facts, or not produce any not-already observed facts, it nevertheless has to produce some statements of fact, some consequences. This is where superstring theory as a theory of particle physics seems to be deficient. What the the consequences of a superstring particle physics theory? It would seem that there are none.

“Carroll told about having asked various string theorists if they could imagine any kind of experimental result at any energy that would be incompatible with string theory, and getting the answer “No” from at least some of them.”

10. **Garbage**
June 22, 2008

I find the following ad pretty funny:

“Eat s*it… trillions of flies cannot be wrong”

It’s a delicate subject. No one is going to deny the influence of string theory, or better said string theorist, in high energy physics.
String theory provides some sort of *educated EFT guessing*, and promoted the XD revolution, the ADS/CFT correspondence and lots of fun math.
Given the fact that we’ve been playing this game for the last 20 years, I think finally here it comes the time the bushiting is over. Let’s turn on the machine for physics’s sake! And elect Obama by the way

Unfortunately, the era of phenomenologists looks quite grim to say the least…

G

[…]

Whatever theory turns out to be most useful is the most scientific. Because string theory has in the past been the most useful fundamental physics research in helping theorists to get books to sell and to get research grants, it has been the most practical and therefore the most scientific of the various options.

Did it occur to you that the word ‘useful’ has two very different meanings in the context you give? A theory can be ‘useful’ to understand the world we live in. It can also be ‘useful’ to get research grants and to become famous by writing books about it. The problem arises if both versions of usefulness are disconnected from each other.

Best,

B.

12. **milkshake**
June 22, 2008

I grew up in the same country as Lubos Motl and I remember being told that a critique was ofcourse needed – but to be taken seriously one should make a constructive criticism, one should work withing the framework of the regime – and while there were some minor difficulties they were to be viewed in the context with the past achievements. We were told that there were also some enemy detractors who were professional failures, bitter men with a clear agenda but no future.

13. **anon.**
June 22, 2008

The marketing usefulness which string theory enjoys as being the leading theory of everything *helps to fund* the useful ongoing research that seeks to apply the theory to observables. So the two uses you distinguish are interdependent, not disconnected.

14. **Eric**
June 22, 2008

String theory is useful in the sense that it is possible to construct models that agree with the Standard Model, which in addition include gravity. Even if it were not possible at the present time to uniquely predict the values of all the SM parameters, it is still very significant that such a consistent framework exist. Do you know of any other theory which can do the same?

In any case, all of this talk about being successful at selling books and getting grants is nothing more than petty jealousy. If your research area were as promising then you would have no difficulty doing the same.

15. **Buffon**
June 22, 2008

Peter,

And if in 5 years the number of string theory hires are even lower will you stop blogging and start doing actual research? The assumption that the lower number of string theory hirings are due to your acitivities is uber hilarious and comments like that are the main reason I like reading your blog 🙂 If you did not assume that then I have no idea what makes you believe anyone takes you seriously.

Actually, that's a question on its own: what makes you believe that more than 2 people in the particle physics community take you seriously?

Paragraph insulting others and characterizing non-string theorists as crackpots deleted

All the best to everyone, keep up the good work, it's always fun to let out the steam 🙂
Buffon

16. **Peter Woit**
June 22, 2008

"Buffon",

You've completely misunderstood my point. The fact that US physics departments have pretty much stopped hiring string theorists has little to do with me, and a lot to do with string theorists like you. Many of your non-string theory colleagues do read blogs, and haven't failed to notice that string theorists feature prominently, often engaging in anonymous insult of anyone who disagrees with them. Would you want someone like that as a colleague? And since the anonymity means you can't tell who is who, wouldn't you be tempted to just not hire any string theorist to be safe? It's not like the field is having great successes these days anyway…

You've now used up your allotment of juvenile anonymous insulting here. Bye.

17. **Buffon**
June 22, 2008

Peter,

Honest question: have you ever been on a hiring committee in particle physics? If yes, you would know that the selection criteria does not include anything related to blogs and neither do personality issues matter. In other words if someone does good work but at the same time is a real SOB who likes insulting people he/she will be hired no matter what since the requirement is that good work should be done.

Cheers,
Buffon (not a string theoriest, by the way)

18. **woit**
June 22, 2008

"Buffon",

I've been on hiring committees in mathematics, not particle physics. Sure, it's possible to be an asshole and get hired. All you have to do is be a much better candidate than the non-assholes.

Who knows who you are, but if you're really not a string theorist, with friends like you string theory doesn't need enemies….

19. **Bee**
June 22, 2008

Anon,

You completely miss my point. What I am saying is that 'marketing' and 'advertising' shouldn't influence what scientists consider interesting and work on. But this is, as you say, de facto the case. If you allow that, you allow a kind of 'usefulness' to arise that originates in social, political, financial 'usefulness' which a priori has nothing to do with the actual 'usefulness' for describing nature. You can produce completely empty bubbles of nothing in this way. (Bubbles of nothing is a phenomenon we know pretty well from the stock market, this is not a coincidence.) You say, there is a connection between funding and thus how much effort goes into the field. Right! What I am asking is, how can we expect the funding and the resulting research effort to accurately expect the actual promise of a research field if we distort the judgement deliberately with marketing tactics? Best,

B.

20. **anon.**

‘I grew up in [Czech Republic when it was a Warsaw Pact satellite of the USSR] and I remember being told that … to be taken seriously one should make a constructive criticism … We were told that there were also some enemy detractors who were professional failures, bitter men with a clear agenda but no future.’ – Milkshake

That’s not just communist brane-washing! It’s actually an American disease too, for similar reasons (social niceties). See Dale Carnegie’s argument for sycophancy in his bestseller (over 16 million copies sold) *How to Win Friends and Influence People*:

‘Principle 1: Don’t criticise, condemn or complain
‘Principle 2: Give honest and sincere appreciation …’

21. **Peter Woit**
June 22, 2008

“Buffon”

I’ve deleted your latest comment, you seem incapable of writing one that doesn’t trash someone or other. Doing this anonymously is extremely unprofessional and juvenile behavior. If you want to engage in discussion here, act like a grown-up, put your name to your words and take responsibility for them and for your behavior.

22. **Leonard Ornstein**
June 22, 2008

Popper’s “falsifiability” is just one leg of “decidability”.

The pre- and post-Popper criterion of what is or is not science seems to be whether a model might generate ‘predictions’ which would be decidable, WITH SOME CONFIDENCE, by past or future INDEPENDENT empirical observation.

By this broader and more rational criterion, string theory is still found wanting – as is pure math.

Hope this helps.

23. **chimpanzee (aka "joe")**
June 23, 2008

“If you can’t dazzle them with Brilliance, baffle them with B***SH*T”
“If you can’t convince them..CONFUSE THEM”

Marketing & PR (BS’ing to varying degree) is an evolutionary tactic. Insects use camouflage extensively.

“War is about DECEPTION”
— Sun Tzu, “Art of War”

Science is no different from War: it involves competition between groups. Politicians are the best example of “using lies to defend an absurditiy”:

“Every absurdity has its Champion”

Lying quotes

“**If you tell a lie big enough and keep repeating it, people will eventually come to believe it**………….The lie can be maintained only for such time as the State can shield the people from the political, economic and/or military consequences of the lie. **It thus becomes vitally important for the State to use all of its powers to repress dissent, for the truth is the mortal enemy of the lie, and thus by extension, the truth is the greatest enemy of the State.**”
— Joseph Goebbels, German Minister of Propaganda, 1933-1945

“A lie told often enough becomes truth”
— Vladimir Lenin.

My view of all the “way out” theories (which have gone beyond any hope of experimental verification) is that they are defended with equally “way out” explanations for predictive power. In engineering, there’s a phrase for hardware hacking: “kludge upon kludge”. I was at SUSY ’06, & somebody walked past me muttering “making stuff up”.

25. **onlooker**
June 26, 2008

Eric,

re: string theory providing a “consistent model” of *some* unification, what are you referring to, and what value is it supposed to have? We already know that some logically consistent unification should be possible (since the universe exists and contains both QM and gravity). On the other hand, there is no known consistency in the mathematical sense of a rigorously constructed model of axioms that demonstrates their non-contradiction. We don’t even know what the axioms are, exactly, because string theory is not precisely defined at the moment.

It’s true that there are a number of nontrivial consistency checks that the string formalism satisfies (or might satisfy once formalized precisely). That suggest a mathematical project of formalizing at least SOME of the expected properties of a string theory as axioms, and giving a “consistent model” of those. But that would be open to the objection that it's not really the full string theory. It could be that there is a consistent mathematical core (e.g., a topological M-theory) that accounts for all the fragments of string theory currently shown to be consistent, and that things beyond that are wrong and need some further correction to BECOME consistent.

In short, string theory is at the moment a promising web of (not always precise) calculations still under construction, and it seems premature to talk about its "consistency". The rules of calculation are progressively specified and re-specified (fixing various problems over time) so that contradictions are eliminated, and we know that two degenerations of the theory are logically consistent (QFT, GR), so why is it a major surprise that the set of rules converges or doesn't run into fatal problems over time?

26. **Eric**
June 26, 2008

Dear onlooker,
I am referring to the fact that gravitation and quantum mechanics are unified consistently into the same framework. It is consistent framework because of the absence of anomalies. Thus, it is possible to build specific quantum field theories from string theory, which also include gravity. In fact, it is now believed that gravity and quantum field theories are dual viz Ads/CFT. Now, it may be the case that there is no single unique quantum field theory, at least at the present level of understanding, but at least it is possible with string theory to bring gravity into the story

27. **onlooker**
June 27, 2008

Absence of anomalies doesn't mean that the theory is consistent, only that one particular type of inconsistency in a particular family of calculations doesn't show up. This is a "consistency check", not consistency as such. If the theory itself is ill-defined, i.e., the rules separating valid from invalid computations are not completely specified, then however impressive the anomaly cancellation calculation, it doesn't rule out that there is an equal and opposite calculation giving a nonzero anomaly.

Also, is it ruled out that anomalies re-appear nonperturbatively, as an obstruction to writing down a consistent theory (rigorous mathematical model) whose expansion near some point(s) is perturbative string theory?

[I am not a string supporter; I'm just explaining why string can't be undone.]

–quote–

By all means, theories are not to be valued at the basis of how many books it sells, how many blog entries are attributed to it, or other such qualifications, since that has nothing to do with what scientific theories are for, namely: to explain facts about reality in a cohorent and consistent way such that predictions made by the theory can be tested, and using the least assumptions.

Further, I do very much oppose the idea of a 'theory of everything' since any real physical theory can only explain specific facts and only part of reality (and besides, there is already is a trivial 'theory of everything' namely the theory that 'everything is caused by everything' which is true in the tautological sense, yet does not explain anything in particular, and hence has an information value of exactly zero).

Perhaps this is just a matter of terminology, and such 'theories of everything' (such as string theory) should be better termed 'frameworks' or 'models', which could be quite usefull to develop specific theories, which are scientific theories in the sense of the definition mentioned above. A tool, framework or model can be very handy, indeed, but does not qualify as such as a theory, unless it makes specific new testable predictions.

Specific theories should have specific testable predictions.

The example given about the theory of general relativity is a bit non-sense, since the theory makes many predictions which can be tested, and which makes it possible to distinguish the theory of gravity of Newton with that of General relativity since it leads to different outcomes. There are numerous new predictions that can be made which can test for that.

Wether a new theory can be said to be a new theory, if it merely explains facts already covered in existing theories in a new framework (and supposedly more generic way) is a bit of an acedemic question, but one should expect that such a new theory covers some new ground, and on that is able to make new predictions that could be tested, which the theories it mererely replaces, could not.

Rearranging or reformulating a theory without increasing the level of understanding, or making any new predictions, would not qualify as a new theory in my opinion. Rearranging the seats of an old car, does not qualify the car as "new" either. Which does not contest that such could be usefull in some cases.

The Black Hole War

June 23, 2008
Categories: Book Reviews

Leonard Susskind has a new book that's now out in the bookstores, entitled The Black Hole War: My Battle With Stephen Hawking to Make the World Safe for Quantum Mechanics. It's about the black hole information paradox, structured around his story of debates with Hawking over the years on this topic.

Back in 2005 I wrote a review here of his previous book, The Cosmic Landscape, which I found pretty much appalling (and my opinion hasn't changed). There Susskind deals with the failure of string theory by promoting out-right pseudo-science, of a sort that unfortunately has been highly influential. I'm happy to report that his new book is about 10^{500} times better. In its 450 or so pages, the string theory landscape, the multiverse, and anthropic reasoning make no appearance, with Susskind sticking to legitimate science. Instead of breathless promotion of string theory as a unified theory, here he is cautious about this, emphasizing repeatedly that he is just invoking string theory as a presumably consistent framework for resolving conceptual problems raised by quantum gravitational effects of black holes:

> How do we use String Theory to prove something about nature if we don't know that it's the right theory? For some purposes it doesn't matter. We take String Theory to be a model of some world and then calculate, or prove mathematically, whether or not information is lost in black holes *in that world*.

He even notes that:

> Being called a string theorist irritates me; I don't like being pigeonholed so narrowly.

The style of the book is often over the top, going on about battles and wars, with chapter headings from Churchill's history of World War II. As is the custom for books in this field, the fly-leaf copy is pretty much nonsense. But, at a general audience level, Susskind gives a good introduction to lots of topics in physics and to the black hole information paradox in particular. It is livened up with various entertaining color and anecdote, starting with a description of hearing about the paradox from Hawking back in 1983 at a conference held in Werner Erhard's mansion. He describes discussing black holes with Feynman, approaching him first at a urinal in Pupin, the Columbia physics building, and moving later to the local West End Bar (recently turned into a Cuban restaurant).

He ends not with triumphant claims of victory in his war, but with an appropriate description of the current state of fundamental theory:

> Confusion and disorientation reign…. Very likely we are still confused beginners with very wrong mental pictues, and ultimate reality remains far beyond our grasp… The more we discover, the less we seem to know. That's physics in a nutshell.

It turns out that Susskind is now a fellow blogger, blogging at Susskind's Blog: Physics for Everyone.

Update: At Backreaction, there's a new posting explaining what the paradox discussed in Susskind's book really is, at a level more appropriate for physicists.

Update: Some links to reviews. Paul Davies, Sean Carroll, George Johnson. See here for a review of the Johnson review by John Horgan.

Comments

1. **Observer**
   June 23, 2008

   To whom it may concern,

   I realize that this is a bold question but I dare ask it anyway: do we have any objective evidence from astrophysical observations that Black Holes follow the principles of Quantum Mechanics? If not, what entitles both Hawking and Susskind to start from the fundamental assumption that the physics of Black Holes can be described in a quantum framework dominated by locality and unitarity?

2. **Peter Woit**
   June 23, 2008

   Observer,

   The questions about black holes being studied here have nothing to do with currently feasible astrophysical measurements.

3. **Bee**
   June 24, 2008

   Hi Peter,

   Thanks for the review! Sounds as if I should give it a read (when I'm through with the ten books I'm currently reading that is). I've tried the Cosmic Landscape, but lost interest halfways and didn't like the writing style either, so never finished it (though I probably read the epilogue if there was one). Since you mention the urinal in Pupin, I've always wondered what a women in science misses just by using a different restroom 😉 (Otoh, I worked at an institute where the Prof used to distribute duties while the men's restroom, as a result several of the guys started using the women's restroom, no kidding.) Best,

   B.

   PS: Do we know it's really Susskind's blog (or attempt thereof)? I mean, everybody could download a photo and sign with whatever.

4. **anon.**
   June 24, 2008

   'The questions about black holes being studied here have nothing to do with currently feasible astrophysical measurements.' – Woit

   So it's analogous (in not being tied to experimental facts) to stringy theories resolving imagined Planck scale physics problems.

   Bee: since imitation is the sincerest form of flattery, a fake Susskind blog would be easily distinguishable from the real thing.

5. **Peter Woit**

June 24, 2008

Bee,

My personal experience is that I haven't found any significant networking or mentoring opportunities while relieving myself at the Pupin urinals (or any others, for that matter). But maybe that's just me…

The Susskind blog mentioned in my posting is legitimate. I learned about it from information on one of the cover pages of the book. Looks like it's just a blog associated with an introductory course he was teaching, not clear if he intends to use it for other purposes, for instance to discuss his new book.

6. **Christine**
June 24, 2008

Excuse me for being off-topic. At the end of this [interesting news](), one reads:

By continuing their research into the forces of nature, the astronomers also hope to find a window into the extra dimensions of space that many theoretical physicists think may exist.

But no reference is made on how this could be accomplished in terms of the observational research in question.

7. **Professor R**
June 24, 2008

Thanks for bringing it to my attention. I had a look on Amazon and enjoyed the blurb

" an effort that would eventually result in Hawking admitting he was wrong, paying up, and Susskind and t'Hooft realizing that our world is a hologram projected from the outer boundaries of space". Ah

One serious point – I don't like the use of Hawking's name in the title. While I'm sure Stephen won't object, it's a fairly obvious marketing ploy, and can only result in yet more hyping of one particular scientist.
Hard to imagine Bohr writing a book entitled'My battle with Einstein…" isn't it?

8. **observer**
June 24, 2008

Peter,

With all due respect, I disagree with your reply:

"The questions about black holes being studied here have nothing to do with currently feasible astrophysical measurements" – Woit

Physics near any Black Hole singularity most likely falls outside the domain of validity of quantum field theory and statistical mechanics, as we know them. Anon. is right when he states that the situation "it's analogous (in not being tied to experimental facts) to stringy theories resolving imagined Planck scale physics problems"

Regards,

Observer

9. **Peter Woit**
June 24, 2008

Observer,

I don't see what you disagree with. There are no current or planned astrophysical measurements relevant to seeing what happens at a black hole singularity.

Susskind is writing about the study of toy models of quantum gravity, he makes no claim to be considering anything that even in principle can be directly compared to the real world (unlike in the "Cosmic Landscape", where he was advertising supposed potential unified theories).

10. **Christine**
June 24, 2008

There are no current or planned astrophysical measurements relevant to seeing what happens at a black hole singularity.

Not exactly, but of course rotating black hole solutions to Einstein's equations can be inferred from the modelling of iron emission line of accretion disks around black hole candidates, see, e.g., [here](), characterizing the black hole spin.

11. **David P**
June 24, 2008

Dr Susskind explains how physicists think about information theory:

Go to 01:15:30 in the Perimeter Institute Public Lecture: The Physics of Information: From Entanglement to Black Holes

http://www.perimeterinstitute.ca/Outreach/Public_Lectures/View_Past_Public_Lectures/

12. **anon.**
June 25, 2008

The black hole information problem is *not* an "imagined Planck scale physics problem", for those of you who are worried about that; it has nothing to do with physics near the singularity and can be seen entirely within effective field theory on weak-curvature spatial slices.

13. **Bee**
June 25, 2008

Thanks for the link! It was a coincidence I just wrote this post, it had nothing to do with Susskind's book. Best,

B.

14. **George**
June 26, 2008

Why does Susskind accept Intelligent Design Creationism? This was in his Lecture 1. Seems a scientist would, well, be more of a scientist.

15. **Chris W.**
June 26, 2008

George,

I think you misunderstood Lecture 1. He has been known to declare (suggest?) that, if an multiverse-based anthropic explanation for the values of certain apparently universal quantities left underived within the Standard Model does not work, then we will be forced to fall back on intelligent design as the only alternative. I don't know how serious this assertion is supposed to be.

(Leaving aside the essential vacuousness of ID, that is an overstatement.)

16. **hmmm**
June 26, 2008

Susskind was just using a dubious debating ploy, saying in effect that the String Theory Multiverse is not a bad idea, because Intelligent Design Creationism is an even worse idea. It's a bit like saying Aristotlean Epicycles is not a bad idea, because Planets Pushed Around the Sky by Angels is an even worse idea.

Astute listeners/readers see through this debating ploy by noting that there are more than there are more than two ideas, and that not being the worst idea is not the same as being the best idea.

17. **hmmm**
June 26, 2008

I have ordered the book. I'm looking forward to it. I tried reading "An Introduction to Black Holes, Information And The String Theory Revolution: The Holographic Universe", but was completely baffled by it. I might learn some interesting physics from this new book, though I'll read it with a sufficiently large grain of salt when it comes to the author's personal opinions, as with any such book.

However, I am curious about something that maybe physics people might know. Is Susskind actually serious about some of the things he says? He seems funny and entertaining on TV documentaries that I have seen (including one on the topic of this book), but I can't tell if he's just pulling people's leg with what he says. He says that since the String Theory Multiverse idea compares favorably to the Intelligent Design Creationism idea, then the String Theory Multiverse idea must be right! Really? Does such an intelligent person actually believe that kind of logic? He says he at **war** with Hawking! **War**? Really? Especially when you compare it to the hyper-polite debate the Susskind had with Smolin on edge.org, why does poor Hawking get war?

18. **Chris Oakley**
June 27, 2008

Hmmm,

Erm, no.

Susskind is not actually at *war* with Hawking, it is just that Hawking is better known than Susskind and Susskind wants to have his name associated with him.

19. **hmmm**
June 27, 2008

Surely if Susskind really wanted to cynically title his book to boost sales he easily could have worked the word "God" somewhere into the title.

20. **anon.**
June 27, 2008

hmmm, I think that Hawking is bigger than God in the publishing industry. According to the Foreword of Hawking and Leonard Mlodinow, *A Briefer History of Time*, Bantam, 2005, p1:

'*A Brief History of Time* was on the London *Sunday Times* best-seller list for 237 weeks and has sold about one copy for every 750 men, women, and children on earth.'

21. **go**
June 27, 2008

>Astute listeners/readers see through this debating ploy by noting
> that there are more than there are more than two ideas, and
> that not being the worst idea is not the same as being the best
> idea.

As a matter of fact, there really aren't any better ideas other than the multiverse to deal with things like the cosmological constant problem. Multiverse is a logically allowed, but cheap explanation for the problems of physics. There are no successful non-cheap explanations I know.

Anyway, Susskind was just being his quirky self, people who pontificate about his "unscientific" attitude to creationism make me laugh.

22. **George**
June 27, 2008

Chris W.

I do not think I am wrong. Dr Susskind said plainly that, while he preferred Darwin, that those that prefer an Intelligent Designer, that's fine.

That statement is clearly providing "his scientific" credence to ID Creationism. This is something no real scientist could ever do. He has lost the battle for credibility in scientific light – his thinking is clearly not lucid.

His statement is in no way related to physics it was a comment about human evolution or design (as he says is an acceptable alternative view to evolution.)

23. **Peter Woit**
June 27, 2008

Given everything I've seen from Susskind, I don't believe he's a supporter of the idea that ID is as scientific as Darwinism. He clearly enjoys trying to be provocative and outrageous. In one story he tells in the book, he and Feynman are getting a "Feynman sandwich" at the local deli, and Feynman remarks that a "Susskind sandwich" would be similar, but with "more ham".

Anyway, people can watch the video segments involved and make up their own minds, but enough already about this one.

24. **Jonathan Vos Post**
June 27, 2008

I don't remember — what is a Feynman sandwich?

Is it constructed by his path integral formulation of quantum mechanics, his theory of quantum electrodynamics, different from all classical sandwiches because of quantum computation, or extremely small as per his invention of nanotechnology?

The Feynman sandwich on the largest number of shelves is a volume 2 of the Lecture Notes on Physics sandwiched between a volume 1 and a volume 3.

All that I remember was the sandwich he had the owner of the topless bar in Pasadena add to the booze menu, after the City shut it down. That was a ham and cheese sandwich.

Feynman, who liked going there ("after a hard day dealing with oscillating bodies, it's nice to see some oscillating bodies"), succeeded in keeping the place open a few more months. When the city tried enforcing the anti-topless-bar ordinance, the owner could now say: "we're not a topless bar. We're a topless restaurant."

25. **hmmm**
July 1, 2008

go Says: "*As a matter of fact, there really aren't any better ideas other than the multiverse to deal with things like the cosmological constant problem. Multiverse is a logically allowed, but cheap explanation for the problems of physics. There are no successful non-cheap explanations I know.*"

By "multiverse" I am sure you mean the Anthropic Principle. But there are certainly much better ideas than this, for example, Cosmological Natural Selection, as explained by Smolin, Dawkins and others. Susskind knows the arguments. He may not agree with them, but he shouldn't pretend these ideas don't exist.

26. **somebody**
July 1, 2008

hmmm said: By multiverse I am sure you mean the Anthropic Principle. But there are certainly much better ideas than this, for example, Cosmological Natural Selection, as explained by Smolin, Dawkins and others.

The multiverse does not necessarily mean the anthropic principle. In fact your example, cosmic natural selection, is a dynamical (non-anthropic) selection principle in the multiverse. But as it stands, it is more wishful thinking than something concrete. That of course doesn't mean that it is wrong.

27. **hmmm**
July 1, 2008

Ha! I thought somebody might make that point. (Not you specifically "somebody", but *somebody*!) Yes there are many proposals for why the universe is the way it is, and terms such as "multiverse" may potentially be ambiguous, although usually the context makes it pretty clear what is meant, as was the case above.

Anyway, there are ideas that are much better than what Susskind and "go" mean by "multiverse", and they shouldn't pretend these ideas don't exist or irrationally dismiss them.

28. **somebody**
July 2, 2008

"Anyway, there are ideas that are much better than what Susskind and go mean by multiverse, and they shouldn't pretend these ideas don't exist or irrationally dismiss them."

"Much better" ideas? Sorry, I am not sure I know any. There are a lot of wishful thinking/brain-fart level ideas that I know of. But nothing that seems to hold promise for anything concrete (including your favorite cosmic natural selection). Landscape/multiverse is pretty concrete – even though it seems useless for making predictions. But this might be just like field theory: it is useless for making predictions of for example, charges and masses of particles. Its through experiments, not theory, that we fix parameters. Unfortunately, this is an era where experiments are hard.

There, I have the entire "string controversy" in a nutshell for you. 🙂

29. **hmmm**
July 14, 2008

Re: Chapter 20 of Susskind's book.

What's the deal with Alice's Airplane and Bonzo Dog Food? Is he describing something conventional and common knowledge here? I hadn't seen this idea before in popularized physics writings.

Actually these fractally nested propellors would make for a pretty interesting comical hat.

30. **hmmm**
July 20, 2008

Okay, so the book is fun to read and is educational, but maybe the title should be "The Black Hole storm-in-a-teacup". Sure, the underlying questions are deep, and Hawking, Susskind and many others have made important contributions, but QT and GR have not been unified, and nothing has been resolved or proved here.

31. **Dorothy**

July 24, 2008

I recently downloaded Susskind's book from Audible.com and put it on my iPod. I am finding it extremely interesting. Susskind is funny, explains things very clearly. So far, I am about half-way through, I am enjoying it very much. Highly recommended.

32. **Christine**
July 31, 2008

Paul Davies wrote a review of Susskind's new book, it has just been published in Nature.

33. **anon.**
August 27, 2008

The hyperlink to Paul Davy's Nature review of Lenny Susskind's book isn't working, but the correct link is here:

Supplemental US Science Funding

June 27, 2008
Categories: Experimental HEP News

The Senate last night agreed to the House version of a bill that adds some supplemental science funding for FY2008, as part of a large "emergency" bill used to fund the the Iraq and Afghanistan wars. The DOE Office of Science and NSF will each get $62.5 million. The bill contains language giving priority to stopping layoffs and furloughs, and to funding neutrino research at Fermilab. It should allow Fermilab to stop planned involuntary layoffs (furloughs had already been ended by an anonymous $5 million donation).

For more, see this from Oddone, as well as more here and here.

Comments

1. **chris**
   July 1, 2008

   while i of course applaud this additional money to ammeliorate an emergency situation, i find it highly distressing for the future of our field to see how tightly coupled the whole high energy community still is to military expenses and developments. i think that this is an extremely unhealthy development for the long term future of our field. not only will politicians at some point realize that there is no further gain from hep research for the construction of new weapons, but on a more general level, hep will – at the level of the society – not be seen as a cultural endeavor to understand the fundamental workings of nature, but rather as groundworks for the war industry.

   extrapolating maybe 30 years into the future (i know how ludicrious that might be), i am afraid of the scenario where hep research is still in need of large money for large machines and will therefore be all but assimilated by the military complex and distested by public opinion.

2. **Peter Orland**
   July 1, 2008

   People in the highest places of government have long aware that high-energy physics has no military applications, except through spin-offs. I don't think it has been true since the 1970's that we were viewed as an extension of national defense. R. Wilson gave his famous testimony advocating constructing Fermilab ("It has nothing to do directly with defending our country except to make it worth defending.") in 1969. See

   http://www.news.cornell.edu/releases/Jan00/RRWilson_obit.hrs.html

   The attachment of funding to the military is probably a coincidence and should not be taken too seriously.

   Some politicians value our field and others do not, and my impression is that there is little connection with ideology, party affiliation or closeness to the Military-Industrial Complex. We just need to do a better job of promoting ourselves.

Wonders of Gauge Theory and Supergravity

June 27, 2008
Categories: Uncategorized

A workshop in Paris/Saclay is taking place this week entitled Wonders of Gauge Theory and Supergravity and the talks are now online. They show that some exciting new things have been happening in the study of gauge theory and supergravity amplitudes, and I'll make the prediction that this field will attract a huge amount of attention in the coming years (at least until the LHC experiments announce results incompatible with the Standard Model…).

Perhaps the most remarkable part of this whole story is the mounting evidence that N=8 supergravity amplitudes are finite in perturbation theory. Remember the standard story about how quantum theory and general relativity are incompatible that has dominated discussion of fundamental physics for years now? Well, it turns out that this quite possibly is just simply wrong. See Zvi Bern's talk on UV properties of N=8 supergravity at 3 loops and beyond for the latest about this. Bern shows that divergences everyone had been expecting to occur at 3 loops aren't there, and gives evidence that they might also be absent at higher loops. He even sees this as a phenomenon not special to N=8 supergravity, but also occurring in theories with less supersymmetry, e.g. the N=5 and N=6 theories. Among the other talks, Nima Arkani-Hamed's is also about this, advertising the idea that N=8 supergravity is the Simplest QFT.

Much of this story is about the N=4 SYM amplitudes and new insights into them and their relations to supergravity amplitudes, with some of this research growing out of and motivated by the AdS/CFT conjecture of the existence of a string dual to N=4 SYM. Quite a few of the talks are interesting and worth trying to follow, with a much higher proportion of new ideas than is usual at particle theory workshops in recent years.

To go out on a limb and make an absurdly bold guess about where this is all going, I'll predict that sooner or later some variant ("twisted"?) version of N=8 supergravity will be found, which will provide a finite theory of quantum gravity, unified together with the standard model gauge theory. Stephen Hawking's 1980 inaugural lecture will be seen to be not so far off the truth. The problems with trying to fit the standard model into N=8 supergravity are well known, and in any case conventional supersymmetric extensions of the standard model have not been very successful (and I'm guessing that the LHC will kill them off for good). So, some so-far-unknown variant will be needed. String theory will turn out to play a useful role in providing a dual picture of the theory, useful at strong coupling, but for most of what we still don't understand about the SM, it is getting the weak coupling story right that matters, and for this quantum fields are the right objects. The dominance of the subject for more than 20 years by complicated and unsuccessful schemes to somehow extract the SM out of the extra 6 or 7 dimensions of critical string/M-theory will come to be seen as a hard-to-understand embarassment, and the multiverse will revert to the philosophers.

Many of the titles of the talks at Strings 2008 have recently been announced. The plenary talks will include several talks mostly not about string theory, including 3 about the LHC and one by Lance Dixon on the amplitudes story. It seems that the string theory anthropic landscape is a topic the conference organizers don't want anything to do with, since the only person from the Stanford contingent speaking will be Kallosh on prospects for getting something observable out of string cosmology models of inflation. As for what is popular, it clearly helps a lot to be from one of my alma maters, with Princeton (7 speakers), and Harvard (3 speakers) the best-represented institutions.

Update: For an extensive rant about this, see here.

Update: Last week was Paris, this week it's Zurich. Amplitudes are all the rage this summer.

Comments

1. **Coin**
   June 27, 2008

   Something I hear about occasionally is some group of researchers somewhere who believe gravity has a "UV fixed point", which would apparently make gravity renormalizable. Is this "UV finiteness" thing Zvi Bern is describing the same thing or is that a different research program?

2. **Peter Woit**
   June 27, 2008

   Coin,

   The "UV fixed point" proposal is something different, using the renormalization group to tell you how to handle divergences. In what Bern is describing, the divergences are just not there, presumably for some still poorly understood symmetry reason.

3. **Daniel de França MTd2**
   June 28, 2008

   Let me see if I understood the main objective of this line of research. They are trying to prove that N=8 supergravity is renormalizable, and use this to prove that other supergravity theories with lower and lower N can also be renormalizable, until they get N=0, which is just the usual gravity. Is this correct? Why not?

4. **majorana**
   June 28, 2008

   OMG, this is so funny. You and Smolin criticize string theory for not being fully defined and not having precise rules for computing multiloop diagrams and you think N=8 sugra is in better shape? You think the theory will make sense non-perturbatively without string theory? You think you're going to get the SM?

   You're deluded.

5. **Peter Woit**
   June 28, 2008

   Daniel,

   The main point of this research program is that it is showing that something is going on in these higher-loop calculations making the divergence structure much better than expected, something which is not fully understood. There is evidence that at least some quantum gravity theories with enough supersymmetry are finite or renormalizable. I haven't seen any claims that this will be true for N=0. For trying to unify gravity and the SM, you actually don't want the N=0 theory by itself to make sense, but rather have consistency determine the extra fermionic and other fields that we observe.

   "majorana",

"OMG, this is so funny."

You know, you give all appearances of being a 12-year old whose knowledge of this subject is based on reading Lubos's blog. If you actually know anything about this, and want to have a serious discussion about science, please stop with the juvenile behavior.

6. **Daniel de França MTd2**
   June 28, 2008

   Hi Peter,

   "I haven't seen any claims that this will be true for N=0." Well, I point this out: p. 35 (No known susy armunte explains these cancellations). p.38, p.40

   I thought that it was a claim…

7. **Peter Woit**
   June 28, 2008

   Daniel,

   What I meant is that I didn't see any claim that for N=0 you would get cancellations at all orders. It is certainly true that even for N=0 Bern et. al. are finding unexpected cancellations.

8. **Robert**
   June 28, 2008

   Arkani-Hamed aparently previously gave the same (very nice) talk at Perimeter Institute, which is online on video here:

   http://streamer.perimeterinstitute.ca/mediasite/viewer/NoPopupRedirector.aspx?peid=ff9a6fa8-bfde-44b3-a91b-bba7c382720f&shouldResize=False

9. **Daniel de França MTd2**
   June 28, 2008

   Hi Peter,

   He does not claim, but at least this is the impression I got when I read everything, with p. 42 on my mind… Nevermind then…

10. **Patrick Labelle**
    June 28, 2008

    Interesting stuff. But it is my understandind that phenomenologically, theories with N>1 are not viable because they necessarily treat left-handed and right-handed spinors the same way so they cannot accomodate the SM.

    So what is the situation:

    a) For now this is seen as a purely formal exercise to try to understand these mysterious cancellations (that apparently go beyond the usual SUSY cancellations) with no goal to connect to phenomenology

    b) This is only the first step of a program in which the second step would be to somehow reduce the N=8 theory to N=1. (by breaking 7 of the SUSY explicitly? By another approach?)

    c) Something else that I am completely missing

    Thank you for the very informative blog, btw.

11. **Peter Woit**
    June 28, 2008

    Patrick,

    For now the situation is a), Bern says this pretty explicitly. As you note, there are well-known problems with getting the SM out of N=8 supergravity. A lot of people worked on these in the early 80s, but most gave up once the conventional wisdom became that the theory was non-renormalizable, and string theory got going. Maybe some people will start looking at these problems again. In any case, it would be very intersesting to know what is causing this, presumably some sort of non-obvious symmetry in these theories.

12. **Anonymous**
    June 29, 2008

    Hi Peter,

    Two questions:

    (1) I'm new to hep. Can you suggest a suitable text to study gauge theory (perhaps the one you studied from)?

    and

    (2) When is the LHC expected to officially start (at least tentatively)? And how long is the data-gathering process expected to last? If no Higg's particle/s is/are found, will it mean another odd no. of decades before another set of experiments are to replace the current set?

    Would love to read your feedback.

    Regards,
    Jeffrey

13. **Peter Woit**
    June 29, 2008

Jeffrey,

Among the newer QFT books that discuss gauge theory, the one I like best is probably the one by Nair.

Latest about the LHC is that it will be ready to try injecting beams in August, first physics collisions maybe by October, with a month or two of data-taking at low luminosity this year. This won't be enough to find the Higgs. That will take another year or two of data-taking.

Getting to higher energies than the LHC is going to take a long time. The best prospect is probably to increase the LHC energy by using new magnets, but that is probably at least 20 years off if not more.

14. **chethan krishnan**
June 29, 2008

"Perhaps the most remarkable part of this whole story is the mounting evidence that N=8 supergravity amplitudes are finite in perturbation theory. Remember the standard story about how quantum theory and general relativity are incompatible that has dominated discussion of fundamental physics for years now? Well, it turns out that this quite possibly is just simply wrong."

Is perturbative finiteness anything more than a red herring? Of course, it might have useful spinoffs for computing QCD amplitudes etc., but as a fundamental theory, I fail to see the point.

In partidular, it is known that in string theory, just N=8 sugra cannot be consistently decoupled at low energies (Green, Oooguri, Schwarz). So the full UV of pure N=8 sugra is not understood at all, to say the least.

Besides, the perturbative finiteness of N=8 is not that surprising because type I open string amplitudes "square" to type II closed string amplitudes (Kawai, Lllewelyn, Tye), and in d=4 open strings result in the finite N=4 gauge theory, while the closed strings give rise to the supergravity.

What I am surprised by is the claim that some theories other than N=8 might also be finite (even if only perturbatively). Does it have any understanding in terms of strings? Is there something basic that I am missing ?

15. **Arun**
June 29, 2008

If the current program of N=8 supergravity amplitudes being finite works out, it will nevertheless be a four-color-map theorem type of proof. What is encouraging is that there may be a new physical principle to be discovered.

16. **Roger Schlafly**
June 29, 2008

Peter, you are going soft on us. This is just another wacky theory with no connection to reality. It does not because valid or useful just because some of the infinities cancel.

17. **anon.**
June 29, 2008

chethan krishnan wrote:

What I am surprised by is the claim that some theories other than N=8 might also be finite (even if only perturbatively).

Where did you encounter this claim? The claim that is circulating seems to be (a) N=8 may be finite; (b) N<8 is less divergent than expected (but not finite).

18. **Peter Woit**
June 29, 2008

Chethan,

If "the perturbative finiteness of N=8 is not that surprising" because of a simple string theory argument, how come just about all elementary string theory discussions motivate the subject by saying that you need string theory to get perturbative finiteness?

I just don't see any evidence that you need string theory to define N=8 supergravity, or the relevance of the string theory decoupling argument.

N=4 SYM can be defined as a 4d QFT completely independently of string theory, and I don't see why the same shouldn't be true of N=8 supergravity. More interesting though than N=8 supergravity is the larger phenomenon that seems to be going on here of gravity QFTs having some sort of still not understood extra structure or symmetry that may make them finite or renormalizable.

19. **DBM**
June 29, 2008

I think that the problem to get the SM from N=8 sugra is that the R-symmetry sector can not accomodate the SM gauge groups, there are some old papers of kaku-townsend-van nieven…. about it.

20. **chethan krishnan**
June 30, 2008

anon. says:

"The claim that is circulating seems to be (a) N=8 may be finite;
(b) N<8 is less divergent than expected (but not finite)."

So you are saying that the finiteness hope is there only for N=8 sugra, but not so for other theories. But then I do not understand Peter's claim:

"More interesting though than N=8 supergravity is the larger phenomenon that seems to be going on here of gravity QFTs having some sort of still not understood extra structure or symmetry that may make them finite or renormalizable."

Peter also says:

"N=4 SYM can be defined as a 4d QFT completely independently of string theory, and I don't see why the same shouldn't be true of N=8 supergravity."

Does this mean that you consider a Feynman diagram expansion a full description of the theory? The only possible non-perturbative completion of N=8 sugra that I know of is in string theory, and there it does not decouple. That does not bother you?

"If the perturbative finiteness of N=8 is not that surprising because of a simple string theory argument, how come just about all elementary string theory discussions motivate the subject by saying that you need string theory to get perturbative finiteness?"

There are many field theories which are finite. Nobody invokes string perturbation theory to argue their finiteness. The string theory lesson here is NOT about the finiteness of N=8 itself, but that the gauge theory divergence structure here might be related to the gravity case, and so the gravity case might not be as bad as one would have imagined naively.

"N=4 SYM can be defined as a 4d QFT completely independently of string theory, and I don't see why the same shouldn't be true of N=8 supergravity."

Because of gravity! Gauge theories usually have good non-perturbative definitions. Not so for gravity.

21. **Boels**
June 30, 2008

Just some comments:

– The expectation that N=8 diverges at three loops is based on 80-ies technology in proving nonrenormalisation theorems. People like Stelle and collaborators have updated their techniques recently and also find that the 3-loop divergence is not there. I'm not quite sure what the latest prediction is. They are still hoping to find a symmetry proof of finiteness.

– A topologically twisted (?) version of N=8 is not interesting phenomenologically, I think.

– At the exact same conference Berkovits announced that he and Maldacena have some understanding of the appearance of 'dual conformal invariance' in N=4 multiloop computations. This understanding is based on string theory through the AdS/CFT correspondence.

22. **EDT**
June 30, 2008

Peter,

Those links are dead. Am I the only one who can't access them?

23. **Peter Woit**
June 30, 2008

Chethan,

I just don't believe claims you're making about "non-perturbative completion".

The main claim always made for string theory is that it is a "UV completion" of supergravity. This is based on the conventional wisdom that supergravity is ill-defined at high energies due to divergences in higher loop terms of the perturbation expansion, something which is not supposed to happen in superstring perturbation theory. If Bern et. al. are right, N=8 supergravity doesn't need a "UV completion", it is UV complete, in the conventional sense of that term, which is about perturbative calculations.

Sure, for both QFT and string theory, a truly well-defined theory requires a formulation more general than perturbation theory. It's one of the fundamental problems of string theory that this is missing for string theory, so I don't see how one can claim that the significance of string theory is that it provides a "non-perturbative completion".

In AdS/CFT, a perturbative string is supposed to allow a useful approximation to the strong coupling limit of the gauge theory, but there the situation is exactly the opposite of what you want. The gauge theory by itself appears to be defined non-perturbatively, at all couplings (e.g., use a lattice), whereas the string theory is only defined at weak coupling. Here the QFT provides a "non-perturbative completion" of the string theory, not the other way around.

24. **Peter Woit**
June 30, 2008

EDT,

That server seems to be down now, presumably it will come back up at some point. If it doesn't, and the web-site for that conference has moved, please let me know and I'll update the links.

25. **wm**
June 30, 2008

FWIW, it has been suggested recently (link below) that the "still not understood structure" responsible for finiteness involves string theory dualities and symmetries, which points to a much more prominent role for string theory than the role allowed in the post here.
http://arxiv.org/abs/0806.1726

26. **somebody**
June 30, 2008

Though it MIGHT be a logical possibility to think about N=8 supergravity as a standalone theory, it really makes a lot of things (BPS solitons for example) significantly more artificial. From such a point of view, it is merely an extraordinary coincidence that the theory seems to have a natural 11 dimensional origin.

Maximal supersymmetry is most natural in 11 dimensions. If we are working with maximal local supersymmetry, it takes a lot of effort to NOT believe in string theory, considering all we have learnt in the last decade or so. Most of what we have learnt is based purely on supersymmetry.

27. **p falor**
July 1, 2008

Hi Peter:
Read your book but I am confused on a couple of things that are unclear to me. Maybe you can help. I understand that ST is referred to as not A QFT. But I read one QFT

book (the first section) that suggested ST was a QFT but just used a different way of treating time as opposed to standard QFT. If ST is not a QFT are there still virtual particles in ST? Please help. Also I have read that GR is/is not a gauge theory. Obviously only one viewpoint is correct. Thanks.

28. **Daniel de França MTd2**
July 1, 2008

Hi Peter,

I found an argument somewhere else…

"You might propose to break the N=8 supersymmetry spontaneously. However, N=8 supersymmetry cannot be spontaneously broken to N=1 or N=0 supersymmetric – the latter being realistic choices. In fact, even N=2 supersymmetry is too constraining and cannot be spontaneously broken to N=1 or N=0, at least not by field theoretical methods in four dimensions. If you can't break the N=8 supersymmetry spontaneously, you may want to break it explicitly. However, in that case, you lose the cancellations completely [unless you break it explicitly by using M-Theory/String Theory."

I would add, unless cancellations at lower N are also a myth. Is that correct? Or is there more to it?

29. **Peter Woit**
July 1, 2008

Daniel,

As I keep repeating, completely independently of its divergence problems, no one knows a viable way to get the SM out of N=8 supergravity. You can try and do this by adding explicit breaking terms, but then it's no longer N=8 supergravity. What's interesting here is NOT just the specific result about N=8 supergravity, because we know that theory by itself is not enough to give us what we need. What is interesting is that the assumption the whole field has been built on for 25 years, that QFT is inherently incompatible with quantum gravity because of high energy divergence problems, appears to be wrong. The interesting question is what is causing this, and how to identify the class of QFTs that don't have divergence problems and can give quantum gravity. Maybe one of these will be viable.

One interesting sociological question is how long it will take for string theorists to stop repeating the claims about incompatibility of QFT and gravity that they have convinced almost everyone about, now that these claims appear to be wrong.

30. **Peter Woit**
July 1, 2008

p falor,

String theory is a quantum theory, but not a theory of quantum fields on space-time, and thus not a QFT. You can try and formulate it as a theory of quantum fields on the infinite dimensional space of all paths in space-time ("string field theory"), but that's not what you normally mean by QFT.

Perturbative string theory is given by an infinite sum of terms, each term of which can be thought of as a QFT on a 2d surface of a given topology. This QFT is a conformal QFT, and you have to couple it to a 2d quantum gravity on the surface (i.e. integrate over all possible metrics on the surface). But string theory is supposed to be something non-perturbative, and so go beyond this infinite sum of terms, each of which can be thought of as a (different) QFT.

When we say "gauge theory", we normally mean a theory with internal gauge symmetry (mathematically, the symmetry of all "vertical" automorphisms of the bundle structure), and the Yang-Mills action (curvature-squared). Gravity isn't a gauge theory of this kind. But there are two ways you can try and think of it as something similar. One is to use the bundle of orthonormal frames, which has a standard gauge symmetry. But this bundle has extra structure (the vierbeins), not available in usual gauge theory, and this gets used to construct the Einstein-Hilbert action. So, this goes beyond the usual gauge theory: there are extra fields and different terms in the action. A second way to go is to try and think of the infinite dimensional symmetry of space-time coordinate reparametrizations as something like a gauge symmetry. One can do this, but it is a different kind of symmetry than the standard gauge symmetry.

Sorry for the somewhat technical answer, but it's a rather technical question…

31. **manyoso**
July 1, 2008

Peter,

I see you've posted a link to Motl's insistent plea that N=8 Supergravity is intimately tied to his beloved String Theory. Do you have a technical response?

32. **Peter Woit**
July 1, 2008

manyoso,

I've already responded to the claims that "you need string theory to define N=8 supergravity non-perturbatively" above. See my response to Chethan.

As for the rest of what Lubos writes, he goes on and on about all sorts of things that just aren't relevant. Sure, there are all sorts of interesting relations between N=8 supergravity and string theory, but they don't add up to "string theory is needed to define non-perturbative N=8 supergravity". String theory itself has a much more serious unsolved problem of how to define it non-perturbatively than supergravity does. It's true that perturbative supergravity for instance can't completely describe black holes, but this is equally true of perturbative string theory.

In any case, for the N'th time, what's important here is not the special case of N=8 supergravity, which in any case isn't a viable unified theory. What is important is that it appears that there are QFTs for quantum gravity which don't have the expected divergence problems. This is big, exciting news and opens up a lot of non-string theory possibilities to investigate for anyone interested in quantum gravity. Lubos and others are just trying to obfuscate this simple fact.

33. **Daniel de França MTd2**
July 1, 2008

I guess the techinical response is shown in the conference articles… I would just like to find what is the reason many of these guys suspects that the renormalizations effects are not due to supersymmetry. I mean, I would like to find an article, in which a calculation makes them to think like this.

34. **Observer**
July 1, 2008

Peter,

“What is interesting is that the assumption the whole field has been built on for 25 years, that QFT is inherently incompatible with quantum gravity because of high energy divergence problems, appears to be wrong.”

As of today, quantum gravity remains a theory plagued with many unsolved computational challenges, with no firm foundation and no experimental basis. Apart from renormalizability, there are many unsettled questions such as: Does quantum gravity require smooth manifolds and can it be consistently built in a perturbative framework ?. On the contrary, there is overwhelming evidence that perturbative quantum field theory is a correct framework, at least at the Standard Model level. If such a huge gap exists, on what basis can one say that the two appear to be compatible?

Regards,

Observer

35. **p falor**
July 1, 2008

Hi Peter:
Thanks for the reply. I believe it does help improve my understanding. Still there is one other issue that I am really have a hard time understanding that you alluded to in your book. The CC problem. Now I understand a QFT calculation gives the CC 60-120 orders of magnitude too large. This calculation is based on supposely sound physics principles. The same ones that are used to calculate the Hawking radiation from a black hole that is apparently accepted by most (all) HEP theortical physicists.

How can the current QFT frame be valid, i.e., assumptions etc, if this supposely basic calculation is so wrong? Maybe the vaccuum energy doesn’t couple to gravity but this would counter GR correct?

But more puzzling to me (you may not be able to answer this) is that in ST assuming a landscape, a vacuum state is being searched for that has a small CC. This suggests to mean that ST does not view the vacuum energy the same way as a QFT does. How can one a assign a value to a basic calculation? Shouldn’t the theory determine the value?

All of this maybe very obvious to those in the know but to someone like me I am hopelessly confused. Can you help? Thanks.

36. **Peter Woit**
July 1, 2008

Observer,

I’m not claiming that QFT and gravity are definitely compatible, just noting that the conventional reason given for claiming that they are definitely incompatible now appears to be wrong.

37. **Chris W.**
July 1, 2008

Maybe these unexpected cancellations in supergravity will ultimately throw new light on the failure of past efforts to calculate a sensible vacuum energy density in QFT.

Just a thought…

38. **Aaron Bergman**
July 1, 2008

Now I understand a QFT calculation gives the CC 60-120 orders of magnitude too large.

This isn’t true. The cosmological constant is a superrenormalizable parameter that can be set to whatever you want. The problem is that making it small is a huge fine tuning.

39. **somebody**
July 2, 2008

Like any useful toy model of gravity, N=8 sugra has black holes. Because of the gauge fields that are automatically there in the theory, these can be charged black holes. The only way a purely perturbative notion of consistency can exist for N=8 sugra, is if one declares by fiat that these perfectly reasonable objects in the classical theory are not states in the quantum theory. This is very hard to justify, especially in a supersymmetric theory because in supersymmetric theories, these ideas have produced perfect agreements with classical black hole entropies etc.

On the other hand, if one includes these as states in the theory, and imposes the uniqueness of the wave function, the theory (or rather its BPS sector, which has sufficient structure to make the comparison non-trivial) is exactly the same as what one expects from string/M theory. People who believe in string theory believe that this coincidence (and many others) could not have happened if there was no truth behind it. It must be admitted that this kind of evidence is still circumstantial, but I personally find it highly non-trivial and therefore compelling.

I think Peter is right that the oft-cited problem of gravity is its perturbative non-renormalizability. Often the sales-picth for string theory has been that strings are finite. But I think people focussed on this issue because before N=8 came along, this was argument enough! But now that there exists a theory that is perturbatively (perhaps) finite, we really have to emphasize that it is the full quantum consistency that we are after. Perturbative finiteness is necessary, but certainly not sufficient.

The good news is that even without having a FULL non-perturbative definition of gravity/string theory, we can still make non-trivial statements about non-perturbative aspects from quantum consistency alone. This is the sense in which string theorists say that N=8 is not “non-perturbatively” complete. This statement certainly does not imply that we have the full non-perturbative definition of the theory. The claim is that in the only quantum mechanical framework where we know how to make sense of the classical BPS objects of the theory, it does NOT make sense to just look at the supergravity multiplet – because there are extra massless fields around.

String theory might or might not be directly useful for building a model for our universe. I think arguments against string theory have maximum mileage when they focus on the practical usefulness of string theory in understanding our vacuum. But as a theoretical superstructure, I think it is hard to argue against it.

40. **p falor**
July 2, 2008

Aaron Bergman:
According to Sean Carroll

"Unlike supergravity, string theory appears to be a consistent and well-defined theory of
quantum gravity, and therefore calculating the value of the cosmological constant should,
at least in principle, be possible."
He isn't suggesting that the CC is a constant to be defined but something that can be calculated from a theory. Other references clearly imply(at least to me) that the vacuum energy should be calculable from QFT.

Obviously I am missing something but would appreciate a simpler explanation of what that is.

Thanks.

41. **somebody**
July 2, 2008

p falor,

The idea is that vacuum energy gets contributions from all the fields in the theory, like electrons, photons, etc. Lets say that before you added these contributions, the "bare" CC was some number A (we do not know its value beforehand). After you add the contributions from everything, lets say that the result is A+B. It turns out that in quantum field theory, B is usually a huge (computable) quantity. But the final result for CC, namely A+B, is experimentally known to be a miniscule number. This means that we are forced to choose ("fine tune") A to be a huge, but negative number almost (but not exactly) equal to B so that the sum of A and B is the small experimentally measured value of CC.

We say that the "natural" scale of the cosmological constant is that of B, and that the observed CC is absurdly small.

What Aaron is saying is that because CC is a certain kind of parameter, you are in fact allowed to tune it. You are not in a situation where there is actually a contradiction, because you are not tuning something that is NOT allowed to be tuned. In that sense, the CC problem is not really a problem, because it just refers to the unease that physicists feel, when they do this fine-tuning.

What Sean was talking about was the hope in string theory that perhaps CC would be automatically fixed by the theory itself. But nowadays, it seems much more likely that CC in string theory is essentially like a parameter in field theory. So it might not be dynamically determined. This just means that string theory is much more like like any other theory than many string theorists hoped: it needs experimental input to fix its parameters.

42. **Peter Woit**
July 2, 2008

somebody,

I'm not disagreeing that how to come up with a consistent non-perturbative N=8 supergravity is an issue, just with the idea that we know that the answer to this is non-perturbative string theory, since we don't even know what non-perturbative string theory is (the BPS sector story provides an interesting possible constraint, but you still don't know what the theory is that you are claiming solves the problem, or even whether there is more than one way of doing this).

p falor,

Sean Carroll's statement makes two assumptions. The first is that gravity QFTs inherently are non-renormalizable (which now appears to be wrong), the second is the existence of a single consistent non-perturbative version of string theory (which doesn't yet exist). If such a single consistent string theory existed, presumably you could calculate the CC in it. Nowadays, with the "landscape", most string theorists seem to have adopted the ideology that the CC actually can't be calculated, since there are essentially an infinite number of very different grounds states, all with different CC.

As for the argument that all we have to do to get predictions about string theory is "fix a parameter", sorry this is nonsense. String theory does not provide a prediction about what will happen at the LHC in terms of some number of parameters that need to be fixed by experiment. It predicts nothing about what will happen at the LHC, no matter how many parameters you give it.

43. **Chris W.**
July 5, 2008

Off-topic, but perhaps worth mentioning: Lincoln Wolfenstein has reviewed in PhysicsWorld a new book for a general audience by Helen Quinn and Yossi Nir, which focuses on matter-antimatter asymmetry but also appears to offer a nice overview of the Standard Model.

44. **p falor**
July 6, 2008

Somebody, Peter,

I think I see Somebody's point: QFT calculates a very large number, but the observed CC is very small (relatively) so to make the calculation come out we just subtract another very large number. And presto it works. My point was more along the line since QFT supposely can calculate the vacuum energy generated by the virtual particles but gets the wrong answer is there some reason to doubt the virtual particle framework of QFT?

Others have suggested that there is only suggestive evidence for virtual particles as predicted by QFT. Since the 1920's particle physicists have been aware of this CC potential problem but ignored it until yhe last 25 years or so. It sounds like the problem is just going to be defined away. True the constant that must be added to the calculated vacuum energy has to be very fined tuned but what is the current alternative?

45. **somebody**
July 6, 2008

> My point was more along the line since QFT supposely can
> calculate the vacuum energy generated by the virtual particles
> but gets the wrong answer is there some reason to doubt the virtual particle
> framework of QFT?

A few pointers:

1. As I said, QFT does NOT make a wrong prediction for CC. The freedom of adding the bare value is not an option, it is a must. In the case of other renormalized couplings also (like fermion mases, charges etc.) we do this. But in those cases, the bare piece and the computed piece and the actual value are all roughly the same order of magnitude.

2. QFT is simply the most spectacularly successful theory there is in everything else.

3. Any local, quantum mechanical theory that respects special relativity at low energies will look like a QFT. This is almost a theorem, but maybe there is some way to tweak it, in which case you have to deal with #2.

46. **Peter Woit**
July 6, 2008

p falor,

Virtual particles appear in any QFT calculation above tree level, and many of these (especially in QED) are tested to very high precision. You can't get rid of either virtual particles or QFT.

The fact that we can't calculate the CC is not surprising, since we don't have a viable unified theory of gravity and the SM. What is (a little) surprising is that naive order of magnitude estimates are completely wrong. This is a hint, but not much more, and we don't know what it means. About all one can say is that it means that there's more to the solution of this problem than a naive gluing together of the SM and GR would indicate.

47. **Observer**
July 12, 2008

Peter, you say:

"The fact that we can't calculate the CC is not surprising, since we don't have a viable unified theory of gravity and the SM."

Is there any legitimate basis for the assumption that the vacuum of GR and the vacuum of QFT are identical entities? GR refers to macroscopic scales and ceases to be relevant below the scale of nuclear processes. Why then do you expect that a consistent quantum theory of gravity is the root cause of the CC problem?

Best regards,

Observer

48. **commonsense**
July 12, 2008

While we're at it, let me (mis?)interpret what Peter said another way. I took it that if some physical model tells us that two quantities are fine tuned so as to cancel to 120 (or 60?) decimal places, and that such fine tuning is an extremely improbable circumstance, then instead it is the physical model itself that should be regarded as being extremely improbable to be the right one. In other words, maybe when a unification of GR and QFT is found, it will be understood that the concept of fine tuning was simply mistaken.

49. **Peter Woit**
July 12, 2008

Observer, commonsense,

You really need some way of putting QFT together with GR to make the question of calculating the CC a well-posed one.

The "10^60" number one sees refers to SSYM, where supersymmetry breaking will introduce a CC of the wrong scale. I think supersymmetry breaking is already a deadly problem for conventional SSYM models, this is just one more reason not to believe them.

The "10^120" number is based on assumptions about quantum gravity and the Planck scale, there the lack of a convincing theory is the problem.

50. **Eric**
July 12, 2008

"The "10^60″ number one sees refers to SSYM, where supersymmetry breaking will introduce a CC of the wrong scale. I think supersymmetry breaking is already a deadly problem for conventional SSYM models, this is just one more reason not to believe them."

Of course you are ignoring supergravity theories where the cc can easily be fine-tuned, or in the case of no-scale supergravity, the vacuum energy automatically vanishes at tree-level.

51. **Observer**
July 12, 2008

Peter, regarding your reply:

"You really need some way of putting QFT together with GR to make the question of calculating the CC a well-posed one."

I'd like to suggest that this is precisely the source of misunderstanding defining the CC problem. Vacuum in GR is an idealized cosmic state devoid of matter and energy. On the contrary, QFT vacuum is a quantum state embodying the contribution of all zero-point fluctuations. There is no compelling argument for relating the two concepts in a meaningful way.

Best regards,

Observer

52. **Peter Woit**
July 12, 2008

Eric,

It's rather well-known that the CC problem is not that it can't be fine-tuned, but that it has to be.

53. **Eric**
July 12, 2008

Peter,
All that means is that the theory we are using is an effective theory. It's really no different than having to fine-tune the masses of quarks and leptons in the Standard Model.

54. **p falor**
July 13, 2008

Peter:
It seems like that the CC problem is to be treated as just a renormaliztion issue as is the mass and charge of the bare electron in QED. Correct? But the bigger question is: Is QFT a fundementally correct approach if a basic calculation is so wrong? If QFT is deemed to be fundemental correct what mechanism(s) would potentially have to be included in some extention of the SM to avoid this problem (fine tuning)?

55. **Peter Woit**
July 13, 2008

p falor,

All I'm doing is repeating myself at this point, but again:

1. The "CC problem" is ill-posed unless you have a viable unified theory. We don't.
2. Naive expectations about what the scale of the CC would be in various possible unified theories lead to a completely wrong scale.

Personally, I don't think one can conclude anything very interesting from 1. and 2.

56. **Daniel de França MTd2**
August 11, 2008

There is a new interesting paper from Arkani-Hamed, and collaborators, "What is the Simplest Quantum Field Theory", http://arxiv.org/PS_cache/arxiv/pdf/0808/0808.1446v1.pdf. It has interesting claims :

"Both tree and 1-loop amplitudes for maximally supersymmetric theories can be completely determined by their leading singularities, it is natural to conjecture that this property holds to all orders of perturbation theor. This is the nicest analytic structure amplitudes could possibly have, and if true, would directly imply the perturbative finiteness of N = 8 SUGRA. All these remarkable properties of scattering amplitudes call for an explanation in terms of a "weak-weak" dual formulation of QFT, a holographic dual of flat space.

Physics Nobel Laureates at Lindau

July 1, 2008
Categories: Uncategorized

This week there's a Nobel Laureate Meeting in Lindau, devoted to physics. Many of the talks can be viewed on-line. From 3-5pm today (Lindau time) there will be a session devoted to a panel discussion of expectations for the LHC. Besides the Lindau web-site, a webcast will also be available here.

Blogging (in German) is going on here, including accounts of the late night activities there, featuring pictures of physicists dancing to the tune "Sex Bomb".

Update: The panel discussion included two questions from the audience about the multiverse. At first Gross refused to address them leaving cosmologist Smoot to try and say something. Finally 't Hooft broke in to say that there were a lot of misconceptions being spread about the multiverse, but that the truth was that the LHC will never have anything to say about either the multiverse or string theory, and Gross did not disagree with him. 't Hooft explained that while in principle there could be indirect evidence for a multiverse (from direct evidence for aspects of a theory that implied multiple universes), at the moment the idea was completely untestable and the LHC would have nothing to say about it. Gross agreed, describing multiverse models and research as "very ill-defined".

At the end, an argument between Veltman and others broke out over the selling of particle physics using astrophysics. He described claims that the LHC will "recreate the Big Bang" as "idiotic", and as "crap". He said that this is "not science", but "blather", and that the field would come to regret this, arguing that if you start selling the LHC with pseudo-science, you will end up paying for it. Gross and Smoot politely disagreed.

Update: See here for Gross's talk on expectations of what will be seen at the LHC. He predicts definite observation of a Higgs particle, and says he has taken bets that supersymmetry will be seen, at 50-50 odds. Nothing about string theory at the LHC.

Comments

1. **MIM**
   July 1, 2008

   I watched part of it, thanks to this post, and I am still amazed by Veltman's opinion on astroparticle physics. I am not talking about this Big Bang advertising you are reporting, but about the other part of the argument: it was quite clear that for him astrophysicists and particle physicists did not belong together. What is wrong with trying to join efforts in our understanding of Nature? I naively thought everyone agreed that both domains are intimately connected and that more communication is not only useful, but crucial. He also mumbled that astrophysicists had 'invented' the dark matter and dark energy problems, that this was the astrophysicist's way: inventing things when they did not understand the data. For this, I agree, they are puzzled by data and try to explain it. Isn't it the essence of science after all?

2. **Peter Woit**
   July 1, 2008

   MIM,

   I think part of this is that Veltman enjoys taking extreme positions….

   While he goes too far, I think he does have a point that some of the claims being made about the intersection of particle physics and astrophysics are misleading and nonsensical. No, the LHC is not recreating the big bang.

3. **Shantanu**
   July 1, 2008

   MIM, See Veltman's talk at the 2001 space-time odyssey symposium. the talk is online , but I can't find the link now and I think it was discussed on Peter's blog her earlier. If I understand right Veltman believes that teh dark problem is a failure of gravity.

4. **Bee**
   July 1, 2008

   Interestingly, only yesterday I was replying to a comment over at our blog that referred to the 'big bang recreation' advertisement. It is very misleading indeed, and I am not actually sure where it comes from. I have heard as a motivation for heavy ion collisions that one will recreate conditions 'closer' to the big bang than ever before. That I can at least relate to, but 'closer than ever before' is far off 'recreation of'. Besides, I don't see what pp collisions are supposed to recreate in this regard.

   I totally agree with Veltman, one should be way more careful how one 'sells' science. All this advertising isn't something that should play any role in research, not even when it comes to 'selling' it to the public. Scientists have above everything else a responsibility to be careful and accurate. That is our job, and if we neglect it we will have to pay for it with losing trust that is very hard, if not impossible, to reestablish.

5. **MIM**
   July 1, 2008

   I agree that the LHC should not be advertised as a 'Big Bang machine'. Even the claims about heavy ion collisions, which seem more justified than the LHC ones, are laughed at by some heavy ion physicists. Some were telling me recently how this claim was always made to get fundings but how they had no idea, and no program, to link their analysis with early times. This is a problem in the long term, as people will eventually ask: well, what have you learned about the early universe from LHC? About Veltman's position on astroparticle physics though, I am still puzzled. If dark energy can most probably be explained in the GR framework, what about gravity and dark matter? Has any MOND ever explained the acoustic peaks in the CMB anisotropies? One obviously can't rule out the particle hypothesis but then, if Veltman is only amusing himself by taking extreme positions…

6. **Shantanu**
   July 1, 2008

   MIM,
   I would say that the answer to your questions about acoustic peaks is yes.
   See http://arxiv.org/abs/astro-ph/0505519

7. **Observer**
July 1, 2008

Peter,

Thanks for this informative link!

What is your take on the fact that an important meeting of this caliber is held in Germany and not in US? Does this simply mean that US has lost its role as leader in many fields of scientific endeavor ? (it may unfortunately be a rhetoric question…)

Regards,

Observer

8. **Bee**
July 2, 2008

Observer: The Lindau meetings are always in Lindau. See the website.

9. **Markk**
July 2, 2008

"What is your take on the fact that an important meeting of this caliber is held in Germany and not in US? Does this simply mean that US has lost its role as leader in many fields of scientific endeavor"

Uhm.. Lindau meetings are over 50 years old and were established when one could say US influence on particle physics was at its highest. I think you have to look at teaching, funding and excellent research to see how healthy the US scientific endeavor is – not comparisons to others. I sure as heck hope that others are at least the equal of the US in "scientific endeavor"! Speaking as an American the stronger science is in the world the better for science everywhere. It is not a zero sum thing.

10. **Deane**
July 2, 2008

I don't know about the sciences, but in mathematics I do have the impression that most small high caliber conferences, especially those in the summer, take place in Europe. I offer two possible reasons:

a) There are a lot more venues specifically designed for these conferences available in Europe. Moreover, if one wants to attend more than one within a short period, it is easy to travel between the different locations.

b) A lot of American mathematicians, given the choice, would prefer spending the summer traveling around Europe over the US.

11. **theoreticalminimum**
July 2, 2008

Completely out of context (apologies). Just found out that Indian string theorist Sunil Mukhi (TIFR) has a blog.

12. **big vlad**
July 2, 2008

just listened to David Gross' on the web. Really great talk! I like the way he emphasized the 'fermionic dimensions' aspect of susy, which is often not mentioned. In fact, listening to this talk has inspired me to relearn the superspace formalism, which I forgot long ago…

13. **Professor R**
July 2, 2008

Thanks for that super link Peter.
I just sat through David Gross's talk in its entirety, absolutely excelent talk. I particularly enjoyed his 'big three' reasons for SUSY, and his explanation of difficulties in detection at LHC…I wonder who his bet was taken with.

14. **Bee**
July 3, 2008

Hi MIM

Even the claims about heavy ion collisions, which seem more justified than the LHC ones, are laughed at by some heavy ion physicists. Some were telling me recently how this claim was always made to get fundings but how they had no idea, and no program, to link their analysis with early times. This is a problem in the long term, as people will eventually ask: well, what have you learned about the early universe from LHC?

Indeed. I've been sitting among heavy ion physicists for quite a while and the 'big bang' motivation appears always and everywhere where it goes to a non-specialist audience (that includes grant proposals), despite the fact that the actual relation is weak. This isn't a problem though that is special to heavy ion physics or physics. It's a far more general trend, the constant dumbing down of information and the idea that one has to 'sell' and 'advertise' and so on. It's a trend that should have no effect on science, but sadly it has.

Seems I say that a lot – that sociological trends reflect in the scientific community and have a very negative influence. Best,

B.

15. **a.k.**
July 3, 2008

a bit off-topic, off course, one could remark, since the link was given, that at least on the blog-level the Lindau-meeting helped to elucidate some facts which are, apart from producing Nobel-laureates, still part of the german culture: producing prejudice and condescendence towards the 'lesser developed' cultures. While this in not a exclusively german phenomenon, I am glad that for instance this interview was not translated into english, were one introduces a PhD-student from Cameroon as someone who 'is allowed to take part', there are similar examples of near-to-racism occuring in this blog. I should apologize that I introduce these themes at this point, since their relation to heavy-ion-collisions and the big-bang is not-so-obvious, nevertheless it exemplifies what the word 'dialectic' means for the relation between science and humanities.

16. **Cormac O'Raifeartaigh**
July 4, 2008

Still enjoying the talks at that link, thanks again Peter..

That siad, I was underwhelmed by George Smoot's talk. Entitled ' The beginning and development of the Universe', it promised a lot more than it delivered. This was what I call a type II lecture – everything was probably there somewhere, but not in any order one could make much sense of.

Smoot mentions the acceleration of the universe early on, without any discussion of the universe expansion. or Hubble's law. Similarly, he launches into a description of measurements of the cosmic microwave background without giving any explanation of its importance as a snapshot of the early universe. Finally, while there was plenty of talk of both the COBE and WMAP satellite experiments, there is no mention of the 'why' – i.e. the advantages of satellite measurements over ground-based observation.

In summary, this talk was strangely reminiscent of a talk given by Smoot's co-laureate John Mather at Trinity College Dublin last year. There should be a law for experimentalists – if you're going to give a talk about your area (cosmology), you need to spend a few minutes on the basics – univ. expansion, nucleosynthesis, backgound radiation and inflation models etc

I'm fairly sure any members of the audience not familiar with BB theory left that lecture no wiser than before…

17. **Bee**

Regarding the 'Recreation of the Big Bang', we have written a brief post that hopefully explains the major differences between the LHC and the beginning of the universe: Recreating the Big Bang?

18. **Professor R**
July 7, 2008

Peter, I'd be interested to hear the LHC discussion session you mention, but the link you give doesn't seem to go anywhere, nor does the webcast seem to be listed on the CERN webcast site. Do you have another link to it?
Cormac

19. **Peter Woit**
July 7, 2008

Cormac,

That link was for the live webcast, I haven't seen a recorded version. If someone knows of one, let me know.

Proof of the Riemann Hypothesis?

July 2, 2008
Categories: Uncategorized

Last night a preprint by Xian-Jin Li appeared on the arXiv, claiming a proof of the Riemann Hypothesis. Preprints claiming such a proof have been pretty common, and always wrong. Most of them are obviously implausible, invoking a few pages of elementary mathematics and authored by people with no track record of doing serious mathematics research. This one is somewhat different, with the author a specialist in analytic number theory who does have a respectable publication record. Wikipedia has a listing for Li's criterion, a positivity condition equivalent to the Riemann Hypothesis.

Li was a student of Louis de Branges, who also had made claims to have a proof, although as far as I know de Branges has not had a paper on the subject refereed and accepted by a journal. He describes his approach as using a trace formula and "in the spirit of A. Connes's approach". Li thanks

> J.-P. Gabardo, L. de Branges, J. Vaaler, B. Conrey, and D. Cardon who have obtained academic positions in that order for him during his difficult times of finding a job.

but it is a little worrisome that he doesn't explicitly thank any experts for consultations about this proof. If the arXiv submission of the preprint is the first time he has shown it to anyone, that dramatically increases the already high odds that there's most likely a problem somewhere that he has missed.

I'm no expert in this subject, so in no position to check the proof or to have an intelligent opinion about whether his method of proof contains a new, promising idea. I suspect though that experts are already looking at this proof, and it appears to be written up in a way that should allow them to relatively quickly see whether it works. Given the history of this subject, I think the odds are against Li, but I'm curious to know what experts think of this.

This also has appeared on Slashdot. If your comment is like any of the ones there, please don't submit it, but comments from the well-informed are strongly encouraged.

Update: It looks like a problem with the proof has been found. Terry Tao comments on his blog

> It unfortunately seems that the decomposition claimed in equation (6.9) on page 20 of that paper is, in fact, impossible; it would endow the function h (which is holding the arithmetical information about the primes) with an extremely strong dilation symmetry which it does not actually obey. It seems that the author was relying on this symmetry to make the adelic Fourier transform far more powerful than it really ought to be for this problem.

Update: Another Fields medalist heard from: Alain Connes comments as follows on his blog:

> I dont like to be too negative in my comments. Li's paper is an attempt to prove a variant of the global trace formula of my paper in Selecta. The "proof" is that of Theorem 7.3 page 29 in Li's paper, but I stopped reading it when I saw that he is extending the test function h from ideles to adeles by 0 outside ideles and then using Fourier transform (see page 31). This cannot work and ideles form a set of measure 0 inside adeles (unlike what happens when one only deals with finitely many places).

Update: The paper has now been withdrawn by the author, "due to a mistake on pg. 29".

Comments

   July 2, 2008

   Peter,

   If you will accept a comment from a competent mathematician who is NOT an expert in analytic number theory, Li's claimed proof of the Riemann Hypothesis looks like it might be the real deal. First, it is impressive that Bombieri and Lagarias thought enough of his positivity criterion to generalize it. Second, his paper is clearly written, and in fact serves as a good roadmap into various arcane developments in number theory such as adeles and ideles. Third, his paper follows a program, first enunciated in the 1970's, for approaching the Riemann Hypothesis by studying the reals and the p-adic numbers simultaneously in one large entity, the direct product of all of these. Fourth, he clearly understands the deep relationship between the Mellin transform, the Riemann zeta function, and the invariant measure dt/t on the positive reals. In fact, the measure dt/t is Haar measure on the group of positive reals under multiplication, the Mellin transform is the Fourier transform with respect to this invariant measure, and the zeta function is essentially the Mellin transform of the fractional part function, t – [t]. Fifth, there are some new ingredients in his proof, especially his positivity criterion and various things about special functions from Whitaker and Watson.

   The only errors I could find are a misspelling of Dedekind's name on page 2, and a few lapses in English of the sort to be expected of a non-native speaker. I'm rooting for him. I hope someone more expert than I will peruse his work and give a more detailed and expert opinion.

2. **Walt**
   July 2, 2008

   I'm sure that he's no crank, but as the field stands, using ideles and adeles and the Mellin transform is pretty standard stuff in the area. The proof looks awfully elementary to me. (I'm not an analytic number theorist either.) It would be great that if a famous open problem like the Riemann hypothesis had a proof sufficiently elementary that I could understand it, but I would be pretty surprised.

3. **Chris Hillman**
   July 2, 2008

   Hi, Walt!

   JA, love your blog!

   And most urgent: ditto Chip. I had the same initial thought as several others when I realized that Li is a former Ph.D. student of Louis de Branges, but after looking over Li's papers– which have been published and cited— it seems to me that they appear to fit into a community effort involving some of the best mathematicians of our time, most notably Bombieri and Lagarias (who seem to have generalized a RH criterion due to Li). While I don't know much about this area, I recognize (or think I do) some ingredients which leading mathematicians have said might play a role in a proof of RH. A genuine proof of a long open conjecture which uses familiar ingredients in ways which had somehow been previously overlooked would be VERY surprising (de Branges's proof of Bieberbach conjecture is said to fit that bill), but not unprecedented.

   So I think this might actually be the real deal! Wow, if so!

4. **Chris Hillman**
July 2, 2008

Er.. sorry, Peter, thought I was posting in John Armstrong's blog. (Embarrassed grin.) But you have a great blog too!

5. **Walt**
July 2, 2008

My impression is that de Branges' proof of the Bieberbach Conjecture was very technical, but that later someone found a more elementary (and shorter) proof.

6. **Ian Agol**
July 2, 2008

Terry Tao thinks it's incorrect:
http://terrytao.wordpress.com/2008/02/07/structure-and-randomness-in-the-prime-numbers/#comment-30714

7. **Peter Woit**
July 2, 2008

Thanks Ian, I've added that to the posting.

8. **Abhishek Saha**
July 3, 2008

Xian-Jin Li has posted a new version (actually two new versions!) of his preprint on the Arxiv. Most pertinently, the definition of the function h on page 20 has changed; so perhaps this addresses Tao's objection on his blog.
The reason I will be very surprised if this proof turns out to be correct is that it involves mostly functional analysis on the adeles. It has been generally believed that such techniques are not sufficient to prove Riemann. It would be a stunning achievement indeed if Riemann is solved using only such elementary tools!

9. **Eric Chopin**
July 3, 2008

Hi All,

Apparently the half of the paper (at least) is "copied"
from Alain Conne's paper cited in reference, especially the
part metionned by Terence Tao. So I guess Connes would
be best placed to evaluate this paper. For instance the definition
on which Tao focuses on corresponds to eq. 18 p42 in Connes'
paper.

Also, it's really a detail, but I was really surprised that in this paper,
which seems to be quite a serious work (especially compared
to previous papers published in the last months…), the reference
to Weil famous paper (ref 15) serves only to reference the
definition of the Schwartz-Bruhat space….. Even Connes in his
paper references Bruhat paper, which is much more relevant!
Weil paper has probably much more to do with RH, but certainly
not with the definition of the Schwartz-Bruhat space….

Eric

10. **ninguem**
July 3, 2008

Connes has commented on his blog
http://noncommutativegeometry.blogspot.com/2008/06/fun-day-two.html?showComment=1215071400000#comment-c8876982000013974667

11. **Peter Woit**
July 3, 2008

ninguem,

Thanks, I added the information about Connes's comment to the posting.

12. **Abhishek Saha**
July 3, 2008

And now we have version 4!

13. **Daniel de França MTd2**
July 3, 2008

Indeed. I checked the places where Connes and Tao pointed out, and that's where he made the chages.

P.20, the definition of the formula 6.9 (Tao)
p.29, the first paragraph of the theorem 7.3 (Connes)

I didn't look anywhere else.

14. **Chris Hillman**
July 4, 2008

After reading the comments by Tao and Connes, my enthusiasm has considerably diminished :-/

15. **Eric Chopin**
July 4, 2008

Actually I had first a similar doubt as Tao had, but
comparing a bit more closely Li and Connes papers,
I am now more confident in this part of the paper: actually
this part is almost copied and pasted from Connes paper,
and if it were wrong, it may also possibly be wrong
in Connes paper (assuming I have not missed a difference
between the two papers).
However the point raised by Connes is really a major objection
to Li' results (as for me)…

eric

16. **Benjamin**
July 4, 2008

Terence Tao made a further comment on problems with the proof. He also explaines in more detail what Connes pointed out.
http://terrytao.wordpress.com/2008/02/07/structure-and-randomness-in-the-prime-numbers/#comment-30714

17. **Moeen**
July 4, 2008

Benjamin,

That was Tao's earlier comment about the paper. Perhaps you're thinking of this comment:
http://terrytao.wordpress.com/2008/02/07/structure-and-randomness-in-the-prime-numbers/#comment-30763

18. **kathrine martinez**
July 5, 2008

It will be interesting to know the opinion of Xian-Ji Li himself.
Has Li something to say to his "critics" ?
It will be very important to know also the point of view of
Prof. Xian-Ji Li.
Can anybody tell us anything on this?

19. **math idiot**
July 5, 2008

Li hasn't withdrawn his paper. He is very confident in it?

20. **Felipe Zaldivar**
July 5, 2008

Regarding Connes, Kowalski, Silberman and Tao comments on the quotient space A/k^*, I recall a comment by André Weil that could be translated as "The search for an interpretation of [the idele class group] seems to me to be one of the most fundamental problems in number theory today; it is possible that one such interpretation holds the key to the Riemann hypothesis" (Sur la théorie du corps de classes).

21. **math idiot**
July 5, 2008

Just found that Li had withdrawn his paper.

22. **anon.**
July 6, 2008

I'm glad that such pure mathematical research is discussed here. Seeing how proofs are checked and commented upon, and withdrawn if an error is found, makes it very interesting. It's clear that there is a lot of discipline involved in step-by-step proofs of theorems in pure mathematics because it is possible to make an error which breaks the chain of reasoning.

Applied mathematics is far less risky, because where a model is being constructed a logical error can usually be corrected without the whole model collapsing. I think this the distinction between the kind of model building mathematics being done in string theory, and the formal proofs of pure mathematics.

23. **Christine**
July 13, 2008

Interesting to read about this case. Fortunately, I see no backfire as in the case of, as I remind, Penny Smith on the Navier-Stokes Equation problem.

It is also very interesting that the error was pointed out in the blogosphere…

Interview With Atle Selberg

July 4, 2008
Categories: Uncategorized

Sticking with the theme of the Riemann Hypothesis, the AMS has recently posted some articles to appear in an upcoming issue of the AMS Bulletin, one of which contains a long interview with Atle Selberg, who died last summer at the age of 90. Selberg had been a professor at the IAS and an expert in analytic number theory, responsible for some of the most important developments in the subject during the 20th century. A large part of the interview concerns in one way or another the Riemann Hypothesis, which is a central concern of Selberg's mathematical research, with his work on it beginning during the German occupation of Norway when he was still a student, Some thoughts from Selberg on the subject:

> "If anything at all in our universe is correct, it has to be the Riemann Hypothesis, if for no other reasons, so for purely esthetical reasons." He always emphasized the importance of simplicity in mathematics and that "the simple ideas are the ones that will survive."

About whether there is a spectral problem that gives the zeros of the zeta-function, useful for proving the RH:

> That is certainly a thought that several people have had. In fact, there have been some people that have been able to construct such a space, if they assume that the Riemann hypothesis is correct, and where they can define an operator that is relevant. Well and good, but it gives us basically nothing, of course. It does not help much if one has to postulate the results beforehand—there is not much worth in that.

About his own attempts to find a proof:

> Once I had an idea that I thought perhaps could lead to a proof….
>
> After a while I became more and more convinced that it would not work as I had thought initially. It just seemed unlikely to me. However, I have now and then seen that people have attacked a problem in a way that seemed "hare-brained", to use an English term, but then it turned out that they could make it work. They have proven something that would not be easy to prove in another way. On the other hand, I have seen people have ideas that seemed absolutely brilliant, but the only problem is that if one follows these to the end one is not able to get anything out of it after all. So it works both ways: sometimes a good idea does not work, and what seems like a bad, even idiotic idea, may actually work.

About Connes's work on the RH:

> Yes, that is a new way to arrive at the explicit formulas—a new access, so to say—but it basically does not give more than what one already had. Connes undoubtedly believed to begin with that what he was doing should lead towards a proof, but it turned out that it does not lead further than other attempts. When I last talked with him he had realized this. This often happens with types of work that are rather formal. There was, for example, a Japanese mathematician, Matsumoto, who gave several lectures that made quite a few people believe that he had the proof.

and finally:

> I think it is a good possibility that it will take a long time before it is decided. From time to time people have been optimistic. Hilbert, when he presented his problems in 1900, thought that the Riemann hypothesis was one of the problems that one would see the solution of before too long a time had elapsed. Today it is a little more than one hundred years since he gave his famous lecture on these problems. So one must say that his opinion was wrong. Many of the problems that he considered to be more difficult turned out to be considerably simpler to solve.

Comments

1. **ninguem**
   July 4, 2008

   What was surprising to me in that interview is his negative view of collaboration. These days if somebody gives a non-trivial contribution, they get their name in the paper. I found Selberg's attitude (re Erdos) bordering on the unethical, but those were different times and maybe different standards.

2. **theoreticalminimum**
   July 5, 2008

   It appears that the IHES is currently working on editing and publishing Grothendieck's "Récoltes et semailles". It is mentioned that it would be out before the end of this summer. Something sure to please at least Alain Connes 😉

3. **geometer**
   July 5, 2008

   ninguem:

   Clearly Selberg did not like to collaborate but I think the way Selberg and Erdos resolved this issue was quite ethical: they published separate papers in which they clearly described who contributed what. BTW, in MathSciNet the papers are reviewed in a single 4-page-article (by Ingham).

4. **oldman**
   July 6, 2008

   I found it refreshing to hear a mathematician of evident quality express a distaste for collaboration. It was also pleasant where he said prizes don't advance science.

   The non-collaborating mathematician still exists. Taubes is a good example of this beast that pursues its own interests in privacy and seriousness.

   Perhaps I know too many folks too busy inflating their publication counts through incessant collaborations in which their principal contribution appears to be their name.

5. **George**
   July 7, 2008

   Another similar annoying thing is how it's now expected that young mathematicians collaborate with senior mathematicians, whether they want to or not. You're at such a disadvantage in the job market if you do it alone, because even if you're successful, your peers will have the advantages of working with senior well-known mathematicians, not just in terms of the quality of the papers but also the top journals are more hesitant to accept papers from unknowns. I've seen utterly incompetent people get tenure-track positions through these "joint efforts." One time at a talk I attempted to get the speaker to define the basic objects of his talk. He couldn't do it, guessed incorrectly, then emailed me the next day with the actual definition. To preserve anonymity I won't say what the terms in question were, but it would be like if an algebraic topologist couldn't define cohomology. This person had multiple joint papers with multiple leaders, all in good journals. I was amazed that this could happen when the incompetence was so blatant. I have seen two talks from this guy, so it was not a fluke.

6. **ninguem**
   July 8, 2008

   geometer:
   One of the things that I meant was the fact that he tried to throw Erdos offtrack and he seemed almost proud of how clever he was.

   George:
   What you describe is a bit surprising. Why would the senior mathematicians bother to write papers with this guy? Maybe he has something to offer.

7. **olderman**
   July 10, 2008

   ninguem,

   The answer to your question to George is simple: this guy physically writes the papers the senior mathematicians do not feel like taking the time to physically write. This is the sort of thing he `has to offer'.

LHC Update

July 7, 2008
Categories: Experimental HEP News

Latest press release from CERN about the LHC says first beams "currently scheduled for August". According to a presentation at the July 2 meeting of the LHC Technical Committee, the latest news is that "circulating beam not before September" (the presentation includes a detailed version of the schedule of what has to take place between now and the end of August). At this point the second to last sector is just about cool, the final one will take another two weeks. The last of 470 trucks of liquid nitrogen has arrived. Assuming it will take 1-2 months from first circulating beam until physics collisions, it looks like time for data-taking will be rather short before the shutdown for the winter.

Comments

1. **A quantum diaries survivor**
   July 7, 2008

   Hi Peter,

   indeed, I think we will be lucky if we get 20 inverse picobarns of data. And, at 10 TeV. The difference between 10 and 14 TeV is significant for the discovery of high-mass bodies.

   However, let me keep the enthusiasm up -finding for once my well-concealed vein of optimism. If we look back at the Tevatron, it took data in 1987-88 with no silicon detector in CDF, and triggered 4/pb of data. Those data were amazingly interesting! They kept us busy for the following four years! Here is a sample of publications from that period:

   – Measurement of mass and width of the Z (still competitive back then)
   – Measurement of W asymmetry (a first)
   – Inclusive jet cross section (ranging 9 orders of magnitude)
   – (then best) measurement of the W boson mass
   – inclusive J/psi, Psi(2S) production (showing disagreements with theory of up to two orders of magnitude!)
   – lower limits on top quark mass (up to 91 GeV)

   A total of more than 50 papers thick-rich with new amazing stuff.

   Plus, let's not forget, the very first top-antitop candidate was seen back then -and it created in fact a huge controversy (ask Tony for the details).

   So, are we going to be disappointed with the amount of data ? Yes. Are we going to be amazed by it ? YES!

   Cheers,
   T.

Back to the Future

July 7, 2008
Categories: Uncategorized

Several things have come up recently that brought up the year 1985, the year the film "Back to the Future" came out.

This summer the IAS will be running a two-week program at the IAS on Strings and Phenomenology, designed to train a new generation of graduate students and postdocs in the details of compactification methods which mostly go back to 1985, quite possibly before some of the attendees were even born. No evidence that there will be any mention of the fact that 23 years of work on these topics has led simply to a dead-end: the landscape.

At SUSYO8, the first two speakers harkened back to the 1985 period, with Hans Peter Nilles (who also will be lecturing at Princeton) quoting his own words from 1984 (Physics Reports 110):

> Experiments within the next five to ten years will enable us to decide whether supersymmetry at the weak interaction scale is a myth or reality

He notes that "This statement is still true today!"

Andrei Linde in his talk on cosmology crows about what he sees as Witten's recent capitulation to the anthropic landscape point of view about string theory that Linde was pushing back around 1985 (actually 1986) when he wrote:

> An enormously large number of possible types of compactification which exist e.g. in the theories of superstrings should be considered *not as a difficulty but as a virtue* of these theories, since it increases the probability of mini-universes in which life of our type may appear.

which he compares to this from the New York Times

> Now, Dr. Witten allowed, dark energy might have transformed this fecundity from *a vice into a virtue*, a way to generate universes where you can find any cosmological constant you want. We just live in one where life is possible, just as fish only live in water.

At the same time, I've been reading and thinking about some papers written back in 1985 which deal with the mathematics of gauge theory and anomalies. At least some of these were never published, including one that I've seen references to (by Igor Frenkel and Iz Singer), but never a copy of (does anyone have a copy?). Looking at the history of this subject, it is clear that some very good people were working on this until 1985, at which point quite a few of them dropped it to take up the new fashion of string theory.

Perhaps the LHC will revive the subject of particle theory, by producing a wormhole that will take the world back to its other end, opened up in 1985 by a DeLorean in the movie, from there setting us off into a more promising part of the multiverse.

Comments

1. **roland**
   July 7, 2008

   >At the same time, I've been reading and thinking about some papers written back in 1985 which the mathematics of gauge theory and anomalies.

   Is this a valid english sentence?

2. **Peter Woit**
   July 7, 2008

   roland,

   No, it's not, but now I've fixed it. My proof-reading is not all it should be. Thanks for helping.

3. **MathPhys**
   July 7, 2008

   It is sad to see people rehashing what they were saying in 1985. Compactification is too simple minded. I'm surprised that supersmart people like Witten are still into that.

4. **Tony Smith**
   July 7, 2008

   Peter, you refer to "… the mathematics of gauge theory and anomalies. At least some of these were never published, including one that I've seen references to (by Igor Frenkel and Iz Singer) …".

   Is that work related to what Alex Jay Feingold describes
   on his CV page at SUNY Binghamton?
   There, he says:
   "… During the period from 1981 to 1991 I had several collaborations with Igor Frenkel (Yale University) … with J. F. X. Ries … Our main objectives were to obtain independent vertex and spinor constructions of chiral algebras,
   the isomorphism between the two viewpoints,
   known as a "boson-fermion correspondence"',
   and constructions of the exceptional affine algebra E8(1) based on D4(1) spinor constructions and the principle of triality. …
   Some of these results were announced at the 1988 Conference on Lie Algebras and Related Topics, Madison, Wisconsin.
   Those results which only involve the spinor constructions are in our Contemporary Mathematics monograph …
   A sequel (with Ries only) was planned to give the vertex picture and the boson-fermion correspondence,
   but the untimely death of Ries has substantially delayed the completion of that project …".

   Do you know of any available publication in detail of that Feingold-Ries work involving "the vertex picture and the boson-fermion correspondence"?

   It seems to me that such a Feingold-Ries project might be related to, and improve on, the E8 model of Garrett Lisi,
   and

be a way that "respectable" math/physics people could work on such stuff.

Tony Smith

5. **Peter Woit**
July 7, 2008

mathphys,

I don't know what Witten will be talking about, but the strange thing about this whole subject is that the circa 1985 ideas about compactification are still in some sense the most aesthetically convincing ones. Since then, attempts to do better have pretty much all led to much more complicated and ugly constructions. So, I can see why someone asked to talk about this subject might want to talk about the 1985 version. Some of the other lecturers will be talking about more these more recent ideas. and trying to lead the students into the landscape…

6. **Peter Woit**
July 7, 2008

Tony,

That's a different subject. I don't know anything about the unfinished Feingold-Ries work, but it sounds like it's closely related to the Feingold-Frenkel work on spinor constructions of vertex algebras, which has been published (although I don't know much about that literature).

The paper I have in mind is about the Hamiltonian approach to the gauge anomaly in 3+1 dimensions.

7. **Frank Quednau**
July 8, 2008

Has it been that long? Incredible. However, I quite like this timeline, thanks. I do not want some Biff Tannen-style physics 🙂

8. **Chris Oakley**
July 8, 2008

> "I do not want some Biff Tannen-style physics"

I see this more as a "Terminator" scenario than a "Back to the Future" one. The dominance of String Theory was intended by our time-travelling descendants as it has prevented discoveries in fundamental physics (you know – real physics: remember that?) that would have been dangerous to society.

We will know this for sure if Peter suddenly finds himself pursued by a Killer Robot from The Future (or maybe this is already happening)

9. **Markk**
July 8, 2008

"Experiments within the next five to ten years will enable us to decide whether supersymmetry at the weak interaction scale is a myth or reality
He notes that "This statement is still true today!""

This is very true and in a sense is a specific effect of the cancellation of the Superconducting Super-Collider. You could say that it cost a generation of physics advancement in particle physics. We would have had answers to a lot of things and a lot more data to eliminate ideas with.

We are becoming like the mid 80's again in that sense: We again (an for real this time we hope) are just before looking at new information about a new level of energy in particle collisions.

10. **Peter Woit**
July 8, 2008

Markk,

I agree that the SSC cancellation has set things back a generation, but this isn't relevant to the Nilles quote. He made it back in 1984, and was explicitly claiming that SSYM would be seen by the time you got to a 100 Gev scale, i.e. he was talking about the Tevatron, not the SSC. The SSC project was not even approved until 1987 (canceled in late 1993), so couldn't have been what Nilles had in mind when he wrote that SSYM would be seen in "5-10" years from 1984. Even under the most optimistic assumptions, there was no way that in 1984 one would think that the SSC would be built and operating in 1989-1994.

It isn't hard to find quotes from the 80s about how SSYM was definitely going to show up at the Tevatron, it is only in the 90s as it became clear this wasn't happening that the assumed scale of SSYM got moved up from 100 Gev to the "Terascale".

11. **misslemon**
July 8, 2008

"…quoting his own words from 1984 (Physics Reports 110):

Experiments within the next five to ten years will enable us to decide whether supersymmetry at the weak interaction scale is a myth or reality

He notes that "This statement is still true today!""

A good example of someone whose timeline/logic/truth interfaces need adjusting

12. **wilbur**
July 8, 2008

> but this isn't relevant to the Nilles quote.

My interpretation of that quote was quite similar to Markk's, actually. I think a lot of people would tend to read the quote that way. The fact that the original text was referring to the TeVatron and not the SSC completely changes the context. In fact, it makes this post much more interesting.

> It isn't hard to find quotes from the 80s

I think quoting one or two more of those would do a lot to strengthen your point.

13. **Peter Woit**
July 8, 2008

wilbur,

OK, here's one more:

Haber and Kane, Physics Reports 117 (written in 1984)

pg. 82

"While there is no compelling supersymmetric model, all the ones studied produce some detectable superpatrners that are light, often with masses well below m_W. More technically, the models can be tuned to have a larger scale of supersymmetry breaking and still account for m_W at tree level, with no partners below m_W,but then they are unstable and have to be retuned as soon as radiative corrections are included. Models where such radiative corrections are less than the masses themselves have detectable, light superpartners."

pg. 89

"Finally, we note that it is not a problem for supersymmetric ideas that superpartners have not yet been found. As we will discuss in chapter 9, most of them are expected to have masses of order m_W,and could not have been detected yet. Those that could have been observed, such as the gluino, are allowed to be heavy enough to have been unobservable so far. But as we will see, the machines available in the next decade will have a high probability of detecting supersymmetric partners if supersymmetry is relevant to understanding the weak scale."

"Machines available in the next decade" clearly refers to the Tevatron, LEP and HERA, this is also clear from the argument about m_W.

14. **wilbur**
July 8, 2008

thanks for the quotes. Fascinating stuff, looks like a time tunnel. In summary, if the LHC doesn't find susy, the HHC probably will.

15. **MathPhys**
July 9, 2008

wilbur,

It's very, very easy to find quotes from the 80's of the type that you want to see. Peter Woit gave the simplest examples, but trust me, the literature is full of them. I only want to see/hear/read anyone of these guys own up and say "In about 50 papers that I wrote in the 80's and 90's, I made predictions that now I know were simply totally wrong. Now let me start all over again". But no, they always carry on as if they were always on the right track and things are progressing linearly. And they call themselves scientists.

16. **Jason Starr**
July 10, 2008

In my department there are some great "LOLCat"-style posters with an image of a black hole and the caption "Im in ur LHC, eatin ur universe". The posters announce a light-hearted debate of the graduate students in the Physics and Astronomy department on July 11th with the following premise: if a relativistic heavy ion experiment at the particle physicists' accelerator produces black holes, which group of physicists should be liable for the damage 🙂

17. **hidalgo**
July 11, 2008

Actually I remember the times of which you speak very well. We all got very excited about the fact that gauge fields were connections on principal fibre bundles. Just when it was dawning on us all that this line of research was leading absolutely nowhere, Witten came along and saved the day. I can assure you that the times for which you hanker were even worse than now, and that "not even wrong" applies far more convincingly to the things you favour than to string theory.

18. **Peter Woit**
July 11, 2008

hidalgo,

Funny, I remember those time quite well myself. The mood among particle theorists was rather different than it is now, I wouldn't exactly describe it as "even worse" though….

19. **somebody**
July 12, 2008

>It's very, very easy to find quotes from the 80's of the type that
> you want to see. Peter Woit gave the simplest examples, but
> trust me, the literature is full of them. I only want to
> see/hear/read anyone of these guys own up and say "In about
> 50 papers that I wrote in the 80's and 90's, I made predictions
> that now I know were simply totally wrong.

To me the sarcastic way in which Nilles was referring to his own quote is precisely that. I completely fail to see in what sense Nilles is supposed to "apologize". Wrong ideas are merely left by the wayside in science and not held to court, and thats what happened to the guess about the exact energy scale of new physics (actually the general prediction for the energy scales, that it is around TeV, might still be right).

People were hoping back then that something would be seen close to TeV, and that hope is still there. The EXACT energy scale is what the bets were made about (and lost). In fact, I am certain that many people on this thread know this, and are actively ignoring it because it is conveneinet for their agenda.

Nilles was certainly "wrong" in that sense. But contrary to your subtle implication, nobody (including him) claims today that they were right back then in that narrow sense. Of course, many of them still believe that TeV scale susy is a possibility, but thats based on scientific judgement, and because we don't seem to have any better ideas.

In any event, being wrong is hardly an isolated event in physics. It comes with the territory of "trying". The "hindsight is 20-20" type talk has only one purpose and that purpose has nothing to do with science. Incidentally, let me just point out one obvious thing because the discussion here has taken a condescending air: it is clearly an easier task to sneer at people who try, than to try oneself.

> Now let me start all over again". But no, they always carry on as
> if they were always on the right track and things are
> progressing linearly. And they call themselves scientists.

Thats only because we (not "they") still don't have any reason to believe that we were qualitatively wrong back then. The hope is still that around TeV is where the action is – if anybody has any better ideas they would of course be welcome, but the fact of the matter is, as it stands we don't. In fact, we could still be wrong, and ten years later some others like you might mock us. But that possibility is totally useless in deciding how we do science now.

The ONLY thing that can save us from mediocre ideas is a great idea: not personal attacks and uncreative criticism.

20. **Peter Woit**
July 12, 2008

Somebody,

No, people in 1984 were not expecting to see SSYM breaking at 1 TeV, they were expecting to see it at 100 Gev. The Haber/Kane quote that I reproduced explains precisely why (you have to do some fine-tuning to avoid superpartners below m_W).

The fact that SSYM was expected to show up, didn't, and now requires fine-tuning to explain why it hasn't been seen is something that its proponents don't ever mention. Some readers here didn't seem to originally believe me that this is the case.

Let me point out that I am not engaging in personal attacks on Nilles or anyone else. I do think though that this particular bit of history, failed prediction of SSYM, and required fine-tuning is something that deserves to be better known to anybody who wants a clear idea of the prospects for seeing SSYM at the LHC.

21. **Eric**
July 12, 2008

Peter,
The MSSM only requires that the superpartners be in the 1 TeV range in order to solve the hierarchy problem. This requires no fine-tuning. It is only now with the LHC that the full parameter space can be explored. Back in the eighties, they were only beginning to probe the lowest energies of where one might expect to find the superpartners. So, some of them were overly optimistic. So what? This was also true in regards to the top quark.

22. **somebody**
July 13, 2008

SUSY always had problems – it did then, and it does now. But the balance of evils seemed somewhat in its favor back then, and it still does.

The books and reviews on phenomenological susy invariably leave you with the impression that there are plenty of things that are NOT pretty about it. Every fine tuning that you can possibly talk about, from higgs mass to susy flavor problem are all discussed in the textbooks. So I totally fail to see in what sense you are suggesting that the fine tunings are not well-known. The scientific facts are entirely well-known. The only thing missing from the textbooks is the personal attacks.

About your claim that we were expecting to see susy at 100 GeV: you are ignoring what I emphasized in my previous post, that the PRECISE scale was where the "predictions" went wrong. If you want to split hair at the 10% level, there are actually even worse problems. Eg: the mu-problem which requires not 10% level fine tunings, but 1% level fine-tunings. The existence of fine-tunings is a fact about susy, but the fact still remains that it is still pretty much the best idea we have. So any attacks of this kind about our past follies (without any suggestion for a better idea) accpomplish absolutely nothing.

I am actually charmed by the disarming honesty with Nilles pointed out one of his own old "wrong" predictions. It would be nice if we had radically new predictions now, but unfortunately we don't.

23. **Haelfix**
July 17, 2008

Supersymmetry only requires finetuning (of the Stop) if various eventualities occur.

1) The mass of the Higgs cannot be too heavy. Its best if its right around 115-120, at least for the MSSM

2) Refinements in the top quark mass have moved around in the previous decades, which also affects things.

How much finetuning you are willing to accept is a bit of an aesthetic requirement. We've seen finetuning in nuclear physics up to about 2 orders of magnitude before, so it shouldn't surprise people if there is a little bit. Its when you start talking about 16++ orders where people start really wondering if we've gone insane.

Its true that the minimal 'bayesian' models from the 80s of phenomenology would have arranged the masses a little bit differently. We should have seen a lighter Higgs, a different top mass, and some SuSY already on those grounds, but nature doesn't always pick the simplest solution either (see the expanding universe).

After the LHC, if we still haven't seen SuSy, the original premise is gone and it might juts become something quantum gravity people are interested in, and not day to day phenomenologists. Still i'd say theres still a good percent chance that we will see weak scale SuSy (I'd give it a good oh.. 1 in 3 chance, which is much better than any alternative).

24. **invcit**
August 2, 2008

Peter,

Witten talked about the work of Vafa et al on how to embed GUTs into F-theory. Not quite the stuff of 25 years ago. There is a lot more hope of uniqueness in this picture than in the flux compactifications.

25. **anon.**
August 3, 2008

invcit: what is ‘F-theory’?

(Sorry Peter if this question sounds off-topic, hostile, and adding noise, but I genuinely don’t know what F-theory is!)

26. **Arun**
    August 3, 2008

    Wikipedia has an answer:
    http://en.wikipedia.org/wiki/F-theory

    “F-theory is a branch of string theory developed by Cumrun Vafa. The new vacua described as F-theory were discovered by Vafa, and it also allowed string theorists to construct new realistic vacua — in the form of F-theory compactified on elliptically fibered Calabi-Yau four-folds. The letter “F” stands for “Father” much like the “M” in M-theory is often taken to stand for “Mother”.”

27. **anon.**
    August 3, 2008

    Thanks, Arun. I had seen a post on this blog some time back about the experimental predictions of F-theory:

    http://www.math.columbia.edu/~woit/wordpress/?p=697

    but I didn’t understand F-theory. There is a nice paper on ‘Evidence for F-theory’ by Vafa on arxiv: http://arxiv.org/abs/hep-th/9602022 The math isn’t really hard.

This and That

July 8, 2008

Some quick links:

The Clay Mathematics Institute is now making available for free online the books whose publication it has sponsored. These include the Morgan-Tian exposition of the proof of the Poincare conjecture. Surveys in Non-commutative geometry, which contains two excellent articles by Jeffrey Lagarias and Paula Tretkoff explaining ideas about the Riemann Hypothesis that have been motivating Connes and others recently. Also the excellent huge group-effort expository volume on Mirror Symmetry, and a more recent volume on the topic, which includes a good review article by Michael Douglas about the string theory motivations for this work.

There's an interview with Susskind here about his latest book. About anthropics and the multiverse he claims

> …since I wrote "The Cosmic Landscape," it has practically become the conventional view.

A couple of relatively new physics bloggers are Sunil Mukhi and Marco Frasca. P.P. Cook has revived his blog and is reporting from Eurostrings 2008 here and here.

Among the posts worth reading over at Secret Blogging Seminar, there's a nice posting by A. J. Tolland explaining what a "stack" is. The comments contain a valuable discussion about the different versions of a "classifying space" that show up in this story.

Comments

1. **anon.**
   July 8, 2008

   "There are powerful reasons to believe that the universe may also be a consequence of random mutation. It sounds crackpot, or at best, like fringe speculation, but by now the idea is very firmly established in the mainstream physics and cosmology literature. That's was what my book "The Cosmic Landscape" was all about. … The next generation of physicists and cosmologists will have the fun and excitement of discovering the right mathematical formulation of a "multiverse."' – Lenny Susskind, http://calitreview.com/790

   I love this suggestion that analyzing the landscape of 10^500 metastable vacua in the multiverse will be an exciting and fun challenge for the next generation. The next generation should be eternally grateful. 😉

2. **A.J.**
   July 10, 2008

   Hi Peter,

   Thanks for the post rec!

   Is Marco Fresca really arguing that "lattice results about propagators seems to indicate that Yang-Mills theory is trivial"? That's an amazing claim.

3. **Peter Woit**
   July 10, 2008

   A.J.,

   I confess that I don't understand this claim of his, but haven't had a chance to look carefully at what he is up to. As far as I can tell, he's looking at the gluon propagator, which is not gauge invariant, so the significance is unclear.

4. **theoreticalminimum**
   July 11, 2008

   I might, if I may, bring to your attention that the *Institut des Hautes Études Scientifiques* (IHÉS) in France is celebrating its 50th anniversary this year, with events taking place since March 27 (to coincide with Grothendieck's 80th birthday, which was on March 28). Apart from IHÉS' disposition to publish Grothendieck's *Récoltes et Semailles*, one other nice collectible is the photo-book (published in France by *Éditions Belin*) *Les Déchiffreurs: Voyage en mathématiques* ("The Unravelers"), which "comprises photographs and texts, including more than 200 photographs of some of the 40 or so researchers who work or at or have visited IH in the course of their career'. A small sample of the photos can be seen here. I'll get a copy of it next month when I visit Paris.

5. **Richard**
   July 12, 2008

   theoreticalminimum,

   Thanks for alerting us to this photo-book! I looked at the sample pictures, and was pleasantly surprised to see that they are in black and white, which is now practically a lost art. In photos of people, black and white photos often capture "the moment" and the personality in a way that color photos do not.

6. **Chip Neville**
   July 13, 2008

   Peter,

   It would be wonderful if Harvard could see it's way clear to put Tate's 1950 thesis on the web. The same is true for Uppsala and Nyman's 1950 thesis.

   Tate's 1950 Harvard thesis, which from the fragments I have seen quoted, for instance in Li's failed preprint, seems to be simpler and clearer on some points than parts of most accounts of adeles, even the excellent one by Paula Tretkoff on page 150 of her article.

   Nyman's 1950 Uppsala thesis, which is important in completeness approaches to the RH, is often quoted. Nyman was a student of Beurling, and his thesis is what led to Beurling's 1955 Proc. Nat. Acad. Sci. article referred to at the beginning of Sarnak's appendix to Paula Tretkoff's article.

7. **Jason Starr**
   July 13, 2008

   Chip,

   I believe Tate's thesis is in the volume edited by Cassels and Froehlich.

   MR0217026 (36 #121)
   Tate, J. T.
   Fourier analysis in number fields, and Hecke's zeta-functions. 1967 Algebraic Number Theory (Proc. Instructional Conf., Brighton, 1965) pp. 305–347 Thompson, Washington, D.C.
   10.41

8. **Marco Frasca**
   July 14, 2008

   Hi Peter,

   Thanks a lot for the citation. About Yang-Mills theory being trivial you should not check the gluon propagator but rather the running coupling. Current definitions analyzed on the lattice show clearly that no non-trivial infrared fixed point exists as people used to think. Recent phenomenological analysis due to Prosperi's group in Milano support this (e.g. see Phys. Rev. Lett. 99, 242001 (2007) or http://arxiv.org/abs/0705.0329 and related papers on arxiv all published on archival journals). The point is how to get a proper definition of running coupling in the infrared but it does seem that whatever is your choice this goes to zero at lower momenta. For a discussion see again Prosperi et al. http://arxiv.org/abs/hep-ph/0607209.

   Marco

9. **Sebastian Thaler**
   July 14, 2008

   Peter,

   There is an article about Garrett Lisi in the July 21st issue of The New Yorker, unfortunately not online.

10. **Peter Woit**
    July 14, 2008

    Sebastian,

    Thanks. I talked to the writer of that piece a couple months ago, and to a fact-checker at the New Yorker, was wondering if they were going to publish it. Will look forward to reading it tonight.

Surfing the Universe

July 14, 2008
Categories: Uncategorized

This week's New Yorker has a quite good article by Benjamin Wallace-Wells entitled "Surfing the Universe" about Garrett Lisi and the controversy generated last year by his paper An Exceptionally Simple Theory of Everything (which I wrote about here). Unfortunately the article is not available on-line as far as I know.

One of the main themes of the piece is how Garrett ended up getting enmeshed in the controversy over string theory. I'm quoted as agreeing with the writer's impression that one thing that got Garrett "enlisted in the string wars" was having my name appear first in his acknowledgements:

> "It was probably not the most politic thing to do," Woit said.

The description of the state of the string theory controversy is pretty accurate. Wallace-Wells got the following from Steven Weinberg

> String theory still has great attractions, and there aren't any alternatives… Well, there are alternatives and they're worse.

and describes the situation as follows:

> In physics, as in politics, the competition is crueller in lean times. "In terms of development of new theories, it has been maybe the slowest period in two centuries," the science historian Spencer Weart said. By 2006, the fight over string theory had begun to leak out of the scientific community. Smolin and Woit published widely reviewed books criticizing string theory, and USA Today published an account of the assault headlined "HANGING ON BY A THREAD?"

The article explains the role of the arXiv and the blogs:

> In recent years, as science reporters and interested amateurs have turned to the arXiv – and as some physics personalities have started blogs – the audience for physics has both expanded and fragmented. "I know for a fact that many of the leading figures in the field read the blogs, but so do high-school science students," Woit, the Columbia mathematician and string-theory critic, said. "The scary thing is that frequently you can't tell which is which." The leading blogs have readerships that, while including some loud dissenters, tend to align with the perspectives of their authors – Distler, of the University of Texas, has a blog that attracts many string theorists and enthusiasts, while Woit's blog draws more skeptics. It works somewhat in the way the blogosphere operates in politics. Andreas Albrecht, a physics professor at the University of California at Davis, said that the blogs had opened physics to a new sort of populism, one that the academic establishment had to figure out how to manage. "It just pushes thoses buttons," Albrecht said. "There's some really good stuff, but a lot of really sloppy stuff." What you have, in other words, is the erosion of the referee and the rise of a scientific underclass.

The above quotes are from passages about the string theory controversy and ones where I had some involvement, but that's only one aspect of the piece. There's quite a lot more about Garrett, his story, and the physics/math context he is working in, together with a reasonable take on its significance, with everyone acknowledging that the ideas he is pursuing have problems and are still not such that success can be claimed. At the end of the article, Garrett explains that he's still at work, now trying to see if an alternate form of E8 will work better.

Update: Lubos has the usual sort of rant about this. He doesn't seem to have access to the article itself, so is basing his rant on my extracts. As a result, it includes an extensive personal attack on Spencer Weart….

Update: I hear that Bert Kostant has posted on his office door at MIT a copy of his e-mail exchange about E8 with the author of the New Yorker piece. So I guess that it's all right to point to these files. Also, there's an on-going Distler/Lisi exchange going on here. I haven't followed the technicalities of this particular discussion, but the trademark Distlerian argumentation tactics are in operation, ensuring vastly more heat than light.

Update: It turns out that not everyone involved in that e-mail exchange had given their permission to make it public, so the files linked to above have been removed. Kostant has made his comments public, posted here.

Update: The New Yorker article is now available on-line.

Comments

1. **Observer**
   July 14, 2008

   Peter,

   I am curious to hear your opinion on Albrecht's view that:

   "…the blogs had opened physics to a new sort of populism, one that the academic establishment had to figure out how to manage. "It just pushes thoses buttons," Albrecht said. "There's some really good stuff, but a lot of really sloppy stuff." What you have, in other words, is the erosion of the referee and the rise of a scientific underclass"

   Do you agree with this assessment ?

   Regards,

   Observer

2. **Peter Woit**
   July 14, 2008

   Observer,

   I agree with with Albrecht's characterization of physics blogs. I guess it's also true that the "physics establishment", whatever that might be, doesn't know what to make of blogs.

   Academia is a very hierarchical and structured system, and the blogs mess with that. Not clear what the effect will be. At this point I think it's hard to generalize, since the number of blogs is rather small and they're often very different in nature.

3. **Dave**

July 15, 2008

There was no mention of Lubos Motl. His blog is the best physics blog, period. Not surprising that his blog goes un-noticed…he's a conservative, and his opinion is certainly not required by the hysteria crowd!

4. **Bee**
July 15, 2008

Ah! I was beginning to think this article would just never appear. I am totally with Albrecht: the academic establishment has to figure out how to arrange with that populism. That's neither a trivial question, nor something that is likely to just work out by itself. I just wrote on the weekend a rather lengthy post about how crucial objective peer review is to progress in science (with that I don't only mean peer review in publishing, but generally critical feedback by the community). There's most importantly three factors that influence researcher's opinions: financial pressure, peer pressure and the public opinion. All of which are too influential today – the blogosphere touches on the two latter factors. See: We have only ourselves to judge on each other. The very least one can do is to raise awareness that such influence can hinder progress.

5. **Urs Schreiber**
July 15, 2008

It almost seems as if one statement by Albrecht amounts to

> [Blogs lead to] the erosion of the referee and the rise of a scientific underclass.

(I can't tell for sure, but this is the message I got from Peter's summary.)

I would strongly disagree with this statement. But maybe something else was meant.

6. **Peter Woit**
July 15, 2008

Dave,

Lubos was mentioned in the article, with a typical quote from him of the sort that makes it very hard to take him seriously. His political views aren't the main reason string theorists find him an embarassment…

Urs,

That statement was not in quotes, so I think more an interpretation by Wallace-Wells than something Albrecht said. Wallace-Wells is also a writer and reporter on politics, I think he was fascinated by the political dimensions of this story, here especially by the analogs to the role blogs have had in politics.

7. **Bee**
July 15, 2008

Hi Urs,
Technological developments are a priori neither good nor evil. It depends a lot on how one uses them. To this one needs to critically look at assetts and drawbacks. The drawbacks of blogs I think are mentioned in the quote from that article are a) blogs tend to polarize people into camps of pro and con and don't actually stimulate communication between these camps b) they make discussions about community matters public which isn't always a good thing because it can make an exchange significantly more complicated and hinder constructive criticism c) blogs aren't peer reviewed papers or textbooks, there's a lot of 'sloppy stuff' indeed and journalists as well as beginners need to be aware of that d) 'it just pushes those buttons': online communication isn't as easy as it looks like. There are many aspects to it that don't work in the way we are used to them from face-to-face discussions and it would help a lot if people were aware of that. One is eg that many writers seem to believe their message is evidently clear and perfectly obvious, whereas for somebody who just stumbles across a blog for the first time it is very hard to extract without knowing the writer, his story, or just the vocabulary used. Such kind of misunderstanding is easy to detect from frowned foreheads but not from blog comments that can easily heat up. (There are other complications to online communication but I'll stop here, I think you get the point.) Best,

B.

8. **Urs Schreiber**
July 15, 2008

Hi Bee,

just a few random comments on your remarks:

> blogs tend to polarize people into camps of pro and con and don't actually stimulate communication between these camps

Are you sure the polarization is caused by the blog? I certainly know that I had communication in blogs with lots of people (some of them in some camps some not) which I would never ever had otherwise, and I keep seeing some (little, though) cross-camp communication exclusively in blogs. It never happens elsewhere because these camps don't attend each other's conferences.

> blogs aren't peer reviewed papers or textbooks

Yes, because if they were, they'd be called peer reviewed papers or textbooks. Seriously: also discussion in the conference coffee break is "not peer-reviewed" in this sense and yet it tends to be the most useful discussion there is (and often even the most useful peer-review, actually!).

> journalists as well as beginners need to be aware of that

That's of course true. Journalists should even be aware of the fact that even peer-reviewed published journal articles may be contain nonsense. Generally, journalists should be very aware that the truth™ is hard to come by.

I guess we agree on the main point: mistaking blogs for peer-reviewed journals is a problem of the "media competence" of the one doing so, not of the communication channel "blog". Do we? 🙂

9. **George**
July 15, 2008

Serious question, Woit. I realize you may be offended, but I want to know what you have to say. It may be that what you have to say about string theory is right… but is the primary motivator for your intense desire to bring down string theory your own lack of success at becoming a physicist? Are you just trying to drag them down so you can think that you didn't fail, that instead the establishment was flawed? Or just to see the ones who did succeed fail too?

10. **Peter Woit**
July 15, 2008

George,

If you actually knew me personally, I think you'd find out that the idea that I'm an embittered failure striking back at my betters doesn't have much to do with reality.

Actually, as far as my career goes, I've done far better than I ever expected, I'm extremely pleased with how it has turned out, and consider myself to be someone who has been both extremely lucky in life, and extremely well treated by the powers-that-be in academia. Columbia has recently promoted me to the position of "Senior Lecturer", with a large pay increase. I like pretty much everything about my work, my colleagues, my department, and life in general. I'm a very happy camper. When I went into this business, I figured I'd end up working under very difficult circumstances at a community college (or maybe quit and try Garrett Lisi's route…).

My criticisms of string theory and what has been going on in physics have nothing at all to do with resentment about how I have been treated. Sorry, this is about science.

11. **George**
July 15, 2008

Ok, ok. One other (less serious) question of this general category. Have you ever met your arch-nemesis Lubos Motl in person? If so, how did it go? 🙂

12. **Daniel de França MTd2**
July 15, 2008

George,

Pay attention at the following pic, and try to deduce who took it.

http://en.wikipedia.org/wiki/Image:PeterWoit.JPG

13. **Peter Woit**
July 15, 2008

George,

Lubos and I have only met in person once, at Harvard at the conference in Sidney Coleman's honor. The picture of me on Wikipedia was taken by Lubos at the time. I think we both were smiling…

He and I over the years have had many often friendly exchanges by e-mail, since the time he was a graduate student. In recent years less so, as he has come to the opinion that I'm the anti-Christ, out to destroy physics.

14. **Aaron Bergman**
July 15, 2008

I haven't been able to read the article yet (the local BN was sold out because of the cover), but I'm not really sure I see that Lisi got caught up in the "string wars", except to the extent that most of the people involved in talking about hep-th on the internet have been unavoidably involved in such to some extent or the other. I don't recall anyone (with perhaps an obvious exception) attacking Lisi in a string theoretic context. Instead, the arguments were all about field theory and representation theory, and one of the more vocal participants was "amused" who's not a string theorist. If anyone brought string theory into the subject, it was Lisi who made the rejection of string theory part of his "origin story". What got people going about Lisi's paper was the extravagant title, a certain comment by someone in Canada, and, by far most importantly, the ridiculous media coverage. That you (PW) were cited in the acknowledgments isn't even a minor perturbation on that (again, except perhaps with the obvious exception.)

I'll see if I can find the article elsewhere, but it sucks being in a one bookstore town.

15. **Peter Woit**
July 15, 2008

Aaron,

The writer of the article also writes about politics, and I think got interested in the role of the blogs, and the "politics" of string theory, so that colors the story. He certainly noticed Lubos, quotes him about Lisi as follows:

"Every high school senior excited about physics should be able to see that the paper is just a long sequence of childish misunderstandings… I understood these things when I was 14"

There were quite a few blog comments posted by people attacking Lisi, often explicitly bringing string theory into it, e.g. see the first comment at Jacques's first posting on the topic, from "Moveon". True, these are pretty uniformly from people who don't put their names to what they write, hard to tell whether they're serious string theorists, juvenile string-theory partisans, or physicists with no stake one way or another as far as string theory goes.

It's an interesting intellectual exercise to think about what would have happened if Garrett hadn't brought string theory/LQG into it, or if he had embedded his E8 stuff into some kind of string theoretical context. If the latter had happened, and he had ended up getting a lot of attention because of his attractive "surfer-dude" story, I think what you would have seen would be Lubos and many others taking a very different and much more polite attitude, along the lines of "nice try, glad to see Lisi is working on this, even outside academia, but this particular idea doesn't work because of X, Y, Z, too bad."

16. **Bee**
July 15, 2008

Hi Urs,

As I said above, new technologies are a priori neither good nor evil. Blogs do not necessarily polarize people, I never said that must be the case, but it just often is the case. Many people just prefer to be among others who share similar interests. I certainly see that blogs have the potential to foster cross-camp communication, and I certainly wish that potential was used better. What I am saying is that this can also go into the wrong direction if one doesn't pay some attention to it. Social networks that are created online enable us to select our `neighbors' according to our liking much easier than was the case with actual neighbors.

Further, I never said what is written on blogs is useless because it is sometimes sloppy. I just said one has to be aware of that. I don't think this is an issue in the community, but for many non-experts what the expert (or the person thought to be an expert) says is taken very seriously. I therefore think writing a blog brings some responsibility on the one hand, on the other hand journalists as well as beginners should be aware that the level of accuracy is often not on a very high scientific standard. Again, this is a priori neither good nor bad, it is just a matter of how one deals with it. Best,

B.

17. **Haelfix**
July 15, 2008

The only problem with blogs atm in particle physics at least, is that there are only about 6-7 that are around and putting out serious physics content and being actively updated.

Meanwhile you have about 10,000 crackpot sites.

When a layman looks on the internet to find physics related discussions, he invariably gets a horribly jilted view of what academics really think and are doing.

18. **somebody**
July 15, 2008

OF COURSE blogs are not inherently good or bad. But the essential point is that blogs give a lot of visibility to opinions (on things which require expertise) from non-experts. They give the impression that democracy and public relations are more important than scientific judgement/truth.

Popular opinion is often reactionary and emotional. Emotional appeal has NOTHING to do with science, and that crucial point is often lost in the popularity contest.

Case in point: real or imagined "controversy" is more interesting to the public than the actual science that Urs blogs about, so the New Yorker does not even think about Urs as a science blogger. (I am assuming this – I haven't read the New yorker article, but I would be surprised if Urs got as much attention as Lubos or Peter. I would not be surprised at all if he was not even mentioned.)

19. **somebody**
July 15, 2008

Put another way, the more popular "science" blogs deal mostly with the sociology of science and not science itself. There is nothing wrong with this (I personally enjoy talking ABOUT science and scientists almost as much as I enjoy talking science), but the distinction is a very important one that is often blurred over in the discussions about "science" blogs.

20. **Peter Woit**
July 15, 2008

As Haelfix points out, there are only a relatively small number of blogs that are regularly updated with serious physics content. The interesting thing to me is that they're pretty much all quite different, reflecting different interests, points of view and goals of different bloggers. I think anyone who starts reading the things quickly realizes this, and also quickly gets a feel for who the people writing the blogs are, what their point of view is, how reliable their information is likely to be, etc. It's not really different than the situation with blogs in other subjects. People reading blogs know very well that they have to sift through them to find the ones that seem reliable. Stupid people will gravitate to stupid blogs, smarter people can be trusted to recognize smarter ones. The thing that is different here is that the blogs are operating outside of the usual credentialing system: anyone can start a blog, the things don't come with the sorts of institutional imprimatur that people are used to.

What the physics blogs don't necessarily do is reflect either the median point of view (the statistics are too low), or the point of view of leaders of the field (because they're not writing blogs, I wish they were). The one highly peculiar aspect of theoretical physics blogging is that we've had one Harvard faculty member doing it, and his blog continues to claim (with some justice) to reflect the point of view of leaders in the string theory commmunity. Unfortunately, he's kind of obviously out of his mind. If members of the mainstream string theory community feel that their point of view is not reflected by blogs, so that the general public is not getting their message, or is getting it from someone who makes them look bad, the solution is simple: start a blog. It's not hard, and, depending on how one does it, not necessarily highly time-consuming. I think it would be a wonderful thing to see one of the many sensible people I know working on string theory blogging about it, and putting out a reasoned view of what is going on in the subject.

21. **somebody**
July 15, 2008

"If members of the mainstream string theory community feel that their point of view is not reflected by blogs, so that the general public is not getting their message, or is getting it from someone who makes them look bad, the solution is simple: start a blog. It's not hard, and, depending on how one does it, not necessarily highly time-consuming."

I would in fact LOVE to see a blog on string theory which addresses things at a level like that of Lubos's but without the "Lubos-ness". But I am really sceptical about your optimistic expectation that it is NOT going to be a time-sink.

I also have one comment to make about intelligent people being drawn to intelligent blogs. I would in general agree with this, but I do think that the disagreement about (for example) string theory happens at such a rarefied and sophisticated level, that there is no way for an intelligent layman to judge who is talking sense, just based on the general "smartness" of the blogger. You, Carroll, Motl, Distler are all smart people. Is it going to be easy for the layman to distinguish whose scientific judgement is the most sound? I doubt it. This is where the emotional appeal of string theory being the "establishment" etc. come into play.

In fact, because I know some physics, I find Lubos's posts on scientific things reasonable even though he is psychotic otherwise. I suspect that this is in general going to be a tough call for an average left-of-center intelligent layman. The real problem is that even though he posts some good stuff, it is impossible for a layman to tell what is well-established and what is merely opinion because he states both with equal vehemence.

22. **A quantum diaries survivor**
July 15, 2008

Interesting discussion. I think that the concerns over the "level of accuracy" of scientific information offered in physics blogs are ill-posed. I often write inaccurate explanations, but their purpose is to bridge the gap with people that do not have the means to understand more precise descriptions. The inaccuracy has no harmful effect, on the contrary it helps!
One of the things I learned in over three years of blogging is that by getting down the pedestal is the way to go to get people interested. If I write something sloppy and an informed commenter points it out, I do not rush to correct it, but actually publicize my ignorance. This makes it clear to everybody that there is nothing scary in being ignorant, if one is willing to try changing that status.

Cheers,
T.

23. **Peter Woit**
July 15, 2008

somebody,

Well, I hope you start up a blog!

It would be better if there were better string theory blogs, but I think any smart person looking at the blogs dealing with the subject is going to get the accurate idea that, while they can't decide about the technical issues themselves, what is going on is that there are some wide disagreements among knowledgeable people about certain issues. Some think that multiverse and anthropic studies are nonsense, some don't. Some think string phenomenology and string cosmology are going nowhere, some don't, etc. String theorists who believe, like Lubos, that those who think there is a serious problem with string theory must just be ignorant and ill-informed are as delusional as he is.

All in all, I think the perception of the educated public about string theory is much closer to reality now than it was 5-10 years ago. At that time, the only information sources available to the public were pretty uniformly unrealistically optimistic about string theory's prospects, these days the other side of the story has become widely known.

24. **Mitch Miller**
July 15, 2008

Garett Lisi is a marketing genius:) We can add being featured in what will likely be the best selling New Yorker of all time to his already impressive achievements!

25. **MathPhys**
July 15, 2008

Peter,

Have you seen the art work on

http://lubos.motl.googlepages.com/crackpot-not-even-wrong.html

Lubos goes from high to higher.

26. **Peter Woit**
July 15, 2008

MathPhys,

Yes, I've seen that. The guy is endlessly entertaining…

27. **Bee**
July 16, 2008

I think he used the same pot already for Lee.

Anyway, regarding the question of scientists and the Web 2.0, I've recently had a post about this. Time and incentives are an important factor generally. If it is unclear to people what writing a blog is good for they will regard it a waste of time. Then there is (unfortunately) the fact that the reputation of the blogosphere is at best so-so. This is something that can change though. Another factor that Michael Nielsen pointed out to me which I found very interesting is that public discussions require an atmosphere of openness which might not work well in a community where people are protective about their insights (that's not exactly what Michael said, but how I understood it). E.g. consider there's a discussion about a paper on the arxiv. Will you just go and read what others say, or will you offer your own opinion? I am afraid most people would rather collect other's insights than offering their own. Of course that can't work.

Hi Tommaso,

Just to clarify, I didn't mean to say I find inaccuracies on blogs problematic, I was just trying to summarize that paragraph Peter quoted. You know that my writings also are often not overly accurate to make them more readable. It has happened then however, that people come and nitpick around on single sentences which I admittedly find extremely annoying. I find myself repeating again and again: if I had wanted to write a paper I had written a paper, this is a blogpost, and yes it's sloppy and it's inaccurate and it's full of believes and speculations and subjective opinions – live with it, or go read peer reviewed journals.

And yes, then there's the inaccuracies arising from lacking knowledge. I have certainly learned a lot from our commenters. The problem is however that I am afraid the barrier to publicly admit lacking knowledge can be quite high, esp. if it results in insults of the kind 'you're so stupid and know nothing'. I suspect that comments of this kind (which I keep getting in many instances when I do not write about a field I have worked in myself but would like to know more about) are very obstructive to a fruitful exchange.

Best,

B.

28. **mathandphysics1**
July 16, 2008

Peter

I have been reading your book. I have to ask whether you wrote it with the scientific underclass in mind?

I think that the real danger in physics populism (and Title IX in science as well), is that real math and physics will be less and less accessible to the public in general. Those who have the talent and the motivation will continue to pursue math and physics regardless of the social and governmental constraints imposed to make physics "fair and balanced".

Some of the great minds in history did their work in math and physics on their personal time (or rather, many had day jobs). Intelligent people who want to learn with an attention to truth will tend to seek each other out. The real loss is to the general public, who in their ignorance, will eventually tear down and destroy institutions of learning to achieve political ends (just look at the early christians and their destruction of any school of philosophy or knowledge that contradicted their world view).

These forces are ever present in the world, and yet their are those who would feed them for personal gain.

So I ask again, who was the intended audience of your book?

29. **anon.**
July 16, 2008

‘I think that the real danger in physics populism (and Title IX in science as well), is that real math and physics will be less and less accessible to the public in general.’ – mathandphysics1

Clearly, ‘Not Even Wrong’ caters for a wide audience of people interested in physics, a similar audience to those who read Feynman’s book QED. E.g., students, physicists in other areas than quantum fields, and the lay public who want a readable introduction to the key concepts and problems. It’s neither popularist hype for speculations, nor a heavy-going textbook of extremely advanced mathematics. Once you read these books, you get interested enough to start looking into the mathematics.

30. **Marion Delgado**
July 16, 2008

George, Dave, and others of the Motl-ite end of the string pool:

That exact tendency you’re showing, right here, above, to try to settle abstract physics issues by personal attacks, bizarre political tacks, and so on is exactly WHY people sometimes don’t respond, and never should respond. Or not to the alleged specifics – but to the paradigm that says this is any way at all to deal with science. Ever.

There’s a saying at law – when the facts (data) are on your side, hammer on the facts. When the law is on your side, hammer on the laws. When neither the facts nor the laws are on your side, hammer on the table.

You’re hammering on the table.

If you were representative of some “partisan” facet of physics, which you aren’t, properly, your posts would represent an admission of how bankrupt it was.

31. **Lucy in the sky**
July 16, 2008

Well the blog master seems to be very content with his career which is according to him way more than bashing people who do devote most of their time to science. I encourage anyone to check up on PW on Web of Science (you could get criticized when using Spires as Spires mostly focusses on hep). Quite interesting… 10 entries to be found. First scientific paper in 1983, eighth and last one in 1989, two more papers hitting on people who do actually work in 2002 and 2007, both papers completely void of any scientific content. He is 184 times cited in total, during the past 10 years he got a grand total of 18 citations. So a few questions pop up: how can a non scientist attack a whole field where – according to his own words – some of the best young minds of our time work? Here above he mentioned his promotion to “Senior Lecturer”. How is it possible that a person makes promotion at one of the world’s foremost universities without a single tracable sign of scientific activity in nearly two decades? Do we miss something? Or is a senior lecturer somehow disconnected from the regular body of professors doing science? I am pretty sick of this endless ranting against part of elementary particle theory by someone who has certainly not deserved his right to speak and who is not able to present any valuable or even just interesting alternative… Please keep us updated on conferences, talks, other blogs etc. but stop this incredible petty nonsense.

32. **Peter Woit**
July 16, 2008

mathandphysics1,

Despite what you might read some places, I’m not at all a physics “populist”. As far as progress in theoretical particle physics goes, it is an extremely demanding subject, and requires talented people working in the right sort of environment. The health of our elite institutions in this area is something I’m quite concerned about. But I don’t see the threats as coming from “populism” or the general public. Most people’s attitude towards these institutions seems to me to range from complete lack of interest to moderate degrees of respect. The more serious threat comes from within: if things get to the point where pseudo-science like the multiverse dominates and this is what you have to work on if you want a job, then these institutions are doomed as serious places.

The book was intentionally written to be readable by a wide range of people. One audience is mathematicians and physicists with a serious interest in the subject. I’ve been very pleased to hear from some colleagues I respect enormously that they enjoyed reading the book and learned some things from it. At the other end of the spectrum, much of the book tries to be a readable history and overview of the current state of the subject, accessible to any serious reader willing to deal with the fact that they won’t understand some of the more technical things I try and explain about.

While writing the book, I didn’t think much about who I was writing for, just trying to get down a story I wanted to tell as clearly and accessibly as possible. Later on, at some point I realized that there was one ideal reader that I had been writing for. In some sense it was aimed at myself, 35 years ago, explaining to a teenager just starting to get curious about this subject everything that I had learned about it. In that respect, it is intended as an introduction into the subject, hopefully a guide for someone who wants to learn more. It’s not a technical textbook, but I hope it can be useful when read in conjunction with books that do explain the actual technical tools needed to seriously understand the subject.

33. **Peter Woit**
July 16, 2008

“Lucy”

I think Marion says it well. When people are on the losing side of an argument, they descend to the ad hominem attack and start pounding the table in a desperate attempt to draw attention away from the question at hand.

Doing this while hiding behind anonymity is just pathetic beyond words.

34. **George**
July 16, 2008

Some active researchers do agree with Woit’s views, so Lucy in the sky’s comments aren’t that pertinent in my mind. If anything, the fact that someone who isn’t an active researcher can make this sort of attack on the physics establishment, whatever his motives, and have their response be so ineffective, is more evidence there’s something wrong with the way physics is today.

35. **George**
July 16, 2008

Also, to “Marion Delgado” above, I am not a Motlite by any stretch, or even a physicist for that matter. I don’t really know who’s right about this controversy. My comments above were mainly just curiosity if there were some personal motives behind his opposition to string theory. Clearly, looking at the two blogs, Motl’s and Woit’s, Motl’s definitely comes across as being more political and less professional. And if he is an active researcher, it doesn’t look like he will be much longer 😉

36. **p falor**
July 16, 2008

Peter et al:

I think Peter’s blog attracts lay people like myself (retired engineer) because they want to understand the issues (that’s right issues) that HEP and cosmology are attempting to address. The point that Peter has made repeatedly is that string theory makes no verifiable predictions and that ideas like the multiverse are untestable. The general response is typical: “Woit is not a researcher so ignore him.” Or these are research programs in progress.

After a while someone like me begins to think that fundamental physics research is starting to look more and more like a religion. Physicists start worshiping their equations, holding meetings to discuss their equations and claiming how the equations are the answer to all that is knowable and unknowable. No measurements that validate the equations are available but no problem. It is the beauty of the equations.

I have absolute no problem with individual doing this as long as it is not at the taxpayer’s expense. The lay public is in no position to question the technical details of any particular research but the lay public can certainly recognize when there is no connection to the real physical world. I think that has been a big advantage of the internet and particular blogs. More and more information is available to the lay public.

People like Peter are just trying to inform the public as they see physics research it. If others different then they should go all out to correct any misperceptions that Peter or anyone else is fostering. String theory and the multiverse idea are just two examples where the advocates are not presenting convincing (at least to me) arguments for their positions. So I would certainly welcome more dialogue from the other side. I am opened minded but very skeptical as of now.

37. **Peter Woit**
July 16, 2008

Since I just spent the morning trying to figure out what to do about a section of a paper I’ve been writing that has me confused, I kind of take exception to the “not an active researcher” characterization. I’m not someone who has ever been an active researcher in string theory, and my research work does move embarrassingly slowly, but it does take up a lot of time right now that I could otherwise be using to enjoy a restful summer vacation…

38. **Observer**
July 16, 2008

It is discouraging to see the String propaganda mount such vicious attacks against any form of serious criticism and against whistle-blowers like Peter. It is quite clear that all these personal attacks are nothing short of attempts for character assasination and, at the end of the day, reinforce the very failure of the String Theory program.

39. **a.k.**
July 16, 2008

‘..but I do think that the disagreement about (for example) string theory happens at such a rarefied and sophisticated level, that there is no way for an intelligent layman to judge who is talking sense,..”

The actual interesting point is that this is, at least concerning the current state of fundamental physics, in fact in a certain sense wrong. The essential ‘disagreement’ about (for example) string theory, as it seems, cannot be decided on any ‘positive’ level, as it would be sufficient for the constitution of an exact science, the disagreement about string theory takes place on a normative level, a level which couldn’t be more distant to the techniques and results which should actually discriminate valid reasoning from ‘nonsense’ in the exact sciences. This is the actual fate which fundamental physics seems to face at the moment: the unabilty to construct itself beyond normative ‘knowledge’ and methods. What could be a positive disagreement about string theory today is almost completely resolved by mathematicians, it is, to cut it short, the physical discourse itself, being not able to produce ‘positive statements’ and methods anymore that produced the ‘scientific subclass’ that initiated the threat to the ‘truths’ and ‘standards’ of physical reasoning, not some external program or entity as the internet, especially not the phenomenon ‘blog’.

40. **Marion Delgado**
July 16, 2008

George:

Regardless of what you now say is your actual position, which cannot be otherwise derived from your posts and hence would have to be obtained by mind-reading, the fact is your “question” is a very typical ad hominem attack disguised as an attempt to elicit information. You do not, let me say this emphatically, deserve the benefit of the doubt when you resort to such tactics. Indeed, it’s discernibly worse than simply saying what you’re asking about.

Moreover, you are decidedly being part of the effort to shift the ground from the only real issue – the current state of theoretical physics as it relates to string/brane/M theory – to picking out one person raising issues and asking completely irrelevant and ad hominem questions – making the theorist or challenger the issue instead of the theory or challenge.

And whether you are a string theory partisan or not, you are explicitly resorting to tactics that Motl and his supporters have endorsed by using them. If you posted something about how the LHC will be a valid test of a major swatch of string theory, for instance, and I or Peter Woit or anyone asked you if you were saying that only because you were a drug addict or had a crush on Lubos or something, that would be an ad hominem attack disguised as a question. I hope this clarifies the issue.

Because the point is, Woit’s history is simply not germane to the issues raised with string theory. The “theory”, if i can unfairly dignify it with that term, that you are referencing – that only academic failures attack string theory – does not hold very well when you consider the many fine physicists (penrose and feynman are just the tip of the iceberg) who have raised identical issues.

There is no OBJECTIVE reason for you to probe into someone raising issues that have been raised by probably at least a hundred other physicists, including some string theorists, asking if they’re MERELY raising those issues, again, but in a systematic way, out of spite because they are personally an academic failure.

It still boggles my mind and is very disheartening to think that something as abstract as particle physics could be subject to this level of tendentious and unsound discussion.

41. **Marion Delgado**

July 16, 2008

Let me add that Garrett Lisi's kewl surfer dewd persona is also not at all germane. He gets publicity for it, but I hope he neither gets dismissed nor respected for it.

42. **Peter Woit**
July 16, 2008

Marion,

Enough, the point has been made. As far as I can tell, George, like probably lots of other people who see Lubos's blog, was just curious to hear what I had to say in response to the way Lubos describes me. Fair enough. Lubos is so far out there it's hard to even get annoyed with him, and he at least puts his name to what he writes and takes responsibility for it. What's much more creepy are string theorists like "Lucy" who think anonymous character assassination is a good tactic. Undoubtedly this kind of thing works to some extent with people who don't know much about me, but on the whole I think it does much more damage to the reputation of string theory and string theorists than it does to mine. Go right ahead…

43. **George**
July 16, 2008

Marion, you really have me all wrong. I prefer to stay anonymous on these blogs, but I guarantee I have nothing vested in the string theory debates one way or the other. I've been around the academia block a few times, and I have seen the lowest motivations. I don't know Woit, Motl, or any of these people, and I'm not secretly on anyone's side.

I even bought with my own money the Smolin book, and probably would have bought Not Even Wrong if I had seen it in the bookstore first. Anyhow, I'm not going to argue this anymore, it's not like I am in a position to prove anything.

44. **Chip Neville**
July 16, 2008

I find it remarkable, and a bit scary, that the social and political context of the excellent "Surfing the Universe" article in the current New Yorker has only been mentioned here in passing. I am referring, of course, to the scandalous cover for the issue, depicting Michelle and Barak Obama as Black Panther revolutionaries and Islamic terrorists. Motl, who features an image of the cover on his blog, could not possibly have done worse.

The New Yorker's claim is that they were simply trying to parody the attitudes of some of Obama's opponents. If so, certainly a lot of the country misunderstood their intention. To relate this to the discussion here on Peter's blog, the misunderstandings that may arise from this misplaced imagery in a thoroughly mainstream and conventional medium are likely to eclipse by far those from blogs. So while Bee is correct to point out the perils of being misunderstood on a blog, there is really nothing new about this. For as long as there have been printing presses, there have been things written (or drawn) which would not have been misunderstood in personal, face to face communication.

45. **Curious Observer**
July 16, 2008

"…just look at the early christians and their destruction of any school of philosophy or knowledge that contradicted their world view…"

Every once in a while, someone just has to inject surreptitiously an unfair attack on Christians that has nothing to do with the topic of this blog.

46. **A.J.**
July 16, 2008

I find it remarkable, and a bit scary, that the social and political context of the excellent "Surfing the Universe" article in the current New Yorker has only been mentioned here in passing.

Peter has a long-standing habit of discouraging political discussion here. I wouldn't read too much into the absence of discussion of the New Yorker cover.

47. **Marion Delgado**
July 17, 2008

Peter:

Sorry, and I agree the point's hammered in. By the time I'd responded there were another few posts I hadn't seen.

George:

That is fair enough, and when I say "you" I should rather say, "one" or "anyone who…"

48. **Peter Woit**
July 17, 2008

Thanks A.J.,

Yes, once people start discussions of politics or religion, they then drown out everything else. Please don't do this, it's not like there aren't plenty of other places on the internet for such discussions…

49. **Russell Van Rooy**
July 17, 2008

To Haelfix:
I'm a rank amateur math and physics groupie – no physics or mathematics degree – hell I can barely count. And yet I ended up at this blog and I don't see any crackpots around here…
Here is a partial list of blogs this amateur follows:
Ars mathematica, Cosmic Variance, God Plays Dice, Good Math-Bad math,Low Dimensional Topology,MathTrek,NonCommutativegeometry,Rigorous Trivialities,The n-Category Cafe (my favorite), The Unapologetic Mathematician, Not Even Wrong (I come here a good bit even though I'm more partial to string theory) and ZeroDivides.
I sometimes go to Lubos's blog too – he's a bit of a crack pot though (just kidding Lubos! It's a joke, yes really)

50. **mathandphysics1**

July 17, 2008

“Yes, once people start discussions of politics or religion, they then drown out everything else. Please don’t do this, it’s not like there aren’t plenty of other places on the internet for such discussions…”

Peter

I will swallow my pride and humble myself. My last comment was removed and must have been in violation of the policy.

I will even confess to being a trickster, a physics underclass wonk.

51. **Aaron Bergman**
July 17, 2008

Is Kostant really saying that Lisi is the first to use E_8 as a gauge group? Perhaps he means one of the noncompact forms? Otherwise, the statement is simply false.

52. **Peter Woit**
July 17, 2008

Aaron,

Maybe he did mean the non-compact form, but in general I’m afraid Kostant is not a reliable source about many topics in physics. He’s one of the greatest figures in representation theory, responsible for some fantastic stuff, but he’s not a physicist. This isn’t really unusual among mathematicians, I’ve more than once run into excellent mathematicians with an interest in physics who were under the impression that the Standard Model was a supersymmetric QFT.

53. **Kea**
July 17, 2008

Kostant was careful to point out to the reporter that he was not a physicist, so one must forgive him his errors in this regard.

54. **Peter Woit**
July 17, 2008

Aaron,

Rereading Kostant’s e-mail (see link in update above), I noticed that he did also write “I remind you that I am not a physicist and cannot comment one way or another on the physics involved”.

The most interesting thing I saw in the Kostant e-mail was his story of meeting Einstein shortly before his death, and being told that Einstein thought Lie groups would turn out to be very important.

55. **H-I-G-G-S**
July 18, 2008

Dear Peter,

Since you haven’t followed the technicalities of the Distler/Lisi exchange, how can you possibly know that there is more heat than light? It seems to me the exact opposite. Distler has devoted a great deal of time and effort trying to understand Lisi’s proposal and is trying to get him to make clear and correct mathematical statements. It is one of the few exchanges on this topic where there is actually some mathematical substance rather than just discussions of sociology. I think your attitude towards Distler has blinded you to this fact. I do think that David Gross had the most appropriate quote in the New Yorker article when he said that he was “extremely reluctant to add fuel to this silly story.”

56. **Peter Woit**
July 18, 2008

“H-I-G-G-S”,

I have extensive personal experience engaging in on-line discussions with Distler, and have found them to be mostly a waste of time due to his unprofessional behavior. I took a quick look at the Distler/Lisi exchange, and it seemed to be pretty much more of the same, with no sign of an honest attempt to deal with the arguments Lisi was making. In any case, as I’ve repeatedly pointed out, I’m not a big fan of the project of trying to fit known symmetries into a larger simple group. If Lisi can get somewhere with it, great, but I’d rather spend the limited time I have thinking about other things. For those who are interested, I put the link there to follow, but just was reporting the impression I got from it.

Speaking of unprofessional behavior, I’m really getting thoroughly sick of people like you who seem to think that posting anonymous comments on blogs about physics criticizing others is a legitimate form of behavior for a scientist to engage in. Either be willing to take responsibility for what you write and put your reputation on the line behind it, or knock it off.

57. **Aaron Bergman**
July 18, 2008

I understand all that about Kostant who certainly is a great mathematician. It’s just somewhat dismaying that this sort of misinformation can get out there.

58. **H-I-G-G-S**
July 18, 2008

Peter,

I was simply pointing out the inconsistency between your statements that “I haven’t followed the details” and now your most recent “I took a quick look” and your claim that Distler adds more heat than light and doesn’t deal with Lisi’s arguments. He does deal with Lisi’s arguments, and adds a great deal of light, but there is simply no way you can tell this unless you are willing to enter into the technical details and have more than a quick look. It’s very superficial of you to jump to conclusions when you don’t understand the substance of the argument.

As for your being sick of my posting anonymously, I assure you I find your constant complaints about it equally tiresome. And no, I see nothing at all unprofessional about what I am doing.

59. **anonymous spiritually old man**
July 19, 2008

Aaron,

In his papers Kostant is careful about what he says. His papers are wonderful to learn from because they are carefully organized, detailed and precise, as well as deep. Something posted on his office door is presumably meant for the consumption of his near neighbors, and perhaps with it he has not taken the care he does with his papers. And, as the example of Serge Lang shows very well, an expert in one area can be a fool in another (although I would not accuse Kostant of this), particularly if he lets himself believe that the area in which he is expert is fundamentally more difficult or more fundamental than are other areas, or he lets himself believe that he is the intellectually honest one in a sea of scoundrels.

Woit,

Distler's exchange with Lisi seems to me quite reasonable. You do yourself no favors by characterizing it another way without having read it. Lisi claimed something that can't be, and Distler explains pretty clear what it is and why it can't be, and to ignore this is to stick one's head in the sand; to his credit Lisi doesn't ignore it. I find Lisi an appealling character, but one a lot like a lot of folks I have known, who does not appear to have written a solid, careful paper of the sort I like to see. It seems for this last reason that he has inpsired the wrath of the experts; this is human if not always nice – but it is natural that people that work hard, take care, think deeply, etc. get peeved when some guy who has perhaps not taken as much care finds is on the front pages ballyhooed as having done what they have not. Many experts are like small children emotionally.

60. **Peter Woit**
July 19, 2008

ASOM,

I did read Distler's exchange, or at least enough of it to see that he was engaging in the same argumentative tactics that I have extensive personal first-hand experience dealing with. For a good example, take a look at this, from one of the first postings on my blog more than four years ago:

http://www.math.columbia.edu/~woit/wordpress/?p=3#comment-30

Jacques started out insulting me anonymously, but his style was just too recognizable, so he stopped doing that. His argument was much like his one with Lisi, that the person he was arguing with was ignorant and didn't understand a technical point about chirality that an expert like himself did. Except in the 2004 case I was well aware of the technical issue he going on about, it was just not relevant to the argument I was making (that we don't understand nonperturbatively the electroweak interactions, since we don't have a good way to handle that kind of chiral gauge theory).

Anyway, in the 2008 case, maybe his complicated representation theory argument shows that Lisi has a problem with getting a chiral theory. As I've repeatedly pointed out, that doesn't interest me enough to work through the details. Maybe Distler is right on the technical point, and doing science a service in working this out. Maybe his technical point is irrelevant. I don't know. I'll stick to my characterization though of how he chooses to argue points like the one in question here.

61. **ERic**
July 19, 2008

The whole Lisi story seems to me to have just been a media phenomena which was started on various blogs, given credibility by the comments of Smolin, and picked up by newspapers and television who liked the idea of an independent surfer dude being the next Einstein. Otherwise, there's really nothing else there. The paper is wrong, and no different than 1000 other wrong papers that come along every day. The attention it received was completely unjustified. It's sad to see Lisi strutting around now as though he's actually done something.

62. **John Baez**
July 19, 2008

Are there any particularly interesting or inflammatory quotes by me in that New Yorker article? Apparently not, since nobody has mentioned any. But I'm curious: I don't have easy access to a copy, and I'd like to know if my attempts to stay out of trouble succeeded.

63. **Aaron Bergman**
July 19, 2008

There's only one quote by you (JB):

> "If a figure is so beautiful and intricate and clear, you figure it must not exist for itself alone," John Baez, a professor of mathematics at the University of California Riverside, said. "It must correspond to something in the physics world."

Anyways, having finally found a copy of the article, really, there's very little to it at all; it's more of a profile than an article about physics. One can argue about various characterizations. Just to pick one, Lisi doesn't use a trick or handwaving to incorporate three generations; he just doesn't do it and expresses a vague hope that maybe triality might have something to do with it. Mainly, the real impression I get from the article is that the person most interested in making this part of the string wars is Lisi. Why didn't Lisi get a postdoc doing Clifford algebras after writing a thesis on a subject completely unrelated to them or anything else in hep-th or gr-qc? String theorists. Why don't string theorists like his theory? Because he uses loop quantum gravity techniques (which he doesn't actually.) Or maybe because he acknowledged Peter Woit. Why was the audience at Davis not particularly impressed? Full of string theorists. It's all a bit tiresome, but I suppose I only think that because I'm a string theorist.

64. **Urs Schreiber**
July 19, 2008

> Because he uses loop quantum gravity techniques (which he doesn't actually.)

Right. What he does is mention that he has, or is imagining to have, a theory whose configuration space is entirely one of connections. But then, if so, it is some kind of superconnections.

I agree with and would tend to promote the very constructive summary and outlook that Jacques Distler gives at

http://golem.ph.utexas.edu/category/2008/05/e8_quillen_superconnection.html#c016877

which ends with:

> That said, there is something kinda cool about the elements of the construction:

1. An embedding of Spin(d−1,1) in G gives a Z_2 grading on $\mathfrak{g}$.

2. Using the corresponding Schreiber superconnection, one naturally gets a theory with fermions, corresponding to the odd generators of $\mathfrak{g}$, transforming as spinors Spin(d−1,1).

It would be mildly interesting to see what sort of actions one could build with this construction.

The punchline being: it's not a working "theory of everything", but there is an interesting idea used here which deserves to be further investigated.

65. **Tony Smith**
July 19, 2008

John, the New Yorker Garrett Lisi article is long (7 pages) so maybe I missed something, but I think that you did succeed in staying out of trouble. I don't recall you being quoted directly, but Bertram Kostant was quoted a lot, and you were his host when he made the E8 talk that was widely seen on the web, so maybe you are indirectly there through him. I think the things that he said were interesting, such as:
"… "Columbus made mistakes and thought he was in India. Lisi made a few errors, but this pales in significance to his possibly opening up a whole new world for exploration … E8 is like North America, South America, and the Pacific Ocean rolled into one. …[Lisi's]… daring … possibly creates an agenda for scientists for the next hundred years or more." …".

Peter, as to Jacques Distler's behaviour on n-Category cafe about Garrett Lisi (here I am avoiding any mention of substantive physics),
Jacques Distler put up a post there (now deleted) saying:

""Ginsparg's Law
Summerizer wrote "Any phenomenologist or grand unified model builder would be absolutely flabbergasted that the discussion here is even taking place."
I suppose that now would be the time to invoke Ginsparg's Law"
Posted by Jacques Distler on July 19, 2008 4:23 AM …"".

Following links that Distler put in that deleted post lead to such things
as:
xkcd comic number 386 (about a compulsion to correct people who are "wrong" on the internet)
and
a (now deleted) paste.lisp.org paste number 63894 saying in part:
"… More comments from Paul Ginsparg
Jul 18, 2008 … Don't they realize that this makes them look like chumps-by-association? . feel free to refer them to "my" law below …".

So,
I wonder if Jacques Distler thinks of Bertram Kostant as a chump-by-association with respect to Garrett Lisi ?

Tony Smith

The New Yorker has the following "Abstract" online. Not sure how long until the full article is also online.

Benjamin Wallace-Wells, Annals of Science, "Surfing the Universe," The New Yorker, July 21, 2008, p. 32
July 21, 2008 Issue

Keywords
Lisi, Garrett;
Theoretical Physics;
E8;
String Theory;
Mathematics;
Science, Scientists;
"An Exceptionally Simple Theory of Everything"

ANNALS OF SCIENCE about physicist Garrett Lisi's "An Exceptionally Simple Theory of Everything." Writer describes Lisi giving a talk at a conference in Morelia, Mexico in June of 2007. The conference was attended by the top researchers in a field called loop quantum gravity, which has emerged as a leading challenger to string theory. Lisi believed that he had discovered what physicists call a Theory of Everything—a unifying idea that aims to incorporate all the universe's forces in a single mathematical framework. Within four months, Lee Smolin, one of the founders of loop quantum gravity, said that Lisi had "one of the most compelling unification models" he had seen in years. Discusses the persistent legend of the hermit genius in physics, from David Deutsch to Albert Einstein. Lisi got his Ph.D from the University of California at San Diego and, at thirty-one, dropped out of academia. For almost a decade, Lisi moved on no fixed schedule between Maui, where he likes to surf, and the mountains of the West, where he snowboards. He worked intermittently, but mostly he tried to think about physics. Five months after the Morelia conference, Lisi published the theory in a paper called "An Exceptionally Simple Theory of Everything" in an online forum. In the acknowledgements to the paper, Lisi thanked Peter Woit, a Columbia mathematician, whose name signaled a declaration of partisan affinities. Woit is best known for his one-man campaign to discredit string theory. Describes string theory and Lisi's skepticism of it. Describes Lisi's personality, which is self-depreciating and ironic and not particularly hermitlike. Lisi feels that his isolation from the academic world gives him advantages over his contemporaries who need to publish regularly for the sake of career advancement. Describes how Lisi developed his theory, in particular, his use of the mathematical entity E8. (A circle has one degree of symmetry; a sphere has three; a space whose symmetries are described by E8 has two hundred and forty-eight.). Lisi discovered that he could plot all the universe's components on E8. On the terrain of E8, he believed, general relativity and particle physics were no longer out of joint. Tells about the arXiv online forum where Lisi published his paper. Describes criticisms of Lisi's theory, including Jacques Distler noting Lisi's use of a mathematical trick to incorporate the second and third generations into his model. Tells about Lisi presenting his theory to professors and students at the University of California-Davis. More recently, Lisi has begun to feel a set of responsibilities—to the broader physics community and to those who supported him, but also to fully extending his ideas. Last May, he headed to the Perimiter Institute in Ontario as a visiting researcher.

67. **John Baez**
July 19, 2008

Thanks for giving my supposed quote, Aaron.

What an unhappy quote! A fact-checker for the New Yorker send me an email with a lot of question including one about this, saying:

> Ben writes that you told him that if a figure is so beautiful and intricate and clear, you figure, it must not exist for itself alone. It must correspond to something

> in the physical world. Is this correct?

to which I replied:

> I was trying to say that this is a feeling physicists often have. I was *not* trying to say I personally believe this!
>
> There's no rational reason why something beautiful "must" correspond to something in the physical world. This "must" is more like an avid hope.

but of course none of this came through. I also thoroughly dislike using the word "figure" in two such different ways, so close:

> If a figure is so beautiful and intricate and clear, you figure it must not exist for itself alone…

More importantly, I would never call E8 a "figure"… maybe Wallace-Wells was focused on that famous figure of the root system of E8. Indeed, the fact-checker asked this question about E8:

> We say that its most common representation looks like a dense and precisely symmetric cloud of spider's web, thousands of threads exploding out from hubs of concentric spheres. Is this okay?

to which I replied

> Far be it from me to argue with a poet! Decide for yourself; [here's the picture].

Oh well, at least they didn't have me saying anything inflammatory or utterly ridiculous.

68. **moshe**
July 19, 2008

Aaron, I detect a case of bad attitude. Just admit it is all your fault, and we'll be back to the glory days of physics, when patent clerks and surfer dudes revolutionized physics. It's not that hard really, and with some luck we might get a cure for cancer also.

69. **Bee**
July 20, 2008

Gee, what happened to this thread since I last looked at it?

Since I above mentioned Michael Nielsen, [he just wrote a really great post on the question of openness in science and the Web 2.0], I can really recommend it.

70. **Michael Gogins**
July 20, 2008

Bee, thanks for the link to Nielsen's post, which I have just read.

Somewhat against Nielsen's thinking, it's much easier to become a productive programmer (I am a programmer, both commercial and open source) than it is to become a productive physicist (I am not one). And it's much easier to see if open source software will build, or run, or do what you want, than to evaluate a physics paper, vet a grant proposal, or build a large particle accelerator. Therefore, part-time physicists have a much greater competitive disadvantage than part-time programmers. And FULL-time physicists are inherently expensive….

It is true that online publication and collaboration are growing, but this whole Lisi discussion makes me think that anonymous posts are a major problem. If everyone had to sign their real name, I think a lot of hateful and useless posts would just go away. But would there be any useful posts left? Maybe just an informal enforcement against personal comments would do the job….

I don't expect the anonymous posts to go away until signing one's posts costs nothing in terms of academic politics. Indeed, until posting online is seen as making a positive contribution to science.

Regards,
Michael Gogins

71. **Professor R**
July 20, 2008

Peter, I think there is a far better article on the Lisi paper in this month's issue of Physics World. Or rather, there is a very nice article on the role of symmetry groups in particle physics, with an extremely brief description of the Lisi paper at the end.
Which puts it into sensible context I think…it should have been discussed in this manner in the first place!

Hawking to Perimeter?

July 16, 2008
Categories: Uncategorized

The Canadian press today is putting out the story that Stephen Hawking may be abandoning Cambridge to move permanently to the Perimeter Institute, where he would join recently appointed director Neil Turok, as well as Lenny Susskind.

From the stories it appears that Hawking plans to visit Perimeter next year for a month or so, and that he hasn't actually made any decision about a permanent move.

For more, see here, here, here, and here.

According to Sam Blackburn, an assistant of Hawking's, Hawking is just mulling the idea over with no move imminent, but he is "obviously a man of few words so the first we would probably know of it is when he packs his bags."

Comments

1. **anon.**
   July 16, 2008

   Exciting news. BTW, from the first link you gave, there is a link to a new exciting string claims by Michio Kaku in the 16 July Spirituality section of *The Times of India:*

   http://timesofindia.indiatimes.com/Speaking_Tree/Looking_for_a_higher_theory_of_everything/articleshow/3108752.cms

   "… String theory can be applied to the domain where relativity fails, such as the centre of a black hole, or the instant of the Big Bang. … The melodies on these strings can explain chemistry. The universe is a symphony of strings. The "mind of God" that Einstein wrote about can be explained as cosmic music resonating through hyperspace. … String theory predicts that the next set of vibrations of the string should be invisible, which can naturally explain dark matter. … when we get to know the "DNA" of the universe, i.e. string theory, then new physical applications will be discovered. Physics will follow biology, moving from the age of discovery to the age of mastery."

   (I respect him for now making such claims in the "Spirituality" section, rather than making them in the science section as usual.)

2. **Chris W.**
   July 16, 2008

   This just in: String theory justifies the efficacy of homeopathy.

3. **jhk**
   July 16, 2008

   Hawking is probably just using this as leverage in his salary negotiations with Cambridge.

4. **Coin**
   July 16, 2008

   Hm. My understanding was that Stephen Hawking was mostly a teacher or lecturer these days, whereas Perimeter is a research institution. I ask this purely out of ignorance– is Stephen Hawking really someone to be considered a particularly active researcher right now? Would a move to Perimeter, assuming he's actually considering it, likely mean a move toward a greater focus on research on his part?

5. **Peter Woit**
   July 16, 2008

   Coin,

   Actually Hawking has always been and continues to be more of a researcher than a teacher or lecturer. He has several recent papers on the "no boundary proposal", and is involved in the all-too-active hot subject of how to count universes…

6. **Coin**
   July 16, 2008

   Alright, thanks.

7. **Anon**
   July 16, 2008

   One should bear in mind that Hawking reaches Cambridge's retirement age in six months' time. The last person to retire from his position, Paul Dirac, chose to move to Florida, so a transatlantic move would not be unprecedented.

8. **Chris W.**
   July 16, 2008

   A few more specifics on what Hawking has been up to lately:

   See arxiv.org/0803.1663 and this popular account. Note his co-authors.)

9. **Marion Delgado**
   July 16, 2008

   Chris W:

   Is homeopathy as internally consistent as string theory, I wonder?

Also the competing medical theories covering the same ground as homeopathy are much more robust than, say, twistors or LQG are compared to string theory.

10. **Chris W.**
    July 16, 2008

    Marion,

    My comment was a *joke*. If it's going to be taken as a knock against anything, the knock can be considered to be directed at Kaku, who seems to have misplaced whatever taste he might have had. With friends like this, string theory doesn't need enemies.

    (Speaking of Hindu spirituality [of a sort], I wonder if the TM crowd still employs references to string theory, as they used to do when John Hagelin still had an academic career.)

11. **Bee**
    July 17, 2008

    Globe and Mail: Hawking visit dubbed 'a single trip,' not relocation

12. **Marion Delgado**
    July 17, 2008

    Chris W:

    Sorry, my response was sort of idle musing. I was thinking very much of the "bottom up" organizing theories and Smolin's account of how they let people like Capra run away with themselves.

    It was not really intended as a rejoinder.

13. **stevem**
    July 17, 2008

    There was a 2-part program on Hawking and his work
    on UK tv recently. It is posted on youtube (in 10 parts or segments) if anyone is interested. In this segment (at 7.10) check out the eerie music with six Ed Wittens sitting at a table.

    http://www.youtube.com/watch?v=7zxBdm1bNGw

14. **mathphys**
    July 20, 2008

    Is Hawking still married to his (second) wife? I ask because their marriage was also the subject of headlines news a couple of years ago.

15. **John D**
    July 21, 2008

    I delete a lot of the comments posted here, often especially ones critical of string theory, on the grounds that they aren't saying anything either new or relevant to the posting, just adding noise to this comment section. What follows is one of these which I've repeatedly deleted, but "John Dee" has more time available to waste than I do, so I have to give up. Please do me a big favor by not responding to off-topic comments from "John Dee" or anyone else. It's a continual struggle to try and stop the comment section here from being dominated by pointless off-topic comments like this one, a struggle that on some days recently I've just about decided to give up on, shutting down this section or turning it into a purely moderated one. Also fun to deal with is the deluge of spam comments (the counter says 43,382 such in the last two years), many of which look much like the "real" comments…. OK, I'll stop complaining now.

    «when we get to know the "DNA" of the universe, i.e. string theory, then new physical applications will be discovered. Physics will follow biology, moving from the age of discovery to the age of mastery.»

    Anyone suggesting that Physics should resemble Biology more is seriously misguided. If anything biology should turn into a more quantifiable/predictable field instead of mainly an ad-hoc collection of barely related data.

    This multiverse fad is turning Physics into Biology. Getting hard predictions is getting increasingly more difficult and data is getting more and more unrelated with contrived "solutions" created just to save face.

Awaiting a Messenger From the Multiverse

July 17, 2008
Categories: Multiverse Mania

As particle physicists eagerly await results from the LHC, many theorists are already promoting interpretations of what they hope it will find. This week's Chronicle of Higher Education has a cover story on the LHC entitled [The Machine at the End of the Universe](#) (see associated articles [here](#) and [here](#)). In it, Gordon Kane enthusiastically describes the LHC as "It is certainly the most important experiment of any kind in the past century, without qualification" and "the most important thing ever in our quest to understand the fundamental laws of nature and the universe."

The question that the LHC will actually address, that of electroweak symmetry breaking, doesn't get much attention. Instead, the focus is on supersymmetry, extra dimensions and string theory. While noting that there's no evidence for string theory, the article reports:

> The new collider could change that, says Joseph D. Lykken, a physicist at Fermi National Accelerator Laboratory. "Either the discovery of supersymmetry or extra dimensions is a triumph of string theory." While such a finding would not conclusively show that string theory is correct, it would provide a first crucial experimental test, he says.

At New Scientist this week, there's another article about the LHC, entitled [Awaiting a messenger from the multiverse](#). In it, Savas Dimopoulos explains that there's already quite a lot of experimental evidence against weak-scale supersymmetry:

> "After a lot of experiments there has not been any hint of SUSY," says Dimopoulos. For each individual one of those predictions, he says, you can find plausible explanations for why they are not seen. "But by the time you look at the whole package of 'things that should have happened but didn't', you start getting a somewhat baroque structure."

Dimopoulos instead promotes his joint work with Nima Arkani-Hamed on the idea of "split-supersymmetry", where the supersymmetry breaking scale is very high, so can't explain the hierarchy problem. One possible experimental signature of such models would be a long-lived gluino. They promote the idea that such a thing would be a "Messenger From the Multiverse", the idea being that if supersymmetry doesn't explain the hierarchy problem, the explanation must be the anthropic landscape:

> That powerful piece of evidence would have dizzying implications. "It would be a strong indication that there is a string landscape or a multiverse," says Dimopoulos. "I think the majority of opinion would come around to that point of view."

One aspect of this argument is that it also works if no gluino is seen. If no superpartners at all are found at the LHC, and thus supersymmetry can't explain the hierarchy problem, by the Arkani-Hamed/Dimopoulos logic this is strong evidence for the anthropic string theory landscape. Putting this together with Lykken's argument, the LHC is guaranteed to provide evidence for string theory no matter what, since it will either see or not see weak-scale supersymmetry.

The New Scientist article does explain that this kind of argument for anthropics has its critics:

> However, anthropic arguments remain controversial, and despite the authors' heavyweight reputations, split supersymmetry is no exception. "I'm not a big fan of it," says John Ellis, a theoretical particle physicist at the CERN laboratory, where the LHC is being prepared for its first run later this year. His criticism is that the anthropic approach gives you too much freedom to answer any troublesome question in physics. "At some point you might just as well say 'let's fine-tune everything' and go home," Ellis says.
>
> Theorist Frank Wilczek at the Massachusetts Institute of Technology is also unhappy with the idea of split SUSY. "I think it's a logical possibility, but if we really have to appeal to anthropic considerations I think that's a big retreat. It would mean the explanatory power of theoretical physics would be limited."
> …
> And even if the LHC does find Dimopoulos's stopped gluinos, not everyone will be persuaded that arguments based on the multiverse are good science. "My opinion of anthropic reasoning is likely to remain unprintable," says Ellis.

Update: Forgot to add one more piece of LHC-related news. France is now joining the [US](#) with its own national LHC web-site: [LHC-France](#). Because of the Gallic fondness for cartoons, it includes a section [Le LHC en BD](#).

Comments

1. **Yoo**
   July 17, 2008

   Is string theory becoming more like a mathematical framework like algebra? Or is it still something that should only be considered as a possible theory of the physical world?

   The way I keep hearing about string theory being able to be almost anything and that any experiment would only be providing evidence for the theory is getting me confused.

2. **Peter Woit**
   July 17, 2008

   There's nothing confusing about how to interpret the phenomenon of a theory that can explain almost anything. It's what's known as a failed theory.

3. **Observer**
   July 17, 2008

   It is interesting to note that the major topic of electroweak symmetry breaking (EWSB) remains somehow overshadowed by the strong desire to discover evidence for SUSY and extra-dimensions. Many people tend to forget that the lack of evidence for SUSY at LHC may carry serious implications for the validity of the Higgs mechanism.

4. **David Nataf**
   July 17, 2008

   Peter,

I'm wondering why you very frequently post links to New Scientist.
My early impression is that you promote advocate a conservative, cautious science, where claims should be qualified and skepticism is best.

I'm a former subscriber to New Scientist (3-4 years back), and I didn't renew because I found every issue engaged in ultra-sensationalism. While I found their coverage of politics, the environment, and the social sciences interesting, these are fields where my knowledge is shallow. In physics, and in astronomy, it was always my impression they went for the dramatic. The next Einstein is just around the corner, and he's going to establish contact with aliens by traveling to the multiverse through his LHC time machine. Or something like that.

I remember a cover story where people were claiming that pendulums oscillate differently during solar eclipses because of the ether. Right.

As there are zillions of different publications it's most probably you specifically chose to read NS as opposed to being compelled to read it due to a lack of options. I'm perplexed by your focus on NS as it does not strike me as a Woit-like publication.

5. **Peter Woit**
July 17, 2008

David,

New Scientist is definitely a mixed bag, with a lot of reasonable stories about science (as well as book reviews, opinion columns, etc), but also a fair number of overly sensationalistic stories about physics. Most of these I just ignore, although sometimes I can't resist making fun of some of the sillier ones that invoke string theory.

But this story is an example where I think the magazine is actually straightforwardly reporting about research claims being made by leaders of the physics community. It's not the reporter who is putting out sensationalistic nonsense, but two of the most well-known researchers in the field, from Stanford (Dimopoulos) and Harvard/IAS (Arkani-Hamed). Sure, NS stories about how some obscure researcher has an idea for a time machine are just silly and should be ignored by everyone. But when leading figures in particle theory start going on about how the LHC is going to prove the existence of a multiverse, I can see why NS would cover this, and here they seem to have done so responsibly and pretty accurately. The sensationalist nonsense isn't the fault of the NS writer or editor.

In this particular case, I also thought the quotes from two other leading figures (Wilczek and Ellis) were highly newsworthy, given the ongoing controversy about the multiverse among theorists. Wilczek has had some sympathy for and worked on some anthropic sorts of explanations, here he was critical of this one, which was interesting. The fact that John Ellis's view of anthropic reasoning is "unprintable", and that he says it will remain so even in the face of claims from the anthropic crowd to have experimental evidence was definitely news to me.

6. **Lucy in the sky**
July 18, 2008

Hi PW, no I am not a string theorist. Quite convenient to label anyone who doesn't agree with you with the same label. I have a problem with a string theorist at the IRS… Anyway I used – some while ago – to work on theoretical elementary particle physics (QCD related) but turned since then to more condensed matters… So nothing at stake here except that I am quite upset that a single person can mislead numerous non-experts without any rebuttal from leading scientists (I am not claiming to be one). This explains my anonimity, even a hint that one looks at your blog is highly suspect in any serious physics environment (and no I am not talking about string theory departments).

I think that you mistake my point. You continously attack a main field of research. But whenever a concerned person takes his or her time to give you a serious answer – which unavoidably is technical – you manage to change the topic or you start writing your standard paragraphs (actually this is not only on your blog, we did meet in person and that confirmed the statemenet I just made). A few examples for the non-expert readers who might still believe that you are a leading scientist: reread the thread after "Wonders of supergravity etc." some items below here. If you go to the Musings blog by Distler or Asymptotia by Johnson, you should make a search on "Woit" and read the discussions. In at least half a dozen instances you manage to completely avoid answering very concrete technical/scientific questions, instead always reiterating the stuff we've read many times by now. In fact doing this I see that for many years you are alluding to your slowly progressing research. It remains a fact (give me a counter example if I am wrong) that since 1989 you did not produce a single (published) scientific result. At the same time the innuendo in your blog is such that any uninformed person can only get the idea that you are an active scientist. In my book this is called cheating. Anyway, a few threads below you announce that you are finishing up a project. I am looking forward to see the result of 19 years of hard work… So long, I am out of here for good…

7. **Peter Woit**
July 18, 2008

"Lucy"

You're not hiding behind anonymity because you fear damage to your reputation if someone finds out you have looked at the "Not Even Wrong" blog. You are doing this because you are dishonest. Your anonymous comment comes from the same block of network addresses as those of an identifiable string theorist who has posted critical comments here (and who, when you google him, the second link that turns up is one about how dishonest he is, on matters unrelated to science). Maybe this is you, maybe it's someone else from the same institution, but looking at the names of physicists working there, there's no one answering the description you give of yourself, in particular the only person I've personally met there is a senior string theorist (not the one who commented here on the blog).

So, I'm convinced that you're just a liar, using anonymity to lie and engage in character assassination with impunity. As for your characterization of my exchanges with Distler or Clifford Johnson, people can read them for themselves and make up their own minds.

If you have anything else to say, you better do it under your own name.

8. **p falor**
July 18, 2008

Peter:
Good comeback to "Lucy". I read your book and understand that basically the SM was formulated in the time frame 1973-1974. Since then experimental results have been confirmed some parameter values. Other than neutrinos having mass (accepted fact?) have there been in other deviations from the SM?

Now there is continuing reference to leading particle physicists, other than the recent Nobel prize winners Gross, Politzer, & Wilczek (2004), 'T Hooft & Veltman (1999) and Glashow,Salam & Weinberg (1979) has there been any particular HEP physicist that really stands out? Not about speculative ideas such as ST but an idea that really attempts to address an issue with the SM? You seem to have great respect for Witten but can you cite anything that Ed has doen that would merit a Nobel? Who is your leading canidate for work done since 1973?

9. **woit**
July 18, 2008

p. falor,

Besides neutrino masses, no definite deviations from the SM have shown up at accelerators. From astrophysics, there's evidence for "dark matter" of a sort that doesn't seem to fit into the SM.

Since 1973, no theorist has come up with a big breakthrough in experimentally testable HEP theory. That's why there have been no Nobel prizes for work done since then in this area. Many people have done significant work that helps to better understand QFT. A lot of this is from Witten, whose investigations of the relations of QFT and math won him the Fields medal, a recognition in math even harder to get than a Nobel prize in physics. The work of Witten's that I can think of that is related to experiment and might be worthy of a Nobel prize is his early 80s work on large N, current algebra and the "skyrmion". This is a quite beautiful approximate model for the low-energy behavior of QCD. Other people also contributed to this though, and the goal of this work, a good 1/N expansion for QCD, still hasn't been achieved.

10. **Observer**
July 18, 2008

p. falor and Peter,

I wish to add few comments on deviations from SM. It is important to remind ourselves that, while SM is remarkably consistent with experimental observations, it is considered incomplete for the following main reasons:
a) SM does not include the contribution of gravity and gravitational corrections to both QFT and renormalization group equations; b) SM does not fix the large number of free parameters that enter the theory (in particular the spectra of masses, gauge couplings and fermion mixing angles); c) SM has a gauge hierarchy problem, which requires fine-tuning; d) SM postulates that the origin of electroweak symmetry breaking is the Higgs mechanism, whose confirmation is sought at LHC and ILC. The number and physical attributes of the Higgs boson are neither explained by SM nor fixed from first principles, e) SM does not clarify the origin of its underlying gauge group and why quarks and leptons occur in certain representations of this group, f) SM does not explain why the weak interactions are chiral, that is, why the force transmitted by the triplet of massive vector bosons is sensitive to handedness g) SM does not explain the origin of CP violation and the underying cause of the lepton anomalous magnetic moment.

11. **Sulfur Surfer**
July 18, 2008

The Wilczek quote is particularly ironic because his latest paper, arXiv:0807.1726, is about making predictions using anthropic reasoning. I think this reflects the general situation: no one likes it, but there are reasons to believe that anthropic selection plays a role in determining why our universe is the way it is, and if so then we have to learn to deal with it.

12. **Peter Woit**
July 18, 2008

Sulfur Surfer,

The problem with anthropic reasoning has nothing to do with whether one "likes it", but with whether it can be used to do real science, or is just being used as an excuse for propping up failed ideas, in such a way that even though they don't work, they can never be shown to be wrong.

I take Wilczek's point of view to be that some uses of anthropic argumentation are a legitimate part of model-building, and that's what he's trying out. Interesting to see that it appears that he doesn't see the Dimopoulos/Arkani-Hamed argument as falling into this category. Perhaps all there is to it is that he recognizes the obvious fallacy in the argument that: "If supersymmetry doesn't explain the weak scale, it must be the string theory anthropic landscape".

For more from Wilczek about his point of view on this, a good source is:

http://arxiv.org/abs/hep-ph/0512187

where he warns:

"let me lament our prospective losses, if we adopt anthropic or statistical selecton arguments too freely…"

and notes

"Resort to anthropic reasoning involves plenty of pain, as I've lamented, but so far the gain has been relatively meagre, to say the least."

13. **Chip Neville**
July 18, 2008

Peter,

Just a thought from a refugee from the '60's. "Lucy in the Sky with Diamonds" is a very good Beatles song that turns out to be about LSD. I wonder if "Lucy" realizes this.

Maybe I should have signed this "Yellow Submarine," which is about amphetamines.

14. **somebody**
July 19, 2008

> Putting this together with Lykken's argument, the LHC is
> guaranteed to provide evidence for string theory no matter
> what, since it will either see or not see weak-scale
> supersymmetry.

String theory is a framework for constructing UV complete theories while having gravity. It is really a paradigm in that sense, like QFT was for theories without gravity. ANY experiment at low energies is "evidence" for QFT. That hardly means that a specific QFT is not falsifiable.

The real problem is that constructing models with the stringy paradigm is hard because we don't understand the theory well enough. That would be a valid and perhaps fatal criticism for string theory as a useful theory. But comments like the above are merely strawmen.

15. **Peter Woit**
July 19, 2008

somebody,

The above was not a criticism of string theory, but of string theory partisans, at least those who think it's a good idea to go to the press with bogus claims that the LHC will test string theory or the the anthropic multiverse.

16. **ERic**
July 19, 2008

Peter,
I'm just curious what your position on string theory would be in the case that either the superpartners are found or there is evidence of large extra dimensions such as black holes or KK modes? Would you consider this evidence in favor of string theory?

17. **Peter Woit**
July 19, 2008

Eric,

Depends exactly what you see, but, in general, no. For instance, it might very well be that some variant of N=8 supergravity gives a finite quantum theory of gravity, which is not a string theory. If supersymmetry shows up at the LHC, maybe it's that…

18. **Marion Delgado**
July 19, 2008

Peter:

Going beyond the anthropic, and even the string issues, to the more important problem of the stagnation of particle physics in general, do you have any sketched-out notions on what particle physics – or better, that segment not wedded to theories/programs that are too adaptable to be tested – could do to be prepared to test things with the tests the LHC could do?

Even if the various measurements and experiments that can be performed with the LHC don't effectively test, say, stringe/brane/M theory, is it possible for them to test other things? Advance particle physics and weed out theories the way the lack of proton decay did, for instance?

Is LQG, are twistor theories, is Lisi's extension of standard physics, as untestable w/r/t the LHC as the current dominant line of string theory is?

Also, will some string theory lines probably be closed off by LHC-performed measurements and experiments?

19. **Chris W.**
July 19, 2008

[RE: "ANY experiment at low energies is 'evidence' for QFT."]

Somebody,

Even as a framework, QFT has certain empirically founded underpinnings, does it not? (I have in mind special relativity.) What are those, and what evidence supports them?

Similarly, *as a framework*, what empirically founded underpinnings does string theory rely upon? Does it assume anything that QFT doesn't assume? If so, what is the empirical support for those assumptions?

20. **Shantanu**
July 19, 2008

Peter, have you found anything interesting among the talks at
titled
"In Search for Variations of Fundamental Couplings and Mass Scales"

21. **Observer**
July 19, 2008

Somebody, you say:

"The real problem is that constructing models with the stringy paradigm is hard because we don't understand the theory well enough"

How long should one wait for String Theory to reach maturity? Would reaching that stage guarantee that the astronomical number of vacua will suddenly disappear or that the theory will yield testable predictions?

22. **somebody**
July 20, 2008

"Similarly, as a framework, what empirically founded underpinnings does string theory rely upon? Does it assume anything that QFT doesn't assume? If so, what is the empirical support for those
assumptions?"

Ok, I'll try.

Perturbative string theory has something called conformal invariance on the worldsheet. The empirical evidence for this is gravity. The empirical basis for QFT are locality, unitarity and Lorentz invariance. Strings manage to find a way to tweak these, while NOT breaking them, so that we can have gravity as well. This is oft-repeated, but still extraordinary. The precise way in which we do the tweaking is what gives rise to the various kinds of matter fields, and this is where the arbitrariness that ultimately leads to things like the landscape comes in.

In principle, this is a model-building/technical control issue. But it is a pretty damn serious one, and probably something that will require us to understand the theory much better than we do now. Besides, the kind of understanding that we have of string theory at the moment allows us to build only certain kinds of models.

About other empirical expectations: string theory has a lot of GENERIC features we expect from a good theory of the world. It can easily give rise to things like multiple generations, non-abelain gauge symmetry, chiral fermions, etc. some of which were considered thorny problems before. Again, constructing PRECISELY our matter content has been a difficult problem, but progress has been ongoing.

But the most important reason for liking string theory is that it shows the features of quantum gravity that we would hope to see, in EVERY single instance that the theory is under control. Black hole entropy, gravity is holographic, resolution of singularities, resolution of information paradox – all these things have seen more or less concrete realizations in string theory. Black holes are where real progress is, according to me, but the string phenomenologists might disagree. 🙂

Notice that I haven't said anything about gauge-gravity duality (AdS/CFT). Thats not because I don't think it is important, but because I think it is THE most important thing. But at the same time, I don't know of a good way to convince a layman (assuming you are one) of its importance. Because it is one of those cases where two vastly different mathematical structures in theoretical physics mysteriously give rise to the exact same physics. In some sense, it is a bit like saying that understanding quantum gravity is the same problem as understanding strongly coupled QCD. I am not sure how exciting that is for a non-string person, but it makes me wax lyrical about string theory. It relates black holes and gauge theories. Things like AdS/quark-gluon-plasma stuff is interesting not merely because we can make some semi-quantitative predictions, but also because it has opened up new ways of THINKING. You can find a bound for the viscosity to entropy ratio of condensed matter systems, by studying black holes – thats the kind of thing that gets my juices flowing. Notice that none of these things involve far-out mathematical masturbation, this is real physics – or if you want to say it that way, it is emprically based.

To me, the immediate reason for doing string theory is not falsifying it at LHC. Of course, to get funding you need to sell it to the powers-that-be, and LHC is perhaps all they care about. But really, LHC is just a miniscule blip in the energy-scales all the way up to Planck scale. Should we expect to see ANYTHING interesting at LHC? Perhaps. Perhaps not. Of course it would be nice to see some indication of string theory there because public relations is unfortunately important in science, but I personally think that people are being short-sighted when they hedge their bets on LHC when selling it to the piublic.

String theory is a large collection of promising ideas firmly rooted in the emprirical physics we know which seems to unify theoretical physics[1], and thats why it should be worked on. The spinoffs are in that sense are OBVIOUS, but they are not necessarily going to fit anybody's schedule for making a collider.

[1] I don't mean unification of forces necessarily, I mean convergence of the different ingredients that constitute theoretical physics.

23. **anon.**

No it's not real physics because it's not tied to empirical facts. It selects an arbitary number of spatial extra dimensions in order to force the theory to give the non-falsifiable agreement with existing speculations about gravity, black holes, etc. Gravity and black holes have been observed but spin-2 gravitons and the detailed properties of black holes aren't empirically confirmed. Extra spatial dimensions and all the extra particles of supersymmetries like supergravity haven't been observed. Planck scale unification is again a speculation, not an empirical observation. The entire success of string theory is consistency with speculations, not with nature. It's built on speculations, not upon empirical facts. Further, it's not even an *ad hoc* model that can replace the Standard Model, because you can't use experimental data to identify the parameters of string theory, e.g., the moduli. It's worse therefore than *ad hoc* models, it can't incorporate let alone predict reality.

24. **somebody**
July 20, 2008

"How long should one wait for String Theory to reach maturity?"

I have no idea about this of course, but I think this question arises from the feeling that string theory is like a tunnel. You get into it on one side and the enterprise is "wasted" unless you get out the other end with predictions for electron masses or whatever. But the truth is that there is a lot of understanding+spin-offs that we have gleaned on the way, some of which I mentioned in my response to Chris W.

Another thing I have noticed is that people tend to conflate the fact that we have not managed to solve the problem FULLY, with the incorrect statement that we have not managed to solve it AT ALL. This arises because theoretical physics is such an esoteric enterprise and it is hard to give people a feel for the progress until you reach a concrete enough punctuation mark, like say, "predicting electron masses". But there has been tremendous progress in constructing string vacua which was unimaginable even ten years ago.

I just think that string theory has some great tools and ideas and it would be ridiculous not to use them when thinking about fundamental problems. For instance, holography in gravity was a very interesting observation, but nothing really concrete, before Maldacena. When Maldacena came along, connected up gauge theories with strings&gravity and broke new territory, holography actually became a useful TOOL and not merely a curiosity. These sort of insights are certainly of relevance in our way forward. To brush them all off and just stick to what we knew before strings would be counter-productive – even if you are convinced that strings are ultimately NOT a central ingredient in the construction of the universe. In particular, string theory allows you to do quantum gravity thought experiments, especially in the context of black holes, which would have been impossible without it.

"Would reaching that stage guarantee that the astronomical number of vacua will suddenly disappear or that the theory will yield testable predictions?"

If we reach that stage (if pigs had wings), we would be able to construct MODELS that yield testable predictions. The existence or non-existence of the landscape is not what makes a theory non-predictive, despite popular impression. Most theories (general relativity, QFT) have landscapes. It is not their existence, but our inability to systematically construct them that is the problem.

Or at least this is one way (the boring, frontal, difficult way) in which a solution can be realised. But there might be new ideas that can come up which might mix things up. It is only because people kept plugging away back in the days of the heterotic string (even though we had no idea how to stabilize moduli) that we have understood things about black holes and ads/cft. Right now is CERTAINLY not a worse off position than many other periods in the strange history of string theory.

Anyway, thanks for those questions, it made me think about what is important and what is not in string theory myself.

25. **somebody**
July 20, 2008

Anon.:

The problems we are trying to solve, like “quantizing gravity” are already speculative by your standards. I agree that it is a reasonable stand to brush these questions off as “speculation”. But IF you consider them worthy of your time, then string theory is a game you can play. THAT was my claim. I am sure you will agree that it is a bit unreasonable to expect a non-speculative solution to a problem that you consider already speculative.

Incidentally, I never said a word about supersymmetry and Planck scale unification in my post because it was specifically a response to a question on the empirical basis of string theory. So I would appreciate it if you read my posts before taking off on rants, stringing cliches, .. etc. It was meant for the critics of string theory who actually have scientific reasons to dislike it, and not gut-reactions.

26. **woit**
July 20, 2008

This has gotten pretty much completely off-topic, and nothing new or informative is being said. Enough.

27. **Chris W.**
July 21, 2008

Thanks, Somebody, for that response. It was helpful to see the main threads brought together that way. (And yes, I am a layman.)

28. **Paul Sagi**
September 10, 2008

my view of anthropic arguments such as the anthropic principle is that they are not scientific and have no place in physics.

it seems to me to be a priori that the existence of human beings has no role in how the universe works. the universe existed long before human beings.

that the constants of nature happen to be those that allow us to exist does not say anything, of course they are that way, otherwise we would not be observing them.

to invoke a premise that there is some grand design at work is not physics but rather religion.

real science produces testable refutable theories, the anthropic principle is not in that category.

The Emperor's Last Clothes?

July 21, 2008
Categories: Multiverse Mania

Bert Schellekens has posted on the arXiv an extended 87 page argument for the anthropic string theory landscape, entitled The Emperor's Last Clothes? While most string theorists find the existence of the landscape and the corresponding inability to get any predictions out of the theory about particle physics rather discouraging, Schellekens instead sees this as an argument in its favor:

> Initially, when string theory was touted as the "theory of everything" around 1984, there were hopes it would lead to exactly the opposite: a unique derivation of all the laws of physics. Evidence that quite the opposite was true started emerging almost immediately after 1984, but most people chose to ignore it. In 2003, after important additional evidence had been found, Leonard Susskind published a paper entitled "The Anthropic Landscape of String Theory", which finally started a debate that should have started fifteen years earlier. What is at stake in this debate is not only the uniqueness of our universe, but also the fate of string theory as a fundamental theory of all interactions.
>
> In my opinion string theory gives the right answer, and the fact that it does adds to the evidence in its favour. I can say this without being accused of trying to put a positive spin on the recent developments, because I actually wrote in 1998 that I hoped string theory would ultimately lead to a huge number of possible choices for the laws of physics, a point of view I have been advocating since the late eighties. I reached that conclusion after having been involved in one of the first papers pointing out that the number of possibilities was humongous…
>
> We all hope to live during a time when big things are happening in our field, and I have never doubted that this is one of those things. I have spent the last twenty years trying to convey my sense of excitement to my colleagues, but with little success. But in the last few years I have been delighted to see more evidence coming in supporting this point of view, so that the mood has started to change. I hope this is the right time to make one more attempt.

Schellekens describes in great detail the anthropic argument and the arguments for the string theory landscape. He addresses some of the counter-arguments, especially in three appendices. He doesn't explictly deal with the main counter-argument that I've made repeatedly here: the anthropic landscape is not science (since it is not testable), rather it is just an elaborate excuse for the failure of the speculative idea of getting the SM out of a 10/11d string/M-theory.

Schellekens has the following comments about "string phenomenology", noting that he worked in the area around 1987 and recently, finding not much has changed:

> I have been active in this are around 1987 (which led me to the conclusions presented here) and again in the last few years, and to me the similarities are more striking than the differences. There has certainly been progress: we can obtain string solutions that are more similar to the Standard Model than twenty years ago, and we have more methods to construct them. There has been major progress in moduli stabilization and supersymmetry breaking. There is more interest in "landscape statistics". But very little seems to have changed in the way many people view the problem we are facing. Although many of my string phenomenology colleagues claim that it was clear to them a long time ago that there are many solutions, I cannot help noticing that they still talk about their most recent "model" as if it would actually have a chance to be *the* Standard Model. And even nowadays one still hears the occasional expression of hope for the unknown and elusive dynamical principle that will select the vacuum. The most common way of dealing with the large vacuum degeneracy is to say "I do not care about the other 10^{500}vacua, I only care about the one that describes our universe". That may sound reasonable, and fact it may sound like the very definition of phenomenology, but it is actually an escape from reality.
>
> First of all, if indeed there are 10^{500} vacua, it is highly unlikely that anyone will find "*the* Standard Model" in string theory. One should expect to find a huge number that satisfy all current experimental constraints. In addition, although we now have many techniques at our disposal to construct string theories in four dimensions, it is quite clear that we are just scratching the surface. Statistically speaking, our chances of finding even one of the expected huge number of Standard Model realizations is essentially zero. Furthermore, even if we do find one, we can only make predictions about novel phenomena if we know *all* the other solutions and their predictions for the same phenomena. This is a crucial change in comparison to the state of the art about ten years ago: with 10^{20} solutions (the largest number anyone may have expected), if one is found that agrees with all current data, the probability that there is a second one is extremely small. With 10^{500}, the same probability is astronomical. So we should forget about the idea of finding *the* Standard Model and then making predictions based on it.

As for LHC predictions, Schellekens argues against the idea that it will see supersymmetry:

> One could say that supersymmetry is a non-solution to a non-problem: the large weak scale hierarchy is already understood anthropically, and supersymmetry by itself does not even explain it…
>
> With the start of the LHC just months away (at least, I hope so), this is more or less the last moment to make a prediction. Will low energy supersymmetry be found or not? I am convinced that without the strange coincidence of the gauge coupling convergence, many people (including myself) would bet against it. It just seems to have been hiding itself too well, and it creates the need for new fine-tunings that are not even anthropic (and hence more serious than the one supersymmetry is supposed to solve). But even if evidence for low energy supersymmetry emerges at the LHC, in the context of a landscape it will not be the explanation for the smallness of the weak scale. The explanation will in any case be anthropic. The landscape will undoubtedly allow a distribution of values for the weak scale, including values outside the anthropic window.

Schellekens ends up making the currently fashionable argument that it doesn't matter that string theory doesn't predict anything testable about particle theory, that the important thing is that it is a theory of quantum gravity:

> During the last two decades there was some reason to hope that we might be able to do that by means of some prediction of a Standard Model feature. That hope is fading now. I am not saying that this will never happen, but I have seen too much wishful thinking to make an optimistic statement about this. Essentially, we came to that conclusion already in 1986 . We are dealing with a theory of gravity. Getting information about it through the back door of particle physics is a luxury that we once had good reasons to hope for, but that may not exist. Rejecting a theory of gravity that makes no particle physics prediction may be like rejecting the theory of continental drift because it does not predict the shape of Mount Everest

He then goes on to acknowledge that we're not going to get any experimental tests out of the quantum gravity aspect of string theory either:

> One cannot count on any direct experimental check of a theory of quantum gravity, since any observable consequences it might have are extremely small, unless we are extremely lucky.

In the end, he seems to argue that the only evidence for string theory we may ever get is its consistency, something which is a very long ways from being shown. He does argue that string theory is in principle falsifiable, but the example he gives (that string theory would be wrong if coupling constants varied observably on astronomical scales) is not an uncontroversial one since other string theorists have argued that varying coupling constants would be evidence *for* string theory. There's also the usual "who knows?" argument used against anyone who points out that evidence against an idea is overwhelming:

> On longer timescales, it is clearly ridiculous to pretend that what we currently know will be the state of the art forever. When Darwin formulated his theory of

evolution he was unaware of Mendel's results on inheritance, and could not even have imagined DNA.

The truly peculiar thing about this is to see a scientist almost gleeful at the idea that a theory they have worked on their entire professional lives doesn't predict anything:

> To me, what is emerging looks very appealing. It fulfills and even exceeds the hopes I expressed in 1998. It is has been amazing to see this theory leading us in the right direction, sometimes even against the initial expectations of most of the people working on it. We should continue to follow its lead, and do everything in our power to strengthen its theoretical underpinnings. The emergence of a huge landscape" makes this more worthwhile then ever before.

Unfortunately, Schellekens is far from alone in this. At the FQXI web-site there's an article about the string theory/cosmology couple Andrei Linde and Renata Kallosh entitled A Perfect Match ("How do you tie down the physics of the multiverse? With string.") In it, Kallosh explains how "string cosmology" is now the hot topic:

> These days, in fact, collaboration be-tween string people and cosmology people is all the rage.
> "To give you a funny example, I had an invitation to give a talk at the Strings 2008 conference at CERN," Kallosh says. "The way the invitation was writ-ten was, 'Of course you are welcome to speak about any topic . . . but we would be very happy if you would give us a mini-review on string cosmology!'"
>
> Suddenly, everyone is interested in their kind of union.
>
> "I'm also working on other very formal, very stringy topics, which were always part of my skills," Kallosh says. "But, at this moment, people want to know about string cosmology. I'm happily working on it . . . with Andrei's help."

Cosmology is now ascendant, with Kallosh arguing that it will be needed to explain what is seen at the LHC:

> "Soon the LHC will start giving new information on particle physics," she says. "But we know it will be difficult to interpret this data unless you also can digest all the data from the sky—all the observations from astrophysics and cosmology."

The article ends with a large picture of one of the LHC detectors, captioned "Cradle of Collaboration: Will the LHC provide evidence for string theory?"

FQXI is funded by the Templeton Foundation, the goal of which is to bring science and religion together. Cormac O'Raifertaigh is at another Templeton funded event, a conference in Cambridge on From the Big Bang to the Brain: Current Issues in Science and Religion. This Wednesday will be devoted to cosmology, featuring talks on the anthropic principle, fine-tuning, God and time, and God and the Big Bang.

For another take on cosmology, this October the ENS in Paris will host a conference on Evolution and Development of the Universe. For more about this parallel universe of cosmologists who also study anthropics and the multiverse , see EvoDevoUniverse.

   Sure, it is natural to accept that any mathematically consistent theory of quantum gravity can be extremely difficult to be tested experimentally. But at the basis of any expectations like this lies the specific, unambiguous predictions of the theory, whatever the difficulty in observing them. The latter does not preclude the former, which is actually indispensable for any theory.

   The obvious point here is one of posture. The landscape does not represent different mathematical descriptions of the same physical content (something that could be manageable by, e.g., extracting the observables or invariants of the transformations between the various solutions) — a common situation in many physical theories –, but a set of 10^500 independent solutions, representing different physical realities, in which our universe is supposed to be one of them. The acceptance of this state of affairs indicates a strong epistemic attitude in the sense that one embraces a substantivalism point of view towards the landscape, in the sense of assigning an independent physical reality for each of these vaccua, but is not willing to consider the possibility that this indicates a failure that needs revision.

   Such epistemic attitude is acceptable if one proves that it does not actually break any logical reasoning or consistency, or is justifiable or even needed at some point, or under some physical grounds. I can accept such a posture in the sense that it is just part of learning, exploring a difficult subject, etc. But what I cannot easily accept is the lack of a critical reasoning on facing the consequences that result from the position taken, to the degree that one is using the scientific method as a guide and not dismissing it or deforming it in order to fit the consequences of one's personal attraction for the theory.

   I see all this as a crisis and do not understand how can one believe that the situation is an indication of progress, except if one is really inclined to redefine what science is, which is of course, the easiest route (to go nowhere).

2. **Christine**
   July 22, 2008

   Just a question: why is the paper authored by "A.N. Schellekens" and posted by "Bert Schellekens"?

3. **Peter Woit**
   July 22, 2008

   Christine,

   Schellekens goes by the name "Bert", I'm guessing the "A" is for "Albert"

4. **Christine**
   July 22, 2008

   Right.

   At his old homepage, he writes:

   > Research interests
   >
   > String Theory, whatever that is

   🙂

But seriously, it is quite a fair way to put it, valid for many areas…

5. **Jim Clarage**
July 22, 2008

I don't see why String Theory per se is responsible for this "remarkable paradigm shift in particle physics" which Schellekens refers to in his abstract. That is it's unclear how the shift towards anthropic reasoning follows logically, or inevitably, from the principles of string theories. Rather it is a philosophical shift, one which could have happened at any time in the history of physics.

For example Newton could have easily adopted an anthropic approach to his inverse square law, perhaps assuming any value for the exponents in the radial and mass coordinates of the gravitating objects; and then agreeing to anthropically derive these exponents based upon e.g., what values allow and disallow stability of human bones, large tree trunks, or other mechanical properties of organisms living under the influence of Earth's known gravitational field. Nothing in this alternative history is inconceivable, especially considering Newton himself had no trouble mentioning God and Creator in his work.

However, instead of appealing to anthros Newton appealed to physics. He tried to pick the exponents and form of the law based upon reproducing previous physical laws, viz., Kepler's laws. Replace Kepler's laws with Standard Model and I think it is clear what is occuring is a philosphical shift, not a shift in physics.

6. **Chris W.**
July 22, 2008

Right, Jim. Ironically enough, it is a philosophical shift in a field that, for the most part, eschews and dismisses overt philosophical reflection; philosophy is just a lame attempt to get at the truth by people who lack the chops to do science. From this viewpoint, having the chops has come to be what matters, and the situation celebrated by Bert Schellekens provides unlimited scope for exercising one's chops. That seems to be the source of the peculiar glee noted by Peter.

7. **Mitch Miller**
July 22, 2008

Is Schkelens view on the history of the multi-verse standard? I was under the impression that Witten and Gross had technical arguments as late as the early 2000s on how it was possible that there may only be a few string theory vacumns. I may be wrong as I am only an undergrad and have not been following this as long as everybody else.

8. **manyoso**
July 22, 2008

Can it be mathematically or logically demonstrated that every one of the experimental results known to the Standard Model can be produced by even one of the unique 10^500 vacua?

Schellekens states that there are likely an astronomical amount of the 10^500 vacua that would be in agreement with the Standard Model. How does he determine this? I mean does there exist a mathematical proof that at least one of these vacua would give the Standard Model?

I mean if we can't find the Standard Model in the haystack that is the landscape, what reasons do String Theorists have to believe that the Standard Model is even *in* the haystack other than faith in the flexibility of String Theory?

9. **Peter Woit**
July 22, 2008

Mitch,

Schellekens has a view of the history of the string theory landscape very much oriented around his claims to have realized its importance before just about anyone else. The more standard history is that the "string vacua" known from the mid-80s on did not have stabilized moduli, so most people hoped that once one figured out how to stabilize moduli, one would end up with a small number of vacua. It was only with KKLT that exponentially large numbers of (presumably) stabilized vacua were constructed. I don't know of any claims by Gross or Witten to have an argument pointing to a small number of vacua.

manyoso,

No, it can't now be demonstrated that you can get the the SM out of known constructions in the landscape. Many string theorists like Schellekens now argue that the efforts of theorists should be devoted to studying the landscape to see if it can be proved that the SM is there.

Personally I don't see the point of this, and Schellekens even gives some of the arguments why. Even if you prove the SM is somewhere in there, this doesn't allow you to predict anything or test the theory. If you prove the SM cannot come from known string vacua constructions, there's no reason it can't come from still unknown ones. People keep coming up with more all the time, there's nothing like an understanding of what "all" string vacua are like. But working on this is an extremely complex problem that could keep an exponentially large number of people busy an exponentially large amount of time, some seem to want physics to go this way.

10. **manyoso**
July 22, 2008

Peter,

If that is true that it has not been proven that the SM is somewhere in the 10^500 "known" vacua, then it seems impossibly arrogant for Schellekens and other landscape proponents to declare anything like 'success' with anthropic arguments.

How can anyone argue for anthropic origins for the Standard Model via String Theory when it can't even be demonstrated that the Standard Model is represented in the landscape. Not even theoretically! It seems that landscape proponents are arguing that because we now have hints at an absolutely *huge* number of stringy universes… our universe just must be in there somewhere. For no other reason than blind faith.

Just awesomely odd.

11. **Peter Woit**
July 22, 2008

manyoso,

To defend the landscapers, from what is known about the string theory landscape, it is plausible that there are "string vacua" that reproduce the SM at observable energie. They would point out that showing that such a thing is really there is work in progress.

I don't think the problem is that they are advertising something that is not likely to be there. The problem is that even if it is there, it's completely useless.

12. **Richard**
July 22, 2008

"In my opinion string theory gives the right answer, and the fact that it does adds to the evidence in its favour."

Huh? It's hard to tell for sure what was meant by this comment, but doesn't this sound a bit circular?

13. **Esornep**
July 22, 2008

Penrose argues that the initial condtions of *our* universe are fine-tuned to one part in 10^(10^(123)). How are you going to get fine-tuning to that extent if you only have a miserable 10^(1500) attempts?

14. **mike**
July 23, 2008

"Soon the LHC will start giving new information on particle physics," she says. "But we know it will be difficult to interpret this data unless you also can digest all the data from the sky—all the observations from astrophysics and cosmology."

Shouldn't this be the other way around – do astrophysicists tell particle physicists how matter works? Maybe it's just the experimentalist in me, but I believe the machine in front of me before I believe something we interpret from afar.

15. **F Borg**
July 23, 2008

Shellekens should be acknowledged for his attempt at presenting his points in a clear and accessible form. It very much centers around the old issue on what to expect of a "fundamental theory" in physics. Should such a theory e.g. fix all the 28 parameters or so of the Standard Model (as an effective low energy approximation)? If so would such a "fundamental theory" just replace one mystery by another mystery (remember Eddington and 137)? Maybe in a more encompassing theory one can find a mechanism that drives the parameters toward the region of the observed values, but it is conceivable that such a mechanism will rest on new "ad hoc" principles. Another option is to think that "the fundamental theory" will only be about the main structures and equations ("the grammar of nature", Souriau) without singling out any unique solutions. The general assumption has been that unification will lead to "uniqueness" but it is possible that instead the space of solutions is enlarged with no recipe for picking the right one that will correspond to our observations. (Shellekens denies that e.g. "beauty" and "simplicity" will be useful guides.) I think quite a few physicists believe that we have potentially an infinite ladder of effective theories that never bottom out despite the apparently absolute scale set by Planck energy, but for "practical reason" we need only work up/down to a some level of this ladder that applies to the world (or part thereof) which we are able to observe. Against this background one may understand the optimism by those who think the stringy landscape demonstrates that there is indeed a bottoming out instead of an infinity of "onion layers". Although the "landscape" may preclude sharp predictions (and thus "verification" in a "traditional sense") it at least may show the basic "fabrics" (or the "template") that reality is built of, according to the adherents. This is how I interpret the "optimism".

16. **Christine**
July 23, 2008

F Borg wrote:

Although the "landscape" may preclude sharp predictions (and thus "verification" in a "traditional sense") it at least may show the basic "fabrics" (or the "template") that reality is built of, according to the adherents.

I think you have summarized all very well. But suppose that it is really our fate that our fundamental theories can never be ultimately tested (through "verification in a traditional sense"), so that what we have at the end will always be some layout, some "basic fabrics that reality is built of". How will we know that even this is true?

17. **Chris W.**
July 23, 2008

Christine is exactly right. There is massive presumption in supposing an allegedly empirical assertion has been "shown" to be true, when we have no way of saying, *on the basis of observation*, how we would ever know that it is false. This describes the essence of string theory's lack of testability.

That is, we can't say this except in a sort of lame and parasitic way, eg, that string theory would be wrong if Lorentz invariance at low energies is wrong. Of course, even on this point bets can and have been hedged, even though hardly anyone is seriously expecting the issue to arise.

18. **Professor R**
July 23, 2008

Thanks for the mention Peter!

Today lived up to expectations – Prof Paul Shelton , a colleague of Stephen Hawking at DAMTP, Cambridge, gave a spectacular overview of today's cosmology with a thorough review of inflation, eternal inflation, the multiverse and the landscape. Shelton went through the WMAP evidence, explaining that the evidence for some sort of inflation was very strong, but the mechanism under-determined (his word, glorious understatement -he showed a hilarious slide listing all possible flavours of inflation)…

Shellard's discussion of eternal inflation and the multiverse was thorough but accessible, with emphasis on the viewpoint that this may be the price we have to pay for the success of inflation (in explaining the standard BB riddles), yet emphasising also the speculative nature of the multiverse idea…

If this weren't enough, the high point of the day for many was 'Meta-stories of Fine-tuning ' by Sir John Polkinghorne. In typical fashion, Sir John gave a succinct overview of the fine-tuning problem from a philosophical viewpoint. In particular, he focussed on a choice between the multiverse explanation and the anthropic principle from a philosophical perspective. He was clearly unimpressed with the theory of the multiverse, describing it as meta-physics and probably contrary to the principle of Occam's razor. Calling on Lewis's famous example of the firing squad, he suggested that it was a little excessive to suggest that the firing squad engaged in a gigantic number of shootings in order to explain a miss – suggesting that it was more likely that they simply missed by design…

He was also unimpressed with a third possibility (from me) that an unlikely outcome – however unlikely – can simply occur without the need for an explanation. I can't do justice to John's persuasive arguments here, but you can get the DVD of the talk here.

Peter Woit of NOT EVEN WRONG would be pleased to note that, along the way, Sir John gave a very terse overview of the opinion of his generation of particle physicists of string theory – not very high!.

19. **Ralph**
July 24, 2008

Re:

"it doesn't matter that string theory doesn't predict anything testable about particle theory, that the important thing is that it is a theory of quantum gravity"

I think this idea can be read in a sensible manner, but it still doesn't help string theory.

Quantum gravity has purely mathematical problems: e.g., giving any completely rigorous, mathematical theory incorporating both gravity and the SM would be a huge advance (You get a Clay prize for just the 'SM' bit of that, more-or-less?), and physical testability is not a part of that mathematical problem.

That changes the issue from judging string theory by physicist's standards to judging it by mathematical standards.

And string theory is just as badly deficient from mathematical standards as it is from physicist's standards – the parts of string theory that are even vaguely plausible as ways of getting gravity+SM aren't anywhere near mathematically rigorous.

20. **Bee**
July 24, 2008

I was very puzzled by the abstract of this paper, I haven't noticed any paradigm shift. Possibly the majority of my friends and colleagues is just more down to earth than the average string theorist but I never had the impression anybody seriously believed one would find THE fundamental theory of everything and that was that. There's no paradigm shifting, if anything, people who believed that are recovering their sanity.

That's not quite what Schellekens was aiming at with THE fundamental theory, but I hope the present confusion is only a temporary stage and eventually people will realize physics is about describing nature and not equal to philosophy. There's enough topics people could do real work on.

I was just checking the arxiv today and I find hep-th an increasingly depressing collection of highly specialized detail investigations that in almost all cases will remain absolutely irrelevant for actual descriptions of nature.

21. **Yatima**
July 26, 2008

For those interested in further thinking/reading about the Anthropic Principle, Scott Aaronson (He of the Complexity Theory) has published some lecture notes on the same:

PHYS771 Lecture 17: Fun With the Anthropic Principle

as referenced from his recent blog entry

22. **Arun**
July 26, 2008

Just as it took a long while and effort to get to "N=8 supergravity might be finite" and will likely take a long time (if at all) to get to "N=8 supergravity is indeed finite", it will likely take equivalent effort and time to get to the next step in superstring theory. Maybe the era of easy surprises is over. The anthropic ideas make such effort to seem pointless however. It will be interesting to see if the field can avoid decaying entirely.

23. **Gphillip**
August 11, 2008

This all reminds me of the story of the madman who had created a perfectly mad, but perfectly logical reasoning behind his paranoia. His story was so creative, logically sound and finely interwoven that even his doctors found themselves looking over their shoulders from time to time. In the end, the doctors were never able to demonstrate the error of the logic to the madman, because they couldn't find any. All they could say was his view of reality couldn't be correct because it was totally different from that which all sane people agreed upon.

Gauge Theory and Langlands Duality

July 21, 2008
Categories: Langlands

At the KITP in Santa Barbara there's a wonderful program on Gauge Theory and Langlands Duality starting up this week, with some of the talks beginning to become available. The main topic will be the relations between S-duality in quantum field theory and geometric Langlands duality that Witten and collaborators have been working on the past few years.

I started trying to watch the talks, but the fact that the video quality is such that one can almost but not quite tell what is being written on the blackboard makes this a bit of a trial. I'm hoping that David Ben-Zvi or someone else will make available notes, which would help a lot. I did very much like Edward Frenkel's description of the Langlands story as a "Grand Unified Theory of Mathematics", and was interested to hear that he still feels that there are two different stories about the relation to QFT here, whose relationship is not at all understood (S-duality in 4d QFT is one, 2d CFT and vertex algebras is the other). It seems that A.J. Tolland is there, maybe he or someone else will do some blogging. As I get time to take in the lectures, I hope to write some more about them here.

Update: Notes for the talks are now also being posted, making following them on-line much more feasible. The quality of the talks is excellent, with Ed Frenkel so far giving a beautiful introduction to the roots of the Langlands program in number theory, David Ben-Zvi explaining the structures in topological quantum field theory that mathematicians are trying to exploit, David Morrison and Paul Aspinwall explaining mirror symmetry, D-branes, and the relation to N=(2,2) superconformal field theory, with examples, and Anton Kapustin starting on the 4d N=4 TQFT used to turn S-duality into a mirror symmetry.

Comments

1. **Daniel de França MTd2**
   July 22, 2008

   Hi Peter,

   there is a funny buzzword sometimes when I read something of witten's most recent words…

   What is wild ramification?

2. **Phil**
   July 22, 2008

   Daniel,

   In the context of geometric Langlands, \`wild ramification' refers to the case when the connections or Higgs fields are allowed to have \`irregular singularities'. Basically this means they can have poles of order two or more. Heuristically having a meromorphic connection with simple poles on a curve is akin to having punctured the curve at the poles, whereas having higher order poles is more complicated. The word "wild" arises from an analogy with wild ramification (of maps between curves) in characteristic p. One can also look at the growth of horizontal sections approaching such a pole: with simple poles such sections have polynomial growth ("tame") whereas with higher order poles one can get exponential growth (or decay) as the pole is approached in different directions.

   Phil

3. **Daniel de França MTd2**
   July 23, 2008

   Thank you very much.

   Do you know any source that introduces "wild ramification"?

   I am also curious about "Langlands conjectures for GLn of a function field". What is that? Why is that so important? I found this, but I would want something more complete and with applications

   http://arxiv.org/PS_cache/math/pdf/0212/0212417v1.pdf

4. **Peter Woit**
   July 23, 2008

   Daniel,

   For more about "wild ramification" in the geometric context, see references in Witten's paper with that in the title (what is at issue are "irregular connections").

   To answer your question about Langlands conjecture would be a major effort. Best source I can recommend is expository articles by Edward Frenkel, as well as the talks he is giving now at the KITP, where he is addressing exactly the topic you are asking about.

5. **Kea**
   July 24, 2008

   Opening the pdf notes by Frenkel and then listening to the audio works well.

6. **Kea2**
   July 24, 2008

   Grand unified theory of nothing.
   If you want to see what mathematicians think is important in mathematics, you should look at the Millenium Problems. Except possibly for the one on Yang-Mills theory, the geometric analogue of Langlands theory has nothing to say about any of them. The Langlands program is very profound with deep arithmetic content. In comparison, its geometric analogue appears to be more superficial and without arithmetic interest.

7. **A.J. Tolland**
   July 24, 2008

If you want to see what mathematicians think is important in mathematics, you should look at the ~~Millenium Problems~~ Fields Medals.

8. **Peter Woit**
July 24, 2008

It's true that as far as I know geometric Langlands has not led to any new insight into the arithmetic case, and because of this some mathematicians are skeptics. But there are quite a few extremely good mathematicians working on it, and the field does have all sorts of connections to deep questions in mathematics, as well as the connections to quantum field theory and physics. Personally I think it's definitely fascinating and still mostly unexplored territory, and may turn out to be one of the great themes of 21st century mathematics. Time will tell….

9. **David Ben-Zvi**
July 24, 2008

Of course Frenkel's comment on the "grand unified theory" is tongue in cheek, but in any case he was referring to the entire Langlands program, not just to its geometric aspects.

Also the claims about the disconnect with arithmetic are not very accurate. First the Langlands program for function fields has profound connections both with the arithmetic and the geometric Langlands programs.
And most spectacularly, Ngo Bao-Chau has used ideas originating from the geometric setting (in fact from the study of Yang-Mills!) – namely the Hitchin system – to resolve one of the major outstanding conjectures in the arithmetic setting, the so-called "Fundamental Lemma", which has numerous immediate number-theoretic consequences (work which to many suggests he should be honored with a Fields medal).

The geometric Langlands program itself doesn't claim to the profundity and impact of the arithmetic conjectures (few areas in math do), but it has had spectacular successes, for example the work of Bezrukavnikov and collaborators resolving various conjectures of Lusztig on the deep relations between quantum groups, loop groups and algebraic groups over finite fields, one of the central problems in representation theory.

10. **onlooker**
July 24, 2008

As the term "geometric Langlands" should suggest, a cardinal motivation for the development of the theory by Drinfeld and Beilinson was to apply and refine the analogies between number fields and function fields. A big part of the issue is learning how to properly formulate and generalize the picture in the arithmetic setting and the geometric picture is very valuable for that. Hitchin fibrations are presumed to be the first of many examples of this.

11. **Kea**
July 24, 2008

Putting the mathematical worth of geometric Langlands aside, it seems to me that the Physics is actually closer to the arithmetic and finite field channels anyway. By Physics I mean the science that actually has some bearing on testable predictions in the real world.

And Kea2? Cute.

Blogging Heads Science Saturday

July 26, 2008
Categories: Uncategorized

Today's "Science Saturday" on Bloggingheads features me and Sabine Hossenfelder, supposedly talking about What's wrong with string theory. Actually, we both agreed that we were pretty tired of that topic, so tried to discuss some more interesting related issues we both have an interest in. Here's a clip from the full thing, I promise to not start regularly embedding video in this blog:

I hope this thing came out all right. It was recorded a couple weeks ago, in a process involving no trouble on my end, but heroic efforts on Sabine's. While Sabine had to set the whole thing up on her end, and ended up crouched in an attic since it was the only place she could get a connection of good enough quality, I just sat at my office chair and someone from Bloggingheads took care of everything. Unfortunately we couldn't see each other while talking. I can't really bear the thought of watching myself on video, so I guess I'll never see exactly how this turned out, but I'm glad to see that the turtles on the bookcase behind me made it into the frame.

Sabine has her own posting about this here, and the full thing is here.

Comments

1. **Bee**
   July 26, 2008

   I just made the heroic effort of indeed watching the whole thing again! It is actually quite good, we managed to cover a lot of interesting topics. I was as well somewhat confused by the title the bloggingheaders chose.

2. **mike**
   July 26, 2008

   Peter,

   This is a great video blog but I have a few comments regarding "the market place of ideas". First, any marketplace of ideas as I see it (like an economic marketplace) is an open market – open to exchanges by any and all individuals like the free market that we currently barter in for goods and services. This is almost universally seen as the reason free markets are successful – they are "open" to exchanges by many without much intervention on control (although we understand that some intervention may be necessary). To exclude the public from the string theory debate seems counter this market philosphy, as it is the public that seems decides our fate in terms of economics and political process. The beauty of our system in this and other free countries is that regardless of how bad a product is, or how limited the intelligence of a political candidate, the system manages to correct itself through some magical feedback loop (bad product –> unhappy customer –> product is not purchased and company goes bankrupt). This system is probably what keeps us a float even when the most limited intelligences occupy positions of power in our government or economic system.

   This being said, I believe that the public should (and always will – we have no choice in a free market) be involved in the string theory debate. The last time we may have had a true vacuum in science was when a certain oligarchy taught and enforced without debate to a select few ideas of about an earth-centered universe. We have fortunately moved away from this, but like all dynamical systems that we rely on, cycles are the inevitable result and we are perhaps in a down cycle in terms of the "idea marketplace". The solution to getting out of this down cycle, as the government well knows, is to stimulate the economy, and for ideas it's the same. We stimulate the "idea economy" by involving the public, and earnestly hope as we do every election year that the right idea or candidate floats to the top of the pile over some time. As part of that process, we have to tolerate the ideas we don't like and because that feedback loop that finds a happy medium for all of us, in the end things seem to get better for everybody (GDP in this country is still pretty good).

   Therefore, I don't think there is anything to be feared about a public debate – the lack of understanding of QFT or string theory is irrelevant. Ideas that survive the market place rise to the top, ideas that don't sink to the bottom. In the end, the public becomes more educated (which is more than they might get in public schools in some cases) and it's better to have a somewhat educated public voting on science funding than a non-educated public doing the same. In fact, it seems like there is little input from the public on science funding and the more interested they get in the debate, the more likely they are to let congress know about it. Vacuum's of knowledge never kept theories alive nor did they stimulate growth. Only open debate – not just academic debate (which as you both mentioned doesn't seem to be happening anyway) but open public debate, can bring us to an understanding of the truth.

3. **Bee**
   July 26, 2008

   Hi Mike,

   I have written two long posts on the topic that you touch: We have only ourselves to judge on each other and The Marketplace of Ideas that I recommend you read. What you miss is the following:

   a) Especially in theoretical physics, there is potentially a long time in which there is no evidence (in form of observation or experiment) to judge on the promise of a research program.

   b) During this time then when judgement by Nature is still absent, judgment is left to experts in peer review – which is thus essential for ideas to survive and grow to adulthood. The public opinion should play no role in this, this isn't the way science works. The public opinion is relevant to the question what fields are generally of importance for our societies and how money should be invested to be as beneficial as possible, but the public never 'votes' on research funding on the specialist level. There is a reason why funding agencies have an elaborate referee process.

   There is a priori no problem with leading these discussions publicly, as long as this does not influence the truth finding process. But the danger of such influence when people worry about their funding is very obviously there. It should also give us a lot to think that apparently in the case of string theory it was not possible to lead this discussion without exerting public pressure (or possibly it wasn't tried hard enough?). This is my opinion shows that the judgement process on our own 'Marketplace of Ideas' works very insufficiently.

   Best,

   B.

4. **Peter Woit**
   July 26, 2008

Mike,

I think I, like Sabine, have mixed feelings about this whole "marketplace of ideas" business. What I've seen in particle theory over the past 20 years has been a massive failure in how that particular marketplace is supposed to work, and that was one of the main concerns of my book and Lee Smolin's.

There are different marketplaces at work here, an internal marketplace inside string theory, where different proposals within string theory battle it out, a marketplace within particle theory, where the traditional lines are phenomenologist vs. string theorists (although with many trying to cross those lines to gain marketplace advantage) and the marketplace within physics departments, where decisions are make about who to hire. This is a relatively closed system, and I don't think the public has much of a role to play there, since good decisions require significant technical expertise.

There's also a public marketplace of scientific ideas, and string theory has traditionally been extremely successful there, due to the impressive public relations efforts of some of its proponents. This has changed the last few years, with the public seeing a much more balanced range of views, and string theory losing market share. String theorists are naturally upset about this now, while they were relatively pleased with how things were going back when string theory was being heavily promoted, and its problems pretty much ignored. When my book and Smolin's first came out, one frequent claim made was that the books should be ignored, since string theory had already triumphed in the marketplace of ideas. The books were very much an effort to engage in this marketplace, and I think did so quite successfully.

The relation between these two marketplaces is a complicated one, and that's something Sabine was repeatedly asking me about. One of her questions was why I chose to enter the public marketplace, as opposed to sticking to the professional marketplace. One answer is that the book was intended to address both, aimed at both professional physicists and mathematicians (who generally know very little about what the state of string theory is), as well as the public. Both marketplaces needed a countervailing force to the promotional effort that has been backing string theory.

The public marketplace affects the professional one, as ideas that get public attention get more funding from various sources and more support from university administrations. I wouldn't want this public attention to determine the fate of a scientific research program, but some influence is unavoidable. In the past string theory was probably better funded and supported because of the promotion to the public. The professional marketplace affects the public one too, largely through the popular science press, which observes the professional marketplace, tries to evaluate what is new and how things are going in a science, and then transmits some understanding of this to the public. Part of the most serious problem for string theorists now is that a sizable and vocal contingent amongst them has taken to promoting a research program (landscape anthropics), which can be readily explained both to their colleagues and to the public (anthropic papers tend to have few equations…), but most people recognize pseudo-science when they see if. If you're not a string theory ideolog, this stuff looks extremely dubious.

5. **Roger Schlafly**
   July 26, 2008

   I am watching as I write this, and I was surprised to hear you agree with her statement that it is bad to make arguments about String Theory to the general public, because it polarizes people. What does that mean — that you regret writing the book? That laymen should not know about Physics controversies? That it is bad to express polarizing opinions? C'mon, you ought to defend yourself better than that.

6. **mike**
   July 26, 2008

   Peter,

   I also think that both your book and Lee Smolin's did well in countering the string theory promotion that went on so long in the public – they rose to a high level of public opinion with no tangible evidence to show. Both books did a good job in countering string theory claims of TOE and I think the public market place was a better venue to have this discussion than professional journals because there appeared to be a bias in the journals towards "the new trend" without giving it much scrutiny. It's always good to get a public sanity check once in a while – it's not that I think the public will help comment immediately on formulas or theories, but just that they act as a sounding board and "ethical referee" check for professional scientists who engage in a debate where the cards are clearly stacked on one side. It's kind of like a jury of one's peers – they aren't supposed to be experts in forensics or other specialties because a bias may exist – but they still are presented with highly technical facts in which they use to make a decision. In the end, it leads to a rather unbiased opinion (the fact that lawyers trust the average person on the street to make a decision about medical evidence is a fascinating concept). Perhaps this is the advantage of science in the public – just to keep what we know as science and the scientific method going and to call pseudoscience what it is. That being said, I am definitely not in favor of landscape anthropics which appears to be epicycles all over again (but with more advanced mathematics). I think the sooner these concepts of "anything is possible" are examined in the public view, the faster they will go away.

7. **Bee**
   July 26, 2008

   Hi Roger,

   I did not say it is bad to make arguments about string theory (or any other scientific topic for that matter) to the public. I said it is of great concern this was necessary, since doing so has predictable drawbacks eg, as you say, in that it polarizes people. Uncertainty is an elementary ingredient of science, but there seems to be no place for this in public discussions which usually forces people to take either side, leaving out detailed nuances. This is not a good environment in which to discuss whether the present research directions are pursued in a balanced way, and if not what the reason is for this. Instead, it will prompt a food fight. Best,

   B.

8. **Peter Woit**
   July 26, 2008

   Roger,

   I'm obviously not opposed to communicating with the general public about string theory and its problems, since I've done a lot of it. I think that exchange was more about how it was a shame that discussion of the problems of string theory within the theoretical physics community was often suppressed (string theorist referees stopped publication of an earlier, less popular, version of my book by a university press), with the result that it ended up taking place in public forums not necessarily known for civility or a high standard of informed professional discourse.

9. **mike**
   July 26, 2008

   Hi Bee,

   I definitely don't advocate that the public take over the technical referee process – there's obvious reasons why this wouldn't work, but it appears at times (like when Peter submitted an earlier book to the University press that got trounced by string theorists bent on keeping their shrine sacred) that professional peer-reviewers stop acting professionally when they let their personal opinions get involved of what should be an unbiased observation of facts. During these times it seems many who feel the peer review process is biased seek the public domain and in the case of string theory this rightly seemed to correct the problem. I don't believe this is because the public decided string theory was bad, but I believe it because the embarrasment of potentially being proven wrong in the public domain about a theory is much worse than anything that happens in the peer review process and therefore has the effect of correcting peer-review so it becomes less biased and more effective.

This also affects funding to a certain extent as you mentioned in one of your posts about the funding for string theory starting to dry up. What is popular does get funded and I agree with you that this is a real problem. Perhaps some funding should be set aside for "fringe theories" so that it's not always "right or wrong" to fund something. This is already taking place, like Naval research funding cold fusion well into the last decade, or NASA funding the blacklight propulsion project a few years ago. These funding sources take it upon themselves to ensure the research gets done even if it's unpopular. I sometimes take issue with funding some of these projects but as in a democratic system, I believe we have to tolerate some things we may not like so we can meet common ground and create a better environment for research overall.

I agree with your ideas about what happens in the market – it's not a "pure process" and I don't think the market place is the ideal place to bring about change in science, but sometimes it may be necessary if the peer-review process isn't working as it should (which then hopefully gets corrected). In mathematic terms, the relationship between science and the public seems to be non-linearly dependent.

Best regards,

Mike

10. **Roger Schlafly**
July 27, 2008

What is the problem with "public forums not necessarily known for civility"? You mean that if you denigrate String Theory, then Lubos Motl will write nasty things about you on his blog? He is apt to do that whether you write for the general public or not. You don't need to give excuses for writing for the general public.

11. **somebody**
July 27, 2008

The reason why only the public debate has gotten any traction, and why the attitude of the particle/gravity community to string theory is the same before and after the books, is simple: there were no new scientific ideas in either book that was not already well known.

Woit and Smolin did a good job of counterbalancing the Kaku style nonsense that was being promoted to the public as string theory. Many string theorists (eg: myself) would have liked nothing better. But the relative merits and difficulties of string theory were well known to string theorists before the books, and the books did nothing to affect that scientific judgement.

Also, discussions even about well-known things usually get caught in ruts – the typical example is that of the landscape. The oft-repeated claim that "having many vacua which look like ours at low energies kills predictability" is simply an incorrect one, and no sensible discussion about the landscape is possible when this sort of factual errors are not acknowledged. What could potentially kill predictability is the difficulty of constructing vacua, and it is not easy to find the motivtion to debate against (for example) the comment thread on Schellekens' article below.

12. **John Brock**
July 27, 2008

I really don't understand the problem some people have with the Multiverse. To me the idea seems both plausible and very satisfying. If the Earth were the only planet that existed, the philosophical problem of coincidences would be exceedingly difficult to deal with. But the minute you realize that there are many planets the problem simply disappears, and I don't see anything at all upsetting about the way it disappears, rather it seems to me that it disappears in the best possible way.

Likewise, the Multiverse hypothesis makes the (very serious!) problem of cosmic coincidences disappear in the best possible way. The complaints about it all strike me as the equivalent of being unhappy with the Multiplanet hypothesis because it means that you will never be able to derive the distance from the Earth to the Sun from first principles. Well no, in actual reality you can't, and that's just the way it is. And isn't it satisfying to discover why you don't have to?

13. **groan**
July 27, 2008

(@ John Brock)
… and you can argue for anything in a Multi-Strawman post.

14. **Eric**
July 27, 2008

The thing that you must keep in mind is that it is in fact possible that the anthropic landscape could be the correct description of reality. In this case, then it would be utterly impossible to make unique predictions, although this is not the case within the confines of specific vacua. This just may be a fundamental limitation of reality, just as it's impossible to simultaneously measure position and momentum. So, you can criticize string theory because of this, but if this is the true reality then we have no choice but to accept it. Is it the true reality? Nobody can really say at the moment, and so more work must be done.

15. **woit**
July 27, 2008

somebody,

Schellekens is the one making the claims about predictivity that you say are in error. Instead of arguing with my often ill-informed commenters, you should e-mail him and demand that he retract his paper from the arXiv since it is wrong.

I don't think it's just the public debate about string theory that has gotten traction, so has the professional debate within the physics community. I find that the way physicists in general think about string theory is quite different now than it was 5 years ago. Probably one of the main reasons for that is not my book and Smolin's, but the public relations efforts of some string theorists themselves. Lubos and Lenny Susskind have done more to discredit the subject than I ever could. The one place where there hasn't been anywhere near as much of a serious debate as there should be is within the string theory community itself. People there would be well advised to start acknowledging the problems they are facing and engaging in serious discussion about what to do about them.

John Brock and Eric,

For about the 100th time, the problem with the multiverse is not that it is logically impossible or can't be used to solve a philosophical problem. The problem is that it's not an idea that can be tested and so isn't science.

16. **John Brock**
July 27, 2008

Woit,

I'm sure this is probably the 1000th time, because it is such an obvious point, but although I've done some graduate work in physics (decades ago) I'm nowhere near the level of you guys, and I am just trying to understand.

My problem is that when you say it "isn't science," it sounds a lot like you are asserting that this is a *problem* with String Theory, and I just don't understand what the problem is.

Let me put it this way, suppose that tomorrow I were to resolve all the technical issues with String Theory, and I handed you a well defined and consistent theory which demonstrably included our own universe, but which also included a huge number of alternative universes. What would you do with this theory? Would you reject it, because it isn't testable, and insist we continue looking for a theory that could be tested, even though such a theory might not exist? That's what seems to be implied by equating "not testable" with "not science."

And why would you even want to keep on looking? The point I was trying to make in my post that if a theory happens to yield a Multiverse that should be seen as a bonus, not a negative, since it does after all resolve what is otherwise a difficult philosophical problem. You don't seem to agree that a Multiverse is a good thing to come out of a theory, and that is basically what I'd like to understand.

17. **somebdoy**
July 27, 2008

"Schellekens is the one making the claims about predictivity that you say are in error."

No Peter, his argument is perfectly clear. He wants to go anthropic because he doesn't know how to systematically construct vacua. That is his only real argument. Take away the difficulty to construct vacua, and he has no argument.

But your claim is stronger – that string theory is INHERENTLY non-predictive because of the landscape. What I am trying to say is that if we had infinite powers of model-building there is absolutely no philosophical difference between QFT and string theory. So it is a logically defensible stand to try to get string theory under better control so we can build models.

Anyway, I have some marginal disagreements with Eric as well. The only way in which I can make sense of his claim is by the statement that there might be many ways to UV complete our low energy physics. I don't see why this is bad for making predictions. Because at any energy scale, all I can even in principle hope for, is to identify equivalence classes of theories which could potentially differ from each other at higher scales. We will be able to resolve the different models as we probe higher and higher energies. Again, the thing we really need is control on string theory.

18. **Robert**
July 27, 2008

"Lubos and Lenny Susskind have done more to discredit the subject than I ever could"

I really doubt that, since, Lubos keeps giving clear and patient expositions of the central tenets of string theory on his blog, and Lenny has done string theory a big service by drawing the inescapable discretuum of vacua to the center of the debate. Even if one doesnt like that idea, it doesnt help to ignore it, as mother told us.

19. **woit**
July 27, 2008

somebody,

Schellekens (see the paragraph I quoted starting "First of all") is very explicitly claiming lack of predictivity, based on what is currently known of string vacua constructions. Sure, you are welcome to argue that the problem is that we just don't understand these well enough, and that when we do the problem will go away. I think he would respond to this the way I would: you're engaging in wishful thinking.

John Brock,

I just don't care whether a proposed fundamental theory includes a multiverse or not. If you present me with a theory that can be tested, it passes the tests, and it also predicts a multiverse, that's evidence for a multiverse. If you present me with a theory that can't be tested, even in principle, you're just not doing science, but something else that I don't care about. The problem with the string theory multiverse is that its role is precisely to make the theory untestable. You can imagine plenty of multiverse theories that are still testable, the problem here is that this one just isn't, and all the going on about anthropics, the distance from the earth to the sun, etc. is just blowing smoke to avoid acknowledging that there's a speculative idea here which simply has failed.

Robert,

Have you talked to many non-string theorist physicists and asked them what they think of either Susskind's promotion of anthropics, of Lubos's behavior?

20. **Eric**
July 27, 2008

Somebody,
My point is that even if there is a specific model in which it's possible to reproduce everything we know at low energy, it will not generally be accepted or recognized as unique or even interesting. This is due exactly to the fact that many within the string theory community have the same view as Schellekens, who doesn't think it's important to try to construct models where gauge couplings and particle masses can be calculated. This is the real danger of the anthropic argument, that people don't even think it's worthwhile to find solutions which agree with our world simply because we cannot say it is a unique solution.

21. **John Brock**
July 27, 2008

OK, I feel I'm getting closer. I had thought that you considered all theories with Multiverses to be in principle untestable, but apparently not. I may already be over my head, but I do appreciate your making the effort! A couple of further questions:

1) Is there any way you can explain what distinguishes a testable Multiverse theory from a non-testable one? I don't see any obvious way to create two categories; to me it would seem that they would all have to be equally untestable experimentally.

2) How do you deal with the possibility that a theory, like String Theory, might be both untestable and true? Or do you feel that String Theory is just wrong for reasons that have nothing to do with testability, in which case why does the issue of testability come up at all? If the Multiverse is being invoked simply to cover up other failings of String Theory, why not just put it that way, rather than bringing up testability?

3) Do you really not care at all whether a theory implies a Multiverse?!? To me it seems like such an obvious Good Thing, because of the philosophical considerations. All else being equal, an incomplete theory that seems to imply a Multiverse would seem to have a leg up over one that does not, because the Multiverse is such a compelling resolution to the cosmic coincidences problem.

22. **theoreticalminimum**
July 27, 2008

> I really doubt that, since, Lubos keeps giving clear and patient expositions of the central tenets of string theory on his blog, …

Robert, do you really think someone who has written a book like "*L'équation Bogdanov*" should be taken seriously? That he writes clearly about string theory is no surprise (it would be quite unfortunate if it were otherwise); he was hardworking and lucky enough to be involved in some developments in string theory, in one of the most specialised, almost carefree academic environments in the world (Rutgers, Harvard), from a relatively early period of his physics education. He had all his time to understand the technical details of much of what he has been writing about, when it comes to string theory.

I am a physics graduate student, and if I took Motl's rants seriously (with or without the string theory), I would never have thought about spending time studying this subject, or interacting with string theorists (I'm quite frankly relieved that he's no longer part of the mainstream community). Sadly, he has given a bad image of string theorists (and consequently has made the subject itself less "friendly"), for sure! I have so far met a number of string theorists, and thankfully almost all of them are very different to Motl's blog-personality. I know of at least 5 other physics graduate students (all in HEP, and all in Europe!) who would agree with me on these terms.

23. **Peter Woit**
July 27, 2008

John,

1) The multiverse aspect of a theory may be testable via statistical predictions, and, more importantly, the parts of a theory with a multiverse that just involve our universe may or may not be testable.

2) If string theory is inherently not testable, then the question of whether it is true or not is just not science. The idea that the we live in a simulation performed by higher beings is also not testable, and could be true. You're welcome to think about this and believe it or not believe it, but you're not welcome to claim that this has anything to do with science. As for string theory, my specific claim is that the idea that a 10/11d string/M-theory can provide a successful unified theory is simply a failed idea. One way speculative ideas fail is that they turn out to be vacuous, and thus explain nothing. That's what has happened here, with the multiverse being invoked to avoid admitting failure. It's an interesting and important exercise to examine exactly what goes wrong with the string theory unification idea, but the bottom line for any scientific theory is whether it provides a testable explanation of some phenomenon. String theory unification fails this test.

3) No, I honestly don't care. I spent a lot of my youth studying philosophy, and at some point lost interest in the idea that philosophy was going to provide by itself some insight into the nature of the universe. Philosophy can be quite useful as a tool for clearly thinking things through, but that's not at all how I see it being used in this multiverse story.

24. **somebody**
July 27, 2008

Eric says:

"My point is that even if there is a specific model in which it's possible to reproduce everything we know at low energy, it will not generally be accepted or recognized as unique or even interesting. This is due exactly to the fact that many within the string theory community have the same view as Schellekens, who doesn't think it's important to try to construct models where gauge couplings and particle masses can be calculated."

My point is that uniqueness is not a problem if we know how to build models in string theory. Uniqueness is not how we EVER built models. The virtue of stringy models is not that they are unique, but that they are UV complete. There could be many UV complete models, and to pick between them we need experiments – just like we needed experiments to determine standard model as the QFT at low energies. But this is still a perfectly predictive framework. Predicting gauge couplings and particle masses has never happened in the histoty of physics, but still we have had predictive theories.

There is a subtle but all too important distinction between the anthropism that Peter and Schellekens see in string theory. The former is based on the belief (see his previous comment) that there is an inherent impossibility of constructing predictive models, the latter is based on the fact that constructing models is very hard. My claim is that the effort to understand string theory non-perturbatively is the best way we can gain control of model building. Peter (invoking Schellekens) calls this wishful thinking. I must admit that he could be right, because the problem is in fact very hard. For that the only answer I have is that one must try!

In any event, the way it is often presented on this blog – that even if everything went well for string theory, STILL it would not cut it – that is simply wrong. If we only could wield string theory with sufficient ease, we would have a perfectly predictive framework. Whether we should work on solving this problem, or whether we should give up because it is too hard, thats where only history can be the arbiter. My suspicion is that a problem of this level of difficulty will have to be solved one way or another in any theory that purports to be a fundamental theory.

25. **Thomas D**
July 27, 2008

Why should we assume that the rejection by (Cambridge?) University Press was necessarily a bad thing, or unjustified, or unprofessional? We don't know what the earlier version of the book said, we don't know much of what the referee reports said, we simply assume it was a representative case of big bad string theorists using their power unjustifiably? Surely it could simply be a very typical University Press decision. Academic publishers, for quite good reasons, don't deal with works which are primarily criticisms of other scientists and their research. CUP publishes research, monographs, reviews, textbooks, they don't publish controversialists or polemics.

That rejection also didn't in any way force Peter to rewrite the book into a popularizing kitchen-sink attack (which may or may not be an accurate description…)

It simply isn't necessary or productive to write and publish academic books that are primarily critical of some trend in theoretical/mathematical physics: if and when that trend gets mined out, people will get bored and do something else. Researchers' time and effort are never well served by deliberate negativity in publications, whether academic or popularizing.

26. **Peter Woit**
July 27, 2008

Thomas,

1. The book as published is quite close to what was considered by Cambridge University Press, what was added were mainly some summaries at beginnings of chapter, and suggestions for further reading. No, I didn't rewrite it into a "popularizing kitchen-sink attack", which it isn't. Have you actually read it? The fact that the book ended up getting published by a non-academic publisher didn't change the actual book, but did make sure the book got more attention and a much wider distribution.

As for whether it deserved to be published by CUP, people can read the book and make up their own minds. I've been extremely gratified to hear from a large number of mathematicians and physicists that they learned a lot from the book and had a high opinion of it.

2. The referee reports from non-string theorists were quite positive and endorsed publication, the two from string theorists quite negative. One of the string theorist ones said that they would only give one example of what was wrong with the book because they couldn't believe any referee would favor publishing the book. The example he or she gave was a perfectly accurate sentence that he or she changed to make it inaccurate. None of the referees or Cambridge editors ever suggested that the problem with the book was that it was just a "criticism of other scientists and their research". Again, have you read it? There is nothing in the book personally critical of any scientist, or even of any scientists as a group. The only significant discussion of any particular scientist is about Witten, and there the discussion is extremely positive.

3. The book was rejected later on by Princeton University Press because of a referee report from Lubos Motl. For this story, see

http://www.math.columbia.edu/~woit/wordpress/?p=438

27. **Johnson**
July 27, 2008

I have thought about it for many years but I still don't get it… Can someone explain to me how an "anthropic argument" is different to a normal "scientific argument"? (Please don't delete this comment, I can assure you I am a well-meaning honest academic who'd just like to understand this point, I'm not a heckler). For instance, in a previous comment, Jim Clarage wrote:

"For example Newton could have easily adopted an anthropic approach to his inverse square law, perhaps assuming any value for the exponents in the radial and mass coordinates of the gravitating objects; and then agreeing to anthropically derive these exponents based upon e.g., what values allow and disallow stability of human bones, large tree trunks, or other mechanical properties of organisms living under the influence of Earth's known gravitational field.

…
However, instead of appealing to anthros Newton appealed to physics. He tried to pick the exponents and form of the law based upon reproducing previous physical laws, viz., Kepler's laws."

[italics added]

Could someone help me out here? Surely it amounts to exactly the same thing… what is the difference here?

(a) Newton makes the ansatz F = G m_1^a m_2^b r^c for a Law of Gravitation, in terms of some unknown exponents a,b,c,d. He then performs a rigorous mathematical tour de force and shows that large tree trunks can only exist if a=b=1 and c=-2.

(b) Newton makes the ansatz F = G m_1^a m_2^b r^c for a Law of Gravitation, in terms of some unknown exponents a,b,c,d. He then performs a rigorous mathematical tour de force and shows that elliptic orbits (whose existence is gleamed from previous astronomical observations by Brahe, Kepler, etc) can only exist if a=b=1 and c=-2.

Why on earth is (a) called an anthropic argument and discredited as "pseudo-science", while (b) is considered as valid science? They are the same thing, no? *What is the difference between observing the existence of large tree trunks with binoculars and observing the existence of elliptic orbits with a telescope?*

28. **Johnson**
July 27, 2008

"I've been extremely gratified to hear from a large number of mathematicians and physicists that they learned a lot from the book and had a high opinion of it."

Indeed, I considered buying the book (I read it in a bookshop) simply for the clarity of its mathematical presentation of the history of the ideas coming from witten, segal, atiyah, etc. Believe me, as a mathematician I find the usual description of these topics written by conventional string theorists very difficult to understand.

29. **Peter Woit**
July 27, 2008

Johnson,

I'm glad you liked the book. But please, the discussion of anthropics is getting off-topic and I don't want this comment section to turn into yet again another endless discussion of this issue.

30. **Johnson**
July 27, 2008

Okay… I will wait until this issue comes up again.

31. **manyoso**
July 28, 2008

Somebody said,

"In any event, the way it is often presented on this blog – that even if everything went well for string theory, STILL it would not cut it – that is simply wrong. If we only could wield string theory with sufficient ease, we would have a perfectly predictive framework."

I'm just a layman struggling to understand the ideas presented here, but I'd really like to know what evidence you have that forms the basis for this belief? How do you *know* that String Theory would "cut it" if only we had enough control over how to construct vacua? What guarantee do you have that our Universe is correctly modeled (not at just the currently known low energy results) by one of these sufficiently well constructed vacua?

Even more, what guarantee can you give that if only we knew how to construct the vacua better that the Standard Model would fall out at even low energies? To me, it seems that the only answer I've ever heard from String Theorists is that the math is just sooo elegant that, "It must be so!" This is not particularly convincing for a theory that hasn't even been demonstrated to be consistent yet.

I just don't understand the confidence you guys voice when top guys like Witten admit that you don't even know what String Theory *is* yet. How can you be sure that it'll end up describing our Universe at any energy level when so little is known of String Theory?

John Brock said,

"How do you deal with the possibility that a theory, like String Theory, might be both untestable and true?"

How on earth would you ever know that it was true if you couldn't test it? More to the point, there are countless theories one could come up with that 'might be true', but are untestable. We're all living in a VR made by higher beings… The Spaghetti Monster did it…

"Do you really not care at all whether a theory implies a Multiverse?!? To me it seems like such an obvious Good Thing, because of the philosophical considerations."

How so? I don't understand how some vacuous idea about a 'Multiverse' can be useful to explain anything? It sounds like you are arguing for ignorance. Just suppose for a minute that the Multiverse was true: we're all living in just one of the countless number of Universes in existence. Ok, what can you tell me about the Multiverse itself? What are it's physical principles and dynamics? Since we're already supposing a Multiverse, it is only fair to suppose this Multiverse's physical dymamics are also inscrutable (at least at first). We form theories with new physical constants that seem to have just popped out of nowhere… Now should I start supposing a Multi-Multiverse?? Perhaps the Multiverse concept is only appealing because it is so void of content that people can ascribe anything they wish to it.

32. **somebody**
July 28, 2008

"Even more, what guarantee can you give that if only we knew how to construct the vacua better that the Standard Model would fall out at even low energies?"

I cannot give you any guarantees whatsoever. But neither can I give you any guarantee that Yang-Mills has a mass gap, nor that black holes radiate, nor that the gravitational coupling doesn't change with time. But I still believe all these things are "true" in the contingent sense that scientists use that word. The point is that I see no reason why my quality control should be any ore "string"ent with string theory.

Anyway the reason why I think the standard model can arise from string theory is pretty simple, and I have a suspicion that it will not convince you: string theory permits many kinds of standard model like models, and there doesn't seem to be any reason why standard model should be particularly impossible. That is it. Proving it one way or another, I think, is going to be HARDER than actually constructing one.

Just to draw a caricature to drive home a point: if you ask me why I don't believe in telepathy, the answer is again only that it seems pretty unlikely. I have been held to court and asked whether I can PROVE it doesn't exist. This business is all about judgement calls and thats something people don't seem to get. Its not about worrying about exceptions even before the get-go.

" To me, it seems that the only answer I've ever heard from String Theorists is that the math is just sooo elegant that, "It must be so!" "

You asked a string theorist why he believes the standard model could arise from string theory, and the answer you got was that because the math is elegant? You should certainly talk to better string theorists.

33. **manyoso**
July 28, 2008

Somebody says,

"Anyway the reason why I think the standard model can arise from string theory is pretty simple, and I have a suspicion that it will not convince you: string theory permits many kinds of standard model like models, and there doesn't seem to be any reason why standard model should be particularly impossible. That is it."

Ok, let's presume that String Theory provides a sufficiently malleable framework wherein we'll eventually learn to construct vauca to accommodate the Standard Model. Given this, what reason is there now to believe that this will elucidate or provide predictive power for future experiments beyond the Standard Model?

34. **John Brock**
July 28, 2008

manyoso,

Peter seemed not to want to continue on this topic, so I wasn't going to press him, although I wasn't content with his answers. But I'll take a shot with you.

"How on earth would you ever know that it was true if you couldn't test it? More to the point, there are countless theories one could come up with that 'might be true', but are untestable. We're all living in a VR made by higher beings… The Spaghetti Monster did it…"

The thing is, Virtual Reality and the Spaghetti Monster are obvious and uninteresting cheats. They are strawmen. Yes, you can trivially come up with any number of theories like that, and who cares. But can you come with any number of mathematical theories which are well defined and consistent, in some way mathematically elegant and unique, and demonstrably include, as one of a huge number of possible solutions, a solution which describes our actual universe? How many of those can you come up with in the next five minutes???

Now here is the point: my understanding, as one of the ill-informed laymen who are part of the intended audience of Peter's book, is that such a theory is what the String Theorists are still hoping to find. This seems like an entirely reasonable judgment call to me! I do understand they haven't found it yet, despite decades of searching. I understand there are many possible reasons why they may never find it (that it doesn't exist being only one of the possibilities!). But if they did find such a theory, wouldn't you have to agree that it would be enormously more compelling as a candidate for the Theory Of Everything than the Spaghetti Monster, even if the theory included a Multiverse which made testing impossible?

That's it in a nutshell. The Spaghetti Monster will never be a compelling TOE. A well defined and consistent String Theory which actually described our universe (along with many others) would be, even if you couldn't test it. If you believe the universe is describable by mathematics, and I hand you a mathematical theory which can be shown to describe the universe, doesn't that have to count for something? Unlike Spaghetti Monsters, such theories are not a dime a dozen. So far we don't even have one.

35. **Peter Woit**
July 29, 2008

John,

I find the idea that there is a mathematically simple and compelling TOE that doesn't predict anything is about as plausible as the FSM. You're making up mythical creatures that there is no evidence for and debating their properties.

36. **John Brock**
July 29, 2008

But is that what the String Theorists are looking for?

If they believe they can find such a thing and you don't then this whole thing is just a difference of opinion at a level where there is no point talking to the lay reader such as me. What I'm trying to figure out is whether their is some problem with String Theory which can be understood at my level. I understand that you don't think they can come up with the sort of well defined theory that I am talking about. But do you understand why it seems to me that if such a theory were found it would have to be given a lot of weight, predictions or no?

The thing is, presumably the String Theorists are more or less as smart as you are, and if they think they can find such a theory, and you think they can't, and the argument is on technical issues, then there is no way I can take a side. The only level I can deal with involves questions such a Multiverses and testability, and so far I just don't see that String Theory has any problems that can be expressed at that level.

37. **somebody**
July 29, 2008

manyoso:
"Ok, let's presume that String Theory provides a sufficiently malleable framework wherein we'll eventually learn to construct vauca to accommodate the Standard Model. Given this, what reason is there now to believe that this will elucidate or provide predictive power for future experiments beyond the Standard Model?"

You could ask the exact same question with QFT : "yeah, sure, you can build models, but why should we believe it is going to be predictive?"

Model-building is something which requires ingenuity and intuition, and what we are seeking is a paradigm to do that in. QFT provided that for non-gravitational theories.

If you don't see the answer from that comment, see my other responses on this thread. This fallacy of "predictivity implies uniqueness" seems to be too deeply ingrained in everyone's mind, but right now I don't have the time to go through it again.

38. **manyoso**
July 29, 2008

John Brock,

"But if they did find such a theory, wouldn't you have to agree that it would be enormously more compelling as a candidate for the Theory Of Everything than the Spaghetti Monster, even if the theory included a Multiverse which made testing impossible?"

You are misstating the situation I believe. If in the future String Theorists discover that the theory is consistent and provides a way to calculate the Standard Model, then they'll have found a theory that is testable. If this same theory goes on to predict multiple universes or other bizarre and fantastical physical outcomes so be it. Even if we can not find a way to test all of the predictions, the theory would still provide others. I'll bet that the entire community of physical scientists would celebrate such a discovery.

However, the current situation looks nothing like that from what I can discern. What exists is a mathematical framework that has not been proven consistent and has not been shown useful to calculate any known physical result. It has not been shown a super set of the Standard Model.

All we have is this hugely malleable framework and a landscape of possibilities describing perhaps ~10^500 different universes. Currently, the String Theorists take it on faith that our Universe is some needle described by this huge haystack. And why do they? Because they've found some other needles which if you squint your eyes and turn your head kind of resemble the needle we're looking for. That and because the framework has an elegant way of including gravity.

The guys that argue for the anthropic landscape throw up there hands at ever having to find the actual needle in this landscape. They don't even see a particularly compelling reason or need to find it?! They are ready to argue that String Theory is a success even without finding the part of it that makes contact with our known world. This is the point where I think the exercise becomes completely unscientific.

Again I'm just a layman myself, but this is the situation from what I understand. Upshot? If String Theory wants to predict fantastical things that is fine with me, but largely irrelevant. The test for any physical theory is whether it can be used to model known experimental measurement.

39. **Gilbert**
July 29, 2008

Hi John,

I rarely butt in here, but this one is like a thorn in my side. It just seems to me that you would expect a theory which "*demonstrably* include[s] a solution which describes our actual universe" to be testable, whether it includes a multiverse or not, especially if it is "mathematically elegant and unique". Such a theory would have to go beyond the Standard Model and have something to say about, for example, neutrino masses, the hierarchy problem, dark matter and dark energy, the number of Higgs bosons and their mass, particle masses in general etc.

If it can't do that, it's just another pretty model, a curiosity. Worse, I think we're really talking about little more than a unicorn, since, as far as I can tell, these conditions—an elegant and unique TOE description of our actual universe that provides nothing more than the SM—are mutually exclusive.

It's not the presence or absence of a multiverse in the theory, in and of itself, that's the deal breaker. And I think this is what Peter is saying: he's multiverse agnostic. Just because a theory spawns a multiverse doesn't—or shouldn't—make it intrinsically untestable. If it also includes a beautiful, unique, and complete description of our universe, it must have something new, unique and testable to say about it. The confirmation of such a feature, or features, of our universe would just, at that point, lend credibility to the theory's multiverse.

The problem is that in a kind of logical « tour de force » this has been spun around backwards and upside down in, uh, certain circles, so that the inherent untestablity of a theory gets blamed on the multiverse it spawns.

Best,

Gilbert

40. **Eric**
July 29, 2008

For those such as Gilbert and manyoso who have made claims that string theory does not contain anything that looks like the Standard Model, I suggest you do a search of the literature. You will find that there are several good models, both heterotic and Type II, which resemble the SM closely at low energies.

41. **Peter Woit**
July 29, 2008

John,

Claiming that string theory unification should be believed if it is completely unpredictive is an extreme minority viewpoint among string theorists. You can find such people, but most string theorists know that if string predicts nothing it will have failed. Some have given up on string theory as providing predictions about particle physics, but think it worth studying for other reasons (e.g. as a model for quantum gravity, as an approximation scheme for strongly coupled gauge theories, etc.). Others are still trying to get predictions. But virtually none are out there telling their non-string theorist colleagues that string theory can be a successful unified theory that doesn't predict anything. They are well aware that their colleagues would laugh in their face if they did this, and never take them seriously again.

42. **manyoso**
July 29, 2008

Eric, please read again. I never made that claim. And I don't see where Gilbert made it either.

43. **Gilbert**
July 29, 2008

Hi Eric,

I think you're reading things into my post that aren't there, as I certainly make no such claim. I mean, it's just simply not there, unless your browser is seriously mangling the text somehow.

And while I wouldn't want to speak for manyoso, I don't see that he (she?) does either. In case you missed it, "…they've found some other needles which if you squint your eyes and turn your head kind of resemble the needle we're looking for" lines up *better* with "there are several good models… which resemble the SM closely at low energies" than "does not contain anything that looks like the Standard Model." Seems to me, the difference being a (rather large) difference of opinion as to how close the models line up to the SM.

Methinks perhaps you're making too many assumptions here.

Best,

Gilbert

44. **Eric**
July 29, 2008

Manyoso, you said

"If in the future String Theorists discover that the theory is consistent and provides a way to calculate the Standard Model, then they'll have found a theory that is testable."

I suppose you mean to calculate the SM parameters since you acknowledge that there exists models which look like the SM with three generations. Essentially, this boils down to stabilizing the moduli which parameterize the size and shape of the compactified manifold, upon which all couplings depend. For a given MSSM-like vacua with all moduli stabilized via flux or other nonperturbative effects, all couplings are determined and everything is predicted.

45. **Peter Woit**
July 29, 2008

Eric, Gilbert, Manyoso,

This discussion has become both off-topic and completely unenlightening. No more about this.

46. **Mikael**
July 29, 2008

Peter,
I think that Sabine's claim, it would have been better to keep the string theory discussion within the physics community leads to the questions, whether you agree and if so, why you saw the need to write your book still. In other words, I would think Sabine's position would have required a stronger response from your side. In would be interesting to hear more along these lines now.

47. **Peter Woit**
July 29, 2008

Mikael,

I think I already responded to this at Sabine's blog, but here's some more. There were two distinct problems at the time I wrote my book (2002). One was an unwillingness of string theorists to acknowledge to their colleagues how bad the situation of the theory was, and to engage in thinking about what to do about this. When Sabine says that it would have been better to have this discussion among physicists, I don't think she's saying that string theorists were willing to do this, but I somehow insisted on not engaging with them and went to the public. We both agree that there is a discussion that needs to take place among physicists, and that this was not happening. I tried to get an article published in Physics Today in 2001, this was rejected. The book I wrote was aimed at a scientific, university press audience. String theorists stopped university presses from publishing the book.

To this day, string theorists are still stone-walling, refusing to admit what the problems are and that something needs to be done about them. All that has happened since 2002 is the arrival on the scene of the anthropic landscape pseudo-science mania, which really has not made string theory look good. At this point, string theorist's plan seems to be to just do nothing until LHC results arrive, and hope that will change things. We'll see how this works out. In the meantime, their colleagues are noticing this and I've heard sometimes explicitly deciding not to hire string theorists until they see what the LHC says. The kind of discussion that should take place hasn't happened, and that's a shame.

The other problem was that the discussions of string theory available to the public (and to mathematicians, who are a significant audience for the book) were pretty uniformly overhyped and misleading. I thought outsiders deserved a more honest explanation of what was going on. The book was written to be as accessible to as many people as possible, while giving a serious discussion of the subject. I think this was worth doing. I'm not at all sorry that the book ended up being published in a way and at a time (with Smolin's) that got a lot more public attention than I ever expected. I'd have preferred to have the book published two years earlier by CUP, where maybe it would have been ignored, maybe it would have generated some more serious discussion (although I fear this was not very likely).

48. **Coin**

July 29, 2008

The oft-repeated claim that "having many vacua which look like ours at low energies kills predictability" is simply an incorrect one, and no sensible discussion about the landscape is possible when this sort of factual errors are not acknowledged.

Hi Somebody,

Could you possibly briefly explain exactly how predictability is possible in the case where there are many vacua that look like ours at low energies? (Assuming we pretend for the moment that actually constructing those vacua, as you are concerned with, somehow turned out to be easy.) If we find that we can identify a whole bunch of string vacua which produce the standard model at observable energies, but split off into a variety of higher-energy behaviors past that depending on which vacua you choose to study– I am unable to understand how to proceed in this case. What do you do next? How is the prediction made?

What I am trying to say is that if we had infinite powers of model-building there is absolutely no philosophical difference between QFT and string theory.

So let me see if I understand what you're saying here. You're suggesting something like that the general QFT toolbox allows us to construct many different models; each of these models is basically a "vacua", or analogous to one. We can thus imagine there is a "landscape" of QFT "vacua", each describing a different QFT which one might construct; and by nature there are many different QFTs which reproduce the standard model at "low energies" but do different strange things at higher energies (i.e. SU(3)xSU(2)xU(1) is one, SU(5) is another). Do I understand your argument correctly?

But surely this is not how people actually *use* QFT? Nobody I've ever heard of actually treats the space of usable QFTs as something to work with directly. Instead we pick one QFT "vacua" (say, SU(3)xSU(2)xU(1)) and stick with it. We say QFT is predictively successful not because "QFT" produced useful predictions, but because *a* QFT produced useful predictions. Moreover the problem you describe– that there are many different QFTs with different high-energy behavior and we have to pick one– it's not that this is a standing problem with QFT which we have simply chosen to excuse, it seems more that this is a problem in QFT which can be *addressed* because the different QFTs are highly distinguishable and some QFTs (say, ones which are *simpler*) are going to be inherently considered preferable over others. We can recover predictability despite a multiplicity of choices, because some of the choices are better than the others. I have never heard of any analogous selection principle being offered for string vacua. Am I missing something?

From my perspective as an outsider, it looks like faced with the problem of there being more than one potential QFT which produces the Standard Model at low energies, physicists seem to have coped just fine with picking the QFT to use going forward; they even seem to be coping with this problem in extending the Standard Model, we have things like the MSSM and the minimal dark matter model (chosen as I understand based on the simpler-is-better rule). But what would physicists do when faced with more than one potential string solution that fits experiment at low energies? You say what you need for predictivity is a vacua-construction method; if you had one, what would you do with it? I'm not trying to be snarky or difficult, I'm just trying to understand what the procedure here would be.

49. **Mikael**
July 29, 2008

Peter,
I think it was good (or at least necessary) you wrote the book.

You know, what really strikes me is that even a guy like David Gross seems to have become a little more skeptical about string theory in recent years. You'd think that somebody like him as an independent thinker would give a damn about such books and still he seems to have been influenced by this ongoing discussion.

50. **Peter Woit**
July 29, 2008

Coin and Somebody,

Claiming that the situation of QFT (which makes a huge number of non-trivial, verifiable predictions of high accuracy), and string theoy (which predicts absolutely nothing) are the same is just sophistry. QFT would be in the same situation as string theory if simple QFTs didn't work, so you had to keep adding more fields and complexity, just to evade falsification, ending up with a complicated mess, unusable for predictions. That's where string theory is now, it's not where QFT is.

51. **somebody**
July 30, 2008

"Claiming that the situation of QFT (which makes a huge number of non-trivial, verifiable predictions of high accuracy), and string theoy (which predicts absolutely nothing) are the same is just sophistry."

The entire conversation was about an idealized scenario IF we had model-building freedom in string theory. And there, sorry, I still stand by my claim.

Incidentally, "sophistry" implies malicious misrepresentation. Lets avoid personal commentaries and attacks in discussions of physics, shall we? I just want to nip it in the bud because I have seen (as I am sure you have) this sort of thing degenerate into online foodfights.

"QFT would be in the same situation as string theory if simple QFTs didn't work, so you had to keep adding more fields and complexity, just to evade falsification, .."

The real reason why we are forced to complexities in string theory is because we are tied to certain kinds of models because of the technical tools we have for model-building. Its like trying to build a ladder, but only using forks. It is entirely unlike the situation in QFT where you have the freedom to build models following ideas, and not technical tools.

Also, "simplicity" is an extremely slippery fish when you are only in the phase of trying to understand the (non-perturbative) principles of the theory. If we did not know about non-Abelian gauge symmetry of the Lagrangian description, there is no sense to saying that a QFT is "simple" because the gauge groups are. If somebody just gave you a bunch of rules for constructing messy scattering amplitudes, we would first have to come up with a (non-perturbative) Lagrangian description before even having a notion of "simplicity" of that description. This is EXACTLY the state in string theory. So it is really not clear to me what is the simplicity that we should expect from string theory at this stage.

Again, if you notice, both these issues stem from the lack of understanding/control we have of string theory. I am entirely willing to give you that these are real problems, and not merely details, but if you give me those, I find no reason whatsoever why it is any less of a framework predictively than QFT. Besides, I know that it gives me many generic features of particles physics, I know that it has all the expected features of a quantum gravity including black holes (at least once we fix the asymptotic boundary), and that it seems to incoroporate and generalize the most successful ideas in physics like gauge symmetry, spacetime geometry etc. It seems crazy not to want to understand that structure.

52. **somebody**
July 30, 2008

Coin,

If there is more than one model that fits data at low energies, it is no longer within the realm of science to want to distinguish them while doing only low energy experiments. What we call the standard model is merely a collective tag for all models that look like it at low energies. We can have more resolution in the space of theories only as we probe higher energies. The real problem with the low energy physics of today is that we know it has to fail being consistent at some scale because of gravity etc. So we know it cannot be the thing. If we understood string theory better, we could do UV complete model-building.

To make any successful model, we need ingenuity and creativity like Weinberg and Salam had back in the day. I am saying that one way in which string theory could deliver (one of the more unlikely ways, actually), is by being such a PARADIGM in which one can exercise that creativity.

There are many questions to ask here, and many string theorists would not be happy with this possible paradigm that I am suggesting here. But thats only because the ways in which truth is going to be realized in the future is vague speculation at this point. The only real way to find out is to work. My point was only that the blanket statements that people make about predictivity are often a result of confusing between preditivity with uniqueness. So I was demonstrating by a scenario that uniqueness and predictivity are entirely different beasts.

I am kind of busy, so perhaps this message is not very clear.

53. **stranger than fiction**
July 30, 2008

> The public opinion is relevant to the question what fields are generally of importance for our societies and how money should be invested to be as beneficial as possible, but the public never 'votes' on research funding on the specialist level. There is a reason why funding agencies have an elaborate referee process.

Sure but what are you willing to pay back?

String theorists paid back a little in the form of launching "The Elegant Universe" into popular culture and speculative articles and popular science books and TV shows on how string theory changes our view of the universe. I think that's part of the role science has to play within a culture that *believes* in science and funds the creation of a particular world view and appreciates the scientific method.

I'm not sure how this process can be avoided? Physics is not an auxiliary science that can hide itself into obscure academic discussions but the very foundation of the big picture. In that sense I also do understand physicists like Susskind who try to launch ideas that are compliant with our knowledge of the universe although they aren't empirical. It is correct that they are used to avoid the capitulation of string theory where they arise from but in the absence of a stronger alternative they also avoid capitulation of fundamental research. It compromises empirism in favour for science as a belief system that lets research continue as it is. This is less ironic in the sense that we in fact know it is not true but it is paradox: it lets something work by virtually terminating it.

Back to the public audience. You can't avoid paying back and becoming criticized for poor gifts, but the public has also no alternative to take what you give them unless it wants to give up their faith in reason and embraces either scepticism (postmodernism) or old obscure gods.

54. **Dexter Johnas**
August 1, 2008

Sitting in the attic? Ha, all the better, that's always a fun place to be curled up with a book, or in this case a cam. Great discussion. So much talk about string theory.

55. **Daniel de França MTd2**
August 5, 2008

Since this post is about videoblog, recently lubos made a post on Youtube concerning criticism of string theory. The tone is very light heart, I was really surprised.

http://www.youtube.com/watch?v=5ZxPTRfztsE

56. **Daniel de França MTd2**
August 5, 2008

Sorry about the post, I found it at http://dorigo.wordpress.com/2008/08/01/new-bounds-for-the-higgs/#comments , but I couldn't refrain from posting here. It just shows the guy on a different light.

57. **Chris Oakley**
August 6, 2008

I saw Lubos's YouTube effort and remained puzzled as to why he chose to post it. The only thing I can think of is that it is a coded message to his (alien) controllers, pleading for clemency following the initial failure of his campaign to subvert terrestrial science.

58. **GC**
August 23, 2008

I don't remember it adding multiple trackbacks here in the past like it did now, and I nearly always edit my posts after I publish them. Even now, I saw a few edits I'd like to make, but I'll wait until later to see if does it again.

ICHEP 2008

August 4, 2008
Categories: Experimental HEP News

A major HEP conference, ICHEP 2008, is taking place in Philadelphia at the moment, and many of the talks are already available online here. This is mostly a conference devoted to experimental HEP, and the big news is the joint announcement by CDF and D0 that they are just barely able to exclude, at 95% confidence level, the possibility of a Higgs with mass of 170 GeV. This is the first new information about (ignoring neutrinos…) the one remaining parameter of the Standard Model since LEP showed that the Higgs mass can't be below 115 Gev. For more about this, see Sunday's ICHEP plenary talk by Matthew Herndon.

Also announced at ICHEP and providing constraints on the possible Higgs mass are new fits using precision electroweak measurements. Tommaso Dorigo has a nice explanation of this story in a new posting here. Don't miss the comment section, which has a hilarious exchange between Lubos and an anonymous physicist who can't believe what is going on, asking Tommaso to check IP addresses to see if someone is impersonating Lubos. The point of physics being discussed is an extremely interesting one, but the mode of discussion ensures that enlightenment will not result.

Lyn Evans of the LHC gave a report on its progress. They expect to first try to inject a beam about a month from now, with first collisions and data maybe two months later, at 10 GeV center of mass energy. Evans is guessing that luminosity in 2008 will be about 10 pb^{-1}.

This morning, Joe Polchinski will give the plenary talk on "Recent Progress in Formal Theory", and Witten gave a public lecture Monday night. Nima Arkani-Hamed was supposed to give a "Concluding Inspirational Talk", but that appears to have been canceled.

Update: It's worth noting that the Higgs mass getting excluded is right in the middle of where Alain Connes's prediction from his NCG model comes in. Connes has a new blog posting about this here, where he admirably notes how discouraging this is for his model. Jacques Distler has a quite good new posting about the NCG model here.

More about this from Gordon Watts here.

Comments

1. **somebody**
   August 5, 2008

   Thanks for the link to Tommaso's blog.

   I must say that I have not been able to gather the verdict on the debate between Lubos and Guess Who. Does the experimental data that Tommaso presents constrain any effective Higgs that does the job of electroweak breaking? Or does it assume certain classes of models for Higgs (like simple SM Higgs or MSSM Higgs doublet)? Lubos seems to be arguing for the former while Guess Who seems to be arguing for the latter (specifically, that technicolor models need to be dealt with separately).

   Much as I would hate teaming up with Lubosian lunacy, I must say that I find Guess Who's claim suspicious, and if true, something of a letdown – I was hoping that those curves were "really" constraining the Higgs.

2. **Peter Woit**
   August 5, 2008

   somebody,

   Those curves are based upon a straightforward fit to the SM model, so they tell us where the Higgs is going to be found if we have just the SM, but I don't see how they tell us in general about very different models. The argument about whether they "favor supersymmetry" just seems empty to me. As for whether Lubos or "Guess Who" knows more about what they are talking about here, that's a point that doesn't seem arguable at all…

3. **DB**
   August 6, 2008

   A Russian Academician has leaked the inauguration date for the LHC: October 21st.

   http://en.rian.ru/world/20080805/115771418.html

4. **Chip Neville**
   August 6, 2008

   Peter,

   This is off topic, but Sean over at Cosmic Variance has a very nice rundown on what the LHC is likely to find, and not find, here.

5. **Peter Woit**
   August 7, 2008

   DB,

   I thought that date had been public knowledge for quite a while. Those here who predicted that CERN would do everything it could (including lowering the energy of the beams) to get beams in the machine by the inauguration date were on the money.

6. **John Baez**
   August 9, 2008

   Peter wrote:

   > they are just barely able to exclude, at 95% confidence level, the possibility of a Higgs with mass of 170 GeV.

   Of *exactly* 170 GeV? I think I can exclude that with 95% confidence without even doing any experiments. 🙂

Of *less than* 170 GeV?

Within *some range* of 170 GeV?

7. **Peter Woit**
   August 9, 2008

   John,

   What is being excluded at 95% confidence level is some small mass range about 170 GeV. The experiments don't quote a range, and it appears to me that this is because, however they have binned their data, they are just able to get above the 95% confidence level at one bin, that at 170 GeV. Under the circumstances, quoting any particular small range about 170 GeV wouldn't be very meaningful.

8. **Coin**
   August 9, 2008

   A Russian Academician has leaked the inauguration date for the LHC: October 21st.

   I'm looking at this press release which says that the "first attempt to circulate a beam" will be september 10, and that they're this weekend (this is apparently confirmed at uslhc.us) doing the first beam tests of any sort.

   Does this information alter the Novosti article, or is it just describing something different? Is the idea that the "inauguration" on Oct. 21 the same as first physics collisions, and the september 10 event will be the first full-power full-circulation beam test?

9. **Peter Woit**
   August 9, 2008

   Coin,

   The October 21st event is a ceremony for dignitaries (including President Sarkozy I believe) that was planned long ago. It doesn't correspond to any particular state of progress of getting the machine into operation.

10. **Coin**
    August 10, 2008

FQXI and Templeton News

August 5, 2008
Categories: Multiverse Mania

The FQXI organization has just announced the details of $2.7 million dollars in grants that it will be handing out. The winners and their projects are described here. As usual, one of the main topics funded by FQXI is multiverse studies. There's also another news story on the topic from them here, which examines the question: "Are we in danger of a fatal crash with another universe?"

At the same time, FQXI announced an essay contest on the topic of "The Nature of Time", first prize is $10,000.

FQXI is funded by the Templeton Foundation, an organization whose goal is to bring science and religion together. The founder of the Foundation, Sir John Templeton, died last month at the age of 95, leaving his son in charge of the place. While the father seems to have been a rather Unitarian sort, the son Jack is the money behind the right-wing PAC Let Freedom Ring. Sir John's death will provide Jack Templeton with a lot more money to spend. The Chronicle of Philanthropy has a story about this, which explains that the plan is to hire new vice-presidents, with the goal of coming up with new ideas of how to spend more money to support free enterprise and virtue. Not clear yet what this means for FQXI, or for some of the other physicist beneficiaries of Templeton largess over the years.

Comments

   August 5, 2008

   I sincerely wish the interest among cosmologists in multiverse story-telling were due to evil influence and money from quasi-religious lobby groups as you keep insinuating. But it isn't. The Templeton foundation has no influence on the scientific decisions of FQXi.

2. **H-I-G-G-S**
   August 5, 2008

   Based on title alone, my favorite award is:

   Peter Byrne, Oxford University Press, $35,000, The Devil's Pitchfork: Multiple Universes, Mutually Assured Destruction, and the Meltdown of a Nuclear Family.

   In an ideal world Mr Bryne would soon announce that this was a Sokal-like hoax, but I fear we do not live in an ideal world.

3. **Peter Woit**
   August 5, 2008

   H-I-G-G-S,

   Actually, it seems to me that's one of the better grants. It's not a grant supporting science, but rather the writing of what sounds like an interesting book about Hugh Everett.

   Urs,

   I don't claim Templeton is giving money to scientists and telling them to work on the multiverse. When it decided to fund FQXI, it was backing two scientists (Aguirre and Tegmark) who are among those most interested in multiverse studies. I think this reflects the Templeton point of view on science.

   FQXI says that its grants "target research unlikely to be otherwise funded by conventional sources." Some of these grants, e.g. the one to Linde, are for what appears to be mainstream research conducted by a prominent scientist at a leading institution, research that one would normally expect to be funded by NSF/DOE. Does this mean that NSF/DOE peer review panels are refusing to fund multiverse research? If so, what does it mean for the field to have a very wealthy private group devoted to promoting religion come in and heavily fund this research, when the physics community as a whole doesn't think it deserves support?

4. **Professor R**
   August 5, 2008

   Essay contest on the topic of "The Nature of Time"?

   I like the sound of that, and the max length is 5000 words, good scope there. Less impressed with the judging method – on the form, you are invited to suggest 3 reviewers. Hmm.

   P.S. The London THES used to have a competition like this, pity they stopped it

5. **JC**
   August 5, 2008

   If string theory ever lost a significant proportion (or all) of its NSF/DOE funding, what are the odds that they will resort to Templeton funding?

6. **Elisha Feger**
   August 5, 2008

   It's fine to be suspicious of the source of funding for people's work, but ultimately I think it's better to have more money available to go around. Yes, it means more crap will get published. It also means more good work will get funded. If nothing else it takes some of the pressure (political, social, and otherwise) off of the NSF and other governmental actors to fund the latest fad when there are private foundations giving out money as well.

7. **Coin**
   August 5, 2008

   Actually, it seems to me [The Devil's Pitchfork: Multiple Universes, Mutually Assured Destruction, and the Meltdown of a Nuclear Family.]'s one of the better grants. It's not a grant supporting science, but rather the writing of what sounds like an interesting book about Hugh Everett.

   …huh. Speaking as a long-time fan of a band called the Eels, whose frontman and only static member ("E") I later found out was Hugh Everett's son, I'm actually rather curious about that.

(A lot of the Eels songs make oblique reference to E's troubled family life, which was something that left me suddenly curious for details once I found out who E's father was. Actually looking on the website for the Devil's Pitchfork guy I find he's got kind of a short prototype version of his book up, wherein he notes Everett's son, the Eels guy, actually wrote a memoir called "Things the Grandchildren should Know"… very interesting!)

8. **Tony Smith**
August 5, 2008

From glancing at the 2008 FQXi award list, I noticed a few institutions with more than one award winner:

UC Berkeley – 3
Oxford University – 2
Theiss Research – 2
Tufts University – 2

What might account for their success?

Tony Smith

9. **Kea**
August 5, 2008

I have at least heard of all but three of the awardees before. Many are well known and many of them know each other (I know this first hand). And Aguirre had the audacity to tell me that the judging was in no way biased!

10. **Peter Woit**
August 5, 2008

Tony,

The 3 from Berkeley probably just reflects the fact that Berkeley is a very large university..

11. **Nigel Cook**
August 5, 2008

'I sincerely wish the interest among cosmologists in multiverse story-telling were due to evil influence and money from quasi-religious lobby groups as you keep insinuating. But it isn't. The Templeton foundation has no influence on the scientific decisions of FQXi.' – Urs.

Yes, I believe that – because it's not the Templeton Foundation that's to blame for scientific decisions in handing out the rewards, but the scientists they choose to make the decisions! Any ideas about who makes the decisions, Urs? Not the multiverse and string theory fanatics, I presume.

http://golem.ph.utexas.edu/category/2008/05/fqxi.html

'I agreed to participate in the review panel of FQXi's new round of grant competition.' – Urs Schreiber

12. **bob**
August 5, 2008

Concering the two Oxford affiliates, Julian Barbour is completely self-funded and has always been. Since he lives close to Oxford the philosopy of physics group here provides him with an affiliation so he can get library access etc, but he never got a penny as far as I know. He more than anyone is someone who decided very early in his career that institutions aren't going to make him do good science. It's great to see him get funding. Myself I found `refuge' in a computer science department, and this grant enables me to do foundations of physics stuff, and hire someone who otherwise would have a hard time getting a postdoc job given his field. While there is much activity here on many worlds/universes etc, neither Julian Barbour nor I have any interest in that stuff.

13. **A.J.**
August 5, 2008

Nigel,

Urs is about as far as one can get from being "a string theory & multiverse fanatic". But don't let that stop you from talking trash.

14. **Esornep**
August 5, 2008

PW said: "If so, what does it mean for the field to have a very wealthy private group devoted to promoting religion come in and heavily fund this research, when the physics community as a whole doesn't think it deserves support?"

Since when does "NSF = physics community as a whole"?

If indeed Linde has trouble getting money from the NSF, something I find hard to believe, then this is an appalling piece of incompetence on the part of the NSF. And it if is true, then all the more we should thank Aguirre and Tegmark et al for getting hold of money for people who want to do interesting research.

15. **Urs Schreiber**
August 6, 2008

Peter,

it seems to me that valid criticism of certain points — which might potentially lead to controversial but constructive discussion — is at risk of being diluted if accompanied with what comes across, if I may say that, as more or less random mud-slinging that linearizes a complex reality to what almost sounds like a Brownian conspiracy plot. In reality the issues — which are there — are much more mundane.

16. **Peter Woit**
August 6, 2008

Hi Urs,

I agree with you. I was initially about to delete the hostile comment from Nigel Cook (as I delete a lot of comments here…), but thought the link to your posting was valuable. So, then I thought about somehow extracting the link and posting it separately, or editing the comment, finally decided it was better to just let this one through. Anyway, all, I'll be even more vigilant in deleting empty hostility from now on….

I'd certainly be curious to hear your thoughts on some of the more interesting questions the FQXI grant decisions raise. It's obviously a difficult task to choose among unconventional research that the usual funding sources and many people would dismiss, trying to identify what deserves support. Much of the FQXI list is a reasonable take on this, and those like you who spent time working on this deserve thanks. If people want to discuss this aspect of FQXI, one place to do it would be Kea's blog

http://kea-monad.blogspot.com/2008/07/fqxi-proposal.html

where you can see what this looks like from the point of view of an unsuccessful applicant.

While I can see how these decisions probably went, the thing that I'm more curious about is the decision to fund research that I would have thought couldn't possibly qualify as "unlikely to be supported by conventional funding sources". Linde, Vilenkin and Bousso are among the most prominent people in their fields, working at major institutions, giving high-profile talks at conferences, appearing regularly in the press, etc. On the one hand anthropic multiverse proponents regularly claim that their view is increasingly the dominant, conventional one in the field, here we have FQXI saying this is unconventional research that can't get funding elsewhere. Which is it???

One other decision about "unconventionality" that I found odd was that about Subir Sachdev's proposal. He's a Harvard professor, and as far as I can tell the topic of using AdS/CFT to do condensed matter physics is one of the hottest topics in string theory. A Harvard professor proposing to work on one of the most fashionable topics around is something it is hard to see as unconventional. Maybe this has something to do with the politics of condensed matter research funding, where I guess this might look unconventional, even if it is highly conventional from the string theory side.

17. **Belizean**
August 6, 2008

Confusion about Templeton funding conventional research by established researchers in venerable institutions might be eliminated by the considering the foundation's apparent objective: to purchase legitimacy.

18. **Anthony Aguirre**
August 6, 2008

Hi All,

I think this discussion is valuable, because FQXi is continually working to improve how well it serves the scientific community, and because it struggles with these very same issues. There are a few comments it might be worth making from the 'inside' perspective.

1) This is hard. The questions you have been raising are tricky, and the grant panels don't get the luxury of just complaining or applauding — they have to actually weigh all of these factors and make decisions. I would also say that the panelists are talented, careful, fair, and very open-minded people making decisions on the very criteria that are contained in the FQXi request for proposals. I think they have done a great job and am grateful for their somewhat painful decision making.

2) To those that complain loudly that their application was unsucessful, I would say: I'm sympathetic, but welcome to the club! Even top scientists *often* have proposals rejected. FQXi funded 33 grants (and many with reduced budgets) out of 190ish initial proposals. The NSF often funds 10-20% of theirs.

3) "Well-known" and "at a top institution" often means "well paid" but it does not always mean well-funded. In some cases, you'd be surprised. Also, in some cases grants going to "famous" people support postdoctoral positions and are in that way really supporting less-known researchers.

4) Specifically, in terms of the multiverse, I would say that these proposers simply out-competed many others. A great majority of the top people in this field applied, and they wrote good proposals. Number of well-written proposals arguing *against* the multiverse, or suggesting compelling alternative early-universe scenarios: small or negligible. I think the panel would have more than welcomed them.

5) Along these lines, while I'm very happy for FQXi to be funding what it did, to those that have more negative views, I would say: write better proposals! There are some great people from whom I would personally have liked to see proposals but didn't. And there are others from whom I would have liked to see different (more unconventional or bold, perhaps) proposals. And there were lots of proposals that just did not make as compelling case as they could have.

6) More money would also help. Tell your rich friends. While the Templeton Foundation has generously funded FQXi's first years of operation and *appear* to like what we are doing (they are in fact very hands-off), they have given no guarantee of future funding.

19. **Peter Woit**
August 6, 2008

Anthony,

Thanks for the comments on this. Good luck finding suitable funding for the future….

20. **Esornep**
August 6, 2008

My comments are directed to Anthony Aguirre.
[a] You're doing a great job! Really. This thing really boosts morale, even for people like me who did not apply. Keep it up!
[b] Are the recipients of last year's grants encouraged or required to report on the progress they have made? I am *not* thinking in terms of "accountability", I'm just thinking that most of the projects looked really interesting and I just want to know what the recipients did, even if no spectacular progress was made. I realise that this would have to be handled diplomatically, but could you ask them to tell us what they now think is the state of the art in their respective fields? That would be useful and interesting.
[c] You say "There are some great people from whom I would personally have liked to see proposals but didn't. " Did you write to these people to encourage them to apply? Whatever their reasons for not applying, I'm sure that they would be deeply grateful for such a letter.

In that connection: PW points out that some leaders in the field have the habit of claiming that the multiverse view is the dominant one in some sense. The reality is somewhat more complex. Last year I submitted a multiverse paper to [famous journal] and the editor returned it saying that they felt it was too speculative. I subsequently published it in [equally famous journal]. I suspect that the truth is that the acceptabilty of papers on this subject is strongly dependent on the name of the author and/or his affiliation. Hence my references to morale-building.

21. **Peter Woit**

August 6, 2008

Esnorep,

It does seem that the legitimacy of multiverse research remains a contentious issue. Unfortunately, to me the morale of its proponents seems all too high…..

22. **Daniel de França MTd2**
August 6, 2008

@Anthony Aguirre

"Number of well-written proposals arguing *against* the multiverse, or suggesting compelling alternative early-universe scenarios: small or negligible."

So, next year, I foresee a great number of people applying against The Flooding and astrology.

23. **V.T.**
August 7, 2008

> "Number of well-written proposals arguing *against* the multiverse, or suggesting compelling alternative early-universe scenarios: small or negligible."

Maybe this deserves further qualification:

a) the "multiverse idea" may be quite correct and still problematic as a research topic at the moment: there is so very little known on which to base concrete scientific discussion on.

Similar problems exist for potentially scientific topics such as, for instance, extraterrestrial life: while it may well exist, at the present stage a scientific article on this topic is bound to be lacking a basis.

So one may not want to argue against the "multiverse idea" and still feel troubled by the amount of attention it is getting. Whereof one cannot speak (yet) thereof one must be silent, as the saying goes.

b) It seems one should clearly distinguish between, on the one hand, relatively concrete and valuable aspects of the "multiverse scenario" where concrete cosmological models are treated, which can be handled quantitatively in terms of equations to some extent and — on the other hand — general far-out non-quantitive speculations inspired by the "multiverse idea". The main concern about research inspired by the "multiverse idea" that I have seen is that the latter aspect is tending to dominate the former.

24. **Chris Austin**
August 7, 2008

Hi Anthony Aguirre,

Perhaps I could make a comment about the 500 word limit on the initial proposal. Of course I appreciate that there has to be some reasonable limit on the length of such initial proposals. I sat down to try to write the most concise summary possible of what I wanted to do, and then counted the words, which unfortunately came to about 1500. I then tried to reduce this down to 500 while still presenting something coherent, and by the time I had finished, there was nothing left but parts of the first and the last paragraph, with most of the summary of the proposed work gone. So I was not really surprised when my initial proposal was rejected. Of the 500 words, approximately the last 250 were taken up by demonstrating that my proposal was topical, foundational, and unconventional.

Best regards,
Chris

25. **Anthony Aguirre**
August 7, 2008

Esornep:

a) Thanks for your kind words!

b) Yes, FQXi requires that the grantees send annual renewal applications (for multi-year grants) and final reports for all grants. We keep track of the publications associated with each grant as well. We don't display all of this in public, but do take care that grantees are doing something like what they said they would, and that for funding to be continued after the first year, that they are actually making progress.

c) No, FQXi did not really reach out to individual researchers. I feel that the desires I mentioned are more my personal wishes as a researcher than something to be pushed with my FQXi hat on, where my main goal is to be evenhanded and not push any particular agenda.

VT and Daniel de Franca:

I agree that the people most likely to point out actual problems with the multiverse idea are those that take it seriously and actually work on it. Indeed, some of the strongest and most detailed criticisms of mulitverse ideas are in papers of mine, though I might reasonably be termed a 'multiverse aficionado'

I also strongly agree that it is important to distinguish between various versions of the 'multiverse', since some (like different Hubble volumes) are completely innocuous and hard to avoid, whereas others (such as the ensemble of all possible conceivable universes) seem nearly impossible to test or even discuss with any rigor.

Chris:

Thanks for this — it is something we have been considering for future rounds: 500 is a real challenge for both proposers and reviewers.

26. **Physics Professor**
August 7, 2008

Does anyone know what the "giant void" is that is mentioned here?

http://www.fqxi.org/large-grants/awardee/details/2008/mersini-houghton:

"One of our predictions here, the existence of a giant void was confirmed by observations only 7 months later. "

Where was this giant void observed? When was it predicted?

27. **Peter Woit**
August 7, 2008

Physics Professor,

That claim was covered in an edition here of "This Week's Hype"

http://www.math.columbia.edu/~woit/wordpress/?p=621

28. **Physics Professor**
August 7, 2008

Thanks Peter,

Now it all makes sense.

The giant void and multiverses were created to contain the FQXI funding and protect physicists from it.

29. **Esornep**
August 7, 2008

Anthony: sure, I have no doubt that you keep an eye on how the money is spent, but what I meant was that *I* [and others] would just like to know how the awardees are going. I'm not suggesting that they be forced to make this public, but perhaps they could be encouraged to do so? A lot of very interesting stuff there!

AA also says: "I also strongly agree that it is important to distinguish between various versions of the 'multiverse', since some (like different Hubble volumes) are completely innocuous and hard to avoid….."

Exactly. I think that critics of the multiverse should begin by familiarizing themselves with the paper that started it all: Coleman and De Luccia 1980. I assume that PW and other critics would not regard Coleman as a pseudo-scientist, yet he and De Luccia explicitly consider the possibility that *our* Universe is the interior of a CDL bubble. Granted that we live in what is probably an eternally expanding universe, the onus is on the critics to show that CDL bubbles can't form, or that if they do form they can never resemble our Universe, etc etc etc. Likewise *if* our universe is infinitely large: if you don't like the consequences of that, write a paper showing that the idea is inconsistent with something. Too much of the anti-multiverse polemic takes the form, "Gee, that's really weird, therefore it's ridiculous to think about it!"; the critics don't seem to realise that a multiverse *seems* to be an inevitable consequence of our current [observationally favored] theories. [It may not be, but showing that would be a diffcult technical exercise.]

In short: if you don't like it, master Coleman and De Luccia and write a paper proving that they made some fatal mistake.

30. **Peter Woit**
August 7, 2008

Esnorep,

I don't know of any way to use Coleman – De Luccia to make any testable predictions about anything. Do you? The problem is not a fatal technical mistake in their work

I'm a skeptic about the possibility of multiverse studies leading to anything testable in observational cosmology, but willing to admit that such a thing is not in principle inconceivable. I just don't see any evidence of this going anywhere.

My main interest though is not in cosmology but in particle physics. It is there that the "string theory anthropic multiverse" is out-and-out pseudo-science, nothing but an attempt to find some way of refusing to admit the failure of the string theory unification program. Promoting this to young scientists and to the public is having disastrous effects on the subject and how it is perceived.

31. **Richard**
August 7, 2008

Several years ago there was a single panel cartoon in the newspaper called I Need Help that pointed to where we may look for evidence of a multiverse.The caption on top of the panel says "In a parallel universe, not far from out own …". Within the panel, a woman has just removed clothes from a dryer, and she's holding a pair of socks in front of her. She exclaims,

"For cryin' out loud … extra socks again!"

As a bonus, this may also suggest a new law of physics: conservation of socks.

Hmmm, maybe I should quit working on topological dynamics tonight and head to the basement and start disassembling that dryer. I wonder if I could get a grant …

32. **somebody**
August 8, 2008

"I don't know of any way to use Coleman – De Luccia to make any testable predictions about anything. Do you? The problem is not a fatal technical mistake in their work."

If there is no mistake, why do you reject the consequences of it? If you agree that Coleman – De Luccia is a consequence of standard QFT and gravity, I don't see how you can justify NOT pushing forward so we either understand the consequences of tunneling between universes or see a contradiction. Like (penrose)^T says, most of the criticism about this issue is knee-jerk, many examples of which you can see on this thread.

Besides, I don't see why it is it manifestly impossible that there cannot be any signatures of tunneling. A tunneling bubble is a like an expanding cavity, and cavity-radiation can leave signatures on the CMB (for instance), depending on the ambience into which it expands. To see whether it is actually measurable or too small, is an actual computation and no amount of talk will settle it. This is just one example.

"I don't know of any way to use Coleman – De Luccia to make any testable predictions about anything. Do you? The problem is not a fatal technical mistake in their work."

Here is an example for non-testability which is actually even worse (not even direct CMB is not of much use here):

Hawking radiation (and for that matter most of black hole physics) does not make any testable predictions either. By your standard, a tremendous amount of intelligent extrapolation that we currently call theoretical physics will have to go out the window. I am not saying that this is not a reasonable view to hold, but I am saying that it is not very meaningful then to complain against this or that specific issue.

Testability is certainly important, but the way you are proposing it here sounds like a very short-sighted way to go about it. You give absolutely no value to what many people would call "understanding" or "insight". I think most practicing theoretical physicists will be of the opinion that thinking about black holes, tunneling etc. has taught us the few things that we actually think we know about quantum gravity.

33. **woit**
August 8, 2008

Somebody,

You are completely ignoring what I wrote and arguing against a straw man. What you quoted was just a response to the suggestion that if one doesn't like the multiverse hype, the only thing to do is to find an error in Coleman De Luccia. The problem that concerns me has nothing to do with the technical validity of that calculation.

I'm all in favor of speculative research devoted to trying to better understand physics at the deepest level, even when this research is still far from being able to make experimental predictions. That's actually what I spend much of my time doing. What I'm not in favor of is pseudo-scientific research aimed not at getting a deeper understanding, but at avoiding admitting the failure of an enterprise that many people have a lot invested in.

34. **Esornep**
August 8, 2008

The point is that there are many *kinds* of multiverse research, ranging from concrete calculations and — yes — predictions [such as the kind of work Anthony Aguirre, and several others, have been doing] to much more way-out stuff. Likewise, some of it is closely related to string theory, while a large amount [such as anything connected with CDL bubble universes] has nothing whatever to do with string theory, except that string theorists hope that it might instantiate their Landscape. On the other side, critics range from whackos who think that *all* talk of multiverses is evil or laughable, right up to people who have concrete technical reasons for thinking [for example] that the string landscape does not exist. *It is important to be precise about where in these spectra one stands. *

PW says: "I just don't see any evidence of this going anywhere."
Well, I don't see any evidence of geometric Langlands going anywhere of interest to physicists. In fact, nobody has explained what that stuff would be good for even if geometric Langlands turns out to be a "success". So what? I hate most kinds of white wine. Do you care? Shall I set up a blog called "Not Even Vinegar"? Well, blogs are often nothing but a way to vent, but I think you hope to achieve more than that…..

Short version: the perception many people get [see Urs' posts] is that you, PW, are dismissive of *all* multiverse research, think that it is the work of shadowy cult-like crypto-fascist organizations, etc. It now appears that we may have been mistaken about this, since you are "willing to admit that such a thing is not in principle inconceivable" but you really can't blame us when you see a post like this one. Nor can you blame people for feeling offended.

35. **Peter Woit**
August 8, 2008

Esnorep,

I think it is highly misleading to claim that multiverse research has produced predictions. Finding some scenario (for which there is not the slightest evidence now) in which some small imprint of the universe before the big bang appears in the CMB is very different than coming up with a testable prediction based on invoking a multiverse. For one thing, the multiverse hypothesis can't be falsified this way.

I've never made any comments about "shadowy cult-like crypto-fascist organizations". I've made very specific claims that the Templeton foundation likes to fund multiverse pseudo-science because they're explicitly in favor of blurring the boundaries of what is science and what isn't. Scientists should be worried by this kind of thing.

If multiverse proponents find my comments offensive, too bad. I find what most of them are doing offensive pseudo-science. No, it's not all the same. Some of it is science, although of an extremely speculative sort that has not led anywhere, and for which there are good arguments that it can't. Much of it though is nothing but a bald-faced attempt to avoid admitting failure by trashing the scientific method.

Geometric Langlands may or may not lead to anything important in physics. But even if it doesn't, it's definitely important mathematics, and worth attention because of this.

36. **gs**
August 10, 2008

Dear somebody,
CDL obtained their results by boldly applying the semi-classical Euclidean path integral methods to the case of gravity. Do you know of any calculable settings (AdS/CFT, matrix theory?) in which the formation of CDL bubbles has been demonstrated?
Cheers

37. **Terry Hughes**
August 13, 2008

Practical application of the "multiverse" concept exist! Here's one as summarized in Wikipedia [http://en.wikipedia.org/wiki/Sinestro] which might be especially important since Warner Brothers has just greenlighted a new Green Lantern movie:

52 Multiverse

In the final issue of DC Comics' 2006-07 year-long weekly series, 52 #52, it was revealed that a "Multiverse" system of 52 parallel universes, with each Earth being a different take on established DC Comics characters as featured in the mainstream continuity (designated as "New Earth") had come into existence. The Multiverse acts as a storytelling device that allows writers to introduce alternate versions of fictional characters, hypothesize "what if?" scenarios, revisit popular Elseworlds stories and allow these characters to interact with the mainstream continuity.

The 2007-08 weekly series Countdown to Final Crisis (or simply Countdown) and its spin-offs would either directly show or insinuate the existence of alternate versions of Sinestro in the Multiverse. For example, Countdown #16 detailed that the Sinestro of Earth-51 has been murdered by the pro-active Batman of his world, in a crusade against its villains. Countdown spin-off series Countdown Presents: Lord Havok and the Extremists depicted a version of Sinestro in its 3rd issue (2008) from an alternate world referred to as "Green Sinestro", depicted as a part of the villainous Monarch's army. This version has his original green power ring, but is no less vicious than his mainstream continuity counterpart and the official designation of his world is unrevealed.

38. **Coin**
August 14, 2008

Hi Terry,

The problem with comic-book-based predictions is that predictions concerning superhero comics are as a rule not *falsifiable*, due to comic authors' tendencies to retcon everything and anything the instant it would be convenient to some particular plot. As a result of this effect any statement you can formulate concerning comic characters or universes will, with probability approaching one as time goes to infinity, at some pair of points have been both true and false respectively, thus making it impossible to ever to satisfy the Popperian criteria

39. **Terry Hughes**
August 14, 2008

Coin,

Yes, yes, what you say makes good sense. On the other hand, what you say also seems to apply as well to string theorists as it does to comic book authors, which is probably your pretty subtle and witty point. In fact, I would argue that there seems to be more in the way of reality checks and falsifiable predictions in the DC multiverse theory than in, say, the Suskind Theory(ies) and other multiverse theories that have been subject to more extensive academic analysis. As a preliminary matter, let's not forget that the DC Theory POSTDICTS all prior developments not just of Green Lantern but in the entire Justice League of America ouevre, which is surely as impressive as string theory postdicting gravity in the wrong dimensions. And the DC Theory actually predicts that there are EXACTLY 52 alternate universes and that the Sinestro in Universe 51 has a GREEN power ring (not yellow, as in our universe). Those are predictions one can get one's hands on, at least in principle. I would have thought that it was as important to any good multiverse theory to predict an exact number of multiverses as it is for a good piano to have exactly 88 keys. But what the hell do I know?

Peter,

You wrote:

> I'm all in favor of speculative research devoted to trying to better understand physics at the deepest level, even when this research is still far from being able to make experimental predictions. That's actually what I spend much of my time doing. What I'm not in favor of is pseudo-scientific research aimed not at getting a deeper understanding, but at avoiding admitting the failure of an enterprise that many people have a lot invested in.

If I understand correctly, your foundational studies likely focus on "not just unification of physics, but unification with mathematics…"

I've been trying to understand if this should be interpreted as "unification [of physics] with mathematics…," or "unification [of] mathematics…"

I would really appreciate any clarification of this you might feel inclined to offer, but in either case, do you think you could ever see yourself writing a FQXI proposal (or essay), based on your thinking along these lines?

41. **Peter Woit**
August 14, 2008

Doug,

Personally I believe that deep mathematical ideas and deep ideas about physics tend to come together, so, sure, there is some deeper unification of physics and mathematics out there that awaits our understanding. We'll see.

At the moment I don't have any particular need for grant funding so I'm not about to apply for any from FQXI or anywhere else. I don't have an absolutist position that one shouldn't take money from organizations whose goals one disagrees with, but I do think one should avoid this if one can. So, because of its Templeton funding, FQXI would not be the first place I would think of applying to for a grant.

42. **Terry Hughes**
August 16, 2008

This just in
[http://www.telegraph.co.uk/earth/main.jhtml?xml=/earth/2008/08/15/sciwarpdrive115.xml]:

"Two physicists have boldly gone where no reputable scientists should go and devised a new scheme to travel faster than the speed of light. …. All this extraordinary feat requires, says the new study, is for scientists to harness a mysterious and poorly understood cosmic antigravity force, called dark energy. …. The new warp drive work also draws on "string theory", which suggests the universe is made up of multiple dimensions. We are used to four dimensions – height, width, length and time but string theorists believe that there are a total of 10 dimensions and it is by changing the size of this 10th spatial dimension in front of the space ship that the Baylor researchers believe could alter the strength of the dark energy in such a manner to propel the ship faster than the speed of light. They conclude by recommending that it would be "prudent to research this area further.""

Talk about practical applications for string theory! Of course, there are the predictable nit pickers and naysayers standing in the way of such visionary thinking.

43. **woit**
August 16, 2008

Terry,

I was tempted to write a posting about this, including links to the press release that the authors had their university put out, and to the many places which now feature stories about how "string theory is used to make a warp drive".

But sometimes I guess I should try and exercise restraint, and just ignore the stupider things that string theorists do and promote to the press…

44. **Terry Hughes**
August 16, 2008

Peter –

You are correct, in my opinion. Expressly criticizing the stupider string theorists' self promotion efforts (like this warp drive nonsense) could easily turn counterproductive because it could easily open the critic to the charge that he is distracted and wasting time shooting down ideas that are not central to the development of string theory or the product of string theory's stronger advocates. That's why it's better for the criticism to come in a stray comment than a post!

By the way, I also believe that deep mathematical ideas and deep ideas about physics tend to come together. That's why I'm very skeptical that the physics of string theory could turn out to be essentially empty (which has not been definitively proven, but seems increasingly likely) but the mathematics derived from, characteristic of, and spun off by, string theory could turn out (or has turned out) to be as wonderful and profound as is now maintained in many quarters of the higher mathematical world (in my opinion, among many people who should know better). If there is some deeper unification of physics and mathematics out there that awaits our understanding, then I do not see how it is likely to unify trivial and/or incorrect physics with brilliant, profound mathematics. Sadly, mathematics lacks even the one weak check physics has on errant enthusiasms: a demand for predictions and falsifiable experimental results.

But what the hell do I know?

Furby, Tamagachis, string theory…

August 8, 2008
Categories: Uncategorized

Things don't seem to be going well these days for string theory in the "marketplace of ideas". From an article about gasoline-saving pedals:

> The 1990's were the host of many great fads. Furby, Tamagachis, string theory, the examples are as numerous as the many incarnations of Prince.

2. **Van**
   August 8, 2008

   Well, I have to admit that this is clear evidence that string theory is going out of fashion and Peter Woit has emerged victorious.

3. **Daniel de França MTd2**
   August 9, 2008

   String Theory should be out of fashion, but it isn't at all. Just check how many articles are posted everyday…

4. **M. Wang**
   August 9, 2008

   Blame that on the tenure system. It is rather anachronic to offer lifetime job protection after just a few years of work experience in this day and age.

   Tenure system was largely responsible for stifling out-of-box thinkers in academia and therefore partially contributed to the rise of String. Now it will continue to protect people who really belong to the trash heap of history.

5. **big vlad**
   August 10, 2008

   M.Wang, surely on the contrary the tenure system encourages out of the box thinkers. Once you've got tenure you don't have to worry about publishing x papers per year, or how many citations you have. You can just work on whatever you want.

   If you're a postdoc who has to make applications to new institutions every 2 years you're forced to work on whatever is fashionable.

6. **M. Wang**
   August 10, 2008

   With or without tenure system, the postdocs will have no job security until they make it to the next (or the next next) level.

   Full professorship, however, will be available to younger researchers if we do away with the tenure system or at least lower the mandatory retirement age. FBI agents have to retire at the age of 57. Why do physics professors stay on into the 60s or 70s? How many innovative advances were done by people older than 50 anyway?

7. **chris**
   August 11, 2008

   what's wrong with tamagotchis? thay are cool 🙂

8. **David B.**
   August 11, 2008

   Dear Wang:

   The tenure system is far better than the alternative you are suggesting. If you want to have an example of how bad things can get, consider the case of someone who gets to recompete for his professorship every few years without any security and a salary that is considerably below what you could get in industry positions, where they pay better so you to take the risk of lossing your job. You would not be able to get the best people to do research and public universities would not have the funds to pay for their salaries (they would be considered too expensive). There has to be something at the end that will make such an investment on time for individuals to be worth their while and tenure plays an important role in guaranteeing the quality of the research. It is not neccessarily fair, but it is cost-effective and I would say that it is being put to good use.

   Mandatory retirment in professions where there is physical rigor and you could potentially harm someone by not being able to react quickly enough or where you might be taking a risk on your life is rather standard. For most other professions around the world, retirement age is around 65.

   In academic positions the experience of professors far outweighs their drop in productivity as they age: they train new generations that relish the opportunity to be able to work with them. Consider the fact that retiring people early is just an added cost to society: you have to pay their retirement benefits after all.

   Also, tenured professorships, especially in theoretical physics, usually involve people spending ten to fifteen years previous in training for the chance to get one: a pHD plus a few postdoctoral positions plus the time as a junior professor with no guarantees of getting tenured. I would not call that 'just a few years experience', but rather a very expensive investment in funds trying to get the best people for the job. You want to keep that investment giving returns for as long as you can.

9. **ninguem**
   August 12, 2008

I'd be happy to retire at age 57 if I was given a nice pension. Under the current system in vogue at most US universities, I can't afford to retire at 57 and I probably won't be otherwise employable at that age.

10. **M. Wang**
August 12, 2008

David,

I understand where your arguments come from. Unfortunately, they are basically the same ones that socialists the world over had used in the past hundred years to justify lifetime job protection. The reality, which if you want you can find in any Econ 101 textbook, is that a rigid job market shaves off about 1-2% in annual productivity growth. Why would university jobs be immune from this universal law of economics? No reason whatsoever.

A common mistake made when arguing in favor of continuing the socialist status quo is to assume that the rest of the system will remain unchanged when the obvious safety net is dismantled. In reality, human society is a dynamic organism. Without the rigid job protection, the employers and the employees (as well as other stake holders such as students) will set new rules and form new norms that maintain a better balance among efficiency, fairness and safety.

Experience is important in a lot of other disciplines. For example, the French railroad workers can easily argue that it takes decades to learn to operate their railroads safely and proficiently, but look at the end result of their rigid job protection: a ridiculously low productivity level. Forty years ago, the French GDP was significantly higher than the British. Now it is the other way around, thanks to the Thatcher revolution in 80's, which, if summarized to one principle, is about unleashing creative destruction through increase in job mobility.

Ironically, theoretical particle physics is the one academic field where experience has had very little to do with meaningful achievements historically. This is a profession that should value innovation above all else, much like the silicon valley. Can you imagine Google or Intel offering tenures to their employees? Don't Intel engineers deserve the job security? Doesn't their experience count?

Theoretical particle physics is also rather unique among academic fields in that nowadays young PhDs have to do 4 or 5 postdocs on a routine basis. The mathematicians don't have to. The chemists don't have to. The EE majors don't have to. Don't you think this is very wrong to these young researchers and detrimental to the whole discipline as well? With a serious problem such as this plaguing the field, Physics really is crying out for structure reform. Breaking down the job protection for senior staff is a time-tested way of improving the welfare of entry-level personnel. If there is a better way to help the postdocs, I don't know it.

I should add here that the cruel practice of a potentially career ending review every one or two years was unheard of in the capitalist world until Jeff Skilling introduced it into Enron. Somehow, it never quite caught on among other corporations. I am just aghast at the way the physics community takes as a given.

The entrenched interests may be too strong to even allow the mere contemplation of reform in academia right now. But in a few decades, when the economic center of gravity moves to China and India, tougher competition in higher education may finally force some real changes. I can think of a few rational possibilities, such as clearer separation of teaching and research duties, more flexible hiring and firing practices, greater emphasis on students' welfare, and, yes, better pay for the junior faculty members. Until then, my sympathy to all the struggling postdocs.

12. **Anonymous**
August 13, 2008

As a tenured professor, I certainly see some of my colleagues who should have retired long ago. On the other hand, most professors are still quite competent at teaching at 65 and 70 (and some are still so as they get into the upper 70's, but this is much less common), and a few are still doing very good research at this age. So I would suggest 57 is much too low for retirement age.

Actually, I believe it is illegal for universities to have mandatory retirement ages in the U.S. It is definitely possible to have one-time retirement incentives, and I suspect from this fact that it would be possible to have a system where you received a somewhat larger pension if you retired between 65 and 70 than if you stayed on longer. I think this would be a good idea (with maybe very rare exceptions for outstanding indivicuals).

13. **bane**
August 13, 2008

One way of reconciling M Wang's viewpoint on Professors, retirement and innovation from people over 50 is that maybe Professors don't have that much to do with actual direct innovative research? They teach, sit on departmental committees, know how to write grant proposals in appropriate language that funding committees are comfortable with, they sit on funding committees, write funding letters to alumni, engage in networking, etc, all useful jobs that really don't have much to do with being innovative.

Of course that's probably a heretical viewpoint.

14. **bane**
August 13, 2008

I see I was a bit unclear: above I meant to say "maybe under the current system Professors don't have that much to do with actual direct innovative research anyway?"

15. **M. Wang**
August 13, 2008

David,

I understand where your arguments come from. Unfortunately, they are basically the same ones that socialists the world over had used in the past hundred years to justify lifetime job protection. The reality is that a rigid job market shaves off about 1-2% in annual productivity growth. Why would university jobs be immune from this universal law of economics? No reason whatsoever.

A common mistake made when arguing in favor of continuing the socialist status quo is to assume that the rest of the system will remain unchanged when the obvious safety net is dismantled. This is a profession that should value innovation above all else, much like the silicon valley. Can you imagine Google or Intel offering tenures to their employees? Don't Intel engineers deserve the job security? Doesn't their experience count?

Theoretical particle physics is also rather unique among academic fields in that nowadays young PhDs
have to do 3 or 4 postdocs on a routine basis. The mathematicians don't have to. The chemists don't have to. The EE majors don't have to. Don't you think this is very wrong to these young researchers and detrimental to the whole discipline as well? With a serious problem such as this plaguing the field, Physics really is crying out for structure reform. Breaking down the job protection for senior staff is a time-tested way of improving the welfare of entry-level personnel. If there is a better way to help the postdocs, I don't know it.

I should add here that the cruel practice of a potentially career ending review every one or
two years was unheard of in the capitalist world until Jeff Skilling introduced it into Enron. Somehow, it never quite caught on among other corporations. I am just aghast at the way the physics community takes as a given.

The entrenched interests may be too strong to even allow the mere contemplation of reform in academia right now. But in a few decades, when the economic center of gravity moves to China and
India, tougher competition in higher education may finally force some real changes. I can think of a few rational possibilities, such as clearer separation of teaching and research duties, more flexible hiring and firing practices, greater emphasis on students' welfare, and, yes, better pay for the junior faculty members. Until then, my sympathy to all the struggling postdocs.

16. **ninguem**
August 14, 2008

Wang starts his spiel with "Econ 101" and ends it with his sympathies for the postdocs. I see a contradiction there. Maybe these struggling postdocs are part of the problem. The market is way oversupplied. Maybe people should realize that there are no jobs in theoretical physics and bail out way before they get into the multiple postdoc mill. Isn't it painfully obvious already? What are all these people doing in graduate school? If you are not the next Witten, try solid state, maybe you can get a job at Intel.

17. **David B.**
August 14, 2008

Dear Wang:

The truth is that there is no practical reason to employ all the people who graduate in studies in theoretical physics in academia. If people want to stay, the shortening of positions at the end means that they have to take temporary jobs more often. There is a reason why people do more postdocs in theoretical physics than in math. It is a market effect: there is enough funding for postdocs to stay around a while. If there was more soft money in math, you would have people doing more postdoctoral positions as well. You are also wrong on another count: a postdoc position is not the same thing as an entry level position. Junior professorships are entry level positions. A postdoc is a temporary position with a definite time limit. The review system is there because there is a lot of competition for those positions. This is not the Enron system you are describing.

You can complain about the system all you want, but the following fact remains true: if you do truly outstanding research, you will get a permanent position quickly. This has always been the case and this is a reward for truly innovative research.

My statements about having incentives to keep the best people motivated are still true. You can set up these incentives in two ways: with money incentives, or by giving some protections. There are places where there is no tenure in place and they pay more. If you can outcompete the individuals out of their jobs in those places, go ahead and do so.

The protections that are in place are there for a reason: you can get fired for having the wrong kind of opinion, and you can politicize positions to a degree where innovative research is essentially impossible. This is a more common danger in the humanities, but it is not unheard of in sciences, especially if you are going against a well entrenched belief of some community. This is, you would not give protection to dissenters who might be right. You can not base a robust system of academic dissent on utopian assumptions about the way individuals behave, so you have to put mechanisms in place to prevent certain abuses. The tenure system is one of those mechanisms. It might not be perfect, but it works sufficiently well and so far it has worked better than the alternatives. On my part, I have no illusions about idealism on this regard.

You also fail to understand that there is a lot of risk in doing research: most of the times it does not pay off, but when it does, it pays big. There is some element of luck in this. Sometimes it takes years to actually get progress done. If you are measured by Wall Street style standards (quarterly profits, etc, the same thing as recent citation counts) or any short term style metric, a lot of innovation goes down the drain. This is why most of the fundamental research is handled by public investment rather than private investment.

18. **M. Wang**
August 14, 2008

Dear David,

You speak like a true beneficiary of the status quo. The system works great. Those who suffer are not as good as I am and therefore just sour-graping. My job should be secure no matter what. There cannot possibly be any justification for contemplating any changes. Guess what? I read corporate earnings announcements for a living, and must have seen similar arguments a hundred times over. Unfortunately, these arguments inevitably come from failing executives who have cost their shareholders billions and are on their way to the guillotine.

I can pick apart your arguments one by one. For example, physicists do more postdocs than chemists or EE because the field of physics has more money!? You must be living in one of the other universes. But anyway, these details are not really essential to the issue here. Whether or not the system needs reform ultimately comes down to whether it works well, i.e. does it generate good returns for the investors. If the firm is failing, we don't care if the CEO is Jesus reincarnated. Out of the door he goes. If the firm is booming, the managers can be caught stealing money from the company (Think Steve Jobs' backdated options grants at Apple) and still get a big round of applause.

Had theoretical particle physics been a private enterprise, what would its annual report look like? Well, that is actually a trick question, because no companies would not be producing an annual report after burning through billions of dollars of taxpayers' and donors' money in the past few decades and generating nothing but hot air. It would have been forced into bankruptcy a long time ago.

So, the basic fundamental difference between you and me is that you think the field works great while I think it has failed completely in the past three decades. As long as we come from these opposing premises, there can be no agreement in our conclusions.

I am not insider. My involvement with physics is basically that of an activist shareholder. I become a shareholder of the field by way of donation and tax, which in a good year is enough to pay the salary of a professor for many years. In all honesty, I am offended by a member responsible for the failure of the field who has the gumption to tell me that he knows how to judge the quality of young incoming practitioners. Don't you see that it is the tenured professors who need to be judged here?

19. **David B.**
August 14, 2008

Dear Wang:

I've heard a lot of rhetoric through my life, and you are spouting quite a lot of it. Let me set the facts straight for your benefit:

Theoretical physics is dirt cheap. It is in experimental physics that the billions of dollars are spent. And they have a lot to show for it. Most of what is currently known as the Web came out from the solutions that were worked out by experimenters that needed to be able to access data all over the world for experiments in particle physics. You should read the Wikipedia article about the origin of the WWW. I don't know how much of the world's Economy runs on the web, but if I were you I would stop making ridiculous statements about the value of the physicists contributions to the economy.

Lasers where a theoretical conjecture of the 1930's. In the 60's the first laser was built. Now, many technologies that people use depend on lasers, and there is a comparable number of working lasers to the numbers of people in the world. It can take 60-90 years for ideas to mature.

Many things that start their life in physics labs end up being engineering problems afterwards that produce enormous amounts of wealth. All of this is byproduct of fundamental research.

From many points of view, theoretical physics is there to help understand the experiments that are performed all over the world and society has benefitted directly from that. A true understanding of physics requires theory, and the corresponding experts are theoretical physicists.

The most important contributions of modern theoretical particle physics (last 30 years) have been related to establishing the standard model of particle physics as a law of nature, matching the model to data to unprecedented accuracy. Puzzles of how the neutrino flux from the sun was off led to extraordinary experiments that showed that neutrinos have a mass. This was a direct contribution from theory to the understanding of nature and I would say that is pretty impressive considering how messy the sun's nuclear reactions are.

There have also been enormous improvements in the understanding of various mathematical structures from studies in theoretical physics, particularly with the insight of techniques developed in the string theory community.

Need I say more? Probably I do, because you seem to believe that theoretical physics is a bunch of nonsense practiced by a coven of evil tenured professors who are full of hot air and decide by finger what goes on.

Theoretical particle physics has not failed. A lot of ideas have been falsified by data however. But such is life in research: it is the norm rather than the exception.

Also, nowhere have I said that my job should be secure no matter what. But if you ask me to take risks, then the pay should match the risk expectations. It is the same as with interest rates in banks.

If the tenure system cuts down productivity by 2%, but it is 30-40% cheaper, most people would favor the tenure system. If you come up with a better alternative, I'm all ears.

Go ahead and pick at my arguments one by one. I would like to hear a well documented research monograph on why the tenure system is so corrupt, rather than a lot of posturing and an attitude of "I do understand economy and you don't". Trust me, I do understand it well enough.

The reason I posted the 'apology' for tenure, is that there are good reasons for the system to be in place. If I quote those reasons as a matter of an explanation, that does not mean that I refuse to see alternatives or that I am just supporting the status quo just because I'm an insider. Your arguments are not convincing because you are not proposing a real alternative.

You maybe felt insulted because I answered your post with a differing point of view? I don't know. What I do know is that you resorted to name calling and less than civilized conversation. Fortunately I come from another universe where we don't take the bait so easily. You feel that we are not judged and reviewed? Trust me, the tenured professors are judged by their piers and by the granting agencies. The grant contracts are allocated according to how people's output in research is perceived. Also, I do have the capacity to judge my junior colleagues. As a matter of fact, it is part of my job description, and I take it very seriously.

Sincerely yours,

Prof. David Berenstein.

20. **M. Wang**
August 15, 2008

Prof. David,

This discussion is getting too personal for my comfort, so I will try to conclude it with very brief statements of facts.

I was talking about THEORETICAL particle physics in the past 30 years, not experimental, not solid state, not math and not the 1930s or 1970s.

The WEB came out of CERN. -> Experimental.

Laser prediction -> 1930s.

Physics lab Technology. -> Experimental.

Standard Model. -> 1970s.

String Math. -> Not physics.

Solution of Solar Neutrino puzzle. -> Experimental.

As for working with experimentalists, I would be more sympathetic if nonzero neutrino mass and/or small positive cosmological constant have been predicted before discovery. Instead, they cause consternation. (Clarification: All those papers published without nudging us closer to the right answer are considered negative contributions by me, regardless of their very positive contributions to the authors' careers.)

Rigid labor market reduce the ANNUAL GROWTH RATE of productivity by 1-2%, not the productivity itself. The overall growth rate can turn negative in extreme cases, as I suspect TPT is one such case.

When I talked about judgment, I meant objective or at least disinterested 3rd-party judgment. A community of tenured professors judging themselves does not qualify.

My complaint about the tenure system is largely focused on TPT, as my original post indicated. The other fields, well, have produced results, so they can keep doing whatever they were doing with public money.

21. **M. Wang**
August 15, 2008

By the way, I do think TPP is under-funded. No real revival will come unless more money is invested. But no more money will come unless TPP produces some real results first. I hope LHC will lead to such real results and allow the community to break out of its 30 year torpor.

Despite my outsider status, I do wish the field well. TPP is close to the ultimate intellectual pursuit in my mind, but any collective human endeavor has to be subject to the laws of economics and TPP is no exception.

I have had some really terrible managers and have been a bad one myself, at least initially. I know how hard it is to manage people. Realistically, the tenure system will not change, but the tenured professors, if they want, can easily take some one or two weeks courses at the B-schools to learn the art of management. I found the experience silly at times but very helpful overall.

Another suggestion is for the decision makers of the field to consciously promote young people NOT in their mold. I don't mean nasty personalities and out-of-the-world behaviors, but conformity leads to inbreeding, which in turn leads to degeneration. This seems to be one of the causes of TPP's current problems.

22. **DB**
August 15, 2008

There are two issues which affect mathematical physics:

1) As a discipline it is amorphous. The jobs are spread around maths, physics and even engineering departments. As such it lacks a clear identity and is often viewed with suspicion by members of the host departments. Until recently they were accepted because of the stunning record of achievement of mathematical physicists up until the late seventies.

2)The shelf life of a researcher in mathematical physics is shorter than in any experimental field. It is well established that there is very little prospect of anyone over the age of 45 making any significant breakthrough. Even the greatest names were effectively burnt out by this age and were relegated to pursuing unproductive research paths while training the younger generation.

The problem is particularly acute in String Theory, where an entire generation of theoretical physicists now occupy tenured positions. No longer productive, and fearful that their entire research career may have been in vain they grimly hold on in the hope that a new generation will make the breakthroughs that will validate their own work. Their counterparts in maths and physics departments view them with increasing resentment. In return, string theorists feel increasingly under siege and band together even more strongly.

Either a breakthrough comes or this doesn't end well.

23. **gs**
August 15, 2008

Dear M. Wang,

"..while I think it [theoretical particle physics] has failed completely in the past three decades."

Why do you feel that the field has failed in the past three decades? What in your mind would count as a success?

24. **David B.**
August 15, 2008

Dear Wang:

I agree that it was getting personal. It was exactly for that reason that I gave my full name. I believe anonimity kills many discussions and invites trouble.

I am definitely open to new ideas and suggestioons as to how to improve the system. I also appreciate the notion of expert advice. It is ill-informed to believe that the merits of individuals in our fields of knowledge should not be measured by the experts in the field, but that an outside committe who does not have experience in the field will know better. A proper answer that addresses this issue of judgement should be a lot more nuanced and should provide a realistic set of rules for implementation, rather than what you described.

The truth is that in order to make progress in physics in terms of possitive results (as you called them), one needs new experimental data that needs to be explained. If there are no prospects for new experimental data ever, then the corresponding theory fields die. The reason funding has not stopped in physics, is beacuse the positive contributions to technology from physics research have not stopped happening. In this situation, you keep on funding areas that have promise, but there are never guarantees on results. This is a situation where in order to win the lotery you buy as many tickets as you can, and so long as the ones that pay do it big, you keep on doing it. If there was a way to decide in advance which tickets are loosers for certain, then people usually wouldn't buy them. However, such a thing is not there and history has shown that betting on fundamental research has been a good bet so far.

Physics essentially moves forward when new technologies make it possible for people to observe new phenomena. It is a sad thing that we don't celebrate the technical ingenuity of experimentalists more. Their results are what have made physics into one of the most successful developments in the understanding of nature that humanity has ever seen.

In high energy particle physics we have had a lack of new experimental evidence for new stuff other than the standard model for many years.

The addition of neutrino masses to solve the solar neutrino flux problem was one of those cases where there was a puzzle and a theoretical solution. The solution predicted various new phenomena that were later observed experimentally and parametrized them. These were seen later, and the parameters are being measured. Thus, it was verified. This is the way progress usually happens. There are very few cases where somehting started as abstract theory than was then seen.
Historically theory has followed data and not there is a feedback mechanism that makes theory give new ideas of where to look for stuff.

Also, confirming that a model of nature is correct is an incredible arduous task. Even though we would personally like some deeper understanding of nature, it is presumtuous to assume that we are entitled to it. If and when it happens, we should all celebrate.

Currently, there are experimental hints that supersymmetry might fit the current High energy physics data better than the Standard model.
Supersymmetry is one of those theory inventions that could be seen at the LHC and it would be a triumph of theoretical physics in the sense you described.

As I said above, theoretical particle physics aims to explain results of experiments and it is necessary to understand the data that is already there and to know where to look for new things. Most ideas can be thrown away because they predict deviations from current data that are beyond the experimental bounds.

Knowing where to look is especillay important in an experiment like the LHC where the output of information makes it impossible to keep all events that are produced. Designing the triggers so that one does not throw away the new physics requires an enormous amount of theoretical input and experimental know-how. In the end, we might come out with empty hands. But this is the nature of scientific research.

Another myth is that string theorist are no longer productive. The ideas of string theory, and in particular the gauge/gravity correspondence are being used to explain and analyze the data of the heavy ion collisions at RHIC. They also provide good models for the hydrodynamic behavior of strongly interacting systems and can give new models for solvable systems that might be good at describing condensed matter systems that we have already observed in the lab. Very little of this information makes it to the newspapers, but it is all happening as we speak.

The other myth is that string theorists do not promote diversity of thought or of ohter approaches. Some do and some don't. Over-generalizations and demonizing a whole community does not help towards having productive discussions.

25. **M. Wang**
August 15, 2008

GS,

As I mentioned, if the TPP community had come up with a cohesive theory about the neutrino masses or the small positive cosmological constant before the experimental discovery, it would have counted as a big triumph in my mind. Even after the fact, such a theory would still have been respectable and well worth the public investment.

At the next rung of lowered expectation, something coherent to replace the ridiculously pointless SUSY extension in Higgs physics would be nice. But I am a realist. Chances are the theorists of this generation will not come up with anything remotely close to the truth until the truth scream in their faces from LHC.

26. **M. Wang**
August 15, 2008

DB,

I want to apologize for the use of the phrase "econ 101" in one of my earlier post. It was unnecessary and counterproductive.

I meant to write in a blunt manner, but that comes across as rude, which was not my intention and I regret it.

27. **Aaron Bergman**
August 15, 2008

if the TPP community had come up with a cohesive theory about the neutrino masses

Huh? The theory behind neutrino masses was completely developed long before said mass was detected.

Also, to say that supersymmetry is pointless is silly. It may well not be right (and it looks less likely than it used to), but SUSY has a number of independent motivations (none of which have to do with string theory FWIW) that made it the most popular extension of the SM out there.

Anyways, theory preceding experiment is a nice dream, but it's not how things usually work. Rather, the experiments come first and theories develop to explain the data. It is an unfortunately disadvantage of the past few generations of theorists that we haven't had data to play around with. It'd be great if we could discern the secrets of the universe through thought alone, but the number of people who have managed to do that in history can probably be counted on one hand.

28. **M. Wang**
August 15, 2008

David,

I am criticizing the entire TPP community from a sociological/economical point of view. Nothing I said should be taken as personal.

I do not consider the idea of neutrino mixing as a comprehensive theory because it is not well integrated into a large framework.

String application on RHIC physics is positive but unfortunately minor. Overall, the return on investment in String remains miserably low.

The failure to promote a diverse set of talents is universal. It is so deeply ingrained in human nature that even well-meaning people may subconsciously favor young people who remind them of themselves. But tenured professors wield too much power over the postdocs and doctoral students, and many become so arrogant that they laugh at the idea of diversity. Senator Fulbright's famous sentence, "Power confuses itself with virtue and tends also to take itself for omnipotence." definitely applies to some big-name physicists.

My biggest problem with the tenure system is exactly the concentration of power of the old over the young. This is basically a carryover of the medieval apprentice system. Putting aside to fairness issue, one still has to consider its effects on a field facing strong headwind already.

My feeling is that tenured professors in TPP have only one thing in common: They were smart physicists, at least at one time in their careers. Otherwise, they are not guaranteed to have good tastes, much less real-life wisdom. To give every single one of them so much power over aspiring young scientists is truly not prudent.

To be a good manager, one has to have that wisdom. Humility and broad view outside the field also help. Unfortunately, these qualities are exactly those that are suppressed in the selection process of a successful physicist, where narrow-mined focus and unrealistic confidence (in self or in the adviser) are the necessary ingredients to make it to the top.

Therefore, it was not surprising that TPP community has gone over the string cliff like rats following the pied piper. Here the pied piper role is played by the de-facto leaders of the field in the past three decades: Susskind, Weinberg, but most important of all, Witten.

I have never met Dr. Witten personally. From what I have heard, he is a brilliant theorist and a nice guy too. Unfortunately, as a leader, his failure was total and complete. Certainly, he holds no official title of the kind and most likely does not want the leadership responsibility. But there is no denying that almost everyone in TPP thought of him as the leading light from the mid-80s to mid-2000s. And leadership is something that one simply cannot shirk at will.

In wielding his enormous unofficial power over the flock, Dr. Witten failed to promote the diversity we talked about. He failed to suppress the idol worship that became more and more obvious and unhealthy over the years. In fact, he failed to recognize any sociological aspect of the leadership task befalling on him and did nothing to guide the community onto a more productive direction. For this failure, I consider him the most responsible for the current miserable state of TPP.

Finger-pointing is not a very productive exercise itself. But I am surprised that nobody in physics ever utters this obvious truth, not even Woit or Smolin. Facing the truth, however, is often the first step toward progress. So there you have it. I have spoken the unspeakable. If anyone wants nominate other candidates as the guilty, I am all ears.

29. **M. Wang**
August 15, 2008

Aaron,

Please read my last comment about why neutrino mixing is not really a triumph for the theorists.

I presume that you were referring to the hierarchy problem as one of the "independent motivations". But this only makes sense if there is a natural way to break SUSY at much-lower-than-Planck scale. Does such a way exist?

You are absolutely right in saying that it is rare for theory to precede experiments. But knowing this fact, how can the whole field spend the past 30 years building conjectures upon previous conjectures and extending the whole process to the 6th or 7th power? If SUSY itself is a questionable extension, why waste time building String other than to pad one's publication list?

Where is the first-order conjecture that has at least a 50-50 chance of being true?

30. **jpd**
August 15, 2008

I am no string theory fan, but i don't think you can blame
it all on Witten.
He's just this guy, you know?

31. **Aaron Bergman**
August 15, 2008

Neutrino mixing a triumph? I don't know about that. Neutrino masses are pretty much obvious from the point of view of effective field theory. There's an operator you can write down, and you expect it to be surppressed by the inverse scale of some new physics, and voila, that's what you get. The seesaw mechanism goes back to the seventies, I think (although I'm very bad with physics history), long before the detection of neutrino masses.

As for SUSY, the hierarchy problem is certainly a motivation. So are the existence of a natural WIMP candidate, the unification of the couplings, ewsb, and maybe other things I'm forgetting. By themselves, none of these are at all conclusive, but if you take them all together, it's not too hard to see how people got excited.

As for natural breaking of SUSY at small scales, this is hardly a new question. See this, for example. (If you're not at a university, it's not too hard to find a copy on the web.) Anyways, things have progressed considerably since then. Are there still problems with SUSY? Of course, but I hardly think that means that one should discard the entire idea.

32. **wilbur**
August 15, 2008

> But knowing this fact, how can the whole field spend the past 30 years building conjectures upon previous conjectures and extending the whole process to the

6th or 7th power?

This does not make any sense to me. We all know that the SM has been a phenomenal success. But we wouldn't know that if not for the work of the particle physics community, both experimenters ant theoreticians, over the last 30 years.

So, how can one say at the same time that the SM is successful and that the past 30 years have been spent by the whole community building speculations? I think Mr. Wang is seriously confused about the nature of particle physics.

33. **Peter Shor**
August 17, 2008

Does Witten really consider himself the leader of the string theorists? My impression is that he thinks of himself as a really smart guy looking at interesting things, but not as somebody who sets the direction for the entire TPP communicty.

34. **M. Wang**
August 17, 2008

Aaron,

See-saw mechanism is not just old but also isolated from the overall theoretical framework. There has been very little effort on integrating it with the rest of the beyond-SM project.

The Witten paper you quoted is a standard string effort. That is, all it says is that dynamic breaking of SUSY is not impossible in string. But the fact that anything is possible with string is something we already know without having to waste any time.

When the right idea comes out, it should link different pieces together in a previously unimagined and natural way. TPP practitioners are so ruined by string that they no long care about this any more.

Wilbur,

The great majority of the progress in particle physics during the past 30 years is in experiments. What did theorists do that contributed to the verification of the SM, which was already 99% complete by the mid 70s?

Peter,

Witten certainly did not want to be the leader, but that was the problem. People still treated him like one. The weight of responsibility did not find the shoulder that could or would carry it.

35. **Eric**
August 17, 2008

Wang,
My memory could be wrong, but it seems to me that the idea for the see-saw mechanism comes originally from grand unification, in particular SO(10)-type unification. In fact, one of the reasons that SU(5) GUTs are disfavored (besides proton decay) is that they do not have a singlet for the right-handed neutrino. If neutrinos had turned out to be massless, then this would have almost certainly meant that the SM came from an SU(5) GUT, and proton decay would probably have also been observed.

Regarding your claims about a supposed lack of progress in theoretical particle physics over the last thirty years, nothing could be farther from the truth. What has generally been lacking is the tools necessary to fully test ideas such as the Higgs mechanism and supersymmetry. In more recent years, other ideas such as warped extra dimensional theories have been proposed which will also be tested at LHC alongside older ideas such as supersymmetry and technicolor. The only way that any of your above arguments can possibly have any merit is if there is no evidence for any of these ideas at LHC. As David mentioned earlier, all evidence at present seems favor low-energy supersymmetry.

As an aside, I don't believe the paper of Witten's linked by Aaron above was written within the context of string theory as it was written in 1981.

36. **gs**
August 17, 2008

Dear M. Wang,
A question for you, just to get an idea of what you expect from physicists… phenomenologists and theorists have studied a variety of scenarios for TeV scale physics, e.g. SUSY, technicolor, composite Higgs, extra dimensions, etc. If upcoming experiments end up supporting any one of these scenarios, would you still consider the efforts of the past 30 years to be a failure?

37. **Thomas Larsson**
August 18, 2008

One way to quantify the amount of recent progress (or lack thereof) in theoretical physics is to look at the age of the youngest theory Nobelist around. At this time it is Wilczek, who is around 55. I don't think that there ever (after 1902) was a time when the youngest was that old, and made his discoveries so long ago.

38. **Thomas Larsson**
August 18, 2008

"If upcoming experiments end up supporting any one of these scenarios,"

gs, isn't this is a quite big IF, given constraints from the Tevatron and elsewhere?

39. **Eric**
August 18, 2008

Dear Thomas,
Once the results from the LHC are in, it is quite likely that many Noble prizes will be awarded to theorists, e.g. Higgs, Zumino, and so on depending on what is found. Theories have to be confirmed by experiment before Nobel prizes can be awarded.

As far as whether or not it is likely that something will be found at LHC, the answer to that is almost certainly. Either the Higgs will be found or something equivalent to it. If the Higgs is found, then there must be something which stabilizes its mass against quadratic divergences. Whatever the case may be, it should be seen at LHC. In the case of supersymmetry and the Higgs, it is hardly surprising that no signal (above background) has been seen at the Tevatron as the beam energy is just not high enough to produce large numbers of events.

40. **wilbur**
August 18, 2008

> The great majority of the progress in particle physics during the past 30 years is in experiments. What did theorists do that contributed to the verification of the SM, which was already 99% complete by the mid 70s?

Mr. Wang,

your statement that the verification of the SM was complete by the mid 1970s is completely ludicrous. What was complete by then was the formulation of the SM. Notice that the weak bosons where first experimentally observed in 1981/1982, so no direct verification of the SM could have taken place before that.

You seem to believe that after the SM was formulated only experimental work remained to be done. That is wrong. You fail to realize that the theoretical work needed to *quantitatively* match the experimental results, and also to guide the experimental effort, is gigantic and absolutely non-trivial. And, since you don't know it, it's first-rate physics.

To give you just two obvious examples: the computation of QCD scattering amplitudes *at tree level* is an active subject of research even today. (And one, by the way, which has received inputs from string theory.) Another example is the verification of the CKM model of CP violation, to which an enormous amount of theoretical work has been, and still is, directed.

If you want to see literally hundreds of other equally relevant examples just take a look at the current literature. Take, for example, the areas of hadron spectroscopy, jet physics, deep inelastic scattering, electroweak boson scattering, flavor physics, …, even QED, … the list is virtually endless. That is what is called particle physics.

According to your wrong idea of how physics research is conducted, one should say that, for example, condensed matter physics is a purely experimental field, since the Schroedinger equation has been known since the 1920s. Obviously, that's not how physics works.

41. **Thomas Larsson**
August 19, 2008

Eric, do you really think that Higgs or Zumino is below 55? 🙂

It is standard lore that it is impossible to find nothing at the LHC, because of the Landau pole. That's why nothing would be so exciting – it would make LHC the most important null experiment since Michelson-Morley. I wouldn't bet against a Higgs, though. On second thought, I might risk a hundred bucks if Sean Carroll still offers 19:1 odds.

However, yours is a stronger claim: that just an SM Higgs is also impossible. It will be interesting to see how that prediction pans out in the next few years.

42. **M. Wang**
August 23, 2008

Wilbur,

Your points are well taken. But how many TPP papers published during the past 30 years have been on the subjects you listed? How many were not? Is the ratio around 1/2, 1/5, or closer to 1/20? If the bulk of publications fall into categories that you would rather not mention, what does that say about the overall progress in TPP?

43. **wilbur**
August 23, 2008

M. Wang,

I don't have statistics on the last 30 years of theoretical physics papers, so I cannot give a definite answer to your question. I don't know whether detailed studies of that kind actually exist.

Like I said in my post, the topics I mentioned were just examples, not an attempt at a complete classification of particle physics subfields. For example, I didn't mention lattice QCD, where much progress has been made in the last two decades.

All I can say is that if you're trying to prove that SM physics has been a marginal field in theoretical particle physics for the last 30 years, you're going to have a very hard time doing so.

Grothendieck's Later Years

August 8, 2008
Categories: Uncategorized

Alexander Grothendieck's 80th birthday was this past March, and the September Notices of the AMS has several articles about his later years. There's a long piece entitled Who is Grothendieck?, by Winfried Scharlau, who is writing a three-volume biography. The first volume (in German) is available here and mainly deals with the stories of his parents. The article contains the only pictures I've ever seen of the post 1970s Grothendieck and a wealth of information about his activities after leaving the mathematical research world.

The same issue contains a short piece Memories of Shourik, by Valentin Poenaru reminiscing about his friendship with Grothendieck during the 1960s. The most shocking thing in it to me was actually the part about Barry Mazur's wife, who Poenaru describes as being only 17 when he met her living with Mazur at Bures-sur-Yvette.

Note added: Mazur's biography here mentions just one wife, Grace Dane, a Harvard biology postdoc he married in 1960. If she was, as Poenaru claims, 17 in 62-63, that would have made her a 15 year-old postdoc when they married….

Finally, there's a piece by Allyn Jackson about Grothendieck and the IHES, which is having its 50th birthday this year. Evidently Grothendieck has recently been in communication with the IHES:

> Six months to the day before the start of the IHES anniversary celebration, Grothendieck wrote to the institute with a request for books. The IHES sent him the books as quickly as it could. But the exchange of letters between Grothendieck and the IHES administration culminated in his writing a furious "open letter" recounting his view of the exchange, which he took as deeply insulting towards him. He requested that copies of the open letter be sent to all members of the IHES Scientific Council and explicitly states that this letter is public (though he also says he will make no efforts on his own to publicize it). Having seen the open letter, I can say that it conveys an extreme outrage that indicates how difficult it would be to conduct reasonable communication with him.
>
> At the same time, the open letter reveals the vivid personal tie that Grothendieck clearly still feels to the IHES. The letter also reveals an isolated individual who is reaching out in the only way he is able. In one place he speaks of his open letter as being a letter of farewell ("adieu") to a world with which he no longer has anything in common. He ends on a note of apocalyptic foreboding, saying "that the time is near when…this letter, this cry will be known by all. In a world of the living." This cry does not seem to concern misunderstanding over his original request for books. Rather, it speaks of anguish in the heart of one of the great mathematicians of modern times.

The IHES is having *Recoltes et Semailles*, Grothendieck's long meditation on mathematics and his withdrawal from it, published this summer. Articles about this are beginning to appear in the French press, see here and here.

Comments

1. **egan**
   August 8, 2008

   The real link for the science et avenir article is http://sciencesetavenirmensuel.nouvelobs.com/hebdo/parution/p737/articles/a378150-.html

2. **Peter Woit**
   August 8, 2008

   Thanks egan, fixed.

3. **Michael Bacon**
   August 8, 2008

   "The most shocking thing in it to me was actually the part about Barry Mazur's wife, who Poenaru describes as being only 17 when he met her living with Mazur at Bures-sur-Yvette."

   Shocking? Really? They were married afterall, so you wouldn't be shocked they were living together. 🙂

4. **Joseph**
   August 8, 2008

   Wow. Thanks for the info. Ever since I started studying algebraic geometry, I have been absolutely mesmerized by Grothendieck.

5. **Peter Woit**
   August 8, 2008

   Michael,

   See my added note. Something about the Mazur story doesn't add up…

6. **Chris W.**
   August 8, 2008

   You might have mentioned that Barry Mazur was only 25 at the time. Better yet, you might have omitted mention of that sentence altogether.

7. **MathPhys**
   August 8, 2008

   Peter,

   I agree with Chris W. Maybe you can remove that sentence altogether. Someone made a small mistake somewhere about someone's age.

8. **commonsense**
   August 8, 2008

If I said Grothendieck looks 100 if he's a day, does that imply he got his Fields Medals when he was in his 50's. (Answer: no.)

9. **Peter Woit**
   August 8, 2008

   commonsense (and others)

   Poenaru wrote that Mazur's wife was 17, not that she looked 17. This is rather odd, so I mentioned it. If you don't find it worth mentioning, ignore it.

10. **Martin R.**
    August 9, 2008

    I also find it surprising that you quote this sentence about Mazur's wife. Who cares ? It's not your style. I am a French physicist who read you blog regularly with pleasure and interest. Without knowing you directly, I got the impression that you are a sensible and honest man. So please, leave this kind of remark to those in the US who think that sexual attraction is the source of all evil…

11. **DPG**
    August 9, 2008

    A. Grothendieck: Should we continue scientific research?
    see http://bareglow.blogspot.com/2008/07/should-we-continue-scientific-research.html

    on my blog dedicated to "Basic research in a global world"
    http://bareglow.blogspot.com

12. **Peter Woit**
    August 9, 2008

    Martin R.,

    My comment had nothing to do with any moral judgment. Perhaps the problem here is a poor use of words. All I meant to say is that I found this to be surprising and hard to believe. As far as I can tell, that reaction was correct, since it appears that the story is not true.

    Everyone,

    Unless someone actually knows the explanation for Poenaru's odd claim in the article, enough about Mazur's wife.

13. **Martin R.**
    August 9, 2008

    Ok, sorry for the misunderstanding.

14. **richard**
    August 10, 2008

    Where is it possible to read this open letter, referred to in the quoted text ?

15. **Peter Woit**
    August 10, 2008

    richard,

    As far as I know it has not been made publicly available.

16. **Russ Van Rooy**
    August 10, 2008

    Anyone is welcome to view my amateurish ,but earnest salute to A. Grothendieck here:
    http://uk.youtube.com/user/russvr

17. **richard**
    August 11, 2008

    it is not so much of an "open" letter then 😉

18. **Kea2**
    August 11, 2008

    The "International Who's Who of Authors…" entry for "Mazur, Grace Dane" reads in part: Born 22 April 1944; m. Barry C Mazur; BA Harvard College 1971; Ph.D. Harvard University 1981.

19. **Professor R**
    August 11, 2008

    Bures-sur-Yvette? I haven't heard that name in a long while.
    I spnt a year as a child in Bures, while Dad took a year's sabbatical with Louis Michel. It was a wonderful year for the whole family, and indeed for all the families of visiting professors.
    We all lived in a little Residence specially for the familes of visiting academics, and went to the local french school (excellent) and music college (excellent).
    Theoreticians have such a wonderful life, who else gets to do this…

    Bures seemed like a small, delightful village nowhere in particular- it was only years later that I realised it is host to a world-famous Institute , and right in the middle of several top-class universities and institutions

20. **Howard**

August 12, 2008

OK, so Kea2's research indicates the answer to your puzzlement: Ms. Mazur was not a post-doc at the time she married Mazur. In putting together the Poenaru memoir and the biographical note about his wife, you committed the common logical error of "post-doc ergo propter doc".

21. **D R Lunsford**
    August 14, 2008

    Reading this, I am sadly reminded of Cantor.

    -drl

    what does "shourik" mean?

23. **Anonymous**
    August 30, 2008

    In Russian, Shourik to Alexander is like Bob to Robert in English.

24. **Eugene Stefanovich**
    August 30, 2008

    Alexander -> Alexasha -> Sasha -> Sashoura -> Shoura -> Shourik

The Landscape at CERN

August 14, 2008
Categories: Uncategorized

The current plan at CERN is to celebrate my birthday by trying to circulate the first beam around the LHC on September 10 (actually my birthday is September 11, but in recent years my family, like CERN, has tended to celebrate on the 10th, feeling that 9/11 has too unfortunate connotations). One can follow this at a special web-site set up by CERN called LHC First Beam, which now is running a daily countdown.

String theorists have been flocking to CERN this summer trying to somehow connect their subject with the LHC. The big yearly Strings 08 conference will be starting there next week. The organizers don't seem to have a lot of sympathy for anthropic pseudo-science, with no talks scheduled on anthropics, the landscape, or the multiverse. Instead they'll be wisely sticking mostly to talks on topics related to better understanding more formal issues in string theory and quantum field theory.

In the weeks leading up to the conference though, CERN is hosting a theory institute on String Phenomenology. The web-site of the institute has a section on its "Scientific Case", which, with remarkable chutzpah makes the claim that:

> … the past few years have provided a drastic improvement on the potential for string theory models to be confronted with low-energy data

a claim that is diametrically opposed to reality.

For a look at the reality of what the landscape has meant for the "potential for string theory models to be confronted with low-energy data", one can take a look at the slides of talks by Wati Taylor and Michael Douglas. Taylor describes the importance of distinguishing two possibilities he calls A (anything goes) and B (constraints), and finds in IIA intersecting brane models that the evidence favors A. It seems that such a landscape can give one pretty much any kind of low energy physics, with the things one can compute (the gauge group and number of generations) randomly and independently distributed. He looks for some hope in cosmology, noting that a large class of IIA models are incompatible with slow-roll inflation, while at the same time also pointing out that there are lots of potential ways around this particular constraint, although most of them involve uncontrolled approximations.

Douglas's talk was entitled String Landscape: A Status Report, and in it he describes evidence for the existence of order 10^{500} "quasi-realistic vacua". If you don't impose some constraints from experiment, you'd have an infinite number of possible vacua. He claims that there is no way to rule out any of these vacua, other than to try and compute detailed predictions of each one (something no one has a clue about how to do). Douglas explained why it isn't possible to make even the crudest prediction that initially he and others had hoped for, that of whether the SSYM breaking scale would be at observable or Planck energies. There's an odd speculative section about how since SU(2) and SU(3) have shown up on energy scales of 100 MeV to 100 GeV, maybe one gets two new gauge groups for every factor of 1000 in energy (which he calls the "jungle scenario", as opposed to the conventional "desert scenario"). There's a final "No Conclusions" section, admitting that "at this point it seems likely that we will not have definite conclusions of predictions before LHC data comes in." He ends with the standard piece of wishful thinking that now is all that is left of the project of connecting string theory unification models with physics:

> Let us hope that discoveries here at Cern will reveal enough about the real world to make contact possible.

Yesterday there was a discussion session on "the string theory landscape and its impact on particle physics and cosmology", but it doesn't appear to be online. I wonder what conclusions the participants reached…

Update: Jester at Resonaances has a posting up about this. His impression of the Vafa et al. recent claims about "F-theory phenomenology" seems to match mine:

> For the neutrino physicists the important piece of information is that the neutrinos are Dirac or Majorana and their masses are roughly of the order of what is observed. I heard some sceptics saying that back in the old days phenomenology meant a different thing, but such grumbling should not be taken seriously.

Comments

1. **mike**
   August 14, 2008

   If the landscape theorists don't want to make predictions, it means nobody has a valid theory that can predict anything. Waiting for the results from CERN is like seeing the test answers before taking the test.

2. **Kea**
   August 15, 2008

   Well the term **jungle scenario** is one good thing to come out of all this discussion, and it could be applied outside stringy physics.

3. **Ptolemy**
   August 15, 2008

   There's no way to rule out an uncomputable number of possibilities for at most one of which there is any evidence of its existence? That's closer to religion than it is to science (only religion just posits one possibility and sticks to it, no matter what). One can imagine all sorts of mathematics that is beautiful, consistent, etc. and has some resemblance or even connection to established physical models, but that does not make such mathematics physics, and the approach of trying to winnow down the possibilities to the one that is right (!) will be swamped when along come Kepler and Galileo.

4. **anon.**
   August 16, 2008

   How old will you be on 9/11?

   I'm just a bit worried about whether you'll have to retire from Columbia University before popular non-falsifiable ideas have kissed the dust, which may take decades. I hope you'll be able to to continue blogging for a long time yet.

5. **Peter Woit**
   August 16, 2008

   anon.,

I’ll be 51 next month. I fully expect some misguided but popular ideas to be around longer than I am, since many of their proponents are younger than me, and seem quite devoted to soldiering on, no matter how bad things get.

Then again, if the LHC sees nothing that supports these ideas, their proponents are going to have a very hard time continuing to be taken seriously by their colleagues. Change will come, by the usual means of younger people choosing to not follow, and older people dying off.

6. **Thomas Larsson**
   August 16, 2008

   Desperately seeking Susy.

   Madonna is 50 today.

7. **dir**
   August 17, 2008

   anthropic ideas are not necessarily pseudo-science, sometimes they have predictions. for examples, the so-called split susy does have testable new particle spectrum; cosmological constant is another example.

8. **Mirek Kozlowski**
   August 18, 2008

   Dear Peter
   We are eyewitness the crash of the so called “string theory”. Now the future results of the LHC(one of the most expensive toy of the string mafia) is also under question.What is the plan B for the experimentalists if the Higgs has greater mass?. Can we ,theorists ,help to overcome the results of the blind faith of the “stringers”?
   PS Thank you for your book. Here in Poland we read it with great pleasure and understanding.
   MK

9. **Peter Woit**
   August 18, 2008

   Mirek,

   I’m glad you like the book, but I strongly disagree with you about the LHC and the “string mafia”. Despite the impression some string theorists try and give, the LHC has nothing at all to do with string theory. Depending on what results come out of it, they may or may not be very helpful in re-orienting the subject away from some of the excesses caused by string theory.

Strings 2008

August 17, 2008
Categories: Strings 2XXX

Strings 2008 starts tomorrow at CERN, with about 400 physicists in attendance. CERN will be providing a live webcast for the rest of us. The timetable of the talks is here. The first afternoon will be devoted not to string theory, but to the LHC.

Those in attendance without their own blogs are encouraged to report on the goings-on by writing comments here when they get bored by the talks. I'll try and watch some of the talks (or at least look at the slides), and use this posting to write about them.

Update: I'm not likely to be up early enough to catch the morning talks on the webcast, but Lubos is, so you can follow his virtual live-blogging.

Update: Live, the conference seems to be suffering from not always being up to the technology of displaying slides on a Mac to the audience. But slides of the previous talks are now beginning to be available here.

Update: After looking through the slides of the talks and hearing a few of them, the thing that strikes me most about Strings 2008 is how little there has been about strings. Particle theory may be moving to a model where the big annual conference is labeled "STRINGS", and speakers make nods of respect toward string theory, but actually talk about something else.

The three big hot topics of the conference are

- the LHC (talks by Evans, Engelen and Buchmuller), which has nothing at all to do with string theory
- New 3d superconformal quantum field theories (talks by Lambert, Maldacena and Mukhi). One motivation for these is that they can be fit into a pattern of dualities, much like the famous 4d superconformal theories that have dominated particle theory research since Maldacena.
- Scattering amplitudes, especially those of N=4 SYM and N=8 supergravity (talks by Veneziano, Kallosh, Dixon, Cachazo, Green, Sokatchev and, to come, Alday). Some of this looks a lot like particle physics from the mid-60s, based on the study of the analytic S-matrix, including the presence of Veneziano. While there has been a lot of progress in studying certain kinds of QFT S-matrix amplitudes in recent years, some of it coming out of string theory, the most dramatic news is that about the possible finiteness of perturbative N=8 supergravity. Remember all those talks you've heard where someone draws a Feynman diagram and a string diagram, then explains how this shows that perturbative QFT has deadly divergence problems due to point-like interactions, while perturbative string theory doesn't? Well, it appears that you can forget about all that now. In a rear-guard action, some speakers point out that you need to understand non-perturbative N=8 supergravity, and maybe this can't be done in a QFT context. Unclear why non-perturbative string theory is supposed to help here, since the only viable non-perturbative version of it is, by duality, a QFT itself…

Looking at the talks that actually are about string theory unification, you quickly see why most people are talking about something else. Ibanez starts off by asking whether string theory makes physical predictions, then claims that it does, with one of them being exactly the reason it doesn't make predictions about physics: "There is a large landscape of string vacuum solutions…", which he then goes on to describe. Donagi's talk, about Heterotic Standard Models, was remarkable in how much the situation there hasn't changed since 1985. You can come up with such models with the right quantum numbers (and actually, just about any quantum numbers you want…), but to get anything else, you have to address how to stabilize moduli and break supersymmetry, and Donagi just mentions these problems at the end as tasks to address in the future. For more about the F-theory-motivated models reported on, see the comments at this posting, where "anonymous" has an informed discussion with him (or her)self.

Comments

1. **Thomas R Love**
   August 19, 2008

   Clicking the link to Motl's site, one is subject to a rant which includes
   this:

   "Virtually everything written on the blog you visited a minute ago is nonsense and virtually all contributors are crackpots. The owner of the blog, Peter Woit, a computer administrator and a lecturer in discipline, is trying to revenge to the high-energy physics community for his inability to become a physicist himself.

   You can check that during the last two decades, Peter Woit only wrote 3 rants against string theory and one unpublishable, 0-citation demonization of spinors in quantum field theory, earning less than 10 suspicious citations in total. For comparison, Edward Witten wrote nearly 200 articles during the same period, earning almost 40,000 citations from them. Peter Woit is not a scientist in any sense; he is just an activist. "

   First, your Columbia webpage does say you are a lecturer in discipline, it should be Lecturer in Mathematics, shouldn't it?

   Secondly, Motl has confused quantity with quality. The number of articles written and the number of citations has nothing to do with the quality of the work.

   Third, why do you provide a link to a site which says you (and I) are crackpots?

2. **Peter Woit**
   August 19, 2008

   Thomas,

   I should update my web-page. For one thing, I've been promoted, and my title is now "Senior Lecturer" (the "in Discipline" part isn't very meaningful, the discipline in question is mathematics).

   The links to Lubos's blog are there when there's something interesting on his blog. The ad hominem attacks he puts out on anyone who criticizes string theory I think speak for themselves. He's done (and continues to do) more damage to the public perception of string theory than I ever will.

   Following his stream of consciousness about the talks is actually pretty fascinating. On the one hand, he's giving an extremely competent and expert commentary of exactly what the conventional wisdom is at the top levels of the string theory establishment about currently fashionable research. On the other, he's clearly a complete fanatic and out of his mind. Quite an amazing combination to watch…

3. **PAMELA**
   August 20, 2008

   An interesting result was presented at another conference, about Dark Matter in Stockholm. Preliminary data from the PAMELA experiment show an excess in the energy spectrum of astrophysical positrons. If this will turn out to be the first observation of Dark Matter annihilations, the authors will have to come back to Stockholm for the Nobel prize.

4. **Peter Woit**
   August 20, 2008

   Thanks PAMELA,

   I saw a mysterious rumor about this last week. If anyone knows of anywhere there's slides or some details of this, please let us know.

5. **DB**
   August 20, 2008

   I imagine this is the talk that has got the rumour mill running:

   http://agenda.albanova.se/contributionDisplay.py?contribId=389&sessionId=257&confId=355

   By the way, congrats on the promotion Peter.

6. **anon.**
   August 20, 2008

   The PAMELA slide was shown at ICHEP, but they're publishing in Nature (*exasperated sigh*) and consequently there's an embargo on actually releasing the plot in advance of publication. So as far as I know it's not available anywhere online; you have to talk to someone who saw it. There is a Nature News story about it, complete with crackpot comments.

7. **Shantanu**
   August 20, 2008

   There have been many such claims for "excess" in such
   indirect dark matter detection experiments, but none of them
   are smoking gun. I guess we will have to wait until the paper is out.
   Peter : congrats from me too.

8. **Click**
   August 20, 2008

   "After looking through the slides of the talks and hearing a few of them, the thing that strikes me most about Strings 2008 is how little there has been about strings."

   Peter,

   This is not surprising at all as a lot of people are focused as the most expensive experiments in the history of science is about to be conducted. As far as I see the underlying motivation has come from string theory. I am constantly surprised why you hate the word "string theory" so much.

   However, I would like to thank you for putting good informative links on math and physics.

9. **Peter Woit**
   August 20, 2008

   Click,

   Despite what you have heard, the LHC has nothing to do with string theory. String theory is not the underlying motivation for the experiments at the LHC.

10. **PAMELA**
    August 21, 2008

    indeed there is an embargo: the result of PAMELA was flashed during conferences but the slides cannot be published on-line. I don't know if a photo of the result taken during the talk would violate the embargo.

11. **nbutsomebody**
    August 21, 2008

    Point about N=8 super-gravity is indeed very important. If we can have a finite theory of gravity, then who needs string theory ?

12. **Per**
    August 21, 2008

    Matthias Staudacher just gave a talk about the spectral problem of AdS / CFT. With the help of integrability, it is quite amazing how close this problem is to a complete solution.

    This is actually something which is quite outstanding, and I sometimes get the feeling that you neglect this in your critique (which, in my opinion is often well based) against string theory. If you compare to any research in theoretical particle physics at the moment, would you say anything is as interesting as this? My vote would be that it ties with the N=8 stuff that's going on at the moment (however, if I were to make a bet it would be against N=8 working out and for AdS / CFT being solved (in the planar limit)).

    Best wishes, P

13. **Daniel de França MTd2**
    August 22, 2008

    Any positive reaction to Carlo Rovelli talk? According to Lubos, he was almost ignored.

14. **Peter Woit**
    August 22, 2008

Per,

There certainly has been real progress in the AdS/CFT calculations you mention, and I wouldn't be surprised if sooner or later a complete understanding of the planar limit was achieved, which would be great.

The problem though is that this doesn't really change much, since everyone has been assuming that this works for 10 years now. The N=8 stuff is much more exciting, partly because it is much newer and much more poorly understood. If N=8 finiteness is true, it opens up all sorts of possibilities that had been thought to have been closed off, and these are possibilities relevant not just to solving QCD, but to unifying physics.

Daniel,

Lubos was just watching the webcast, I doubt that from that he could tell much about what the 400 people in the audience thought. Presumably some had the same juvenile thoughts as him, others may have been more interested. As string theorists are careful to point out, there's a wide range of attitudes within their community, with Lubos just one extreme point.

15. **Daniel de França MTd2**
August 22, 2008

Peter,

I know that. But did you, or anyone else too, see the webcast? His coverage of the string subjects was excelent, but not about this one… So, it's like I missed his talk…

16. **Peter Woit**
August 22, 2008

Daniel,

I just caught the first few minutes of Rovelli's talk, then had to leave. Maybe if one saw the question section one might have gotten more of an impression of the reaction of the audience, but I kind of doubt one could really tell much from the webcast.

17. **Per**
August 23, 2008

The talk by Rovelli was one of the talks that received most questions after wards. My impression was that it was very well received and the audience was genuinely interested. After the talk a rather big group assembled around Rovelli and asked him questions privately. This went on for quite some time if I am not mistaken. As part of the audience, it was very pleasing to see that none of the string / anti-string aggressiveness was there.

18. **Daniel de França MTd2**
August 23, 2008

Peter,

Renata Kallosh provided a proof for N=8 renormalizabily, given that there is no anomaly in the expansion. She published it in the same day of her talk:

http://arxiv.org/PS_cache/arxiv/pdf/0808/0808.2310v1.pdf

Do you agree with her? Also, do you agree with the argument that for d>3, it must be tied to strings? Why(not)?

19. **Urs Schreiber**
August 25, 2008

> I just caught the first few minutes of Rovelli's talk, then had to leave. Maybe if one saw the question section one might have gotten more of an impression of the reaction of the audience, but I kind of doubt one could really tell much from the webcast.

One question was if the LQG methods had been applied to 3d gravity and results compared with the information one has about that, including Witten's latest connection to 2d CFT.

(Answer: unfortunately not.)

One question was how one can talk in LQG about black hole entropy without being able to talk about black holes, due to a lack of semi-classical limit.

(Answer: there are two different ways to define a horizon, globally and locally.)

One question was if the advertized "loop quantum cosmology" is really be derived from LQG.

(Answer: no, it is just quantization of cosmological models with some LQG inspired modifications.)

One question was if the problem with the Immirzi-parameter has been resolved, since two different arguments seem to require two different values.

(I think as a reply Rovelli reviewed what the Immirzi-parameter is.)

My impression from watching the webcast of talk and question session: the audience was not ignorant about LQG and might have apprectiated a less introductory talk addressing more of the technical issues. It remains a bit frustrating to see Rovelli using up so much time to explain the bare idea of a "spin network" to an audience that is familiar with the concept of Wilson line and non-perturbative gauge theory on the lattice.

Generally I think: everybody would be happy if a non-perturbative description of gravity using a parameterization of configuration space by Wilson loop observables were available. Lots of stringy work in supergravity is routinely using first-order Lagrangians that encode the Einstein-Hilbert action in terms of a connection. If there is disagreement about LQG, it seems it is not so much about this premise but about technical issues that follow.

20. **Thomas Larsson**
August 25, 2008

"including Witten's latest connection to 2d CFT. "

But that was wrong, wasn't it?

21. **Chris Austin**
August 25, 2008

Hi Daniel,

"Renata Kallosh provided a proof for N=8 renormalizability … Do you agree with her?"

The claim was actually of UV finiteness, i.e. the cancellation of all UV divergences, rather than renormalizability, which means that UV divergences can be absorbed in infinite redefinitions of coupling constants.

It seems to me that there might be a problem with Kallosh's argument, which was based on finding an inconsistency, at the linearized level, between counterterms in Lorentz-covariant gauges and light cone gauge, because the corresponding counterterms appear to be consistent between Lorentz-covariant gauges and light-cone gauge in d = 11, and we would therefore expect the same to be true after dimensional reduction to d = 4.

Specifically we are considering local quartic vertices that are super-Poincare covariant at the linearized level, and in 11 dimensions these were constructed in Lorentz-covariant gauges by Deser and Seminara, in http://arxiv.org/abs/hep-th/9812136 and http://arxiv.org/abs/hep-th/0002241, and in light-cone gauge by Metsaev, in http://arxiv.org/abs/hep-th/0410239.

Metsaev uses a formalism in eleven dimensions where only so(7) invariance is manifest, so as to have a completely unconstrained d = 11 superfield based on an 8 component so(7) spinor, but on dimensional reduction to d = 4, choosing the R and L transverse dimensions to be among the compact dimensions, this should reduce to the Brink, Kim, and Ramond formalism of Kallosh's eqn. (1.5). In fact the superfields in Metsaev's eqn. (2.16) and Kallosh's eqn. (1.5) exactly match term by term, including the powers of p^+, if we reverse the order of the terms in comparing the two papers, and note that Metsaev uses the notation \beta for p^+, see eqn. (2.17).

Metsaev explicitly constructs all the Poincare generators to verify Poincare invariance in d = 11, which should imply Poincare invariance in d = 4, and also finds, in eqn. (5.29) on page 23, the most general local quartic vertex that is super-Poincare covariant at the linearized level, and thus should contain terms built from four Riemann tensors, with possible covariant derivatives acting on them. This should reduce in four dimensions to counterterms such as Kallosh's eqns. (3.3) and (3.6).

Metsaev's light-cone gauge result for the most general local quartic vertex that is super-Poincare covariant at the linearized level, namely that it is obtained from the leading one, that contains the t_8 t_8 R^4 term built from four Riemann tensors, by applying derivatives corresponding to the most general non-vanishing symmetric polynomial built from the Mandelstam invariants, see e.g. Metsaev's formula (5.34), on page 24, is consistent with Deser and Seminara's manifestly Lorentz-covariant construction, and shows that Deser and Seminara obtained the most general such vertex.

To try to pin down further why Kallosh found a Lorentz-non-covariant numerator factor (p^+)^4 from her counterterm eqn. (3.6), we note that Metsaev's local formula (5.29) involves, in effect, four powers of p^+ in the denominator, since \beta_{13} means \beta_1 + \beta_3, from (5.4) on page 21, and \beta_a means p^+ for the a'th leg of the vertex, see e.g. the footnote on page 3, or (2.17) on page 8, or (2.26) on page 9, and the top of page 12. Furthermore, there is nothing hidden in the other factors in (5.29) to cancel these overall denominator powers of p^+, and when we combine with the superfields and the measure factors as in (5.1), on page 20, taking the superfield and measure factors from (3.6) to (3.9) on page 11, to obtain the formula which on dimensional reduction to d = 4 should contain Kallosh's eqn. (3.6), we see that Metsaev's formula contains four overall powers of p^+ in the denominator, which it would appear could cancel the four numerator powers of p^+ found by Kallosh.

Best regards,
Chris

22. **Jeff McGowan**
August 25, 2008

OK, no doubt silly question, but I'm a mathematician, last physics classes I took were GR and relativistic QM around 1984. Is the excitement about the finiteness of N=8 supergravity simply because there is then ONE known finite theory? Assumption then being that if one theory is finite, others which might actually be relevant to the real world (whatever that might be 🙂 might also be finite?

Don't hold it against me that I study Riemann surfaces, really, I don't have anything to do with strings (although I do remember a talk at a conference maybe 15 years ago where the number 26 kept coming up, and one of the questions at the end was "is that the 26 dimensions from string theory?")

23. **Peter Woit**
August 25, 2008

Jeff,

One reason for the excitement is that this indicates there is some new symmetry or important unexplained feature of this theory. If one can figure out what it is, the implications could be very important. Whatever it is, it seems to get around what was always considered a fatal disease of the theory.

The fact that this destroys the main argument always used to justify the idea that to do quantum gravity one must abandon QFT and do string theory is one that string theorists are doing their best to ignore.

24. **Jeff McGowan**
August 25, 2008

Peter,

Thanks. I have some sense of the issues in QFT with infinities, and that this finiteness might give physicists some hope that there might be a way around that. I have the mathematicians caution about generalizing from cases (and about renormalization, I know it seemingly works quite well thank you), but appreciate that it is always nice when you can find a case that works with the hope that it gives you an idea about how to handle the bad case. My joke (lame as it no doubt was) about Riemann surfaces and 26 dimensional string theory, was meant to indicate that I have always had issues with physical theories that are too "flexible" (26 dimensions, no 10, no 12, no 11….).

Interestingly (to me at least), the issues between physics and math which somehow seem embodied in the string theory mess are just silly. Physics and math have always been good for each other, in both directions. I'm not so sure how much really interesting math there is in string theory, although there is clearly some. I owe a very useful part of my doctoral education to a physicist, my orals were explaining Witten's beautiful JDG paper on Morse theory.

Freed on Chern-Simons

August 20, 2008
Categories: Uncategorized

Dan Freed has a wonderful preprint out on the arXiv this evening, based on a talk he gave at the celebration of MSRI's 25th anniversary, entitled Remarks on Chern-Simons Theory. It's mainly about the current state of attempts to better understand the mathematical significance of the Chern-Simons-Witten quantum field theory.

This is a truly remarkable and very simple 3d quantum gauge theory, the significance of which Witten first came to understand back in 1988. He quickly showed that the theory brought together in an unexpected way several quite different but important areas of mathematics and physics (3d topology, moduli spaces of vector bundles, loop group representations, quantum groups, 2d conformal field theory among others). This work was the main reason he was awarded a Fields medal in mathematics in 1990. While Witten and others worked out many important aspects of this story back then, many important puzzles still remain, and it is these that Freed concentrates on.

Perhaps the biggest puzzle is that of how to actually define the theory in a local manner. The standard definition thrown around is that this is just the QFT with Lagrangian given by the Chern-Simons number CS of a connection A, so all one has to do is evaluate the path integral
$$\int e^{i2\pi k CS(A)}$$
While this is a good starting point for a perturbative expansion at large k, it doesn't appear to make much sense non-perturbatively. Freed points out that it is known that the theory must depend on additional topological structure on the 3-manifold (e.g. a 2-framing), whereas the path integral looks like it only depends on the orientation. If you try and think about how you would actually calculate such an integral numerically, by discretizing it and taking a limit, it looks like you will end up with something hopelessly dependent on the details of the discretization and the limit. For a much simpler toy example with some of the same problems, consider the path integral on closed curves on a sphere, taking as Lagrangian the enclosed area.

Freed describes in detail the state of attempts to rigorously define the theory without dealing with the path integral, but instead exploiting the fact that it is supposed to be a topological qft, and thus may have an abstract definition in terms of generators and relations. He describes the current situation as follows:

- There is a generators-and-relations construction of the 1-2-3 theory via modular tensor categories for many classes of compact Lie groups G. This includes finite groups, tori, and simply connected groups, the latter via quantum groups or operator algebras.
- There are new generators-and-relations constructions – at this stage still conjectural – of the 0-1-2-3 theory for certain groups, including finite groups and tori.
- There is an *a priori* construction of the 0-1-2-3 theory for a finite group.
- There is an *a priori* construction of the dimensionally reduced 1-2 theory for *all* compact Lie groups G

The bottom line is that we only have a local construction of the theory for the case of finite groups, where one can make perfectly good sense of the path integral. For the case of a 3-manifold that is a product of a circle and a Riemann surface, one can define things in terms of a 2d theory, and Freed explains the connections to the Freed-Hopkins-Teleman theorem.

To convince mathematicians that there is something to the path integral, Freed writes down the asymptotic expansion for large k that it leads to, and shows that this gives a highly non-trivial conjecture relating quite different mathematical objects associated with a 3-manifold. He shows strong numerical evidence for this conjecture.

Finally, he ends with some extensive and interesting comments about the relationship between quantum field theory and mathematics, as it has been pursued by both physicists and mathematicians over the past quarter-century, with some speculation about what direction this might take in the future.

Comments

1. **James Robson**
   August 21, 2008

   I wouldn't normally have commented here as the level is usually well above me and the discusssion is usually frantically mathematical (or overly personal). But, it seems like nobody else has commented yet so I'll take this opportunity to ask the simplest thing: what does this mean:
   "For a much simpler toy example with some of the same problems, consider the path integral on closed curves on a sphere, taking as Lagrangian the enclosed area."

   Simple as it may be I've forgotten loads of my differential geometry and QFT from college, as without use, maths just seems to evaporate, and would plead an indulgence if there are no better replies t deal with. Does the patah integral relate to the enclosed are via stokes?

   -james.

2. **Knight who says ni**
   August 21, 2008

   Off topic:

   Could you please recommend a good survey of conformal field theory for mathematicians? Something where one could find the main ideas explained in geometric terms, without long formulas with indices all around, e.g. Atiyah's "The geometry and physics of knots" etc.

3. **Peter Woit**
   August 21, 2008

   James,

   Yes, via Stokes you can expressed the enclosed area as an integral over the closed curve. This is well-defined modulo the total area of the sphere (you have a choice to make about what is "inside" the curve, what is "outside", the difference is the area of the sphere)

   This is just the action though. To get a path integral, you are supposed to multiply by i, and exponentiate, getting a phase, then, integrate this phase over the infinite dimensional space of all closed paths. It's this last step which is highly problematic.

4. **Peter Woit**
   August 21, 2008

   Knight,

   One place to start is Gawedzki's "lectures on conformal field theory", in the IAS volume (Quantum Fields and Strings, a course for mathematicians).

Graeme Segal's notes on CFT give a different and quite interesting perspective, definitely few indices there…

5. **mike**
August 21, 2008

Peter,

I have to admit that this one is a little over my head as well, although I seem to remember that path integrals are integral (sorry!) to QFT so just to inquire about your comment,

"If you try and think about how you would actually calculate such an integral numerically, by discretizing it and taking a limit, it looks like you will end up with something hopelessly dependent on the details of the discretization and the limit",

Forgive my lack of understanding if it seems too simple a question, but would it help to use a Taylor series for the exponential and to find an approximation on the discrete terms or does this action through away the important parts of the result?

6. **Peter Woit**
August 21, 2008

mike,

The problem is that the space of closed paths is infinite-dimensional, so you're trying to integrate over an infinite-dimensional space. Normally what you do in such a situation is pick some way of discretizing the problem, so that it becomes finite dimensional, then take the limit as the discretization goes to zero. The problem isn't that you can't do this kind of calculation, it's that the limit (if it exists) is going to depend on the details of how you discretized.

This kind of path integral is quite different than the usual ones. There you can analytically continue in time, and get something with gaussian fall-off, that can be made well-defined. Here if you analytically continue, the phase stays a phase.

As far as I can tell, the situation here, like Chern-Simons, is that some additional structure is needed that will allow a well-defined formulation of the integral.

7. **mike**
August 22, 2008

Peter,

I am not sure how you would make the integral converge, but an alternate guess is that perhaps you can try representing the discrete function as a complex function, like a z-transform. Then, instead of taking the limit as the discreteness goes to zero, you can just look at the causality of the function which produces a region of convergence for solutions that are stable (ROC < 1). This is sort of a "landscape" solution that graphically may show where the bounds of the solutions lie in complex space. If there is convergence on the path integral, I would guess it should be bounded when represented as a complex function, but maybe that's a big guess.

8. **James Robson**
August 22, 2008

Peter,

Many thanks for your reply.

I said I had forgotton most of the maths I once knew – which is true and I regret it – but I did remember the (generalised) Stoke's theorem – honest! It's one of those unifying beautiful results that you get taught and time does not erode. Thanks all the same for taking time to explain things, which you did very clearly.

My real concern was about the path integrals, and I was hoping your "toy" example would help me out. I still remember a patchy smattering of measure theory, but, how would you try to get a measure on the space of all – I guess simple closed curves (?) – on a sphere? What branch of maths helps you out here? (probably "measure theory" Doh!), but, from what I've read, construction of suitable measures for the job is a real problem.

Do you think that, in the long run, these path integrals will become rigorously defined, and, like Newton/Leibnitz calculus, Dirac deltas, differentials /"one-forms", etc, become important branches of maths in the future?

-James.

9. **Peter Woit**
August 22, 2008

James,

My point here is that the problem of making sense of this kind of path integral is ill-posed. I don't think you can do it without adding some structure and changing the problem. This is true both for Chern-Simons and for the toy model. You can change the toy model problem into a QM problem where the answer is clear and given by representation theory. There you find you need to add a kinetic term and fermionic terms to the path integral. I suspect something similar needs to be done for CS, but don't know how to do this.

10. **Hans de Vries**
August 29, 2008

The abelian Chern Simons theory for the electromagnetic field provides lots of useful insights. For example the spin-density of the electromagnetic field, which can be expressed as S = D x A + HV. The combination of this pseudo vector together with the axial Dirac current forms a preserved quantity.

The concept of an EM spin density has yet to trickle down from QFT to the more general EM audience. I devoted a chapter in my coming QFT book to work out two elementary examples:

The EM spin density of an electron with charge and magnetic moment as well as the spin density of arbitrary polarized radiation from an atomic spin 1 transition. Both examples result in what you would expect from an EM spin density.

Gross on Outlook for String Theory

August 22, 2008
Categories: Uncategorized

David Gross just finished giving the closing talk at Strings 2008, on the outlook for string theory, following a talk by Hirosi Ooguri summarizing the conference. Strings 2009 will be in Rome next June, and it appears that there is a tentative plan to have Strings 2010 in College Station, Texas.

Gross began his talk by recalling his days as a postdoc at CERN in the late 60s, working on an early version of string theory (e.g. trying to extend the Veneziano model). At the time he felt CERN was a great center of theory, but somewhat of an experimental backwater, with the real action he was interested in happening at SLAC. Now, forty years later both string theory and CERN have flourished. CERN is in the process of becoming the single world umbrella lab doing particle physics, driving all the others out of business. Unfortunately, Gross sees the same thing happening in particle theory and seems rather pleased about it, saying that only one umbrella in theoretical physics will survive, string theory, eating up everything else. Except LQG, which he says has not yet been brought under the umbrella, and "we're not sure we want to".

I found this display of string theory triumphalism truly appalling. The fact of the matter is that string theory has failed miserably to do what it was supposed to do, explain unexplained features of the standard model and predict what happens beyond it. Under the circumstances, to claim victory and write out of particle theory anything that doesn't fit under the string theory "umbrella" is completely inappropriate. The message to any young particle theorist from Gross was clear: fall in line with string theory ideology, or there will be no place for you under the "umbrella", i.e. no job for you (the phenomenologists have their own umbrella, you better try that one). The fact that HEP experiment is being forced to consolidate in one lab by economic realities is a really unfortunate one. There is no similar reason for HEP theory to be forced to consolidate around one topic.

Later on in the talk, Gross started channeling Lee Smolin and me, urging young people to stop sticking to the same well-worn ideas, to stop looking under the same lampposts, and to go out and search for something really new. He argued that they would find wandering in the darkness less competitive since few people were doing it. It was unclear whether one is allowed to get out from under the umbrella when one goes out to investigate the darkness, presumably not.

While he made lots of positive comments about current work in string theory in order to rally the troops, much of his talk was rather pessimistic and critical of trends in string theory research. He acknowledged that there hadn't been any "great breakthroughs" in the field in quite a while. String phenomenology was described an attempt to make string theory "a predictive, or at least imitative" framework. He didn't comment on what it means for theorists to give up on predicting nature, and settling for imitating it.

About the LHC, he acknowledged that it is unlikely to have anything to say about string theory. He finds the idea of seeing black holes, strings, etc. "extremely unlikely", but is betting that the Higgs and supersymmetry will show up. Unfortunately, even if supersymmetry is found "it's not clear that we're going to learn enough", this won't answer any deep questions about string theory or prove that it is relevant. His "most optimistic hope" is that the LHC will see something unexpected, and "we will realize that this was an obvious prediction of string theory". He notes that this is "almost our last chance", if nothing relevant to string theory shows up at this energy scale, it is unlikely that anything relevant will show up at any energy scale accessible for an extremely long time.

Gross commented on two topics that hadn't been mentioned in the talks. He's still hoping for a non-anthropic explanation of the CC, and noted that no speaker had brought up the anthropic landscape explanation of the CC, with it getting a mention only at one after-dinner talk. Despite what Susskind claims, perhaps the battle between the anthropicists and their opponents is not going so well for the anthopic side. They may get pushed out from underneath the umbrella…

The second topic was the still unsolved question of "what is string theory?". Gross noted that there were no talks on string field theory, since it and most other ideas about how to define string theory non-perturbatively have gone nowhere. The one thing that is still alive is AdS/CFT, which now completely dominates the subject. More and more, particle theory research under the umbrella is focused only on things related to the duality of N=4 SSYM and string theory on AdS^5 x S^5. Gross noted the progress toward showing this duality, with the planar limit perhaps being done within the next few years.

By the way, in Ooguri's talk, he mentions an AdS/CFT discrepancy that has been resolved, saying he was surprised that some blogger didn't claim this discrepancy as disproof of AdS/CFT. Lubos in his commentary helpfully explains that Ooguri was referring to "numerous pigs and Woits". Since I've never argued that there's a problem with AdS/CFT duality, I guess he must be talking about someone else. Maybe Jacques Distler has some postings about problems with AdS/CFT that I missed.

Gross takes the attitude that there is no more value in working on "tests" of AdS/CFT, that the conjecture is now well-tested and it is time to move on to try and understand what AdS/CFT is good for, especially what it says about the question of "what string theory is?". The planar limit is just the classical limit, and he discusses prospects for moving beyond it . On the QFT side, this means deforming the gauge theory by non-renormalizable operators, so it is not clear what to do.

Update: More summary commentary and prizes at [Resonaances](). Clifford Johnson watched Gross's talk and [summarizes]() it as follows:

> David Gross summed it all up, took stock of where we are, and where we aren't, and looked forward. A sort of "state of the union" speech if you like. And the state is good. Very good indeed.

Comments

1. **anon.**
   August 22, 2008

   The planar limit is just the classical limit, and he discusses prospects for moving beyond it. On the QFT side, this means deforming the gauge theory by non-renormalizable operators, so it is not clear what to do.

   Going beyond the planar limit just means going to finite Nc on the field theory side (and computing g_s corrections in the dual). Non-renormalizable operators are a separate issue: they let you deform away from asymptotically AdS, with the hope of somehow probing properties of flat-space string theory. I wouldn't have high hopes for that, but then, Gross is smarter than I am….

2. **Peter Woit**
   August 22, 2008

   anon.,

   Thanks for the clarification, I wasn't careful enough writing that, should have made it clear that Gross was speculating about moving beyond the AdS/CFT duality, changing the background, not just further tests of AdS/CFT at higher orders in 1/Nc. I've edited the post slightly to clarify.

3. **Esornep**
   August 22, 2008

   D. Gross said:

"Much like other string meetings, it's been extraordinarily exciting."

Tongue firmly in cheek, I suspect.

4. **Shantanu**
   August 22, 2008

   Peter and others, are the the vidoes of the meeting archived?
   Or are they only avaiable in realtime?
   Thanks

5. **Daniel de França MTd2**
   August 23, 2008

   There were really interesting things in the meeting, one of them was covered here by Peter. On Wednesday, it happened really nice talks concerning advances towards the proof of renormizability of supergravity N=8 and some useful nice side effect from this, like more efficient ways to calculate the perturbative terms of the usual QCD.

6. **Umesh**
   August 23, 2008

   Were there no comments on Rovelli's talk on LQG?

7. **hvtek**
   August 23, 2008

   Hahaha! You find the display of string theory triumphalism appalling? And that it failed miserably in its objectives? What about LQG? Did you watch Carlo Rovelli talk? It was pure comedy, to put it lightly. Even he admitted in one of his slides (one of the first, in fact) that the low energy limit of his theory is pretty much work in progress. What a joke! So, if he and his people can't derive Einstein equations from their formalism, it is not a theory of quantum gravity. It is not even a theory of gravity (let alone the other interactions, or matter content)! His talk should have ended there! Instead he continues, talking about black holes (solutions of the low-energy limit he can't derive) and diffeomorphism groups (not the Lorentz group we're interested in, as Alvarez-Gaume put it in one comment), Immirzi parameters (that must be fixed in different ways to get the different answers he wants to achieve), and many other stand-up comedy pieces.

   String theory, on the other hand, has GR as its long-distance limit. No doubts about that! And it's a consistent quantum theory. Therefore, it is a theory of quantum gravity! Crystal-clear! The "phenomenological" work in progress in string theory is the derivation of the effective model for the remaining interactions, which must contain the Standard Model in the energy range of present accelerators. But that requires the understanding of the stringy vacuum, and that is not for the faint-hearted or amateurs. And, of course, there is no deadline to solve that problem. What does that even mean?!

   String theory is indeed the only theory of quantum gravity in existence. And by that I mean a theory that can be explicitly shown to contain Einstein gravity in the large-distance limit, and it is an anomaly-free quantum theory. The possibility of construction of such theory should, as a consequence, contain enough freedom to accommodate all the other interactions, and string theory does just that. It even provides a prescription to calculate particle masses and other physics parameters from the geometric properties of the vacuum, once you find it. It is a hard task, but is not impossible. It is by far more likely than LQG being consistent with low energy physics.

   The reason why I defend string theory is that it contains too many beautiful and meaningful results to ignore it as one of the greatest achievements in physics (and mathematics). It gives us so many hints that it is correct that it must be so. Just like Gross' comment on AdS/CFT. It's like Riemann's hypothesis: it's beautiful, it provides so many outstanding results, and it's verified up to the first 10^13 zeros. It has to be true! But even if it's not, I thing that it would be also very interesting (if not more), because you would have to explain why the zeros don't fall on the critical line only for the 10^500th zero, for example. And even if string theory is proved not to contain our world as a solution (which I doubt), you would still have to explain why not! Because you can already model strings to get toy models for particle phenomenology. They are not the real world, but they are not far removed from it. So, even the absence of a solution containing the Standard Model would simply mean that string theory as we know it would have to be slightly extended instead of completely replaced.

   In conclusion, I believe that the answer will arrive, and it will come from string theory. But be patient, because there are no deadlines to fill.

8. **somebody**
   August 23, 2008

   "CERN is in the process of becoming the single world umbrella lab doing particle physics, driving all the others out of business. Gross ses the same thing happening in particle theory and seems rather pleased about it, saying that only one umbrella in theoretical physics will survive, string theory, eating up everything else."

   There is a world of difference between Gross' claim that string theory contains all the great ideas known in particle physics and gravity, and your claim that string theory is "eating up everything else". You have managed to turn a scientific point that someone was raising (in this case, Gross), into a sociological statement.

   String theory contains gravity or gauge theory or non-commutativity or whatever NOT because it is evil and wants to take over other disciplines. It is just an inherent mathematical feature of string theory. To subtly redefine the problem into a sociological one only helps to misguide your untrained and/or gullible readers.

9. **Arun**
   August 23, 2008

   hvtek – The three notions that I disagree most with are:

   It gives us so many hints that it is correct that it must be so.

   And even if string theory is proved not to contain our world as a solution (which I doubt), you would still have to explain why not!

   The comparison of string theory with Riemann's hypothesis is the third.

   All three are pinnacles of anti-scientific thinking.

10. **somebody**
    August 23, 2008

    Arun cites hvtek's claim that "[string theory] gives us so many hints that it is correct that it must be so"
    as a
    "pinnacle of anti-scientific thinking."

I disagree. If you had said hvtek could actually be WRONG, I would have agreed. But being "scientific" is an entirely different thing. Trusting an idea that goes through many of the wickets, and trying to take it to its completion so we can reap the full rewards, is in fact the way theoretical physics SHOULD work. Is it conceivable that the idea is wrong? Of course it is. But that is completely beside the point. Doing science is in fact about taking bets that seem reasonable at the time and dealing with ambiguity. HVTEK was emphasizing that at this point the most reasonable bet is string theory.

Here is the status quo as I see it: string theory has all the features of quantum gravity one would hope for, including solutions to black hole puzzles, singularity resolution, holography, possibility of topology change etc. etc. It contains the broad outlines of realistic particle phenomenology including chiral fermions, generations, gauge groups etc. etc. It brings together almost all (if not all) of the most experimentally successful ideas in theoretical physics including gauge symmetry, Lorentz invariance, etc. etc. Experimentally, it is gradually bringing up connections to some condensed matter systems which are experimentally accessible (with some quantitative, but not very well-understood successes).

Any one of these would have been enough to make an idea interesting. It is inconceivable that string theory will have nothing to do with reality, because it already does. The valid question is whether it is going to be a useful tool in doing particle phenomenology, model-building etc. About that: despite all the nonsense claiming the contrary, progress has been steady, so there is no reason to think that we should give up now. Stabilized vacua are only five years old.

11. **fh**
August 23, 2008

hvtek, maybe Rovellis talk wasn't the best introduction given the audience, but you obviously have no clue what you are talking about. Yes LQG has some severe problems. No they are not the "problems" you mention. That's just misinformed blather. E.G: The Immirzi parameter is free in the Holst action, Ashtekar choose a value for mathematical simplicity, later it was found that in QM you have to choose it for consistency with BH entropy. Thus Ashtekars original simplifications could not be used. There are no conflicting scenarios for Immirzi, the original choice was purely for mathematical simplicity before its physical meaning and the way to fix it physically became known.

Since the low energy limit is such a joke to you could you please elucidate me how, given any background independent quantum theory, to even construct observables that would indicate it?

After all it is well known that pure gravity does not have good/unique thermodynamics (what is equilibrium in the absence of a timelike killing vector field?), nor energy scales (Black Holes come in all sizes).

And yes, it is probably fair to say that String theory is the only theory of Quantum Gravity, however at the enormous cost of shitloads of stuff that nobody has ever observed (e.g. 11 dimensions) or that is, even in priunciple, unobservable. Furthermore we have control over the theory only in ways (dual, perturbative) that obscure the conceptual questions that a final formulation must answer one way or another.

12. **Aleksandar Mikovic**
August 23, 2008

Hvtek's claim that string theory is a theory of quantum gravity is not a precise statement. The precise statement would be that string theory is a perturbative theory of quantum gravity since the arbitrary genus amplitudes are finite (again there is a caveat, since there is no proof for arbitrary genus, but string theorists beleive that it is finite). On the other hand, the nonperturbative string theory is less well-defined mathematically, and results like AdS/CFT
are conjectures, and even if true, it is not clear how it can be used to learn something about quantum gravity phenomena. When compared to Loop Quantum Gravity, one can see that LQG is a nonperturbative formulation, and this is the reason why it is difficult to see what is the flatspace limit (although, the recent work of Rovelli and collaborators has shown that the theory has room to accomodate gravitons, and hence the Einstein equations in the classical limit). Hence the claims that the string theory is the only viable candidate for a quantum gravity theory are not true.

13. **somebody**
August 23, 2008

"And yes, it is probably fair to say that String theory is the only theory of Quantum Gravity, however at the enormous cost of shitloads of stuff that nobody has ever observed (e.g. 11 dimensions) or that is, even in priunciple, unobservable."

This is misleading. String theory can have four dimensions as well.

The better way to say it is that string theory allows many classical solutions, of which one specific choice corresponds to ten dimensions. The ten dimensional theory is special only because it gives rise to the easiest perturtbation theory: the worldsheet CFT is free.

"Furthermore we have control over the theory only in ways (dual, perturbative) that obscure the conceptual questions that a final formulation must answer one way or another."

I have sympathy with this statement. But it depends a bit on what kind of conceptual questions one has in mind. What seems conceptually important at low energies is not always what is conceptually important at high energies. What is important is that the theory should REDUCE at low energies to the expected principles that we know and love at low energies. But I would say that to rigidly hold on to ideas stemming from a manifold-model of spacetime (such as naive spacetime diff. invariance) all the way to Planck scale, is unwarranted.

14. **bpz**
August 23, 2008

ft:"When compared to Loop Quantum Gravity, one can see that LQG is a nonperturbative formulation, and this is the reason why it is difficult to see what is the flatspace limit "
I think the question was about obtaining Einstein's equations in the low energy limit of LQG, and not about the flat space limit. The fact is that in the low energy limit ST automatically predicts not only the graviton in the spectrum, but also gives Einstein's equations from the worlsheet CFT beta functions, without specifying the background metric, and LQG does not even come close to achieving this.

15. **David Berman**
August 23, 2008

I feel the comments made above and indeed the tone set by Peter's reportage are not indicative of how stirng theorists think at all. This idea of an ongoing battle just isn't there. We are open to ideas and indeed Rovelli was invited to speak and everyone I met at strings was glad he did. This persistent itch to create and imagine conspiracies of string theorists excluding people really does verge on the paranoid. We are happy LQG people exist its just we choose something different. Each to their own tastes. I simply would encourage construction rather than criticism. Do your work and let others do theirs instead of moaning about hegemonies.

16. **Daniel de França MTd2**
August 23, 2008

David, do you read Lubos' blog?

17. **A.J.**
August 23, 2008

Daniel,

Citing Lubos is as a bad an argument as citing Lubos' arguments.

18. **Moshe**
August 23, 2008

fh, factual question regarding the Immirzi paramater: is there a choice of the parameter that makes the BH entropy come out right for more than one type of BH? first kind of BH can be regarded as calibration, anything after that is a test…

19. **Peter Woit**
August 23, 2008

somebody,

I don't think I was at all misrepresenting Gross's comments. People can listen to them and make up their minds. He was explicitly making an analogy between the dominance of CERN in HEP experiment and string theory in HEP theory. You can try and claim that this dominance of string theory is not a matter of sociology, but just reflects its huge success as a scientific research program. I strongly disagree.

David,

I think I was accurately reporting Gross's comment on LQG, including its tone. In other venues, Gross has publicly made dismissive comments about the subject. He's clearly no fan of the subject.

I don't doubt that many string theorists adopt the attitude you endorse of "each to their own tastes". But I also think that many, including many quite powerful ones, share what I fear is Gross's attitude that the hegemony of string theory is justified, that ideas that aren't somehow related to it are just not that interesting. Lubos reflects this attitude in its pure, uncensored form, but in less extreme form some of this attitude seems to be held by a lot of other people.

20. **Alberto G. P.**
August 23, 2008

The Minwalla's conference was about the 'Non Linear Dynamics from Gravity':

http://indico.cern.ch/getFile.py/access?contribId=24&resId=0&materialId=slides&confId=21917

I am not an expert in the subject, but this conference seem me very interesting. It's means that we can obtain analytic solutions of Navier-Stokes equations in a completely different way, by means a new and amazing duality, Isn't it?. Is this new mathematical tecnique powerful and elegant? If it is true, then turbulent flow could be explained by analytic solutions of Navier-Stokes equations. Can we obtain new insights on turbulence?.

Maybe God could have an answer for Lamb's second question , i.e. why turbulence?

21. **Luboš Motl**
August 24, 2008

Dear David Berman,

your comments about these matters are stunning. Science is not about "tastes" (even though the postmodern people who have contaminated 99% of Academia by now clearly think otherwise): science is about finding objectively correct answers to well-defined questions, in this case questions about quantum gravity, and it is essential for the scientific method that hypotheses that have been proved incorrect are abandoned, regardless of people's "tastes". In the context of sociology, it is equally important to pick people who are able to look for correct answers and not to pick those who aren't.

Rovelli's talk at Strings was a very weird experiment. It brought nothing to the participants because it was addressed to an audience that wants to be manipulated by simple propositions with some buzzwords, audience that doesn't know what a "path integral" or "Wilson line" means, and the speaker had no idea what the participants (theoretical physicists) are working on now, not even approximately: and he was not interested. The talk covered some basic "motivating concepts" that haven't changed for 10+ years and that haven't led to any successful checks in the last decade(s) even though they have led to failed tests. And there is arguably no work in loop quantum gravity that could be useful for more well-informed groups of physicists than those who need to be introduced to the concept of a "path integral".

Every single question after the talk was from a physicist who has already heard about their framework i.e. learned why it is inconsistent. (Rovelli was not interested in the questions, either: the work in LQG has switched from the search for meaningful and relevant ideas to a P.R. business indefinitely promoting a dead horse, motivated by the proponents' personal interests.) It is likely that this experiment (an LQG talk at a major string conference) will never repeat itself. There's no reason for another introduction to LQG at future conferences because the string community has already been "officially exposed" to LQG, and there will also be no reason for more detailed talks because the organizers will now be officially able to see why all the other work is wrong (or at least incomprehensible to all of them) so they will regain the freedom to choose all the speakers according to the merit rather than politically correct desires for "diversity". From this perspective based on the merit, no LQG researcher could make it to a prestigious global annual conference about high-energy theoretical physics.

Rovelli was the only name of a speaker (in English) that didn't appear in Hirosi Ooguri's summary of the talks and LQG was drawn as a disconnected piece from "the" theory studied by the participants. And David Gross indeed said, as this blog correctly reviews, that we're not sure whether we want to eat this discipline, LQG (like other disciplines in the past). And he did say that string theory was a hegemony in theoretical particle physics because it indeed is one and it is one for extremely good reasons that were revealed during the last 40 years. By looking at objective data, your statement that "everyone" was happy that Rovelli was invited sounds extremely bizarre. Every string theorist whom I consider good has been exposed to the assumptions of the LQG framework years ago, because they try to re-answer some very important questions that every expert in the field should care about, and every one of them knows why the LQG answers are incorrect, because it is not difficult to see.

By this category, I mean people like Susskind, Gross, Polchinski, Seiberg, Witten, Strominger, Vafa, and many others. There exists no genuine "open-mindedness" or "freedom to choose physics according to tastes" because these questions have been answered and the only difference is whether physicists choose to be silent about these facts (none of the people in my list has been quite silent about the inconsistency of LQG, though; I could tell you dozens of details based on private conversations but because it might be sensitive, they won't appear here). It is very plausible that there exist many students and other junior people who are not getting these points because similar topics about "alternative theories" became a part of political correctness that cannot be taught or talked about freely (because it could insult someone to explain why a class of theories is known to be wrong, right?) and they were not able to analyze these problems independently (so far). So people who don't really mean anything in physics, such as Urs Schreiber, A.J., or someone like that, can be ambiguous about this question: this includes everyone who thinks that the discussions at this blog are intelligent and relevant for actual physics, rather than being emotional exchanges mostly between cranks who have no clue what they're talking about. But be sure that the physicists who actually represent the "bones" of the skeleton supporting the "lampposts" of string theory are not ambiguous at all. LQG doesn't work and there is no known promising & surviving route in this context that would deserve to be studied. That's also why no new LQG person should be hired at any institution that knows what it is doing.

Also, I think that if you actually think that these LQG things have a significant probability to be correct, or they're not excluded, then all of your work lacks a basic scientific integrity because your papers seem to be assuming that LQG is incorrect but you never state it. For example, all the comments you have ever made about anomalies should supplemented with a citation of an LQG source where it is argued that anomalies can't exist because they, and all effects coming from UV divergences, might be removed by the "discrete nature of space" at short distances. In all cases, you should honestly consider both possibilities, that LQG is correct and LQG is wrong. The same thing applies to all sections of your papers where you use a classical solution because you should be studying these things in a background-independent way, if the LQG teaching is correct, and so on and on. If you really think that LQG might be correct, your papers are an example of hiding of the facts in science which would probably be even worse than to misunderstand why LQG is wrong.

In other words, if you have the "tastes" that you expressed and you think that LQG is more than a collection of ideas that can only be promising for 1 minute until one makes any test, ideas that are addressed to journalists rather than experts, research programs where all the hopes have already been proved unsubstantiated, you should really work on it because if it were a promising approach to quantum gravity, as you seem to think, then it would surely be an understudied one. Meanwhile, it would be desirable if you stopped trying to intimidate the physicists who actually know why LQG is not serious physics and create dishonest propaganda about "consensus" about your ludicrous opinions about "diverse tastes", "happiness" about the useless talk, and "encouragement of construction" at corners of the space of ideas where nothing constructive can be constructed.

It would sad if, as you indicate, young people were so absorbed into work under "particular lampposts" that they would become unable to see the big picture and if they become ambibuous about key conceptual questions thare are not ambiguous. But it would be even worse if physics switched into a hypocritical mode where people think something else than what they write in their papers. For me, your comments about LQG were shocking because they seem flagrantly incompatible with everything I have read in your papers and everything we have ever discussed in person.

Best wishes
Lubos

22. **G**
August 24, 2008

Wow Lubos, that's a long post for someone who "Sorry but I really can't afford to share readers…" of this blog 😉
If ST is so fantastic, why did you quit physics? you complain about production but yours is zero in the last 2 years…

I may agree with you Rovelli's talk wasn't very exciting, but neither is ST these days when it comes to QG.

I agree ST has inspired very beautiful and potentially (yet to be seen) useful stuff whereas LQG hasn't moved pass a few neat ideas but no clear progress. But as a theory of everything is as useful as LQG so far, let alone talk about phenomenology…That's the reason why there aren't many jobs out there for string theorists anyhow. Evolution at work…

G

G

23. **Luboš Motl**
August 24, 2008

Dear G,

I quit the Academia in 2005 when the feminist Nazis effectively took over Harvard, after preventing president Summers to say facts about biology that every person who is not a complete idiot knows – e.g. about cognitive differences between sexes. Because I spent the first 1/2 of my life in a totalitarian society, I know what it means to lose freedom of speech and I would never tolerate anything comparable to repeat in the place where I live. At that time I simply decided not to be extending/replacing the H1 visas which expired in June 2007, so I resigned.

But it is true that even if this thing didn't happen, I would be tempted to run away because of related things that were happening around physics. I got annoyed by people similar to David Berman who were implicitly helping those self-serving fraudsters and liars similar to Mr Woit and Mr Smolin to get away with their lies and to create an unjustified gloomy atmosophere in the field. At least, David Berman is brave enough to sign, but various anonymous people – a moral waste similar to you – apparently began to influence the course of things as well.

Of course if there are people who can't touch the ankles of David Gross, they won't be appreciating how fantastic the progress in string theory has been and it is still remarkable. The Strings 2008 conference was kind of impressive and I am convinced that even the people who can follow 10% of the relevant concepts only know why it is the case. At any rate, I just want to keep the freedom to know and say and why a fantastic theory is fantastic and why rubbish is rubbish, and the growing influence of mediocre, dishonest, and often anonymous people on the Academia was incompatible with my unbreakable standards about the scientific integrity. These things began to influence even things like my organization of seminars (lousy speakers wanted to speak about nonsense for the sake of "diversity" all the time, not respecting that they would have to be invited), teaching, etc. The job simply sucked given the existing conditions.

I agree that pigs, Woits, and Smolins have had a very bad impact on the perception of theoretical physics within the public and the broader scientific community, influence funding as well, which is why they deserve a very tough punishment. But you're still heavily exaggerating the importance of these two jerks and their gullible followers. Concerning jobs, Xi Yin was just hired at Harvard (after Frederik Denef), Allan Adams was just hired at MIT, Jason Kumar was hired at Hawaii, Dan Kabat was hired at Lehman College, and sorry if I missed other people. Add the new stringy IMP (fundamental physics = string theory) center paid for by the Japanese government. That's arguably a comparable number to the recent years (many of these jobs were announced really recently) and I am convinced that by the next year, the impact of the anti-theorist hysteria supported by the likes of the owner of this blog will completely fade away and everyone, except for a few anonymous posters at Not Even Wrong, will know that the propaganda by Woit and Smolin was based on lies and the anonymous people supporting Woit on this forum are scum if not Woit himself.

String theory is fantastic and whoever doesn't see it even though he claims to be interested in theoretical physics is simply not a high-quality thinker and I find it unacceptable for these people to dictate what others can think and say about their work or even what they should work on.

Best wishes
Lubos

24. **David Berman**
August 24, 2008

Hello all,

I do feel obliged to respond to make my position clear.

I personally do not think LQG is the right approach to the quantum gravity for the many reasons that are well known to the community so Lubos I will not be replacing my papers with LQG citations.

My point was simply that I thought Peter's description of a conflict between LQG and strings not to be accurate in terms of how people think. In my quote where I said people were happy that there was a LQG talk. I did not say that the same people agreed with LQG but were simply happy to see a talk that could make manifest the issues involved.

I think this was part of the thinking of the CERN committee. After all one of the critical questions that followed was by Alvarez-Gaume who was surely involved in the decision to invite him.

I suppose, Lubos our disagreement is how as string theorists we should behave to people who disagree with us. Your criticisms of LQG as a theory have been valid but I feel you do us no favours by adopting an aggressive attitude. This is a PR question which you don't like, but I never made any comments about the validity of LQG physics.

To balance this post let me say how exciting strings 2008 was. For me one of the best in recent years both in terms of the work presented in the talks and in the many discussions behind the scenes where people were being genuinely excited by emerging questions. I came away somewhat inspired…

25. **fh**
August 24, 2008

Moshe: Yes. Once you have fixed it for one black hole, the others all come out the same.

26. **fh**
August 24, 2008

"My point was simply that I thought Peter's description of a conflict between LQG and strings not to be accurate in terms of how people think."

I second this from the other side. Though I have to admit there are exceptions, most people don't.

On another note, the questions to Rovelli were excellent and cut to some of the core conceptual issues of LQG. It's not that people ignore these questions, it's just that because the setup of the theory is so different from familiar QFT, that the questions that are most natural/important from the PoV of QFT end up being the hardest to answer.
And then there are genuinely different opinions in the community, and another speaker would have given different answers to his. There isn't one theory of LQG after all, or even one complete framework.

27. **Jean-Paul**
August 24, 2008

Even perturbatively, low-energy string theory is not a theory of quantum gravity. It is a theory of wrong (experimentally excluded) gravity with spin 2 graviton accompanied by an unknown number of massless scalar Brans-Dicke fields (dilaton/moduli). So in the first approximation it is some sort of Brans Dicke theory, not Einstein's GR.

Yes, I agree that Gross' talk was at least very strange. He should have encouraged the participants to jump away from a sinking ship instead of living in denial.

28. **Tom O'Bulls**
August 24, 2008

Come on Peter, you are slipping up — your "Lubos Motl" 'bot, cunningly designed to make string theory look bad, is looking less and less realistic. Better iron out the bugs and re-launch! Or, better, write an entirely new program. Better make him a US citizen this time, the current implementation is a bit unfair on the Czechs.

29. **Peter Woit**
August 24, 2008

I don't understand why commenters keep referring to my supposedly inaccurate description of the conflict between LQG and strings. The only mention of LQG in the posting was an accurate quote from Gross about it.

As for the main piece of editorializing I did in this posting, objecting to Gross's string theory triumphalism, I see that Lubos agrees with my description of what Gross said. And as far as I can tell, David (Berman) share Lubos's point of view, just thinks that the aggressive way he expresses it is unfortunately counterproductive. I fear that this is an all too common attitude among string theorists.

30. **Moshe**
August 24, 2008

For useful interaction between different approaches to quantum gravity, look at the talks in

http://www.kitp.ucsb.edu/activities/auto/?id=332

For lots of people, including myself, the attitude towards LQG is basically curiosity mixed with a heavy dose of skepticism. There are sufficient number of really basic problems and unanswered questions to discourage people from jumping in and participating, but that could change in the future. Also, lots of people are completely oblivious to LQG and its main program, being exposed to the media and /or blogs it is easy to forget what a tiny community that is.

31. **Arun**
August 24, 2008

What are the exciting emerging questions (mentioned above) in string theory?

32. **A.J.**
August 24, 2008

Lubos wrote: *So people who don't really mean anything in physics, such as Urs Schreiber, A.J., or someone like that, can be ambiguous about this question:*

Why exactly should I take sides in this “debate”? As far as I can tell, only the internet sees it as a conflict.

33. **nbutsomebody**
August 24, 2008

arun,
none i guess 🙂

34. **nbutsomebody**
August 24, 2008

Dear Luboš,

I do not exactly share your views on string theory. However it is nice to know why you left academia. It seems to me as a very honest and justified reason.

35. **fh**
August 24, 2008

“There are sufficient number of really basic problems and unanswered questions to discourage people from jumping in and participating…”

Briefly out of curiosity, what are those (or the most important ones) from your perspective?

36. **moshe**
August 24, 2008

fh, probably not the time or place, but ask me in person next time we meet…let me just say that I’d personally would need to be convinced about the very basics – making connection to known conventional physics (apples falling from trees, harmonic oscillators having quantized spectrum,…), before taking seriously any claim about exotic things like BH entropy and big bang bounces, not to even mention some claims of experimental signatures…in other words I think the framework is too undeveloped to discuss applications at the moment.

37. **G**
August 24, 2008

Dear Lubos,
I wished you had the same passion for science as you do for criticism. Regardless of Academia, I wonder why did you stop contribuiting to ST? Wherever you are right now I’m sure you can still post in the arxiv don’t you? Stopping research due to a bunch of anonymous posts is a bit pathetic don’t you think? What kind of scientist would do that at the first sight of confrontation? Only the weak I should say… or perhaps you just don’t have anything intelligent to say anymore, in which case I would understand your reactions…

Do you truly believe that calling people ‘a moral waste’ can inspire anything more than a laugh? Lubos, if anything, you are really childish, but entertaining gotta admit 🙂

Regarding jobs, we all know MIT and Harvard are 5 year postdocs with teaching duties, perhaps MIT not as much as Harvard though… The rest probably finally woke up to real physics after all… “oops, the LHC.. we forgot…” 😉

best of lucks to you, you’ll need it 😉

G

38. **Daniel de França MTd2**
August 24, 2008

Carlo Rovelli answered on Lubo’s blog, about the comments on his talk:

https://www.blogger.com/comment.g?blogID=8666091&postID=4736312203995727650&pli=1

39. **Kea**
August 24, 2008

Hmmm. I must agree with Lubos that this statement by Rovelli is very grating:

LQG studies the hypothesis that this problem can be addressed in the context of quantum general relativity plus the standard model.

This so called context really makes no sense at all, since the term *quantum GR* can only really make sense in a theory of QG, and the latter cannot possibly be an ad hoc mixture of GR/SM. This is a serious criticism of LQG, which its proponents, as far as I can tell, have never addressed even qualitatively.

But now I simply must watch Gross’s talk, because his comments on BI sound insightful….

40. **M**
August 25, 2008

thank you Daniel, it was interesting to read answers to the very explicit criticisms by Lubos. I hope Rovelli knows that there is no point in insisting, as no logical argument will convince Lubos when he wants to believe something else. Debating seems as useless as rationally arguing with a female about emotionally sensible issues.

(In case PC nazi-feminism really exists: this is a joke!)

41. **Kea**
August 25, 2008

M: it’s not very funny.

42. **chris**
August 25, 2008

hi lubos,

you say:

"From this perspective based on the merit, no LQG researcher could make it to a prestigious global annual conference about high-energy theoretical physics."

i guess that is true, but it only was a string conference anyways. 🙂

btw: my favorite quote of this conference is from gubsres finite temperature talk. he was presenting some double-peak experimental signal from RHIC with the words:
"the first thing you ask yourself when you see these data is of course how to understand them in terms of black holes"
well, yeah. that about sums it up for me.

43. **somebody**
August 25, 2008

Gross is saying that string theory subsumes other ideas and thinks of this feature as one of its strengths. You take this to mean that he wants to actively vanquish other ideas. I have never heard any string theorist, let alone Gross, ever make such a cartoon-villain-like statement.

You are of course welcome to have your opinion about how string theory interacts with other ideas, but the problem is when you attribute a claim that was clearly not made by your opponent.

Even at the level of facts (and not just about the incorrect attribution), I am not sure you have got it right. How many good ideas have been killed off because of the prevalence of string theory? Maybe there are some, but I cannot recall even one at the moment. On the contrary, I know some ideas which I think are not exactly well-motivated, but which still manage to survive in academia despite the machinations of the evil string theorists. I can also list a tremendous number of independent ideas in high energy physics that have been naturally subsumed and strengthened by string theory: gauge theories, Riemannian geometry, supersymmetry, supergravity, Kaluza-Klein theories, noncommutative geometry, and many more.

44. **Peter Woit**
August 25, 2008

somebody,

You should address what I actually write, not make things up to attack. I did not say Gross "wants to actively vanquish other ideas". I did say that Gross is explicitly making a triumphalist argument: that string theory, like CERN, is all that remains. He feels that it has subsumed other, related ideas that are valuable, and that it is now an "umbrella" covering a range of research.

The problem with this is what happens to ideas that don't fit under the umbrella? I would characterize Gross's attitude as not that he wants to vanquish such ideas, but that they are already vanquished. Just like CERN, with the LHC, has no competition at the energy frontier, string theory similarly has no competition. This is explicitly what he said.

The problem with the idea that "string theory has subsumed gauge theory" is that there are many important problems in gauge theory that have nothing to do with gauge-string duality, and these now don't fit under the string theory "umbrella". Actually, logically the way things should be is that, with AdS/CFT, gauge theory subsumes string theory, with those parts of string theory unconnected to gauge theory being abandoned.

Don't you think there's something funny about going on about how one research program now is the umbrella under which everything must fit, when that program has been spectacularly unsuccessful at accomplishing its goals?

45. **Shantanu**
August 25, 2008

This is a bit OT. But anyone know of any live-blogging of the
following 2 meetings?
o emergent gravity workshop at MIT
http://www.rle.mit.edu/emergent/

o COSMO-08
http://www.physics.wisc.edu/cosmo08/
If so, maybe someone could post links here.

46. **a quantum diaries survivor**
August 26, 2008

Given the fertility of the field of String Theory, rather than of an umbrella, I would speak of a condom. As to Gross's encouragement to youngsters, it seems like telling them to f*** around unprotected.

Cheers,
T.

PS sorry for the slip to inappropriate commenting…

47. **somebody**
August 26, 2008

Peter says: "You should address what I actually write, not make things up to attack. I did not say Gross "wants to actively vanquish other ideas". "

Dear Peter, of course you did not write those specific words. That was my summary of what you say, for example, here:

"Under the circumstances, to claim victory and write out of particle theory anything that doesn't fit under the string theory "umbrella" is completely inappropriate. The message to any young particle theorist from Gross was clear: fall in line with string theory ideology, or there will be no place for you under the "umbrella", i.e. no job for you (the phenomenologists have their own umbrella, you better try that one)."

I see no way to NOT characterize this as a threat of aggressive assimilation (hence the word "vanquish").

Anyway, since you are at the stage where you say I am making things up and attacking you, perhaps further discussion on this topic is unlikely to lead to any clarification.

48. **Peter Woit**
August 26, 2008

A comment that appeared here yesterday purporting to come from Renate Loll has been deleted, along with all responses to it. She assures me it was fraudulent. It was submitted by some moron from a Time Warner Cable connection in New York City. Unfortunately, the LQG vs. string theory debate over quantum gravity seems to attract too little serious scientific discussion, and too much idiotic, unprofessional behavior.

49. **Jimbo**
August 26, 2008

Stringers vs. Loopers is starting to eerily parallel Repubs vs. Demos ! The Stringers have been `in-power' way too long, and the Loopers have not. The Stringers have peverted physics, and lost sight of its constitution, while the Loopers have deviated from the Minkowskian norm, and embraced the Einsteinian vision as reality.
The Stringers have a Lubosian attack dog, and the Loopers a Rovellian troubador. Both await the CERNian election outcome.
May Popper rule the house and senate forever !
And who-in-the-hell co-scheduled Emergent Gravity and Cosmo the same week ?? How are we supposed to go to both, in Cat States ?

50. **Chris W.**
August 28, 2008

From Steve Hsu, a warning from von Neumann.

51. **Kea**
August 29, 2008

Most of the talks are now up on the CERN webcast site, but frustratingly not Gross's talk, although a page linking his talk is there.

52. **Marcus**
August 29, 2008

Kea,
Yes, too bad video of Gross's talk is missing from the collection at CDS.
However the video of Rovelli's talk is there. I watched it and was impressed
by the level of interest shown. The hall was packed—people were standing. After the 30 minute presentation there were several excellent questions—and the Q/A dialog went on for another 13 minutes. After which the moderator asked that they continue outside during the break. I counted 8 questions from the audience during the Q/A period. All genuinely constructive, it seemed to me. It spoke well for those attending the conference, and the tone set by the organizers.

53. **chimpanzee (aka "joe")**
August 29, 2008

I can offer some perspective of research strategies for solving XXX problem, based on personal experience.

I got some good advice in grad-school:

"Don't do yyy, it's mature field & well understood. Try something in a new area"

So, I tried a new area. Turns out, the entire field (incl my PhD advisor & current grad students) were STUCK. Everyone was doing the same thing ("followers"): the typical Clustering Phenomena in research.

"In the game of Life [or Research], there are Drivers [leaders] & there are Passengers [followers]. Which are you?"
— Volkswagen commercial

Aka, the classic "cluster f**k" in Research. All fields run into this periodic bottleneck, where there is a stagnation of results. Also, known as temporal pessimism.

"I'm locally pessimistic, GLOBALLY OPTIMISTIC!"
— Dr. Jordan Pollack, Brandeis Univ/CS Dept
[my grad-school colleague in Artificial Intellgence, his PhD advisor D. Waltz ended up at Thinking Machines, the same company R. Feynman worked at 1 summer]

It appears as if String Theory is in this lull, with some dissidents (P. Woit & L. Smolin) raising concerns about any Global Optimism (they ain't!) So, D. Gross is basically saying, "keep on keepin' on". T. Dorigo has an interesting condom/penis analogy with the theme "ST is F**D!" In New York sland, he is saying "Fahgetaboutit!!". If it were me, I would certainly be investigating Alternative Models, like LQQ (or anything else). If the best minds haven't cracked it yet (Witten, et al), it seems unlikely a newbie could do it. However, there are Historical examples of newbies "cracking the safe"

"They're really smart guys, right? Everyone's been trying to unlock the safe (solve the problem) from the front. But, eventually someone tries an "end around" (football term) & tries to unlock it from the rear"
— Leon Lederman

It happened at the 2007 Fiesta Bowl, an "end around play" won it for Boise State. Could String Theory engineer such a miracle play?

I was that newbie in my chosen PhD research field 25 yrs ago, who led a breakthrough in my field. The Establishment was pretty much embarassed & shown up by a grad student (me)! I _singlehandedly_ took a global exhaustive search of research strategies, & found a commonality between 2 constraint equations. I found them to be the consequence of ONE geometrical topological structure. The computations were simply 3D vector computations in a homogeneous (n+1) space, within the capabilities of a high-school student! I achieved the "Simple answers, to simple questions..turned out to be REALLY EXCITING" mantra (Murray Gell-Mann). Simple/Elegant solution, a minimalist solution was achieved thru a true reductionist approach

Of course, I was a threat to the Establishment & my research was NEVER published in journals (due to political back-stabbing). Well, actually there was 1 (early on). However, they were widely published in conference proceedings & I achieved a lot of notoriety.

My advice to the field:
Continue on as per David Gross, in the chance that there might be a breakthrough (nobody is holding their breath, apparently, except a few fanatics). I would put a LOT of effort in a _global search_ for that magical TOE model: through the process of Convergent Evolution (multiple path solutions converging to ONE), it could be found. The latter is how I pulled off the coup in my field (single handedly)

I might be a player in this wacky game of Theoretical Physics. My competition in my field 25 yrs ago, were some physicists including H.C. Longuet-Higgins (do a Google search on Gell-Mann & Longuet-Higgins, you may recall that MGM was dabbling in Psychology. My research field was the Computional Theory of Vision). If I could summarily waste these guys as a grad-student, maybe I can do it again.

“Out of the Blue” lightning strike, Research area punked!

(example) Geophysics
The classic case was Geophysics in the early 1900s. Everything in status-quo “get along mode”. Until, a wayward researcher (German meteorologist) by the name of Wegener came onto the scene. He had an incredibly simple theory termed Continental Drift (a child who builds puzzle could see it), that had some corroborative data from paleo-archaelogy. Naturally, he was laughed off as a crackpot by the so-called establishment (peer reviewed experts, in complete political control of research journals). Of course, Wegener was right & we now know it today as Plate Tectonics. Turns out, it took nearly 60 yrs for the “crackpot theory” to catch on. Time was needed to gather additional corroborative data (Paleo magnetism, from sea floor spreading), Technology played a part. Interesting point: a female grad student (Tanya Atwater, aka Mrs. Plate Tectonics) @Scripps was a critical player in the feverish activity in the 60’s. “She was sent up the pole” (male sexist comment, about she was used as a guinea-pig for the crackpot idea), but she came thru with flying colors & defended the new theory against the backdrop of the male-establishment.

“If you don’t play [new wave of research or Technology], YOU GET LEFT BEHIND”
— xx, comment on Video on Demand revolution (stimulated by Apple video iPod)

“Those researchers [old boy network], CEASED TO BECOME FUNCTIONING MEMBERS OF THE RESEARCH COMMUNITY”
— Dr. Marcia McNutt/MIT (now Director of Monterey Bay Aquarium)

Theoretical Physics is on the cusp, of getting hit by “Lightning Bolt out of the Blue”. Somebody (or group) will come up with some “crackpot idea”, which will eventually be shown to be the “Final Solution”.

“It’s not a matter of IF, but WHEN [& Who]”

Would it be Kea & her Category Theory? Any other candidates?

54. **Marcus**
August 29, 2008

Chimp: “Any other candidates?”

Sure. there is evidence of a global convergence—the kind of thing you suggested one could look for.
Add et al after each name mentioned here:

Renate Loll has constructed a new 4D continuum (not a diff manif) in which dimensionality varies with scale. De Sitter space arises from it at large scale in the absence of matter.

Laurent Freidel has modified spinfoam—loop gravity path integral—dynamics so that it fits better with Loll’s approach. Convergence you were talking about.

Yidun Wan has shown how particles could arise in the Loll continuum as topological variation in how blocks are joined. This needs more work.

The Loll continuum is a fundamentally new continuum. They don’t come along too often (new mathematical models of the continuum.) When a new model of spacetime appears, with fundamentally different properties at a microscopic level, it’s a good idea to check it out. Loll et al have a piece in July 2008 Scientific American. It has references to their papers if you want more information.

55. **Kea**
September 2, 2008

Gross’ talk is now up on the CERN site. Wow. The first 15 minutes was indeed the most absolutely appalling waffly flattery of string theorists, but the second 15 minutes was completely different, and excellent, managing to mix the basic message of a need to attack basic questions with a concrete illustrative example of our ignorance in terms of deformations of exact solutions to AdS/CFT.

Boltzmann Brain Domination

August 30, 2008
Categories: Multiverse Mania

A burning question in theoretical physics these days is that of whether Boltzmann Brains dominate the string theory anthropic landscape. It seems that to answer this question one must study the details of how BBs nucleate and how string vacua decay. String vacua can do pretty much anything, so attention is focused on the detailed study of how to make the Brains and ad hoc choices of "measure" on the multiverse, with these issues occupying the attention of many leading figures in cosmology. While the question of BB domination of the multiverse remains open, it is becoming increasingly clear that BBs may soon dominate hep-th. Their nucleation rate is increasing, while the decay rate of the rest of the field also appears to be increasing. Doing phenomenology and extrapolating data a few years into the future, Boltzmann Brain domination of hep-th appears inevitable.

The latest hep-th arXiv postings include two new contributions to BB studies. One is from a group of three physicists at Berkeley, the second is from a large collaboration of six cosmologists on both coasts, including three of the major figures in the subject. For a third, more intellectually substantive, contribution of similar length, there's a new posting on the subject from Lubos.

Comments

1. **Arun**
   August 30, 2008

   Thanks, Peter, Luboš was certainly worth reading in this case!

2. **Bee**
   August 30, 2008

   Well said, Peter 🙂

   I'll use the opportunity to warm up The Return of the Boltzmann Brains

3. **Thomas D**
   August 31, 2008

   I see no actual evidence that non-Boltzmann-Brainy hep-th is shrinking or dying. But with statistical methods like 'Select 2 papers about BB's that happen to appear on a single day, and ignore all the other papers that month' you can prove anything.

   For my sins I read almost all of Lubos' post and he doesn't actually produce anything relevant to the question. If you understand the BB argument, and the people who are do are hardly stupid, part of it is that there is a finite probability that any given BB has (false) memories consistent with orderly physical laws and decreasing entropy. So Lubos' Bayesian argument using his observations of a 'normal' universe doesn't work, because the correct prior might be so overwhelmingly in favour of BBs that even Lubos' entire history of observations can't tip the balance.

   I believe the correct reason why it doesn't make sense to worry about BBs in cosmology is philosophical: it is that the proposition 'I am a BB' is self-defeating. It's the same reason why we can assume that we are not brains-in-vats or simulations. And why (if we are religious) we implicitly assume that God will not intervene tomorrow to produce a completely different state of affairs from what we expect.

   Simply this:
   1) Either we are 'normal' or BB.
   2) But if we are BB, then none of our physical reasoning or theories make any sense: they are all unreal and false, based on an absolutely meaningless chance occurrence.
   2a) In particular, if we are BB, the physical reasoning that led us to think we might probably be BB is also unreal and false.
   3) In doing science, we proceed implicitly on the basis that our physical reasoning is not necessarily unreal or false.

   And, in fact, that we are not brains in vats, or simulations, and that God (should He exist) will not intervene tomorrow to completely change the results of whatever experiment or observation we are planning.

   Note that 3) doesn't mean that theories that seem to show we are probably BBs are necessarily false: it is only necessary that we be in the minority of 'normal' brains.

4. **Arun**
   August 31, 2008

   If you understand the BB argument, and the people who are do are hardly stupid, part of it is that there is a finite probability that any given BB has (false) memories consistent with orderly physical laws and decreasing entropy.

   Compared to all possible memories, most memories will be consistent with chaos, Santa Claus, the unicorn, the tooth fairy, etc., There are infinitely more contradictory memories than consistent memories.

5. **Arun**
   August 31, 2008

   And that is the other point – there is no "correct" prior – how do you establish it?

6. **Esornep**
   August 31, 2008

   To me, the funniest part of LM's performance [apart from his serious declaration that his own brain is "normal"….] is the way he shows such disrespect for people like Linde, Guth, and Vilenkin. That sits rather oddly with his constant appeals to authority, references to how many times Ed Witten has been cited etc.

   What I find strange is the way that people seem to think that the existence of BBs is somehow bizarre or laughable. On the contrary, in a Universe which is [apparently] infinite in space and time, such things most certainly do/will exist. We are all taught this when we learn elementary statistical mechanics: surely all of us have done the ancient problem of computing how long one would have to wait before all of the molecules in the air in the lecture theatre will rush into one corner and asphyxiate everyone? The answer, of course, is that the time required is negligible — by the standards of an infinite universe.

What *is* bizarre and very much in need of explanation is the existence of *normal* observers. How did such fantastically low-entropy systems come into existence at all, given that it *didn't* happen as the result of a Boltzmann-style fluctuation? The only strange thing about the [brilliant] papers being mocked here is that they don't consider this question, ie the provenance of the low-entropy state at the Big Bang.

7. **Aleksandar Mikovic**
September 1, 2008

The reason why I beleive that Boltzman brains have nothing to do with our Universe is simple: if a theoretical concept leads to a conclussion that our Universe should have properties which are in sharp contrast with what is observed, that means that the assumptions are not good or incomplete.

8. **Marty Tysanner**
September 1, 2008

Esornep:

> in a Universe which is [apparently] infinite in space and time, such things most certainly do/will exist. We are all taught this when we learn elementary statistical mechanics […]

We are taught it in elementary statistical mechanics, but that doesn't mean it is relevant to reasoning about the relative improbability of the big bang versus a deluded Boltzmann Brain… It assumes that our usual understanding of, e.g., entropy in accessible macroscopic systems, applies to cosmology in something like a "multiverse" setting where anything (some people assume) can happen. Statistical mechanical reasoning requires something like a well-defined phase space within which it makes sense to talk about fluctuations, relative probabilities of different kinds of structures forming spontaneously, or even comparing energies.

No experiments have been done that can say whether a background phase space exists (even in principle) prior to the big bang, so its existence (or absence) must be regarded as an assumption. Recognizing the contingent nature of a background (why need Nature supply it to us?), it is hard to see how we can justifiably believe that Boltzmann Brain arguments and reasoning about measures over a multiverse can say anything definitive about Nature other than, "*If* such a background phase space can be defined, *then* (and only then) our conclusions are true." That seems like a qualification worth making clear…

9. **Thomas Larsson**
September 1, 2008

The only bizarre thing about Boltzmann brains is that anybody cares. Ironic science in its purest form.

10. **Peter Woit**
September 1, 2008

Thomas L.

For Boltzmann Brains, I think a new phrase is required, this is getting way beyond "ironic science", and into the realm of beyond even the laughable. The behavior of physicists that it has led to is really comic beyond belief, with Lubos's meditation on whether his brain is normal just one of the priceless absurdities.

Another funny thing about all this is that here I'm in the role of expressing not a controversial position, but the consensus view of the physics community. At his public talk at the opening of the IPMU earlier this year, David Gross referred to BB papers as "totally preposterous" and said that physicists work on this "to my regret". In private one finds that most physicists consider this to be a really bad joke. One can get a wrong impression of this from the blogosphere, where anonymous commenters describe this work as "brilliant", and the proprietor of one of the most prominent blogs is a big BB promoter. If you think this is widely taken seriously in physics departments, try asking around…

11. **Arun**
September 1, 2008

Penrose-backwards:
On the contrary, in a Universe which is [apparently] infinite in space and time, such things most certainly do/will exist. We are all taught this when we learn elementary statistical mechanics: surely all of us have done the ancient problem of computing how long one would have to wait before all of the molecules in the air in the lecture theatre will rush into one corner and asphyxiate everyone? The answer, of course, is that the time required is negligible — by the standards of an infinite universe.

Yes, but I think it is true, and Luboš also points that out, that by whatever measure the "density" of such events is very, very low, even if they occur with probability one. It is very unlikely that we'd encounter (or be) one of those events. That our current state ensued from a preceding lower entropy state and that this is true of all visible space and all the way back to the big bang is much more probable than I being a Boltzmann brain imagining you and this blogpost and everything else. And the further back we are able to go, the larger the entropy fluctuation has to be to explain us as a Boltzmann universe. It is just a bad idea.

12. **somebody**
September 2, 2008

(penrose)^T says:
"What is bizarre and very much in need of explanation is the existence of normal observers. How did such fantastically low-entropy systems come into existence at all, given that it didn't happen as the result of a Boltzmann-style fluctuation?"

This is bizarre only because you are in love with thermal equilibrium and want to believe that everything that is NOT in thermal equilibrium is a fluctuation. What motivation (experimental/theoretical) is there for this?

To me this is how it looks like:
(1) The universe is what it is, (2) you are imposing your equilibrium prejudice on it when building models, (3) you end up finding strange consequences like over-abundance of Boltzmann brains[1], and then (4) you use this as a selection principle between your models. Most people do not think that your initial assumption is nothing more than a prejudice to begin with, so they find your efforts to make the world safe from Boltzmann brains as cheap speculation. "Cheap", because the papers seem to contain little more than this (seemingly simple-minded) overall philosophy. Please correct me if I am wrong about this impression about the general approach.

[1] There are some well-defined issues here, which makes me suspicious even about the details, but lets ignore them.

13. **Jeff McGowan**
September 3, 2008

Well, as someone who came reasonably close to going for a Ph.D. in physics, but ended up in math, all I can say is whew 🙂 My goodness, I have (vague) memories of stoned conversations about this sort of stuff when I was an undergrad, trying to work out whether the argument that using statistical mechanics anything with probability >

0 *will* occur might give a good argument for the finiteness of the universe. Of course one might get a BB even in a finite phase space, but as pointed out above one is probably unlikely to meet one on the subway. Then again, I met some pretty strange people on the subway.

Now that I think of it, maybe a physics Ph.D. would have made life easier, I mean if people post this stuff seriously on arXiv, I could churn out papers, maybe 2 a month….

14. **Thomas D**
September 5, 2008

No, the relative probability of a BB having 'chaotic' or nonsensical memories versus 'normal' ones is not infinite, because memories have a finite (and perhaps not very large, on cosmological scales) information content.

That's basic. It's why one talks of Boltzmann 'brains' rather than 'planets' or 'galaxies', because the information/'negentropy' required to put a planet or galaxy into a 'normal' state by chance fluctuation is much much larger than for a brain, with or without 'normal' memories.

I think Carroll's way to express it is neatest: the possibility that the observer who sees a 'normal'/orderly universe is actually a BB is **cognitively unstable.**

As to priors, the purpose was to show that Lubos' statistical argument, which assumed a (completely arbitrarily) prior probability of 0.5 each for normal and BB, could break down **if** the appropriate prior was one heavily tilted towards BBs.

In Bayesian statistics the 'correct' prior should come from the physical theory or theories you think are applicable. But the question we can answer with them is not 'Are we BBs or not'. It is:

"Is Theory A, which has realistic features (eg a cosmological constant) and predicts that BBs are numerically dominant over the universe, better or worse than Theory B, which is less realistic but has few BBs?"

The correct Bayesian way to set this up is slightly tricky, because in the case where the observer is a BB, all the apparent observational evidence that she considers to make Theory A realistic is false and meaningless. So one needs to split up the hypotheses:

A1, Theory A is correct, I am a minority 'normal' brain living in a 'normally' evolving Universe, my observations are reliable
A2, Theory A is correct and I am a majority BB, my observations are utterly unreliable
B, Theory B is correct and I am a 'normal' brain (since there are few BB's), my observations are reliable.

Given a set of observations seen by me, I want to know which they favour. Suppose that they favour A1 over B because A1 has a nonzero cosmological constant. Where does that leave A2? Note that A2 is compatible with *any observations whatsoever*… so any observation that apparently favours Theory A is a red herring, and we might as well have

A2′, Any of theories A, C, D, …, Z in which BBs dominate are correct, I am a BB, my observations are worthless

This is an inevitable ill-definedness of any hypothesis that includes 'I am a BB', and finding any prior for A2′ vs. A1 is an ugly task. But: any subsequent observation compatible with A1 will increase its posterior probability enormously relative to A2('), simply because A2(') doesn't predict anything, or equivalently that every observation is equally likely.

Also, if we have a hypothesis

C, There are no laws of physics, God just happened to make it look that way

although our prior belief in C may be overwhelming, any observation compatible with A1 should rationally diminish our belief in C – because C doesn't predict anything.

15. **Thomas D**
September 5, 2008

So just to finish the argument, A2 and C are examples of hypotheses which we usually consider 'not scientific' and discard instinctively. However, Bayesian statistics allows us to consider them, and gives us the reasonable answer that since they 'predict' all possible observations (including chaotic, 'unphysical' and nonsensical ones) to be equally likely, their posterior probability will decrease hugely if the actual observations are compatible with a theory which has 'normal' physical laws.

This leaves us in peace to consider the 'scientific' and 'normal' hypotheses A1 vs. B.

16. **Arun**
September 6, 2008

No, the relative probability of a BB having 'chaotic' or nonsensical memories versus 'normal' ones is not infinite, because memories have a finite (and perhaps not very large, on cosmological scales) information content.

The probability of 'normal' versus nonsensical memories likely has as an upper bound the probability of monkeys at typewriters producing Shakespeare.

17. **Shantanu**

BTW see this
for a diffent point of view of the Boltzmann Brains problem

Yau Birthday Conference

August 30, 2008
Categories: Uncategorized

There's a conference at Harvard this week celebrating (somewhat early) the 60th birthday of the geometer Shing-Tung Yau. Since I was passing through Cambridge on the way back from a short vacation, I managed to catch a few of the talks, including two quite nice ones on mathematical physics from Is Singer and Edward Witten.

Singer's talk was entitled "The Interface between Geometry and Physics, 1967-2007", and summarized some of the advances in this area that he has been involved with over the years. 1967 was the year of a Battelle conference in Seattle on the intersection of mathematics and physics, organized by DeWitt and Wheeler. Singer displayed a copy of a 1966 letter from Feynman to Wheeler turning down an invitation to attend, with the explanation

> I am not interested in what today's mathematicians find interesting.

At the 1967 conference Robert Geroch talked on the topic of singularities in GR, and Singer recalled inviting Geroch to talk at the 1973 geometry conference at Stanford on this topic and the positive mass conjecture. By 1975 Singer had learned from Jim Simons at Stony Brook that non-abelian gauge fields were exactly the connections on principal G-bundles studied by mathematicians. The news of the BPST instanton solution and its significance for physics caused him to seriously start working in this area, work conducted with Hitchin and Atiyah at Oxford. They made use of the index theorem to both calculate the dimension of the moduli space of instantons, and to show that the Dirac operator had zero-modes in instanton backgrounds. Later, Atiyah and Singer interpreted the local gauge anomaly using the farmilies index theorem.

Just as Atiyah did at his recent talk at the Bott conference, Singer interspersed his historical talk with remarks identifying unsolved problems that he thinks are worth attention. The first of these has to do with K-theory, extended to depend not just on vector bundles, but on vector bundles with connection. Here the open problem has to do with the analog of the families index theorem. There's a topological index (that takes values in the extended K-theory of the family), and the open problem is to define an appropriate analytical index and show topological=analytical equality. Singer had been hoping to have some new results to report on this, but he says that things turned out to be trickier than he had expected, so maybe he'll have an answer at Yau's 65th birthday.

The next topic was that of quantum Yang-Mills theory and the Millennium problem of proving the existence of a mass gap. Singer talked mainly about 2+1 YM, his conversations with Feynman about this, and his hopes that the positivity of the sectional curvature of the natural Riemannian connection on the space of gauge potentials modulo gauge transformations could be exploited to prove that there must be a mass gap. Proving this in 2+1d was his second open problem.

His final topic was mirror symmetry and S-duality. Here he speculated that this (and M-theory in general) might have something to do with a phenomenon from operator algebra theory. Unlike for N by N matrices, where all maximal abelian subalgebras of self-adjoint operators are conjugate, for certain C* algebras (rings of operators of type II), there are inequivalent such maximal abelian subalgebras. I gather that his idea is that these might correspond to the existence of lots of inequivalent limits of M-theory.

The next morning Witten gave a talk on quantum Yang-Mills and the Millennium problem, saying that this was in response to a request from Yau to explain at a basic level to a wide mathematical audience what this is about. He gave an extremely lucid explanation of the mass gap problem, taking the Hamiltonian point of view. This supplements what he and Jaffe did in the official write-up of the problem, which deals more with the Euclidean picture. As motivation, he explained in detail what happens in the Abelian case, where one can compute everything and there is no mass gap. The audience was appreciative and I think got something out of this, unlike quite a few talks of physicists to mathematicians, which tend to start at much too high a level of complexity, ensuring that only experts can follow.

Witten avoided one aspect of this problem, the one that most fascinates me, that of how you handle the gauge symmetry. In the Abelian case there are several equivalent ways of doing this, but in the non-Abelian case, at least in the continuum, one needs to understand BRST symmetry non-perturbatively, and this remains a difficult problem, one with deep connections to open problems in mathematics.

Comments

1. **Eric Weinstein**
   August 31, 2008

   Hi Peter,

   Thanks for the post. Probably just a typo but calling 'Is' 'Iz' drives 'Is' crazy because it's hard to stop once it gets going.

   I am particulary glad to see discussion about the period of intense activity between geometry and physics before the anomaly cancelation. I believe that for Is the great epiphany was realizing that the BPST instanton was exactly the Hopf fibration. At that moment, I believe he understood immediately (and likely better than anyone else at the time) that the interaction between the two fields was all but destined to be a full fledged revolution. I've heard him tell the story two or three times and it is clear to me that he has no self-interest beyond preserving some understanding of his part in the exact chain of events. Yang and Atiyah have also spoken and/or written elloquently on this subject, but I have always found Singer's role to be particularly interesting.

   It is going to become increasingly hard for modern mathematicians and physicists to understand that the major stumbling block was the lack of a single mature example connecting the two fields. How can it be that 'differential forms' were once 'exotic'? How could the quaternionic Hopf fibration be anything other than an excercise for beginning students?

   And yet to some of those who made the initial leap, those first steps were more amazing than the unbelievable story which followed.

   Also Singer is personally very kind to Bob Hermann on the issue of the Wu-Yang dictionary. While taking nothing away from Simmons, Wu or Yang, he believes that more credit should have found its way to Bob Hermann and his unusual set of books on geometry and physics. Hermann spoke of his 'probable mistake' in leaving tradional forms of peer reviewed research behind. I myself felf after meeting the man after a lecture I gave at MIT that he simply had no choice. He was simply a man ahead of his time and a marvelous case study about where peer review fails abjectly.

   I have always thought Singer a mensch for going out of his way to make sure that everyone involved got full credit for his role in this revolution. If only all history was written by such winners we would have a far better road map for the revolutions to come.

   History has been very kind to Singer but, at least in my opinion, not yet kind enough.

   Best,

   Eric

2. **MathPhys**

August 31, 2008

Eric,

Could you please elaborate on the Robert Hermann aspect of the story?

3. **Peter Woit**
August 31, 2008

Eric,

Thanks, fixed Singer's name. Thanks also for mentioning Hermann. His books are remarkably ahead of their time.

Mathphys,

For example, see Hermann's books "Vector Bundles in Mathematical Physics", published in 1970. I've always assumed that there were other mathematical physicists well-aware of the gauge theory/connections on bundles dictionary before this became well-known after 1975 (if only from reading Hermann's books…). This only started getting attention though after the Standard Model came together in 1973, and people started thinking about non-perturbative questions in it. The 't Hooft-Polyakov monopole in 1974 and the BPST instanton in 1975 were the crucial examples that got a lot of people interested in this.

4. **Deane**
August 31, 2008

I'd like to concur on how wonderful Witten's talk was. As a nonexpert who normally gets left in the dust in less than 5 minutes of any talk on quantum field theory, I was amazed and delighted that I either understood or had the illusion that I understood Witten's talk from beginning to end. Naturally, that means that Witten successfully hid all of the reasons why the mass gap conjecture is so difficult. But I was able to gain a reasonable appreciation of what the goal is.

The conference itself is quite overwhelming (I left yesterday with 2 and half days to go). At first, I could not understand why anyone would want to schedule so many talks (about 50, I think) in such a short time. But then I finally realized that Yau himself has no trouble processing this amount of information; he is sitting in front and clearly understanding every talk. But many of us mortals are being left in the dust.

And I also agree that it is nice to hear Hermann's name mentioned after all these years. When I was a graduate student learning differential geometry and interested in physics, Hermann's books were fascinating, if maddening. They provided a reasonable guide to modern differential geometry, but I could never understand his explanation of the connections to modern physics.

5. **Tony Smith**
August 31, 2008

With respect to Robert Hermann as "… a man ahead of his time and a marvelous case study about where peer review fails abjectly …"
consider these quotes from two letters he published in his 1979 book "Cartanian Geometry, Nonlinear Waves, and Control Theory: Part B":
"… I am not the only one who has been viciously cut down because I tried to break out of the rigid shell and narrow grooves of American mathematics. … My proposal was to continue my … work with … Frank Estabrook and Hugo Wahlquist of the Jet Propulsion Laboratory. … I most deeply resent the arrogance of the referee #3 toward their work … typical … arrogance of Referee #3 is his blather about the "prematureness" of our work … Now, we are working in a field – nonlinear waves – which is moving extremely rapidly and which has the potential for the most important applications, ranging from … Josephson junction to … fusion … and I am supposed to sit back and wait for Professor Whosits to tell me when he thinks problems are "mature"…
I sent the papers he mentions to very few people … I am also interested to note that he did look at them, since there is considerable overlap in methodology with a recent paper by one of his students, with no mention of my papers in his bibliography …
any money spent by NSF on a Mathematics Research Institute would be down the proverbial rat hole – it would only serve to raise Professor Whosits' salary and make him ever more arrogant. It would do more good to throw the money off the Empire State Building: at least there is a chance it would be picked up and used creatively by a poor, unemployed mathematician …
This issue transends my own personal situation …
Most perversely, the peer review system … works as a sort of Gallup poll to veto efforts by determined individuals … As budgets have tightened, the specialists fight more and more fiercely to keep what little money is available for their own interests. Thus, people with a generalist bent are driven out …".

6. **MathPhys**
August 31, 2008

My understanding is R Hermann was a professor at Rutgers in the 70's. Did he quit to devote himself to writing his books?

7. **Tony Smith**
September 1, 2008

MathPhys asks "… Did … R Hermann … quit … Rutgers … to devote himself to writing his books? ..".

Hermann said in letters published in his 1979 book "Cartanian Geometry, Nonlinear Waves, and Control Theory: Part B":
"… In 1975 … I had essentially quit my academic job at Rutgers (so I could do my research full time), and my main support came from Ames Research Center (NASA) for my work on control theory. I was also starting a publishing company, Math Sci Press, writing books for it to hold out the hope that, some day, I would get off this treadmill of endless grant proposals. (Unfortunately, it is still [March 1979] at best bearly breaking even.) …
Ever since I lost my ONR grant in 1970, thanks to Senator Mansfield, I have been trying to persuade NSF … that my work on the differential geometric foundations of engineering and physics is worthy of their support … I see my colleagues who stay within the disciplinary "clubs" receiving support much more readily … Thanks to Freedom of Information, I finally see what the great minds of my peers object to, and I see nothing but vague hearsay, bitchiness, and plain incompetence in reviewing … specialized cosed shops that blatantly discriminate against the sort of … work that I do.
I can deduce the sort of bureaucratic-administrative pressures that encourage this … However, when I look in the Physical Review today, … subjects which people … so enthusiastically supported ten years ago … [such as] "S-matrix theory" … are now dead as the Phlogiston theory …".

About S-matrix theory, Hermann said "… the … "S-matrix theory" boom (and bust) of the 1960's … constituted a very ingenious and compelling set of ideas whichinvolved areas of mathematics (e.g., the theory of functions of several complex variables) which were unfamiliar to physicists. They were, so to speak, led into this swamp because they were familiar with functions of one complex variable, but were naive enough not to appreciate the completely different order of complication involved in the generalization, while also not willing to invest the effort in developing and understanding the mathematics needed to make the ideas fruitful. …".

One mathematician of those times did try to apply the mathematics of several complex variables to physics, and succeeded in getting a realistic calculation of the fine structure constant. However, the American physics community not only made no serious effort to understand and develop Armand Wyler's work, but acts to suppress such work.

8. **Marco Frasca**
September 1, 2008

My view is that the question of "mass gap" has became a kind of legend since the proposal of Clay Institute for the prize. So, most of the work people is carrying on in the field of QCD and Yang-Mills in the infrared is blatantly ignored while solutions at this problem are pretended to come from I do not know what kind of exotic theory. An example over all is given by AdS/CFT that is often claimed to be the principal way toward answering this problem. AdS/CFT to work needs the mass gap as an input and does not prove anything about Y-M presently! This input value is generally taken from lattice computations that do not seem so reliable for pure Y-M spectrum. Time will say but I think that the true challenge implied into infrared QCD has not been completely caught by the community.

Marco

9. **Peter Woit**
September 1, 2008

Marco,

Witten didn't mention AdS/CFT at all, there is no mass gap there. He emphasized that the crucial problem is to show that pure QCD breaks conformal symmetry. The statement of the Millenium problem is mathematically precise and unambiguous.

10. **Marco Frasca**
September 1, 2008

Peter,

This is exactly what people working on QCD and Y-M are doing as knowing the spectra means something directly observable in accelerator facilities. I understand that Witten's requirements are more stringent from a mathematical point of view but hints coming from physicists are generally sound enough for mathematicians to build upon. My view is that behind this problem may hide a paradigm change that, if it would have been emphasized enough, today more people would work on it rather than multiverse…

Marco

11. **Sumar Ongi**
September 1, 2008

Regarding the mass-gap millennium problem, I take it that Terry Tomboulis' proof of confinement discussed here some time ago didn't cut it? Put another way, is he considered a candidate for the prize?

12. **Peter Woit**
September 1, 2008

Sumar,

The rules about the Millennium prize require first of all publication of a referreed proof. As far as I can tell, Tomboulis's paper has not been published. It also doesn't appear to meet the usual mathematician's standards for a complete, rigorous proof. Finally, what he is trying to show (confinement) is significantly different from what the official problem asks for, a proof that a construction of quantum YM exists satisfying a list of properties including a mass gap.

In his talk, Witten did not mention the Tomboulis paper.

13. **Marco Frasca**
September 1, 2008

Stated in another way, is it Witten who knows all research that is going around on this matter? Either, can he only know about mathematical proofs? Or people working on QCD and YM is not worth considering, just they are not mathematicians? This situation is not so good.

Marco

14. **Peter Woit**
September 1, 2008

Marco,

Witten could have talked on many topics, but he chose this one, and made it clear that he regards understanding non-perturbative QCD as one of the central problems in theoretical physics. While he'd like to get mathematicians interested in thinking about this, I don't think at all that he considers it a problem of purely mathematical interest.

15. **roland**
September 2, 2008

http://de.youtube.com/watch?v=j50ZssEojtM

16. **Doug**
September 2, 2008

rowland,

Thanks for that link. I'm rofl.

Deane,

For an interesting insight into Witten's own journey into the intimidating jungle, with Singer and Atyah guiding his steps, see Witten's 1999 acount in "MICHAEL ATIYAH AND THE PHYSICS/GEOMETRY INTERFACE" at:

http://www.intlpress.com/AJM/p/1999/3_1/AJM-3-1-lxi-lxiv.pdf

17. **Thomas R Love**
September 2, 2008

I was delighted to read the comments about Robert Hermann since he was on my PhD committee. I read his Lie Groups for Physicists in 1975 and eventually I read all of his published books, except the self published work. His "Yang-Mills, Kaluza Klein and the Einstein Program" was especially important to me. My dissertation, "The Geometry of elementary Particles" was very much in the Hermann tradition.

When I attended Singer's course on geometry and gauge fields at Berkley, everyone spell his nickname as "Iz"

18. **Eric Weinstein**
September 2, 2008

Doubting Thomas,

So you wish me to make the point that it all depends on what your definition of 'Is', is?

Hmm. I think In Hollywood, setting up an obvious line like that is called 'laying pipe' within the industry.

At worst, Is has tricked me (and now Peter) into using the same mis-spelling of his name that he has also conned Witten, Atiyah and others into using.

I was simply trying to do the smallest of favors and have very little interest in the topic …. shall we agree not to distract ourselves further?

Best,

Eric

19. **Thomas R Love**
September 3, 2008

I didn't mean to continue the discussion, but I was looking for the book with Witten's article and found it at

http://www.intlpress.com/books/FoundersIndexTheory.php

And there in the table of contents I found:

Letter to Fritz, Is and Michael – R. Bott
Letter to Michael, Raoul and Iz – F Hirzebruch

But let's leave it "AS IS"

20. **John Baez**
September 3, 2008

Does anyone know if Robert Hermann is still alive and well?

He sent me an email in October 1999 saying he had been trying to understand renormalization for many years, and asking if anyone had used Colombeau theory to understand the products of operator-valued distributions that show up in quantum field theory.

In 2005 I sent him an email asking if he knew about an English translation of Felix Klein's *Erlangen Program* speech. He never replied.

(According to Thomas Love, Hermann had mentioned such a translation in a book of his. By now it's available on the arXiv.)

21. **Eric Weinstein**
September 3, 2008

Hey John,

He is alive in your old stomping ground. I will be happy to give you (or any other colleagues interested) his contact information if you like.

In his words, he's sort of just a 'senior' who's 'given up'. He has neither email nor academic connection any more. From talking to him, I wonder whether anyone at all has seriously interviewed him about the history of the geometric physics revolution, though I could be wrong about that. There are now many more readable books on these topics and I can guess his ultimate reward.

For an objective field, it is just really really interesting how we go about subjectively creating our system of selective pressures.

Anyway, I read him a few of the comments in this thread. Thanks to all of you who had a kind word for a greying rebel. I hope I conveyed your sentiments as accurately as possible.

Regards,

Eric

22. **Thomas R Love**
September 4, 2008

The Multiverse at Perimeter

September 2, 2008
Categories: Multiverse Mania

This week, the Perimeter Institute is hosting a conference entitled A Debate in Cosmology – The Multiverse. Here's the schedule, and talks have started to appear on-line here.

Some of the speakers will be discussing the Many Worlds interpretation of QM. It has always mystified me why this sometimes gets put together with the string theory landscape sort of multiverse. It will be interesting to see how many of the speakers address the fundamental problem of the subject, that of coming up with a plausible falsifiable prediction. Lee Smolin has generally put that problem front and center, but he tends to be alone in doing this. The more usual thing in this subject is to go on about what an important idea the multiverse is, then make some sort of excuse for not being able to predict anything with it.

Also dealing with the problem of multiverse predictivity is this new preprint on the arXiv about the landscape, and this laudatory commentary from Lubos. According to him, it's not much of a problem that one is talking about measuring low energy observables to 500 digit accuracy, when one can't now even predict their rough order of magnitude.

My colleague Brian Greene will be at Perimeter this week, giving a public talk about his new book Icarus at the Edge of Time. It is being released to bookstores today and I haven't yet seen a copy, but it appears to be a science fiction book mainly aimed at children, illustrated with pictures from the Hubble Space Telescope. There's a blog entry about the design of the book here, with some pages of the book here.

Update: Sabine Hossenfelder has reports from the conference and public lecture.

Comments

1. **Michael Bacon**
   September 3, 2008

   "It has always mystified me why this sometimes gets put together with the string theory landscape sort of multiverse. "

   Peter,

   I agree with this, but I was curious why you've reached this conclusion. Thanks.

2. **Peter Woit**
   September 3, 2008

   Michael,

   They're two completely different ideas on completely different scales addressing completely different questions. It's not really that I've reached a conclusion, just that I've never seen anyone even try and give a reason why the two should be connected.

3. **John Baez**
   September 3, 2008

   I think one can try to combine the landscape idea and the many-worlds interpretation by imagining the universe in a superposition of quantum states corresponding to different points in the landscape. Then according to the many-worlds interpretation, all these "branches" "really exist" in some sense.

   I don't have the energy to explain my own attitude towards this line of thought. But, I have a feeling it's something a bunch of people have on their minds — perhaps only half-consciously. That might explain why they talk about both kinds of "multiverse" in the same breath.

   It might be good to ask them.

4. **James Robson**
   September 3, 2008

   "It might be good to ask them", but unfortunately I don't move in those circles!

   Surely these are two independent ideas? You may well be able to combine them: and a proper understanding of nature might require such a combination, but logically they are distinct I think?

   We could perhaps imagine a completely classical theory where our local situation depended upon the history of the way things evolved and settled down in our neighbourhood. Perhaps things could have turned out vastly differently elsewhere. So we would have some kind of multiverse where we might use an anthropic principle to explain why we see things to be the way they are around here.

   Or we could have a QM theory that was water-tight and allowed no flexibility and just told us the way things were – except that being QM things would be a superposition of all the states of that fixed world, and a QM multiverse would seek to separate these different possibilities through some kind of "decoherence" which renders the different possibilities effectively non-interacting and so different worlds.

   Don't believe either myself, but what do I know, not my job 😉

   James

5. **Peter Woit**
   September 3, 2008

   John,

   Since the universe is quantum-mechanical, I'd always assumed that the multiverse was too. So, yeah, you get a quantum superposition. But my understanding of Many Worlds is that it is supposed to deal with the measurement problem; you're supposed to have Many Worlds splitting off all the time as you do measurements. That's what seems to be something completely different.

6. **Hal**
   September 4, 2008

   Max Tegmark has identified four different types or "levels" of multiverse. The level 0 multiverse is composed of the infinity of replications of our local "Hubble bubble" within our universe if it is infinite in size. The level 1 multiverse is composed of all the local bubbles of ordinary space-time that exist within a larger universe in inflationary cosmology. The level 2 multiverse is the Everett many-worlds model. And the level 3 multiverse is the everything-exists level, where all mathematical structures have Platonic existence and structures with sufficient internal complexity correspond to physical universes. Interestingly, this taxonomy does not include the string theory landscape.

7. **Aaron Bergman**
   September 4, 2008

   But my understanding of Many Worlds is that it is supposed to deal with the measurement problem; you're supposed to have Many Worlds splitting off all the time as you do measurements. That's what seems to be something completely different.

   Many worlds is just ordinary quantum mechanics. New worlds don't split off; the "worlds" are supposed to be different "branches" of the wavefunction that have decohered. It's more of a lack of interpretation rather than an interpretation, and I don't think it actually answers any questions, but some people seem quite fond of it.

8. **Mikael**
   September 4, 2008

   Peter, I think you are a little too obsessed with predictions regarding the discussion about the nature of physical laws and the multiverse. At least currently this discussion is within the realm of philosophy and not science. But well, we know that philosophy can help create great science and Einstein is the biggest example of all. As an example regarding the multiverse think of the hierarchy problem and naturalness. If you believe in the multiverse, you might expect other things what the LHC will see as if you believe in uniquely determined eternal laws. So as a physicist you will probably be working on different things. So in a way philosophy helps to limit the infinite search space of physical theories. Once you have the theory and it meets predictions, it gets science and independent of philosophy. You can then use this theory to refine your philosophy again and so on. Of course it also works the opposit way which you can also see from Einstein. It seems that philosophy lead Einstein into darkness, when he was searching for a unified theory at the end of his life. But this is life I guess.

9. **Peter Woit**
   September 4, 2008

   Mikael,

   I have no problem with philosophy of science of various kinds. Some interests me, some doesn't. Within that context, discussion of a multiverse is reasonable. My problem is with the way the multiverse is being used not by philosophers, but by physicists at the highest level of the profession. They are not doing this because they like philosophy (many of them despise it), but because they are desperate to find some way to avoid admitting the failure of string theory as an idea about unification. The string theory "landscape" is exactly the sort of thing you get when an idea fails: something you have to make more and more complicated to avoid falsification, never actually predicting anything.

   This use of philosophy by leading scientists to prop up an utterly failed scientific project is what I have a problem with. It is doing a huge amount of damage to the field.

10. **Mikael**
    September 4, 2008

    Peter,
    one question, do you consider loop quantum gravity (LPG) a failed project, too?

    LPG can not predict the scattering amplitude between gravitons. Why? Because there are no gravitons in the theory. Why? Because Minkowski space is not shown to be the low energy limit of the theory. Worse, one can't see how it will happen. Not a very encouraging state of affairs I think. The only prediction of loop quantum gravity is a breaking of Lorentz invariance I think.

    On the other hand string theory does some predictions. It predicts extra dimensions. It predicts supersymmetry. Furthermore it offers a solution to the black hole information paradox based on duality.

    Let me add, that I am an outsider and I am asking from honest interest, and not in order to push any view that I have.

11. **Peter Woit**
    September 4, 2008

    Mikael,

    As theories of quantum gravity, both LQG and string theory have their pluses and minuses, this debate has gone on ad nauseam here and elsewhere. The bottom line is that neither has produced a completely consistent and satisfactory quantum theory of 4d gravity, or come up with any way one can experimentally test them.

    My objection to string theory is that it has failed as a theory of what we can observe: the Standard Model. The unwillingness to face up to the implications of that failure are what is damaging the field.

    Saying that "string theory predicts supersymmetry" or "string theory predicts extra dimensions" is a completely empty statement until you specify the scale of supersymmetry breaking or the size of the extra dimensions. String theory has nothing to say about this, and this is why it is an empty failure as far as particle physics goes.

12. **Aaron Bergman**
    September 4, 2008

    It is not true that LQG predicts Lorentz violation.

13. **Mikael**
    September 4, 2008

    Peter,
    it is true, that we do not have a consistent and satisfactory quantum theory of 4d gravity. But it is also true, that this statement is in a way empty, because it does not offer any help on what to work on tomorrow. Imagine I was a young student, who wants to work on quantum gravity and I'd asked you on what approaches to study, what would you answer me? Or would you say, I was waisting my time because the problem is just too difficult?

And I strongly disagree that predictions about supersymmetry and extra dimensions are empty, just because you do not know the scale. One thing to see this is that models based on these ideas already influence what patterns people are searching for in the LHC data. (probably even the detector optimizations). Another way to see this is that Carlo Rovelli was asking the LHC guys on strings 2008, when they will be able to tell if the world is supersymmetric, if it is on the accessable scale. He also mentioned in an interview, that he will have great respect in the intutions of string theorists, if supersymmetry is found. My very personal guess is he would even stop working on LPG in this case. How can an empty statement have such consequences? Also, how can the emptyness of a statement be dependent on our current experimental abilities?

14. **Mikael**
September 4, 2008

Aaron,
please elaborate. Predicting doubly special relativity means predicting a deviation from special relativity, right?

15. **Peter Woit**
September 4, 2008

Mikael,

If anyone wants to work on quantum gravity, fine. They should learn about what the various approaches are, what their problems are, and then see if they can make some sort of progress. The kind of hype and misleading talking points being thrown around in this subject are not helpful at all. If they are going to do this, they also need to understand and think seriously about the fact that, for very good reasons of dimensional analysis, no one knows any way to connect the subject to experiment, and learn anything about it by looking at the real world.

As far as I know, there is no defnitive prediction of Lorentz violation, or of what the scale of it should be, from LQG. You seem to like to talk about "predictions" when there aren't any, that's really misleading and a bad idea. There's a huge amount of less than honest claims being made these days about "predictions". I would bet against the LHC discovering supersymmetry, but if it does, that will be a huge revolution in physics, and a vindication of many people's interest in supersymmetry, most of which has nothing to do with string theory. See David Gross's comments at Strings 2008

16. **Mikael**
September 4, 2008

I am sorry for the careless use of the word prediction. My point is that there is something in between a prediction and an empty statement and I tried to explain why. "Learn about the various approaches and try to make some progress" is an advice so true, that you can apply it to anything.

17. **Michael Bacon**
September 4, 2008

Peter,

Back to the original topic, I listened to the Albert and Greaves talks — pretty impressive. As you may know, I feel affinity for the MWI, but in all events, I thought the level of enquiry was impressive. Hard questions, good answers all around. Just what science should be.

18. **Kea**
September 4, 2008

Heh, cool! The Banks talk is just **fantastic** – a must see for great physical intuition and a crucial alternative viewpoint with solid analysis backing it.

19. **Michael Bacon**
September 4, 2008

Haven't listened to the Banks' talk yet, but this does raise the question of the relationship between the MWI multiverse concept and the string landscape. I know John Baez mentioned that maybe you can tie them together, but I agree with Peter (if that's what you meant) that it's pretty odd wrapping them up in the same conference.

20. **Kea**
September 4, 2008

Actually, from my understanding, Banks is against both the Landscape and MWI: the former because it cannot reproduce the holographic cosmologies they consider, and the latter because he talks loosely in terms of isolated islands of 'lonely' universes in the dense black hole fluid, but it may be that he is headed towards a more MWI vision of the multiverse.

21. **Michael Bacon**
September 5, 2008

I think Banks did raise some questions (if it was him) during the Greaves talk, but as far as"interpretations" of QM go, it sounded like his view (to the extent he had one) was some sort of combination of consistent histories with wave function collapse.

22. **Kea**
September 5, 2008

Consistent histories, yes, but wave function collapse is a trickier question. He was careful to explain that he used ordinary vanilla QM only because he didn't know how to do better quantitatively. On the other hand, his description of emergent geometry (as a kind of collapse from collective observers) is much more sophisticated than the naive universal wave function ideas one often hears touted by MWI proponents.

23. **Michael Bacon**
September 5, 2008

Kea,

I'll go back and listen, but I'm pretty certain that he acknowledge some kind of collapse as a way to get our apparently real situation to fall out of the numbers, and I think he said that once that occurs (however it happens) you just set aside the other histories and basically start the process all over again — but maybe my recollection is wrong. Anyway, I thought his questions were thoughtful and probing, as were Hartle's (I think it was Hartle 🙂)

24. **Rexus**
September 11, 2008

With all do respect, the multiverse is crap! The many worlds interpretation is the worst model for interpreting quantum theory. While the whole concept of parallel universes might make for a handy plot device to be used in a bad Michael Chrichton novel, I do not see any utility for the hypothesis. There are far better interpretations of wave-particle duality and the measurement problem. For starters, the only reason why humans find wave-particle duality to be problematic is because it is difficult for the average human to comprehend who something could be a particle and a wave. In fact, such entities are not exactly “both particles and waves” rather they are neither. These entities are wavicles, having properties of both waves and particles, but not necessarily being one or the other. Likewise, the Copenhagen interpretation is a useful starting point, despite its shortcomings, but I personally think that Penrose’s hypothesis that gravitation causes the collapse of the wave function has great potential to resolve this measurement problem. Sci-fi babble about parallel worlds violates the principle of Occam’s Razor. Whereas the Copenhagen model, Roger Penrose’s hypothesis, or any other proposed solution is infinitely better.

PROBLEMS WITH MULTIVERSE

1. Falsifiability
The existence of “other universes” is not falsifiable in principle once we accept that universes besides our own might exist. After all, these parallel realities are not supposed to interact with our own, to be separate, connected only in the sense that they diverged off our universe (or we diverged off theirs). If the universes do not interact, how do we test to verify or falsify their existence. There *COULD* be other universes just as there *COULD* be a sinister conspiracy of Jews and Masons who rule the world (as rediculous as that sounds). Because these universes supposedly exist outside our universe, there is no way to test it. In this respect, arguing with ardent defenders of the many worlds interpretation is akin to arguing with creationists, Holocaust deniers, or 9-11 “truthers.” You cannot “prove” that God (or Satan) placed fossils in the ground to test our faith and that God did not create the universe like in Genesis but made it look as if evolution occurs, or that Bush did not plan the attacks.

2. Plausibility
I would argue that, in fact, I can “prove” that the multiverse does not exist. This might seem like a contradiction, but I only argued that the many worlds hypothesis is unfalsifiable if you open to the possibility of it being true. [Once you accept that, it becomes an argument from agnosticism (you can’t PROVE it ain’t so). But this admission that the multiverse is untestable cuts the ground from under the feet of the “many-worlders.” By admitting that the multiverse is unfalisiable, they admit that their speculation is not science, just very bad metaphysics.] However, I argue that to even grant that multiple universes CAN exist is a huge stretch. I can disprove the notion using logic alone.
[A] The universe, by definition, is all that exists. [The prefix “uni” implies one. The entirety of reality.]
[B] It follows that nothing else phyiscially exists beyond the universe.
[C] The multiverse hypothesis suggests that there are other universes beyond ours.
Either
[D1] These “universes” do not exist (because there is by definition only one universe).
OR
[D2] These “universes” are not separate universes at all, just part of THE universe.
A -> B, [(A & B) + C] -> D1 OR [(A & B) + C] -> D2.
Assuming that the universe = all of phyisical reality, the concept of the multiverse presents an internal contradiction. Either our universe is the only one, or our “universe” is not a universe at all, just a quantum accident. This falls into the whole “reality is an illusion” problem. Curiously, the many-worlders never attempt to explain where these other universes are. If they inhabit the same space-time as our universe, then they are merely overlapping quantum states. This does not solve the problems of quantum phyisics at all!

3. Simplicity & Parity
According to Occam’s Razor, the simplest explanation should be expected to be the correct one. Especially because we are not supposed to multiply entities unnecessarily. The many worlds interpretation attempts to solve a mystery with an even greater mystery! Postulating an infinite (or virtually infinite) number of universes to explain an anomaly is very bad science. The Copenhagen interpretation follows logically from quantum theory without being unnecessarily complex. Likewise, Penrose’s solution might work, but we may find out as gravitation is understood in light of quantum theory.

CONCLUSION
I think the fact that Hugh Everett’s pipe dream is even taken seriously is a sad indication of the state of modern physics and cosmology. Other than David Deutsch, I was unaware of any REAL physicist (i.e. with tenure, this excludes armchair physicists who watch Star Trek and believe it’s real) taking such speculation seriously. On the other hand, I can see the connection between multiverse quantum cosmology models and string theory, even if Dr. Woit doesn’t. I would not say that the string theory landscape is fundamentally different from the quantum “many worlds” interpretation. Even if they are on different scales, both models attempt to answer discrepancies in observations by creating more universes… Physics has strayed far from the sober analysis of Galileo, Newton, Einstein, Heisenberg, Schrodinger, Dirac, Pauli, and Fermi into the Star Trek pop-sci of Michio Kaku…

What’s Up With PAMELA?

September 2, 2008
Categories: Uncategorized

There were some comments about this in a previous posting, but I thought it worth remarking on the unusual situation that papers have started to appear reproducing plots of new data from the PAMELA satellite, even though no such data has been officially released.

This all seems to have started with a July 31 talk at ICHEP 2008, with slides here, but evidently some other slides of preliminary data were flashed on the screen. There was a news story in Nature about this, but still no official release of data. Then, on August 20th there was this talk at idm2008, with no slides made available on-line, but interesting slides again flashed. Evidently some enterprising theorist decided to do some of his or her own data acquisition.

Soon, a preprint on Minimal Dark Matter predictions and the PAMELA positron excess was on the arXiv, complete with PAMELA data, with the notation:

> the preliminary data points for positron and antiproton fluxes plotted in our figures have been extracted from a photo of the slides taken during the talk, and can thereby slightly differ from the data that the PAMELA collaboration will officially publish.

There are now at least two other papers on the arXiv featuring PAMELA data, evidently from the same source, here and here. Andrew Jaffe has a new blog posting up entitled Stealing Data? where he expresses discomfort with this situation. I can’t quite see that one is “stealing” data if it is being presented at major conferences.

Are there any of my readers out there who can tell us what’s up with PAMELA?

Update: Nature has a new article about PAMELA being “outed by paparazzi physicists”. One of the paparazzi, Marco Cirelli, is quoted as saying that “we had our digital cameras ready”, and claiming that the PAMELA people at the conference didn’t have a problem with this. On the other hand, a PAMELA PI is quoted as being “very, very upset” about this.

And I should have linked earlier to this posting at Resonaances: Hot Photos of PAMELA.

Update: According to Science News, the problem is not a *Natur*e embargo. They just haven’t finished a paper yet:

> “We plan to have final results ready by early October and submit a paper to a peer-reviewed journal,” Boezio told Science News. Until then, he says, the findings remain preliminary, and “We prefer to withhold further comments.”

Comments

1. **Kea**
   September 2, 2008

   Well, I have no idea, but a visiting colleague here who works with some Italian PAMELA people said they were ‘very happy’ about new results.

2. **Stan**
   September 2, 2008

   Really, this sort of behavior is just going to make collaborations more reluctant to show preliminary plots at conferences before the paper is ready. (Maybe they should be anyway…)

   I’m told by people I work with on SNO that they stressed a lot about this before their first paper. They wanted to show event distributions at a conference, but were worried that someone might try to eyeball-integrate the number of events in the curve. In principle, someone could use that information plus published whitepapers about the detector response to guesstimate the neutrino flux SNO was seeing before the proper analysis by the collaboration would be published. (Never mind that since SNO was doing a blind analysis, the answer would have been wrong anyway.)

   They finally decided that hiding the y-axis was sufficient to prevent this. I must admit, years after the fact, this sounded pretty paranoid to me, but I guess I was wrong…

3. **Seth Zenz**
   September 3, 2008

   Stan, the issue isn’t that the paper isn’t ready—it’s 100% ready and submitted. The issue that the journal won’t allow the collaboration to release plots officially while it’s waiting for publication.

4. **800GeV**
   September 3, 2008

   Stan, probably you remember that when your SNO collaborators presented their first results, they published the slides with the data on the web, together with a web page with extra details of the data (http://www.sno.phy.queensu.ca/sno/results_09_03/howto.ps), and the SNO paper promptly appeared on arXiv, and later on PRL.

   If you consider that the PAMELA collaborators did something different while knowing that one cannot be partly pregnant and that results shown at major conferences become public, maybe you can guess the answer to the question by Peter.

   Since some people confuse “stealing data” with sharing informations, it is better to wait the papers that will be published by PAMELA and …

5. **graviton383**
   September 3, 2008

   I find it embarassing that ambulance-chasing theorists would stoop to this level to beat out rivals for a publication. Everyone know what they did & they do themselves no credit by doing it…even if the experimenter giving the talk doesn’t mind.

6. **Ned Wright**
   September 3, 2008

   Nature is explicitly OK with posting preprints at the arxiv.
   Just don’t do press. See http://arxiv.org/abs/0802.1712

7. **Riccardo De Maria**
   September 4, 2008

   I don't see why a collaboration should protect data from the community. They can just release raw data as such and analyzed ones when ready and people can use whichever is more suitable for their research. Good ideas or valuable experimental data are more important than who delivers them, no?

8. **Thomas D**
   September 5, 2008

   Depends if anyone else knows what to do with the 'raw data' to get a correct analysis of the physics in it. You certainly don't want people to start putting out wrong analyses before you've brought yours to presentable form.

   Anyway 'raw data' never appear on conference talks except singly as pretty pictures (eg here's a track in our detector) from which no science follows.

   The usual situation is that someone will flash a slide of unpublished results with 'PRELIMINARY' over it, which certain favoured theorists/collaborators will already know about, and people in the audience can then write speculative papers at their own risk.

   What's happened here is just this Nature protocol that the journal wants an unusual degree of secrecy of the results over however long it takes to approve them for publication – and that technology has reached the point where people take digital pictures rather than make handwritten notes of what the curve looked like.

LHC Roundup

September 4, 2008
Categories: Uncategorized

The first attempt to circulate a beam in the LHC is still set for next Wednesday, and the media is already full of LHC stories, with a lot more to come next week. Events are being organized all over the world to celebrate the day, including a 1:30 am pajama party at Fermilab (see here). Today's Wall Street Journal carries a page one story about preparations at CERN that focus on improvisational comedy training for physicists to help them communicate.

For more serious news from the LHC, you can try following progress at CERN's startup site for the public, or at the technical LHC commissioning site. Latest available minutes from the Installation and Commissioning Committee are here, including a timeline and objectives for the next few days and for September 10. The "also going on" column for September 10 lists just "chaos".

Science magazine has some excellent LHC-related stories in this week's issue. In this one, various people explain what the LHC is looking for and why it will take a while to get results. Gordy Kane is having none of that though, predicting discovery of supersymmetry next month:

> "We predict a signature that they could see with five events," says Michigan's Kane. "They could see it in the first week of running in October."

Another article, Researchers, Place Your Bets!, features bloggers Tommaso Dorigo and Jacques Distler. Tommaso has bet that the LHC will see no deviations from the standard model, although from what I remember, he did this just because if this happens it will be so depressing that at least some cash will cheer him up. Gordy Kane and Stuart Raby claim supersymmetry is such a sure thing that they can't find anyone who will bet against it. Distler's comment on this is:

> I wonder how hard they tried.

The same article gives links to sites where you can bet on the Higgs boson discovery date.

Nature magazine is running an LHC-related editorial Cool Philosophies in this week's issue. It is inspired by an interesting recent preprint by philosopher of science Alexei Grinbaum: On the eve of the LHC: conceptual questions in high-energy physics. Grinbaum gives an extensive discussion of the current state of particle theory and its societal context. He ends with a philosophical section on fine-tuning and currently popular anthropic arguments, arguing that these often invoke an invalid use of counterfactuals.

Comments

1. **T**
   September 4, 2008

   Why does Gordy say this kind of thing? Such a respected theorist who shows absolutely zero understanding of experimental physics. They'll be lucky if they can understand a single part of the detector in a month of running. Let's just try to ease into calibration and hope nothing serious breaks.

2. **GR**
   September 4, 2008

   Well, I'm glad they're doing improv, if anything it should help improve matters in the communication-to-outsiders department. I'm part of an improv group here, and physics majors seem to be disproportionately represented, for whatever reason, and it really does help. A lot more people in physics should give it a try. Not the string theory people, though, as it seems they're already pretty good at spinning a yarn…

3. **anon.**
   September 5, 2008

   Never mind supersymmetry speculation. How long is it likely to take the LHC to check the electroweak symmetry breaking Higgs theories?

   In one Higgs field theory, there is supposed to be a doublet of Higgs bosons, both having +1 weak hypercharge; but one of them has +1/2 weak isotopic charge and +1 electric charge, while the other has -1/2 weak isotopic charge and no electric charge. There are also other more complex versions of the Higgs field including versions with supersymmetry.

   I'm wondering whether the LHC is really likely to check this part of the Standard Model, and identify the correct Higgs field (or if there is something else needed instead)? Is there any paper with assembled predictions from the landscape of different Higgs field theories. From my perspective, searching for supersymmetry (which doesn't really make falsifiable predictions since the energy of the hypothetical partners can be higher than experiments can test), isn't very exciting. It's like looking for life on Mars; it may or may not exist.

   But the Higgs field research is far more interesting because something has to give mass to the particles in the current Standard Model, and something has to break electroweak symmetry into electromagnetism and weak interactions at low energy.

4. **Peter Woit**
   September 5, 2008

   anon,

   In the SM, there is just one observable Higgs field (the other components of the field can be gauged away). It has electromagnetic charge 0, and all its couplings are precisely known once one knows its mass. For the expected mass range, the LHC will produce lots of Higgs particles no matter what the mass, but the backgrounds are different for different masses. The low end of the mass range is the most difficult, and my understanding is that if the Higgs is there, it will take until at least 2010 to see a signal.

   If you start adding in more Higgs fields, you will get much more complicated possibilities. In supersymmetric models these are more constrained, and also intensively studied. I don't know of references off-hand, but they can't be hard to find, this is an extremely intensively studied subject, and has been for decades now.

5. **graviton383**
   September 5, 2008

   To answer anon's question, it will take an integrated luminosity of ~10 fb^-1 or so
   AFTER the detectors are well understood to start covering all of the mass range

for the Higgs favored by fits to electroweak data. Some masses may take longer, some less. This sort of luminosity may take 2 years to accumulate & more to analyze so think 2010-11 just to be safe. If the Higgs idea is wrong, discovering the true nature of what replaces it may take somewhat longer requiring ~100 fb^-1 of data.

6. **anon.**
September 5, 2008

Thanks for these answers. Is the Higgs field is supposed provide the charge for quantum gravity, since mass is gravitational charge?

E.g. could there be a gauge group for quantum gravity, like U(1) for electromagnetism, in which the charge is the Higgs boson and the gauge boson is the graviton?

7. **a quantum diaries survivor**
September 5, 2008

Graviton,

while it is true that one first has to understand the data and only after can one look for a signal of a new particle, you gave the impression that the two phases are separate. Rather, it is a continuous improvement. The same data used to understand the detector response are also used for searches and measurements.

Indeed, what we will do first is to measure W and Z cross sections (which will be possible this fall, with thousands of them in the bag), top pair production (also easy with just 10 inverse picobarns, when about 8000 events per detector will be produced, let's say a thousand good ones to study), and high-Et jet spectra.
Missing energy will be tough -probably the one variable which will take more time to tune. It depends on a good calibration of jets, cosmics, out of time stuff, everything basically.

What sucks, if we think at the SM Higgs, is that the 1.7 sigma excess found by LEP II (mostly ALEPH in truth) will be the very last thing we can study. I imagine that in one year or so we will start excluding masses above 135 GeV, those that are already improbable by EW fits, and in the meantime already partly excluded by the Tevatron (which, next year, should probably exclude down to 150 GeV or so).

Another note on the bet reported on Science Magazine: Peter is correct. The article does not mention it, but mine is an insurance bet, in the style of a blackjack addict such as I am. That, however, does not change one fact: I do not believe in SUSY.

Cheers,
T.

September 5, 2008

"That, however, does not change one fact: I do not believe in SUSY."

This is not a particularly scientific attitude. Science isn't about belief, it's about facts. It concerns me that someone with obvious prejudice is involved in experiments which require an objective analysis.

9. **Peter Woit**
September 5, 2008

Victor,

I think Tommaso is just saying he thinks the probabilities are against SUSY. There's significant circumstantial evidence against SUSY: basically if it is doing what it is supposed to (stabilizing the electroweak scale), it's hard to understand why it hasn't shown up at the Tevatron (where Tommaso has spent much of his career working hard looking for SUSY or anything like it).

I don't think there's any danger at all that he or others at the LHC will not look just as hard for SUSY there as they have done at the Tevatron. Theorists may allow their investment in certain speculative ideas to affect their work, but experimentalists don't have that kind of investment in such ideas. One sad thing about the heavily ideological way in which theoretical particle physics has been pursued in recent years is that it gives people the wrong idea about how most scientists go about what they do. On the whole they're much more interested in finding something new than worrying about whether or not it fits some particular theoretical prejudice.

10. **a quantum diaries survivor**
September 6, 2008

Very well said Peter.

I can only add that personally, what I believe and what I do not has absolutely nothing to do with the way I perform an analysis.

My beliefs instead can (and should!) shape my decisions on what to work on – despite the fact that they are not, at least right now: my only Ph.D. student is working with me on something connected to SUSY. That, indeed, is the nice thing about being part of a large collaboration which will explore everything, with multiple teams in some instances assigned to the same topics.

When, however, decisions have to be taken concerning where to place the chips -say, in a trigger meeting where thresholds on physical objects are to be set on different data streams, to reduce the trigger accept rate facing an increase in the machine's instantaneous luminosity, and thereby affecting the discovery reach of different experimental signatures- well, there a leadership is needed to sort individual opinions out. Usually one just relies on the experiment's pre-defined goals. But, in principle, tough decisions may be required in some not-clear-cut cases, and then one's beliefs might in theory end up having their weight. That is the only case when I can give it to you – my (mild) bias against SUSY being the correct theory might suggest I would be unfit to lead such a group. It would still be a stretch. So ultimately, your concern is ill-posed.

Cheers,
T.

11. **Cormac O'Raifeartaigh**
September 6, 2008

Hi Peter, surprised to read "Gordy Kane and Stuart Raby claim supersymmetry is such a sure thing that they can't find anyone who will bet against it."

I thought Stephen Hawking had taken a bet that no physics beyond the Standard Model will be seen – have I got this wrong?
I personally would be happy to take a public bet that evidence of SUSY will be eventually be seen at the LHC – if only to publicise the theory, and to draw attention to the disgraceful fact that Ireland is not a member of CERN ..

12. **Victor**
September 6, 2008

Peter,
When you say that there is significant circumctantial evidence against SUSY, can you give a more detailed explanation of this statement? My understanding is that there is a lot of circumstantial evidence for SUSY as well, which is why there are many who expect to see it at LHC. As far as the hierarchy problem associated with the electroweak scale, I've been told that SUSY is still a viable solution for this, even if the supersymmetric particles are too heavy to have been seen at the Tevatron. What gives?

13. **woit**
September 6, 2008

Victor,

The fact that there were good arguments that supersymmetry should have shown up at the Tevatron and it didn't is the circumstantial evidence I'm referring to. It was discussed in another posting, see

http://www.math.columbia.edu/~woit/wordpress/?p=710#comment-40040

This evidence is not conclusive, but it seems fairly strong to me. The facts typically given by SUSY proponents as circumstantial evidence in its favor seem to me much weaker. Anyway, we'll see….

14. **Peter Woit**
September 7, 2008

Cormac,

If Hawking has bet against no physics beyond the SM, I hadn't heard about that, and it seems surprising. I don't know any reason why he would make such a bet. Perhaps you're confusing him with Tommaso…

15. **a quantum diaries survivor**
September 7, 2008

Hah, this would be the first time I get confused with a theoretician. And our accent is quite different also.

Cheers,
T.

16. **Manel**
September 7, 2008

The closest thing to what Cormac O'Raifeartaigh wrote that I know of is this:

http://img241.imageshack.us/img241/8962/susyzr5.png

17. **Coin**
September 7, 2008

Manel: I like 't Hooft's asterisk.

18. **Manel**
September 7, 2008

Yes, I agree. Sad but very plausible.

To what physics has sank into…

I still hope the LHC will have a positive and break the status quo and allow for real physics to be made.

19. **Cormac O Raifeartaigh**
September 8, 2008

Thanks Manel, fascinating sheet!
Tommaso, who have you taken the bet with? How about an inter-blog bet, that could be fun.

Apart from the two reasons above (to draw public attention to SUSY, and to the fact that Ireland is not a member of CERN), I do have another, slightly naive reason ..

If I understand right (as a humble experimentalist) SUSY, or something like it, is the only way around the comprehensive set of no-go theorems discovered in the 1960s – in other words, it is the last symmmetry left that could provide a unified framework that would include the strong force , and possibly gravity.

I find it hard to accept the unification of only 2 forces – and therefore plumb for SUSY, despite large uncertainties in the mechansim of SUSY breaking etc
Regards, Cormac

20. **Peter Woit**
September 8, 2008

Cormac,

Susy doesn't help at all to unify electroweak and strong. They're both internal symmetries. Attempts to unify these typically involve GUTs, but these have their problems, and the LHC will have nothing to say about the GUT issue.

21. **a quantum diaries survivor**
September 9, 2008

Hi Cormac,

my bet is indeed an inter-blog one, since both challengers (Distler, 750$, and Watts, 250$) have their own site.

Cheers,
T.

More LHC Predictions

September 8, 2008
Categories: Uncategorized

Roger Highfield has gone out and asked several theorists for LHC predictions, with the following results.

About supersymmetry:

- Arkani-Hamed

> My hunch is that there's a better than evens chance that supersymmetry will show up at the LHC…

- Veltman

> I would be surprised if supersymmetry were found. I supported the idea when it was first suggested, but I've gradually lost confidence in it, though I might well be wrong. To be sure, if the LHC finds nothing to support supersymmetry, its advocates will just make excuses and keep using it. As for string theory, it's all mumbo jumbo, with no connection with experiment.

- Silverstein

> Some of my intuition comes from string theory, an appealing candidate for a theory of all the forces of nature. According to many – perhaps most – versions of string theory, supersymmetry does not hold good at the energies probed by the LHC, so its discovery might require further explanation from this point of view.

(*it appears that the excuses Veltman is predicting are already in place…*)

- Llewellyn-Smith

> …(with 60% probability) supersymmetry…

- Lisi

> Many physicists also think it likely that evidence will be found for supersymmetry, strings, or new dimensions — but I disagree.

About the Higgs:

- Arkani-Hamed

> I've already bet a year's salary they will find the Higgs particle.

(*anyone know who took the other side of that bet?*)

- Veltman

> It would not surprise me if the experimenters don't find the Higgs particle. I don't trust the theory behind it. But if it does appear to show up, it will be crucial to check that it behaves as the theory predicts.

- Silverstein

> I'd be extremely puzzled if they don't find the Higgs…

- Llewellyn-Smith

> My hunch is that a Higgs boson will be found (95% probability)…

- Lisi

> The most likely result from the LHC is detection of a single Higgs particle.

John March-Russell goes all-out:

> …our quest for a source of almost unlimited climate-friendly energy might be answered by the creation of exotic unstable, but long-lived, charged particles… It might also turn out that the number of space and time dimensions is ambiguous…

Comments

1. **Sumar Ongi**
   September 8, 2008

   Taking just a superficial look at SUSY GUTs, their particle spectrum, and the SUSY desert, what comes to mind is that if Nature is *that* clumsy it may well not be worth studying.

2. **D R Lunsford**
   September 8, 2008

   I predict no single Higgs – if any it will be composite and technicolor will be revived.

   -drl

3. **Fran**
   September 8, 2008

Re: Veltman on Higgs: Since when was there doubt on the theoretical existance of the Higgs (I know there's doubt in its mass)? I thought it was pretty much a dead cert, as the rest of the Standard Model needs it in order to be correct/have mass?

4. **Peter Woit**
September 8, 2008

Fran,

What's certain is that something is breaking electroweak gauge symmetry. It's not at all certain that it's an elementary scalar field.

5. **Chris Oakley**
September 8, 2008

These exotic particles for catalysing fusion, which apparently do not need absurdly high temperatures to be produced, but appear to still require a Large Hadron Collider. How is one better off? Is Elvis is going to appear from the 6 1/2th dimension to show us what to do?

6. **James Robson**
September 8, 2008

Chris,

I, for one, am skeptical about seeing the Elvis Particle at the LHC – at least within the first 5 or so years beore upgrades to the luminosity and are made.

As is well known, the EP is expected to increase in mass and strangeness during its lifetime, which poses detection problems. Also, its influence on neighbouring particles is suspected to induce an "impersonation" interaction, which will make detection of the genuine article even more difficult.

Still, its pehaps more likely than some of the other suff mentioned.

7. **Mitch Miller**
September 8, 2008

Is Arkani-Hamed's statement supposed to be literal? I thought maybe he meant that he has already invested so much into the idea in terms of time and effort, but maybe not.

8. **Peter Woit**
September 8, 2008

Mitch,

He was quoted elsewhere saying he was willing to bet a year's salary on this, but I hadn't heard that anyone had taken him up on this. Perhaps this is just a misquote.

9. **db**
September 8, 2008

I'm no particle theorist, but I am willing to bet £50 (ukp) that the next generation of accelerator will be plagued by exactly the same doom criers as the LHC.

Furthermore, I bet 50p that anyone else with* BSc physics could come to the same conclusion.

*or without.

10. **chimpanzee (aka "joe")**
September 8, 2008

"Nature is predictably UNPREDICTABLE"

I am always amazed at "betting" amongst physicists, after all it is a "hard science". Look at planetary exploration in our localized domain (solar system, an inconspicuous thing in a inconspicuous part of the Milky Way, itself an inconspicuous galaxy, etc):

– wild volcanoes on Io
– unusual geology on moons of Jupiter & Saturn
– Comet Shoemaker-Levy 9
indicates the solar system is way more dynamic than originally thought (chance of extra-terrestial hits is not insignificant)
