> Modular invariance, mutual locality of operators, Dirac quantization rules, similar conditions, and their generalizations play an important role. But it remains to be seen whether there is a concise, ultimate principle or set of principles, why it generalizes the conformal symmetry (and modular invariance) in the perturbative limit, and why it admits old perturbative solutions as well as new, non-perturbative solutions such as the 11-dimensional vacuum of M-theory.
>
> Of course, one of the most obvious testing grounds for such new sets of ideas is the exceptional U-duality group of M-theory on tori – i.e. the maximally supersymmetric supergravity. The exceptional groups are pretty and they must have a pretty cool explanation in terms of a structure we still don't fully know.

Like Gell-Mann, Lubos expects the right theory to emerge not from choice of a specific set of dynamical degrees of freedom, but by a "bootstrap": discovery of some sort of consistency conditions that uniquely pick out the right theory. The idea is that you don't have to get to fundamental variables at the bottom of things to rest your theory on, but can by some other means "pick yourself up by your bootstraps". Since this doesn't work in real life, I've always wondered why its advocates didn't pick a more convincing name…

Lubos ends his posting with:

> I think that some kind of bootstrap is needed to determine what "M" and its structure of symmetries really is. Is there a third person in the world who cares about this possibly most important question of science? These core topics of string theory are currently understudied at least by two orders of magnitude.

The question of why so few string theorists work on this question is an interesting one. The M-theory conjecture drove string theory research for many years. My own suspicion is that the fact of the matter is that most string theorists have just given up on it. The AdS/CFT correspondence appears to give a non-perturbative definition of string theory in a particular background (in terms of a QFT), and string theorists are more interested in investigating that than in continuing the so-far futile search for "M-theory". In addition, arguments of landscapeologists indicate that if you did find the conjectured "M-theory", it might be a useless untestable "theory" that could explain just about anything.

Physicists with a sense of history also have another good reason to be suspicious of calls for a new "bootstrap" program. This idea was all the rage during the sixties, but ended up a dismal failure. The conjecture that some known powerful principles (analyticity, crossing, etc..) would have a unique solution satisfying them just turned out to be wrong as a way of understanding the strong interactions. There are lots of possible solutions, and finding the right theory requires identifying the correct one: an SU(3) gauge theory with a specific, very beautiful set of geometrical degrees of freedom. This theory remains poorly understood, and the project of better understanding it recently has revived some of the bootstrap ideas, but in the context of trying out a new choice of geometrical degrees of freedom (twistors). This is now the hot idea of the subject, but it's no longer one that promises unification via string theory. I suspect Lubos will be increasingly lonely in the pursuit of the dream of his youth, as his colleagues mostly give up on it and move on.

   September 14, 2009

   Peter,
   your link on Lubos' page refers to this page:

   http://lubos.motl.googlepages.com/crackpot-not-even-wrong.html

   So I don't think that he'd calmed down….

2. **capitalistimperialistpig**
   September 14, 2009

   As a one time student of Lubology, I would say that there have always been two Lumos, the vengeful prophet and the insightful scientist – Dr. Lubos and Mr. Motl. Good Lumo writes nice biographies and elegant explanations all the while pondering the deep questions of physics. Evil Lumo is obsessed with his many enemies. One cheers for the good guy, but you have to know the other one is waiting with … whatever.

3. **Thomas Larsson**
   September 14, 2009

   "Just one of many such attempts that I remember was that of Friedan/Shenker in 1986, who hoped that in some sense the moduli space of all Riemann surfaces would somehow carry a unique vector bundle with flat connection."

   I met Friedan in 1990, at a conference to which I travelled with a mathematician friend who was very excited about the Friedan/Shenker work. Friedan himself did not show any interest to discuss it though. He dismissed his work as "very abstract", and it was clear that this was not meant in a positive way.

4. **Franz**
   September 15, 2009

   I can testify that Lubos has NOT calmed down. I have copies of very recent emails in which Lubos told an aquaintance (on Lubos' posting about Gell-Mann's interview) that "careful observations" show that the world has either 10 or 26 space-time dimensions and that whoever believes that space has 3 dimensions has a "lethal disease" and is full of "blinded religious dogmatism". (I am not making this up.) Despite believing in 3 dimensions, my acquaintance does not seem offended, but he sure is astonished.

5. **a quantum diaries surivivor**
   September 15, 2009

   CIP, I agree – Lubos gives the impression of having two personalities. I think it bothers him a bit if I bring this up when he starts talking foul in my blog. He mostly behaves with me now. Right, Lubos ?

   Recently, I have also found out that he drops the conversation if I threaten him physically. He was suggesting that my male organ is undersized, and I offered to pay him a visit and have him experience it, adding that he should prepare lots of Lube, shave carefully, and use little makeup. I think that was too much for him to handle, and he dropped off the thread.

   Cheers,
   T.

6. **Peter Woit**
   September 15, 2009

   Tommaso,

   Now, now, this is supposed to be a PG rated blog, as well as one that firmly espouses non-violence (at least in the string wars).

   Interesting to see from Lubos's latest comments on his posting that he's upset not only about me and Smolin, but about the recent behavior of the powers that be in particle theory:

   "This is about forces that have penetrated almost everywhere into the "official" scheme of things. This is about the Chamberlainian attitude of the physicists who actually know what the truth is. It is about the drivers that lead people, especially the young ones, to decide about their "focus" and "excitement" which is so rarely real these days. All these things are wrong and I don't want to be a part of it."

   Particle theory is in a sad way these days, and, as usual, I suspect that Lubos and I agree about more things than most people realize…

7. **TomK**
   September 16, 2009

   Would it be a good idea to place a short warning within this posting to warn future readers what will happen when they follow that particular link?

8. **Franz**
   September 16, 2009

   Peter, as you cited already, in the fast comment section on his posting on Gell-Mann, Lubos criticizes the patrons of physics: "it is about the drivers that lead people, especially the young ones, to decide about their "focus" and "excitement" which is so rarely real these days."

   At the beginning of that comment section he behaves in exactly the way that he criticizes: he writes incorrect and offensive statements about a researcher and his unification attempt. I am really shocked by this double standard. Lubos turns out to behave in exactly the same way as the people he criticizes.

   Let us hope that Gell-Mann's proposed search for an underlying principle will be undertaken by more people. Lubos narcissistic personality disorder will prevent him to find any such principle. We need professional scientists to achieve it, people who are focused and determined.

9. **big vlad**
September 16, 2009

I am really shocked by this:

"I am really shocked by this double standard. Lubos turns out to behave in exactly the same way as the people he criticizes."

10. **Tim vB**
September 16, 2009

concerning Lubos: One basic rule of psychology is that what you dislike most with other people are your own biggest faults.
BTW: Since it seems that Lubos doesn't know: Gell-Man took the name quark from the novel "Finnegan's Wake" by James Joyce,
but Joyce himself did probably hear the word during his stay in Austria, it is a common German word meaning "curd cheese".

11. **Dave Miller**
September 16, 2009

Peter wrote:
> Particle theory is in a sad way these days, and, as usual, I suspect that Lubos and I agree about more things than most people realize…

I've always suspected that. Lubos comes from that Central European milieu where, in print, you take no prisoners, but I've always suspected that you guys might actually have a pleasant dinner together (if you're ever in Sacramento at the same time, you have a standing invitation).

I took a freshman course on particle physics from John Schwarz, who I thought was a truly nice guy, during the early days of string theory (too early for John to tell us frosh about it). I think Gell-Mann does deserve credit for "protecting" what was, after all, an interesting idea – even if it later became a fad.

I've always had this nagging suspicion myself that there is some underlying geometric-style symmetry behind all of the string/post-string math. Maybe Gell-Mann, Lubos, and I are all still blinded from our youth by having learned about how Einstein worked out GR.

Or, maybe, Lubos will actually stumble upon something.

Dave Miller in Sacramento

12. **chris**
September 16, 2009

but Joyce himself did probably hear the word during his stay in Austria, it is a common German word meaning "curd cheese".

i don't think he heard that in Austria, since it's called "Topfen" there, not quark 🙂 afaik, he read a grocers ad "Musterquark fuer 3 Mark" and transformed it into "3 quarks for muster mark".

13. **Tim vB**
September 16, 2009

Hi Chris,
I stand corrected, so the ad was a German one, since the currency in Autria would have been Schilling, not Mark, right?
Anyway, Murray Gell-Man was looking for a name for some mysterious entity and ended up with the name of a milk product, which is an anecdote worth telling in every class on QFT 🙂

14. **Chris Oakley**
September 16, 2009

According to this you're all wrong about quarks as "three quarks for muster Mark" refers to derisory squawks directed against King Mark, the Cornish king whose bride – the Irish Princess Iseult (or Isolda) – turned out to be far more interested in Tristram (or Tristan), one of his knights, than the king himself. One of my ambitions is to make a movie of Wagner's version of this legend (his opera *Tristan und Isolde*) but as I have just turned 50, and have yet to make any movies, it is looking ever less likely.

BTW: perhaps the only thing I agree with Jacques Distler about is that giving air time to Lubos or to comments about him is a Bad Thing. Can I propose a similar policy here?

15. **Kea**
September 16, 2009

They serve quark cake at some mountain restaurants in the Bernese Oberland in Switzerland … and maybe further afield, but I'm not sure.

16. **Marcus**
September 16, 2009

Yes, deliciously rich, with butter and higg-yolks.

17. **Jack Sarfatti**
September 18, 2009

Parts of string theory will survive and be testable. It is basically the quantization of the classical Einstein-Cartan localization of the 10-parameter Poincare group + supersymmetry. I am on way to Trinity College, Cambridge and will elaborate on this another time. Agreed on the MPD of Lubos who has a webpage from Rutgers that he is a transexual ET – humorous of course. If Lubos did not exist I would have had to invent him as a larger-than-life character in a Pynchon or Borges story. 🙂

Various and Sundry

- General Relativity and Gravitation has a special issue on quantum gravity, available here.
- Some out-takes from photographs taken for the recent Forbes article are here. You can see what part of my office looks like…
- I haven't regularly been following the TV show *Big Bang Theory*, which features a main character (Sheldon) inspired by Lubos Motl. Someone who has is Bad Astronomer Phil Plait, who is interviewed here, with the following exchange:

> Alan: My geek barometer question for the Big Bang Theory is, Do you ever pause it and look at the board and try to decipher the equations?
>
> PP: I don't need to pause it, just a quick glance. Actually, it's all really advanced stuff, like string theory and more. Actually I don't think it's string theory because Sheldon said some nasty things about string theory in the past. But I never really understand it. There's some other things that they've got in there that I recognize.

I assume Phil is just confused, but if things have gotten to the point that Sheldon is saying nasty things about string theory, it's really in trouble…

- Physics World has two interesting interviews by Matin Durrani on-line, one with CERN Director General Rolf Heuer, the other with CERN head of communications James Gillies.

One topic discussed by Heuer is CLIC, and CERN's hope to be the place where the next generation electron-positron collider gets built. Here's a recent presentation about CLIC's status. If one were the wildly optimistic sort, one could see R and D on this finished next year, a complete design by 2016, construction starting in 2018 and first beam in 2025.

- Even further down the road than CLIC would be a muon collider. Fermilab now has a web-site devoted to the topic.
- You might want to keep up with the activities of the Bogdanovs here.
- John Hagelin's Global Financial Capital of New York (or someone they sold to recently) seems to be selling its building, which includes 3 stories configured as luxury apartments. $45,000,000 and it's all yours. For some more of Hagelin's activities over the last few years, there's this.
- The New York Times Book Review has a nice review of the recent biography of Dirac I wrote about here, which is now out in the US.
- If, unlike Dirac, you prefer your spinors real, there's a very interesting review article in Nature by Frank Wilczek, entitled Majorana Returns. I hadn't realized that these things now seem to be finding a place in condensed matter physics and even quantum information processing.

1. **John Armstrong**
   September 16, 2009

   Phil's confused. Sheldon (Jim Parsons) is a strong proponent of string theory. He's repeatedly slammed recurring character Leslie (Sara Gilbert) for her advocacy of loop quantum gravity.

   And actually there's plenty of equations on the boards that are on the level of quantum field theory, or even just some integral identities (ostensibly in the service of QFT). But they *are* all reasonably accurate, especially when you consider that this isn't even a sci-fi series, but a straightforward situation comedy.

   One particular exchange deserves pointing out. One morning Sheldon wakes up, walks past his board, and is pulled back by the recognition that the direction of an inequality has been changed. He expresses outrage, at which point Leslie (who has evidently stayed the night with Sheldon's roommate) wanders in and says, "Oh yeah, I did that. Now your quarks are free at high energies" (or something similar), which is actually reasonably close to what the change would do.

2. **Veronica Mars**
   September 16, 2009

   Yeah, I allways check what's on the board! 😀
   And no, he never said something bad about string theory, as far as I remember.

3. **capitalistimperialistpig**
   September 16, 2009

   I follow the show pretty closely, always try to read the equations, and have never heard Sheldon bad mouth strings.

4. **chris**
   September 17, 2009

   John Armstrong,

   i'd love to see 't Hoofts reaction to that particular joke 🙂

5. **Kevin**
   September 17, 2009

   Who cares what a stupid and unfunny TV show like "Big Bang Theory" says? It's not even worth mentioning.

6. **onymous**
   September 17, 2009

   Yeah, I allways check what's on the board! 😀

   As if Veronica Mars would misspell 'always'.

   The odd thing was that in the bit where Sheldon is slamming loop quantum gravity, you can see on his whiteboard in the background that there's something about the Immirzi parameter.

7. **Thomas Larsson**

September 17, 2009

LM did [some work](#) on the Immirzi parameter. So maybe he is the model for Sheldon after all 🙂

8. **The Vlad**
September 17, 2009

The Motl paper contains a sentence starting with a lovely phrase that I don't recall seeing in a scientific paper before:

"Morally speaking, the perturbation…"

9. **Adam Helfer**
September 17, 2009

This use of "morally" definitely exists in a subsector of physics and mathematics. I believe Michael Atiyah and Raoul Bott used it, and I recall some around them using it. I wonder if to some degree Atiyah was influenced by his brother Patrick, a legal scholar whose work on torts inevitably touches on the issue.

10. **Coin**
September 17, 2009

The article about the CLIC requires some sort of CERN account to view it.

How does the CLIC fit into the sort of overall scheme of collider plans? Like, how does it compare to the ILC? Wikipedia's page on the CLIC says it would be like the ILC but run at a higher energy. What is the reasoning for building the ILC then? Is the idea that the CLIC is just the ILC's successor?

11. **Peter Woit**
September 17, 2009

Coin,

I guess CERN management seems to have decided that the recent update on CLIC's status was a bit too recent for public consumption…

CLIC uses a very different acceleration technology, one that still has not yet been definitively proven to work as hoped. In principle one could start building the ILC very soon, if the money were available, whereas CLIC is a decade or more from that point. I guess the current thinking is that if the LHC soon discovers something at low enough energy to be studied by the ILC, it would be worth going ahead with the ILC, not waiting one or two more decades for CLIC.

12. **D R Lunsford**
September 17, 2009

Sigh, the first article in the gravity volume is on superstring perturbation theory :/

Amazing there is no mention of Finkelstein in the Wheeler plaudits. He of course made the current state of the GR art possible by re-inventing black holes in a way accessible to calculation. I would have thought Wheeler would have mentioned that as it happened in the '50s

-drl

13. **David Garvin**
September 17, 2009

David Saltzberg is the science advisor and there is a really interesting interview with him about his input. Re: the whiteboards:

"I send the set designers the material for the white boards and they put it up during the week before the taping. Sometimes the scribblings pertain to the topic of the show. For example, in the episode where the boys buy a time machine replica, the equations for time travel using wormholes, are on the whiteboards. One mathematician blogger criticized the way they were adding spins on the whiteboard as clumsy, but he also recognized that this is the way physicists would actually do it."

http://the-big-bang-theory.com/saltzberg.interview/

September 18, 2009

Sheldon's defense of string theory: http://www.youtube.com/watch?v=FMSmJCKaaC0

15. **Chris Oakley**
September 18, 2009

I saw two episodes of the show on the flight home (NY to London) yesterday, which included the above clip. I was hoping that it would be squirm-making, but it wasn't. The only thing that they've accurately captured is the arrogance. Sheldon and Leonard are far too normal. Some of the physicists and mathematicians I worked with (was – ?) were total freaks, and it might actually be funnier to tell it like it was/is, e.g. a mathematician who is perfectly capable of saying nothing for an entire evening (I knew a few), to name but one example of eccentric behaviour.

16. **Deane**
September 18, 2009

"morally correct" was widely used at Harvard, when I was a math graduate student there (this is also when Atiyah visited Bott regularly and often and gave "secret seminars" in Bott's office). It means a proof that is incomplete or incorrect, yet it elucidates the critical insight or idea that motivates the theorem.

Although Bott probably did use this term, I believe it was used more often for analytic proofs of algebraic geometry theorems, where the rigorous proof required a more algebraic and, for some of us, totally opaque proof.

There was another noun used in a similar spirit, maybe "yoga"? It would mean the overall philosophy behind a particular proof. I recall Melrose at MIT using this regularly.

This, I think, was a reaction to how much time and effort was being devoted by students to learning about and building mathematical machinery, as well as filling in all the rigorous details of a proof. Although these are all necessary steps to becoming a research mathematician, people such as Atiyah and Bott stressed that, after you had mastered the skills for constructing rigorous definitions and proofs, then once you understood the critical idea or insight underlying a given theorem, you could usually construct a complete proof of that theorem yourself without having to read every line of the proof given in a book or paper.

The most extreme expression of this view was by David Kazhdan. He would constantly show one of his graduate students a book or paper and say, "See this? You should know everything in it, but don't read it!"

17. **Peter Woit**
September 18, 2009

Hi Deane,

I definitely remember hearing "morally correct" from Bott way back when, probably also from others. "yoga" I believe I first heard from Blaine Lawson. From the context I took a "yoga" in mathematics to be a package of results and techniques that required a certain amount of training and exercise to know how to apply, but were powerful tools in the hands of adepts, and reflected some deep aspect of mathematical reality. Think homological algebra…

18. **Jeff McGowan**
September 18, 2009

"Moral" seems to me to be quite common in the math community. It was certainly used by a number of folks at the Graduate Center when I was a student there in the late 80s. Scott Wolpert from U MD uses it all the time, he got his doctorate at Stanford in the mid 70s. My colleague Eran Makover uses it, both his undergraduate and grad degrees are from Hebrew U.

Yoga in math I don't know, other than http://math.gc.cuny.edu/Faculty/dodziuk/
(my advisor, I can do one too, but there are no existing photos of that 🙂

19. **Giotis**
September 18, 2009

This character is inspired by Lubos? Why are you saying that?

20. **anon.**
September 18, 2009

Giotis, see: http://physics.about.com/b/2009/03/04/big-bang-theory-emmy-movement.htm

21. **Felipe Zaldivar**
September 18, 2009

Hi Deane and Peter, the expression "yoga" is widely used by Grothendieck and Serre (and their school) from the early 60's (see, e.g. the Grothendieck-Serre correspondence, p. 146 in a letter from April 1, 1964 in the AMS translation).

22. **Geoff**
September 20, 2009

As a string theory critic it appears your priorities are backwards. On your "top shelf" it appears you have Kaku, Polchinski, Zwiebach, and Becker Becker Scwarz. Below that it looks like Peskin and Schroeder and possibly Ashok Das. And below that it looks like t'Hooft's 50 years of Yang Mills. Shouldn't you apply a parity operation to your book shelf?

23. **Shantanu**
September 20, 2009

Characterising Science and Beyond

September 21, 2009
Categories: Multiverse Mania

This week the Templeton Foundation is funding yet another conference on the Multiverse, this one is entitled [Philosophy of Cosmology 2009: Characterising Science and Beyond](). The conference is also celebrating the 70th birthday of Templeton Prize winner George Ellis. The conference web-site includes a [page]() showing the book covers of recent multiverse books, noting that:

> The selection of books shown here (at both the popular and technical level) demonstrate the fact that the notion of the Mutliverse is becoming increasingly mainstream.

Ellis has expressed some skepticism about the question of whether the multiverse idea is testable, but, as usual with these Templeton conferences, there seem to be rather few skeptics invited. On the other hand, there do seem to be quite a few philosophers of science, and some philosophers of religion, (Alex Pruss of Baylor and Robin Collins of Messiah College), which I guess is appropriate.

Sean Carroll, who seems to have overcome his [earlier qualms]() about Templeton funding, is live-blogging the conference (see [here]() and [here]()). He notes that Ellis is worried that the multiverse may be inherently untestable and thus not science, but doesn't himself think this is worth worrying about. Presumably he'll continue tomorrow, covering the rest of the conference.

Update: Sean Carroll's live-blogging of the Templeton conference is the lead item of the front-page news on their [web-site]().

Comments

1. **Tom S.**
   September 21, 2009

   Dr. Woit. I see you discuss posts that seem to link the concept of the multiverse with religion. (Or at least with templeton.)

   Not that it matters, but I was just curious, are you implying that since some religious people see the concept of a multiverse strengthening their beliefs a sign that the concept of the multiverse is a bad thing?

   For a specific example, once you pointed out that mormons are liking the multiverse. Are you suggesting that since some mormons find a use for the idea this proves the idea is bogus?

   Not that I care, I was just wondering how a scientific idea supporting religious views in the minds of some make it so that such a scientific idea should be frowned upon.

2. **Peter Woit**
   September 21, 2009

   Tom S.,

   My problem with multiverse research is that it's mostly not science and is often conducted with the motivation of trying to use pseudo-science to explain away the failure of string theory as a unified theory.

   What religious people think about the multiverse is pretty much irrelevant to me, and no I don't think the fact that Mormons believe something is any kind of argument for or against it. Some religious people may think the multiverse gives an argument for their faith, others an argument against their faith (e.g. one can use the multiverse to counter the argument from design). Either way, their interest in the topic is motivated by something other than science, something I don't care about.

   What I do find worth pointing out is the role being played by organizations like Templeton. They have an agenda to bring together religion and science, and are implementing it by funding this kind of conference. The participation of philosophers of religion is just one indication that something funny is going on here, something that has nothing to do with legitimate science.

3. **Marcus**
   September 21, 2009

   Why is Joe Silk involved?

4. **Peter Woit**
   September 21, 2009

   Marcus,

   It's a cosmology conference at Oxford and he's a cosmology professor at Oxford…

   There are several mainstream cosmologists participating.

5. **Marcus**
   September 21, 2009

   Of course I know he's at Oxford. Even if disinclined he'd almost be obliged to participate, if for no other reason than to nominally honor George Ellis.
   But I think that such a slanted meeting, greased with Templeton fat, is no real honor to Ellis. It is sad to see people like Ellis and Silk drawn in. Just my personal view. I have enormous respect for both Ellis and Silk—think of them as scientists of the great integrity. Sad to see them roped into a event that looks rigged. Used.

6. **Robert L. Oldershaw**
   September 21, 2009

   Einstein advocated combining Spinoza's "religion" with science.

   He said: 'Religion without science is blind; science without religion is lame', or words to that effect.

If the Templeton Foundation was promoting this specific, and far more mature, form of combining science and "religion", would you still object.

Is there any credible evidence for a more dubious hidden adgenda pursued by the TF?

Might TF be promoting the Deism of Democritus, Spinoza, Jefferson + Franklin, and Einstein rather than Theism? There is a profound difference between the two, but both could be labeled "religion".

RLO

7. **Peter Woit**
September 21, 2009

I don't think the problem here is the Templeton Foundation, the problem is the toleration of pseudo-science by mainstream scientists. Templeton funds some real science, all sorts of things that have nothing to do with science, and some pseudo-science. If they didn't have prominent scientists signing on to participate in their pseudo-science activities, there would be no real problem.

It's unclear to me who at this conference besides Ellis is skeptical about the claims of multiverse studies to be science. Presumably there are quite a few. I get the impression though that the idea behind this conference was a somewhat misguided one: to bring together philosophers and physicists to examine the "is the multiverse science" question. The problem is that it's not a philosophical question, it's a physics question: do you have a theory that has any hope of giving what is needed? No one does, and as far as I can tell, the reasons for this are not being examined. They're the same reasons string theory can't predict anything about non-cosmological physics.

8. **Marcus**
September 21, 2009

Dear RLO,
what the Templeton Foundation is promoting is neither honest religion nor honest science.
You ask for evidence of (what I would call openly harmful and misguided, but not hidden) agenda. Look at the program of talks. It is slanted to promote multiversalism with a speaker lineup with celebrated proponents not balanced by strong critics.

Had they wished, I expect the organizers would have had no difficulty finding speakers to argue that religion has no need for a multiverse, nor does multiversalism do religion any good.

Likewise they could have found speakers (e.g. Paul Steinhardt) to argue that acquiescing to a landscape of multiple versions of physics is a betrayal of scientific values and not even opportune: Aside from some specialists in a stalled line of research who would benefit by abandoning the goal of a predictive as well as explanatory physics?

Left to itself, without the support of Templeton money, the multiverse speculation of the years 2003-2007 would have dried up. We wouldn't be hearing it discussed. Science has self-regulatory mechanisms. For instance the string theory landscape was almost entirely excluded as a topic from the main conferences Strings 2008 and 2009. A big change compared with 2005. Templeton funds tend to drag the clock back.

"Religion" is fine. "Deism" is fine, they're not the issue. I think Jefferson Franklin, and Einstein would have seen though the multiverse hype, and seen Templeton for what it is, a corrupting manipulation.
In my humble opinion.

9. **Mark**
September 21, 2009

I attended the Wheeler Symposium: Science & Ultimate Reality. (Mar 2002) which was funded by TF. Lots of great talks. Zeilinger explained a new delayed choice experiment he had carried out and Smolin argued that LQG was the long sought quantum gravity, to which Cecil DeWitt replied smiling, "This is probably the Xth time I've heard that announcement. Let's hope you fair better than your predecessors." Bryce DeWitt was there. Raymond Chao. There was only one mention of anything to do with the sponsor — someone said this was the first time he'd heard of talks motivated by the phil-anthropic principle. I'd attend a conference like that regardless of who funded it — Satan, the Pope — it was a great conference!

10. **Kea**
September 22, 2009

Well, I am fairly certain that Roger Penrose is also skeptical of such multiverse ideas.

11. **anon**
September 22, 2009

Marcus,

The Templeton foundation just provides the funds for a proposed conference. They don't have any say in who is invited. I attended and it was a good workshop with a lot of participants for and a lot against the multiverse idea. Peter, I bet if you attended one of these workshops you might actually soften your stance a bit on the whole multiverse issue. I got the impression that even Ellis did and he's probably even a bigger sceptic than you.

12. **Peter Woit**
September 22, 2009

anon,

The problem with Templeton funding is not that they choose the speakers, but that they use their money to try and legitimize a pseudo-scientific subject as science, a project then carried out by legitimate scientists. I believe that the majority of physicists consider most multiverse research to be pseudo-science, and would object to a conference about it being funded out of standard peer-reviewed sources.

From Sean Carroll's account, of the many speakers there, the only one who spoke about the problem of multiverse research not being science was Ellis (were there others?), and you say the conference may be causing him to soften his stance. From your account, the Templeton money is having the desired effect….

13. **anon**
September 22, 2009

Peter,

Roger Penrose, Robert Brandenberger and a number of philosophers where talking against the multiverse. Some speakers like Joe Silk where taking a more neutral position. I disagree with you about the multiverse being pseudo science. I think it provides the only solution to the cosmological constant problem. Until someone comes up with an alternative explanation I think people will be interested in the multiverse. the hope is that eventually some other signature will be found. People once said "don't study quarks because you can never see an individual quark so its not science". I think its good to be skeptical but then there are also advantages to keep an open mind on things. I don't agree with religion being mixed with science but as long as the templeton foundation keeps a hands off approach to the projects they fund, I think it is nice to have the opportunity to have a conference about some slightly more speculative issues as well the usual hard nosed stuff.

14. **Peter Woit**
September 22, 2009

anon,

The cosmological constant is about the only "prediction" of the multiverse anyone seems to be able to come up with. Here's my alternative theory of the cosmological constant: "I have absolutely no idea whatsoever what determines it, so it's equally likely to be any value". That theory makes exactly the same experimental predictions as the multiverse theory. They're both equally vacuous, and if I were to organize a conference devoted to my theory, it would be a conference devoted to pseudo-science.

This is really the heart of the matter: unless your "multiverse theory" is something with non-trivial content, i.e. it makes different predictions than the "I have no idea what is going on" theory, all you are doing is cloaking your ignorance in grandiose nonsense and trying to promote yourself as doing science when you aren't.

The argument about quarks is silly, this has nothing to do with the problem of direct vs. indirect observability. The quark hypothesis was a non-trivial one that made a lot of strong, testable predictions which worked. If Gell-Mann had started going on about his quark theory, which was functionally the same as the "I have no idea what is going on in the strong interactions, could be anything", people would have (rightly) dismissed him as a crackpot.

15. **anon**
September 22, 2009

Peter,

I disagree with your description of the multiverse solution to the cosmological constant problem. If there is a potential landscape which covers a broad enough range of values then somewhere the overall vacuum energy will be small enough to allow galaxies to form. Inflation then provides a natural mechanism to populate the landscape and then string theory KKLT extra dimension stabilization provides the landscape. There are several ways this scenario could get into difficulty. For example if gravity waves are detected by PLANCK and supersymmetry is detected by the LHC, see recent papers by Linde and Kallosh. Also if SNAP (or one of its reincarnations) finds w not -1 that will also be hard to incorporate into the above picture. Yes that is not directly falsifiable of the landscape but I really think this Popper view of science is very overly simplistic. In practice I think science works more by induction and finding supportive evidence than falsification. Also another interesting ways that more supporting evidence could be found for the landscape is in studies like http://arxiv.org/pdf/0712.2454 .

16. **Peter Woit**
September 22, 2009

anon,

Do you really believe that the din of rejoicing from string theorists if supersymmetry is found at the LHC would be affected at all by a subsequent discovery of gravity waves by Planck? Or that string theorists will proclaim string theory dead if SNAP finds w not equal to -1?. Of course not. In both cases, finding string theory "scenarios" that could reproduce whatever is found is not likely to be hard, if it hasn't already been done.

The Hall et. al. set-up is rather complicated and I haven't followed its details. From spending a little time looking at it I don't see any use of any fundamental theory of the multiverse, their fundamental multiverse theory is effectively the same theory as my "I got no idea what is going on" theory. They do seem to be doing something potentially interesting, putting into the anthropic mix some information about the physics of electroweak-symmetry breaking, but, again, I haven't invested the time to follow the details.

By the way, a more useful sort of multiverse conference would be one that dumped some of the philosophers in favor of physicists, and concentrated on examining this issue of whether the "string theory landscape" is capable of being tested in any conventional manner. All claims I've seen so far about this appear to be bogus, sorting them out and seeing what's really there would be a public service.

17. **anon**
September 23, 2009

Peter,

The multiverse explanation of the size of lambda is not the same as a theory saying "I have no idea of what lambda is". Such a theory would have a prior with a uniform distribution of lambda over some large range of values. The multiverse calculation puts the prior probability of lambda being proportional to the fraction of matter that collapses into galaxy sized objects or larger. This gives a prior distribution whose peak is quite close to the Omega_lambda \approx 0.7 that is observed. This was done BEFORE the supenovae measurements surprisingly showed Omega_lamda \approx 0.7s, see eg
http://arXiv.org/pdf/hep-th/0511037 for a history and references. With a bayesian analysis your "I have no idea of what lambda is" would be hugely disfavored compared to the multiverse calculation.

18. **Peter Woit**
September 23, 2009

anon,

By "prior" I mean the probability distribution of values that you get out of your underlying model of the multiverse, before you fold in your favorite way of doing anthropics, selection effects, etc. In the string landscape model of the multiverse, people take this distribution to be flat over the relevant range.

19. **Shantanu**
September 23, 2009

Peter or anon or others, Could one of you point whether we can test anthropic predictions with Tevatron or LHC?
Thanks
shantany

20. **Peter Woit**
September 23, 2009

Shantanu,

Depends what you mean by “anthropic” predictions. Predictions based on no fundamental theory, just anthropics, can’t possibly be wrong, they are true by definition.

If you take as your fundamental multiverse theory my “I don’t know what’s going on, it’s all equally likely” theory, you can get some sorts of statistical predictions, e.g. that we won’t observe things to be out in the tails of statistical distributions. What the string landscape people do is start with this, then when something is found to be out in a tail (e.g. proton decay), they say “well, we don’t actually know what the distribution is”.

There are no predictions about anything at any energy (Tevatron, LHC, Planck) that the people promoting this kind of research will stand behind, saying “if we don’t see this distinctive experimental signature of my theory, it’s wrong”. This is why it’s pseudo-science.

21. **anon**
September 24, 2009

Peter,

I would prefer to say its work in progress. Yes its not producing testable predictions at the moment, but its an interesting area worth exploring. Maybe one day there will be some testable predictions, but it may take time. You may think that its not worth exploring, others have a different view.

22. **Peter Woit**
September 24, 2009

anon,

The reason there are no testable predictions about cosmology is the same reason there are no testable predictions about anything else. People have been working on this for 25 years, and everything they have learned has just made it clearer and clearer that this is an inherently vacuous conceptual set-up that can never predict anything. There’s some point at which, if you refuse to admit the failure of an idea you are working on and insist on keeping going, you become a pseudo-scientist. That has happened already in this field.

23. **Robert L. Oldershaw**
September 24, 2009

Sad, but true.

Maybe it is time to back to go back to basic science based on testable predictions. And if tests give negative results, one does not “adjust” the model, but tries new ideas.

Speculation is fine by me, so long as it is clearly labeled as such and not treated as ‘the next big thing’. Unfortunately we have been conflating beautiful science like General Relativity with junk bond science like “string theory”.

RLO

24. **anon**
September 24, 2009

Peter,

I’m not a string theorist but I think you are being too harsh. Research into such large energy and time scales is obviously going to be quite open ended. I don’t think you or anyone else can say it will or wont eventually become a testable theory. My impression as an outsider is that string theory is the best theory of quantum gravity and its intersection with the multiverse and inflation may eventually lead to some very fruitful results.

25. **Peter Woit**
September 24, 2009

anon,

Like most outsiders, your impression reflects very well the hype being put out on this subject, often funded by Templeton. Again, it would have been much more helpful to science if the conference you attended was not devoted to hyping pseudo-science, but instead to a serious examination of the what is known about attempts to describe the multiverse using the string theory landscape. Enough is known to make it very clear that it is a dead-end. Even most string theorists I believe now have begun to agree about this. The people promoting string theory pseudo-science are often not string theorists….

26. **Giotis**
September 24, 2009

Peter, what is the majority opinion? At the end of the day this is what counts. If somebody is not crazy but the majority thinks he is crazy, they are gonna lock him up no matter what. So unless the majority of physicists thinks otherwise string theory ‘hype’ as you say is not a pseudo-science.

27. **Peter Woit**
September 24, 2009

Giotis,

Based on my discussions with many scientists, string theorists and not, I’d say that string theorists are now divided between those who think there still is hope for 10/11d unification and those who have given up on it as a lost cause and are now doing AdS/CFT or something else, with perhaps this last group approaching a majority. Non-string theorists generally take the attitude that string theory itself is too technical for them to evaluate, however they almost uniformly recognize that invocation of the anthropic multiverse is an admission of failure.

Take a look at the “multiverse” conferences and see who is funding them. They are rarely funded by granting agencies that peer-review grants, since getting such a proposal past a peer-review panel is very difficult. Instead they’re funded by organizations like Templeton whose explicit mission involves the promotion of pseudo-scientific ties between religion and science.

For some similar data about this, see this quote:
“in his current view, the effort to regard superstrings as a fundamental theory of everything was a blind alley. Later that year I related Charles’ pronouncement to string theory colleagues on three continents and solicited their own opinions. About half of them agreed with him, more often the younger people.”

from page 58 of this review article

http://arxiv.org/abs/0907.4238

28. **anon**
September 24, 2009

Peter,

I think you are indulging in a bit of sophistry here. Ok you don't like string theory, and some of your arguments are perhaps persuasive, but I think a lot of what you are saying, especially about the sociology, is quite misleading as well. Anyway I'm exhausted with these blog based arguments and will now get back to my own slightly quieter area of research.

29. **Peter Woit**
September 24, 2009

anon,

I can see why you might not trust my views on the sociology, but I don't why you believe that Richard Woodard is lying.

I urge you to look into this for yourself: don't ask the people who attended that conference what they think, virtually none of them know much about string theory. Ask experts who have worked on string theory what they think about the string theory landscape/multiverse. If you do this outside the Bay area, I suspect you might find the result enlightening.

Media Commentary

September 24, 2009
Categories: Uncategorized

Tonight will be the premiere of a new TV series called *Flashforward*, based on a novel with a plot that involves the Alice detector at CERN. CERN has put up a web-site about this, to reassure people that CERN isn't about to change time around. The web-site is along the same lines as the one they put up about Dan Brown's Angels and Demons, to reassure people that CERN wasn't producing quantities of antimatter that could be used in a bomb.

Dan Brown has a new novel out this week, entitled The Lost Symbol. The plot evidently revolves around a researcher in "Noetic Sciences", who is quite the expert on "What the Bleep" pseudo-science, as well as string theory. Here's where she learns that string theory was known to the ancients:

> …I want to study cutting edge THEORETICAL physics. The future of science! I really doubt Krishna or Vyasa had much to say about superstring theory and multidimensional cosmological models."
>
> "You're right, they didn't." Her brother paused, a smile crossing his face. "If you're talking superstring theory …" He wandered over to the bookshelf yet again. "Then you're talking about THIS book here." He heaved out a colossal leather-bound book and dropped it with a crash onto the desk. "Thirteenth-century translation of the original medieval Aramaic."
>
> "Superstring theory in the thirteenth century ?!" Katherine wasn't buying it. "Come on!"
>
> Superstring theory was a brand new cosmological model. Based on the most recent scientific observations, it suggested the multidimensional universe was made up not of THREE … but rather of TEN dimensions, which all interacted of vibrating strings.
>
> Katherine waited as her brother heaved open the book, ran through the ornately printed table of contents, and then flipped to a spot near the beginning of the book. "Read this." He pointed to a faded page of text and diagrams.
>
> Dutifully, Katherine studied the page. The translation was old-fashioned and very hard to read, but to her utter amazement, the text and drawings clearly outlined the EXACT same universe heralded by modern superstring theory – a ten-dimensional universe of resonating strings. As she continued, she suddenly gasped and recoiled. "My God, it even describes how six of the dimensions are entangled and act as one?!" She took a frightened step backwards. "What IS this book?"
>
> Her brother grinned. … "The complete Zohar."

(Thanks to Greg Sivco for the transcription).

Perhaps CERN-TH may want to put up another Dan Brown web-site at CERN to reassure people that the strings in 10d stuff has nothing much to do with reality and isn't likely to lead to whatever trouble it leads to in the novel.

For more on this, Salon has a book review entitled Dan Brown swaps pseudohistory for pseudoscience.

Comments

1. **Chris Oakley**
   September 24, 2009

   Oddly reassuring that. The next time someone tries to convince me that Dan Brown's writings are based on fact, I will be able to point to this. I suppose the story must have a counterpart to Silas (the Opus Dei fanatic in *The Da Vinci Code*). Who could fulfil that role, I wonder?

2. **jpd**
   September 24, 2009

   "the complete zohar" is that a new saying,
   similar to "the whole enchilada" ?

3. **Greg Sivco**
   September 24, 2009

   Thank you, Peter.

   Dan Brown is a highly intelligent man and a product of one of the Phillips Academies and Harvard and that is was vexes me … that he should have read more and not promoted a theory that is quite obviously: dust … save for Susskind, Polchinski, Witten (diplomatically), Motl, et. al. .

   The quote Peter mentions is a "flashback" when Katherine was 19 (she's 50 in the "real time" of the novel, heh, not far off from Peter and me), so doing the Arithmetic (not even Math), the year where that conversation goes down is 1978. Whatever. QCD was the sex then, and QCD was the first thing that kicked ST to the curb.

4. **roland**
   September 24, 2009

   Man, Dan Brown. That is so lame.

5. **Frank Quednau**
   September 24, 2009

   This sounds utterly unreadable. People interested in history probably feel the same with the other books

6. **Chris W.**
   September 24, 2009

   Michael Crichton has a similar pedigree, and also produces schlock for mass consumption. I think they both know what they're doing, even if their readers don't. Indeed, Crichton wrote a piece for *Science* a few years ago in which he responded to scientists' complaints about how they're portrayed in the movies by saying, in essence, "Just get over it; you can't expect anything better from this medium. That's not what it's about."

7. **H-I-G-G-S**
September 24, 2009

Michael Crichton had. Not has.

8. **Yatima**
September 24, 2009

Dan Brown. Pah! Lovecraft was there first ..

"A room was easy to secure, for the house was unpopular, hard to rent, and long given over to cheap lodgings. Gilman could not have told what he expected to find there, but he knew he wanted to be in the building where some circumstance had more or less suddenly given a mediocre old woman of the Seventeenth Century an insight into mathematical depths perhaps beyond the utmost modern delvings of Planck, Heisenberg, Einstein, and de Sitter."

Not half bad for a story written in 1932.

9. **Jeff McGowan**
September 25, 2009

I believe Brown went to Amherst, not Harvard, FWIW. Probably only means something to those of us who went to Hampshire 🙂

I tried to read a page of Da Vinci code, yow it was painful. Actually beyond the "so bad it's funny" level of bad, which I guess is some sort of accomplishment…

10. **David Schaich**
September 25, 2009

Unfortunately, it means something to those of us who went to Amherst as well.

I had hoped that the long delay between books meant that someone was forcing Brown to, you know, check facts and stuff. Guess not. Yow.

11. **Arun**
September 26, 2009

Its a work of fiction!

12. **Greg sivco**
September 27, 2009

Very good Jeff and David, quite correct he graduated Amhurst in '86. His chief protagonist is Robert Langdon, Professor in "Symbology" at Harvard.

TLS IS a work of fiction, an action-adventure treasure-hunt thriller in the traditions of the films "Indiana Jones" and "National Treasure" and the Bond films. Brown however emphasizes a higher degree of Intelligence from the reader, such that those of average IQ who complete the book will feel themselves so much smarter than "scientists."

Because "real" scientists reject Noetic Science, and Brown makes them feel smarter for having read the book. I mention the book because with 5 million copies in the first printing (which I do believe they will sell), I fully expect the book to be the most read in the next month, and just wish to prepare us for having this book and its conclusions brought up at dinner parties and other social get-togethers in the next month or two.

Among the odder "Noetics" in the book is an experiment to measure the mass of the human soul. A dying man is put into an adult sized incubator similar to one we use with premature babies, with a highly sensitive scale. After he passes, his weight noticeably decreases by micrograms as his soul escapes. So says Noetics.

I have finished the book and like it for what it is … fiction. Brown himself is no conspiracy theorist … the Scottish Rite Masons come off rather well except for the villain, who is mentally ill but sane enough to do great damage. The best part for me are the many puzzles it presents, most of which I could solve before Brown spills their beans 2 chapters ahead. The worst part for me is the New Age-presented-as-fact stuff. But in order to criticize I feel it important to read the book.

"Truth is stranger than fiction; Fiction has to make sense." … Leo Rosten

Not necessarily.

13. **Vronsky**
September 29, 2009

An [appropriate comment] on the Dan Brown comments.

14. **Janne**
September 29, 2009

"Non-Euclidean calculus and quantum physics are enough to stretch any brain; and when one mixes them with folklore, and tries to trace a strange background of multi-dimensional reality behind the ghoulish hints of Gothic tales and the wild whispers of the chimney-corner, one can hardly expect to be wholly free from mental tension." -H.P. Lovecraft (The Dreams in the Witch House: And Other Weird Stories)

15. **Chris Long**
October 2, 2009

Look mac, these ain't just higher dimensions, they're wider, more luxurious dimensions. You interested? Best you'll find on the black market.

16. **Ken McKenna**
October 9, 2009

The Zohar (Hebrew: זֹהַר, lit Splendor or Radiance) is the central work of Kabbalah. It is a commentary on the Torah, written in medieval Aramaic. The Zohar is not one book, but a group of books; these books include scriptural interpretations as well as material on what some of its adherents term theosophic theology, mythical cosmogony, and mystical psychology. Its scriptural interpretations have been described as an esoteric form of Midrash (Rabbinic commentary on the Tanach), a description that is consistent with the view of many Kabbalah cultists that it is the concealed part of the so-called "Oral Torah."

In its own weird way the Zohar advances a view of the nature of God, the origin and structure of the universe, the nature of souls, redemption, the relationship of “true self” to the “light of God,” the relationship between the “universal energy” and man, and God-knows-what-else. In short, the “Complete Zohar” is a really rich literary and religious compost.

But there’s no string theory there. A pity, that. Otherwise, I suppose, Madonna might be a string theorist. And while she may be a bit over the hill as an entertainer, her involvement might have really livened things up.

The Edge of Physics

September 24, 2009
Categories: Uncategorized

Nature this week has two stories about the Perimeter Institute. There's a long one entitled The edge of physics, which emphasizes Perimeter's wealth and success, starting off:

> Working at the Perimeter Institute for Theoretical Physics comes with certain perquisites. Whenever recruits arrive at the Toronto airport, for example, they are met by a limousine and driven west along Canada's Route 401 into the rich farmlands of Ontario. Eighty-five kilometres later, the limousine works its way through the streets of the town of Waterloo, and lets them out in front of a sleek building of black, green and glass squares that stands next to a pond in Waterloo Park. Stepping inside, the recruits find wall-to-wall blackboards, working fireplaces, a sauna, multiple dispensers of free coffee and the Black Hole Bistro, which serves free lunches on Wednesdays.

Neil Turok is the new director, and he plans to double the full-time faculty from 12 to 25. The institute already has more theory postdocs than anywhere else in the world (44) and is aiming for a research staff of 250, including visitors. For comparison, the Princeton IAS has 5 permanent faculty in physics and about 20 postdocs. Perimeter has an endowment of 200 million Canadian dollars, a figure they hope to double.

The same issue has a review by Joao Magueijo of Howard Burton's book about his experience as first director of Perimeter (my own review is here). Magueijo's take on Perimeter is rather scathing, seeing it as a "sad tale", having sold out on its original anti-establishment concept:

> The institute's aim was to "make waves, big waves", and it got off to a promising start. Burton — a youthful outsider who had only just finished his physics PhD went about his job with maverick flair, challenging the scientific establishment, attacking its tribalism and allergy to innovation. Here was an opportunity to do things differently: to promote originality, to flatten hierarchy and empower the young researchers actively driving the field. It sounded utopian, but it was worth a try.
>
> Unfortunately, reality failed to comply with Burton's plan. The best days of this haven of free-thinking came while it was still a 'theoretical' theoretical physics institute — before the scientists arrived. The anecdotes Burton narrates in the chapter 'The Trouble with Physicists' ring hilariously true. But there was also a fatal flaw in Perimeter's concept — scientists tend to define 'originality' as what they personally do. Soon the institute's quest for novelty became hijacked by the agendas of the field's usual culprits, and Burton himself came under attack from them….
>
> Burton tried to replicate the US establishment in Canada, but he was often outbid and exploited by opportunists who used Perimeter as a trampoline to boost their US careers.
>
> By the time Perimeter matured, five years later, the divide between the quixotic first hires and the new wave was painfully evident. The openness of the early days was replaced by Princeton-style hush-hush and invitation-only meetings. The idealists openly confessed that they wished they could find another benefactor, to "start anew and this time do it right". Something had gone wrong: the sought utopia had become a dystopia.
>
> Scientific originality has become big business: being anti-establishment sounds great. Yet few want to take the risks necessary to achieve it. Originality is encouraged in public pronouncements only to be punished when practical decisions are made. Perhaps Perimeter's tale proves that there is no recipe for original science: it happens anarchically and by accident, in spite of, rather than because of, scientific institutions.

Update: Sabine Hossenfelder, who recently spent three years at PI, has her take on the Nature articles here.

Comments

1. **tom s.**
   September 24, 2009

   Speaking as someone who knows nothing about the internals or personnel at PI, how does one tell brilliant, quixotic, anti-establishment hires from flakes? I do remember that the first public talk was by Roger Penrose, whom I have always thought closer to the second.

2. **tytung**
   September 24, 2009

   1. It's hard to distinguish anti-establishments from cranks
   2. The established people are unhappy that such anti-establishment young people can be allowed to possess such a good environment/opportunity.

3. **peter shor**
   September 24, 2009

   The "right" way to do anti-establishment science is first to get tenure by doing brilliant establishment work, and then to do your truly original, anti-establishment stuff. Otherwise, everyone will ignore you because you don't have any credentials.

   This is easier said than done.

4. **volunteer**
   September 25, 2009

   @peter shor

   Yes, but what about grants?

5. **Peter Jackson**
   September 25, 2009

   What Perimeter really needs to be doing is not just ensuring nice jobs for scientists to persue their own agendas, but something no academic institutes do, properly check out what's really out there.
   At present everything original gets thrown into the crackpot pit if it's not direct from academia (and some that is!) without even a look.
   Perhaps the best unification of GR and QM we have is Einsteins comment that we dont yet "know 1,000th of 1% of what nature HAS REVEALED to us" and the Quantum tendancy for everything that CAN happen TO happen. Somewhere out there the answer lies, someone, who perhaps thinks differently, has found it, yet it's all

being ignored and consigned to the pit without a glance.
It just needs a policy and minimal time checking over models and evidence proffered. It should be the duty of all staff to spend say an hour a day doing so!
Perimeter has become as self serving and non-inclusive as most other institutes. This includes, yes, the Royal Society, which started with free thinkers like Sir Christopher Wren, but is now as packed with clones as anywhere else. I hope Neil Turok can get back to fundamentals, but I'm not holding my breath.

6. **bane**
September 25, 2009

Peter Shor's comment may well be true in "no scutwork or lab equipment" disciplines like mathematics, theoretical physics and theoretical computer science. In other areas of research, volunteers comment about grants is highly significant.

As a side-bar, I think it's probably noticeably easier to find a place to be "orthogonal-establishment" (with respect to your immediate colleagues, not the whole field) rather than "anti-establishment": if the rest of the faculty don't really understand what you're doing but it looks to have solid foundations then they're generally reasonably supportive. On the other hand if your work is, however politely, suggesting what they're doing is misguided then there's a lot more criticism. I've sometimes wondered if that's why some of the most "original" thinkers seem to be situated in strange departments in smaller places where everyone else in the department seems to work in other areas: if they were somewhere bigger or with more related faculty they'd probably face more friction.

7. **Bee**
September 26, 2009

Hi Peter,

Thanks for the link.

Tom, Tytung, Peter Shor:

Using "anti-establishment" as a criterion to select promising scientists it a completely misguided attempt. It is not only easy to fake, it isn't any scientific criterion whatsoever. It just sometimes happens to be a beneficial attitude for those scientists who chose to take the path less traveled, mostly out of a sense of self-protection. After all, they are smart people who know they are making their life unnecessarily complicated, so there's a tendency to rationalize that with an anti-authoritarian, anti-establishment, anti-something philosophy. That however is neither a necessary nor a sufficient ingredient to find people who have the qualification and courage to work on what the NSF calls "transformative" research (and what others like to call risky research).

There is a very nice song by a German group called "Rebell" (rebel), the chorus being "I am against it, no matter what it is." Unfortunately, this is an equally dumb attitude as brainlessly swimming with the stream.

There are a whole bunch of other criteria that I have found frequently being thrown around, and that are nothing but secondary criteria that are to some extend correlated with what one is actually looking for, yet shouldn't be confused with it. You can count to that "independence" which is easily confused with being unable to work with collaborators, and "broadness," a frequent change of topics, which for some people happens because they jump on any boat that crosses their path.

Bottomline is, there is no way to summarize the necessary characteristics for a scientist likely to cause a great breakthrough with a couple of adjectives.

Best,

B.

8. **steph handel**
September 26, 2009

is garret lisi perhaps the only successful "anti-establishment" physicist who has been affiliated with PI?

9. **Steve Satak**
September 26, 2009

I believe it was CS Lewis who wrote, in a passage I cannot now find, that the more original a person tried to be, the less likely he was to achieve his goal. The truly original, if you ask them, are found to have been focusing on the task at hand, *not* being 'original'.

10. **Phil Warnell**
September 27, 2009

Hi Steph,

"Is garret lisi perhaps the only successful "anti-establishment" physicist who has been affiliated with PI? "

I don't know if the term "anti-establishment" is the right word , rather than unorthodox or ones not following the current trend. If taken as the latter Lee Smolin could be seen as such a person or Lucien Hardy, both of which are not simply associated with Perimeter, yet are actually faculty. If you want a more poignant example it would be someone like Antony Valentini ,who after completing his doctorate spent many years in the wilderness outside of mainstream academia. I believe it was Lee Smolin who was instrumental in having him come to Perimeter as a visitor, which turned out to a visit of a few years. After this he struck out on his own again and received some funding from a a source that is designed to lend such people assistance. One should also be mindful that Einstein spent a few years working in a patent office until his papers of 1905 changed his destiny and with it the course of physics.

Best,

Phil

11. **Bee**
September 27, 2009

Last time I looked, Garrett wasn't affiliated with PI.

12. **Erik Anderson**
September 27, 2009

I suspect that Magueijo is right. PI is going totally mainstream. PI's mission now seems more focused on accruing prestige than than supporting self-directed individuals who are unaccommodated by existing research programs.

Speaking of G. Lisi, does anybody know what ever became of his idea to establish “Science Hostels” ?

13. **Peter Woit**
    September 27, 2009

    I’ve just deleted several content-free comments about Garrett Lisi, both anonymous attacks or claims for his genius. If you have something interesting to contribute about Perimeter, please do so. If you have a stupid comment about Garrett, find someplace else…

14. **Phil Warnell**
    September 27, 2009

    Hi Erik,

    I suspect that Magueijo is right. PI is going totally mainstream.

    When Howard Burton’s contract as director of Perimeter wasn’t renewed, I would say it marked a point in its evolution and not so much indicative of a change in direction. Burton acted mainly as an instrument of Mike Lazadisis’ vision and I would say he did a commendable job a far as the initial stages where concerned.

    Likewise, I see Turok representing simply the one chosen to shape Perimeter through the next phase of its development. Its current expansion demonstrates the continued commitment to the vision and yes the growing pains will continue. I would ask you to be more specific, as to name names of who you would recruit as faculty and those as post docs. I find Magueijo’s comments not much more than sour grapes and find him to hold no less of an elitist attitude than those he criticizes. I don’t mean this so much as a criticism of him, yet more to acknowledge that as demonstrated by many sharp minded, free thinkers, comes a feeling that one’s direction being the only correct one.

    One could say that the vision of what Perimeter represents to be is the product of one man and that being Mike Lazardisis, which continues to be the case. The thing that Lazardisis’ vision is focused around is expressed in what he conveyed to Burton when he hired him; that being he believes the world is on the verge of something groundbreaking and earth shaking and he would like to help expedite its fruition. Mike is a man of action and not one of analyzing methodology, past knowing that in any endeavour or enterprise of scale one is required to have a clear vision, which must be shared by those who are to bring it about.

    Thus I argue that the main tension we are feeling here is that since Mike is not one of those who will actually have it come to be, he should have no part other than to be the banker. I would counter this opinion with asking if Neil Armstrong would have stepped on the moon as early as 1969 without having the force of vision and will supplied by John F. Kennedy. One thing I can assure is if Mike contunues and is allowed to play his role PI will become the place and accomplish the things he has imagined. This dynamic will assure it, as the normal model of academia has seldom been able to manage, for it places goals above the people who serve achieve them and not the other way around.

    Best,

    Phil

15. **Erik Anderson**
    September 28, 2009

    Phil,

    Thanks for your thoughtful remarks. It just so happens that last March I did send a letter of recommendation in support of an applicant for a PI faculty position. Suffice to say that the limousine was not summoned. You may now wonder if I too have a sour-grapes complex, but that’s not where I’m coming from.

    I agree with the notion that we are long overdue for groundbreaking innovations in theoretical physics, but I don’t believe that the endeavor can be properly compared to the Apollo program. Cultivating innovation has little in common with a massively blueprinted engineering project. Nor is lavish spending required. Frugality, on the same budget, would go so much further.

    You have a nice selection of favorite books listened on your webpage. May I recommend to you Norbert Wiener’s classic “Invention: The Care and Feeding of Ideas” (a manuscript from the 1950’s published in 1993)? The culture of ‘Megabuck Science’ was coined by Wiener to describe pathological tendencies of industrial science. Woit’s and Smolin’s most recent books have convinced me that parallel tendencies have spilled over into the theoretical sciences as well.

    Kind Regards,

16. **Kea**
    September 28, 2009

    Just a warm bed, a desk and enough food to eat. Is that too much to ask?

17. **Phil Warnell**
    September 28, 2009

    Hi Erik.

    First let me thank you for your considered response. Thanks also for the books you recommend and I will surely have a look. I would most certainly agree with you that one can’t directly compare the race to the moon with fundamental research, for as you remind the former being more the development of technology, rather the new science; although there was some of that as a result.

    No what I meant mostly is that Lazardisis is the one who holds the vision and the will to maintain it, which I find is something common to both. The other thing I believe they share, is each has to reach some critical mass before they begin to show promise. This current expansion has more to do with growing the scope of the specialties, rather than expanding the numbers in of each discipline and I find that to be a good thing.

    To be honest, I find if anything has changed, not for the better, is the public outreach component of PI’s vision ,of which I’ve been a grateful benefactor almost since it’s beginnings. From my own observations it has shifted under from the direction of Burton , who emphasised the humanizing of scientists and along with it there science, to mainly being a PR imitative to promote and guarantee funding. I find this to be a mistake for I believe that science’s success is ultimately best achieved when a greater sector of the populous not only see it as a methodology for expanding our knowledge, but also as one for guiding us through every day life’s decisions. I’m thus reminded in this regard when Carl Sagan warned *“It is suicide for a society that depends on science and technology to know nothing about science and technology.”* . This I also find to be a important part of the mission to realize PI’s vision, for which I think Burton had the better feel.

    Best,

    Phil

18. **Chris W.**
September 28, 2009

Lest his last name be confused with an obscure medical disorder, here is the correct spelling of Mike’s name:

— Mihalis “Mike” **Lazaridis**

19. **Thaler**
September 28, 2009

> Just a warm bed, a desk and enough food to eat. Is that too much to ask?

If that’s all you need, there are plenty of places offering it. But I suspect that you, and most people, want much more than just that.

Most people want their warm bed, desk and food to be placed in Oxford, Cambridge, Princeton, Stanford or CERN. And that’s a completely different business.

20. **Erik Anderson**
September 28, 2009

Hi again, Phil

each has to reach some critical mass before they begin to show promise.

Doubtful in the latter case. Which massive programs of support produced Kepler, Newton, or Einstein?

Genius springs forth at the level of the individual — not collectives. So if philanthropy can be massive, then it ought to be massively parallel, widening the diversity of individual pursuits. This mode of support, I would think, would best enhance the prospects of genuine discoveries.

But as a rule, money goes where money is. If Lazaridis wishes to make PI into another Princeton, then the redundancy he thereby creates does not advance the cause.

– E

21. **Kea**
September 28, 2009

If that’s all you need, there are plenty of places offering it.

Oh, yeah? WHERE?

22. **Andy**
September 28, 2009

tytung,

only cranks cannot tell non-establishment scientists from cranks.

23. **Jarmo Makela**
September 28, 2009

Steve Satak,

I think that the quotation from C. S. Lewis you are referring to, is this:

“Even in art and literature, no man who bothers about originality will ever be original: whereas if you simply try to tell the truth (without caring twopence how often it has been told before) you will, nine times out of ten, become original without ever having noticed it.” (C. S. Lewis: “Mere Christianity” p. 190 (Macmillan Publishing Company, New York, 1960))

24. **Erik Anderson**
September 28, 2009

Kea,

Perhaps Thaler was making an oblique reference to *homeless shelters*. 😉

Lisi’s ‘Science Hostel’ concept sounded more promising.

At any rate, I agree with the spirit of your previous post. Dedicated researchers do not have a dire need for limousines, glass facades, saunas, fireplaces, etc. But I would add one item to your list of essentials: good Internet connectivity.

Cheers,

– E

25. **Chris Oakley**
September 28, 2009

Erik,

I disagree. *Poor* internet connectivity is far better. Then one might get some work done rather than pointlessly leaving comments on Science Blogs. Oh … but it looks as though … never mind … too late now (my own theoretical phys research is pretty much on ice anyway).

I agree with C S Lewis about originality. Seeking out “original” researchers is only likely to turn up cranks. Equally, looking for the “big ideas” is also, IMHO, doomed to failure. Bear in mind that the non-universality of time and space was only generally accepted decades after Lorentz wrote down his transformations. And Heisenberg tried very hard to avoid non-commuting operators before finally acquiescing to matrix mechanics. No: I think that one should only take the “big” idea on when one is certain that nothing else will do.

26. **Thaler**
September 28, 2009

> Oh, yeah? WHERE?

Peripheral places. Maybe Northern Ireland, or Bosnia, but those are still Europe. Provincial universities in Latin America or Southeast Asia (Colombia, Peru, Philippines, …) I have no idea about Middle East or Africa.

Many, if not most, of those places don’t advertise positions in Physics Today but some of them are willing to hire. You might try going to a conference in the region and finding out what’s available.

The break is over, I’ll submerge now…

27. **weichi**
September 28, 2009

Isn’t all this talk about how to organize research groups pretty much beside the point? Theoreticians at Perimeter face the same problem faced by theoreticians elsewhere: history has demonstrated that unless your name is is Albert Einstein and you are working on a relativistic theory of non-quantum gravity, you aren’t going to make any important theoretical breakthroughs in the absence of new experimental results.

28. **Kea**
September 29, 2009

Thaler

Thanks!! I do look for these jobs, all the time, but they are not advertised. I might just find some conferences in peru or south east asia to go to! Of course, travel costs will be tricky to arrange … but maybe I will manage.

29. **Phil Warnell**
September 29, 2009

Hi Erik,

Which massive programs of support produced Kepler, Newton, or Einstein?

Not so much programs, rather technology, which in this case came with the advent of the printing press. And yes I would agree that breakthroughs are often exclaimated by what happens to present as being a few individuals. However, this hypothesis quickly starts to show cracks if you try to say that those you mentioned could have done it alone, that is without the accumulation of the thoughts and ideas of others. I personally believe we have reached a juncture where the problems we are presented with will only be solved by the collaboration of many minds, along with their ideas and not be attributable to those of any one individual. One could argue that Quantum Mechanics and its extensions marked the juncture where this became first to be evident.

As for Perimeter simply representing being redundant, as such places having already been realized, I would point out it expands the overall numbers able to remain dedicated to fundamental research, instead of them being forced to find employment in things for which they haven’t been specifically trained for or more importantly what they enjoy. I also find it funny that many envision Perimeter somehow as being the Ritz hotel of research centres, for although it has excellent resources and perhaps a few niceties, it does provide what the average person would call a lavish existence. I can see many here have expressed the opinion that without some pain there can be no gain, with which I might agree if you were talking about athletes rather than scientists.

Best,

Phil

30. **Phil Warnell**
September 29, 2009

Hi Erik,

” for although it has excellent resources and perhaps a few niceties, it does provide what the average person would call a lavish existence. ” </i?"

Sorry that should have read:

” for although it has excellent resources and perhaps a few niceties, it doesn’t provide what the average person would call a lavish existence. ” </i?"

This is one reason I prefer blogger over wordpress, as I could have simply erased the whole thing. Thus I find technology can make a difference:-)

Best,

Phil

31. **Mark Stuckey**
September 29, 2009

If PI is simply trying to serve as a launch site for young theorists (nothing wrong with that, but it is a duplication of effort), the theorists will have to work in established areas to guarantee success when they return to the “heat bath.” You shouldn’t really expect these researchers to find a new paradigm under those circumstances. If PI rather wants to facilitate the development of a new paradigm in physics (whatever that might be), they can drill or refine. Right now PI is drilling. Rockefeller made his fortune refining (oil in his case), letting others take the risk of drilling. PI could rather serve as a refinery, which would be something new in the community and it would have a higher probability of contributing to whatever becomes the next paradigm in physics.

32. **Marcus**
September 29, 2009

and it would have a higher probability of contributing to whatever becomes the next paradigm in physics.

will there be a next paradigm if nobody drills?
It sounds reasonable that one design a strategy to be more certain of having contributed, after one recognizes what the next paradigm was, after the fact. I'm skeptical though. Sounds like playing for credits rather than what Robert Frost was talking about—"for heaven and the future's sakes".

33. **Erik Anderson**
September 29, 2009

Phil,

"*this hypothesis quickly starts to show cracks if you try to say that those you mentioned could have done it alone, that is without the accumulation of the thoughts and ideas of others*."

But that's *not* what I tried to say. The pertinent moral is that none of these gentlemen made their mark as a result of some massively *collaborative* research program. They unquestionably had good access to previous knowledge (unfairly delayed in Kepler's case), but were otherwise working on their own.

Marcus,

"will there be a next paradigm if nobody drills?"

Well put. Individual 'explorers' do still exist, though no practical incentives exist to be one. The risk they assume is total. Institutions, however, are risk-averse. Hence the disconnect which Magueijo describes.

The next paradigm is inevitably coming. But it will surely be brought about by a risk-taker — not by practical "men of action."

Cheers,

34. **Haelfix**
September 29, 2009

PI is a worldclass facility. Most everything there is modern and schick and it probably costs a nice penny for the administrators and Canada.

Unfortunately the truth is that in science, going down establishment roads typically yields far more steady, consistent results and revenues than 200 wild idea people, where 1 person of the lot has a legitamate breakthrough every ten years or so.

Particularly so in fundamental theory, where there is no lucrative patent at the end of the process that could recoup the massive losses.

They made the correct decision by bringing in Turok and a few establishment people to balance things out. Of course this will irratate some, but its really the only way for the place to make economic (not necessarily scientific) sense in the long run

35. **weichi**
September 29, 2009

In the driller/refiner metaphor, aren't the drillers represented by experimentalists, and the theorists in general are the refiners? So that the risk-taking you want to encourage is by *experimentalists* at least as much as it is by theorists?

Of course, funding experimentalists is a lot more expensive than theorists (especially the high-energy kind), and their duds are a lot more obvious …

36. **Erik Anderson**
September 29, 2009

No, the role of experiment in this metaphor is to test whether a new well has produced real oil or snake oil. 😉

37. **Phil Warnell**
September 30, 2009

Hi Erik,

My point being that we have entered a stage where collaboration has to be increased, both within and between the disciplines, with PI marking an effort where this is being attempted as a methodology. I would say it might also help if they expanded their faculty to include foundational mathematics and scientific philosophy. The trick of course is how to have these people interact positively or better yet even want to. This is the challenge that lays at the heart of the success or failure of it all, that is as far as I'm concerned.

Best,

Phil

38. **J.F. Moore**
September 30, 2009

"The best days of this haven of free-thinking came while it was still a 'theoretical' theoretical physics institute — before the scientists arrived."

This seems to me a really strange statement. Is there a missing word I wonder, or are there actually theoretical physicists who don't consider themselves scientists?

39. **Peter Woit**
September 30, 2009

J.F. Moore,

I think the author meant that the best days were when it was just a concept, before theorists were hired and it became a reality…

40. **Erik Anderson**
September 30, 2009

Phil,

Put that way, I think your point is an excellent one. The need for an interdisciplinary outlook today is acute. Meanwhile, the breadth and sheer bulk of today's knowledge is such that one wonders if a single individual can ever acquire enough of it.

To solve the trick of making it possible for people to productively share knowledge, I suggest that this mode of collaboration must have organic roots — i.e., spontaneously grown from the bottom-up — not orchestrated from the top-down. It's a matter of which people want to associate with whom *in the first place*, and then: can they all be brought together. It's *not* a matter of hiring top-experts in various fields and hoping for the best. Indeed, the kind of experts needed must include those who are deeply *dissatisfied* with their own respective fields — which is to say: unrecognized experts.

Cheers,

– E

41. **Bruce Bartlett**
September 30, 2009

Just to mention that Neil Turok has, of course, been the driving force behind the African Institute of Mathematical Sciences (AIMS), which he essentially founded six years ago. AIMS is situated just outside Cape Town in South Africa and basically offers a nine-month postgraduate training programme for students from all over the African continent in the math sciences (that includes physics!). Nowadays there are also opportunities for postdoctoral researchers. It's been a big success, so kudos to Neil Turok. Off hand, if anyone is interested in coming to sunny Cape Town (world cup next year!) and delivering a three week postgrad lecture course, or simply spend some research time at the institute, visit the website.

42. **Peter Woit**
September 30, 2009

Thanks Bruce,

I was thinking of trying to get some mention of Turok's role in AIMS into the posting but didn't quite get around to it. Thanks for mentioning it here, AIMS seems to be a remarkable institution that deserves more attention and support.

43. **Andy**
September 30, 2009

Interesting and important institution, the African Institute of Mathematical Sciences (AIMS), and certainly ambitious—I quote from their job opening "Director: AIMS Next Einstein Initiative":

"By developing scientific talent in Africa, AIMS-NEI aims to discover people of rare creative genius, capable of revolutionary advances in various fields of human endeavour. By adding entrepreneurship and leadership skills to the existing AIMS curriculum, AIMS-NEI aims to catalyse the creation of spin-off companies and thereby to help generate wealth creation. As well as the Next Einstein, we hope to discover the Next Gates, Brin and Page in Africa."

44. **Chris W.**
September 30, 2009

The next paradigm is inevitably coming. But it will surely be brought about by a risk-taker — not by practical "men of action." (Marcus)

Very often, practical "men of action" seem to regard themselves as the real risk-takers, and regard the supposed theoretical paradigm-creators as impractical dreamers who can't function in the "real world" — right? That certainly seems to be true in the corporate world, which academic institutions increasingly resemble.

Here is a question: Why wasn't Albert Einstein dismissed as a crank, albeit an unusually talented and articulate crank? It seems that some of his eminent elders had to be willing to go out on a limb for his work to be published and acknowledged. His confidence and perhaps his sanity could have been crushed simply by being ignored for a couple of decades.

45. **Erik Anderson**
September 30, 2009

Here is a question: Why wasn't Albert Einstein dismissed as a crank, albeit an unusually talented and articulate crank?

Because… Einstein's ideas did not threaten anyone else's entire career? Even as late as 1929, Michelson was *still* hunting ether with an even *larger* interferometer.

46. **Marcus**
September 30, 2009

Chris W.
You have a quote there about "the next paradigm" which is actually not from me but from Erik
http://www.math.columbia.edu/~woit/wordpress/?p=2313&cpage=1#comment-50444
which is perfectly all right with me. Hardly worth mentioning, unless Erik objects.

I like the point you made which was essentially about the seriousness and honor of Einstein's community elders—the scientific ethos that prevailed at the time.

I have no way of measuring to what extent, if any, our scientific culture is different from those German Victorians of the class of 1890-1910.

But you are telling me that some cultural intangibles helped to motivate Einstein and get him recognized. He expected that the scientific world would "play fair" and take an objective look, even if he contradicted received wisdom.
And he was right. The physics community of the time did play fair. It recognized that he had done something important and it rewarded him.
This is probably worth a lot, even compared with having lots of fellowships to support unconventional research.

Giving an outsider recognition *at the possible cost of one's own prestige or one's friends' prestige* being open-eyed to recognize the possible merit of an alien idea, is an act of seriousness. In our culture it may be that keeping one's own prestige, funding, and public image intact is more important than that kind of integrity. The "we're the only game in town" mentality, where anything positive said about a rival approach is met with hostile rebuke.

Should be possible to measure these differences in scientific culture by some objective means, and compare different historical eras. I wouldn't know how or if it has been done. But your second paragraph was pertinent. Thanks

47. **Chris Oakley**
October 1, 2009

Read Einstein's Mistakes for a warts-and-all account of the great man and the environment in which he (eventually) prospered. He did not actually get particularly good grades but his relentless energy and curiosity won the professors over. This is something that could not happen now as the technical bar is so much higher. Creative students with less than excellent grades now would be weeded out very early on. This is probably inevitable, but I am sure that something is lost in the process.

48. **A.J.**
October 1, 2009

The next paradigm is inevitably coming. But it will surely be brought about by a risk-taker — not by practical "men of action." (Marcus)

It's not clear to me that people fall clearly into one category or the other. Planck and Schrodinger, for example, both had long histories of "establishment" work before they found themselves with the opportunity to do something extraordinary.

49. **Erik Anderson**
October 1, 2009

I am enjoying the ongoing momentum of this discussion (no big deal that a snippet of what I wrote keeps being attributed to Marcus).

To A.J.,

Ironically, the importance of Planck' 1900 discovery was not initially recognized by Planck himself. He presented it as a curious phenomenon — not as an epoch-defining discovery. Planck's demeanor was thoroughly unassuming. He did not even believe in the atomic hypothesis until very late in his life.

Who are the risk takers? The risk takers are those theorists who, in the course of their research, make definite predictions which can be incontrovertibly arbitrated by future experiment. The risk is, of course, that experiment can rule against them.

Those who are not risk takers are those theorists who immunize themselves from any such liability. Their theories are sprinkled with enough free parameters to weasel out of any experimental result. These folks are not in the business of sticking their necks out; they are in the business of covering their asses.

50. **Peter Woit**
October 1, 2009

Erik and others,

Please, this discussion has gotten too far from any significant connection to the topic of this posting, the Perimeter Institute.

Investigating the Nature of Matter, Energy, Space and Time

September 29, 2009
Categories: Uncategorized

On Thursday on Capitol Hill, the House Subcommittee on Energy and Environment of the Committee on Science and Technology will hold a hearing with the title [Investigating the Nature of Matter, Energy, Space and Time](). Witnesses will be Hugh Montgomery of the Jefferson Lab, Lisa Randall of Harvard, Pier Oddone of Fermilab and Dennis Kovar from DOE. A webcast of the hearing should be available.

To brief the subcommittee, someone put together the hearing charter available [here](). It does a reasonably good job of explaining at a popular level what particle and nuclear physicists are working on and what problems they are trying to solve. Unfortunately the part of the document on particle physics is marred by some stale string theory hype, with the subcommittee told that:

> Unification was Einstein's great, unrealized dream, and recent advances in a branch of physics known as string theory give hope of achieving it. Most versions of string theory require at least seven extra dimensions of space beyond the three we are used to. The most advanced particle accelerators may find evidence for extra dimensions, requiring a completely new model for thinking about the structure of space and time…
>
> Understanding the very early formation of the universe will require a breakthrough in physics, which string theory may provide.

Selling the US investment in machines like the Tevatron and the LHC as being about extra dimensions seems to me to be a mistake. Very few physicists believe it likely that this is what the LHC is going to find, and the failure to find promised extra dimensions at the LHC will not be helpful in a few years when the US particle physics community is trying to convince Congress to fund a next-generation accelerator.

The charter doesn't explain what the LHC is really good for and why physicists are so excited about it: finally the energy-scale of electroweak symmetry breaking is being reached, with the promise of finding out what sort of physics is behind this phenomenon and responsible for mass. There's no need for string theory hype to justify the interest and importance of this sort of very fundamental research, bringing in failed highly speculative ideas is likely to actually be counter-productive. The case for the current and planned US particle physics program is a very strong one, I hope the witnesses are able to make it clearly and forcefully to the subcommittee.

Update: The hearing is going on now, with a break for a vote. The webcast is [here](). The first question from Representative Vern Ehlers, a physicist, was for Lisa Randall, and he asked if there is any experimental proof or corroboration of string theory. Instead of answering the question with a straightforward "No", and explaining that string theory makes no predictions, Randall did what she could to obfuscate the issue. She answered by going on about how, while string theory was speculative, it has led to ideas testable at accessible energies: supersymmetry and large extra dimensions. I suspect her answer left Ehlers and others still confused about the issue he was asking about. Avoiding public acknowledgment of the failure of string theory unification seems to extend even to Congressional testimony….

Update: There's a press release [here]().

Update: The video webcast of the hearing is now available from the hearing web-page.

Comments

1. **Adam Helfer**
   September 29, 2009

   While (I agree) the charter is generally a good one, and really as good as one can expect for something like this, as long as we're caviling:

   The charter repeatedly identifies questions about "the nature of matter, energy, space and time" with particle physics. What happened to relativity?

   It's hard to see how particle physics tells us more about the nature of space and time than relativity (since particle physics requires relativity for its formulation); and while one can argue that somehow quantum-field-theoretic Hamiltonians tell us truly deep things about energy, it's not clear that these should be regarded as more important than understanding energy in general relativity….

   Of course this view in the charter is no very serious matter. It would have been nice to see something a bit more balanced, though — presumably the document was drawn up by staffers in consultation with physicists, who could have demonstrated a broader perspective.

2. **capitalistimperialistpig**
   September 29, 2009

   I worry about the chances for selling fundamental physics to Congress when a large fraction of it seems to be stuck somewhere in the dark ages. It's hard to pitch the quest for knowledge to those who are clinging to ignorance with both hands and teeth.

   The traditional gimmicks – national security and nation prestige – look a little shopworn by now, not to say slightly dishonest. The only notion that looks solid to me is the claim that the frontier of science is also the frontier of technology. The backwoods crazies might not understand that but their corporate sponsors might.

3. **Greg Sivco**
   September 30, 2009

   Interesting choice of witnesses. Lisa Randall's testimony may be key, as she is first, from Harvard, which is highly respected in the halls of Congress, and second, an attractive blond, which definitely interests Congressmen.

   Anyone know her current stand on String Theory? I'm sure she still wants Supersymmetry and the Higgs boson to be proven, but besides that she's always struck me as strangely yet diplomatically 50/50 on Strings (before it was fashionable to be so), accepting just enough of it to support hers and Sundrum's 5D Gravity brane theory. I got that impression from reading her book Warped Passages and her 56-min. Charlie Rose interview, which I must review as its been almost a year since I watched it. Here it is again, for reference:

   http://video.google.com/videoplay?docid=-45154219728824809&sourceid=searchfeed%20#

   Finally, I hope at least one of them mentions the (mild but significant) brain drain from America to Europe since the SSC's cancellation as well as the USA's obsession with Strings. Fingers crossed.

   Also, i hope at least

4. **Bee**
   September 30, 2009

   "In your experience, how important is it in obtaining funding that your project or research area is well covered in the media?"

   Very important/somewhat important: 23.5%

   Results of a survey conducted by UCSB survey center in April 2009 among active researchers in physics in North America. The final number of respondents amounted to 1816, which corresponds to response rate of 14.42%.

5. **Marcus**
   September 30, 2009

   That is a telling 23%. Makes one think. Is there an online source for that survey report? Or some online article that refers to the finding?

   The question sounds as if it could have two different interpretations.
   How important is media coverage to funding *of your field collectively as a whole?*

   versus

   How important is media coverage to obtaining funding *for your own individual project?*

   I wonder if there are tax-base (national or regional) differences in the role played by media in science funding.

   I don't feel like judging anybody on this score, approvingly or dis. To the extent the perception is real it places a burden of responsibility on the press. Relying on the honesty and integrity of the press does not work consistently in politics. One wonders…

   Is life better in Sweden?

6. **Gphillip**
   September 30, 2009

   I just watched a program on the American TV cable "Science" channel titled "Parallel Universe". It turned out to be a one hour propaganda film about how string theory has already solved all the questions of Physics. While I object to calling this mess a "theory", as it really seems to be more of a hypothesis, I'm really more concerned that with propaganda like this, another generation of great physics minds will be sucked down the black hole of the "theory" that explains anything, real or not. I've never seen a PR campaign like this in science. It's astounding.

   Lisa Randall is just being diplomatic and I understand that. Speaking ill of string theory in public is professional suicide in most circles. But to propagate this unproved hypothesis to the public and even to the halls of Congress as the only path to a theory of everything is to bind physics to a theory that may never lead to the advancements that physics promises.

   I feel like I'm living in the Dark Ages and anyone who claims that string theory isn't, and probably can't be proven (or disproven), must be burned at the stake as quickly as possible. In time, this will all pass and other ideas will be considered and tested. I just feel sad for all the young minds destined to be wasted chasing this Holy Grail.

7. **Peter Woit**
   September 30, 2009

   Gphillip,

   By now there are quite a few of these sci-fi shows hyping string theory in rotation on the various science TV channels. The one you mention is due to the BBC, and from 2002. My impression is that by now most string theorists find these to be an embarrassment, but not enough of one to do anything about trying to get them off the air. One of them may be a source for whoever put together tomorrow's hearing charter…

8. **sh**
   September 30, 2009

   Shouldn't they have used a different ordering of what to investigate at least?

   http://en.wikipedia.org/wiki/MEST_%28Scientology%29

9. **J. Reay**
   October 1, 2009

   Frankly, any argument that will precipitate funding from Congress for basic science is a welcome effort. Kudos to those who fight for basic research dollars!

10. **Bee**
    October 1, 2009

    Hi Marcus,

    No, life isn't better in Sweden, but at least it's life.

    Unfortunately, the survey results presently aren't available anywhere . I'm sitting on piles of data with the best intention to bring them into a useful format. So stay tuned, more details are to follow. Best,

    B.

11. **capitalistimperialistpig**
    October 2, 2009

    Perhaps the Congressman should have asked Randall to name one specific experiement that bears on the validity of string theory, and explain how it does.

12. **Shantanu**
    October 2, 2009

Peter or others, Is the video available? I tried to view the webcase, but could not.
Also Peter, what do you think of the fact (in the last year) that experiements with wrong results such as DAMA are getting more citations than most collider/accelerator phsyics experiments? Is there really such a dearth of data in experimental HEP.

Mathematics and Religion

October 1, 2009
Categories: Uncategorized

Unlike physics, mathematics has managed to remain immune from efforts to promote pseudo-scientific agendas, financed with the goal of mixing up science and religion. I don't see any reason to believe this is going to change, but I just noticed that the Templeton foundation is funding a program here in New York later this month on the topic of Mathematics and Religion.

The program will take place at the Philoctetes Center, which is run out of a townhouse on the Upper East Side and supports a variety of activities that you can read about here. The organization ran into serious trouble with its funding recently since its investments were managed by Bernard Madoff. A year before the scandal broke, Philoctetes sponsored a panel discussion (accessible here) on *The Future of the Stock Market*, which featured Madoff as a panelist. Because of these losses, the Center has had to look for funding elsewhere, and has found some from the Templeton Foundation.

One notable thing about the Mathematics and Religion panel is that it doesn't include much at all in the way of mathematicians. Of the six participants, one is Max Tegmark, a physicist prominently involved in Templeton-funded multiverse studies, but the only mathematician is Edward Nelson. Nelson is quite far from the mainstream of mathematics, with a religion-infused recent paper entitled *Warning signs of a possible collapse of contemporary mathematics*, available here. Unlike the case of multiverse pseudo-science, which has drawn support from leading figures in the physics community, this sort of point of view about mathematics has attracted zero interest among mathematicians.

The Mathematics and Religion panel isn't any threat to mathematics, and is part of a larger and much more worthy program about mathematics at Philoctetes funded by Templeon. In November there will be a panel discussion on Mathematics and Beauty that sounds interesting, I might even try and make it over there to see it (last year I did attend a talk at Philoctetes given by Barry Mazur). The Mathematics and Religion panel is associated with something more serious, a talk by Loren Graham on his book Naming Infinity. It's a book I read earlier this year, but don't think I ever got around to writing about here on the blog. I wasn't completely convinced by some of the claims it makes about the relation between religious practices and the work of certain Russian mathematicians. The story it tells about the religious sect of "Name Worshipers" and the history it recounts of one part of the Russian mathematical community are quite fascinating.

   "Certainly, if one needs to believe that beyond the appearances of the world there lies a permanent and transcendent reality, there is no better choice than mathematics. No other conception of reality has led to so much success, in practical mastery of the world. And it is the only religion, so far as I know, that no one has ever killed for."
   ~ Lee Smolin, The Life of the Cosmos

   Sorry, couldn't resist 🙂

   OMF,

   No.

4. **Chris W.**
   October 1, 2009

   From that essay of Edward Nelson:

   > The most impressive feature of Cantor's theory is that he showed that there are different sizes of infinity, by his famous diagonal argument. But Russell applied this argument to establish his paradox: the set of all sets that are not elements of themselves both is and is not an element of itself. Actually, Russell's paradox was in response to Frege's work, not Cantor's. Frege gave a clear and precise account of his work, making it possible for Russell to show it was wrong, whereas Cantor's work was in parts so vague and imprecise that, as Pauli said of another theory, it was not even wrong.

5. **Per**
   October 1, 2009

   The paper by Edward Nelson was really nice. I had never heard about it before, thanks for sharing it. It's nice with some sort of fresh trippy take on contemporary mathematics. God knows it's lacking in physics…

6. **inc.**
   October 1, 2009

   I had a brief interaction with E.N. some time ago; I certainly respected him on the basis of his papers. Hmm, unfortunate that he would find himself in such company.

   The title reminded me of Gödel's ontological proof.

8. **Aleksandar Mikovic**
   October 2, 2009

   Bee´s quote of Lee Smolin's apology of platonism was a pleasant surprise, because very few physicists are platonists. This is contrary to mathematicians, where a lot of them are platonists, which is understandable.

The reason why physicist are not platonist is the idea that everything can be explained from a finite set of elementary constituents (elementary particles, or strings, or something else) moving in space, subject to a finite set of laws of motion and structure. However, when analysing this framework, one has to decide whether the laws of motion are independent entities or they are simply random regularity patterns in the motion of the elementary constituents.

If one chooses the second option, this means that our world can disappear tomorrow and that the ultimate explanation for any phenomena is that it is a random fluctuation. On the other hand, the first option leads to platonism, i.e. there exists a separate realm from spacetime, where abstract ideas like mathematical structures and laws live. Furthemore, it is then natural to identify our physical world with a mathematical structure, as Max Tegmark has proposed, which explains Wigner's question of unreasonable effectivness of mathematics in physics.

Now, why still many physicist do not accept a platonic metaphysics and stick to the chaotic universe metaphysics? My guess is that in a platonic metaphysics the idea of God naturally appears, and many physicist are opposed to it because it is an unscientific idea. However, it is an irony that the scientific metaphysics, i.e. a materialistic metaphysics, leads to the conclusion that the ultimate explanation for anything is that it is a random event, which is contrary to the very spirit of science.

9. **mark a. thomas**
October 2, 2009

It should be noted (myth?) that Hippasus was strangled or drowned by the Pythagorean order for revealing to the world the irrational construction of the dodecahedron. To keep the nature of mathematics divine they then set their sights on the continuum rather than that of the discrete whole numbers. It seems ancient maths had connections to religions or mysteries.

10. **Benni**
October 2, 2009

It seems that Nelson does indeed want to publish real mathematical work. Yet what he wants to write seems not to be ready.

He has a better discussion of his program here. The content is the same, however this is aimed at mathematicians:

http://www.math.princeton.edu/~nelson/papers/hm.pdf

There, one can read that he wants to give a proof of something which he is still working on.

Maybe he goes to such conferences since he is somewhat struggling with his proof.

11. **Benni**
October 2, 2009

Nelson writes in

http://www.math.princeton.edu/~nelson/papers/hm.pdf :

The goal is to produce an explicit superexponentially long recursion and prove that it does not terminate, thereby disproving Church's Thesis from below, demonstrating that finitism is untenable,
and proving that Peano Arithmetic is inconsistent.

It seems that he has problems with this and then he goes to templeton conferences.

12. **Joao Leao**
October 2, 2009

(Aleksandar Mikovic says:
"Now, why still many physicist do not accept a platonic metaphysics and stick to the chaotic universe metaphysics? My guess is that in a platonic metaphysics the idea of God naturally appears, and many physicist are opposed to it because it is an unscientific idea. However, it is an irony that the scientific metaphysics, i.e. a materialistic metaphysics, leads to the conclusion that the ultimate explanation for anything is that it is a random event, which is contrary to the very spirit of science.")

I do take issue with the notion that platonism in particular or idealism in general imply theism. Plato was quite careful in separating god from (the) good and should not be punished by what the neoplatonists and the doctors of the church made of his thought. (The same may be said of the frequent but abusive "equation" of materialism with atheism). That may explain why, even with a majority of platonists among mathematicians, Templeton has not been able to recruit any mathematicians to its campaign gatherings, as Peter noticed. God is NOT a mathematical idea!

13. **Benni**
October 2, 2009

By the way, I think that Nelson's claims in http://www.math.princeton.edu/~nelson/papers/hm.pdf

"The goal is to produce an explicit superexponentially long recursion and prove that it does not terminate, thereby disproving Church's Thesis from below, demonstrating that finitism is untenable,
and proving that Peano Arithmetic is inconsistent."

are quite ambitious. Since the link above does not contain that much fuzzy religious statements as Nelson's other paper, can someone report what is about those claims:
http://www.math.princeton.edu/~nelson/papers/hm.pdf

From what I see, he is indeed using only logic. Yet I'm only a physicist.

So: can some real mathematician report, if Nelson's program has any chance to succeed? Or are there errors in the above pdf?

I'm just curious. Benjamin

14. **Vidkun**
October 2, 2009

Now, Nelson is surely something of a philosopihcal extremist, but he is without any doubt a sound mathematician; he has many results throughout mathematics, logic and mathematical physics.

Also the "problem of induction" in the talk linked led him to develop his Predicative Arithmetic. I don't think many besides Nelson himself regard it as relevant to the foundations of mathematics, but his results were used when others (Sam Buss for example) began developing Bounded Arithmetic, which has strong connections to complexity theory and (variations of) the P=NP problem. Hence, the "zero interest among mathematicians" is rather unfounded (if mathematical logicians are to be included).

I like to view Nelson as a prime example of how philosophically untenable positions could lead to valuable results. (Compare how Einstein's and Heisenberg's dogmatic positivism gave us Relativty and Matrix Mechanics.)

15. **Mark Stuckey**
October 3, 2009

"If a 'religion' is defined to be a system of ideas that contains unprovable statements, then Gödel has taught us that, not only is mathematics a religion, it is the only religion that can prove itself to be one." J.D. Barrow in Between Inner Space and Outer Space, Oxford University Press, 1999, p 88.

16. **BigG**
October 3, 2009

Mark,

That is not a good definition of religion because there are many counter examples that are certainly not religion. If you accept this definition than philosophy and physics would be religions which is ridiculous. The point of a definition is to show somethings' defining characteristic; what makes it different from what is not it.

The definition of religion is a system that contains a doctrine of liberation; i.e. a soteriology.

17. **Mark Stuckey**
October 3, 2009

BigG,

I don't know about philosophy, but here is a quote about physics:

"Many scientists are deeply religious in one way or another, but all of them have a certain rather peculiar faith – they have a faith in the underlying simplicity of nature; a belief that nature is, after all, comprehensible and that one should strive to understand it as much as we can. Now this faith in simplicity, that there are simple rules – a few elementary particles, a few quantum rules to explain the structure of the world – is completely irrational and completely unjustifiable. It is therefore a religion." Sheldon Glashow in The Quantum Universe, co-produced by WETA-TV and The Smithsonian Institution, 1990.

18. **BigG**
October 3, 2009

Mark,

Does Sheldon Glashow of J.D. Barrow saying something make it true? I'm interested in following the idea to its conclusions. The original definition you posted said a "system of ideas that contains unprovable statements." By your logic its hard to find a system of thought that isn't a religion. Why? Because all systems of thought have some unjustifiable assumptions. Physics assumes the validity of the experimental method. Can physics use the experimental method to establish the experimental method? Can light illuminate itself? Can darkness obscure itself?

19. **Peter Woit**
October 3, 2009

Any more comments about religion will be deleted. The internet is full of other places those interested in this kind of thing can have this kind of discussion.

20. **Tony Smith**
October 4, 2009

Bee quoted Lee Smolin as saying that "… mathematics … is the only religion, so far as I [Lee Smolin] know, that no one has ever killed for …".

Whether or not math may have been involved in violent persecution of Pythagoreans, etc,
it seems clear that Nazi Germany did severely persecute what it defined as "Jewish mathematics". In his book "History of Mathematics: A Supplement" (Springer 2007) Craig Smorynski said:
"… the change of mathematical direction … would reach an extreme in the 1930s with the nazi distinction between
good German-Aryan anschauliche (intuitive) mathematics
and
the awful Jewish tendency toward abstraction and casuistry.
…
the proponents of this distinction had to dance some fancy steps in explaining how the abstract mathematics of David Hilbert … was not the bad abstraction of the Jews. …".

Tony Smith

21. **Maynard Handley**
October 4, 2009

"
The story it tells about the religious sect of "Name Worshipers" and the history it recounts of one part of the Russian mathematical community are quite fascinating.
"

Uhh, no. Perhaps the story could be fascinating, but the actual book Graham produced is, let's face it, a waste of time if you are interested in the mathematics. We learn that there are some bizarre orthodox christian practices, that some Russian mathematicians were strongly orthodox and interested in these practices, and that some of the mathematicians were gay.

What we NEVER learn, which would have made the whole exercise worthwhile, is exactly what these Russian mathematicians did that was so spectacular compared to western mathematicians. Sure, we are told over and over again that name worshipping led to mathematics that was too "daring" for French and German and US mathematicians, but we are never told WTF that mathematics was.

This ridiculous, to put it bluntly, c**k-teasing approach to writing history has put Graham on my list of authors to be permanently avoided. Don't waste my time for 150 pages and then fail to deliver the only damn thing that made me interested in your book in the first place!

(BTW do not be confused. Loren Graham is NOT Lauren Graham!)

22. **Elbadudedansky Brodudensky**
October 4, 2009

You can't corrupt math, although it's not because there aren't mathematicians who wouldn't corrupt it if it could be corrupted.
Numerous mathematicians become just as illogical and biased as the pack, once they stray from math.

What can be corrupted is the application of math, and many people confuse the application of math with math.

Because the most useful of math is tied into the real numbers, the foundation of which is standard set theory, standard logic, and the natural numbers, then how could any corruption of note not be logically tracked down? A corrupt construct would most likely be at a higher level than the real numbers, and anything at a lower level, what would be the purpose of that? Very few people have a beef with the way we count or with the law of the excluded middle; it might be better to say that very people would even want to have the awareness that they could be aware of such things.

Also, other than the general status of "mathematician," there's no glamor in math. It's like a foreign language with thousands of dialects, where those fluent in one dialect can't communicate in most of the other dialects.

People will sit for hours listening to talks about physics and astronomy, because it involves the physical world, and there's something to try and visualize. With math, there's no pleasure in hearing someone talk in a foreign language; it's no fun to have your eyes glaze over.

And most people barely tolerate useful math. Why would they tolerate useless math? Especially if it tweaked the useful math in a bad way.

But you don't have to corrupt math to corrupt math-based science. You just have to find a set of unproved assumptions and a mathematical model that will do what you want it to do. The logic behind the math will be solid. And in fact, given your unproved assumptions, why couldn't you get the desired conclusions? At most, you might merely need some additional unproved assumptions. With the right credentials, you'd be good to go.

23. **Elbadudedansky Brodudensky**
October 4, 2009

In the above, please feel free to replace "real numbers" with any other popular and useful algebraic structure.

Bourbaki Archives

October 2, 2009
Categories: Uncategorized

I'd recently been wondering whether the archives of the Bourbaki group would be put on-line, and today noticed that there's a project to do so, with results available here. One can read copies of "La Tribu", internal reports on the activities of the group, up through 1953. There are a wide variety of interesting mathematical documents, often consisting of attempts to write up one subject or another, efforts that sometimes made it into the published books, often not.

One subject that Bourbaki struggled with over the years was that of how to set out the foundations of differential geometry. My colleague Hervé Jacquet likes to tell about how Chevalley at one point made an effort to do so, with the peculiar starting point of defining things in terms of "cubes". I wasn't sure whether to believe him, but here it is. According to Borel, in 1957 Grothendieck presented the group with his own take on the question of manifolds:

> Grothendieck lost no time and presented to the next Congress, about three months later, two drafts:
>
> Chap. 0: Preliminaries to the book on manifolds. Categories of manifolds, 98 pages
>
> Chap. I: Differentiable manifolds, The differential formalism, 164 pages
>
> and warned that much more algebra would be needed, e.g., hyperalgebras. As was often the case with Grothendieck's papers, they were at points discouragingly general, but at others rich in ideas and insights. However, it was rather clear that if we followed that route, we would be bogged down with foundations for many years, with a very uncertain outcome.

I don't see these documents on the list, perhaps documents from the later years are still to appear.

The documents often start out with some unvarnished comments, here's an example, from Chevalley's report on a text about semi-simple Lie algebras:

> Au moment d'écrire ces observations, je me demande si ce ramassis des méthodes les plus éculées et les plus pisseuses, ces résultats les moins généraux possibles établis de la manière la plus incompréhensible possible, ne sont pas un canular intrabourbachique monté par le rédacteur. Même s'il en est ainsi, je me laisse prendre au canular et présente les observations suivantes.

Comments

   October 2, 2009

   éculées –down at the heels, shabby
   canular — hoax

2. **monolingual pleb**
   October 2, 2009

   Curiosity got the better of me so I googled "babelfish" and got the following translation of that french stuff:

   "At the time of writing these observations, I wonder whether this bunch of the most worn down methods and more the baby girls, these results the least general possible benches in the most incomprehensible possible way, is not a hoax intrabourbachic assembled by the writer. Even if it is thus, I let myself take with the hoax and presents the following observations."

   Perhaps our blog host can let us know how faithfully it represents the original french.

3. **Tom O'Bulls**
   October 2, 2009

   It's deeply interesting, and extremely telling, that Bourbaki couldn't handle the most important and profound branch of modern mathematics, namely differential geometry. They ought to inscribe this passage on Bourbaki's tombstone.

4. **Marcus**
   October 2, 2009

   Au moment d'écrire ces observations, je me demande si ce ramassis des méthodes les plus éculées et les plus pisseuses, ces résultats les moins généraux possibles établis de la manière la plus incompréhensible possible, ne sont pas un canular intrabourbachique monté par le rédacteur. Même s'il en est ainsi, je me laisse prendre au canular et présente les observations suivantes.

   As I write these observations, I ask myself if this grab-bag of outworn and infantile methods, these results with the least possible generality established in the most incomprehensible manner, isn't a Bourbaki in-house hoax perpetrated by the writer. But even if it is, I will let myself be taken in by the hoax and present the following observations.

   I think pisseuses refers to infants of the wet-diaper type—pissy ones—an earthy expression.

5. **Marcel**
   October 3, 2009

   Concerning the volume on differential deometry, here is a short extract from a 1990 French radio programme in which Laurent Schwartz and Jean-Pierre Serre shed some light on the matter (at least for those who understand French): http://www.fileden.com/files/2009/10/3/2591723/schwartz_serre.mp3

   Marcus's translation is perfect, including his interpretation of "pisseuses" (sic).

7. **J**

October 4, 2009

The definition in Chevalley's Bourbaki draft is in fact not contrived in any way: it simply specifies a (smooth) manifold as a space which is locally homeomorphic to an Euclidean space, and which carries a distinguished collection of "smooth" functions, in such a way that _locally_ the smooth functions match (via the local homeomorphisms) the infinitely differentiable functions on Euclidean space. Choosing (the interior of) a cube as the local model of a smooth manifold (as the "standard" piece of an Euclidean space) is certainly among the most natural choices.

Chevalley's definition is effectively the same as that of manifolds as (locally) ringed spaces which are locally isomorphic to Euclidean space with its sheaf of smooth functions, only leaving the machinery of sheaves (of rings) out. Among other things, this definition has the benefit of putting smooth manifolds on into the same framework as schemes, analytical spaces etc – usually define as ringed spaces locally isomorphic to a model (such as the spectrum of a commutative ring in the case of a scheme). It also provides a direct route to "synthetic" differential geometry: carrying out the basic constructions such as those of tangent spaces and connection "algebraically", in the same way they are normally done in algebraic geometry (EGA IV).

The above hints at some of the issues, not entirely straightforward, that Bourbaki was facing: how general (and generalizable) framework to choose? Minimum needed for a few future volumes (such as Lie groups) or a basis for a significant expansion of the book series into different types of geometries? In the end, they only published a "Fascicule des résultats", a quick fix for the former use.

It seems that this outcome was to a large etent due to some of the same difficulties Bourbaki faced in writing a book on algebraic topology (which they never finished): sheaves, and category theory in particular, were difficult to embed into the structure of the series at that stage – it would have needed a major overhaul of much of the earlier volumes. Some rather interesting results of this can be seen in Algèbre Ch. 4, where Symmetric tensor functor is mentioned in subsection headings in spite of functors never having been defined nor appearing in the actual text. And the chapter (10) on homological algebra is a curious example of categorical thinking without categories. And all this in spite of many of the key people behind category theory, sheaves etc. were also key members of Bourbaki.

8. **Peter Woit**
October 4, 2009

J,

I think the reason people don't do it Chevalley's way, specifying a cube in R^n (or any other figure in R^n) is that the intersection of two cubes is not a cube. Surely you can do it Chevalley's way, as well as lots of others, but there are good reasons that way of doing things is unpopular.

Looking at all the Bourbaki drafts of a differentiable manifolds book, I can't avoid the conclusion that the lesson is that one shouldn't let algebraists write books on differential geometry. Bourbaki was dominated by algebraists, and I think this was one one of its major weaknesses. It led them to miss out on lots of important areas of mathematics (including the connections of mathematics to physics via geometry).

Besides differential geometry, where they were pretty hopeless, they also never really did even algebraic geometry. This wasn't their fault though, since the foundations of that subject were in flux at the time.

9. **J**
October 5, 2009

Peter,

Rather too harsh criticism on Bourbaki, I would say.

First, whether one uses cubes or other shapes (or just open sets) as the local models for manifolds is not really crucial to Chevalley's approach – even starting with cubes can always saturate by finite intersections. The inconvenience is of the same order of magnitude that one meets in defining the metric topology using balls defined by the metric: the intersection of two balls is not not a ball either.

Instead, it is the definition of smooth manifolds (or other geometric creatures) in terms of (the sheaf of) distinguished functions on them that is important. While it is to certain extent a matter of taste whether to start from the sheaf of functions or from charts, both viewpoints are quite important. Their equivalence is of course rather trivial – it is more the viewpoint that matters. One should also note that the "usual" definition in terms of charts runs into a rather similar issue with intersections: intersection of (the domains) of two charts is not in general (a domain of) a chart – unless one uses a saturated atlas. Finally, as regards this particular topic in Bourbaki, it is fair to note that they eventually settled for the "traditional" definition, and explain the sheaf viewpoint a few pages later, in the published Fascicule des résultats".

Second, whether one likes his (differential) geometry with more or less algebra is also a matter of taste – I've sometimes had the feeling that differential geometry is too important to be left to people with background too much in analysis… But more seriously, expecting a completely universal coverage of all important topics in mathematics by Bourbaki would of course be unrealistic – even if they had continued at the same pace from late 60's onwards. It is moreover clear from a careful look at the Bourbaki archives that a great many later ababdoned topics were planned for inclusion, so seeing a deliberate exclusion from the project is not really correct. Rather, the project seems to have run out of steam by the early 70's, with many plans unrealised. Specifically for the connections between geometry and physics that you presumably have in mind, they were discovered at a time when Bourbaki had already become rather inactive. Not writing on gauge theory in the sense of Atiyah and Donaldson in the late 60's probably should not coutn against them…

As for algebraic geometry, it is fair to note that the biggest names of the field were Bourbaki members (Grothendieck, Serre, Weil,…). While the subject being in flux was a big reason for a book on algebraic topology getting stuck, I think there was an even clearer reason it made no sense for Bourbaki to write a book on algebraic geometry: Grothendieck's EGA (written in by him and the arch-Bourbakist Dieudonné) was already an essentially Bourbaki-style treatment of the subject. No need to duplicate that.

10. **ObsessiveMathsFreak**
October 5, 2009

Considering that Bourbaki never wrote a book on geometry, it's not too surprising that they never got around to differential geometry. For a group supposedly committed to a rigorous presentation of the foundations of mathematics, it was always a serious omission.

Bourbaki had difficulty with geometries of all kinds because they chose to work through the medium of set theory. While some may disagree with me, my own opinion is that set theory and geometry are fundamentally incompatible at the elementary level. That is to say, they are two independent and unconnected ways of doing mathematics and ne'er the twain shall meet. You really cannot talk about geometric elements like points, lines, planes and circles by describing them as sets (though many do!), and sets cannot be encompassed at all by geometrical descriptions. The fundamental disconnect seems to me to be that sets have no notion of order or position, which is what geometry is all about.

My main point is that there is no one road, royal or otherwise, to every place in mathematics. Bourbaki tried to carve a path to all topics using set theory and they unsurprisingly failed. I cannot be done. Mathematics cannot be reduced a linear axiomatic presentation and moreover we have known this since the days of Godel and before.

This isn't to say that Bourbaki's results have been a waste. The Bourbaki framework and style make it possible to rigorously discuss advanced concepts and structures in a way that simply wasn't available before.

On the other hand, Bourbaki has in some way made it *impossible* to talk about anything without smothering the discussion in formality. To whit; what is a manifold? Or a group? Or better yet, what is the determinant of a matrix?

The answers Bourbaki gives to these questions, while correct, leave something to be desired.

11. **Tony Smith**
October 5, 2009

It may be, as J said, that Bourbaki "… seems to have run out of steam by the early 70's, with many plans unrealised …",
but
from the late 70's onward some very geometrical works, such as the books "Manifolds All of Whose Geodesics Are Closed" (Springer 1978) and "Einstein Manifolds" (Springer 1987) were written by Arthur L. Besse whose wikipedia entry states:
"Arthur Besse is a pseudonym chosen by a group of French differential geometers, led by Marcel Berger, following the model of Nicolas Bourbaki. A number of monographs have appeared under the name.",
so
maybe you could say that the geometric view,
in the form of exposition of concrete examples without obscuration by formal abstraction,
has been carried out by a very close relative of Nicolas Bourbaki.

For example, the preface of the 1978 book describes such visualizable geometric structures as "… les espaces projectifs sur les nombres reels, sur les nombres complexes et sur les quaternions (ainsi que l'esoterique plan projectif des octaves de Cayley) …".

Individuals acknowledged to be related to Arthur L. Besse include:
Genevieve Averous, Pierre Berard, Lionel Berard Bergery, Marcel Berger, Jean-Pierre Bourguignon, Yves Colin de Verdiere, Andre Derdzinski, Annie Deschamps, Dennis M. DeTurck, Paul Gauduchon, Nigel J. Hitchin, Josette Houillot, Hermann Karcher, Jerry L. Kazdan, Norihito Koiso, Jacques Lafontaine, Rene Michel, Pierre Pansu, Albert Polombo, Pierrette Sentenac, John A. Thorpe, and Liane Valere.

October 5, 2009

OT, but no Nobel prize rumor-mongering this year? You're losing your touch, Peter!

13. **Peter Woit**
October 5, 2009

weichi,

I retired from the Nobel prize predictions business after this:

http://www.math.columbia.edu/~woit/wordpress/?p=84

My only prediction for this year is that it's not going to be in particle physics, since that was last year's field, and there hasn't been anything prizeworthy in particle physics for a while now.

14. **Successful Researcher**
October 5, 2009

It's not exactly about the Bourbakis but I just learned some very sad news about another great mathematician: Israel Gelfand is no longer with us.

15. **observer**
October 5, 2009

At 96 and after living a very long and fruitful life M.I. Gelfand (working to the very end) passed away. He has been and will be remembered as one of the few truly great mathematicians of the 20 century. Despite of being jewish, managed due to his mathematical ability to stay in Moscow university even in times of anti-semitism. His mathematical work is truly impressive. Rest in peace.

16. **Deane Yang**
October 5, 2009

I didn't read the definition of manifolds using cubes. I see some attempts at defending this by saying it is no worse than using anything else. I'm not sure I agree. But could someone try to articulate exactly why Bourbaki would think that using cubes was somehow *better* than using, say, arbitrary open sets of R^n?

17. **Christine Dantas**
October 6, 2009

The Nobel Prize in Physics 2009

Charles K. Kao – "for groundbreaking achievements concerning the transmission of light in fibers for optical communication" (1/2 Prize);

AND

Willard S. Boyle and George E. Smith – "for the invention of an imaging semiconductor circuit – the CCD sensor" (1/4 Prize each).

Congratulations!

18. **Peter Woit**
October 6, 2009

I seem to be 100% on my Nobel prize predictions. This one was for something I know absolutely nothing about.

I hope someone more able to do justice to him than me will write about Gelfand. He was one of the major figures in developing twentieth century representation theory.

19. **Successful Researcher**
October 6, 2009

For starters one can look here.

20. **Thomas R Love**
October 9, 2009

Bourbaki did write a volume on differential geometry:

Sorry it took so long for me to find it

Varietes differentielles et analytiques – Paragraphes 1-7 (Elements de…
by Nicolas Bourbaki

from

http://www.librarything.com/work/7952041

21. **Peter Woit**
October 9, 2009

Thomas,

Yes, there is a Bourbaki text on the subject, but it’s short and just what they call a “fascicule de resultats”, not a detailed treatment with full proofs of the sort they produced for other parts of mathematics.

Latest From the LHC

October 7, 2009
Categories: Experimental HEP News

Things have been going fairly well at the LHC, with no major problems encountered recently as the machine is being prepared for operation. The last two sectors (34 and 67) are almost cool (see more about this here). Not mentioned in the CERN Bulletin article is that there has been about a week and a half slippage with respect to the schedule of a month ago, with the current schedule having powering tests finishing in the last two sectors around November 20. Attempts to circulate beams and begin the beam commissioning process should begin shortly after that.

CERN has also recently decided how to handle the media campaign for this second attempt to start up the machine. Unlike last year, there will be no media event associated with the first circulation of beams, just press releases issued at that time, at the time of first collisions at 450 GeV, and at the time the beam energy is raised to a world record (above that of the Tevatron, 1 TeV). There will be a media event planned for first collisions at 3.5 TeV/beam, but the date for this will only be planned about 2 weeks before it happens, and confirmed a day or two before the event. It's possible that this will happen later in December, just before the holiday shutdown, but maybe it's more likely for January. CERN has a web-site set up for the media on this topic, see here, where all they say "The first high energy collisions will most likely occur at a date after mid-December 2009."

In other LHC news, there has been an ongoing campaign to simulate the bad interconnections that are still known to be there in the machine, and these simulations have led to much more confidence that the potential dangers in the case of a quench are understood. The simulations show that operation at 3.5 TeV/beam should be safe, but going up to 5 TeV/beam without fixing the interconnections (which requires warming up the sectors involved) still seems risky.

Comments

1. **P**
   October 7, 2009

   Hi Peter,

   When they say 3.5 TeV / beam, does that mean the energy for each beam or is the collision energy (i.e, 2*3.5 TeV) ?

2. **Peter Woit**
   October 7, 2009

   P.,

   They plan to run at 3.5 TeV/beam, for a total collision of energy of 7 TeV. This is 3.5 times the Tevatron energy (1 TeV/beam), half the LHC design energy (7 TeV/beam).

3. **Steve Myers**
   October 8, 2009

   I caught part of a History Channel piece on LHC. They did show the soldering technique (quickly, though). Looks like pressurized hot box. Might be worthwhile to see the whole show.

4. **zanzibar**
   October 9, 2009

   Here's the lastest news from CERN:

   Headline: "Swiss atom lab: Physicist held on terror links"

   http://www.msnbc.msn.com/id/33241768/ns/world_news-terrorism

   (Nothing but the facts ma'am).

5. **zanzibar**
   October 9, 2009

   And from the BBC

   Headline: "'Al-Qaeda-link' Cern worker held"

   http://news.bbc.co.uk/2/hi/europe/8299668.stm

   Apparently, the suspect is a 32-year old non-CERN collaborator on LHCb.

   He and his brother were arrested in south-east town of Vienne (100 km outside of Geneva).

   CERN is cooperating with French authorities in the investigation.

6. **BDO Adams**
   October 13, 2009

   I'm sadden they haven't fixed the interconnections yet. If there going to have to reheat and recool each section before they can get to 5 GeV. The LHC isn't going to get full power in 2010 at all. Is it? Still there is be plenty of room for new particles from 1 to 7 TeV.

7. **Peter Woit**
   October 13, 2009

   The LHC definitely won't get to design energy (7 TeV/beam) in 2010, they may or may not get to 5 TeV/beam. In any case, even the starting 3.5 Tev/beam is 3.5 times the Tevatron energy, so a new energy range will be begin to get explored. In any case, my guess is that much of 2010 will be taken up with understanding the behavior of the machine and of the detectors, getting both working reliably.

8. **Rob**
October 14, 2009

BDO,

Unfortunately it's not that simple. When you consider the production of new particles at a collider you need to consider the collision as two incoming partons (quarks & gluons), not two incoming protons. Even though the Tevatron has a center of mass energy of roughly 2 TeV, it can only produce particles of roughly a few hundred GeV. This is because it is extremely unlikely for a parton to have a large fraction of the total energy of the proton.

If you take into account the fact that the tevatron has recorded roughly 100 times more data than the LHC will be able to record the first year you'll quickly come to the conclusion that nothing new can be discovered the first year. For example: The tevatron has a greater chance of creating a 500 GeV resonance in 5 inv fb than the LHC does (at 7 TeV) in 50 inv pb.

Unfortunately it's going to be a few years before the really interesting results start coming in.

Sounds Familiar

October 8, 2009
Categories: Uncategorized

From a recent blog posting by economist Brad DeLong, entitled The State of Economics in the 2000s Analogized…:

> But I think there also has to be an explanation in terms of the sociology of academic disciplines. And in that light, it seems to me that if I were a journalist, I'd consider writing a piece comparing freshwater economics to the other major recent case in which an academic discipline went completely off the rails, namely English departments' swing into postmodernism in the '80s and early '90s. Offhand, there seem to be some real similarities, e.g.:
>
> 1. In both cases, the people involved maintained, credibly, that you couldn't really assess the work in question without putting a lot of effort into understanding it.
> 2. In both cases, that required mastering difficult stuff. (In econ, all the math and models; in pomo lit stuff, mastering the literally incomprehensible language in which a lot of that stuff was written.)
> 3. In both cases, that deterred a lot of people on the outside who were generally puzzled and skeptical, but didn't want to spend years getting into a position in which they could credibly say: yes, this is, in fact, nuts.
> 4. So in both cases practitioners were largely insulated from criticism they had to take seriously.
>
> Relatedly, in both cases it took shocks from the outside to expose the problems in this (in the case of English, things like the Sokal hoax; in the case of econ, the near-collapse of the global economy.)
>
> Both cases involved a lot of arrogance, and a generally dismissive attitude towards other approaches. Since, in both cases, practitioners were able to seize significant amounts of control over a discipline before their approach crashed and burned, this did real damage to the disciplines in question (leading to, e.g., large chunks of previous disciplinary history being forgotten.)

In the last sentence DeLong identifies clearly what is most sad and disturbing about this kind of story.

Update: As a commenter points out, the text quoted is from DeLong's blog, but is not his own words, he's quoting someone else.

Comments

1. **Marcus**
   October 8, 2009

   That quote from Brad DeLong is beautifully lucid. Joe Polchinski could have it tattooed on his bottom, for string aspirants to read.

2. **hackenkaus**
   October 8, 2009

   Oh great, now that people are finally making the connection between freshwater economic theory and string theory, it can't help but draw Lubos into the debate, which will of course be very productive.

3. **spammophobia**
   October 8, 2009

   The effects of the global crisis on economic thinking and modeling are still to be seen, but what was the net effect of the Sokal affaire on postmodern literature? I guess nothing much has changed actually, but a more, and better, informed opinion would be interesting.

4. **Chris W.**
   October 8, 2009

   It should be pointed out that the text was *quoted* by Brad DeLong, from an email sent to him by one 'chunkyreesewitherspoonlookalike@gmail.com'. His post makes this clear.

5. **Carl Futia**
   October 9, 2009

   I'd be careful about accepting DeLong's (second hand) views as gospel.

   To suggest that economists, especially macro-economists, have taken a collective wrong-turn sometime during the past 30 years is silly.

   As a group, economists are just as smart as physicists. They are just as dedicated to testing their theories against evidence – even though this is much harder to do in economics because controlled experiments are next to impossible to conduct.

   DeLong would have you believe that the current economic crisis proves that economics as currently practiced is bunkum. Does it make sense to imagine that DeLong knows the truth and that everyone who disagrees with him is an idiot?

   Why should economists be able to prevent economic crises? Do they have magical powers? Can they give marching orders to the US government and to you and me?

   The physics of hurricanes is reasonably well understood. Can physicists prevent hurricanes?

6. **Chuckles**
   October 9, 2009

   (…in the case of English, things like the Sokal hoax; in the case of econ, the near-collapse of the global economy..)

   And in the case of physics, what exactly?
   The disapperance of Madagascar?
   I am not a strings fan, but to compare the nonsense that is pomo with the voodoo that is much of macroecon to strings is absurd. At least string theorists arent going around telling us how to think, trying to change society b causing us to experience joussiance (whatever the hell that is) or giving so called economic advice to governments

around the world that ends up damning the lives of millions.

7. **Bob Levine**
October 9, 2009

And I'd be VERY careful of accepting Carl Futia's views, firsthand or not, as gospel. I think I'm a bit more persuaded by the arguments of Paul Krugman—who does know a thing or two about Nobel Prize level economics—given at

http://www.nytimes.com/2009/09/06/magazine/06Economic-t.html?_r=1&pagewanted=all

that indeed, macroecons of the freshwater persuasion got it spectacularly wrong during the past 30 years. Krugman gives specific instances where Chicago-school economists ignored evidence, actual occurences in the real world, to a degree that even the most devoted string theorist would be unlikely to indulge in if contraindications of comparable strength were to emerge from the LHC.

One of Krugman's highly relevant points is that many economists were attached to extremely unrealistic models of economic behavior because the simplifying assumptions associated with 'perfect market' models of the economy allowed them to create wonderfully ramified mathematical models that were too beautiful to be false. Sound familiar?

8. **Armozel**
October 9, 2009

Well I'm glad that someone else is starting to chime in a fundamental crisis that has existed probably since Marshall (and Walras). The attempt to model human behavior in the form of catallactics (interpersonal exchange) by assuming static equilibrium and other physics concepts into the attempt has made more errors than it has solved.

Lets take the idea of the price system as an example. Most theories revolving it simply assume prices exist with *no* concrete explanation (I say most, because at least the Austrians have taken a stab at it, going far back as Carl Menger's own work on the issue), but the theories some how make many conclusions about the nature of how prices move, how capital is influenced (and vice versa), and so on. How can any of these theories survive if they can't start with the basics (how the price itself gets started? how money started and so on?).

Then there's the problem of the implied separation of micro and macro sphere phenomena. Not even in biology (in particular, evolutionary biology) is there such a division, but economists get away with it with little or no criticism. And any criticism that's leveled on this issue is either ignored or attacked in a derisive manner. It's issues like these that makes economics less of a science and more of political ideology meets perennial RTS game sort of situation (where those with the most "street cred" and the loudest voice gets to set the tone of the discourse, and the rest get drowned out like the Austrians and even some Post-Keynesians).

9. **srp**
October 10, 2009

Anyone who accepts the critiques of Krugman and DeLong at face value is making a mistake. The freshwater models certainly have many limitations, but it's not as though the alternative neo-Keynesian models predicted the current crisis any better or explain it any better after the fact. Krugman isn't much of a macro expert in the first place and, for example, was actually cheerleading for the creation of a housing bubble a few years ago.

The truth is that the Keynesian and freshwater types have converged a lot in the last couple of decades in the formal properties of their models. None of these models does a very good job of dealing with financial shocks.

10. **Bob Levine**
October 10, 2009

@srp:

"The freshwater models certainly have many limitations, but it's not as though the alternative neo-Keynesian models predicted the current crisis any better or explain it any better after the fact…
The truth is that the Keynesian and freshwater types have converged a lot in the last couple of decades in the formal properties of their models. None of these models does a very good job of dealing with financial shocks."

I'm not sure that predictive success is really at issue (and I don't think Krugman is really arguing that Keynsian economics predicts financial shock better than any other kind of economics). I think the issue is rather that the freshwater world-view assumes that the largely unregulated market is going to work, that any problems the rest of us face are simply normal corrections, and so on. The insulation of this best-of-all-possible-worlds picture of reality—the kinds of denial that Krugman documents—from events in the actual world, the picture of the Infallible Market that it promotes, is really the problem. And it's just that extreme insulation for empirical challenge that makes de Long's and Krugman's observations relevant to the issue of string theory's overall stance.

11. **Jack Lothian**
October 15, 2009

As someone who has studied and worked in both Physics and Economics, I do believe that economics has gone off the rails. First, it is a pseudo-science – there are no provable theories and no repeatable experiments. Second, most of the basic assumptions (especially at the micro-level) are at best approximations and these assumptions clearly break down at times. It is obvious that people, even in large groups, are not rational & that irrational feed-back loops exists that swamp classical economic optimality cobstraints.

Up until recently, most economists, especially macro-economists, understood these point but starting somewhere around Friedman, economics found religion and this polarized and distorted the field. Capitalism and free-markets are the magic economic hand of god. Today the talk about competition, deregulation, efficient markets & the "magic hand" has become a dogma that is not to be questioned and it need not bother explaining difficult events such as the various "economic bubbles" that keep happening. After all, these events are a result of man's imperfections & we just need to try harder to be pure and everything will turn out perfect.

As an aside, the physicists and mathematicians who recently moved into the field are sophisticated modelers, use to modeling large multi-body problems of various types. In truth, their methods and temporary success say nothing about the underlying economic theories and they brought no real science to economics.

Short News Items

October 9, 2009
Categories: Uncategorized

Mathematician Jim Simons is retiring from the job of running the hedge fund Renaissance Technologies. Construction of the building for the Simons Center for Geometry and Physics is proceeding, with opening scheduled for next fall.

An Algerian physicist associated with the LHCb experiment at CERN has been arrested on charges of having associations with al-Qaeda. The media freak out and CERN issues a statement.

I. M. Gelfand died on Monday at the age of 96. For more about him, see here, here and here.

The fourth and latest installment of Oswaldo Zapata's essay on the history of superstring theory is here.

In Geometric Langlands news, Dennis Gaitsgory is running a seminar at Harvard this fall, with notes and other materials on-line here.

Emanuel Kowalski points out that, morally, Princeton's Peter Sarnak has a blog.

Update: One more.

Comments

1. **Yatima**
   October 9, 2009

   Ah, terrorism!

   So said physicist is "under suspicion of links to terrorist organizations". This could mean he once phoned a guy who has phoned a guy living next door to Bin Laden's driver. On the other hand, the press release does not even mention persons of Middle Eastern origin at all.

   Could be it's just a weird dadaist project to push Dan Brown's latest book.

2. **zanzibar**
   October 9, 2009

   Peter,

   What's your source for saying the arrestee is Algerian? According to all the sources I've seen he's Algerian-born, but could have French citizenship. He probably holds dual citizenship.

   The AP release states he is a French citizen.

3. **Peter Woit**
   October 9, 2009

   zanzibar,

   I think you've probably looked at more sources about this than I have. By "Algerian" I just meant "from Algeria", not his citizenship.

4. **anon.**
   October 10, 2009

   "I'd suggest shutting up and letting him initiate the conversation. He probably won't do this the first night or the second night, but after five nights of silence, I bet he says something. If he doesn't do it, then he doesn't want to talk with you during dinner."

   Thanks for the "update" link. Pity there is no mathematical proof to back up the advice from mathematicians.

Witten on Analytic Continuation of Chern-Simons Theory

October 10, 2009
Categories: Uncategorized

I was down in Princeton last Thursday, and attended a wonderful talk by Witten, which I'll try and explain a little bit about here. Presumably within a rather short time he'll have a paper out on the arXiv giving full details.

The talk concerned Chern-Simons theory, the remarkable 3d QFT that was largely responsible for Witten's Fields medal. Given an SU(2) connection A on a bundle over a 3-manifold M, one can define its Chern-Simons number CS(A). This number is invariant under the identity component of the group of gauge transformations $\mathcal G$, and jumps by 2π times an integer under topologically non-trivial gauge transformations. The QFT is given by taking CS(A) as the action. The path integral

$$Z(M,k)=\int_{\mathcal A/\mathcal G} dA e^{ikCS(A)}$$

is well-defined for k integral and gives an interesting topological invariant of the 3-manifold M. One can also take a knot K in M, choose an irreducible representation R of SU(2) of spin n/2, and then define a knot invariant by

$$Z(M,K,k,n)=\int_{\mathcal A/\mathcal G} dA e^{ikCS(A)}hol_R(K)$$

where $hol_R(K)$ is the trace of the holonomy in the representation R, around the knot K (this is the Wilson loop).

To simplify matters, consider the special case $Z(K,k,n)=Z(S^3,K,k,n)$, which can be used to study knots in $\mathbf R^3$.

These knot invariants can be evaluated for large k by stationary phase approximation (perturbation theory), and for arbitrary k by reformulating the QFT in a Hamiltonian formalism, and using loop group representation theory and the Verlinde (fusion) algebra.

One thing that has always bothered me about this story is that it has never been clear to me whether such a path integral makes sense at all non-perturbatively. At one point I spent a lot of time thinking about how you would do such a calculation in lattice gauge theory. There, one can imagine various (computationally impractical) ways of defining the action, but integrating a phase over an infinite dimensional space always looked problematic: without some other sort of structure, it was hard to see how one could get a well-defined answer in the limit of zero-lattice spacing. In simpler models with similar structure (e.g. loops on a symplectic manifold), similar problems appear, and are resolved by introducing additional terms in the action.

What Witten proposed in his talk was a method for consistently defining such path integrals by analytic continuation. The idea is to complexify, working with SL(2,**C**) connections and a holomorphic Chern-Simons functional, then exploit the freedom to choose a different contour to integrate over than the contour of SU(2) connections. By choosing a contour that is not invariant under topologically non-trivial gauge transformations, and only modding out by the topologically trivial ones, Witten also managed to define the theory for non-integral k, making contact with a lot of mathematical work on these knot invariants, which treats them a Laurent polynomials in the square root of

$$q=e^{2\pi i/(k+2)}$$

The main new idea that Witten was using was that the contributions of different critical points p (including complex ones), could be calculated by choosing appropriate contours $\mathcal C_p$ using Morse theory for the Chern-Simons functional. This sort of Morse theory involving holomorphic Morse functions gets used in mathematics in Picard-Lefshetz theory. The contour is given by the downward flow from the critical point, and the flow equation turns out to be a variant of the self-duality equation that Witten had previously encountered in his work with Kapustin on geometric Langlands. One tricky aspect of all this is that the contours one needs to integrate over are sums of the $\mathcal C_p$ with integral coefficients and these coefficients jump at "Stokes curves" as one varies the parameter in one's integral (in this case, x=k/n, k and n are large). In his talk, Witten showed the answer that he gets for the case of the figure-eight knot.

Mathematicians and mathematical physicists have done quite a bit of work on SL(2,**C**) Chern-Simons, and studying the properties of knot-invariants as analytic functions. I don't know whether Witten's new technique solves any of the mathematical problems that have come up there. He mentioned the relation to 3d gravity, where the relationship between Chern-Simons theory and gravity in the Lorentzian and Euclidean signature cases evidently still remains somewhat mysterious. Perhaps his analytic continuation method may provide some new insight there. It also may apply to a much wider range of QFTs where there are imaginary terms in the action, making the path integral problematic. I'd be very curious to understand how this works out in some simpler models, such as the loop space ones. In any case, it appears to be a quite beautiful new idea about how to define certain QFTs via the path integral.

Update: Witten's slides for the talk are available here, video here. For slides from other talks at the workshop the talk was part of, see here.

Comments

1. **Bruce Bartlett**
   October 11, 2009

   Sounds great. Looking forward to when the paper comes out.

2. **Lefschetz Thimble**
   October 12, 2009

   I don't see the magic words to convince everyone you know the mathematics.

3. **Peter Woit**
   October 12, 2009

   Thanks L.T. for giving us the magic words.

   (the commenter must have attended the talk, during which Witten joked that if you want to show people that you're expert in this subject, you refer to one of these integration cycles as a "Lefschetz Thimble". I considered doing this in the posting, but decided against it, since not only am I not an expert on this, but it's one part of Morse theory I've been completely ignorant about…)

4. **Daniel Doro Ferrante**
   October 14, 2009

   Hi Peter,

For those who are interested, the talk is already online (i watched it yesterday),

• Analytic Continuation of CS Theories (aka, *Lefschetz Thimble* 😉).

It’s a very stimulating and sophisticated lecture, definitely worth watching.

Incidentally, it reminds me of some works that go in this “general direction”, namely: arXiv:hep-th/9612079 and arXiv:0710.1256 [hep-th].

5. **Peter Woit**
   October 14, 2009

   Thanks Daniel,

   I also see that a pdf of the slides is available, will add links to the posting.

In Search of the Multiverse

October 12, 2009
Categories: Multiverse Mania

The ongoing pseudo-scientific multiverse mania continues, with the recent publication in the UK of a new book by John Gribbin promoting this to the public: In Search of the Multiverse.

Gribbin expounds at length the usual string theory anthropic landscape/multiverse ideology, carefully avoiding introducing any mention of the fact that there might be quite a few scientists skeptical about it. On the crucial question of testability he invokes Raphael Bousso, who:

> hopes, and expects, that there will be ways to extract such broad rules of the behaviour of matter at what are low energies compared to the Big Bang, but high by the standards of everyday life, from string theory.

There's no indication given about what these broad rules implied by string theory might be, just a hint that whatever they are, we're not going to be able to test them anytime soon:

> even the the technology of the Large Hadron Collider may not be up to the task of testing such predictions.

Like many multiverse fans, Gribbin wants to mix together the many worlds interpretation of QM and the string theory anthropic multiverse in cosmology, attributing this insight to Susskind, and ending the next to last chapter of his book with:

> This pulls together everything discussed in this book so far in such a pleasing way that it is tempting to end it here. The Cosmic Landscape of string theory is just the many worlds theory of David Deutsch writ large, and with inflation included within itself.

Unfortunately he doesn't end the book there, but adds a final chapter promoting his own interpretation of the significance of the multiverse. His idea is that we are the product of a baby universe created by some race of superior beings:

> The intelligence required to do the job may be superior to ours, but it is a finite intelligence reasonably similar to our own, not an infinite and incomprehensible God. The most likely reason for such an intelligence to make universes is the same as the reason why people do things like climbing mountains or studying the nature of subatomic particles using accelerators like the LHC – because they can. A civilization that has the technology to make baby universes might find the temptation irresistible, while at the higher levels of universe design, if the superior intelligences are anything at all like us there would be an overwhelming temptation to improve upon the design of their own universes.
>
> This provides the best resolution yet to the puzzle Albert Einstein used to raise, that 'the most incomprehensible thing about the Universe is that it is comprehensible.' The Universe is comprehensible to the human mind because it was designed, at least to some extent, by intelligent beings with minds similar to our own. Fred Hoyle put it slightly differently. 'The Universe,' he used to say, 'is a put-up job.' I believe that he was right. But in order for that 'put-up job' to be understood, we need all the elements of this book.

Personally, I think there's an air-tight argument against this: any race of superior beings that produced a universe in which science descended into this level of nonsense would immediately wipe out their creation and start over. Since we're still here, there can't be such a race operating out there.

Gribbin also has a Sci-Fi novel entitled Timeswitch coming out soon.

For two reviews of the book, see here and here.

In other multiverse news, FQXI has a story here promoting Andrei Linde, Renata Kallosh and their work on the string theory multiverse. Linde and a collaborator have a new paper How many universes are in the multiverse? on hep-th (by the way, why are these things not in qr-qc, since they're "quantum cosmology" if anything is?). They come up with a number of 10 to the 10 to the 375 for the number of universes, and seem to argue that one needs to analyze all these to come up with predictions:

> But when we study quantum cosmology, evaluate the total number of universes and eventually apply these results to anthropic considerations, one may need to take into account. Potentially, it may become very important that when we analyze the probability of existence of a universe of a given type, we should be talking about a consistent pair: the universe and an observer who makes the rest of the universe "alive" and the wave function of the rest of universe time-dependent.

Comments

   October 12, 2009

   That's rather sad. John Gribbin is an author whose many books I grew up reading. I don't think I will grow up with this one.

2. **roland**
   October 12, 2009

   "The Universe is comprehensible to the human mind because it was designed, at least to some extent, by intelligent beings with minds similar to our own."

   I guess following the line of universe builders leads to a final source(?). The highest beings there should live in a universe that is uncomprehensible to them. How did their human- like minds develop there? How can they have technology if they can't comprehend their environment. That whole line of reasoning is just absurd.

3. **neo**
   October 12, 2009

   Absolutely right, Roland. Like every "intelligent design theory", it seeks to explain by invoking the inexplicable.

4. **Tim vB**
   October 12, 2009

   You could of course have an infinite hierachy of creators, if each level acts twice as fast as the level below (the higher the more advanced), you could still have our baby universe at the bottom created in finite time, right? No need of some highest entity.
   In that case we should hasten to create our own baby universes, or else we would have to live with the fact that we are the most stupid human like creates of infinite

universes.

5. **Chris Oakley**
October 13, 2009

> … any race of superior beings that produced a universe in which science descended into this level of nonsense would immediately wipe out their creation and start over.

This may be about to happen. Hopefully they will replace it with a universe with no Teletubbies.

6. **Stephen**
October 13, 2009

This argument:
"'the most incomprehensible thing about the Universe is that it is comprehensible.' The Universe is comprehensible to the human mind because it was designed, at least to some extent, by intelligent beings with minds similar to our own."

is actually exactly the same argument invoked by theologians: The Universe is comprehensible to the human mind because it was designed, at least to some extent, by intelligent beings with minds similar to our own=God. The reason being that he is the creator and he has created us similar to himself, we are his image (or even more: he is our father, according to christian theology).

7. **Stephen**
October 13, 2009

and by the way:

the reason why people do things like climbing mountains or studying the nature of subatomic particles using accelerators like the LHC – is not just because they can: but because it is beautiful (and, who knows, perhaps useful).

8. **Oxonian**
October 13, 2009

I am an atheist because I am unpersuaded by the arguments and evidence for theism, not because theism "sounds silly". It is arguments and evidence that I would like to see offered against Gribbins's hypotheses, however "silly" they may sound. Yet as far as I can see, all we are given in that respect is an invocation of falsifiability, which is besides the point since there are observations that could affect the probability that those hypotheses are true or false. So, Peter, could I kindly ask you to articulate, at least roughly, the reasons why you reject Gribbins's ideas? This may actually persuade me and others that these ideas are indeed wrong, moving the discussion forward.

9. **Peter Woit**
October 13, 2009

Oxonian,

The problem with Gribbin's ideas is that they are pseudo-science, not science. They don't actually have anything substantive to say about observations. Sure, it may be true that our universe may have been constructed by a higher intelligence, but this is an hypothesis that can be tested in any legitimate scientific way.

10. **Oxonian**
October 13, 2009

Peter,

Thanks for the response. It is not clear to me why such a hypothesis could not, in principle, be tested in a legitimate scientific way. I agree with Richard Dawkins that the hypothesis that there is a god should be treated like a scientific hypothesis; and I agree with Victor Stenger that this hypothesis is disconfirmed by the available evidence. I don't see why a hypothesis such as Gribbin's (sorry for the misspelling above) should not be treated similarly.

Just out of curiosity, do you think the many worlds interpretation of quantum mechanics is also pseudo-scientific? If so, what do you make of claims by Max Tegmark and others that this interpretation is actually scientifically testable? (If you have written about this in the past, feel free to direct me to the relevant writings.)

11. **Peter Woit**
October 13, 2009

Oxonian,

There is no trivial reason why you can't get predictions out of string theory multiverse models, you need to understand what they are and what their problems are. The bottom line though is that, despite a lot of work, proponents of this have come up with nothing. There is nothing in the Gribbin book in terms of predictions except the assurance from Bousso that he expects his work to be successful and to find something.

I haven't seen Tegmark's claim that many-worlds is testable, so don't know what that refers to. To the extent that many-worlds precisely agrees with other QM interpretations, not postulating completely different physics we mysteriously can't quite test, I don't think it's pseudo-science. But if so, depending on one's taste, one might not find it very interesting…

12. **Rakavolver**
October 13, 2009

"Personally, I think there's an air-tight argument against this: any race of superior beings that produced a universe in which science descended into this level of nonsense would immediately wipe out their creation and start over. Since we're still here, there can't be such a race operating out there."

Superior doesn't mean "good," there is no correlation. They may be the types with horns, not halos, or supra-being equivalents of non-serious high school sophmores in Chemistry lab playing with bunsen burners.

13. **TomInCalif**
October 13, 2009

It's "Turtles all the way down…"

14. **Arrow**
October 14, 2009

Oxonian: "I am an atheist because I am unpersuaded by the arguments and evidence for theism, not because theism "sounds silly". It is arguments and evidence that I would like to see offered against Gribbins's hypotheses, however "silly" they may sound."

Ockham's razor.

15. **Aristarchus**
October 14, 2009

I always thought that God was a grad student from another universe who made ours for his thesis project. We're now sitting on some immense beaker on some dusty shelf in another reality, as our Creator goes in search of a postdoc and a future wife.

I have no proof of this, but these days who needs to?

16. **Charles Hardin**
October 14, 2009

I'm always amazed at the number of people willing to make sweeping statements about a book without actually reading it! I have read it, and it makes a lot of sense. Gribbin isn't so stupid that he hasn't thought of all these points, and discussed them! And as he says, if there is only one Universe, where do quantum computers do their calculations?

17. **Rakavolver**
October 14, 2009

Quantum computers, being quantum computers in our universe, make their computations in our Universe. Was that so hard?

I believe you are referring to Shor's Algorithm, which is rock-hard Mathematics, and Deutsch's interpretation of same, which is speculation.

Would you care to elaborate? Because all of this refers to possible FUTURE Quantum computers far more sophisticated than the ones we have now, and can theoretically can achieve, but have not. Hello, Quantum decoherence?

Gribbin not stupid by any means, but he has the right and the privilege to be wrong, just like everyone else, including you and me.

18. **Rakavolver**
October 14, 2009

"The Cosmic Landscape of string theory is just the many worlds theory of David Deutsch writ large, and with inflation included within itself."

Oh, good Lord. In one sentence, three controversial subjects are combined (NOT "unified", because to call them so would be a insult to TRUE UNIFIERS such as Dirac who unified (without quotes) Special Relativity and Quantum Mechanics), thanks but no thanks, via semantics. Let's break them out. This is (sadly) fun:

– The Anthropic Landscape Mis-Theory of California String Theory
– The Many-Worlds Mis-Theory of Hugh Everett II
– The Inflation Damn-Near-Theory but often Mis-Theory of Alan Guth

Why am I NOT surprised, since this is written for the "middle-brow" "intelligent laymen" target audience that is the English, that this book will NOT sell? In England, anyway.

So sad.

19. **neo**
October 14, 2009

I would describe Everett's many worlds as an "interpretation"of a rock solid theory, QFT. I don't quite know what the anthropic landscape should be called. An interpretation of a speculative theory?

20. **Charles Hardin**
October 17, 2009

Peter Woit says, "many-worlds precisely agrees with other QM interpretations" in other words, other QM interpretations precisely agree with many-worlds. So it passes all the tests other interpretations pass. AND it solves the puzzle of what makes the wave function of the Universe collapse. You can't just dismiss it because you don't like it.

Rakavolver describes inflation as a mis-theory — yet it has passed several experimental/observational tests.

And the President of the Royal Society takes anthropic ideas seriously.

Let's use reason in this debate, not emotion.

21. **Tim vB**
October 18, 2009

@Charles Hardin
Hope the following is not too controversial:
QM is a mathematical model, if you describe your experiment, I can employ that model and calculate the possible outcomes. If there is an error on my or your part we will disagree, find the error, fix it and finally agree, within a relatively short timespan.
An interpretation of QM is an explanation of why the model works. You and I can believe in different interpretations, that does not affect the your experiment or my calculations. I think this is meant by "many-worlds precisely agrees with other QM interpretations".
You cannot rule out an interpretation by experiment.
While the many-world interpretation has many interesting aspects, I am puzzled why I have the impression to live in only one of the many-worlds. Any interesting comments on that? (I knwo some proponents of many-worlds, but they all dismiss this question as metaphysical).

22. **David J. Williams**

October 23, 2009

Deutsch's contention is that a quantum computer would literally be "larger" than any one classical universe:

http://www.edge.org/documents/archive/edge78.html

Interesting interview, regardless of whether you agree with him.

Embarrassing Crackpottery

October 12, 2009
Categories: Multiverse Mania

A while back I noticed that the arXiv had allowed the posting of the preprint Card game restriction in LHC can only be successful!, yet another in a sequence of crackpot articles about the LHC from Holger-Bech Nielsen and Masao Ninomiya. That these authors have managed to get the previous articles in the series published in the International Journal of Modern Physics A presumably has something to do with the fact that Ninomiya is an editor of the journal. I didn't post anything about this, on the grounds that embarrassing crackpottery from well-known physicists that no one except them takes seriously is best ignored.

Unfortunately, this particular piece of nonsense has been picked up by the New York Times, which tomorrow is running a story about it under the title The Collider, the Particle and a Theory About Fate. The writer, Dennis Overbye, presumably contacted some physicists to find out what they thought of this. If any of them told him this was just nuts and an embarrassment, that didn't make it into the story, instead there's:

> …craziness has a fine history in a physics that talks routinely about cats being dead and alive at the same time and about anti-gravity puffing out the universe.
>
> As Niels Bohr, Dr. Nielsen's late countryman and one of the founders of quantum theory, once told a colleague: "We are all agreed that your theory is crazy. The question that divides us is whether it is crazy enough to have a chance of being correct."
>
> Dr. Nielsen is well-qualified in this tradition. He is known in physics as one of the founders of string theory and a deep and original thinker, "one of those extremely smart people that is willing to chase crazy ideas pretty far," in the words of Sean Carroll, a Caltech physicist and author of a coming book about time, "From Eternity to Here."

Perhaps it would be a good idea if physicists would remind journalists that often things that seem to be crazy really are crazy.

Update: See more here from Tommaso Dorigo. I should have mentioned that his posting from a couple years back Respectable physicists gone crackpotty was linked to in the article by Overbye, who had an accurate take on the subject from at least one source.

Update: Somehow I knew that Slashdot could not possibly resist this nonsense.

Update: Sean Carroll has a long defense of the Nielsen-Ninomiya papers as not crackpot at all, but crazy in a positive way:

> There's no real reason to believe in an imaginary component to the action with dramatic apparently-nonlocal effects, and even if there were, the specific choice of action contemplated by NN seems rather contrived. But I'm happy to argue that it's the good kind of crazy. The authors start with a speculative but well-defined idea, and carry it through to its logical conclusions.

As for the argument that prominently-placed New York Times stories promoting crazy ideas about physics might be problematic, Sean is having none of it. He argues that the public is able to differentiate between speculative ideas and solidly tested science, so it's not a problem that:

> My own anecdotal observations are pretty unambiguous — the public loves far-out speculations like this, and happily eats them up.

Comments

1. **ConcernedCitizen**
   October 12, 2009

   It's rather shocking that such garbage actually gets published in journals.

2. **James D. Miller**
   October 12, 2009

   I'm an economist not a physicist so please forgive me if this seems stupid.

   But if the many world's hypothesis of quantum physics is right and if the LHC would destroy the world if it ever became operational then wouldn't we get the result in the paper? In fact, doesn't every time the LHC breaks down increase the probability that the LHC is destroying alternative quantum branches?

3. **Peter Woit**
   October 12, 2009

   James,

   The nonsense coming from Nielsen-Ninomiya is not the popular multiverse nonsense, but their very own private nonsense about "backward causation". It doesn't have anything to do with destroying the world, it's about the production of Higgs particles causing an effect that goes backward in time to stop this production.

   If over the next few years, we see more and more unlikely things happening to keep the LHC from operating, that would be an argument for a many-worlds scenario in which an operational LHC destroyed the universe. Hey, if things got unlikely enough, I might even start believing this….

4. **theoreticalminimum**
   October 12, 2009

   Boy, another let-down 🙁
   Peter, go easy on my childhood memories!
   Overbye was another author I like; what's going on with these people these days? Are they struggling to find truly interesting things to talk about?! :-\

5. **capitalistimperialistpig**
   October 12, 2009

   This looks like fodder for a dramatic TV series in the mold of *Flash Forward*. Maybe the authors are pitching such a project.

6. **abby yorker**

October 12, 2009

Seems like there must be plenty of Higgs produced by cosmic rays over the years. Are these avoided by the theory too?

7. **Tim vB**
October 12, 2009

Just read the paper and laughed my head off: Come on now, this is a pretty good joke and parody of some off-shell stringy style, could not be more obvious.
Well, they could have ended each sentence with a smily, if TeX supports that – don't know.
Do you really think you have to point out that this is not "real science"?
Well, obviously you cannot be too obvious if you do not want to be taken seriously 🙂 which would be the meta joke of the whole affair.

8. **Amitabha**
October 13, 2009

This must be the Eternity machine that Asimov was talking about. Perhaps somebody had gone back to him from the days after the LHC.

9. **a quantum diaries surivivor**
October 13, 2009

Hello Peter,

thank you for linking my piece, which does not make me too proud but did make me chuckle upon reading it back.

if the LHC ends up not running at all for a string of accidents big and small, I'd still not caress the idea that we should start playing card games. It will just be a demonstration that we have built a toy too big to play with.

Every student who has seen the relation between curvature radius and bending dipole field, and the dependence of synchrotron power loss with curvature, has the tools to wonder how large an accelerator humans can build. Unfortunately, though, those are not the only parameters. The space-time failure probability d2F/dVdt depends on the volume of the device, and this becomes a hindrance to scalability. It is obvious if you go to four dimensions and examine time instead of space dependence, trying to ask if you can keep the total failure probability small while increasing the duration of the experiment indefinitely.

The LHC might just be beyond the limit of spatial dimensions allowed by present-century technology. It would be very sad, but I'd argue that we shouldn't draw more conclusions from it, other than some of the project leaders should have known better 😉

Cheers,
T.

10. **Bee**
October 13, 2009

The only thing that's crazy about "anti-gravity puffing up the universe" is journalists who call it anti-gravity.

11. **Umair Rahat**
October 13, 2009

This is the top story on the front page of NewYorkTimes.com as of 4 AM EST, I could not have been more shocked. Even worse is such a paper in a real scientific journal, and then an article written by a physics and cosmology writer Dennis Overbye in a newspaper as NY Times. This type of nonsense needs to be seriously condemned. Even an article of the new-age-movement claims on LHC would have done far more satisfactory result, since even it wouldn't have aligned such utter crackpottery to physics.

And whats going on with this incredibly illogically warped piece of logic this paper is; With the title "Card game restriction in LHC can only be successful!", and even the exclamation mark hints on what is to come. Is this a joke or is this "a new game" of writing scientific papers?

12. **Tim vB**
October 13, 2009

During a recent discussion with (non-scientists) friends I found out that the statement "we hope to observe new physics at the LHC" was interpreted to mean that some events could happen at the LHC that never ever have happend before in the whole universe. That is probably the reason so many people are willing to believe any story anyone with a Ph.D. is telling. Please help and tell your friends that the universe has and probably will be operating at much higher energies than the LHC without distroying itself 🙂
I am getting scared that so many people seem to believe the paper of Nielsen and Ninomiya could NOT be a joke/parody. How could that be? They talk about:
– backreaction of future events leading to the dismissal of the SSH by the congress of the USA,
– a vacuum bomb (meaning a bomb that works through the creation of a new QFT vacuum state),
– tossing cards to find out about the future of the LHC (I admit that there live people who believe in that 🙂
– "Now it is sometimes explained that SSC had bad luck because of
various stupidities or accidents, but had it been a card game nobody could come up with such foolish cards."
– "Therefore, if LHC fails for a reason other than a random
number game, we would have not even truly learned that our theory was right even
though we would say 'it is remarkable that the present authors wrote about the
failure while LHC still looked to be able to work.' "
Ok, if anyone remains that does not believe in a joke (or call it parody or political comedy) I give up, I'll first throw away all my papers and textbooks, get a banking job in London and I won't look back.

I'm not so shocked about the New York Times, obviously the authors were not able to comprehend basic 20th century physics (but all of those kind of articles contain misconceptions).

@James D. Miller
The multi universe interpretation of quantum mechanics does not seem to have anyting to do with all of this, but: Your conciousness appears to live in one universe only, right? (If not, it is called schizophrenia I think). So if you believe in the mulit universe interpretation, you need some explanation why your conciousness seems to constantly choose only one of them to live in. Depending on this explanation, if the LHC destroyes some of the universes, your conciousness could equally well choose the path to one of those, so you would just wake up one morning and realise you don't exist anymore. You would need to assume some mechanism that ensures that your conciousness stays on the right path.

13. **Paul Jackson**
    October 13, 2009

    Wonderful stuff from Nielson and Ninimiya. They should write a book about it — perhaps a romantic novel called BBC rules.

    But isn't it about time evidence-based physics was due for a revival? Then we could do away with backward causation, black holes that form only at the end of eternity, slathers of stringy stuff, so-far unobserved dark energy, and even poor dead-and-alive cats.

    And get on with optic fibres and charge-coupled devices —our real business, don't you think?

14. **ManyMe**
    October 13, 2009

    The paper states that the model
    "begins with a series of not completely convincing … assumptions".

    I think they are right about that.

15. **chris**
    October 13, 2009

    you have to give them credit where credit is due though. "Miraculosity" is certainly the most hilarious observable ever seriously suggested by a physicist 🙂

    oh, and another thing: the "theory" doesn't really fall under 'not even wrong'. it has a very characteristic experimental signature and could quite easily be disproved by an experiment which would cost a few pennies. so what's the real problem? the embarassment of Heuer having to draw from a few stacks of cards? 🙂

16. **chris**
    October 13, 2009

    another thought

    maybe they are begging to be awarded an ignobel price?

17. **Thomas Larsson**
    October 13, 2009

    the "theory" doesn't really fall under 'not even wrong'. it has a very characteristic experimental signature and could quite easily be disproved by an experiment which would cost a few pennies.

    Really? If such an experiment only costs a few pennies, why hasn't it been done already? I might be willing to fund it myself.

18. **Aristotle Pagaltzis**
    October 13, 2009

    Perhaps it would be a good idea if physicists would remind journalists that often things that seem to be crazy really are crazy.

    Would that it were so simple. Unfortunately, a lot of modern physics fare like curved space-time, particle-wave duality and other firmly established ideas seem equally crazy to laymen whose only perspective is their everyday intuition.

19. **Jacques Lacon**
    October 13, 2009

    Here's a hypothesis: this sure reads to me like an elaborate Bayesian joke at the expense of the LHC and the Higgs and a certain sector of the theoretical physics community. I think they are with you Peter, not against you, and this is a Sokolesque parody. At any rate I found it quite funny.

20. **SteveB**
    October 13, 2009

    I have always liked well written science fiction. It gives me ideas, gets me thinking outside the box, provides very interesting connections to possible happenings in reality, and it satisfies that need to have that feeling of "wow, that's freaky!" on occasion. I do not have to accept it as "real", and I like that. Science fiction probably was the biggest influence on me having a career in science.

    However, I really do like my science and my science fiction to be separate. I applaud Peter for calling it out. It is embarrassing that apparently some people can no longer make that separation.

21. **Rakavolver**
    October 13, 2009

    Agreed SteveB, and Greg Egan of Perth, Australia and friend/collaborator of the incredible John Baez is the best one currently writing.

    Well, this was quite amusing and thank you for this Peter, but to get serious for a bit regarding crazy crackpottery.

    Everyone should encourage all their "intelligent laymen" friends (especially those in power) to read the following list:

    http://en.wikipedia.org/wiki/List_of_topics_characterized_as_pseudoscience

    Then, have them read John Baez' crackpot index, so:

    http://math.ucr.edu/home/baez/crackpot.html

    Finally, let's get serious. Of all the important things said by anyone in the last 50 years, the single most important thing anyone has said was said by noted General Relativist Stephen Hawking, who essentially said we have to get off this 8000-mile rock or we're doomed.

    It won't be easy, it won't be cheap, but it IS important. And take a wild guess WHOM our species will depend on to make that happen? Richard Branson? Yes, a bit, but mostly ….. YOU guys.

If you're intelligent enough to have read this website in the first place and far enough down this thread in the second place, then you're capable of making a difference. What have to done today or this month or year to make that happen, for example say, a lunar colony, come about?

What this has to do with crackpottery is simply this:

Peter, PLEASE write a rebuttal to that article, or one of you, please, and politely insist it be front page next week on the NY Times. Because if it doesn't, Hawking's worst nightmare may come to pass. Cheers.

22. **Charlie C**
October 13, 2009

The paper is not even funny.

23. **Yuri Danoyan**
October 13, 2009

"Influence from the Future" idea proposed by C.D.Froggatt and H.B.Nielson in 1996. http://arxiv.org/abs/hep-ph/9607375.
I don't think it is full crazy idea.My be older generations of particles not signals from the Past, but signals from the Future?Some hints about future transformations in the world of particles next epochs?
They are not ancestors, but the descendants ?

24. **Rakavolver**
October 13, 2009

From Yuri's link:

"Our cleanest prediction is the Higgs boson mass being 149 +/- 26 GeV, which in addition assumes that the pure Standard Model is valid until the Planck scale. Adding the assumption that the two vacuum states needed in our model come about naturally requires a strong first order transition between them; together with the assumption of the Planck units being fundamental, this leads us to also predict the top quark mass as 173 +/- 5 GeV, and a more precise value of the Higgs boson mass as 135 +/- 9 GeV."

Those are three rather strong assumptions, eh?

25. **timmo**
October 13, 2009

I'm sure this is a silly question, but I just don't understand what, *exactly*, is the experiment they propose?

I find it further confusing that they keep talking about either drawing a card, or drawing a number from a *quantum* number generator. If the experiment (whatever it is) can be performed by drawing a card, then it could also be performed by a normal, classical random number generator. Why should it be either a deck of cards or a quantum computer?

26. **Geoff**
October 13, 2009

Clearly they left out this reference:

http://www.physics.nyu.edu/faculty/sokal/transgress_v2/transgress_v2_singlefile.html

27. **neo**
October 13, 2009

I think that this paper is a joke (funny or not) by Nielsen and Ninomiya, but apparently Overbye didn't get it.

28. **Peter Woit**
October 13, 2009

If it's a joke, it's part of an act the authors have been putting on now for several years without breaking character…

29. **Tom O'Bulls**
October 13, 2009

Chris said: "oh, and another thing: the "theory" doesn't really fall under 'not even wrong'. it has a very characteristic experimental signature and could quite easily be disproved by an experiment which would cost a few pennies. so what's the real problem? the embarassment of Heuer having to draw from a few stacks of cards?"

As somebody pointed out on Bee Hossenfelder's blog, the problem is that you have to *trust* the person doing the experiment, and that the Higgs has not reached back in time to compel him to conceal the evidence that the "experiment" will reveal. What if the Higgs turns him into a liar? What if the Higgs turns him into an alcoholic?

I still think it's a joke. Somebody evidently pointed out to the authors that the SSC was cancelled because of the fall of communism [!]. To this the riposte is that the Higgs caused the fall of communism. Come on, it has to be a joke.

30. **Yatima**
October 13, 2009

So it's in the NYT? So what. The NYT is the Nigerian Yellowcake and Iranian Imminent Nuclear Threat Newspaper. It will get the hoi polloi confused and into a funk, but that's the way the cookie crumbles.

Now, my banker buddy seems to have decided that he doesn't believe in QM and has locked on to the "Theory of Elementary Waves", another member of the Not Even Wrong category. What do I do? Torture him with Lagrangians? Oh my…

31. **Kea**
October 13, 2009

This simply MUST be a joke. Human stupidity may be infinite, but I find it hard to believe that these guys could be THAT idiotic. And why would they admit it was a joke just yet? The paper is published, they are getting serious press, and the farce just keeps getting more and more ridiculous.

32. **Christine**
October 14, 2009

I would not doubt that even average crackpots find that paper highly embarrassing. That makes some crackpot claims appear respectable scientific works in comparison. I can only conclude that the effective result of that paper is the fact that it undoubtedly expands the limits of crackpotism. John Baez will have to re-scale his index.

33. **D R Lunsford**
October 14, 2009

A comment to Overbye's article sums up the damage done to physics from within and from without:

"I absolutely love physics for just this reason. It's totally crazy. Just like this life. Who knows anything, and it's all magic. Fantastic!"

That is what the intelligent layperson understands about the very thing that underpins most of the modern world.

-drl

34. **Rimus**
October 14, 2009

Oh! And there's not only "miraculocity". There's also the "degree of remarkableness" The more I read it, the better I like it!

35. **Aristarchus**
October 14, 2009

Apparently somebody read Einstein's Bridge and took it seriously:

http://faculty.washington.edu/jcramer/E_Bridge.html

36. **Rakavolver**
October 14, 2009

As bad as the paper is, the article is far, FAR worse.

It's bad enough The New York Times, a once great newspaper, has degenerated as much as it has. It's bad enough all newspapers will be dead and ONLY on-line in the next ten years, but this is really scraping the bottom of the barrel. The journalist takes the impish "respected" Physicists, who are obviously making a joke, at their word.

Do we really have to read about Kurt Vonnegut's FICTIONAL work as "real" Physics? What an insult to the late wonderful Vonnegut. Do we REALLY have to know the author is a life-long Boston Red Sox fan and believes in "jinxes"? I think not.

Worst of all is his taking completely out of context wonderful quotes by Niels Bohr and Albert Einstein. They were great men and deserve better.

I admire the way Europe, in its cute way, is trying to compete with America economically. We'll see how that works out. But in Physics, Europe has already won and will continue to do so. The LHC WILL start up, and the results will be wonderful.

Keep the faith my European cousins.

37. **Aristarchus**
October 14, 2009

THIS is why the Higgs Boson is messing with the LHC – we threatened it!

http://abstrusegoose.com/118

38. **Coin**
October 14, 2009

If over the next few years, we see more and more unlikely things happening to keep the LHC from operating, that would be an argument for a many-worlds scenario in which an operational LHC destroyed the universe. Hey, if things got unlikely enough, I might even start believing this….

Like "intelligent design", it's a theory which is attractive for its nearly unbounded explanatory power. I would note that similar anthropic "otherwise, all life in the universe would have ended" reasoning could prove equally valuable in explaining the difficulties in Democratic efforts to pass a health care reform bill, or Terry Gilliam's recent inability to complete a movie.

39. **Hal Porter**
October 14, 2009

AAArgh!!

I just lost my (very witty) post a moment ago when I hit the wrong key.

Gist:

I thought it was a joke, also.

Now I learn otherwise.

Stop the eye rolling, *dammit*!

41. **Thomas Larsson**
October 14, 2009

Maybe the infinite improbabability drive isn't so unrealistic after all; I'll make myself a nice hot cup of tea.

42. **Joe Eckard**
October 15, 2009

Laugh away. I laughed too. A lot of knee-jerk thinking in these comments. Nielsen is one of the fathers of string theory. He is no dummy, nor a crackpot. He is willing to think. He is willing to doubt what "everyone knows." We could all learn from his fearlessness. He is not afraid of being mocked. He might be correct.

43. **Bob Levine**
October 15, 2009

"Sean is having none of it. He argues that the public is able to differentiate between speculative ideas and solidly tested science …"

Carroll is dead wrong if he believes that. There's an interesting, well-established branch of psychology which studies peoples' pictures of the physical world, based on their intuitive perceptions of what their senses tell them; I've seen it referred to as 'folk physics', by analogy I suppose with 'folk taxonomy'—how people conceive of the biological domain based on their perceptions, and so on—and one of the depressing conclusions from this research seems to be that a substantial fraction of people in the collective subject pool actually do believe that when you drop a bomb out of a plane flying at 30,000 feet, the bomb travels six miles straight down to land at the site the bomber was directly over when the bomb was released. With that kind of foundation, just where does SC get the idea that people are sophisticated enough to recognize the line between the already improbable-sounding tenets of rock-solid modern physics, on the one hand, and nutcase-level fantasizing on the other??

Scientists tend to be rather insulated about the poplular perception of the content of their respective fields… but this is just flat-out bizarre.

44. **chris**
October 15, 2009

"Nielsen is one of the fathers of string theory."
yes
"He is no dummy, nor a crackpot."
yes
"He is willing to think."
yes
"He is willing to doubt what "everyone knows.""
yes
"We could all learn from his fearlessness."
yes
"He is not afraid of being mocked."
yes
"He might be correct."
no way

45. **Aristarchus**
October 15, 2009

We live in a world where many people not only diss evolution but believe that stains on a wall are signs from their god, so whether this is a joke or not, it cannot be taken lightly because way too many people are already off the science wagon (or were never on to begin with).

Or is this just in America? Are Europeans smarter?

46. **Haelfix**
October 16, 2009

I have to hand it to the authors. You would be very hard pressed to come up with a simpler idea that violates more laws of physics so completely and thoroughly.

This one manages to more or less include every single fundamental principle that I can think off, including special relativity, unitarity, cause and effect, the measurement principle, Occams razor, heck quantum mechanics and logic/observation in general.

Kudos. (And Seans defense, even muted as it is, makes me reconsider my Bayesian prior that we are living in 'The Matrix' by maybe a tenth of a percent)

47. **Tim vB**
October 16, 2009

@Aristarchus
I can only speak on behalf of the Germans: Recent polls show that about 30% think that the sun moves around the earth.
There is no "intelligent design" debate because Germans do not care about religion at all (especially in the east, Communism left it's mark) or do not take it seriously enough to engage in any debates about it.
Oh, and I think the German department of defense did not order an anti-gravity weapon because they have not enough money, not because they are smarter than the Americans.
Remember that highschool education takes you to Faraday and no further and imprints a deep unease and frustration and distrust in most students regarding everything that sounds like science. If the fate of the human race would depend on a layperson to understand more of the word quantum than remembering the last Bond movie we would be doomed.

48. **Aristarchus**
October 16, 2009

I thought this blog response to the recent Higgs Boson LHC issue was both
interesting and informative even beyond the main story:

http://backreaction.blogspot.com/2009/10/science-writers-and-public-bizarre-love.html

49. **Proxi**
October 20, 2009

The LHC will fail over and over again and will be closed before 2018.
Just wait and you will see.

Just for fun: draw these cards! 🙂

Nielsen-Ninomiya and the arXiv

October 14, 2009
Categories: Multiverse Mania

Because of the New York Times article discussed here, four recent papers by Nielsen and Ninomiya have been getting a lot of attention in the blogosphere. Pretty much all of it has been unremittingly hostile, when not convinced that these papers must be some sort of joke (except for this from Sean Carroll). I just noticed that these papers have gotten some attention from administrators of the arXiv, who have decided to reclassify three of them, presumably since the appearance of the NYT article.

The first in the series, arXiv:0707.1919 was originally posted in hep-ph, with a cross-listing to hep-th (see the Google cache of Oct. 5), but has now been re-classified as gen-ph (cross-listed as hep-ph and hep-th). Similarly, arXiv:0711.3080 has been reclassified from hep-ph to gen-ph, cross-listed to hep-ph (see Google cache of Sept. 12). I'm not sure what arXiv:0802.2991 was originally classified as, but the Sept. 3 Google cache has it as the same as now, gen-ph, cross-listed to hep-th. Finally, the most recent one, arXiv:0910.0359, was originally classified as hep-ph (Google cache of Oct. 7), now it has been re-classified to gen-ph, cross-listed to hep-ph.

While the arXiv administrators seem to be indicating that they share the common opinion that these are crackpot papers, one thing there does remain constant: trackbacks appear there to various press stories and blog postings about these papers, but trackbacks to this blog seem to be censored.

Update: Trackbacks to blog postings here on this Nielsen-Ninomiya subject have now appeared. The ways of the arXiv remain mysterious to me. About all I can tell is that trackbacks to some sources appear more or less immediately, presumably automatically (for instance the trackbacks to the original NYT article). For other sources, e.g. this one, they only appear in batches, often several days later, presumably after someone has gotten around to considering the matter…

Comments

1. **Kea**
   October 15, 2009

   But gen-ph is supposed to be for papers that no serious physicist would read. Why do they bother, given the publicity these papers have?

2. **ManyMe**
   October 15, 2009

   I am not surprised that Sean Carroll defends the Nielsen-Ninomiya paper.
   He is the expert on the arrow of time problem and the one who can proof the existence of the multiverse by making an omelette.
   And he has a book to sell…

3. **Tim vB**
   October 15, 2009

   What Sean Carroll says is IMHO correct, the critical path of a hoax is that there is enough content to let it appear to be something interesting, something one can discuss, while leaving enough prove of nonsense to reveal the hoax later. That he does it shows clearly how far off the track some (small) part of the string theory community is. Hey, but we can discuss this too, cant' we?
   First of all: What is time? To stay focused, let's add "in GR" to the question. Well, you have events, pick A and B, and these can have a causal relationship, meaning: Either A nor B can influence one another, xor (excludive or) A can influence B xor B can influence A. Lets consider A can influence B. Now and only now you can say "A occurs before B".
   If someone says "we have future and past and the future influences the past" doesn't that mean that she does not use time as a causal relationship? IMHO the authors should therefore explain what concept of time they use before we can take the diskussion any further. (Since Sean mentons the "non-locality of string theory" this has probably been done, in that case please provide a link, I was not aware of any of this).
   And shurly you noticed that the card drawing game depends on the actions taken depending on the outcome. Meaning, if you draw "don't operate the LHC" and then decide "well, that was a test, let's try again", the experiment is spoiled. It only works if you are really really shure about acting accordingly to what the card says. This connection of the outcome of an experiment to ones state of mind (after the execution of the experiment) clearly takes all physical theories way beyound their realm of applicability.
   If any of the authors reads this, I'd rather be more interested if you have your fun, or if you are embarrassed that the scientific community fell and continues to fall for your hoax (or both, this "or" is not exlusive 🙂
   Does anyone know a desperate unemployed postdoc willing to produce papers of increasing nonsense to test experimentally what will be accepted by established journals? (or the arXiv? or Sean? or LM? – strike the last, the Bogdanovs did that already). If so, I'll provide my contact information and will happily share my thoughts on the topic.

4. **DB**
   October 15, 2009

   The Nielsen-Ninomiya papers remind me of an old Larry Niven story, *Rotating Cylinders and the Possibility of Global Causality Violation*. That title was in turn borrowed from a serious paper by Tipler.

5. **Bob Levine**
   October 15, 2009

   "The Nielsen-Ninomiya papers remind me of an old Larry Niven story, Rotating Cylinders and the Possibility of Global Causality Violation. That title was in turn borrowed from a serious paper by Tipler."

   I remember that story—very good, one of Niven's best I thought at the time. But there's a bit of difference between that and the N/N paper, no? In that story, the relevant planet's sun goes nova to stop the "tojan horse" give of time-reversal causality from being presented to the enemy. The point was that the universe doesn't allow time-reversed effects to impinge on its unidirectional causal structure. What N/N seem to be suggesting is the contrary: that the universe itself resorts to time-reversed causal events…

   I gotta say, I find Niven's take on it a good deal more plausible than the N/N story…

6. **Yatima**
   October 15, 2009

The arxiv doesn’t keep a history of its classifications? That’s lousy.

7. **Peter Woit**
October 15, 2009

Yatima,

As far as I can tell, they don’t. I think it’s very unusual for this sort of change to be made, especially for papers that have been posted for a long time (since 2007 in this case).

8. **Coin**
October 15, 2009

DB: I imagine someone’s already mentioned this in one of the previou threads, but isn’t this entire thing basically the plot of Einstein’s Bridge?

9. **zevans**
October 15, 2009

Stephen Baxter – Time – is this idea in reverse, various particle physics events ’caused’ by ‘downstreamers’ ie future selves.

10. **anon.**
October 16, 2009

“… trackbacks appear there to various press stories and blog postings about these papers, but trackbacks to this blog seem to be censored.”

Your blog doesn’t leave the right impression about string theory, and burying the head in the sand (censoring trackbacks) is the natural reaction to bad news exhibited by the ostrich.

11. **Alejandro Rivero**
October 16, 2009

Yep, penalties in the Arxiv block files seem to be ethernal; yesterday I did not remember my actual password and tried accidentally a blocked one, from years ago: it was there, after five or six years. And I guess it will be after 10 or 30. Probably it is because such bans are “legacy”, from orders received or executed by previous sysadmins.

12. **Peter Woit**
October 16, 2009

Trackbacks to these two blog postings appeared today, I’ve added an update about this to the posting.

13. **Per**
October 16, 2009

Hi Peter,

I think your attitude is in general a bit to negative. There is no harm in putting these papers on the arXiv. The people who wrote them are respectable scientists, and allowing something like this from them wont open the door for any crackpot to upload something.

14. **srp**
October 16, 2009

The best story about causality from the future is Benford’s Timescape, which as a bonus has actual realistic scientists as its protagonists.

15. **Peter Woit**
October 16, 2009

Per,

I agree that there are few enough serious scientists posting utter nonsense like the last Nielsen-Ninomiya paper that there’s no danger they will overwhelm the arXiv. I was just a bit surprised to see it originally posted in hep-ph, thought the moderator would not allow it there, especially since it was number 4 in a series. Not surprised that when it drew attention, it was moderated elsewhere.

The real problem though is not posting of crackpot papers on the arXiv, there will always be some of those. It’s when these things get taken seriously by some physicists, and picked up by the media that there’s a problem.

16. **Pawl**
October 17, 2009

The NN papers have been criticized for, among other things, introducing “miraculosity” [actually they use “miraculocity”]; if I understand the papers correctly, this term is supposed to refer to the violations of conventional causality, specifically predictability.

It seems to me that “miraculosity” in a similar (not quite identical) sense should be a problem for brane-world physics. After all, disturbances could appear, to us on the brane, out of the bulk with no apparent (four-dimensional) causation. To suppress these effects, one would need, not only extremely strong constraints on the dynamics, but a theory of what the initial conditions in the bulk were. Ensuring that unwanted “miraculosity” is not present is presumably an extremely strong constraint on branes; I don’t know whether the theory is developed well enough to speak realistically to this.

17. **Chris W.**
October 17, 2009

Pawl’s comment points up what might be the principal value of papers like those of Nielsen and Ninomiya.

If the proposed theory is afflicted with clearly unacceptable side effects, especially side effects that inspire heated discussion, people might well be prompted to ask what protects some other theories—apparently more worthy of being taken seriously—from similar pathologies. It may be that without further constraints—perhaps unrealizable or unacceptably ad hoc constraints—these other theories will also turn out to be vulnerable. The end result may therefore be to identify good reasons to *rule out* several heretofore plausible ideas, some of which already have multiple arguments in their favor.

If this happens, it constitutes genuine progress. Of course, brane-world physics already offers multiple reasons to worry about its ultimate viability.

18. **Delusion**
October 22, 2009

I argued against a theory of infinite universes a few months ago. If I may briefly summarize myself:

If infinite universes exist, we must have some means (now or in the future) to access to them to matter. Infinite universes who we cannot exchange energy, matter, or information with are functionally equivalent to this being the only universe, and is therefore metaphysical garbage.

So, if infinite universes exist, every possible reality that is consistent with fundamental laws of physics is present, an infinite number of times. If infinite universes can have different physical laws, that doesn't change anything; I'm merely taking the most conservative version of this fantasy into account.

Since we are assuming that these universes are accessible to one another, there are literally an infinite number of universes whose most powerful inhabitants consider it their sole mission in life to destroy every other universe, and also an infinite number of universes bent only on destroying our very specific universe, and also an infinite number of universes bent only on destroying you and I in this specific universe.

We're here, so the infinite universe theory is out.

In your experience, do most string theorists believe in an infinite universe theory where everything can physically happen does, in another universe? Even so much as the results of chance interaction between fundamental physical particles? Do they perhaps assume an infinite universe theory where the universes don't have any access to one another, and if they don't, how do they attempt to reconcile this?

Or is it the case that most string theorists who believe in multiple universes believe in a finite number of universes (though that number may be staggering), along with Nielsen-Ninomiya?

To me, the entire subject of infinite universes (or an amount large enough to be functionally similar to infinite) and the idea that we are another race's model universe, or that we will all be virtually resurrected from a perfect data source smacks of wish fulfillment and a desire for a scientific gloss to wrap around what is effectively a science-fiction version of immortality and afterlife.

It can make for good science fiction, I suppose.

Short Items

October 17, 2009
Categories: Uncategorized

- There's a wonderful new research mathematics site: Math Overflow. For some discussion of it, see here and here.
- For yet another wonderful new site about research mathematics, there's the French Images des Mathématiques.
- Why is there nothing in theoretical physics anywhere near as good as the above two sites?
- Via Flip Tanedo, an NPR story about Berkeley's parking spaces for Nobelists. He neglects to mention that, starting with Vaughan Jones in 1990, Berkeley started providing equivalent parking spaces for Fields medalists.
- It looks like multiverse mania is not just an American phenomenon, since there's a new popular book on the multiverse out in Germany Die verrückte Welt der Paralleluniversen, by Tobias Hürter and Max Rauner. For a synopsis in English, see here. The authors have a blog, Multiversum.
- The Perimeter Institute has just announced more details of their expansion plans. The new 55,000 square foot expansion of their building will be named the Stephen Hawking Centre at Perimeter Institute. They have doubled the number of Distinguished Research Chairs to 20, with ten new appointments announced here. Director Neil Turok is giving a talk about their plans today, video should be on-line soon.
- This week at Perimeter they're having a Quantum to Cosmos Festival. It started off Thursday night with a discussion by 9 physicists organized around "what keeps them up at night". String theorist David Tong explained that he used to be kept up at night worrying about whether string theory unification could ever be tested, scientifically justifying the subject. Nowadays though, he says he sleeps fine since he no longer needs to worry about this: even if string theory unification is untestable, string theory research can be justified because it provides approximate calculational methods that might be useful in nuclear or condensed matter physics.

Comments

1. **Patrick Tam**
   October 18, 2009

   One of the creators of mathoverflow told me that stackoverflow.com inspired him. Stackoverflow is similar except for programming. Eventually, stackoverflow offered a service (http://stackexchange.com/) to run sites similar to it. The mathoverflow folks decided to use that. So math use to be in the same position (without good sites) you find theoretical physics. It is conceivable that the theoretical physics community will eventually set up something similar with the stackexchange service.

2. **Anton Tykhyy**
   October 18, 2009

   Actually there already exists a physics site, the problem being that it's still empty — http://physics.stackexchange.com/

3. **PhilG**
   October 18, 2009

   Math Overflow needs TeX support to make it worth using.

   I much prefer the MathLinks forum which is an offshoot of The Art of Problem Solving. It is based around maths contest style questions but you will find discussions about maths problems at all levels there. It has been around for a few years and has over 70,000 registered users thanks to excellent TeX features and an friendly open atmosphere.

4. **Thomas**
   October 18, 2009

   Don't UseGroups (nowadays aka Google Groups) fulfill the same purpose as MathOverflow/StackExchange?
   And they seem to be quiet alive and kicking!

5. **Tim vB**
   October 18, 2009

   Skimmed "Die verrückte Welt der Paralleluniversen", the good thing is that this book does not hype the multiverse, but is just an attempt to draw some money from the existing hype. With some luck this thing will not be published in English. God, I think I lost 2 IQ point by just reading pages 100 to 150.

6. **Bob Levine**
   October 18, 2009

   "Nowadays though, he says he sleeps fine since he no longer needs to worry about this: even if string theory unification is untestable, string theory research can be justified because it provides approximate calculational methods that might be useful in nuclear or condensed matter physics."

   So we've gone in a few short years from 'the only game in town' to computational heuristics?? Wow, how the mighty are falling… reading this statement from Tong, I could not get out of my mind the horrendously vivid scenes from Sergei Bondarchuk's 1968 8-hour ultramasterpiece version of WAR & PEACE depicting the deathmarch retreat of Napoleon's Grande Armée after the disastrous march on Moscow. If I were DT, I don't think I'd be sleeping particularly well at all…

7. **joey**
   October 18, 2009

   > calculational methods that might be useful in nuclear or condensed matter physics.

   might…!? what did he mean, *might* be useful? Just *might*, like in *might* be testable one day?

   I don't think I'll be able to sleep tonight…

8. **Chris W.**
   October 18, 2009

   From the math***overflow*** FAQ:

   > **What is this? Who are you?**
   > Math Overflow runs on Stack Exchange, the hosted service that provides the same software as the popular programming Q&A site Stack Overflow. The hosting cost is paid from the research funds of our generous benefactor, Ravi Vakil of Stanford University.

> Keeping Math Overflow clean, civil, and on topic are its moderators: David Brown, Daniel Erman, Anton Geraschenko, Scott Morrison, and Ben Webster. If you have any problems with the site, contact Anton Geraschenko (geraschenko@mathoverflow.net).

As a long-time reader of Joel Spolsky's blog, and occasional reader of stack**overflow**, I have to wonder why the people behind this new site felt compelled to ape the *name* of Spolsky's and Atwood's original site. After all, the term *stack overflow* has a particular meaning and significance to programmers, whereas *math overflow* means nothing, really. The first offshoot of stack**overflow** based on the Stack Exchange platform is called server**fault**; it's for system administrators and IT professionals. The common theme is that of a breakdown or failure that somebody is trying to understand and resolve, although the scope of the questions on these sites is broader than that.

9. **teaser**
October 18, 2009

So does this mean that string theorists will be absorbed into the condensed matter physics departments at universities everywhere? That should help the department numbers for these folks – and their funding.

10. **Aristarchus**
October 20, 2009

Stephen Hawking's position at Cambridge has been replaced by a string pioneer:

Higgs, Dark Matter and Supersymmetry: what the LHC will tell us

October 19, 2009
Categories: Uncategorized

The Council for the Advancement of Science Writing is holding a New Horizons in Science conference right now in Austin. This morning Steven Weinberg gave a talk, now available online, with the title Higgs, dark matter and supersymmetry, what the Large Hadron Collider will tell us. He described the Higgs as something definitely expected, supersymmetry as a much more speculative possibility, but had nothing to say about string theory during the talk. In the question session, Tom Siegfried of Science News asked him about why he hadn't mentioned string theory, and what its prospects now were, 25 years after first being heavily promoted to the press. Weinberg answered:

> It's developed mathematically, but not to the point where there is any one theory, or to the point that even if we had one theory we would know how to do calculations to predict things like the mass of the electron, or the masses of the quarks. So, I would say, although there has been theoretical progress it's been, I find it disappointing. One of the hopes would be that the LHC would provide a clue to something we're missing in superstring theory and I think there supersymmetry is the most likely place to look.
>
> One of the troubles with superstring theory is that although in a sense the theorists think there is only one theory, there are an infinite number of approximate solutions of it and we don't know which one corresponds to our world. But at least in a large variety of the solutions of superstring theory there is supersymmetry visible at low energies, and if we see supersymmetry at low energies, superstring theorists may be able to derive from it some kind of clue as to how to solve these theories. But I haven't talked about it in this lecture because I don't see how that would work, it would be.. I mean I couldn't say that that was likely with any degree of sincerity, and certainly the LHC and any other accelerator that we can imagine being built will not get up to energies which are high enough so that we can directly see the structures that are described by superstring theory, the strings or the D-branes or whatever it is. Those will not be accessible at the LHC, so any clue we get will be very indirect.
>
> I myself, well I was working on superstring theory in the 80s and gave it up because I… I moved into cosmology, which in the last couple of decades has had the excitement that elementary particle physics had in the 60s and 70s, a wonderful coming together of theory and observation. Cosmology now reminds me of the excitement that I felt when I was younger and doing particle physics.. and it's a pity that superstring hasn't developed better. I still think it's the best hope we have, I don't know of anything else. My own work very recently has been trying to develop an alternative to superstring theory as a way of making sense out of quantum gravity at very high energies. But even though I'm working on this I still find superstring theory more attractive, but not attractive enough…

Siegfried gives an account of the talk here. It includes a new remarkably convoluted and misleading way of referring to the fact that string theory predicts nothing at all about observable physics:

> But despite a quarter century of intense effort, superstring theory has not produced a cohesive and clear guide to testing its fit with all the observable features of physical existence.

   October 19, 2009

   Well, it's a shame that in such conferences speakers do not have a tie-microphone. Hanging a hand microphone is so much dated, and so much painful for old people…

   Whatever, wehn I was a young student, I attended in Paris a conference by Alfred Kastler, about the origin of quantum theory. I must say, what he told us then was so much unexpected and unheard of, that I am still muling his lesson, thirty five years after. Weinberg is a too well known teacher and Noble price, what he can say is much less original… (putting away the fact that I find his books about QFT ones of the less pedagogical, except for references)

2. **Bob Levine**
   October 20, 2009

   "Siegfried gives an account of the talk here. It includes a new remarkably convoluted and misleading way of referring to the fact that string theory predicts nothing at all about observable physics"

   Sigfried's conspicuous lack of—to put it delicately—intellectual candor, so far as string theory is concerned at least, is the main reason that I let my subscription to Science News lapse. If the periodical is going to be turned into just another mouthpiece for string theory 'irrational exuberance', what's the point of supporting it? His skewed choice of coverage (including one particularly contentless last-page essay by some guy whose name I've succeeded in forgetting that made some empty dismissive comments about Lee Smolin's book) shows that he's pretty much just a shill for an agenda in science that has become far more a matter of ideology than a real research program—one that is willing to commit itself to gaining some battle-tested results, as Wheeler put it, before claiming ANY degree of success.

   But I'm glad to see that SW has finally said something publicly about his doubts. I wonder how the latter will affect his pronouncements about the anthropic principle and the predictive possibilities of physics as a science—he was pretty bullish on the AP for a while, as I recall…

3. **chris**
   October 20, 2009

   Bob,

   i think you are mixing things up a bit here. afaik, Weinberg *invented* the anthropic principle (or to put it better was the first one to point out how it can be applied to particle physics/string theory). with so many things that he has pioneered, he really does not need to advertise or push anything (except his book maybe). i always found him extremely honest and lucid in his statements.

   just look how he is talking about the asymptotic safety scenario in this very citation given here. he invented that too, you know.

4. **Bob Levine**
   October 20, 2009

   " with so many things that he has pioneered, he really does not need to advertise or push anything (except his book maybe)."

   Chris—
   My impression was that Brandon Carter and John Barrow were the ones who introduced the AP into the discourse in physics, and that Weinberg's comments invoking the AP were connected with the landscape interpretation of string theory, which seemed to be the only way to give a realistic interpretation to the vast number of possible

vacuum states implied by the theory (or program, or whatever the right term for it is). I could be quite mistaken about that, for sure. But I wasn't thinking of SW's promoting or advertising the AP so much as perhaps dropping it altogether. After all, if you no longer take string theory seriously as a promising direction in pursuing a 'final theory', then a lot of the motivation for the landscape, and hence the AP, disappears along with it. And it certainly sounds as if Weinberg no longer has anything like the view of ST he was articulating earlier. So it makes me wonder if we'll be hearing anything further about the AP from him, or if he instead views the whole AP/landscape quagmire as a dead end.

"i always found him extremely honest and lucid in his statements."

I wouldn't disagree at all with this. It's Siegfried who I find profoundly, um, *disingenuous* in the way he uses SCIENCE NEWS to try to minimize/deny the foundational problems that ST faces (whether it wants to or not).

5. **PhysicsPhile**
October 20, 2009

Bob,

My impression from reading Weinberg's recent papers is that he still believes that the multiverse is the only available explanation for the cosmological constant problems. Note that the multiverse is an independent concept from the string theory landscape. But the latter does give an explicit construction for the former.

6. **Peter Woit**
October 20, 2009

What I found interesting about Weinberg's talk and comments was that, whatever his views on the multiverse, AP, extra dimensions, string theory landscape, etc. might be, he decided not to mention these at all in his talk. He takes a very different approach than many other prominent figures in theoretical physics, who think it's a good idea to get the press and the public "excited" by feeding them all sorts of highly speculative nonsense. Because of this latter approach, people like Siegfried go out and write books based on such nonsense, and have a completely misguided view of the subject. Also as a result, both questioners wanted to ask Weinberg about string theory, which he hadn't talked about, not about the solid science he did talk about.

7. **Peter Woit**
October 20, 2009

Bob,

I think the Science News piece you refer to is this one:

http://www.sciencenews.org/view/generic/id/45196/title/Comment__Five_problems_in_physics_without_the_definite_article

which described Lee Smolin's book as "silly attacks on string theory", but which I'd describe as a silly attack on Lee Smolin…

8. **Bob Levine**
October 20, 2009

Peter—yes, that's the one. I'd already pretty much decided that in good conscience I couldn't really continue supporting SN, and it's been in the back of my mind for a while that if Siegfried is pursuing this kind of partisan agenda in one branch of science, what sort of illusions of consensus is he trying to promote in biology, psychology and so on?…

…and to PhysicsPhile: yes, point taken, except that the AP seems to have been most aggressively flogged of late in connection with the string landscape business, and reading Peter's citation of SW's evident disillusionment with ST suggests that maybe the drunken orgy phase of ST—and its sociological domination of the field in terms of grantsmanship, hiring and the like—is about to come to an end, if even high-profile advocates such as Weinberg are having second and third thoughts.

"Also as a result, both questioners wanted to ask Weinberg about string theory, which he hadn't talked about, not about the solid science he did talk about."

An old, wise professor of mine in graduate school once commented bleakly that you can't kill a bad idea. That's doubly true I think if giving up the bad idea leaves you in a relatively unsatisfactory, frustrating situation given your ambitious hopes for a real working GUT (which is presumably why Siegried and others like him want to keep the party going).

But is it too much to hope that the various bits and pieces we've been reading about here (David Tong's comments, Weinberg's frank acknowledgement that ST has, in terms of real physics, gone nowhere, and the rest) are a sign that the town drunk is beginning to sober up at last?

9. **Cormac O Raifeartaigh**
October 20, 2009

what did he say about DM?

10. **Michael Good**
October 20, 2009

Please blog your thoughts about Green's new post.

I'm interested in what you think about it!

http://www.guardian.co.uk/science/2009/oct/20/stephen-hawking-michael-green-cambridge

11. **Peter Woit**
October 20, 2009

Cormac,

You can watch the video, but from what I remember Weinberg just made conventional points, explaining some of the astrophysical evidence, the possible connection to supersymmetry, and the possibility of production of dark matter particles at the LHC.

Michael,

Green seems like a reasonable choice for the post. While I complain about string theory and the faddish way it has been pursued, it's worth noting that there's a major difference between Green and most other string theorists: he was doing important work moving the field forward at a time that this was a very unfashionable thing to be doing. He and Schwarz deserve a lot of respect for that.

One odd thing I saw mention of somewhere is that Green is only 4 years younger than Hawking, so presumably will be stepping down from this position rather soon after taking it.

12. **Marcus**
October 20, 2009

PP said
…impression…recent papers is that he still believes that the multiverse is the only available explanation for the cosmological constant problems…

Impressions of what someone still believes—rather than what they actually say—can certainly be tricky. I couldn't find anywhere that he actually says that, in his ten papers from the last four years. A lot has happened during that time, so earlier than that would not seem exactly "recent".

http://arxiv.org/find/grp_physics/1/au:+Weinberg_S/0/1/0/2006,2007,2008,2009/0/1

Maybe you can point out for us which of these papers actually says that he still believes such and such. I could easily have missed a reference.

If on the other hand you are using your intuition to guess another person's state of belief, without his explicit statement, that's…well…different. Tells us more about you than about Weinberg.

We should then probably be discussing your own ideas, rather than projecting them on him.

The two *most* recent papers of Weinberg, both from 2009, and his July 6 talk opening a conference at Cern, all cited extensively some work by Reuter, Percacci, and others on the "asymptotic safety" treatment of gravity—allowing Newton's G and the c.c. to run with the renormalization group flow. According to a paper of Reuter et al that Weinberg cited, this offers another way to understand the cosmological constant. I don't know what Weinberg thinks or believes, but he explicitly said in his Cern talk that his current research focus is on asymptotic safety (a concept he introduced in 1976) and its relevance to cosmology.

On the other hand, I've seen nothing from him recently either of multiverse or anthropic argumentation. If you have please provide a reference.

13. **Peter Woit**
October 20, 2009

Marcus,

In his comments at the end of this talk, Weinberg mentions that he is working on asymptotic safety, but says "I still find string theory more attractive". It's a reasonable interpretation of this to think that he hasn't changed the views about the CC, multiverse, string theory landscape that he wrote about in "living in the multiverse" back in 2005. If he has come to the realization that there is something fundamentally misguided about most multiverse research, he hasn't said so publicly, as far as I know.

In any case, I think, as shown in this talk, Weinberg is careful to keep in mind the distinction between what is solid science, with real evidence behind it, and what is highly speculative, and thus likely to be wrong. And all explanations of the size of the CC now available are in the latter category, no matter which of them is your favorite.

14. **Frank**
October 20, 2009

Peter, Weinberg is careful, but not in all statements. For example, he gives talks since 30 years saying that the essence of nature is its symmetry (repeating what Heisenberg said). Symmetry is surely important, but whether it is of fundamental importance is questionable. Weinberg's stress on symmetry and its role was the reason that so many researchers looked for larger and larger symmetries (GUTs, supersymmetry, string theory). It is not at all clear that this is the right approach for fundamental physics – especially since none of these symmetries has shown up. The search for larger and larger symmetries is usually taken for granted, due to Weonberg's constant stress on the issue – but is it the correct approach? Maybe the LHC can give us a hint about this fundamental issue.

If the LHC does not find any new symmetry, then a complete change of mind might be required. Maybe there is no larger symmetry in nature, apart from those that are known?

15. **Peter Woit**
October 20, 2009

Frank,

Weinberg is far from the only one who thinks symmetry is a fundamental principle. This was a very fruitful idea throughout the 20th century. My own view is that it will continue to be one, but one has to keep in mind that new ways to exploit symmetry principles may need to be found. The way gauge symmetry is realized in the electroweak theory is a good example, it's rather subtle and still not completely understood non-perturbatively.

So, if Weinberg is pushing symmetry as a principle, I'm with him. But to get something new it's likely to require something much more non-trivial than just replacing SU(3) by SU(5).

16. **Frank**
October 20, 2009

Peter, I understand what you say: but people have tried GUTs, supersymmetry, quantum groups, BRST, and so many other ideas. None worked. It is quite courageous to think that more symmetries – apart from the gauge symmetries of the standard model – play a role in nature. Thousands of people have looked for more general symmetries, but none has been found. So the question arises: is a larger symmetry really needed?

17. **Peter Woit**
October 20, 2009

Frank,

My own point of view is just that there are fundamental questions about how to handle things like gauge symmetry in QFT that remain poorly understood. They're deep questions both about mathematics and about physics, so worth understanding. It's true that such efforts haven't yet led to any breakthroughs in physics, and maybe they never will. But, historically, looking for new ways of exploiting symmetry principles has been very fruitful, I don't you think you need to be a wild-eyed optimist to suspect this might still lead somewhere interesting.

And, it's not like there are a lot of other ideas out there which are working out…

18. **Chris W.**
October 20, 2009

I think one can make a strong case that the asserted symmetries that have been most fruitful are those that express a *principle of indifference or non-observability*, for which empirical support was already in hand. Special relativity is the obvious case in point.

Asserting that "nature loves mathematical symmetry" strikes me as simply missing the point, and research programs based on such an assumption are likely to get lost in a mathematical labyrinth. Of course, if one loves mathematical structure for its own sake, one may not care to escape from that labyrinth. [🙂]

19. **Eric Habegger**
October 20, 2009

Peter, you said,
"In his comments at the end of this talk, Weinberg mentions that he is working on asymptotic safety, but says 'I still find string theory more attractive'. In any case, I think, as shown in this talk, Weinberg is careful to keep in mind the distinction between what is solid science, with real evidence behind it, and what is highly speculative, and thus likely to be wrong. And all explanations of the size of the CC now available are in the latter category, no matter which of them is your favorite."

It seems to me your observation that his work on the reason for the value of the small CC is probably wrong is somewhat misleading. For one thing it ignores the fact that there is a vital difference between the CC being small and "zero" which was assumed until 10 years ago. The CC is now simply small and the current estimate is about 0.7
.

Much of the work in particle physics, including the SM assumed a zero CC, though it wasn't really part of the SM. This new value of the CC really does require a rethinking of physics and I think it really is a gross exageration to just minimize it and say asymtotic safety "still" has nothing to do with it. When Stephen Weinberg says he finds string theory more satisfying than this new direction, to me it just means he would rather have not had the CC turn out to be non-zero. But now that it is new directions are required because the facts have changed. That doesn't mean he wouldn't have preferred the previous fact, i.e. the CC = 0, to still be in force.

20. **Peter Woit**
October 20, 2009

Eric,

I see no reason to believe that Weinberg's preference for string theory over asymptotic safety as an explanation for quantum gravity has anything to do with the CC. In any case, he explicitly says that string theory, while better than known alternatives, is not attractive enough an idea to be convincing.

The point I was trying to make is that Weinberg, unlike an increasingly large number of people in theoretical physics, understands very clearly the difference between solid ideas which we have good reason to believe are true, and highly speculative ones that are probably wrong. He was carefully avoiding going on about the latter to this group of journalists.

Chris W.

Sorry, but that's just not true. Most uses of symmetry principles in physics involve using the symmetry group to decompose states into non-trivial representations of the group. The action of the symmetry group is very much observable.

Actually, most well-known observables in QM are the infinitesimal generators of symmetry group actions on states (momentum, angular momentum, charge). Non-observability is only relevant in the case of local gauge symmetry, where you expect states to transform trivially (although even in this case, the situation is much more complicated).

21. **Christine Dantas**
October 21, 2009

Eric Habegger wrote:

It seems to me your observation that his work on the reason for the value of the small CC is probably wrong is somewhat misleading. For one thing it ignores the fact that there is a vital difference between the CC being small and "zero" which was assumed until 10 years ago. The CC is now simply small and the current estimate is about 0.7.

To be more precise: observations require, apart from the usual radiation, baryonic and dark matter components, a "dark energy" component, which in dimensionless terms requires a energy density of 0.7 (relative to the critical energy density). One can treat it as a fluid and see that it leads to a "repulsive" gravitational effect. There are several possibilities for this effect. In one of them, usually regarded as the simplest one, is not a fluid, but the cosmological constant. In this case, the theory introduces a length scale related to the dark energy density. There is a dimensionless combination of that length scale, G, c and the Plank constant, and it is this dimensionless combination that is required (observationally) to be of the order 10^{-123}. What people believed previously was, despite of being a puzzling fact per se, that this dimensionless combination was exactly zero. However, what current observations require is that this number is today extremely small in fact, but not zero. This requires a big fine tuning and consequently a big problem to solve.

22. **Christine Dantas**
October 21, 2009

To sum up my previous comment: to begin with, for many decades, the cosmological constant was thought to be exactly zero (although no one had an explanation for that), then came observations leading to a large energy density component, to which several explanations have been offered. The cosmological constant came as one of them, but then it introduces a natural dimensionless combination which is extremely small.

23. **Physicsphile**
October 21, 2009

Christine,

If you want some other source for the dark energy, you still have to explain why the cosmological constant is then zero as vacuum fluctuations and phase transitions imply it should be 10^{many} orders higher. The nice thing about the multiverse/landscape (not necessarily string) explanation is it kills these two birds with one stone. But I do agree with Peter that with our present state of knowledge it is still not a testable explanation. Never the less it is the only one available so I think it shouldn't be treated as irrelevant.

24. **Christine Dantas**
October 21, 2009

Physicsphile,

I agree that if for some reason the dark energy problem "goes away" (whether observationally or by some alternative well-tested explanation not involving the CC) , it is clear that it will still be necessary to understand why the CC is zero. This problem existed before the dark energy problem, and may be independent of it.

As I see it, the CC problem must be explained through quantum gravity; classically the CC can be gauged away, this tells something. I do not think that the multiverse/landscape solves the problem. Conceptually, many more problems arise than vanish. You are entitled to disagree on this.

25. **Peter Woit**
October 21, 2009

Please enough about the CC. This has nothing to do with Weinberg's talk, where he didn't mention this topic at all, for good reason…

26. **Christine**
October 21, 2009

Peter,

Just a suggestion, but of course you run your blog as you find correct. If you thought that the CC was off-topic, why have you not cut the matter from the very root? I thought it was reasonable to make a few clarifications about someone else's comment about the CC, so I took my time to write here, feeling that it was a constructive thing to do. It's not the first time that this happens. I know this is difficult to manage, since I have a blog myself. But at the same time it is hard to receive a "enough of this!" at one's face, when one is just trying to be constructive on a matter *already* accepted and published in the comment's section.

27. **Peter Woit**
October 21, 2009

Hi Christine,

I wasn't criticizing your clarifications, I just wanted to discourage other people from pursuing this topic further here.

It's natural for a discussion to evolve away from the original topic, but I really want to stop comment threads here from evolving into a general physics discussion board, unrelated to the postings. The main reason for this is simply that moderating such discussions is difficult, time-consuming and unrewarding work, something I don't have the time or interest to be doing. It's hard enough to figure out how to sensibly moderate comments that are on-topic…

28. **Marcus**
October 21, 2009

I think it would be a good idea to focus on what SW actually said, and not try to mindread about what he does or does not "still believe". The discussion has been interesting, especially Christine's comment, but we could waste our opportunity to learn, if we don't pay adequate attention to the actual soundbites. Some are just repeats of what we've heard before, but others could indicate a shift of perspective or a change in the zeitgeist weather.

Here are some essential snippets, some oldish, some newish:
==excerpts==
It's developed mathematically, but not to the point where there is any one theory, …

… although in a sense the theorists think there is only one theory, there are an infinite number of approximate solutions of it and we don't know which one corresponds to our world.

… in a large variety of the solutions of superstring theory there is supersymmetry visible at low energies, and if we see supersymmetry at low energies, superstring theorists may be able to derive from it some kind of clue …

… I don't see how that would work, it would be.. I mean I couldn't say that that was likely with any degree of sincerity, …

I myself, well I was working on superstring theory in the 80s and gave it up because I… I moved into cosmology, which in the last couple of decades has had the excitement that elementary particle physics had in the 60s and 70s, a wonderful coming together of theory and observation…

… My own work very recently has been trying to develop an alternative to superstring theory as a way of making sense out of quantum gravity at very high energies. But even though I'm working on this I still find superstring theory more attractive, but not attractive enough…
==endquote==

What mainly impresses me is a certain earthy openness, he's willing to expose his hunches—feelings about what is exciting now (why cosmology rather than particle physics) and what is likely or not likely (deriving clue-help for string from appearance of susy at low energy).

29. **j.**
October 22, 2009

Physicists Calculate Alternative Universes

October 22, 2009
Categories: Multiverse Mania

According to a story in the Stanford Daily, the recent arXiv preprint mentioned here and discussed many other places on the web has given us two new scientific celebrities:

> Two of Stanford's physicists, Professor Andrei Linde and postdoctoral researcher Vitaly Vanchurin, have garnered recent celebrity-status in the scientific community for their recent discovery of the maximum number of alternate universes.

Instead of consulting experts in this field and getting quotes about how significant this pseudo-science is, the writer asks Stanford students, who do a much better job than the experts:

> "I personally find the concept intriguing, but I think we should be wary of scientists who can use it as a way to write things off and stop looking for deeper answers to physical phenomena," Lauren Janas '12 said…
>
> Some Stanford students are not entirely convinced of Vanchurin and Linde's complicated methods.
>
> "I'm quite skeptical," Frank Liu '13 said. "I think it's hard to tell how many universes there exactly are."

The story ends with the mystifying news that the authors hope "that in the future, they can work with modular observations to confirm their findings."

For more media coverage of the multiverse, see here.

Update: Oops, last link was broken, now fixed.

Comments

1. **The Vlad**
   October 22, 2009

   Well, I'm no physicist, but as a computational neuroscientist, I find the following part of the article offensive:

   Linde stressed that their estimate may not be comprehensible to the human brain.

   "Our brain is the final computer to which all the data about the universe is going," she said.

   Linde estimates that the brain's limit to how many alternate states can be processes is 10^10^16, far less than10^10^10^7.

   "If we concentrate on the information our brain can acquire, we're going from real physics to a little bit more philosophical issues," Vanchurin said.

2. **Yatima**
   October 22, 2009

   No need to be offended I would say. It just doesn't make any sense. The article's quotes look like they were cut & pasted by someone with ADHD.

   Still, the incongruous citation of "the number of brain states" makes me suspect that there are Boltzmann Brains involved. Somehow.

3. **Chris W.**
   October 22, 2009

   Meanwhile, Steve Hsu throws a bone to anthropism.

4. **Yatima**
   October 23, 2009

   >>Meanwhile, Steve Hsu throws a bone to anthropism.

   Nice. A whole library of rather well-grounded reasoning about why life should not be improbably at all (starting with Dysons' Origin of Life and ending with modern analysis of genetic algorithms) is thrown out of the window in a handwaving blogpost which also cites Gödel who apparently was caught momentarily under the delusion that life evolves in an environment in thermodynamic equilibrium.

   I want to not believe.

5. **Bob Levine**
   October 23, 2009

   "A whole library of rather well-grounded reasoning about why life should not be improbably at all (starting with Dysons' Origin of Life and ending with modern analysis of genetic algorithms) is thrown out of the window in a handwaving blogpost which also cites Gödel who apparently was caught momentarily under the delusion that life evolves in an environment in thermodynamic equilibrium."

   This is yet another instance of the dark side of The (Internet) Force. Hsu's piece is at best a series of shallow connections fired off in thinking-aloud mode, based in part on the assumption that Gödel's authority based on his consistency/completeness theorems for formal systems gave him some kind of authority in evolutionary biophysics. The Gödel metric notwithstanding, his unsupported assertions on the physics of life strikes me as being kind of on the same level as Hsu's own stream-of-consciousness text. Someone will turn 'cite' Hsu in support of some other bit of dubious semi-science, which will be embedded in yet more vague nonsense, and so it goes.

   This kind of public venting of what is in most cases half-baked speculation that couldn't get to first base against even casual peer review makes the use of the Internet very dodgy for people who have no particular expertise or experience in whatever branch of science is involved. I'll bet Hsu is a lot more careful when preparing his work for that kind of review at, say, Physical Review Letters, but on his blog he can let his hair down and indulge in what is, in polite terms, cocktail party chit-chat. A lot of the public, trawling for information on the internet, probably can't tell the difference. Watch for Hsu's comments to be mirrored endlessly in the creationist blogsphere till hell freezed over by people who are under the impression that his and Gödel's comments constitute actual support for ID.

6. **Tim vB**
October 23, 2009

Did you cry or did you laugh when you read the article? Couldn't make up my mind yet, but I think the quote
"I think it's hard to tell how many universes there exactly are."
would be a good starting point for any Monty Python scene.
How about: Mr. X gained celebrity status by calculating the number of whoffels in the multiverse, "it is probably a prime number" he stated, and conjectured that gaining more insight would probably require to work harder.
Anyone interested to write an article about that?

7. **Christine Dantas**
October 23, 2009

Dantas' Axiom: the number of alternate universes is exactly zero.

In strange times, some people may find what is self-evident as shocking. Now *that* must turn me into a celebrity.

8. **Stephen**
October 23, 2009

It is sad how much Linde has gone away from real physics into wild speculation.

I also point out some sentences:

"Linde describes this as the most accepted theory regarding the creation of the universe."

— inflation is not "creating" any universe, it is just a period of very fast expansion

"Even though the universe is generally infinite in the mathematical sense"

— who told them this? God? or some observation?

"If we concentrate on the information our brain can acquire, we're going from real physics to a little bit more philosophical issues,"

— from real physics?!?

9. **Bob Levine**
October 23, 2009

'"If we concentrate on the information our brain can acquire, we're going from real physics to a little bit more philosophical issues,"

– from real physics?!?'

I know… it's scary, really. When people start talking this way, showing how much they're presupposing, without question or even pro forma caution, whatever pistache of strange assumptions and a priori is current in their hermetically insulated research communities, you start wondering how long science will be able to maintain the credibility it took so many centuries to earn. What the social theory hacks were unable to do, real scientist may well wind up doing to themselves.

Sabine Hossenfelder, in her Blog, has made the case that it's not necessarily the best thing for science to be conducted totally out in the open, so that every single step from initial hunch to decisively confirmed (or not!) prediction is available for public consumption/comment/kibbitzing and so on. I think Linde and Vanchurin would have done *much* better taking her cautions to heart before going public with this stuff…

10. **Arrow**
October 23, 2009

It's amazing that such speculative nonsense actually passes of as physics.

Their absurd statements about human brain are especially appalling, the capacity of human brain would have nothing to do with the "number of universes" even if the latter made any sense. Why do they compare the "states which a brain can handle" with the supposed number of universes? What are they trying to say that each "state of the brain" can somehow represent or comprehend one universe?! This is absurd.

Multiverse idea is dealt with by Ockham Razor.

11. **ObsessiveMathsFreak**
October 23, 2009

A 12 and a 13 year old showing better critical thinking skills than the majority of the theoretical physics community? I think it's time for everyone to take a step back.

12. **neo**
October 23, 2009

"most accepted theory", "popular theory"

It is settled then. We can decide on how many universes there are simply by voting on it.

13. **Peter Woit**
October 23, 2009

OMF,

Those indicate the graduation date of the Stanford students interviewed (2012, 2013), not their ages.

14. **Aristarchus**
October 23, 2009

The so-called reporting I have seen from college students in their local papers who one day hope to become professional journalists concerns me deeply.

So many of them are communications majors who know little about science and it shows. Apparently doing some homework when writing up a story is passé these days.

15. **Peter Woit**
October 23, 2009

Aristarchus,

The young journalist here did a better job than many professionals in terms of coming up with people who could give a sensible response to this particular bit of multiverse mania. The problem with these stories is not the journalist, but the activities of members of the scientific establishment that the journalists are reporting on.

16. **Bob Levine**
October 23, 2009

"The problem with these stories is not the journalist, but the activities of members of the scientific establishment that the journalists are reporting on."

So the question is, *why* are these established scientists doing this sort of thing?

A number of Peter's recent blogposts bear all seem to bear on this question. We have prominent physicists writing about backwards causality mediated by Higgs bosons (talk about a 'God particle'!), exact calculations of bounds on the number of alternative universes… someone has too much time on their hands, is what it looks like. And we all know the reason for that: no new data, no real anomalies to explain, nothing to compute on and get either a match with theory or a discrepancy. The Devil makes work for idle hands… or, another way to look at is is the way people in acquatic isolation tanks, in full sensory deprivation experiments, start to hallucinate. The senses need input and stimulation; if they can't get the real thing, some people think, they'll generate their own spurious signals just to have something to process.

Which is why people like Weinberg have switched fields, in effect, to cosmology. There's actual data there, there are observed effect that need explaining and bear on theoretical models. As long as particle physics lacks something comparable, they'll hallucinate landscapes and backwards causality and all sorts of wondrous things. Please, *please*, let the LHC finally come on stream, and stay there…

17. **Peter Woit**
October 23, 2009

Bob,

Problem is, it's the cosmologists as much if not more than the particle physicists who are hallucinating (Linde, Vanchurin are cosmologists, and the only person who seems to take Nielsen-Ninomiya seriously is a cosmologist…).

18. **changcho**
October 23, 2009

So this is what passes for Physics at Stanford nowadays. Ah, and also the Landscape of course…

19. **Bob Levine**
October 23, 2009

"Problem is, it's the cosmologists as much if not more than the particle physicists who are hallucinating (Linde, Vanchurin are cosmologists, and the only person who seems to take Nielsen-Ninomiya seriously is a cosmologist…)"

Yes… maybe the whole culture of the field has been contaminated by the data-shortage-induced crisis in high energy physics? For several generations, that's the branch of the field that been the flagship of the physics enterprise; if hep starts chasing white rabbits, maybe other theoretically inclined branches are tempted to join in the pursuit?

20. **Tim vB**
October 24, 2009

@Bob Levine
"… no new data, no real anomalies to explain, nothing to compute on and get either a match with theory or a discrepancy."
There are many open problems in hep and cosmology you can work on without engaging in highly speculative ideas with no hope to ever make contact to experiment. That is why I cannot understand why anyone would sit down and try to calculate something like the number of universes in the multiverse. If asked why they did this Linde and Vanchurin will probably not answer "we were bored" or something similar – would be nice if someone at Stanford asked them, I would be interested in the result 🙂
With regard to the Family guy episode: This is hardly new, the whole series Sliders was built on this concept and there are even Star Treck episodes (original series as well as Next Generation) about the existence of multiple universes. Try to calculate what string theory says about the warp drive or quantum torpedoes, that would be slightly more original. ("String theory predicts the warp drive? Bah, LQG predicts the trans worp drive, bruhaha!").

21. **Tim vB**
October 24, 2009

Hello Peter,
Off topic:
there is an interview with Michael Green here:
http://www.guardian.co.uk/theguardian/2009/oct/24/michael-green-new-lucasian-professor
(How do I post a link? Do I just enter the href HTML-Node?).
It is completly unremarkable, at least to me, with the notable exception that Green tells us his opinion about the critics of string theory:
cit. begin:
"Woit [Peter Woit, author of Not Even Wrong: The Failure of String Theory and the Search for Unity in Physical Law] is a blogger – he runs an anti-strings blog, he's an ex-physicist, a PhD I think. He's at Columbia – a systems manager or something [he also teaches mathematics]. So he's not a professional physicist. He has strong views about string theory, which he's entitled to, and he blogs them. And good for him.
"The other one [Smolin] is a physicist who has a view of physics other than string theory and wants to promote that. And the media made a big song and dance about this, which seemed to me to be completely off-scale with what we experience anywhere in any university. The subject's thriving."
cit. end
What good does it do Green (or Susskind or anyone else) to tell people that Peter is a "computer programmer" or "systems manager"?
You probably need to pass some specific initiation ceremony to be entitled to have an opinion about string theory, a Ph.D. in particle physics is not enough.

22. **teaser**
October 24, 2009

Does anybody know how many epicycles were needed to make the Earth-centered solar system match observation? I guess it would make sense that to account for all of the alternate universes, one would need a much bigger number of epicycles than what we used for the solar system.

23. **Thomas Larsson**
October 24, 2009

Mainstream medieval science was up to 13 epicycles when Kepler tried ellipses. However, epicycle theory, with any number of cycles, only works if planets move in closed orbits, which is only approximately true.

24. **Bob Levine**
October 24, 2009

"There are many open problems in hep and cosmology you can work on without engaging in highly speculative ideas with no hope to ever make contact to experiment."

Tim—that's true without any question. But my guess is, it's the TOE which has been promoted as the Holy Grail of physics, and the burning goal of a generation of physicists who have, from what I can tell, believed that such a theory was just a little bit out of their grasp. A genuine TOE, a theory that worked, from which all of the observed forces of nature would in effect fall out as theorems, would constitute the single most important result ever in science—I can't really see any argument on that point—and, conversely, success in any 'lesser' project—what used to be called normal science—just can't begin to have the glamour of grand unification, the 'final theory', however persuasive such results might be in terms of goodness of fit with experiment.

That kind of thinking is bound to have a distorting effect on the climate of opinion in any collective activity. And the result is that for a lot of physicists, switching research activities to something perceived as being less absolutely fundamental would be a come-down of sorts, an admission of failure…

25. **Aristarchus**
October 27, 2009

Hawking says there were an infinite number of quantum beginnings:

http://www.dailygalaxy.com/my_weblog/2009/10/were-there-an-infinite-number-of-quantum-beginnings-stephen-hawking-says-yes.html

And who is going to argue with him?

26. **Nigel Cook**
October 29, 2009

"Mainstream medieval science was up to 13 epicycles when Kepler tried ellipses. However, epicycle theory, with any number of cycles, only works if planets move in closed orbits, which is only approximately true."

Arthur Koestler's 1959 "The Sleepwalkers: A History of Man's Changing Vision of the Universe" actually counted the epicycles up and found 40 in Ptolemy's Earth-centred-system in his "Almagest" of 150 A.D., versus 80 in Copernicus's solar system of 1500 A.D. (which used circular orbits with epicycles instead of ellipses like Kepler). This was contrary to the prevailing history of science, which insisted that Copernicus was accepted on the basis of Occam's Razon due to having the fewer epicycles than Ptolemy. Actually sometimes more complex theories are closer to nature and there were different reasons why Copernicus was preferred. (Viz: Mercury and Venus are always observed from Earth to be on a bearing within 90 degrees of the position of the sun, a fact which is explained very simply in the solar system model by Mercury and Venus having orbits closer in to the sun than the Earth's orbit. Additionally, the apparent size of the Moon seen from Earth in Ptolemy's model should vary by a factor of two monthly due to its epicycles, when in fact it doesn't appear to vary in size. Copernicus's more complex model was preferred because it didn't modelled nature right, not because it was the simplest.)

Master of the Universe

October 24, 2009
Categories: Uncategorized

A couple days ago I got an odd phone call, from a reporter at the Guardian, asking me to comment on the appointment of Michael Green as Lucasian Professor at Cambridge. I told the reporter that I wasn't a really appropriate person to be asking; for one thing I've never met him personally. I did say that from what I knew of his scientific career, he was a quite good choice. He and John Schwarz made great progress in understanding string theory, working on it at a time that this was a very unpopular thing to do. In my view much of the problem with particle theory the past 25 years has to do with the lack of sufficient talented people willing and able to work on the kind of unpopular research that Green and Schwarz took up.

Several people have now pointed out to me the new story in the Guardian, [Michael Green: Master of the Universe], which makes clear the reason for that phone call (although none of my comments made it into the story). There's the usual hype about string theory: "the subject's thriving", and the latest news is that it may lead to better understanding of high temperature superconductors and thus help solve the world's energy problems. In a sidebar, the claim is made that:

> The Large Hadron Collider, at Cern, could provide evidence for the theory by analysing the collisions of fundamental particles at high energies.

although Green admits:

> …that really is wildly optimistic, and I suspect that's not going to happen.

Green deals with criticism of string theory with a laugh and ad hominem attacks on Lee Smolin and me as "two particular people who don't have any particular reason to be knowledgeable about the subject." As for the idea that it might be a good idea for people to look for alternatives to string theory (much the way he and Schwarz worked in the early 80s), his comment is "But there *is* nothing else."

Green seems to be not completely sure I have a Ph.D. For those interested in the question of my qualifications, there's an old blog entry [here]. It should perhaps be updated to note that, while I'm still responsible for the Math department computer system, I no longer have the odd title of "Director of Instruction", but was moved to a non-tenured faculty position as "Lecturer". Recently I was promoted to the position of "Senior Lecturer", still non-tenured, but with a long-term contract.

I wish Green the best with his promotion.

Comments

1. **Marcus**
   October 24, 2009

   Congratulations on your appointment to the Senior Lecturer position!

2. **Marcus**
   October 24, 2009

   A propos the interview in the Guardian, someone mentioned that MG is 63 and the Lucasian retirement age is 67. So it seems we can look forward to four year of ex cathedra pronouncements such as "The subject's thriving," and "There is nothing else." 🙂

3. **Peter Morgan**
   October 24, 2009

   Thanks for the link to the old description of your academic life. Congratulations also on your new appointment.

4. **Sebastian Thaler**
   October 24, 2009

   Apparently class is not a job requirement for the Lucasian Professorship.

5. **Jas**
   October 24, 2009

   I am following your blog for a while now. I am an Undergrad. student.
   It appears that particle physics is dying. But tell me about yours opinion on loop gravity. Thats I guess producing few good results.

6. **C.K.**
   October 24, 2009

   @Jas

   John Baez in week280 of his This Week Finds summes most recent developments in LQG and related theories. The summary is that everything was plagued with problems of different, but equally profound kind like the Strings, but was recently successfully started from scratch. That also means theory is still undeveloped stub.

   I thus think Green may be right saying there is nothing else, in a sense that alternatives are so undeveloped as to not even mimic working. LQG, despite 20 years of development is far from including Standard Model, and Causal Dynamical Triangulations are far from including anything at all, presently being just a very profound and nice, but only curiosity.

7. **James**
   October 24, 2009

   Peter, the interview shaws that Green has no dignity. Green criticizes you because you say (more or less) that
   (1) "string theory is wrong because it has no relation to experiment" Tthis is deeply dishonest.
   (2) "you have no knowledge of the subject"; this comment shows what string theory really is: the belief of a sect.

   Peter, I counted a handful of Nobel Prize winners in particle physics who say the same what you say. And I count only one (Gell-Mann) who promotes it a little. But that is the same Gell-Mann who said that "Bohr brainwashed a whole generation of physicists that quantum theory has no problems." A handful of serious people against one crazy old man. Nobelists thus have clearly spoken out against string theory. Nobody dares to attack them. Instead, string theorists attack you. You will see: the LHC will put string theory aside as a wrong theory. Green's appointment is the swan song of string theory; please be strong and be patient.

8. **C.K.**
October 24, 2009

What Green says is not much arrogant compared to what you people here put on his lips, and downright nothing next to how you attack him for it.

@James

Peter on numerous occasions described why LHC won't settle issue of validity of String Theory. That means it will not be decisively disproved. And as long as nothing else will show up, people will do strings.

Appointment of Green underlines this. On the one hand it is deserved reward for the man's work and there was surely noone else in Cambridge more adequate to take the post. On the other, it is also convenient temporary solution for Cambridge.

9. **theoreticalminimum**
October 24, 2009

I think one important thing to take from this interview is the way Green and Schwarz were spending their time, "more leisurely", thinking about the problems they were faced with. It seems like they enjoyed a long quiet time span of relatively relaxed collaboration without the pressure of publishing, and could think hard about certain problems. I think this leisurely and periodically thought-intensive method of working is what is sorely lacking today in high-energy theoretical physics. Big problems have been solved in mathematics by people who spent about a decade working on these problems, e.g. Wiles and Perelman. There are no such examples that I know of in theoretical physics. Of course, theoretical physics and mathematics are very different fields of intellectual endeavour (even though they are intricately related in many ways, more so now that ever before), but I think this raises an important question (one, of course, which has been raised many times by many people, e.g. you Peter, L. Smolin, A. Connes, to name the few I have heard voicing their concern about this state of affairs), which is the following: are we spending enough time thinking about specific problems? Many problems in physics are hard to define as in mathematics, but I know there are many others which are really well-defined and precisely framed in mathematical physics. Are there people spending enough time looking at these problems? Poincaré and Hadamard have written about the psychology of discovery in mathematics, and I wonder what they would have said if they were alive to witness the pace of things in research in theoretical physics, and more specifically string theory, today.

10. **Roger**
October 24, 2009

Peter, have any string theorists like Green addressed what you actually say in your book?

11. **Anon**
October 24, 2009

Another thing to take away from this interview is to be very careful when speaking with a reporter. I imagine Green regrets this comment. It's the sort of snarky comment I can see making to a colleague as a semi-joke but would be embarassed to see repeated in public. (Perhaps one shouldn't make such comments in the first place.)

12. **Peter Woit**
October 24, 2009

Roger,

There's a review written by a post-doc (Aaron Bergman), and a few comments in a review by Joe Polchinski, but that's about all I can think of in terms of serious responses from string theorists.

13. **Peter Woit**
October 24, 2009

Anon,

Perhaps you're right. I suspect that if I'd had something unpleasant to say about Green to the reporter, then I might have been quoted…

14. **Thomas Larsson**
October 25, 2009

James:

Of the living theoretical particle Nobels, David Gross is the only one who is a leading string theorist, and a string proselyzer. Perhaps you can say that he is in string theory what H A Lorentz was in ether theory.

Gell-Mann, Weinberg, and perhaps Wilczek are (or have been) pro-string, but do not actively pursue the subject. This also goes for David Politzer, but he does not really count.

Glashow and Veltmann appear hostile to string theory.

What 't Hooft and Ken Wilson think is anybody's guess.

15. **Thomas Larsson**
October 25, 2009

And then I forgot that last years Nobel prize went to particle theory. Nambu was working early string theory in the 1960s, I think.

16. **ettore**
October 25, 2009

In regards to t'Hooft, this is what he said ten years ago, when he received the Nobel (you can check it in the Nobel site, in his autobiography)

"In 1984, the superstring revolution took place. Many of my colleagucs were enchanted by the coherence of the mathematical structures they saw in this theory. Would this not be exactly what we are looking for, a new paradigm that naturally generates the gravitational force and an apparent complete unification of all interactions?

But to me, superstring theories presented as many new problems as they may solve; I still cannot quite fathom the fundamental logical coherence of these ideas. The short distance structure is as mysterious as it was before and the predictive power of these theories was disappointing, to put it mildly."

17. **Peter Woit**
October 25, 2009

Thomas,

I don't think it's accurate to say that Wilczek is or has been "pro-string". He has been careful to avoid entering into this controversy. I've never seen anythng anywhere about Politzer's views on the topic.

18. **observer**
October 25, 2009

Take ll this with a grain of salt. First, professor Green Is at 3 or four years from retirement (due to age). So most probably they are giving him the Lucasian Chair as a farewell present.

19. **capitalistimperialistpig**
October 25, 2009

I'm not sure how leisurely Schwarz and Green were able to be. This was a time when early string theorists like Ramond were being dumped by top departments. Schwarz hung on because Gell-Mann insisted, or so G-M claims.

20. **Thomas Larsson**
October 26, 2009

One of the benefits of living in Stockholm is that one can attend the Nobel lectures. My impression of Politzer's views are based on what he said at that occasion, although I don't remember any details.

21. **Anonymous Undergrad**
October 26, 2009

Hi Peter,

[This is somewhat off-topic, but I'd like to inquire about your perspective/s on studying gauge theory as an uninitiated undergrad.

…

– Any words of advice?
– Any specific title/s that come most readily to mind, (e.g. 'The Geometry of Physics', 'Topology, Geometry, and Gauge Fields: Foundations', etc.)?]

Regards,
Anonymous Undergrad

22. **Chris Oakley**
October 26, 2009

Appointing a 63-year-old to a professorship that has traditionally been given to relatively young people indicates to me that there was no obvious (relatively) young person to give the job to. Green would certainly have to take his share of the blame for that, being partly responsible, at least indirectly, for making it impossible for young scientists to work on anything other than the blind alley of String Theory.

23. **Tim vB**
October 26, 2009

@Anonymous Undergrad:

If you would allow me to offer my opinion 🙂
Have a look at John Beaz' blog:
http://math.ucr.edu/home/baez/FUN.html#general_physics
(note the item "books" under Miscellaneaous Fun Stuff).
As an undergraduate interested in theoretical physics you should definitely read Naber: „ Topology, Geometry, and Gauge Fields" (both volumes, Foundations and Interactions). But do that after you had an introduction to quantum mechanics, quantum field theory and differential geometry.

24. **Kris Krogh**
October 26, 2009

Hi Thomas,

The Nobel lectures are on-line. Politzer's is here:

http://nobelprize.org/nobel_prizes/physics/laureates/2004/politzer-lecture.html

On string theory there is only this:

The realm of the conjectured "unification" of the forces of the Standard model, the realm of their possible unification with gravity, and the basic physics of String Theory, the most widely pursued approach to a physics more fundamental than the Standard Model, are all more than a dozen orders of magnitude further away.

25. **Anonymous Grad Student**
October 27, 2009

My impression is that Politzer doesn't much care either way. Last time I talked to him, he was much more interested in Biology anyway. He will however be taking part in the following event in Pasadena tomorrow evening, if anyone in SoCal is interested in hearing his opinions.

`At 7 p.m. on October 28, science writer K.C. Cole will engage in a discussion of the creation of ideas and the sources of inspiration for the next generation of physicists with Nobel Laureate David Politzer, Caltech's Tolman Professor of Theoretical Physics. The event will take place in Hameetman Auditorium, in Caltech's new Cahill Center for Astronomy and Astrophysics.'

26. **Chris W.**
October 27, 2009

Here is the official announcement on the Caltech events site.

27. **Tim vB**
October 29, 2009

Isn't the following statement of Green from the interview worthy to be cited in the main blog entry?
cit.:
Furthermore, string theory, Green contends, "isn't simply something that will, once tested, be either verified or disproved. It's become much more than that".

28. **Allan**
November 8, 2009

Let me run a few words from a post above through the time machine:

"The Lorentz transform so far from including anything at all, presently being very nice, but only curiosity."

I don't always agree with Peter, in general, about the lockstep interplay of experiment and theory. It's a wonderful conjunction when it happens, but just as often, physics enters a wilderness period where the two fail to cross-pollinate until someone brilliant comes along. I suspect the present challenge is not how to best return to the road, but instead how to best thrive in the wilderness until a new road forward emerges.

On one hand, if the available formalisms restrict the potential solution space, you're crazy not to investigate this, regardless of a short term disconnect with experimental corroboration. (Careerist calculations aside, the short term could be fifty years when you're recently passed a road sign lettered "Nirvana 10^70".)

For string theory, initially the formalism had the appearance of a constrained solution: "hey, it only works in 10 dimensions!" Twenty years later we've added the footnote: "but with perhaps in excess of 10^500 solutions". This field has been tilled vigorously for a generation, maybe it's time to let this particular field lie fallow for a while. Worth doing, but not at warp speed, with the foot of the public treasury pumping the accelerator.

It won't surprise me if an insight derived from the formalisms provides an essential clue to the path forward; nor will it surprise me that the path forward turns out not to be string theory itself. The question is not whether string theory is the final answer, but it's prognosis as a useful (or even essential) stepping stone to whatever comes next. Depends on whether this wilderness can be circumvented, or not. I think not.

A problem for physics during its wilderness periods is that its innate immunity to institutionalism breaks down. Physics hasn't developed a strong social immunity to institutionalism, because when physics is going well, it doesn't need one: experiment wields the scythe.

Where string theorists are presently in denial is that after twenty years with little to show as corroboration, the program has now plunged deep in the heart of institutionalism. Physics–falsely in my opinion–prides itself on immunity from this, based on a few rapturous decades here and there. The occasional rapturous decade has earned physics a certain kind of immunity from public scrutiny despite large inputs of public funds. Like the bankers, there's an ingrained attitude among the endowed: let the good times roll.

Most egregious, in my view, are the monoculture apologists: string theory is all we've got, so we have no choice but to continue. When this kind of fungus sprouts up, I can understand an impassioned banging of the shoe on the podium demanding a return to experimental confirmation. Is that possible? Can we roll back time to the glorious sixties? Our drugs have become increasingly expensive. If CERN wasn't a great adventure in determining the largest machine we can almost build, would it have been funded on physics agenda alone?

Concerning the article, I was miffed by Aida Edemariam leaving out an essential paragraph after quoting the remark "The subject's thriving." Based on what criteria, Mr Green? That the jungle is now lusher, thicker, and more impenetrable than ever? That funds are flowing to the most expensive physics project in human history? That the profession has become so abstruse that nothing short of a brilliant, full time practitioner within the inner sanctum is qualified to venture an opinion on whether results obtained over the past two decades justify the cost and talent expended?

Linguistics went through the same expansionary bafflegab: many of the explanatory frameworks Chomsky put forward turned out to be Turing complete, which translates to unlimited horizons for graduate students to elaborate the unconvincing.

My question is this: what if it turns out that the only way forward is for physics to bunker down for a while and function as a social institution, without the luxury and glory of its former immune system? It seems wrong to have a man endowed with a prestigious chair whose insight into institutionalism doesn't seem to run any deeper than "we're successfully spending a lot of money and all our critics are twits who barely completed boot camp at the world's most famous universities".

There's nothing wrong with training smart people to confront the ardours of life at the edge of the jungle (harrumph: that word doesn't mean what I thought it meant) . Like the NASA program, physics has successfully spun off a fair amount of its futuristic gear to the benefit of other disciplines. Fair enough, whether or not physics beats its own jungle back anytime soon.

The unavoidable question becomes: if experiment ceases to wield the scythe, what social criteria must take its place? Who decides? It seems from Mr Green's perspective that the New York Yankees are the only game in town, having no credible competition. Meanwhile, the rapture of the molecular biologists is performing a few blocks down the street and there's actually a pennant at stake that means something.

Latest from the LHC

October 25, 2009
Categories: Experimental HEP News

This weekend successful tests of injection of a beam from the SPS into the LHC were performed. The beam only traveled through a few of the sectors before being dumped, since all sectors of the machine are not yet ready for beam commissioning.

A week or so ago the decision was made to start beam commissioning with the magnets only fully commissioned to 2kA. This means that the machine will be limited to operation at 1.1 TeV/beam this year. The current schedule has commissioning to 2kA finishing November 16, attempts to circulate 450 GeV beams starting November 23. On December 7, the beam energy would start to ramp up to 1.1 TeV. 1.1 TeV/beam collisions would start Dec. 14, with shutdown for Christmas/New Year's starting Dec. 16. This means that 2009 will not see physics collisions, but will perhaps see collisions at energies marginally higher than that of the Tevatron.

By the end of the year, 2 sectors will be commissioned to 6kA, the magnet current needed to run the machine for physics at 3.5 TeV/beam. The rest of the sectors will be commissioned to 6kA and the energy ramped up to 3.5 TeV/beam starting after the shutdown ends in January.

Update: Some more from the latest schedule. January 7 will be the start of recommissioning after the shutdown, and current plan is to have the machine ready for physics collisions at 3.5 TeV/beam by February 8.

Update: The date to begin beam commissioning again by circulating a beam in the LHC is now set for Friday November 20.

Comments

1. **Martin**
   October 26, 2009

   Hi Peter,

   do you know what the reason is for this further delay?

   Cheers,
   Martin

   PS Where do you think will the Higgs be found first: Tevatron or LHC?

2. **Peter Woit**
   October 26, 2009

   Martin,

   I believe the delay in getting all sectors commissioned to 6kA has to do with the new Quench Protection System.

   The Tevatron may rule out a larger range of Higgs masses, but it seems unlikely that, even if the Higgs is there, they'll have convincing evidence of its existence. That should require the LHC, and at least a couple more years.

3. **Coin**
   October 27, 2009

   This means that 2009 will not see physics collisions, but will perhaps see collisions at energies marginally higher than that of the Tevatron.

   Could the LHC uncover new things despite running at the same energy as the Tevatron simply due to higher luminosity?

4. **Peter Woit**
   October 27, 2009

   Coin,

   The LHC will only briefly be running at Tevatron energies, during the commissioning process on the way to 3.5 TeV/beam. During this period it will be running at extremely low luminosity, not in any way competitive with the Tevatron.

   By the way, I see that the NYT seems to have gotten the news about the plan to run at only 1.1 Tev/beam this year from somewhere…

   http://topics.blogs.nytimes.com/2009/10/27/the-cosmic-countdown-in-geneva-goes-on/

News from HEPAP

October 27, 2009
Categories: Experimental HEP News

Last week there was a meeting of HEPAP held in Washington, presentations are available here.

HEP has done very well recently in recent US federal government budgets, due to the stimulus and large deficit spending going on to fight the recession. The FY2010 DOE budget has been passed by Congress, and it includes $810 million for HEP (up 2% from $797 million in FY2009), and there is also $232 million in stimulus package money currently being spent on HEP. The FY2010 NSF budget has not yet made it through Congress, but the Administration request for NSF physics research is up by 9% from FY2009.

DOE is planning to keep running the Tevatron now at least through FY 2011, since it is likely to be competitive with the LHC in the Higgs search business at least that long. The current Fermilab long-term planned run schedule is here.

DOE will keep supporting ILC research through FY2012, but the plan to make a decision about building it at that time now seems to be off the table. The LHC will have just begun producing results, and the current estimates of the ILC cost are so high that making the case for it will be very difficult. A story in Science quotes William Brinkman, the head of DOE's Office of Science as saying:

> With all the contingencies, you're talking about $20 billion. In my opinion, that price pushes it way out into the future, and onto the backburner.

Funding for new high-energy accelerators is likely to mainly be devoted to participating in any upgrade of the LHC at CERN, and the Project X/muon collider proposals at Fermilab. There will be workshops at Fermilab next month to discuss Project X and the muon collider. Brinkman in his HEPAP talk notes that the HEP community will have to come up with a compelling scientific case for these projects, which will largely revolve around an expanded neutrino program.

There was also discussion of a report from PASAG (the Particle Astrophysics Assessment Group). For discussion of the issues surrounding proposed experiments relevant to particle astrophysics and cosmology, see stories from Eric Hand at Nature News here and here.

Comments

1. **Yatima**
   October 28, 2009

   Unfortunately, the long-term signs are not good. It is rather likely that recessions are not fought with (Keynesian) deficit spending but with (Austrian) hands-off management and the return to a "save&invest" mentality. The next ten or so will most probably be a period of stagflation. Once this becomes clear I hope DOE will not quickly revise its spending plans downwards. As for liberating 20 billion+ (an initial estimate?) for ILC, well, the SSC was killed at 12 billion in 1993 dollars (that's arund 18 billion USD in 2009), when the overall economic situation was actually far, far better. So, no.

2. **srp**
   November 3, 2009

   And still no money for early development research on advanced accelerator concepts. You guys need to learn about decision trees…

Short Mathematical Items

October 29, 2009
Categories: Uncategorized

- Riemann submitted his paper on the Riemann Hypothesis October 19, 1859, and it was read by Kummer at the meeting of the Berlin academy on November 3. AIM is organizing a celebration of the 150th birthday of the Riemann Hypothesis, with a "Riemann Hypothesis Day" on November 18th. Talks will be given on that day at many institutions around the world, a list is here.
- The Royal Society in Britain has announced the appointment of six "Royal Society 2010 Anniversary Research Professors". Two of them are mathematicians: Timothy Gowers, of Cambridge, and Andrew Wiles, who will be leaving Princeton to take up the position at Oxford. Wiles has this comment about his current research:

> Over the last several years my work has focused primarily on the Langlands Program a web of very influential conjectures linking number theory, algebraic geometry and the theory of automorphic forms. I am trying to develop arithmetic techniques that will, I hope, help to resolve some of the fundamental questions in this field. I am delighted to be appointed a Royal Society Research Professor in their anniversary year and I look forward to the opportunities this will give me to further my research.

- I spent a couple days earlier this week up in New Haven, attending a conference celebrating Gregg Zuckerman's 60th birthday. Zuckerman's specialty is representation theory, and he's well-known in that subject for several ideas that have been important in the modern understanding of infinite dimensional representations of semi-simple Lie groups. He also has done quite a bit of work in mathematical physics, work which includes a classic paper (Proc. Natl. Acad. Sci. U.S.A. 83 (1986), pp. 8442–8446) with his Yale collaborators Howard Garland and Igor Frenkel explaining some aspects of the BRST quantization of the string in terms of semi-infinite cohomology. As far as I know, he was the first person to study (in a 1986 paper "Action principles and global geometry") the field theory with Chern-Simons action that Witten was to make famous two years later when he worked out its significance as a TQFT giving interesting 3-manifold and knot invariants.
- An hour or so ago I went out for a walk, stopped at the bookstore, and noticed that there's a new book out about Grigori Perelman, entitled Perfect Rigor. It looks worth reading, perhaps they'll be a longer blog post about it sometime soon…

   October 29, 2009

   I see that slides can be downloaded for 3 out of the 18 talks given at the Group Representations conference you attended at Yale.
   http://www.liegroups.org/zuckerman/slides.html
   In particular Garrett Lisi's talk is one of those for which the slides are available.

2. **John Armstrong**
   October 29, 2009

   Unfortunately I couldn't be there for my advisor's conference. Unemployment is a harsh and forbidding landscape.

3. **Marcus**
   October 29, 2009

   J.A. I've read your blog and some of the comments re the current math job market. Sounds very tough–as if they are almost forcing pure math PhD's to go back for applied courses of some type. Sad you were unable to attend your advisor's 60th-birthday conference. Hope things improve soon.

4. **Sakura-chan**
   October 29, 2009

   I am going to order that Perelman book right away!

5. **Tim vB**
   October 30, 2009

   The anniversary of the Riemannian hypothesis should be celebrated with a lecture by Allain Connes in Göttingen, but it semms neither Connes nor Göttingen is involved in this? Too bad.
   Just re-read Riemanns original paper (in Edwards, "H. M. Riemann's Zeta Function"). As you all probably know already, what is called "Riemannian hypothesis" is only a remark in the paper, which is about the "number of primes less than a given magnitude". At the end of the paper Riemann compares his formula with the known number of primes smaller than 3 million! referencing the work of Gauss and Goldschmidt. Wow, they computed all primes lower than 3 million without a computer! (And he mentions that he himself tried to prove his hypothesis: "One would of course like to have a rigorous proof of this, but I have put aside the search for such a proof after some fleeting vain attemps, because it is not necessary for the immediate objective of my investigation". What would he have said if someone had told him that this would become one of the most popular open problems of the 21st century?).

Perfect Rigor

October 30, 2009
Categories: Book Reviews

I just finished reading author Masha Gessen's new book about Grigori Perelman, Perfect Rigor: A Genius and the Mathematical Breakthrough of the Century. It's a short but very well done account of the life of Grigori Perelman, how he came to prove the Poincare Conjecture, and what has transpired since.

The book is really not about mathematics, but about mathematicians and their culture, especially that of Russian mathematicians. Only one chapter deals with the mathematical content of the Poincare Conjecture, with the bulk of the book about Perelman and his career. Perelman's talent's were recognized early, and were nurtured in Leningrad by a system designed to train students for mathematical competitions. He won a gold medal at the International Mathematical Olympiad in 1982. The institutionalized anti-Semitism of the Soviet mathematics establishment of this period is described in detail in the book, together with the intense efforts made by Perelman's supporters (including Alexandrov) to overcome this. He did his graduate work at the most prestigious institution in Leningrad, and then went on to a research position there at the Steklov Institute.

Gessen never managed to interview Perelman himself, but did talk to many if not most of the mathematicians he interacted with. He was brought to Courant by the intervention of Gromov, and for a few years worked there, at Stony Brook and at Berkeley. By the end of this time, he had started to develop a significant reputation in the math community, but he chose to return to Steklov and pretty much dropped out of sight, communicating with very few people for several years. It was during this period that he developed his proof, finally posting what could be described as a detailed outline in a series of three papers submitted to the arXiv.

The story of what happened then is rather remarkable, but it's a story I'm pretty familiar with since I got to watch much of it from up close (Perelman's preprints and the question of whether he really had a proof were discussed intensively here at Columbia, where Richard Hamilton and John Morgan are among my colleagues, and quite a few other people work in this area). Gessen does a good job of telling this story, adding some details I was unaware of.

Perelman turned down the Fields medal awarded him for this work, and sadly, he seems in recent years to have cut himself off from even his closest friends in the math community. Indications are that he is no longer actively working on research mathematics. The book contains speculation from several mathematicians who know Perelman about his thought processes and the reasons for his behavior, but they remain somewhat of a mystery. Some amount of paranoia seems to be at work, together with an intense distaste for any sort of politics, even the most innocuous workings of the mathematical community and its institutions.

The last chapter of the book has some news I hadn't heard. Last year, Jim Carlson, who runs the Clay Mathematics Institute and is responsible for the process that will determine the award of the million-dollar Millennium prize for the proof of Poincare, traveled to St. Petersburg. He talked to Perelman on the phone, but Perelman refused to meet with him. According to the book, Clay was planning on convening a committee to decide on the prize this past May, with a report planned for August. Presumably this all has already happened by now, and perhaps Carlson has already made another trip to St. Petersburg in a last attempt to see if Perelman can be convinced to accept the prize. Perhaps we will be finding out the results soon…

Update: Today's Wall Street Journal has an article by Gessen about Russian mathematics that summarizes part of her book.

Comments

1. **Giotis**
   October 30, 2009

   The poor, lonely, eccentric genius who proves the Poincare conjecture, denies the Fields medal, the money, the honours and the whole world and disappears in oblivion.

   This is the stuff that legends and myths are made of.

2. **tst**
   October 31, 2009

   "This is the stuff that legends and myths are made of."

   And you think Perelman is unaware of that?

   The math he did is first rate, of course. But the drama adds nothing.

3. **milkshake**
   October 31, 2009

   tst: Its not a pose, he withdraws from things which he does not want to deal with. The unpleasant part of the drama was not his making anyway.

4. **Tom O'Bulls**
   October 31, 2009

   What finally happened re Yau and his legal case?

5. **ds**
   October 31, 2009

   Giotis: why do you think he is lonely? Some people can be quite happy on their own and even prefer it, and even choose it as a lifestyle.

   I find it infinitely irritating how the majority of people equate being alone with loneliness. Some people just aren't so shallow that they need constant stimulation and distraction from themselves in the form of others and things. They may restrict their attention to just a few people.

   Perhaps Perelman sees a corrupt institution before him and chooses not to participate. Maybe this should make us stop and think;; instead we just marginalize him and say he is a "poor, lonely genuis," which is saying don't take him seriously, he is brilliant in math, but that same brilliance makes him completely incompetent in social matters.

6. **ds**
   October 31, 2009

   tst:

   "And you think Perelman is unaware of that? "

Do you think he is really so petty as to be motivated by that? I don't think so. You see, this is another attempt at marginalization. Society, the norm, sees an individual who refuses to play by it's rules, and it tries to dismiss him, explain him away as mal-adjusted or petty. That way we don't have to think, we can just carry on as usual; in our petty competitive way, chasing prizes, positions at prestigious universities, and so on.

7. **ds**
   October 31, 2009

   i should just add at the end of the last sentence of my previous message: "or whatever particular aspect of our behavior Perelman may be repulsed by.."

   Sorry for the SPAM!

8. **Giotis**
   October 31, 2009

   ds, I was referring to the way the general public might perceive his life and not to his actual reality.
   In any case I don't give a negative tone to the word 'lonely'. The idea of the lonely hero is omnipresent in literature and in popular culture, captivating human minds throughout the centuries.

   But yes, you are right; a loner is not necessarily lonely although an old saying alleges that if someone lives all alone and doesn't feel loneliness, is either mad or god.

9. **Paul Titze**
   November 1, 2009

   Why not challenge Grigori with another mathematical challenge that's suited to his skills with an even bigger prize? He might be so enticed by it that he'll come out of the woodworks 🙂

   Paul.

10. **D R Lunsford**
    November 1, 2009

    Does any single person understand all the details of the P.C. proof?

    -drl

11. **Sakura-chan**
    November 1, 2009

    The claymath website continues to refer to it as a conjecture. I wonder when they'll dub it as a theorem.

12. **milkshake**
    November 1, 2009

    prizes are apparently not what he is after; maybe they should try to convince him to move to IAS

13. **Peter Woit**
    November 1, 2009

    milkshake,

    Perelman appears to have no interest in a position at the IAS (or anywhere else for that matter).

    Paul,

    He seems rather offended by the whole concept of the prize he already has just about won, I don't think another one would inspire him in any way.

    Sakura-chan,

    Perhaps the Clay web-site will be updated soon…

    drl,

    The mathematicians who wrote up detailed versions of the Perelman argument (Morgan-Tian, Cao-Zhu, Kleiner-Lott) presumably understand the full details, and so perhaps do other people who have read these documents and worked in this area. The Morgan-Tian book was especially carefully refereed, by several of the best mathematicians in the world (ever wonder why Terry Tao has given talks on the proof and written about it in his blog?). I don't know if these referees divided up the sections of the proof, or each of them went through the full thing.

    In any case, this proof now has been about as carefully examined as any.

14. **Christine Dantas**
    November 1, 2009

    If I may make a guess, I think that Perelman would accept a position as a teacher for the very young, smart children, still uncorrupted from "politics" that invades everything and everywhere from the adult world. Although such a position could be seen by many people as an absurd downgrade (teaching kids is usually regarded as a minor profession by society), I think that he would probably enjoy such a fresh air. This is something that I think he needs. And such a "reboot" would perhaps motivate him to return working in mathematical problems again and have his results published independently in the arxiv.

    He has shown clearly not to be motivated by prizes or fabulous positions at all.

15. **Gigel**
    November 1, 2009

    Why is everyone trying to "fix" him? So he can become yet another useful tool for humanity, since if you don't work for society, something must be clearly wrong with you? Maybe he plays world of warcraft all day and that's what he enjoys. Or maybe he's simply crazy. Why don't we just forcefully hospitalize him and make him better, stuff him with meds until he agrees to hold a position at IAS and maybe prove 2-3 more theorems, right? That would make US feel better about ourselves, seing how well our society is working like an ant farm. Well what if he doesn't give a crap about teaching or working in math anymore?

Nobody owes anything to society, unless they personally feel they do.

And btw, he never refused the million bucks. In fact, it was never offered to him. As far as he is concerned, he proved the conjecture, his work is done. If the institute is unable to solve its own policies, that's not his problem. He just said he won't discuss it or anything, because it's done. Finito. Nothing to talk about. Whether it's published where it has to be or not. Now give him the money or back out of the deal because of minor issues.

He'll never beg or ask for the money. That's all.

16. **vincent**
November 1, 2009

I agree with "tst" that the drama aspect should have been irrelevant.

Three other people got Fields medals along with him. He is getting the most publicity out of them all! Self-interest might not be the full story, but its silly to think that he has none of it.

17. **Tom O'Bulls**
November 1, 2009

"Three other people got Fields medals along with him. He is getting the most publicity out of them all! "

That's because their work, outstanding as it is by normal standards, is utterly negligible compared to Perelman's. That was really a bad year to win a Fields.

18. **Andy**
November 2, 2009

Tom O'Bulls — While I agree that Perelman's proof of the Poincare conjecture was amazing, no one who knows anything about math would claim that the work of Tao, Okounkov, or Werner is "utter negligible" compared to it.

19. **milkshake**
November 2, 2009

Christine, you are right – a math Olympiad club, no pressure.

20. **Serifo**
November 2, 2009

I think Perelman and Grothendieck are examples of pure natural thinkers , any young physicist or mathematician should reflect about their stories .They are not motivated by international awards , fame , academic prestige or New York times magazine !

21. **Aristarchus**
November 2, 2009

"But yes, you are right; a loner is not necessarily lonely although an old saying alleges that if someone lives all alone and doesn't feel loneliness, is either mad or god."

Why not both? Even the Bible says that God made humans for companionship and worship.

Boy, he must have been lonely.

22. **abc**
November 2, 2009

I think that people should leave him alone. I guess he just loathes being a public figure. One cannot get the million dollar prize, Field medal etc. and than just disappear. Once you start to play the game, you are already deeply in it, so he refused everything from the very beginning. I would even go on and say, since it has become increasingly difficult for him to avoid publicity, he had to become more reclusive than he probably ever wanted

23. **observer**
November 2, 2009

Cantor, Godel, Sidis, Erdos,Grothendieck,Nash,Von Neumann, Perelman to name just a few of the great mathematicians and all of them had some very peculiar view of the world and some eccentricities to say the least, it seems to came with the profession itself.

24. **Deane Yang**
November 3, 2009

"They are not motivated by international awards , fame , academic prestige or New York times magazine !"

And who is? Anyone who wants any of these things is not going to become a pure mathematician.

I don't really understand either the attacks on Perelman or the effort to put him on a pedestal. There is no question that he's a great mathematician and that it is a loss for the rest of us that he has decided to turn his back on us. But he is not the only one who has done this, and his decision should be treated with respect. He's just a human being trying to lead his life as best as he can.

25. **RMA**
November 3, 2009

Does Dr. Perelman even like people talking about his personal life (as opposed to his mathematical ideas) on public forums?

26. **milkshake**
November 3, 2009

… the paparazzis at his mother's house and random freaks (snapping his pictures on subway with a cell phone) would be a more acute nuisance than some little Internet gossip

27. **Aristarchus**
    November 3, 2009

    I now consider him to be one of my few personal heroes. He did the math for the math and told society to go jump in a lake.

28. **Russ Van Rooy**
    November 4, 2009

    Sounds like shades of Alexander Grothendieck. A great biography of Grothendieck in English is long over due by the way.

Latest from the LHC

November 3, 2009
Categories: Experimental HEP News

The latest official news from CERN about the LHC schedule that I've seen is this from DG Rolf Heuer, who doesn't give specific dates other than "second half of November" for circulating beams, collisions at injection energy soon thereafter, and, if all goes well, "high-energy collisions" before Christmas. He doesn't specify what the value of "high-energy" is.

Physics Today has this story, which has a lot more detail than available officially, including a quote described as "a statement on the CERN web-site":

> This means that 2009 will not see physics collisions, but will perhaps see collisions at energies marginally higher than that of the Tevatron…

which was picked up by the New York Times here, and reported as:

> The lab now says the first collisions, before Christmas, will be even lower, due to delays in finishing a system to protect the powerful superconducting magnets from explosive failures. The initial collisions will be at 1.1 trillion electron volts per beam, just barely above the energy of the Tevatron collider now running at CERN's rival, the Fermi National Accelerator Laboratory outside Chicago.

I can't find that quote on any CERN site, but it and the other details of the story do seem awfully familiar.

Unofficially, what's known about the schedule at the moment is:

Next weekend (Nov. 7-8): Second injection test. If sector 67 is ready, beam will travel through this sector (and possibly even through sector 56) as well as the two (sectors 23 and 78) tested during the first injection test.

November 20th: First attempt to circulate beams at the injection energy of 450 GeV.

Early December: Collisions at 450 GeV.

Mid-December: Ramp to 1.1 TeV, collisions at 1.1 TeV/beam.

December 16th: Stop of beam commissioning for end-of-year break.

January 4: Restart after end-of-year break. About three weeks for hardware commissioning to 6kA, 3.5 TeV/beam.

Late January: Beam commissioning at 3.5 TeV/beam.

Early February: Collisions at 3.5 TeV/beam. First physics run soon thereafter.

Update: Not sure what to make of this. At first I found this hard to believe, but there's another story here.

Update: I guess this actually happened: here's something from CERN.

Update: Looks like they will be able to get a beam through 4 of the LHC's 8 sectors this weekend.

Commenter Yatima points to this at the Register. If you believe the Register (not necessarily a good idea…), CERN's Sergio Bertolucci is promoting the idea that the LHC will open a portal to other dimensions, so:

> Summarising, then, it appears that we might be in for some kind of invasion by spontaneously swelling and shrinking spherical or wheel-shaped creatures – something on the order of the huge rumbling stone ball from Indiana Jones – able to move in and out of our plane at will. Soon the cities of humanity will lie in smoking ruins, shattered by the Attack of the Teleporting Juggernaut-tyrants from the Nth Dimension.

The writer asks LHC Machine Coordinator Mike Lamont what he thinks of all this. He suggests reading Lisa Randall's book.

Comments

1. **Stefan**
   November 3, 2009

   Have there been any comments about the electricity bill expected for this winter, and how this could affect the schedule?

   It seems the main supply from France could be especially expensive this time, as 25% of French power plants currently are offline and France will have to import electricity starting mid-November until at least end of January.

2. **Peter Woit**
   November 3, 2009

   Stefan,

   I haven't seen anything recently about that. Earlier this year, when they decided to not shutdown for the whole winter, they considered this cost issue in detail.

   But, since things are taking longer than expected, and a physics run won't start until at least February, the additional energy cost should be even less than they were projecting. For much of the next three months, the machine will probably be off much of the time, and running at lower energies when it is on. I would guess that that will keep their energy bill down.

3. **cea**
   November 4, 2009

   http://washuu.net/cea-bang.htm

A hydrogen bubble chamber at the CEA (Cambridge Electron Accelerator, Cambridge, Mass, USA) really did explode (1965), hydrogen leaked out of the BC, one person died, so the caution CERN is displaying is well-founded.

4. **Yatima**
November 6, 2009

I would say that caution is justified. The blowout of last year could easily have led to loss of life and limb (Are people allowed in the tunnel of live ring collider? There may be some Bremsstrahlung, which can be shielded against though.

Anyway, more LHC weirdness from El Reg:

http://www.theregister.co.uk/2009/11/06/lhc_dimensional_portals/

5. **Bob LaBla**
November 6, 2009

(Are people allowed in the tunnel of live ring collider?)

No, the ring and detector areas are off-limits when the beam is on!

6. **Paul Guinnessy**
November 9, 2009

Peter,
I went back to my original notes. The 450 GeV and a lot of the other details were mentioned at an accelerators meeting in DC a couple of weeks ago (disclaimer, our CEO chaired a session related to it last Monday), plus there are details on CERN's web site if you know where to look.

You were right that the quote in the piece came from your blog. I apologize for the mistaken attribution and it has been corrected.

I do not know where the NYTimes got their piece, but there's been a lot of coverage in the European press, and I suspect they got it from there rather than from us.

7. **Paul Guinnessy**
November 9, 2009

I should also add that CERN's press office has been very helpful in confirming the revised schedule. Sometimes it pays to pick up a phone and ask 🙂

8. **Peter Woit**
November 9, 2009

Hi Paul,

Thanks for writing and for clearing up the attribution of the quote. I'm perfectly happy to have my words attributed to CERN, but they may feel differently…

It's true that reporters do something very important that bloggers don't: call up authorities and get information + public statements from them. Maybe some of my postings can at least help make it clear what questions to ask.

9. **Martin**
November 10, 2009

Hi Peter,

I assume that these delays are indeed the last. If you had to make an educated guess: When will LHC find the Higgs?

Cheers,
Martin

10. **Peter Woit**
November 10, 2009

Martin,

The 2010 run won't deliver enough luminosity to see the Higgs, so the earliest possibility would be data from runs in 2011 and later, analyzed in 2012 and later.

Of course, much more interesting would be to not find the Higgs, but to find something else.

11. **Martin**
November 10, 2009

Peter,

thanks for your quick reply.
What would you guess are the chances that Fermilab will beat them to the Higgs?

Cheers,
Martin
PS What other things instead of the Higgs are you hoping for?

12. **Peter Woit**
November 10, 2009

Martin,

One place you could read about this question is here http://www.scientificblogging.com/quantum_diaries_survivor/worst_nightmare_scenario_cern_150_gev_higgs

especially note the graph showing the probabilities of 2-sigma evidence as a function of Higgs mass.

But 2-sigma is very marginal evidence of a particle. You need 3-sigma to claim “observation”, 5-sigma for “discovery”. My impression is that 3-sigma is possible, 5-sigma isn’t.

About what I’m hoping for: evidence of some mechanism for electroweak symmetry breaking that no one (including me) has thought of yet…

News From NSF THY

November 5, 2009
Categories: Uncategorized

A presentation at a recent SLAC Users Group meeting included some of the following data about NSF support for HEP theory:

Theory funding (including cosmology and astro-particle physics) for FY 2008: \$11.68 million. For FY 2009, \$11.31 million + \$2.3 million from the stimulus legislation.

In FY 2008, these grants supported 128 senior personnel, 84 postdocs and 104 graduate students. For FY 2009 the numbers were 184 senior personnel, 50 postdocs and 70 graduate students.

During FY 2008, 24 out of 57 new submitted proposals were funded, 17 out 21 renewals were funded.

Group grants were categorized as 11 phenomenology, 11 strings, 2 cosmology, 1 general.

Individual grants were categorized as 17 cosmology, 12 strings, 9 phenomenology, 3 astrophysics, 2 lattice QCD, 3 general.

So, as far as NSF HEP grants go these days, if you're not doing cosmology, string theory, or phenomenology, basically you're out of luck…

NSF THY has a new program manager who started Oct. 1. It's Keith Dienes of the University of Arizona, whose research in recent years has focused on the "string vacuum project". He'll be giving a colloquium at Fermilab next month on Probing the String Landscape, which is advertised with the abstract:

> We are currently in the throes of a potentially huge paradigm shift in physics. Motivated by recent developments in string theory and the discovery of the so-called "string landscape", physicists are beginning to question the uniqueness of fundamental theories of physics and the methods by which such theories might be understood and investigated.

Since the late eighties, the two institutions in the US most heavily invested in string theory have been Princeton and Rutgers. Recently they have been moving aggressively to try and diversify, especially in the direction of LHC phenomenology, with the hiring of Nima Arkani-Hamed at the IAS and Matt Strassler at Rutgers. Last year the two institutions collaborated on a proposal for a new Physics Frontier Center with a budget of \$1 million or so per year. This would be called the PARTICLE Center (Princeton And Rutgers Theory Institute for Collaboration with LHC Experiments) and would aim to be the main US center for LHC phenomenology. The proposal promoted the possibility of experimental anomalies to be discovered by the LHC in fall 2009, quickly followed by PARTICLE physicists inventing a model that would explain the data and predict a subtle effect that would require a new triggering strategy to see. The result of this would be a surprising measurement that would explain supersymmetry breaking.

Anyway, that proposal doesn't appear to have been funded, with reviewers rather dubious about the idea of retraining Princeton and Rutgers string theorists as LHC phenomenologists, as well as the idea of devoting significant new resources to funding the Princeton and Rutgers theory groups, centralizing LHC phenomenology efforts there. However, two new year-long grants for \$130,000 each were awarded to Strassler and Arkani-Hamed, who promise to use them to "create the nucleus of an LHC center on the East Coast" at Princeton and Rutgers. One of the goals of these grants is listed as "to help in the process of … retraining postdocs from more formal areas of high-energy theory", since the job market for young string theorists has more or less collapsed.

Comments

1. **Mitch Miller**
   November 5, 2009

   "This would be called the PARTICLE Center (Princeton And Rutgers Theory Institute for Collaboration with LHC Experiments)"

   I would have funded it based on the acronym alone.

2. **Bob Levine**
   November 5, 2009

   Re Dienes' comment—isn't part of the semantics of 'discover/discovery' an entailment that whatever you're talking about demonstrably exists? Talking about the 'discovery' of something is only felicitous if that something is really *there*, no? Or does Dienes really believe that the landscape is just, well, *necessarily* true?

3. **Peter Woit**
   November 5, 2009

   Bob,

   I wouldn't so much quarrel with the use by Dienes of the word "discovery". One can "discover" a previously unknown feature of a speculative model, and that's how I think he's using the term.

   More dubious is actually the adjective "recent" applied to this "discovery". The Bousso-Polchinski paper that set this off was written nearly ten years ago, in an earlier millennium than the current one.

4. **Pawl**
   November 5, 2009

   Dienes' abstract seems not to quite make sense. If we're "in the throes" of a paradigm shift to landscapes, there's nothing "potential" about the hugeness of the change. (Or maybe there's a "landscape lite" alternative I'm not aware of….)

   There's also the timing issue Peter touched on: people are not "beginning to question" uniqueness of fundamental theories — those who wanted to question it have done so, with limilted success in convincing the rest of the community. (In fact, this sentence of Dienes' sounds depressingly like what appears to be the standard-issue wishful thinking common among some of those advocating the multiverse in public, as opposed to scientific, fora.)

   True, Dienes does go one to say

   > I will also discuss some of the questions to which it has led, and the nature of the controversies it has spawned.

   which at least sounds more objective.

5. **Kea**
   November 5, 2009

   Ah, the way of the world. Retrain the people who did what they were told, rather than hire one single person who was critical, in the right direction, all along.

6. **Serifo**
   November 6, 2009

   Humm , perhapes there is a significant number of people in NSF HEP lobbying for string theory , cosmology and phenomenology ! 🙂

   Regards

7. **Robert**
   November 6, 2009

   any news about consequences of the birds' droppings on a cooling aggregate of LHC?

8. **Matt**
   November 6, 2009

   Peter,

   Any sense of why lattic QCD and astro-particle physics make up such a small grants in HEP theory? With these two subfields having access to the greatest amount of applicable experimental data to fit, I am a bit at a loss of how few grants there are in these areas compared to strings & phenomenology. Also a bit interesting the difference between group and individual grants for cosmology as well.

9. **Peter Woit**
   November 7, 2009

   Matt,

   astro-particle physics overlaps with astrophysics, and that is funded separately from HEP. Lattice QFT is a subject that has never really been pursued at the most prestigious places in the US (for example Harvard, Princeton), and has always been seen as a minority and rather un-sexy subject to be working in. It's an interesting question why this is.

10. **SteveB**
    November 7, 2009

    Like lattice QFT, there is a similar phenomena in fluid dynamics. There is the establishment majority that solves the Navier-Stokes equations with various techniques and a small offshoot that reformulated fluid flow into a Boltzman lattice model. At the end of the day both converge to the right answer and it is nice to have two separate methods for consideration. There is a bit of acrimony between the two camps, and sometimes more than a bit. In my opinion, NS is the most popular since it lends itself to easier application of the necessary approximations and simplifications for solving various different phenomena (turbulence, energy, multiphase, etc.) with a reasonable amount of computer power.

Simons Postdoctoral Fellowships

November 9, 2009
Categories: Uncategorized

The Simons Foundation will be funding new postdoctoral positions at various institutions starting next fall. Details of one of these, at the University of Texas, have been announced, with more to follow in coming weeks. These are three-year postdocs, with a first-year salary of $70K/year.

Comments

1. **Stephen**
   November 10, 2009

   Why is every institute funding postdocs and no one is funding real jobs (i.e. long term)?

   When people look for jobs outside academia, in private companies, they normally look and find long-term jobs. Or at least, if they are doing well after some initial time, they can stay longer.

   Now, why a university cannot work in the same way?

   If you have a Ph.D. and looking for an academic job, this seems impossible for many years, so that you have to struggle all the time with applications, relocating, maintain a personal life, relationships, friendships, etc… and in the end you do not know when you will have a permanent job.

   I find all this completely crazy: if somebody works well, why he cannot stay in the same place more than 2-3 years?
   If a Ph.D. is not enough to get a job immediately, this probably means that there are too many people with a Ph.D. or that the whole system is dysfunctional.

   There is probably the wrong idea that putting people under this kind of situation and pressure they will work more. But competition and fear should not be the motivation to do research….Some competition is good, but when it is too much, this is exactly what kills the creativity, the freedom of thought and the passion.
   And gives people (even the good ones) motivations to leave science.

   There is also the idea that forcing people to travel will make them acquire an international experience. True. But wouldn't be easier and better to have just funding for visit and short stays/sabbaticals?

2. **Franckle**
   November 10, 2009

   Dear Stephen, I completely agree with you. I'm a person who works with bursts of great talent when outside there's the sun in the sweet air of the morning… or I can be depressed thinking about the strange system you described so well in which I'm immersed. Thanks Stephen, words are important…

3. **Andy P.**
   November 10, 2009

   Stephen — because of tenure, hiring someone for a "permanent" position is essentially making a 35-40 year commitment. It's not realistic for the NSF or a private foundation to make that kind of commitment.

   Trust me, the situation in math and the sciences is much better than other parts of academia. We can at least get temporary positions that pay a decent wage and have benefits. In (say) English, you essentially have to live in dire poverty adjuncting for years until you can find a permanent job.

4. **Stephen**
   November 10, 2009

   Hi Andy,
   suppose that you are a doctor working in a hospital or a teacher in high school (or I could give many more examples). Is it unrealistic that you get a permanent job? If not, why having a Ph.D. (and maybe even one or two years of postdoc) is not enough to be trusted to get a job in academia?

   The fact that other parts of academia are worse, does not make things any better. It just make things worse for the poor guys who are in the other fields.

   I believe many of us just got accustomed to be treated in this way.
   Personally I think it is unfair and nonsense, and also counterproductive.

   Many people have also short memory: after suffering for many years and finally getting on the other side with tenure, will they do something to hire young people offering permanent jobs? Unfortunately what happens is that tenured people will try mostly to get grants in order to hire people for temporary jobs.
   It is a self-replicating system, unless somebody is willing to try and change it.

5. **Ming**
   November 10, 2009

   In view of the fact that there are many more Physics PhD's than available faculty positions in Physics, I suppose some form of "weeding" process must be implemented. From what I've seen, the ones who eventually made it to tenure are usually very talented (a necessary, but not sufficient condition) and either very excited and committed to whatever they're doing in just the right kind of research (the ones that are in fashion and get funded) or very ambitious in getting a faculty position no matter what it takes, be it personal or professional sacrifices. If you (like me) don't fit into either category, then it's extremely unlikely you'll end up with a permanent faculty position in Physics.

   Is it unfair? Guess so, but who said life is fair? And besides, there are always other careers for Physics PhD's outside academia. Is it unhealthy for Physics that the top academic jobs in Physics are only given to those who're fashion-chasers often with questionable professional ethics? Yup I think so, but it'll take a literal revolution to change the system…

6. **Andy P.**
   November 10, 2009

Stephen — do you really think that senior faculty can do all that much to increase tenure-track hiring? I can assure you that most departments fight like dogs for every tenure-track line they can get. The money simply isn't there.

I agree that the job situation in math can be frustrating, but blaming it on tenured faculty with "short memories" is simply wrong. Getting grants and hiring postdocs is really all they can do.

Just give thanks that if you end up leaving academia, you will be able to get a very nice job. Your salary will probably be better than most tenured faculty. This is simply false for most other parts of academia.

7. **Peter Shor**
November 10, 2009

Dear Stephen,

When you get a job in a private company, you can be fired or laid off at any time. In fact, I know a number of people who have been laid off and have had to scramble for another job (and they didn't always get one right away). It's not fun. So in some sense, a three-year postdoc position is more secure than many other jobs.

The biggest problem is that there is a big supply of PhD's in physics, and not anywhere near as much demand. In computer science, most PhD's go either directly to tenure-track positions or industry. Only top universities can get reasonable people by offering them postdoc positions, because graduating PhD's have so many more good opportunities than they do in physics.

So if you want a better job market in physics, discourage people from going into physics (say, start up a big String Wars brouhaha to make the field look less attractive …).

8. **POM**
November 10, 2009

Dear Andy,

if the senior faculty cannot help to increase tenure track hiring, then who else can do it ? It is certainly unfair to blame "Senior faculties" as a whole to have short memories, but one can certainly blame some of them (and – to my experience which is quite large on that matter – not only few of them) no to care at all to what happens to the "youngs in their field".

I have heard many times this kind of answer "yes but you know… life is unfair". So what ? One should just shut up and accept it ? This is the kind of attitude which is expected to be promoted in science ?

Many academics consider themselves as bright and clever people, with high morality and self-declared ability to select "the best one(s)". But very often the final decision is mainly politics. This is this hypocrisy that I (and other long-term postdocs) find unbearable:

-on the one side there is a community which keeps on claiming that its main selection criterium is "scientific excellence",

– on the other side as soon as you start hearing what is really going on inside (some) hiring committees, you discover that often more than "scientific excellence" (whose definition by the way varies depending on whom the position has been designed for) what is important are dirty politics, local interest, or simply "délit de sale gueule" (or age segregation, that is unsaid because it is illegal, but that "naturally" applies).

Surely academics in physics or maths is not worst than other segments of the society. But at least in the bank industry nobody claims to be driven by high principles. The aim is to make profit. Full point.

9. **Thomas Larsson**
November 11, 2009

In a steady-state situation, each advisor will on average give birth to one new advisor in the next generation. So if an average professor produces ten PhDs, 90% of his students will not get tenure themselves. It is really as simple as that.

10. **POM**
November 11, 2009

Except that a human society is a not a gas, not even a perfect one. There are many and various interactions between its components, from very short to long range. Moreover "Academy" is certainly not an isolated system. It is neither homogoneous nor isotropic. One does not understand much of it by simply taking global averages.

11. **Chris Oakley**
November 11, 2009

To expand on TL's comment, one should not forget [Weil's Law of university hiring](#) (under "Quotations") either. On average, therefore, the quality declines.

12. **Bob Levine**
November 11, 2009

'Except that a human society is a not a gas, not even a perfect one. There are many and various interactions between its components, from very short to long range. Moreover "Academy" is certainly not an isolated system. It is neither homogoneous nor isotropic. One does not understand much of it by simply taking global averages.'

But TL's comments don't depend on a human society or an academic subcomponent being a perfect gas. The situation is much simpler: under normal conditions, the demand for university faculty will correlate closely with the size of the student population, so that only radical increases in the size of the latter, or some other very unusual combination of factors, will significantly affect the intake rate for faculty. The last time I can recall that happening was in the wake of Sputnik, when all that NDEA Title 4 money poured in to create hundreds of new departments in many fields, and many of my colleagues received calls—as *graduate students*—from department heads pleading with them to accept academic positions in their departments. That's going to happen extremely rarely in any given century. Yet, in line with TL's point, if each professor trains on average only two Ph.D.s in his or her academic career, it would require something at least as spectacular as Sputnik to absorb the whole candidate pool into the tenure-track professoriate—and this at a time when administrators are trying to reduce the size of the tenured/tenure-track faculty by hiring part-time faculty on short-term contracts with minimal benefits and often terrible working conditions. It's a mistake to blame senior faculty for this—we often fight like hell to minimize such practices. But university administrators are committed, in my view, to deprofessionalizing their faculties, and they use every trick in the book to do so.

There's just a fundamental problem here: a department's size is one of its chief guarantors of survival, at a time when graduate programs are being merged or shut down completely. But the only justification of increasing size—hiring more faculty—is that you've admitted more students and need instructors to teach them, not just at the undergrad level but in your graduate programs. And that means you wind up creating way too many Ph.D.s for the market. If senior faculty can be blamed for anything, it's for promoting excessive growth in their programs; but if they don't, those programs themselves may well get the chop. And I've yet to hear of any constructive suggestions to solve this conundrum that were particularly realistic…

13. **Stephen**
November 11, 2009

Dear Andy,
if the money simply isn't there, there are two viable options:
either trying to get more money, or to train less Ph.D. students (or both). Just enough to cover the demand.

Moreover, for instance, many senior people are frustrated with having too much teaching. Teaching often implies teaching to undergrads, also to non-physics students. There is certainly demand for this. Then, why not hiring more young people for mixed long-term positions (teaching+research), so that the load would be less also for tenured people?

14. **Coward**
November 11, 2009

Stephen: I'd love to hire some young people to reduce my teaching load! And where am i supposed to get the money for this, especially in the current economic crisis with most universities in very dire budgetary situations? If anything, I think universities will feel pressure to increase teaching load to save money on faculty salaries.

15. **Lee**
November 11, 2009

Professors are to blame when they hire and retain low-salary postdocs and graduate students while giving them exaggerated prospect of their landing a tenure track job later. The false advertisement comes in the form of overstating the impact of the proposed research to be done together (this project will save the world), and understating the hiring criteria of perceived lower-rank universities (you will be a professor in some state university). Selling the professor's research and training package to a postdoc in this manner is nothing short of selling stock or house with bubbled price, and is downright unethical if the broker intentionally does so to a new customer in the market.

The sad thing is, most of academic research has extremely low value, from the society's point of view. Adding a drop of knowledge in the ocean of existing knowledge is not a good bet. Its best bet for market performance is leveraging its educational value, but letting postdocs to gain teaching experience is what most professors don't like to do – they want isolated and illusioned postdocs in their lab producing results for next NSF funding. This is unethical.

16. **Keith Schilling**
November 11, 2009

"Why is every institute funding postdocs and no one is funding real jobs (i.e. long term)?"
totally agree – however given the state of the economy it shouldn't be too big of a surprise is it?

17. **Michael Gogins**
November 11, 2009

I believe this situation has mixed causes. In the first place, contrary to what many in the system believe, society values university research very highly and funds it at a high level — even if it is not the even higher level that some in the system might prefer.

The funding comes partly because of an expectation that university research is required to win future wars. This is a realistic expectation. However, since we have not had a war that has been decided by university research since 1945, this feeling is dying out with the generation of leaders who feel the motivation, although the reality of the situation in fact persists (think about space battle, or information warfare).

Of course warfare, however important it may be, is an intrinsically unscientific motivation, and accepting funding on this basis is sickening the sciences. The same goes, to a lesser extent, for funding based on expectation of better medicine, or a more productive economy, or maintaining "national competitiveness."

Right now the life sciences are being perverted by a search for means of extending the human life span. I am decidedly in favor of doing this, personally, but I expect a good deal of dishonesty to enter medical science as a result.

The right way to fund the sciences – or the arts, for that matter – is to donate money to the best people for whatever it is that they, personally, feel is worth doing. Since they are of course the only ones even remotely capable of deciding what is worth doing! This is an essentially elitist view and does not sit well in a democratic system. It is ultimately founded on a contemplative, non-utilitarian view of how talented people should spend their time.

The tenure system for all its faults reflects this elitist view, inherited from a far more contemplative age. But it is to be expected that in a crowded world of well-fed, relatively well-educated people, long-lived people there will many more people who want to do this kind of work than there are places for them.

The postdoc system in my view is an uneasy compromise between the elitist and utilitarian views. The postdoc system is sort of like boot camp or hazing, and it does more or less get unserious or mediocre people out of the way. But from the outside, where I sit, it would seem to create a very poor environment in which to contemplate and think. The worst consequence is the inflation of "style" or "fashion" in science where there should be only a small place for it, along with party feeling, purges, and the whole 9 yards.

We desperately need multiple approaches to really hard problems, but the utilitarian, competitive approach, perhaps paradoxically, does not naturally support this. Generous private funding has in fact been necessary to supplement the support of alternative approaches to physical theory in North America.

If you don't want this environment, you will have to find other ways to discourage unsuitable or superfluous people. And better ways to encourage the most suitable people! But in our society, whatever you do will be perceived as unfair.

I don't know what to say about that. Good luck all,

Mike Gogins

18. **Peter Woit**
November 11, 2009

It should be pointed out that Simons has funded permanent positions: the new center for geometry and physics at Stony Brook will have 7 permanent positions (director, 3 physicists, 3 mathematicians).

19. **POM**
November 11, 2009

"If senior faculty can be blamed for anything, it's for promoting excessive growth in their programs; but if they don't, those programs themselves may well get the chop. And I've yet to hear of any constructive suggestions to solve this conundrum that were particularly realistic…"

What I blame (some of) the senior faculties for, is the unbearable lightness with which they manage the hiring process. Indeed the job market is hard. This is precisely why one should expect the hiring process to be rigorous, clear and clean. And to a large extend this process is in the hands of senior academics. I have little experience with the american system, but I have the feeling that in (at least some part of) Europe, applicants are rather used as canon fodder, for the benefits of local interest that one is aware of once the process is over.

Just a simple illustration: why is it so difficult to obtain a constructive opinion on one's application, which goes beyond the useless "your research interest did not meet the priority of our institute. We wish you success in your future academic life" ? Is it because the professional-life of some non permanent staff is not worth the time a permanent researcher would spend answering him ?

20. **Alejandro Rivero**
November 11, 2009

Of course it is possible for private companies to fund long term positions:

"Lucas, in his will, bequeathed his library of 4,000 volumes to the University and left instruction for the purchase of land whose yielding would provide £100 a year for the founding of a professorship"

But they can also endow, at the same price, a fellowship.

21. **Andy P.**
November 11, 2009

POM – In the United States (I don't know about Europe), there is often an explicit policy forbidding people from sharing the reasons someone wasn't hired. It can very easily lead to lawsuits, even if the reasons are totally reasonable.

22. **Stephen**
November 11, 2009

It was not my intention to blame tenured professors, in a generalized way.

I just wanted to remind that, from the point of view of young Ph.D.'s life, it is much better to have opportunities for long term jobs. And I think very few people would disagree with this statement.

Some people made the point that there is no money for this (for permanent jobs or mixed research/teaching positions).

The solution to this conundrum is actually trivial: the money which is spent for hiring postdocs could be spent for paying salaries for long term jobs.

Moreover, many people would by far prefer to have a long-term jobs, even if they were paid a little less. So departments would not have to spend more than what they spend now. Maybe even less.

23. **Andy P.**
November 11, 2009

Stephen –

I don't things are quite as simple as that. Let's assume that all postdocs were converted to tenure track jobs (which will never happen). OK, there would be a spurt of hiring for a couple of years. After that, tenure-track hiring would revert to its usual lousy state, but there would be no postdocs. In the end, young people would be even worse off.

The cold, hard truth is that academia is not growing. If anything, it is shrinking. There will never be a time in which there are enough permanent jobs for all new PhD's to get them.

I suppose one could argue that the solution is to shrink graduate programs, but I assure you that if graduate programs shrank, then so would departments, and tenure-track hiring would slow down even more.

The only solution I see is for universities to do a better job at preparing their graduate students for non-academic employment.

24. **Stephen**
November 11, 2009

hi Andy,
so basically you are saying that a large fraction of graduate student which end up out of academia is necessary to maintain the system.

I might agree for those fields in which graduate studies naturally lead to other career paths (for example law, medical studies, engineering etc… have other options, in a natural way).

For those fields which are mostly academic (such as theoretical studes, maths, etc..) what I am saying is that basically the number of Ph.D. should be equal to the number of academic/teaching positions, by increasing the number of jobs and/or by reducing the Ph.D. if the former is impossible.
It is better, in my opinion, to have a bottleneck (if any is really needed) at the beginning of the studies rather than later on.

I would not worry about the number of graduate students being smaller.

25. **Jeremy**
November 11, 2009

Stephen asks:
"Why is every institute funding postdocs and no one is funding real jobs (i.e. long term)?"

The problem is partially because of the "senior faculties". If the senior faculties are forced to retire when they are 60 years old (like they are in Japan), or 65 years old (like they are in the U.K.), there will be a lot more "real jobs" available.

26. **David B.**
November 11, 2009

Jeremy:

US law forbids mandatory retirements except in some professions requiring certain kind of fitness level (police officers, etc), were not retiring the individuals put others at risk. This is part of the anti-discrimination laws based on age. Suggesting that it be changed to fix academia is at best wishful thinking.

27. **Nicoletta Sabadini**
November 11, 2009

How is it possible that all these apparently intelligent and talented students don't understand that they have voluntarily entered into a mousetrap? The fact that someone has studied for ten years does not imply that anyone should pay them to do the same thing for ever.

To make an example, the conservatoriums are full of students of piano who are skiiled and study for many years, but the need for concert pianists is very limited.

This does not excuse my colleagues who, for their own personal interests, are still advising students with false promises to enter into a process which starts with a PhD and ends with disappointment.

28. **peter shor**
November 11, 2009

Stephen says:

> Moreover, for instance, many senior people are frustrated with having too much teaching. Teaching often implies teaching to undergrads, also to non-physics students. There is certainly demand for this. Then, why not hiring more young people for mixed long-term positions (teaching+research), so that the load would be less also for tenured people?

I don't see how the economics of this works. Are you suggesting that we have two classes of tenured faculty, one with high teaching load and the other with low teaching load? Try selling that to the administration at your university.

Otherwise, hiring more tenured faculty to reduce the teaching load requires more money.

29. **peter shor**
November 11, 2009

Stephen says

> Some people made the point that there is no money for this (for permanent jobs or mixed research/teaching positions).
>
> The solution to this conundrum is actually trivial: the money which is spent for hiring postdocs could be spent for paying salaries for long term jobs.

But the tradeoff is something like 20 postdoc positions for one permanent position. This isn't going to make a dramatic increase in the number of tenured faculty.

[How I get this figure: a tenured professor is going to occupy a position on the order of 10 times the length of a typical postdoc, and the salary is on the order of twice that of a typical postdoc.]

30. **POM**
November 11, 2009

Nicoletta,

I have got a good friend who is a conductor. Certainly he will never conduct the Berlin Philarmoniker (although I wish he will one day :-)) but he found a stable position as an orchestra-conducting teacher in a good conservatorium, he is making concerts, he plays with various "ensembles". In brief, he is doing music.

In maths or theoretical physics this is an "all or nothing" alternative: either in a short window of time after your phD you find a permanent position, or you are supposed to leave research. And a high-school teacher is not with respect to a researcher what an orchestra-conducting professor is with respect to the Berlin Philarmoniker conductor. When my friend plays with a good-although-not-famous ensemble, he is making music. When one is teaching physics at high-school level, one is not doing research (which does not mean that teaching is not a beautiful job, but this is a different job than research).

That is what is extremly difficult to swallow in the academics world: it is a kind of random process, in which some people are "elected", others are "damned", and when you ask why you are damned, you are answered "well, you know, life is unfair". Again, this would be fine if this were not happening in a community which bases all its legitimacy on its supposed "rational attitude". From people that have been "elected" because they were "the best", one is entitled to require higher level of explanation than just "life is unfair".

31. **Walter**
November 12, 2009

I don't think that from a financial viewpoint the ratio of postdocs to tenure-track positions should be viewed as 20 to 1 or anything like that… Many of these postdoc positions are recurring and have been around for decades.

Still I think it's a financial issue. When there's a budget crunch it's simply cheaper to hire a temporary person than a tenured track, say when someone retires. Over time this leads to more temporary jobs. Another issue worth mentioning for the US is that there's a lot more flow from abroad than vice versa, and this makes the job market tighter. Not that this is necessarily a bad thing, it keeps American science and math dominant. But it's not good for domestic PhD's

32. **Thomas Larsson**
November 12, 2009

"I would not worry about the number of graduate students being smaller."

Alas, advising grad students is an important part of a professor's job. Less grad students => less work for professors => layoffs.

Implicit in this discussion is the assumption that a PhD in theoretical physics is totally worthless outside of academia, and that theoretical physics PhD's are too incompetent to find non-academic jobs. Whereas there might some truth in this, I don't really buy it.

33. **Tim vB**
November 12, 2009

@Thomas Larsson
From my own experience on the job market:
Companies do always look for an expert with specific experience and training. A Ph.D. in physics means you are trained to do research in physics, and there are very very few jobs outside academia that involve serious research in physics!
So the typical situation is something like this: A company looks e.g. for a software programmer with knowledge and experience in the development of big object oriented software systems using Java and a three tier architecture with a web client and a relational database.
If they can get one who fits the picture, fine. If not, they will settle for someone with a Master in computer science.
If they don't get one, they may in certain circumstances take someone with a physics Ph.D., if he/her can convince them that he/her doesn't need at least one year of training before he/her becomes productive.
So, our Ph.D. will mostly be considered to as a kind of fallback plan C. Look at the job market and decide for yourself: What are the chances?

34. **Peter Shor**
November 12, 2009

Hi Walter,

Say, over a thirty-year period, with the same amount of money you can fund 1 tenure-track position or 20 3-year postdocs. So if there are currently funds for 400 postdoc positions per year, and you use all this money for tenured faculty, you get 20 new tenured faculty positions a year. What you've done is replaced 300 very disappointed postdocs by 280 very disappointed new PhD's. How much of an improvement is this?

35. **Dave**
November 12, 2009

A new faculty member has several years to attract enough funding, produce his/her first batch of graduate students, and get sufficient amount of research done before the tenure review process kicks in. It's a busy time, especially when one factors in the service and teaching commitments. A postdoc offers a newly minted PhD an opportunity to beef up his/her record as a researcher and time to mature some more as a scientist and a person with relatively few distractions prior to stepping onto the junior faculty treadmill. It may be more of a blessing than a curse.

36. **Walter**
November 12, 2009

Peter.. I know what you mean… adding one tenure-track job this year will result in 20 people not getting postdocs this year. But the way I look at it is that the number of people who can continue on in the profession is determined by the number of tenure-track positions overall. By the pigeonhole principle, most of these 20 people would end out having to leave the profession anyhow unless they can find a way of becoming "life-long postdocs." My opinion is that this should be done earlier rather than later, which is the opposite of current trends.

37. **Walter**
November 12, 2009

Incidentally, from a financial standpoint the 1:20 thing isn't how it works. Most departments have "postdoc lines" which cost a certain fraction of a tenure-track line. So from a financial standpoint a postdoc line is 1/3 of a tenure-track line, and so on.

38. **Thomas Larsson**
November 13, 2009

Tim vB: Based on my own experience, I would say that the chances for a theophys PhD to eventually find a job in the private sector is close to 100%.

Of the 20+ people that got a PhD from the theoretical physics dept at KTH, Stockholm, and were born between ca 1955-1965, I know two who ended up in academia (or stayed longer than I did). One is a professor in solid mechanics, and the other works with biophysics, not sure if he is professor. The remaining 90% have got jobs elsewhere. A lot of people ended up working for Ericsson, which is the local high-tech giant, and nobody is AFAIK flipping hamburgers at McDonalds.

However, things might be somewhat simpler because KTH is an engineering school, like MIT or Caltech, so we have a marketable undergraduate degree to fall back upon.

39. **Tim vB**
November 13, 2009

Agreed, the best insurance against unemployment is an academic degree, and one in the "hard" sciences or in engineering is even better.
My point is: As a physics Ph.D that drops out of academia, you will notice that you spend about 5 years of your life learning stuff that is no longer of any use to you.
And you will spend a few hard years to learn all the stuff that you need for your new job.
Eventually you will catch up with your collegues, but the feeling that the decision to study physics instead of e.g. computer science was wrong will never quite fade away…

40. **Thomas Larsson**
November 13, 2009

Personally I feel rather grateful to the taxpayers, including those spending their days flipping hamburgers at McDonalds, for giving me almost ten years (four years in grad school + a four-year postdoc + some extra time – hey, my academic career was longer than lubos') to pursue my interests, and giving me the opportunity to make a substantial discovery of lasting value. That the physics community hasn't appreciated this discovery (the math community has been more open-minded) is hardly something that you can blame on the taxpayers.

In SUSY We Trust

November 11, 2009
Categories: Uncategorized

New Scientist has an article in the latest issue entitled In SUSY we trust: What the LHC is really looking for, which promotes the idea that the LHC is going to discover supersymmetry. Only supersymmetry enthusiasts are quoted. I'd be curious to see some data on what the distribution of views of particle theorists is on this issue (one piece of evidence that supersymmetry skepticism is in the majority is here). Among bloggers, at one end of the spectrum is Sean Carroll, who gives a probability of 60%, at the other is Resonaances, with 0.1%. Personally, I'm with Resonaances, at least as far as conventional supersymmetric models go. The main arguments against supersymmetry, ignored in New Scientist, are that supersymmetry breaking is both necessary and hideously ugly, and if this was going to solve the hierarchy problem, we'd have seen evidence already at the Tevatron.

The article does a good job of recounting the pro-supersymmetry arguments (hierarchy problem, unification of couplings, dark matter candidate), but then goes completely off the rails with an absurd claim that supersymmetry explains confinement:

> Supersymmetry's scope does not end there. As Seiberg and his Princeton colleague Edward Witten have shown, the theory can also explain why quarks are never seen on their own, but are always corralled together by the strong force into larger particles such as protons and neutrons. In the standard model, there is no mathematical indication why that should be; with supersymmetry, it drops out of the equations naturally.

At least we'll know one way or another within a few years from now…

Comments

1. **Eric**
   November 11, 2009

   I would disagree with the statement that if supersymmetry solves the hierarchy problem then it should have been seen by now at the Tevatron. The Tevatron simply does not cover the entire allowed parameter space. Additionally, even if you think that supersymmetry breaking is ugly, then alternative models such as technicolor are even uglier. In any case, the indications that the Higgs has a light mass do favor SUSY.

2. **factcheck**
   November 11, 2009

   The author of the article doesn't even list the correct institutes of the people in the article. Another excellent piece of journalism by the new scientist.

3. **Peter Woit**
   November 11, 2009

   factcheck,

   The only inaccuracy of the kind you mention that I noticed was the description of Seiberg and Witten as affiliated with Princeton University rather than the IAS in Princeton, but that's rather small potatoes…

4. **Bill K**
   November 11, 2009

   Eric says: "In any case, the indications that the Higgs has a light mass do favor SUSY."

   SUSY favors a light Higgs. Which is not at all the same.

5. **Eric**
   November 11, 2009

   Bill K,
   SUSY favors a light Higgs, and the experimental data favor a light Higgs. For non-SUSY alternatives, there is no reason for the Higgs to be light. By light, I mean less than 135 GeV. As Peter says, time will tell and hopefully we'll find out in the next few years.

6. **Pawl**
   November 11, 2009

   Another curious aspect of the NS article is that they mention Brout and Englert as well as Higgs, but leave out Guralnik, Hagen and Kibble (compare here) .

   I can't really fault them for this — it's really a question of whom they've talked to.

7. **Thomas**
   November 12, 2009

   Of course, there is also the opinion of Veltman, who stated, as recently as October 2009, that he would bet that the Higgs does not exist; in his book on particle physics he also writes that supersymmetry is only "a figment of the human mind".

   The LHC will show us who is right.

8. **Thomas Larsson**
   November 12, 2009

   In a more recent post, the Jester said something very striking:

   "If supersymmetry is relevant at the weak scale it is in general very uncomfortable with a heavy Higgs. Well, they keep telling you that the upper limit in the MSSM is 130 GeV. But that requires stretching the parameters of the model to the point of breaking, while the natural prediction is 90-100 GeV. Indeed, not finding the Higgs at LEP is probably the primary reason to disbelieve that supersymmetry is relevant at low energies."

9. **Arrow**
November 12, 2009

The probability of SUSY being correct is 10e-27 and that of Higgs being correct 10e-9.

However with probability of 10e-2 a newly discovered particle will be wrongly identified as Higgs boson and with 10e-3 a newly discovered particle will be wrongly identified as superpartner of one of SM particles.

10. **Haelfix**
November 12, 2009

The actual 'bayesian' measure on how to determine what mass of the Higgs is most natural for supersymmetry is a complicated story. Impossible to do unless you restrict the range of models (so people talk about the constrained MssM and so forth). For instance there are models that predict a ~80-90 GeV Higgs that are not actually excluded by experiment, b/c their decays are so strange and elusive.

The generic tendency is to prefer a light Higgs, but it is by no means exhaustive and assigning 'weights' to models is a mess.

As far as what most physicists prefer, well if you add phenomenologists, it also gets messy. Everyone has their favorite pet model, but a generic MssM probably beats the nearest competitor (say extra dimension models) 3 or 4 to one.

It has the benefit of simultaneously having the most explanatory power, and in some ways the simplest solution to the variety of problems that are out there.

11. **Mary**
November 16, 2009

The article has either an explicit snub or was very poorly researched. Along with Peter Higgs, Francois Englert, and Robert Brout there was another team that deserves as much, if not more, credit for the discovery of the mass boson. Gerry Guralnik at Brown University, Dick Hagen at University of Rochester, and Tom Kibble of Imperial College London wrote a paper in the same volume of Physical Review Letters in 1964 that laid out the boson in clear terms, lent mass to the gauge particle, and showed how Goldstone theorem was avoided. All three papers were recognized as milestone papers by Phys Rev Letters 50th anniversary.
http://prl.aps.org/50years/milestones#1964

Additionally, all six were recently awarded the 2010 J. J. Sakurai Prize for Theoretical Particle Physics "For elucidation of the properties of spontaneous symmetry breaking in four-dimensional relativistic gauge theory and of the mechanism for the consistent generation of vector boson masses".
http://www.aps.org/units/dpf/awards/sakurai.cfm

Steven Weinberg, who is well versed in this history and quoted throughout Ananthaswamy's article, credits all three teams as recently as a speech he delivered last month. Ironically, this speech occurred at the Council for the Advancement of Science Writing's annual symposium.
http://blogs.physicstoday.org/newspicks/2009/10/higgs-discovery-likely-at-lhc.html

With such an extensive view of history in this article, missing this GHK team certainly seems sloppy at best – or with motivation (at worst).

12. **Peter Woit**
November 16, 2009

Mary,

Personally I think squabbling over credit for this amongst these three groups of six people is a bit absurd. The basic idea is not due to any of them, but is due to Phil Anderson, who discovered it a year and a half earlier. And yes, I know that most particle theorists didn't understand/believe him, mistakingly thinking that his mechanism required breaking relativistic invariance. They were wrong, he was right, and showing this in detail is all that these six people did.

13. **Larry**
November 17, 2009

Here is a recent historical perspective with actual physics work that outlines some of the "Higgs" and GHK work above. Good read.

14. **Peter Woit**
November 17, 2009

Larry/Mary (who share an IP address),

Whoever you are: I see no good reason for you to be posting anonymously, and using different pseudonyms to make it look like comments are coming from different people is dishonest and reprehensible.

The paper you refer to is quite interesting, it answers several questions in my mind about the history of this. However, I should say that I don't find the reaction of the authors to being told that they were scooped by Higgs, Brout-Englert, and even earlier Anderson to be very creditable. Guralnik describes Higgs/Brout/Englert as "aimed in the correct direction, they did not form the basis for serious calculation", but I suspect few other theorists would agree with that evaluation.

He also admits that Anderson's work was brought to his attention, and writes: "In general these comments are correct. However, as they stand, they are entirely without the analysis and verification needed to give them any credibility." and uses this to justify not even referring to Anderson's work. This seems to me not at all the way to behave in the face of evidence that someone else understood the crucial points and worked out an example demonstrating them a year and a half before you did.

15. **Tim vB**
November 18, 2009

I'd like to take the opportunity to ask a little question about anonymity:
I'd like to stay anonymous (well, semi-anonymous since "Tim" happens to be my first name in real life) to the readers of some blogs, but not necessarily to the hosts. Don't the hosts have access to the email address that I enter for each post?
This gives away my full name, plus you got my email address (you can actually contact me via this address).

16. **Peter Woit**
November 18, 2009

Tim vB,

I don't have any problem with people like you who identify themselves to me via their e-mail addresses, but use a semi-anonymous name publicly.

I do have a problem with people who use anonymity dishonestly, engaging in "sock-puppitry" to try and advance their cause.

17. **magicmike**
November 22, 2009

Hi Peter,

I'm a little confused about why you think that the article goes "completely off the rails" with an "absurd claim" that supersymmetry explains confinement. Is it just that you don't agree with the rigor of Seiberg and Witten's computations in their 1994 paper?

18. **Peter Woit**
November 22, 2009

magicmike,

The problem of explaining why quarks are confined is a problem about QCD, a non-supersymmetric theory. Invoking supersymmetry as an explanation of why quarks are confined is nonsense.

The Seiberg-Witten story is about N=2 supersymmetric Yang-Mills, which has rather different behavior than QCD. I don't think there's any problem with their results, but they don't explain confinement in QCD.

19. **Peter Orland**
November 22, 2009

There is an even older 3+1-dimensonal model which displays confinement; the (non-supersymmetric) Georgi-Glashow model with sufficiently small monopole mass and large enough (renormalized) U(1) coupling. Polyakov discussed such models in 1977. As I understand things, confinement in the Seiberg-Witten theory is very similar (and importantly some quantities can be determined exactly).

If the monopole mass is too large, the magnetic monopoles of this model are just particles. These monopoles condense if the mass is small enough (but not zero), leading to confinement. What is much better known is that the 2+1-dimensional model confines for any coupling or mass. But there is confinement even in 3+1-dimensions, under the right circumstances.

As Peter W. says, confinement in QCD is very different from that in such models.

Witten on J Street

November 11, 2009
Categories: Uncategorized

The latest New York Review of Books (December 3 issue, not yet online) contains an article by Edward Witten entitled “The New J-Lobby for Peace”. It’s about [J Street](), an organization set up last year to lobby in Washington in favor of Middle East peace. Witten is on the organization’s advisory board. For more about his views on J Street from last year, see [this article]().

At the moment, he’s both hopeful that J Street will start to have an effect, and fearful that it might be too late, writing:

> The rise of J Street gives strong promise that Jews with a more liberal outlook on the Israeli-Palestinian problem will now have a voice in the American political system.
>
> The real question about J Street may be not whether it will grow but whether it is simply too late. Numerous trends, including the spread of Israeli settlements, the increase of the Palestinian population, the rise of Hamas, and growing Orthodox influence in Israel, may be putting a two-state solution out of reach.

Witten has been involved in this issue for a long time, on the board of Americans for Peace Now since 1991. It’s great to see such a prominent member of the physics/math community standing up on this issue, and encouraging that he sees something positive happening. I share his hopes for J Street, as well as his fears that it may be too late.

Sorry, but I’m not allowing comments on this posting. While I think this is a very important issue and wanted to make people aware of Witten’s article, I don’t want to host political discussions on this blog, especially on this topic.

Update: The Witten article is now available on-line [here]().

A Line on String Theory

November 12, 2009
Categories: This Week's Hype

According to the Harvard Gazette, it seems that string theory predicts a very distinctive experimental signature that should be easily observable at the LHC. The claim is that string theory predicts that the LHC should produce stau particles, with a lifetime of a minute or so. I'm no experimentalist, but I'd think a charged particle with no strong interactions, a mass of many hundreds of GeV, and long-lived enough to go all the way through the detector, should stick out like a sore thumb. This might be the kind of thing you only need one of to claim discovery of a new particle, and could even be expected to show up very early after the LHC is turned on.

So, at least if you believe the Harvard Gazette, we may be only a few weeks away from having an experimental result that will settle the string theory question once and for all. Either Vafa and collaborators will be getting the 2010 (or 2011 at the worst) Nobel prize, or string theory's prediction will have been wrong and we can say goodbye to the theory for good. Next year should be exciting…

Update: Some commenters were pessimistic that the first year LHC would produce these supposed staus at an observable rate. If I read this presentation correctly (page 54), only 40 inverse pb are needed to produce 3 events of a 200Gev stau. Maybe this model will get verified or killed during 2010. From the same conference, see Michael Peskin's summary talk for more about what the LHC might see in 2010.

Comments

1. **Eric**
   November 12, 2009

   The long-lived stau occurs in gauge-mediated supersymmetry breaking with a high scale of SUSY-breaking where the gravitino is the LSP and the stau is the NLSP. This is the type of scenario that is characteristic of the F-theory compactifications that Vafa has been studying with Heckman.

2. **a quantum diaries surivivor**
   November 12, 2009

   Hi Peter,

   "Next year should be exciting" –> if you are gullible enough 😉

   There are indeed searches for decay signals of long-lived particles designed in CMS and ATLAS. The idea being that you get signals when the beam is off! You trap these particles in the detector material, and then they decay at their leisure.

   I doubt anybody would stake a decent meal, let alone their scientific reputation and line of research, on such a prediction. It is just fun to know that we'll be able to knock such a thing off the board with little early-beam data, but not overly exciting.

   Cheers,
   T.

3. **Peter Woit**
   November 12, 2009

   Hi Tommaso,

   This thing is not just long-lived, but it's also charged, so you should see it go through your detector, not have to wait for it to decay, right?. How hard would it be to recognize a, say 200 GeV stable charged particle? And how much luminosity at 7 TeV would be needed to produce a few such particles (assuming MSSM or something like it)?

4. **Javier**
   November 12, 2009

   It is important to clarify tht if that signature isn't actually found it is not string theory what would be falsified but only the F-theory approach of Vafa.

   Still, whatever we would see (or not see9 is quite interesting because this F-theoretical approachsare a whole area of string phenomenology and, nowadays, the best developed one.

   I would add that this F-theory approachs also have concrete implications in cosmology, concerning drk matter and what can find FERNI. In particular it is expected that the ATIC and PAMELA aparent signatures of WIMMPS would be false.

   By the way, this conclusions were presented by Vafa in the slides of the last string theory 2009 in a very assequible way.

5. **piscator**
   November 12, 2009

   look. the chain of reasoning that says that metastable staus are a real prediction of F-theory GUTs (let alone of string theory) is euphemistically described as dubious. i think this is clear to anyone who has studied them.

   btw, there seems to be no text in the linked article?

6. **Peter Woit**
   November 12, 2009

   Javier,

   I see, so the headline of the story is wrong, this isn't a prediction of string theory. Any idea why someone would put an incorrect headline on a story like this?

   piscator,

Maybe you have an idea about how to reconcile the headline with your “euphemistically described as dubious”? Link works for me, giving a web-page with text.

7. **Eric**
   November 12, 2009

   I think the point is that this signature is characteristic of a specific mechanism for breaking supersymmetry. If this is observed at LHC, it would be strong evidence for gauge mediation and could suggest that the specific type of F-theory compactifications considered by Vafa and his collaborators is the right direction in which to pursue phenomenology.

8. **Toma Susi**
   November 12, 2009

   I’m not an expert, but aren’t these pretty big assumptions?

   “Vafa and Heckman devised two constraints that greatly narrowed the possible string universes. First, they assumed that gravity does not have to play a role in the unification of the other three forces. And second, they assumed that one property of string theory, called supersymmetry, is present at the energy levels generated by the LHC.”

9. **piscator**
   November 12, 2009

   >>Maybe you have an idea about how to reconcile the headline with your “euphemistically described as dubious”?

   I think the author or sub-editor has a good future writing articles for New Scientist.

   The link just gives me a large picture of Vafa with no text, although have just discovered the article by looking at the html source.

10. **Thomas R Love**
    November 12, 2009

    Like piscator, when I followed the link I did not get the article, but the entire mag is at:

    http://news.harvard.edu/gazette/wp-content/uploads/2009/11/HarvardGazette11.12.091.pdf

11. **Peter Woit**
    November 12, 2009

    Toma,

    Low-energy supersymmetry has always been advertised as a positive feature of superstring unification. Decoupling from gravity is essential to get anything. Without this, your particle physics predictions depend on the details of your Calabi-Yau, fluxes, etc, and you basically can’t predict anything (this is the landscape problem).

    You can certainly give up one or both of these things, but if you do, it seems likely that you’ll never predict anything that can be observed.

12. **a quantum diaries surivivor**
    November 12, 2009

    You are right, Peter. If it is charged, it can also be seen with other -more mundane- techniques, such as the large ionization it leaves in the tracker. All in all, the limitations in the detection of such things is pretty much driven by their production rate, and so the model details.

    Cheers,
    T.

13. **anon.**
    November 12, 2009

    “It would be the smoking gun for our stringy models,” Vafa said.

    I hope that’s a misquote. It’s a signature of a wide range of gauge-mediated models. “Smoking gun” usually means a direct implication, not a hint. It’s also not at all clear that F-theory GUTs necessarily imply gauge mediation, and there are many issues (like moduli stabilization) that are glossed over in extracting something resembling an effective low-energy theory from their string constructions. They end up with something that is very close to minimal gauge mediation (and signatures that have been studied for more than a decade), but it’s not at all clear that this is the only thing one could get from similar constructions.

    The one hint of high-scale physics that one could hope for in this scenario would be a measurement of the stau lifetime (which would require the sort of trapped particle Tommaso mentions), which would be an indication of the gravitino mass and hence of the fundamental scale of SUSY breaking. For Vafa and company, this is expected to be just below the intermediate scale, roughly as high as gauge mediation can possibly be pushed.

14. **Shantanu**
    November 13, 2009

    Peter , there have been some interesting conferences at PI

    http://www.pirsa.org/C09025
    http://www.pirsa.org/C09026
    anything interesing in this ?

15. **Theodor**
    November 13, 2009

    Something to smile about:

    A well-known physicist writes: (standard) “particle theory predicts supersymmetry”. (This statement is found on http://insti.physics.sunysb.edu/~siegel/vs.html)

    It shows how working 30 years in the same field distorts your perception of reality…

16. **Martin**
November 13, 2009

Hi Peter,

the article states that "Supersymmetry, which was first discovered in the context of string theory,…".
A question for the history of string theory buff:
Did string theory really give birth to supersymmetry?

Cheers,
Martin

17. **Peter Woit**
November 13, 2009

Martin,

No, that statement is not really true. 4d space-time supersymmetry of the kind relevant to the LHC was first discovered by Golfand-Likhtman (in 1970, published in 1971) and Akulov-Volkov (1971/72).

Independently, in 1971 Gervais and Sakita recognized a version of 2d world-sheet supersymmetry in the new fermionic string theory. This led to Wess and Zumino rediscovering 4d supersymmetry in 1973.

For more details, see

http://cerncourier.com/cws/article/cern/28388

18. **Tom Rizzo**
November 13, 2009

Hi,

To directly produce an essentially stable 200 GeV stau would require the 14 TeV LHC to run full out, i.e., 100 fb^-1. The production cross section for the pair production of heavy states by only electroweak processes is quite small. It is more likely that such an object might be found in the cascade decay of a strongly produced SUSY state. At 10 TeV, 100 pb^-1 barely lets you pass the LEP limit for such an object.

19. **Peter Woit**
November 13, 2009

Thanks Tom,

Looking at the Vafa-Heckman papers more carefully, I see that they are claiming a mass range of about 50-300 GeV, less tha 172 GeV if it's going to be the NLSP. I don't see a cross-section, but for the case where a neutralino is the NLSP, they quote 3 x 10^2 fb (presumably at 14TeV) for the production of the kind of strongly produced SUSY state you mention, with branching ratios "relatively large" to the neutralino.

So, OK, maybe not in the first few months…

20. **anonymous**
November 13, 2009

Look, it's obviously extremely irresponsible of anyone to claim that
string theory or specifically F theory predicts something so
specific at this point. That signal could suggest
gauge mediated SUSY breaking, consistent
with many UV completions even within
string theory. We'll be lucky if
SUSY itself is cleanly diagnosed very soon (as opposed to
other kinds of new physics). Gravity-mediated
SUSY breaking is a bit more UV sensitive, as is high
scale Gauge mediation. CMB data has a certain
amount of UV sensitivity. People should try to be responsible
about making accurate, measured (so to speak)
statements about these directions. It's not all or nothing;
the fact that there are not known smoking gun predictions
of F theory or string theory phenomenology does not mean
that we can't test specific scenarios and learn as
much as we can from the data
as well as from the structure of the theory.

21. **Andrew**
November 14, 2009

I'm sure if the LHC produces pink bunnies, string theory can be modified to explain it.

22. **Javier**
November 15, 2009

Hi Peter, some clarifications.

First of all, this F-theory is "landscape free". By this I mean that the requirement of gravity decoupling is enough to allow a very restricted number of choices that resemble the standard model, with concretes values of couplings and masses, unifying to SU(5). This is contrary to the landscape idea that, even after that decoupling (i.e. working in"local models" that intend to engnier the known physic) there are a very large number of different string vacua that result in a low energy effective lagrangian implementing the standard model, but with very different values of the coupling constants (and possibly other quantities) for each of them, which implies that string theory doesn't predict any value for them. This kind of landscape is different from that implied in the solution of the tiny cosmological constant. I must admit that I still don't understand all the details, and in particular I am not sure how the F-theory GUT's are expected to face the cc problem.

The second questions is that the claim of Vafa is that the peculiarities of his F-theory GUT's are so specific that it could be possible to distinguish them for the other similar SUSY models with gauge mediation SUSY breaking, precisely the contrary to what many commenters have said here. The actual paper (I am not sure if that was the one you were referring to in one of your comments) is :http://arxiv.org/abs/0903.3609

I am not the most qualified person to give a authoritative opinion about this topic,but as far as I understand it if the LHC fits the predictions of Vafa there is not too much window for other theories that string theory, in the F-theory in this specific limit to account for the known physic. If it gets falsified one would have to rely on other type II-B brane constructions, that have many restrictions to be unified theories so one would possibly have an standard model tht doesn't unify, or, more probably, natures is not described by type II -b string theory in weak or strong coupling. That is too much to say. Possibly mirror symmetry would also almost invalidate type IIa constructions. As a result possibly if this F-theory GUT is not verified that would mean that nature would be expected to realize some heterotic (M theory heterotic) string vacua. Said this It would be really fine if most informed people as Motl or Distler (or whoever) would comment on what I say.

23. **Gphillip**
November 22, 2009

    I'll give any and all takers 1000 to 1 odds that these particles will never be found. The reasoning is that if these massive charged particles take 1 minute or so to decay, we would be swimming in them from cosmic ray collisions with our atmosphere. We wouldn't even need the LHC. Just the detector pointed at the sky should work fine.

24. **Peter Woit**
November 22, 2009

    Gphillip,

    The number of cosmic rays with energy sufficient to produce interactions of higher energy than that studied at the Tevatron is non-zero but quite small. Since the probability of producing such a new particle is also very small, you're not going to see these things in cosmic rays.

    This problem is very general, and it's why you need accelerators like the LHC: you need to produce not just high energy collisions, but a lot of them, and you can't get this from cosmic rays.

25. **Gphillip**
November 24, 2009

    Perhaps I've misunderstood something here. At 10 ^13eV cosmic rays strike the atmosphere at a rate of a few per sq. meter per year. Many more at lower energies. There's about 197 million square miles on the surface of the earth. That's a very big non-zero number.

    I was just joking about pointing a detector at the sky, but if that many heavy charged particles are being generated, and take 1 minute to decay, I believe we would have (or at least could have) detected them by other means. But as I said, perhaps I've misunderstood something.

26. **Peter Woit**
November 24, 2009

    To get LHC energies in the center of mass you need cosmic rays of something like 10^17 ev. They're rare. And it's not like you can afford to instrument the entire earth's surface.

    Once you have one of these, the probability that it will produce this kind of new heavy particle is extremely low. Remember, at the LHC, you're talking about a few events/year out of a collision rate of 10^9/sec or some such.

    You can do the math, but there's no way you're going to get a non-negligible answer…

27. **Gphillip**
November 24, 2009

    Of course you are right. At or above 10^17 eV only about 10 cosmic rays per sq. kM strike the atmosphere per year. It's enough to eliminate "the LHC will devour the Earth" conjecture, but not enough to generate many particles if only a few are generated per year from 10 ^ 9 collisions per second. I suppose this eliminates the possibility of finding some stuck to my refigerator magnet. I stand corrected.

On the Defensive

November 13, 2009
Categories: This Week's Hype

There's another article here about Michael Green succeeding Hawking as Lucasian chair. It emphasizes the idea that this is all about more funding for string theory:

> MICHAEL Green, the 18th holder of Cambridge University's Lucasian Professorship of Mathematics, is clearly a man with weighty issues on his mind.
>
> He apologetically darts out of our meeting to speak to a colleague about how to submit the paperwork for a 1.5 million euros (£1.35 million) grant application he has just heard has been approved by the European Union.
>
> "I suppose it sounds like a lot of money," he explains, "but it's not that much really compared to the billions spent on some research. Our work is theoretical – we're very cheap."
>
> The money will go towards research on Michael's specialist subject, string theory…
>
> "I have been thinking about how I can make use of such a prominent position to benefit my colleagues. It is difficult to find funding at the moment, especially for subjects which don't obviously have an immediate application for something that will make money.
>
> "But the people who discovered magnetism and electricity had no idea what they could be used for. The MRI scanner wouldn't exist without particle physics. There are so many spin-off industrial investments in things that are being researched, and we need more of this."

Another blogger has the following comments about this:

> There's only so far that one can run away with this. People "…who discovered magnetism and electricity…" had, in their corner, empirical evidence to at least tell them if they are on the right path or not. This is where the analogy to pursuing String Theory breaks down and the similarity ends. I don't believe that there has been, in the history of physics, a study in a field of physics that has gone for so long, and garnered THIS much attention, that has been totally devoid of any empirical evidence which indicates one way or the other that it is on a right path. For many of us who value physics as being guided by empirical evidence, this is the most troubling aspect of String theory.

To be fair, Green notes that it's not all about cashing in for himself and his colleagues, that he would also like to finally have some success with the science:

> But, ever the academic, Michael's eyes twinkle as he admits his "pie in the sky" dream for his tenure of the Lucasian Professorship is not about money, but a breakthrough in the application of his beloved string theory.
>
> "We need something which at the moment doesn't seem to be a fundamental phenomenon," he explains. "To find something we know already, but find an undetected explanation out of string theory. It is a radically new theory; what it needs is a radical new prediction."

I'm not sure though that describing a nearly forty year old theory as "radically new" is really accurate. Any sort of prediction would be radically new.

Also in the business of defending string theory is Sean Carroll, who has a video and transcript up on the Edge web-site on the topic of "Why does the Universe look the way it does?". It's unclear to me what this has to do with the topic, but for some reason much of the talk is taken up with a defense of string theory. It's the usual misleading hype, at great length, leading up to a peculiar defense of the idea that even once you have shown that a speculative theoretical idea is vacuous and can give you anything that you want, you should keep studying it anyway:

> How do you show that a theory is not right if you can get anything from it? My answer to that is we just don't know yet. But that does not imply that we will never know.

From here it's on to the multiverse and his idea that it explains why you can't unscramble an egg, and that one is doing observational cosmology over breakfast:

> The reason we find a direction in time here in this room or in the kitchen when you scramble an egg or mix milk into coffee is not because we live in the physical vicinity of some important object, but because we live in the aftermath of some influential event, and that event is the Big Bang. The Big Bang set all of the clocks in the world. When we go down to how we evolve, why we are born and then die, and never in the opposite order, why we remember what happened yesterday and we don't remember what is going to happen tomorrow, all of these manifestations of the difference between the past and the future are all coming from the same source. That source is the low entropy of the Big Bang…
>
> I like to say that observational cosmology is the cheapest possible science to go into. Every time you put milk into your coffee and watch it mix and realize that you can't unmix that milk from your coffee, you are learning something profound about the Big Bang, about conditions in the very, very early universe. This is just a giant clue that the real universe has given to us to how the fundamental laws of physics work. We don't yet know how to put that clue to work. We don't know the answer to the who done it, who is the guilty party, why the universe is like that. But taking this question seriously is a huge step forward in trying to understand how the universe that we see around us directly fits into a much bigger picture.

Update: Carroll this week will be on a lecture tour in Australia giving talks on the Big Bang/egg unscrambling business. The first will be in Sydney where the "internationally-renowned theoretical physicist" will give the 2009 Templeton Lecture.

Comments

1. **GeofF**
   November 13, 2009

   I think the flushing of a toilet is a much better analogy than scrambling an egg.

2. **Tom O'Bulls**
   November 14, 2009

   Thanks for directing my attention to Sean Carroll's extremely interesting article. He really raises some very profound questions, and it's good to know that there are people thinking about genuinely interesting problems like the arrow of time, and not just about really boring things like [mumble].

3. **M**

November 14, 2009

GeofF, an even better analogy is: by flushing 1.5 million Euro down a toilet we learn about cosmology. Maybe it can get funded.

4. **piscator**
November 14, 2009

‘cashing in’, ‘all about more funding for string theory’? This is a parallel universe – do you know the state of funding for particle theory at this moment?

The UK government has thrown squillions at its banks and is in danger of losing its AAA credit rating. It also wants funding for all research (including even the humanities God help them) to be based on economic impact.

The idea that this environment is one of squidgy slush funds for string theory is so far from the truth it is comical.

5. **Peter Woit**
November 14, 2009

piscator,

I understand that the context of this is one of a difficult budget environment for science in the UK. Still, the article’s focus on the Lucasian chair as a vehicle for Green to raise money for his colleagues and his field is remarkable, if only as a sign of the times.

6. **John Rennie**
November 14, 2009

Re the low entropy at the Big Bang: if gravity were replusive then the state of maximum entropy would be an (approximately) uniformly distributed gas. Doesn’t LQG predict that gravity becomes repulsive as you wind back time towards the Big Bang? In that case isn’t it possible that the low initial entropy is due to gravity flipping from a repulsive to an attractive force?

JR

7. **Tim vB**
November 14, 2009

Here are two quotes from the article that I have some trouble making sense of:
“…with applications in countless different spheres.”
“The theory … has met with many successes over the years.”

Should’nt the first one be “with applications, maybe, sometime in the far future, if the theory succeeds”?

Reading the second one, I thought in this context a success should be something that is of interest to non-string-theorists. The only way I can make sense of this statements is that Green meant that “string theorists succeded in solving many problems that string theory had resp. created”, meaning that, from the point of view of a string theorists, there were many breakthroughs. I could concur with that, but I suspect that this not not what most reades will think.

P.S.: Green uses his position to fund string theory, this is hardly a surprise. Isn’t that what most people in similar situations do?

8. **Kea**
November 14, 2009

Oh, I’ll be in Melbourne for that Carroll talk … but I’ll be busy doing something too interesting to attend … like my washing, maybe.

9. **Marcus**
November 14, 2009

Oh, I’ll be in Melbourne for that Carroll talk … but I’ll be busy doing something too interesting to attend … like my washing, maybe.

LOL

And remember that doing your laundry is a giant clue as to to how the fundamental laws of physics work.

10. **Will Orrick**
November 14, 2009

The reason for the name “Templeton Lecture” is described at this University of Sydney website:

“In 1990, Charles Birch was awarded the Templeton Prize for progress in religion. He donated part of the proceeds of the prize to establish the annual Templeton Lecture at the University of Sydney, under the auspices of the Centre for the Human Aspects of Science and Technology. This generous gift has brought a succession of distinguished speakers to Sydney.”

11. **Peter Woit**
November 15, 2009

Thanks Will, I was wondering what that was about.

12. **chris**
November 16, 2009

JR,

on a cosmic scale gravity IS repulsive.

13. **John Rennie**
November 16, 2009

@chris: I assume you’re referring to dark energy, but this has only recently starred dominating and certainly wasn’t a factor near the Big Bang, or indeed during the formation of galaxies.

Of course there may eventually be a big rip. If so presumably the state of maximum entropy would again be a roughly uniform distribution. That's assuming the concept of entropy has any meaning in such a radically non-equilibrium system!

14. **Alejandro Rivero**
November 16, 2009

TInking about being a "nearly forty year old theory" … is there some plan to celebrate the anniversary. If we count from Susskind "violin string or organ pipe", we should prepare, as it was submitted in 11 July 1969 and published early 1970. If we count from Veneziano, we are already late. We could count from Ramond 1971, as it paves the way to D=10, susy etc.

15. **Thomas Larsson**
November 16, 2009

Veneziano's and Virasoro's advisor is no longer with us.

16. **Chris Austin**
November 20, 2009

Forgive me if this is a silly comment, but isn't the reason that we remember the past but not the future, connected with the fact that field equations in Minkowski signature have well defined solutions when boundary conditions are specified on just a single spacelike surface, i.e. a Cauchy surface? Then, if the boundary conditions on the Cauchy surface do not include non-random correlations between the initial values of the fields at distant points, the time direction away from the Cauchy surface is the direction of increasing time, and we are forced to use retarded potentials in solving, e.g., Maxwell's equations in the presence of classically moving charged particles.

If we wanted to use advanced potentials, or mixed advanced / retarded potentials, the boundary conditions on the Cauchy surface would have to include carefully set up incoming spherical waves for the moving charged particles to absorb, and these would have to be correlated with the future motions of the charged particles. Thus Minkowski signature field equations automatically create correlations away from the Cauchy surface, if there are no correlations on the Cauchy surface.

Furthermore, if the boundary conditions on the Cauchy surface are random, the state of a memory device at any time will in general be correlated with events in its past light cone, and in particular, with events on its past worldline, going back to the Cauchy surface, but cannot be correlated with events on its future worldline except under special conditions of shielding, since events on its future worldline will in general depend on the boundary conditions on the Cauchy surface outside its current past light cone, which have not yet had any impact on the memory device.

Thus the fact that we remember the past but not the future points to nothing more than that the boundary conditions of physical fields have been specified in the simplest possible way, namely randomly on a Cauchy surface, with no correlations.

The reason we can't unscramble an egg is different. First, we have to get the ordered state, i.e. the yolk separated from the albumen. Such locally highly nonrandom states can arise out of initially random states by a long series of ratchet-like processes such as evolution, or by forces that tend to separate the components of a mixture such as a colloid, due for example to differing densities, or high interface energies. Once we have the egg, it is easy to scramble it, because a wide variety of crude driving motions, such as shaking or stirring, can all effectively turn the initial ordered state into a disordered state, via chaotic motions. However the fact that it is difficult to unscramble an egg is a specific property of the yolk / albumen mixture, and tells us nothing at all about other systems. For example, if we "scramble" oil and water together, the mixture will soon separate, due to the differing densities of oil and water, and the relatively high surface energy at the oil / water interface.

A Brilliant Darkness

November 14, 2009
Categories: Book Reviews

Joao Magueijo has a new book out about Ettore Majorana, entitled A Brilliant Darkness. It's a lot of fun to read, and could be described as an example of Gonzo history of science. While it contains a lot of factual information, much of which I was unaware of, it's probably best to think of it like the works of Hunter S. Thompson. Not a good place to go for authoritatively accurate information about, e.g., Las Vegas or the 1972 US Presidential campaign, but a highly personal investigation that manages to get to the heart of the matter, finding emotional if not literal truth.

For some examples, here's Magueijo on Majorana's upbringing:

> Jokes and pranks aside, one should not get the impression that Ettore's youth was a happy one. It was dire. Between the priests and his parents, his basic humanity was destroyed. He was brought up by social outcasts and grew monstrously distorted, lacking social skills and independence, full of ineptitude. People like him — when they don't become criminals, drug addicts or psychopaths — *can't help* being intellectually superior. But they're "Frankensteins," artificially gifted, clever "against nature." And like the literary monster, behind the bestial genius lies a very different nature: tender in a way that can never be fully realized; longing for love, knowing full well that it will always be denied; a furnace of kind emotions that the ogre exterior will always screen.

and here's his account of his own trip on the ferry where Majorana presumably killed himself in 1938 at the age of 31:

> Back on deck, I realize what a gloomy figure I must cut: pensive and stark, staring at the sea. Maybe the insomniac brigade is worried I might be contemplating suicide. A girl comes out to smoke and waits to be chatted up. I move to the rear. What a sad bastard I must look, refusing to play the game of life, shouting and fucking, throwing up against the wind. I watch the wake for a long time, the cigarette butts flying past me into the night, like fireflies from Mars. In our world of the "normal", anyone who thinks is likely to appear suicidal. And yet, suicide or not, we will all be there one day, not just Ettore. We are all the same, only in different seasons.

Majorana was born in 1906 in Sicily, went to Rome for his studies. His career as a physicist basically spanned just the years 1928-1933, much of which was spent working in Fermi's famous group in Rome. For Magueijo, Fermi is one of the villains of the piece, with Majorana a genius much his superior. Unlike the rest of the group, Majorana wasn't interested in experimental work, nor much interested in publishing his ideas, about which Magueijo claims:

> That's how he never got credit for Heisenberg's theory of nuclear forces and the neutron, the Weisskopf-Pauli second quantization of the complex scalar field, or the parity-violating properties of the neutrino, which earned Tsung Dao Lee and Chen Ning Yang the Nobel Prize some thirty years later. They could all have been named after Majorana. But because he never published his work, only the Majorana neutrino — his inseparable soul mate — carries Ettore's name today.

In 1933 Majorana traveled to Leipzig to work with Heisenberg, then to Copenhagen to work with Bohr. When he returned to Rome, some combination of physical and mental health problems led him to become a recluse for several years. He emerged from this state in 1937 to take up a professorship in Naples, but a few months later disappeared after embarking on a ferry taking him from Palermo back to Naples.

Majorana's most important scientific work appeared in a 1932 Nuovo Cimento paper motivated by the desire to find a replacement for the Dirac equation that would solve the problem of its negative energy states (a problem which disappeared in 1932 with the discovery of the positron). In this paper, Majorana investigated for the first time infinite dimensional representations of the Lorentz group, ones whose role in physics, if any, remains mysterious. As part of this work, he discovered the possibility of a real representation of the Clifford algebra and thus a version of the Dirac equation in which a particle is its own anti-particle. Whether this possibility is realized in the case of neutrinos is one of the big open questions of the subject. We know that there must be neutrino mass terms, but we don't know if they're of Majorana or Dirac form.

Magueijo does a good job of describing this important physics at a popular level. He also gives a lot of space to the various myths that have grown up around the story of Majorana's disappearance. There's a whole subculture out there devoted to them. He wisely decides not to sign on to any of these or create his own, concluding:

> And as with the neutrino, Ettore's story is also elusive. Even if we found out for sure what actually happened to him, we'd never know *why* he did it — which is far more important. This absence of a final truth shouldn't sadden us: At leas we don't harbor delusions of omniscience. When I got on that plane to Sicily, I promised myself only this: I won't raise my leg and urinate over my little territory in Ettoreland; I won't invent a solution that is not needed.

Comments

1. **D R Lunsford**
   November 14, 2009

   Now THIS sounds like a good read!!

   BTW it's not quite right to say the problem of the negative energy states was alleviated by the appearance of the positron. Dirac for example kept working at "getting an equation" (as he would say it) with purely positive energy right up into the 70s. See the papers "A Positive Energy Relativistic Wave Equation" from about 1972 or so.

   ok here http://www.jstor.org/pss/77762

   a fascinating work.

   -drl

2. **einblicke**
   November 14, 2009

   I was greatly inspired by the works of infinite dimensional representation of the Lorentz group by Majorana, since the mathematical theorm says that the finite dimensional representation of a non-compact group (like the Lorentz group) is non-unitary, which violate the spirite of quantum mechanics, and I once thought that it may be the key obstacle for our reconciling the quantum mechanics and the relativity. However, an infinite dimensional representation of the Lorentz group is unitary, which I once thought as a possible path, but little progress.

   Today's quantum fields theory of reconciling the quantum mechanics and the relativity is going another way in which the particle number but rather the inner product can be negetive and be interpreted as anti-particle.

3. **mike**
   November 15, 2009

Will the LHC be able to tell the difference between neutrinos of the Majorana and Dirac form? Will will we be able to get an accurate mass reading from one of the detectors?

4. **Yatima**
November 15, 2009

While we are on the memory lane:

http://www.independent.co.uk/news/obituaries/vitaly-ginzburg-nobel-prizewinning-physicist-who-helped-the-soviet-union-develop-the-hydrogen-bomb-1820387.html

"Ginzburg was a pioneering theoretical physicist who often deprecated his own abilities in mathematics, yet made seminal contributions in a number of areas of physics, including quantum theory, astrophysics and radio-astronomy. Following years of nominations, he won the 2003 Nobel Physics Prize for developing the theory behind superconductors; materials which allow electricity to pass without resistance at very low temperatures. His work had been done with his fellow physicist Lev Landau, but he had died in 1968 and awards were not given posthumously. He shared the prize with the British-American Anthony Leggett and the Russian-born US scientist Alexei Abrikosov."

5. **Peter Woit**
November 15, 2009

mike,

The LHC is not useful for studying neutrino masses, they're quite small and you don't need LHC energy to produce neutrinos. There's a wide range of non-collider experiments going on to study neutrinos, including some that in principle can distinguish between Marjorana and Dirac.

6. **Stephen**
November 15, 2009

I strongly recommend this classic book on Majorana:
"The Moro Affair and The Mystery of Majorana" by Leonardo Sciascia.

From the book, among other things, apart from the suicide hypothesis, there appear to be some other explanations: for instance the fact that he may have started secretly religious life, or that he may have escaped to argentina. I like to think that the alternative hypothesis to the suicide are true.

7. **Cormac O Raifeartaigh**
November 17, 2009

I enjoyed Jao's first book, Faster Than the Speed of Light. I suspect a lot of reviewers missed the fact that he is a very good science writer because they doubted his premise. He has a lovely, clear, but chatty style…

8. **Kay zum Felde**
November 18, 2009

I find it interesting how Magueijo conclude, that Majorana must become a superior physicist because of his hard youth.

I myself am a physicist too and suffer from a schizoaffective psychosis and when the illness is on its top, I've often good ideas as pictures in my mind, that don't work, because in such a state my mathematical mind does not work correctly. Afterwards I usually cannot remember my ideas. This is not that problematic since as I implied they wouldn't work correctly. What I wanted to say too, I can imagine the lonelyness of Majorana, especially the longing for love, even it cannot delivered.

Best Kay

9. **jun**
November 19, 2009

I too liked Joao's first book. I remember getting pretty excited about VSL. I was a bit surprised when a well-known string theorist disparaged his ideas.

10. **tomate**
November 21, 2009

The short novel by Leonardo Sciascia that Stephen cites is a great pieace of italian literature devoted to alternative inquire into the subject, so I wouldn't call it "subculture". The main point of Sciascia (maybe a bit too fictionary, but deep and accurate) is that Majorana could have disappeard to subtract himself from the hands of the fascist regime, since he problably foresaw the strategic power of the nucleus that was not yet totally unravelled by Fermi himself. In fact Mussolini had explicit orders to find him alive, when Fermi brought his experimental knowledge in the US, being his wife jew. History could have taken a quite different turn…

11. **tomate**
November 22, 2009

…and I point out this new article that appeared in the arXiv, for the italian readers:

http://arxiv.org/abs/0911.0933

The author is credited for being the most prominent expert about Majorana's legacy; the materials Leonardo Sciascia worked on come from himself. It would be interesting to know if Magueijo got in contact with this guy for his own work…

LHC Update

November 19, 2009
Categories: Experimental HEP News

Yesterday the LHC Hardware Commissioning Coordination Team announced the end of the 2009 Hardware Commissioning Campaign as all 8 LHC sectors were declared commissioned and ready for beam. A two day checkout period is now underway, which should have the LHC ready for beam at 17:00 Friday. Friday evening and night should see beams threaded around the machine in both directions. Saturday the plan is to capture a circulating beam in one direction, Sunday in the other direction. Celebratory drinks are scheduled for 17:00 Monday in the CERN Control Center.

Update: Up-to-date news about beam commissioning is here, and hopefully CERN won't shut off outside access to it. Normally I try and avoid providing links that might be in danger of becoming non-public, but in this case, since the New York Times is linking to this, I suppose I should too.

Update: The LHC Portal is a site with a lot of links to CERN information. For more about the site, see here.

Update: Beam is in the LHC and has made it part way around, to IP3. One place to follow progress is here.

Just as I finished writing that, I see it's now at IP5.

Update: After a short stop to recover from a magnet quench, the beam has now gone all the way around the ring, making two turns.

Comments

1. **T.**
   November 20, 2009

   Nooooooo way, apparently another magnet has quenched..?!

2. **Peter Woit**
   November 20, 2009

   T.,

   Magnet quenches are fairly common. The problem last year was the failure of the system that protects the machine when they happen.

3. **katanakun**
   November 20, 2009

   follow the LHC beam circulation on http://twitter.com/cern

   LHC is back 🙂 🙂 🙂

4. **T.**
   November 20, 2009

   Thx Peter. well this protection system now appears to be doing its job properly -at the very least it didn't fail immediately, this would have been death by ridicule.

5. **Chris Stephens**
   November 22, 2009

   Cool mention of my site. I hope you guys enjoy it. If you want to keep track of daily happenings the best spot is http://cmsdoc.cern.ch/cms/performance/FirstBeam/cms-e-commentary09.htm which is on my site under CMS and Live Log

Higgs Escapes Part of Exclusion Region

November 19, 2009
Categories: Experimental HEP News

This past winter a combined analysis of data from the two Tevatron experiments showed at 95% confidence level that the Higgs mass could not be in the range 160-170 GeV. This was a better result than expected: statistically the experiments should not have been able to exclude any of the mass range, but were helped by a downward statistical fluctuation.

Today a new and improved combined analysis was released using more data, and the new result is that there has been a reversion to the mean, no more help from statistical fluctuation downwards. Statistically, this time they should have been able to exclude 159-168 GeV, but now the fluctuation is a bit upwards, so the actual exclusion region is 163-166 GeV. In essence, better data has shown that the likelihood of a 160-163 or 166-170 GeV Higgs, something that was previously assigned a probability of a bit less than 5%, now has a probability a bit more than 5%. So, any putative Higgs particle in those mass regions has now escaped being tarred with the unfair label of "excluded".

If the Higgs is actually there at a certain mass, as one gets closer and closer to having sufficient data to exclude its existence, one should find oneself doing nowhere near as well as expected as far as excluding that mass. A thoroughly irresponsible person might see some significance in the fact that, unlike the analysis from earlier this year, the new improved analysis with more data does a worse job of exclusion than expected over much of the low mass range, peaking at 1.5 sigma or so for the mass range around 135 GeV.

Update: More detail and rank speculation about this from Tommaso Dorigo here.

Comments

1. **Peter Lee**
   November 19, 2009

   Just wondering if this means that Alain Connes' Non-Commutative Geometry theory predicting a Higgs mass of around 170 GeV might still work out?
   I enclose a copy of his posting in August 2008 when an earlier result excluding a Higgs mass of 170 GeV came out.

   IRONY

   In a rather ironical manner the first Higgs mass that is now excluded by the Tevatron latest results is precisely 170 GeV, namely the one that was favored in the NCG interpretation of the Standard Model, from the unification of the quartic Higgs self-coupling with the other gauge couplings and making the "big desert" hypothesis, which assumes that there is no new physics (besides the neutrino mixing) up to the unification scale. My first reaction is of course a profound discouragement, mixed with an enhanced curiosity about what new physics will be discovered at the LHC.
   I'll end with these verses of Lucretius:
   Suave, mari magno turbantibus aequora ventis,
   e terra magnum alterius spectare laborem;
   non quia vexari quemquamst jucunda voluptas,
   sed quibus ipse malis careas quia cernere suave est.
   —————————————————
   [Pleasant it is, when over a great sea the winds trouble the waters, to gaze from shore upon another's tribulation: not because any man's troubles are a delectable joy, but because to perceive from what ills you are free yourself is pleasant.]

2. **piscator**
   November 20, 2009

   maybe the thoroughly irresponsible person would see 1.5 sigma worth of significance? 😉

3. **Martin**
   November 20, 2009

   Hi Peter,

   I have heard of particles with a signal at the 5 sigma significance level disappearing into noise.
   How often in your experience does it happen that a particle is found in its (e.g. 2 sigma) exclusion zone?

   Cheers,
   Martin

4. **Peter Woit**
   November 20, 2009

   Peter Lee,

   This just improves the bad odds a bit for the 170 GeV prediction of Connes from 5% to something a bit bigger.

   Martin,

   There aren't many examples I know of of this kind, so hard to say. In principle, one time in 20 this should happen. There's also the phenomenon to keep in mind that when experimentalists err, it generally is on the side of thinking their results are more accurate than they really are…

5. **A quantum diaries survivor**
   November 21, 2009

   Hi Peter,
   thanks for the irresponsible link 😉

I think that the 1.5 sigma at 115 GeV are a way more interesting thing than the narrow exclusion, because of the electroweak fits and because of the LEP II excess.
Also, a 160 gev Higgs will be seen or wiped off the board in a few months by LHC, so the 115-140 gev region retains less ephemeral value.
Cheers,
T.

First Collisions at the LHC

November 23, 2009
Categories: Experimental HEP News

Things evidently went extremely well over the weekend at the LHC, with simultaneous circulating beams achieved this morning. Speculation is that first collisions (at the injection energy of 450 GeV/beam) are imminent. Places for up to the minute information include here, here and here.

Update: It looks like first collisions have been seen at the LHC. Announcement comes from a muzzled blogger….

Update: Modified posting title.

Update: For a series of talks about events during the first few days since beam injection at the LHC, see here. Progress was dramatic during the first few days, although it has slowed up recently. As data starts to come in, the first scientific task for the experiments is to re-discover the Standard Model. So far, CMS has managed to rediscover the pi-zero.

   November 23, 2009

   The CMS e-commentary site just splashed a collision image, then pulled it, then put it back. Probably good to mirror that one…
   http://sifter.org/~aglisi/albums/LHCfirstcollisions.png

2. **Marcus**
   November 23, 2009

   Here is the official site's picture.
   http://cmsdoc.cern.ch/cms/performance/FirstBeam/pictures221109/CollisionEvent.png
   Good you have it mirrored.

3. **Yatima**
   November 23, 2009

   Why are they so secretive? We know they are just playing around; this not some sort of political kabuki where everybody has to protect cherished anatomical parts before the poll results are in … or is it?

4. **Marcus**
   November 23, 2009

   Yatima, I laughed out loud reading your post
   Why are they so secretive? We know they are just playing around; this not some sort of political kabuki where everybody has to protect cherished anatomical parts before the poll results are in … or is it?

   I like the turns of phrase. But I have to say that from my perspective I think CERN is now being admirably open. They are being a lot better than they could be. There is an impressive amount of web access. And they also (so far as I know) have been allowing Chris Stevens' unofficial "LHC Portal" website which assembles a huge amount of stuff.

   I think there's been some improvement and they've gotten more enlightened—this openness will, I think, benefit CERN and science generally (assuming it continues.) The public relations benefit of allowing a kind of fly-on-wall participation via web will greatly outweigh any possible temporary embarrassments.

   But obviously my sense of proportion about this is very different from yours.

5. **Ralph**
   November 24, 2009

   They ramped a beam up to 560 GeV also. I guess it will take a few attempts to get it ramping smoothly to over a TeV.

6. **Coin**
   November 24, 2009

   The USLHC blog has some more pictures, which appear to be official releases (?), of what they call "candidate" collision events.

   What does "candidate" mean in this context?

   Trying to make sure I understand: Normally the LHC would use two opposing particle beams, and "collisions" would be between the particles of the two beams. In this case they were only testing 1 beam, however because the vacuum in the detector chamber is necessarily imperfect the beam would have collided with like a marauding atom or something to produce the "candidate" collision. Is this right?

7. **Peter Woit**
   November 24, 2009

   Coin,

   These "candidate" collisions are real collisions, the experiments are just being overly cautious about what they call something that has not yet been carefully analyzed.

   They have two beams in the machine, and got them to cross at the correct interaction points inside the detectors. These are now real colliding beams of the sort the machine is designed to produce, only problem is that the energy/beam is 450 GeV, not 3.5 TeV, and the luminosity is something absurdly low. They have made a huge amount of progress very quickly, this was supposed to take much longer.

   Now all they need to do is to ramp the beam energy up to 3.5 TeV, and work on getting a usable luminosity (a lot more collisions). The machine's quench protection system is only commissioned up to 1.2 TeV/beam, so that should be as high as they can go before Christmas. After Christmas, they'll first have to work on commissioning to 3.5 TeV, then ramping up the beam energy.

8. **Coin**
   November 24, 2009

   Thanks for clarifying.

9. **Mitch Miller**
   November 25, 2009

   Another general question, when they get the energy and luminosity up, do they just sweep the whole energy range and collect data? From what I have read, it seems like it takes an incredible amount of data at to show an unobserved particle exists, so maybe they guess energies and focus on the ones where the not yet signifigant data looks most interesting?

10. **Peter Woit**
    November 25, 2009

    Mitch,

    In these experiments the collision energy is fixed. They will basically always run at the highest beam energy the machine can achieve. There's no structure in the proton-proton cross-section at these energies like a resonance that would make it desirable to run at a specific energy.

    The products of a collision are very complicated, and the search for new particles is all about trying to find evidence for it amongst these collision products. You want as a high a collision energy as you can get, because that will allow you to produce the highest possible mass particles, in the highest numbers.

11. **Mitch Miller**
    November 25, 2009

    Thanks for the answer Peter.

12. **Paul Wells**
    November 25, 2009

    Mitch,

    In electron-positron collisions where (to current knowledge) the particles have no sub-structure the energies ARE tuned e.g. at LEP to Z0 resonance.

    In proton-proton collisions the energy is already smeared out over the quarks and gluons so there is no need to tune.

Short Items

November 27, 2009
Categories: Uncategorized

- To get an idea of what's going on at CERN not at the LHC, but at the theoretical end of things, take a look at the presentations at the recent CERN-TH retreat.
- I was worried that this blog marked the end of the distinguished series of publications of W. C. Gall. Fortunately, I see that there is now more.
- A year ago I attended a talk at NYU by IAS director Peter Goddard on the early history of the IHES and how it was inspired by the Princeton Institute. Cormac O'Raifertaigh reports here on a recent talk by Goddard at the Dublin Institute of Advanced Studies, about how it too grew out of a similar inspiration.
- Via Jordan Ellenberg, there's news of a claimed proof of Leopoldt's conjecture, with details available at a blog entry by Minhyong Kim at the new London Number Theory blog.
- Among courses this semester the world over I wish I could attend, one would be Eckhard Meinrenken's on Lie Groups and Clifford algebras. Luckily he's producing lecture notes, updating those from a previous version of the course.
- Next Tuesday the Science Channel will continue it's great tradition of programming about fundamental physics with the premiere of a new show called Sci-Fi Science featuring Michio Kaku. The first evening's episodes will explain

> a loophole in Einstein's theory of relativity that shows how a spacecraft could travel at warp speed.

followed by

> Dr. Kaku is on a mission to design a gateway to a parallel universe – but which type should he visit? MIT cosmologist Alan Guth explains his recipe for creating your own universe in the lab, and physicist Neil Turok explains how a parallel universe is only an atom's length away from us.

To their credit, sometimes they do actually have some real practical science which is not science fiction: yesterday they had Frank Wilczek on this show.

Update: Lubos has more Kaku.

1. **DavidZS**
   November 27, 2009

   How the hell does Kaku get ANY respect ?
   The guy's clearly on LSD.
   How is it these people still got their positions at Uni's?
   Science is dead and these guys are kicking down it's tomb stone

2. **Cormac O Raifeartaigh**
   November 28, 2009

   Funny thing is, I really enjoyed Kaku's book on Einstein. I was stuck in a hospital for 8 hours once waiting to see a doctor, read the thing several times, really enjoyed it.

   Thanks for the plug for the blog post on Goddard lecture Peter, it was a really interesting talk. Actually, one point the speaker didn't touch on is the downside of the institutes. One problem the Dublin IAS suffers has is size – it's so tiny there is no admin support whatsoever for organising conferences etc, so the professors do absolutely everything themselves. Also, the Institute does not advertise its successes at all well for the same reason- it is much better known outside Ireland than inside. For example, Lochlainn's work is almost completely unknown in his own country – the last 3 collections of Irish scientists ignored him completely.

3. **neo**
   November 28, 2009

   We are all agreed that Kaku's ideas are crazy, but are they crazy enough? To quote a famous man.

   OT–Kaku may be crazy, but his geography is better than that of Lubos. The latitude of England is indeed northern Canada (James Bay), not southern Canada as Lubos claims.

One Reason Science is Having Trouble Banishing Religious Thinking

November 29, 2009
Categories: Uncategorized

Andrew Sullivan, under the title String Theory and Miracles quotes part of a blog posting entitled One reason science is having trouble banishing religious thinking at the Democracy in America site (the original posting text is not there right now, may reappear) which notes that the spectacle of physicists widely promoting to the public the string theory multiverse is having the following effect:

> It's not always readily apparent to non-physicists why this kind of talk is less supernatural than a belief in the persistence of the soul after death….
>
> But strictly in terms of how the argument between theists and atheists plays out in the public domain, there is a different quality to the tenets that are emerging on the atheistic, particle-physics side of things these days.

The string theory multiverse pseudo-science has done a huge amount of damage to the interests of string theory within the academic community, but it also threatens to do damage to the understanding and image of science among the public. Unfortunately, while there is more and more physics content in US popular media, it is often in the form of string theory-based pseudo-scientific nonsense rather than real science. For examples of this, see a new article in the Denver Post which catalogs some of this (while arguing that it's a good thing):

> TV is working through the shock of the age of terrorism and dismay at the broken boundaries of science, right before our eyes. Parallel universes? Bending time? Alternate dimensions? Some heavy-duty thoughts are seeping into prime time every week.
>
> To the extent that TV reflects the culture at large, these shows seem to be saying we're on the cusp of major change — technological, scientific, political or emotional. We may not have answers but we're aware of expanding questions. In 2009, it has become accepted for folks on the couch to converse about the space-time continuum. Not that we understand string theory, but we recognize it when it pops up in TV scripts, peppering a spy thriller. "Lost" pushed the way with its dialogue about "moving the island," leading fans to discuss time-shifting, wormholes and Einstein's relativity theory.
>
> Really.
>
> The newer shows are picking up the string (theory) and running with it. There are hopeful signs in all this. The sci-fi series depict humans taking control of the planet, voting in favor of free will and standing up for the species. Maybe TV can provide some wishful thinking.

   November 29, 2009

   Whether or not, as H.G. Wells observed, a frightful queerness has come into life in general, it certainly seems to have come into scholarship and science. Once upon a time, it seemed that the humanities were pretty much lost for good, drowning in the incoherence and irrationality enthusiastically sponsored by postmodern crit-babble, the kind that was mercilessly dragged into the light by Alan Sokal in his famous expose of SOCIAL TEXT. But there was always the forward march of science to console yourself with… and now it turns out that that what purports to be the leading edge of fundamental physics is aggressively hyping 'fashionable nonsense', as Sokal's 1997 book terms it—nonsense which is every bit as nonsensical as any of the deconstructionist gibberish that Sokal eviscerated more than a decade ago.

   It's implicit (and sometimes explicit) in Peter's work, Lee Smolin's work and that of other observers of the frightful queerness that is contemporary theoretical physics that this is the sort of trap science can fall into when it doesn't have real data to bang its head against and make sense of, and maybe that's enough to explain it. But the side-by-side train wrecks of scientific and literary/cultural theory suggests something more, some kind of intellectual nihilism that I find very, very depressing.

2. **Tim vB**
   November 30, 2009

   I don't think it is scary if the general public grossly misunderstands some concepts from theoretical physics.
   Think about Star Treck, since the invention of quantum mechanics and the multi-world interpretation there have
   always been fantasies about travelling to a parallel universe. It is slightly annoying if someone at a cocktail party tries to explain the uncertainty principle to you because that special someone was enlighted by a Pherry Rhodan comic strip the he or she read in the morning paper. But neither scary or depressing.
   You know what really scares me? A well known and established professor of theoretical physics publishes a scientific paper, claiming that an extra term in the Lagrangian in the path integral of the universe could explain why the LHC broke, and, after recovering from a fit of laughter I find that there are many intelligent people out there who did take this seriously (not believing it was true, of course, but believing that it was not meant as a joke).
   You know what I'm talking about.

3. **Peter Woit**
   November 30, 2009

   Tim vB,

   I think the danger now is not that the public misunderstands what some prominent theorists are up to, but that they do understand it.

4. **Mark Wallace**
   November 30, 2009

   It is hard to stop all the silly speculation, because lack of evidence does not seem to discourage TV popularization or sci-fi plots. Of course there are a lot of ragged edges around quantum mechanics that really need to be worked on, but string theory does not appear to have made much progress in the quarter century or so since I first had it explained to me.

   However, I do think there is merit to applying the same ways of thinking that have been effective for analyzing molecules to larger systems. This leads to a lot of unusual and nonsensical suggestions, but few people have the intuition to avoid the nonsense. It is not clear (to me, at least) that we fully understand why tools like Schrodinger's equation have been so successful predicting chemical and electrical behavior. String theory may have been a distraction, but (as an engineer) my perception is that our understanding of quantum theory and it implications for larger systems is still at a very primitive stage of development. The viewing public is not really naive — they sense the confusion, and are drawn to it just like kids chasing a fire engine.

December 1, 2009

For most folks, even, say, a professional biochemist, the only basis for accepting the claims of high energy physicists is the authority mechanism – the claims are made by people with nice titles at respectable institutions, and there is some evidence (e.g. transistors) that claims made by similar people have translated into something tangible which would not have existed without those people. The professional biochemist, by projecting her own professional experience, is perhaps better situated than the `man on the street' to judge which authorities should be trusted, but in the end it is a matter of picking one's authority.

For many people, the people with fancy titles in elitist expensive institutions are inherently untrustworthy authorities – are not these essentially the same people who run the banks? – and something like the bible, or the minister expounding it, seems more accessible and more believable. Black holes can't be seen with the naked eye anymore than can gods.

I certainly do think there is a basis for accepting certain authorities over others (transistors, h-bombs, genome sequencing, etc.. all attest to the superiority of certain paradigms), but I think also that the scientific community ignores the need to explain to world at large why its authorities should be considered credible, and dismisses too easily the credibility the world at large gives other authorities. Why should a man who can't add fractions (most folks) listen to some nonsense about colored quarks?

You are absolutely right that quasi-religious pseudoscientific multiverses live in the same intellectual multiverse as do things like intelligent design, and they make far more difficult the task of communicating why scientific authorities should be trusted.

6. **Gphillip**
December 1, 2009

I love science fiction. It's great entertainment and I see nothing wrong with it at all. I'm even willing to accept possible conclusions from science and math that can't be tested with current technology. After all, when Einstein's equations predicted the possibility of a gravitational collapse, he did not believe it really would exist in nature, much less someday be observed and studied from Earth. Even still, Einstein's theories were based on sound observations about time and light, space and gravity. Then those theories were peer reviewed and verified by additional observations, many of which he proposed himself. This is the difference between science fiction and the scientific method. In my own humble opinion, a scientist should not propose a conjecture as fact without it being based on sound observation and without proposing a way that it could be falsified or verified.

This is the line between science fiction and the scientific method. When scientists cross that line, they may as well describe the universe the way my elders once did, by saying, "that's just the way God made it". Just to be clear, I have no problem with anyone who wishes to explain the cosmos that way, but it's not science. Just as a particle can be both a wave and a solid bit of matter at the same time, I can allow for multiple explanations for the same thing.

My concern is that true science is not based on any sort of faith. It must be based on observations and include tests that can prove or falsify its predictions. This is an easy line to draw and many of today's so-called scientists have morphed into nothing more than evangelists or science fiction writers. When Author C. Clark first proposed satellites, there was no science to back it up. It was a great idea, years before it's time, but it was science fiction. If scientists want to write science fiction, that's fine. Carl Sagan did a great job with "Contact". But for goodness sakes, let's not confuse a belief by faith, or science fiction, with the scientific method. If we do, science will lose all contact with reality and all those that call science nothing more than a popular paradigm will be justified in their accusation. In the end, scientists have a professional responsibility to separate science from religion and science fact from science fiction. I'm very disappointed in those scientists who fail in this professional responsibility.

7. **Bob Levine**
December 2, 2009

"In the end, scientists have a professional responsibility to separate science from religion and science fact from science fiction. I'm very disappointed in those scientists who fail in this professional responsibility."

I think it's a bit trickier than that.

If you ask the physicists who go on about the multiverse and contact between alternate universes and so on about what they're doing, they would probably tell you that they're not doing science fiction, but exploring possibilities that are already within the scope of what they regard as 'normal science'. The problem is that what's regarded as normal science has changes significantly in the last thirty years or so. Once upon a time, normal science meant systematically extending the reach of one's best hypotheses and analytic frameworks, those which had proven most sucessful to date, to novel problems suggested by new data, or an innovative take on old, previously unresolved problems, to yield a predictively satisfying result. You departed from this MO only when you weren't getting anywhere and needed a *really* crazy alternative to standard models and concepts to make a breakthrough, and you didn't regard that alternative as established until it had proven itself through further application. We all know from experience that most ideas that are just too god to be false wind up in the dustbin sooner or later. And the more drastically such ideas depart from the previous body of 'battle-tested' knowledge, the more likely they are to be discarded. You can count genuine paradigm shifts in physics on a proper subset of the fingers of one hand.

Something has changed that conception of normal science. The lack of new critical data allowing a push beyond the standard model—we're stil sitting on tenterhooks waiting to see what the fate of the Higgs is!—combined with the incredible pressure, in the wake of electroweak unification, to finally finish the bloody job, cook up a successful TOE, and go home—seems to have led physicists to redefine normal science as a glass bead game with only the most indirect connection to any actual *facts*. Once your scientific culture changes in that direction, conflating thought experiments with real experiments, and possible worlds with the real world starts to become 'normal', and we get to… well, to where we are in the OP here.

And it's not helped, of course, by the fact that some people feel that the right way to address string theory's 10^500 vacuum states is to assert, completely seriously, that that outcome has ontological consequences which we must accept. Get all these factors interacting for long enough and the whole view of science that took us all these centuries to build up is in jeopardy…

8. **Gphillip**
December 2, 2009

BL, generally I believe we are in agreement. The question is what is science? What separates the fantastic thought experiments of Einstein from Star Trek fiction? What separates scientific fact from a belief through faith? Perhaps the question is even deeper as you suggest. If science hits a brick wall, is it acceptable to extend its reach with thought experiments that have no observational basis and mathematics that are the equivalent of proving that 0/0=every number?

In my own humble opinion, science is a profession. The pursuit of that profession is guided by the scientific method. Those who claim to be pursuing science, but do not use the scientific method are quacks. They may be well educated and well meaning quacks, but they are quacks nonetheless. I'm not saying that valuable insight cannot be gained by other methods, but rather that those methods are not science and anyone who claims to be doing science by other methods has lost their way along the path to scientific progress.

While I understand there is a great push to complete the job of unifying the fundamental forces, I do not agree that moving outside the scientific method is the correct course. It wouldn't surprise me if it takes a very long time to collect the experimental data to complete this work. It could even be possible that the solution is many orders of magnitude more complex than anyone envisions, or that we may not be able to complete this work for many generations to come. In any case, the unification of the fundamental forces is not the only ongoing scientific work in physics. I do not believe that these attempts to go outside the scientific method are justified when considered in the balance of all the harm that fundamental science in all fields will suffer if scientists stray from the path of the scientific method.

That is of course, my own opinion. Others my feel it is justified to scrap the scientific method if there is any hope at all of solving this vexing problem. I don't begrudge them their attempt at solving the problem, I only object to their calling themselves scientists. I really don't know what to call them. Aspiring profits? Pseudo scientific evangelists? I don't mean any disrespect by calling them quacks, but it's the only term I know that applies to would-be scientists who have abandoned the scientific method.

If, in the end, the only solution to this problem depends on the assumption of something that can never be observed, then in my opinion it can be said that there is no scientific solution to the problem. There may be many problems that have no scientific answer, but that doesn't justify throwing out the scientific method, since there are so many more problems that the scientific method can solve.

But I do not believe we should be willing to accept defeat this early in the game. I firmly believe that if all the time and money expended on trying to come up with pseudo scientific answers to the problem was dedicated to pursuing answers through the fundamental scientific method, the correct answer , if there is one, will be found much faster and with much less damage to other branches of real science. Perhaps we just need to be a little more patient and wait for the results to come out of the LHC over the next few years. Perhaps there is another experiment either here on earth or out in space that will point the way. But in any case, let's not accept throwing out the method that gave us the transistor and the end of small pox, just to pursue a very remote possibility of advancing a few individuals careers.

It is said that we stand on the shoulders of scientific giants. So just how did they become giants? In every case it was through the rigorous application of the scientific method. I can't think of a single scientific "giant" that became so by proposing solutions that can never be observed. Perhaps I need to adjust my thinking though and accept the existence of new pseudo scientific media and internet giants. I can accept that for entertainment purposes, as long as they quit claiming to be performing real science.

9. **Bob Levine**
December 2, 2009

@GP:

"I'm not saying that valuable insight cannot be gained by other methods, but rather that those methods are not science and anyone who claims to be doing science by other methods has lost their way along the path to scientific progress…While I understand there is a great push to complete the job of unifying the fundamental forces, I do not agree that moving outside the scientific method is the correct course…. In any case, the unification of the fundamental forces is not the only ongoing scientific work in physics."

Right, and that's the crucial nub of the issue. What you're saying here is an affirmation of the conduct of "normal science", as it used to be understood, as the default strategy for obtaining hard, defensible conclusions—what used to be called *results*. But in high-energy physics, there is now quite a different ethic in place, where mathematical validations of highly abstract conjectures are seen as normal—regarded as just the latest avatar of what Dirac did with Clifford algebras way back when, and are themselves claimed to be results with *physical* content. Even more central is what you say about unification not being the only ongoing work (of importance) in science. Again, normal scientific practice in the past didn't aim directly at such unification, which was rather an earned result based on patient accumulation of confirmations for progressively more general characterizations of physical phenomena. Plenty of impressive reputations were earned on the basis of normal science, and not a few Nobel Prizes (Hans Bethe comes to mind as a good case in point).

But that's not the way things are seen within a sizable chunk of the professional physics community, apparently. A cash-strapped field with far more Ph.D.s than permanent (or even impermanent) jobs for them, a generation-old theoretical framework that no one seems to be able to take the next step from, operating in a general zeitgeist driven as much by celebrity as genuine earned authority, is almost certainly going to try to solve its problems by changing the rules of the game to play in the way that we're talking about. In the case of Kaku & Co., the counter would almost certainly be, whatever increased people's interest in science is good, and as you mentioned in the other thread, the program is clearly labelled 'Sci-fi'. What worries me is that people may not recognize that not only the concepts (wormholes to other universes, time travel, etc.) but the 'physics' applied to those concepts on the program, are part of the 'fiction' in the 'Sci-fi' label….

LHC at the High Energy Frontier

November 29, 2009
Categories: Experimental HEP News

A few minutes ago, one of the beams of the LHC was ramped up to an energy of 1180 GeV, besting the Tevatron's top beam energy of 980 GeV.

Update: Actually the beam was lost at 1040 GeV, which is still a record high energy.

Update: A few minutes ago both beams were successfully ramped up simultaneously to 1180 GeV.

Update: Wow, that was quick. First publication based on LHC data is now out, from ALICE, based on data gathered a week ago. Nothing at all unexpected, this is just based on 284 total events, at the already well-studied energy of 900 GeV.

Comments

1. **Ralph**
   November 29, 2009

   They just got beam 1 to 1180GeV with 2e9 protons. They started with both beams but lost about 90% of beam 2 around 700GeV.

2. **D R Lunsford**
   November 29, 2009

   What exactly happens when they "lose the beam"? (I've been studying physics for decades and still have almost no clue about what happens at real accelerators 🙂

   -drl

3. **hmmm**
   November 30, 2009

   Has the LHC rediscovered the Standard Model then?

4. **lost**
   November 30, 2009

   DRL –
   "Lose the beam" –
   "The" beam is typically many bunches circulating around the circumference.
   (And obviously two counter-rotating beams in the LHC.)
   In the present case, possibly just one bunch per beam just to verify that the LHC works.
   I do not know.
   Anyway, to "lose a bunch" –
   It may hit the wall of the beam pipe (vacuum chamber) or some aperture.
   Possible reasons –
   – The steering went wrong during the energy ramp and the beam centroid went off-center (typically).
   – The bunch was injected badly and did not line up nicely with the reference orbit. (Then the beam would be lost immediately not at 700 GeV.)
   – There is also beam loss from beam-gas scattering. This is a slow process ~ diffusive. An entire bunch is not lost this way.

   During normal operations, after a fill is over the beams are `dumped' by targeting them onto some beam stop. This is also a beam loss.
   Beams can also be deliberately aborted during emergencies (a quench?).

   When a hadron beam hits a target (wall, beam stop, …) it generates artificial radioactivity.
   This is at least one reason that accelerators are interlocked and everyone must be out before operations can begin.
   (Electron beams produce much less artificial radioactivity but they produce much synchrotron radiation ~ "bremsstrahlung" ~ also a reason everyone must be out.)

   Eventually several parts of the LHC will become radioactive. This is a fact of life for hadron accelerators.

5. **Pawl**
   November 30, 2009

   Peter,

   Would it be possible to give a quick summary of what the sub-screens, etc., in the vistars link you previously gave signify? Or give a link to an explanation? (I can work out some, but not all of it.) Thanks.

6. **Peter Woit**
   November 30, 2009

   Pawl,

   I don't know what the graphics visible on the LHC1 vistar are representing, maybe someone else does. The screen has semi-reliable info about whether the beams are in the machine, at what energy and what intensity. Perhaps the text messages from the operators are the most useful indications of what is going on.

   hmmm,

   They're still quite a ways from rediscovering the standard model (in the sense, for instance, of being able to see W's, Z's and top quarks)

7. **from CERN**
   November 30, 2009

hmmm, for the moment LHC rediscovered the pion

8. **Ralph**
November 30, 2009

Re the graphics on LHC1 vistar these are normally BTV-something:

From http://lhccwg.web.cern.ch/lhccwg/Bibliography/UsefulAcronyms.htm "BTV: Beam Observation TV Monitors based on Screens"

From what I can make out, they have thin screens in front of the beam dumps, presumably with cameras pointing at them, and the images show the beam profile from a recent beam dump.

9. **Ralph**
November 30, 2009

Here's a description of the various BTVs: http://ab-dep-bi-pm.web.cern.ch/ab-dep-bi-pm/?n=Activities.BTVLHC

10. **Yatima**
December 1, 2009

And here's how the LHC "beam dump" looks like. Useful when you have to get rid of your hadrons quickly:

http://lhc-machine-outreach.web.cern.ch/lhc-machine-outreach/components/beam-dump.htm

11. **Martin**
December 1, 2009

Peter,
Regarding the first publication: arXiv:0911.5430v1 [hep-ex] you mentioned.

How stringent are the requirement for an arXiv publication?
This paper just says that they've managed to achieve a few collisions and that 2 parameters are what they expected.

Where's the new physics? Which hypothesis were they testing?
Surely they weren't trying to falsify Holger B. Nielsen's and Masao Ninomiya's paper on "Search for Effect of Influence from Future in Large Hadron Collider" (http://arxiv.org/abs/0707.1919)?

12. **chris**
December 1, 2009

Martin,

arXiv is a preprint server and as long as there is one endorser (basically everyone who has ever put a few decent articles on arXiv) you can upload your preprint there.

also you should keep in mind, that accelerator physics and detector physics in itself is a topic. verifying that you have collissions in a new accelerator and that your new detector can make sense of them is worth a publication certainly.

13. **Paul Wells**
December 1, 2009

Martin,

I think another reason for the rapid publication is that many of the people on the LHC teams are PhD students who need a publication of some sort to graduate and they have been waiting a very long time for LHC data. IMHO – good luck to them all !

14. **Yatima**
December 2, 2009

Apparently the LHC suffered a large-scale power failure, but apparently nothing bad came out of it:

http://www.theregister.co.uk/2009/12/02/lhc_power_failure_again/

15. **student**
December 2, 2009

You can expect similar Min Bias papers from all LHC experiments in the very near future. Alice was simply a lot more aggressive in getting the paper done quickly, but the DG of CERN is asking for all experiments to have them out soon.

16. **Bob Levine**
December 2, 2009

"I think another reason for the rapid publication is that many of the people on the LHC teams are PhD students who need a publication of some sort to graduate and they have been waiting a very long time for LHC data. IMHO – good luck to them all !"

What I wonder is, just how much glory do you *really* get as approximately 1/800th author of a paper which, when the five pages of names and affiliations and the page and a half of acknowledgements are references are subtracted, comes to not quite five and a half pages? Is anyone's career really going to be advanced on that basis?

17. **Peter Woit**
December 2, 2009

Bob,

This has nothing to do with glory, just with many universities not wanting to award a Ph.D. to someone until the point where they have some real data to show.

18. **Me**

December 2, 2009

“Is anyone’s career really going to be advanced on that basis?”

I can assure you, they do advance on that basis.

Sci-Fi Science

December 2, 2009
Categories: Uncategorized

I watched the first two episodes of Michio Kaku's Sci-Fi Science show last night (for a review, see here). The format of the show is that Kaku uses supposedly real physics to design on his laptop a revolutionary new device, then unveils it at the end of the show to a group of sci-fi fans for what I guess is supposed to be a form of peer review. The adoring fans are suitably impressed. In the first episode the device was a warp drive, in the second a portal to other universes, based on a big accelerator and "negative matter". In both cases "negative energy" played a big part.

Neither episode involved a non-negligible amount of legitimate science, instead treating the physics in a completely misleading way. The second episode included participation by Max Tegmark, Alan Guth and Neil Turok. I wonder if they've seen the final product and what they think of it.

Comments

1. **Jeff McGowan**
   December 2, 2009

   Well, someone I work with (Thomas Roman) does research on negative energy (together with L. Ford at Tufts). They have publications going back more than a decade giving clear, small, bounds on negative energy density (see for example http://prola.aps.org/abstract/PRD/v55/i4/p2082_1). Tom frequently gives talks explaining that you won't ever get a stable wormhole, or a warp drive, for exactly this reason. You would think Kaku might have bothered to look for papers about this, I mean Phys. Rev. D isn't exactly obscure.

2. **theoreticalminimum**
   December 2, 2009

   I wonder why Turok bothers getting involved in this kind of stupid stuff, especially when Kaku is the orchestrator. Is he not busy enough helping out African students?! :-\
   sigh

3. **neo**
   December 2, 2009

   Kaku is over the top, but on the positive side, lots of kids may be turned on to science by shows like this. Soon enough they will learn that real science is not like comic books.

4. **Gphillip**
   December 2, 2009

   I'm OK with this because it has "Sci-Fi" in the title. As long as they are clear that it's just having fun with Science Fiction (yes, I know that's questionable), I'm not going to get bent out of shape. If they had titled it "Si-Fi Pseudo-Science", I would have sent them a fruit basket.

   So have fun kids, but be sure to pay special attention to that thing called the scientific method in school. If you think this science stuff is fun, you'll need that method to stay on the narrow path of real science. Those who have strayed off the path and are wandering in the weeds of M-Branes (and you know who you are), go back and review.

5. **D R Lunsford**
   December 2, 2009

   neo – kids destined for science, math, or engineering do not get turned on by BS, today or yesterday or tomorrow. Rather the opposite – they get turned onto it by looking through telescopes, playing with machines, taking things apart, and so on. The brain must be involved from the first minute. It's not a sensual thing.

   -drl

6. **zanzibar**
   December 2, 2009

   Suggested edit to avoid a double negative:

   "Neither episode involved a non-negligible amount of legitimate science,…"

   "Neither episode involved more than a of legitimate science,"
   spattering
   iota
   quantum
   smoot
   smidgin

   I like smidgin, it being the most quantative, although iota does have the fewest letters.

7. **Giotis**
   December 2, 2009

   "Neither episode involved a non-negligible amount of legitimate science,…"

   My mind will explode…

8. **Pawl**
   December 2, 2009

   Oh, I dunno — it was not unmeaningless.

[Cribbed from Thurber]

9. **jpd**
December 2, 2009

i thought it was just me, its actually a triple negative.
how about
"Both episodes involved a negligible amount of legitimate science, …"

10. **Peter Woit**
December 2, 2009

Everyone's a critic. Come on, y'all knew what I meant….

11. **Me**
December 2, 2009

"I wonder if they've seen the final product and what they think of it."

No publicity is bad publicity.

12. **Belizean**
December 2, 2009

Yeah, Kaku is a bit of a media whore and an embarrassment. But I'm sure that he long ago realized that there's no market in commercial TV for shows about legitimate science. He's simply adapted to that sad reality.

When I was a child, there was a physics guy on TV who I found absolutely mesmerizing. But he wouldn't last two minutes in any of today's TV markets.

13. **ChuckO**
December 2, 2009

To show you how things have changed, I'm 65 and, when I was in high school, I lived in the Dayton, Ohio area. During my sophomore year in high school, the local public television station showed a college course on introductory quantum mechanics at 6 in the morning. I used to get up to watch it and try to follow along. It was over my head, but I still managed to learn a lot. I don't see anything like that on PBS these days. Even the science shows, like Nova, have been dummied down from what they used to be.

14. **David Pennell**
December 2, 2009

Isn't Kaku's non-science usually derivable from some interpretation of string theory?

15. **Peter Woit**
December 2, 2009

David,

I don't remember much about string theory in these TV programs, perhaps string theory is too much like real physics to be useful in making warp drives and portals to other universes.

Branes do play a role though, as part of the whole other universes business.

16. **DZS**
December 2, 2009

So honestly, you guys here who practice real science.
What specific parts can you point to that's completely falsified?

17. **Peter Woit**
December 2, 2009

DZS,

Kaku's portal to another universe is based upon constructing a scaled up version of the LHC using the solar system asteroid belt. When the beams collide, they supposedly tear a hole in the fabric of space-time and open up a wormhole to another universe. This is complete nonsense, there's no reason to believe that such a machine would do this. He then goes on to say that he will stabilize the throat of this wormhole by putting in "negative matter". There is no such thing as "negative matter".

Etc….

18. **DZS**
December 2, 2009

What about Jeff McGowan's comment?
He seems to state that negative matter is real, but doesn't possess such properties?
Conflicting views?

I think someone should gather up all of Kaku's major mistakes and when the season is over, recap every episode and it's flaws.
Then make an article about it, presenting this evidence for the layman / future scientists…

19. **Peter Woit**
December 2, 2009

Jeff's comment was about negative energy, not negative matter. Nowhere does he state that negative matter is real.

If someone were to do what you suggest, I suppose it would be a public service. It would also be a huge waste of time, since I see no reason to believe it would have any effect on Kaku or the Science Channel's willingness to keep promoting this nonsense.

20. **Jeff McGowan**
December 2, 2009

Yes, Peter is right, nowhere did I mention, or mean to mention, negative matter. Humble mathematician that I am I would never posit such a ridiculous idea. Now perhaps imaginary matter might be a fruitful idea 🙂

21. **DZS**
December 2, 2009

Sorry I misread his comment.
Well then I guess it means Kaku is wrong about negative energy on top of the existence of negative matter all together.

I understood such a task would be tiring and obviously it wouldnt stop the channel exploiting pseudoscience for money, no.
However it would most likely be picked up by most science related sites.
If he is truly as wrong as you guys state, it WILL be picked up by science sites ofcourse.
Kaku is one of the most known scientists of the 21th century, he lying that much would no doubt stirr up controversy.

It's not a fruitless effort or else, why would you bother to write your book and keep this blog?

22. **buz**
December 2, 2009

It has been my impression that many people, especially young, but also older, develop something that they *think* is an interest in science, but is really a type of 'Cosmic Exhilaration Syndrome'. I think Kaku might be someone in academia who has a special appeal with this fan base.

It becomes important to make a distinction between science and scientists, which are often boring but good, and 'cosmic exhilaration infotainment and entertainers'.

String theory seems like an area of study where it is hard to tell the difference. The idea of 11 dimensions and many universes is exhilarating and entertaining for many, and there is no evidence for it. However there are publications, citations and professorships and scientific awards and fellowships giving these ideas credibility. But the people who read this blog have heard enough about all that.

23. **Javier**
December 2, 2009

The existence or not of traversable wormholes is a topic of research addressed by some people, mainly in the general relativity community. Some major nowadays names are, for example, M. Visser or Francisco S.N. Lobo.

As buz says the idea is not new at all and goes back to Einstein himself. Famous people, as Feynman, consider it curious enough to talk about it in his book on general relativity.

The recent line of interest goes back to a paper of 1988 by M.S. Morris and K.S. Thorne (tow of the authors of one of the most famous textbook on general relativity). The research on the topic follows the scientific method. That is, is based on solutions of a well established theory, general relativity, and discussing it's properties in order to search experimental evidence of their possible existence.

Obviously wormholes are independent of string theory. Still some ideas suggested by string theory (and in general, studies in cosmology, specially dark energy) play a role suggesting candidates for the key missing ingredient that mentions Jeff McGowan. From this computer I have not access to the paper he links, but I have read many papers that offer possible reliable candidates for that kind of mater violating NEC conditions.

At most you could call it search for exotic physics, but certainly wormholes are only a little bit stranger than black holes. Independently of everyone's preferences I seriously doubt that any serious theoretical physicist could say for sure that they don't actually exist.

24. **Peter Woit**
December 2, 2009

Javier,

The question is not whether there are wormhole solutions in GR.

Do you think any serious scientists believe wormholes can be created by colliding particles at 10^7 TeV, then using "negative matter" particles to stabilize them?

25. **Javier**
December 3, 2009

Well, if we haven't technology to send people to mart with guaranties we definitively can't send people to kuipier belt to build an particle collider.

But that is a engineering problem, not a first principles one. If that would be the only problem it wouldn't bee too different, in essence, to the theoretical works in, for example, Bose-Einstein condensates or nanotechnology many years before it could be available in practise. Well, possibly the main difference is economical. It is far more expensive (not to say difficult) to build such accelerators. Governments would need a very good reason to do so.

Actually I think that someone would find, sooner or later, better ways to make such high energy colliders that simply increasing it's radius. Suppose for a moment that such a technical development is achieved and the 10 ^7 TeV could be available for an earth based device. Wouldn't your viewpoint about the idea change if so?

The most serious problem of that idea are to see whether the physic is totally solid. The most common idea is that wormholes are continuously created and destroyed in the "quantum foam". Supposedly high energy collisions could increase that planck scale w-h to macroscopic sizes. Obviously the problem is that "quantum foam" is a byproduct of a quantum theory of gravity and I am not sure if there are any detailed calculations in some of that theories (string theory or whatever) deriving a cross section for the creation of a measurable wormhole. I know that two or three years ago some people presented papers claiming to do that for energies available at the LHC . I read one of the papers and they used some exotic type of branes supposedly derived from string theory. They didn't give details on the nature of that branes and referred to another papers. I didn't follow that other papers but I read a lot of critics about them in a thread in physic forums. Maybe there are other papers on the subject, but I am not aware of them.

And, of course, still the key ingredient to stabilize the w-h, exotic matter, isn't available. without it we could search for signatrues of w-h in colliders, but not stabilize them, and they wouldn't be useful for "practical" engineering purposes.

Resuming, nowadays it could be considered a serious (although exotic) topic for science, but going to the practical side is only Si-Fi, precisely what the title of the program says ;-).

B.T.W I didn't see the show and don't know what they mention. As far as I know in principle it could be possible that a wormhole would connect parts of the universe arbitrarily far away. That includes the possibility of connecting regions out of causal contact. In particular they could connect different universes of the multiverses appearing in eternal inflation sceneries. And one could, in principle, use the wormhole to study that other universes so they would be experimentally measurable science them.

In the economic side wormholes would be potentially useful. If one mouth of the w-h would be connected to a point of great energy (near the surface of the sun for example) they could be used as a source of energy. And, of course, they could be used as a weapon.

So, one would go back to the arguments about the lack of danger of creation of black holes. If w-h could be created in colliders they could be created by collisions with cosmic rays and there is not evidence of them, so maybe , after all, there are good reasons to not be too enthusiastic with the proposal of Kaku and his solar system sized LHC.

S you can guess from this long topic I consider fun the idea of the wormholes, but only as an exotic line of research complementary of more well established topics of interest.

26. **Paul Titze**
December 3, 2009

Myself I don't like the way they convey ideas to the public which are plain wrong such as time travel or stabilizing wormholes with negative matter etc, think the aim is to entertain people at best, however I hope people realise this is all fantasy. I'm not sure why he talks about all this when real Physics dealing with the real world is far more interesting however that's me.

There's also a good post on this at:

http://badphysics.wordpress.com/2009/11/15/how-to-time-travel-4/

Cheers, Paul.

27. **Janne**
December 3, 2009

Who watches TV anyway. Any curious kid nowadays will find lots of good material online, for example Leonard Susskind's brilliant lectures on general relativity and quantum mechanics.

28. **Aaron Davies**
December 3, 2009

alcubierre drive, i assume?

29. **Tim vB**
December 3, 2009

Let me try to clarify a bit the "negative energy" versus "negative matter" issue:
"Negative matter" is mostly used to describe something with opposite properties to "normal matter", e.g. the graviational force between normal matter is always attractive, so the gravitational force between normal matter and negative matter would be repulsive. Up to now there is no reason to believe that negative matter in this sense, i.e. with this property, exists.
Well, since Einstein told us that matter is just a manifestation of energy, wouldn't that mean that "negative energy" does not exist, either?
The point is, that "negative energy" means something different: Let's say we look at Minkowski spacetime with quantum fields on it in the vacuum state. "Vacuum state" means that the expectation value of energy is zero.
But you can create spacetime regions where the expectation value is even lower! One example is the Casimir effect:
If you calculate the energy-stress-tensor you will get negative values! This phenomenon has been verified experimentally, therefore it is an accepted topic to talk about in the physics community.
If you want to, you can visualize the vacuum state as emptyness with quantum fluctuations, with virtual particles constantly created and destroyed. In a region with negative energy this happy dance is supressed. (IMHO this is hardly more than a metaphor).
HTH

30. **Adam Helfer**
December 3, 2009

Tim is correct in saying that relativistic quantum field theories predict states with negative renormalized energy densities, and that the simplest treatment of the Casimir effect (between two idealized perfect plane conductors) is an example of such a state. However:

(a) For realistic models of conductors, it is less clear that one gets a negative renormalized energy density between them;

(b) Experiments have verified the Casimir *force*, but not the Casimir *energy density*; a Cavendish-type experiment to measure the energy density would probably require plates around a light-year on a side;

(c) While it is often assumed (especially by people who would like to create exotic general-relativistic effects) that one can use something like the expectation value of the renormalized stress-energy operator as a source for Einstein's equations (this is called the semiclassical approximation), we don't really know that this is correct. (In fact, it's fairly clear that it *can't* be right in a number of situations.)

It's worth pointing out that the renormalized stress-energy operator is in fact a rather singular object many of whose properties are unintuitive and ill-understood. While it's fun to think of science-fictiony implications, it would be prudent to be bear in mind our limited understanding of this.

31. **Tim vB**
December 3, 2009

Agreed, thanks for the clarification.
I hope this discussion explains to the general public why physicists call "negative matter" science fiction and "negative energy" a research topic.

(I should mention that I did not watch the show with Kaku and don't intend to, I just assumed that he used the concept of "negative matter" in the same sense as I did in my previous post).

32. **S.C. Kavassalis**
December 3, 2009

Thanks Paul for linking me over here. I agree that this is another example, again from Kaku, of popularizes doing a disservice to science. Science fiction can sometimes serve as great inspiration for people to enter into the world of physics, but if that is where their knowledge base comes from, then they are deluding themselves. There is so much beauty in general relativity understood well; if people spent the time to express the wonder in actual solutions to the Einstein equations, then they wouldn't need to pad these specials with meaningless, misleading, fluff.

33. **Simple Mind**
December 3, 2009

i'm just a simple person with nowhere near the education or brain power as most of you on here. i actually despise mathmatics. i am hower a realist and one how and learn from the past. i believer most of the comments made above about how crazy this guy is and how his science is flawed are the exact same attacks that newton and einstien faced. the earth is round. yeah right what a crazy idea that is. lets kick him out of the church and put him to death. the earth revolves around the sun. that guy was considered a crazy outcast as well. shoot even tesla was considered crazy for his experiments. however look at what was acomplised by these people for believing in their crazy stuff. 99% of what we have today was considered crazy and usuless at one point in time. Radio waves, crazy. the horseless cariage, crazy. telephone, crazy. electricity, crazy.
So although i may not understand, or sometimes even agree, i don't think he deserves to be call outlandish or crazy, because most all of the "science" shows him to be wrong. countless others were considered wrong too and look where that got us.

Please don't correct my grammer, spelling or typing. i did not proof this no do i care to.

34. **Steve Myers**
December 3, 2009

I have a son who became a computer scientist by building controls for his electric train & moved on to a Radio Shack assembly language setup; another son went in to physics because he wanted to "discover the rules of the universe" and first started out at 3 by noticing the colors of a sunset & asked, "Who painted that?" I work with a bright scientist who began by picking up trashed electronic parts & tried to get them to work; I know a biophysicist who began by noticing moths on trees (and who spent his honeymoon in the Amazon forest). I don't think too many people are led to science through science fiction or phony science.

35. **DaveC**
December 3, 2009

It's my understanding that serious doubts have recently been cast on the claims of Casimir force detection. It was realized by the people who made the claims (Lamoreaux, Capasso) that there were electrostatic effects that had not been taken into account.

36. **Adam Helfer**
December 3, 2009

DaveC,

I am not an expert on the current experimental status, and so I cannot speak directly to the point you raise — but, equally, that means I should have written a bit more cautiously, and not claimed that the force had been "verified," but rather that there was some experimental evidence for it.

I believe the situation is further complicated by uncertainties about the modeling of real systems which are essential for interpreting the experimental results — and I'm not an expert on those details, either. (And perhaps the electrostatic effects you have in mind are part of that modeling….)

37. **Pawl**
December 3, 2009

Simple Mind,

Of course, it's wrong to dismiss ideas out-of-hand as "crazy," and it's true that some excellent ideas have been dismissed that way by people who should have known better.

But the take-home lesson from that is to think things through carefully. Usually if someone can give a good reason for an idea being crazy, it really *is* crazy. It's when someone short-circuits the thinking process that the mistakes are made. (The lesson is *not*, as you seem to suggest, that all ideas are equally good or equally likely.)

Scientists are human beings, and sometimes they do go off half-cocked. But science at its best considers ideas carefully and gives carefully conisdered reasons for whether thet're good or bad, likely or unlikely. The results are all around you.

38. **Bob Levine**
December 3, 2009

"But the take-home lesson from that is to think things through carefully. Usually if someone can give a good reason for an idea being crazy, it really is crazy. It's when someone short-circuits the thinking process that the mistakes are made. (The lesson is not, as you seem to suggest, that all ideas are equally good or equally likely.)"

This is a crucial point. It *may* be true that a lot of what survives in science may have seemed crazy when it was first proposed—I'm not at all sure that that's been true in general—but even if it had been, that in no way implies that crazy ideas that violate well-tested physical principles are likely to be correct, any more than someone surviving a gunshot wound implies that getting shot is likely to improve your chances of living to a ripe old age.

And so far as the actual examples SimpleMind gives are concerned, I'm a little confused about what s/he could be thinking of. Exactly who thought Einstein's ideas were crazy? His early work was controversial when it first appeared, but was recognized as foundational quite soon by the established leading physicists of the time, and was taken to be a non-negotiable starting point for the extension of quantum mechanics to high-energy physics. As for the general theory of relativity, it was recast within a decade of its publication in textbook form by one of the leading astrophysicists of the day, Sir Arthur Eddington. Again, there was plenty of controversy, but if any of the major physicists of the era regarded the theory as crazy, I'd be VERY interested in getting citation of the source. And similarly with Newton: he became in short order one of the most eminent figures in the Royal Society and very early on in his career had developed a formidable reputation—in fact, he was regarded as something of a national treasure and in his own lifetime members of the RS went so far as to accuse Leibnitz of having plagiarized Newton's creation of differential and integral calculus. Who with any distinction referred to Newton as crazy? Hooke thought he was wrong about the nature of light, but that's a very different thing.

There's absolutely no basis for comparing Kaku's flim-flam on the Science Channel with the foundational work of either Newton or Einstein. I've no idea where this strange legend came from that either of the latter were considered to be wrong, crazy or anything similar by the great majority of people who were experts in the field. The majority of stuff that sounds like nonsense is almost always going to turn out to be just that.

39. **Gphillip**
December 3, 2009

Simple Mind

Don't worry, I'm not into correcting others grammar. I live in that glass house and don't want to supply anyone with rocks. We only tease Peter about his writing because he's made so much more money at it than the rest of us.

I don't believe you are that simple, as you went right to the heart of the issue. I'm not sure if anyone ever called Newton crazy. I doubt it as he was a rather dour sort and rarely got close enough to any other human for them to call him names. They certainly called Einstein crazy until they read his papers. I've heard of hardened scientists actually crying from seeing the sheer beauty of his equations for the first time. Of course, Dr. Kaku is no Newton or Einstein, but he is a trained scientist and knows a lot of his "info-tainment" is based on pseudo science. He presents these Si-Fi shows almost tongue-in-cheek, to make a profit. That's fine; I'm no communist . But when a trained scientist presents science fiction to the lay public for entertainment, he is walking a very thin line. Please allow me to explain why I believe this is so.

Often times a scientist will request funding for a project on not much more than his own reputation. If his reputation is damaged, either by himself or by someone else, his ability to perform real science is hampered, if not completely shut down. When a trained scientist promotes pseudo science, he not only damages his own reputation but that of everyone else in his field. You don't really have to worry about good ideas being quashed. Oh, we may fuss and squall like a bunch of children, but in the end, the best ideas always make it to the top, even if they come from a patent clerk fired from his university post.

Please understand, this is not about name calling. It is about professional ethics. If a doctor performs unnecessary surgeries, it not only hurts his reputation, but also the reputation of all doctors. If a lawyer encourages his client to lie on the witness stand, it harms the reputation of all lawyers. Each profession is guided by a central principal. In medicine it is to, "Do no harm". In science it is to use the scientific method to discover and present scientific facts. When we allow the Doctor to operate, we must trust him to do the right thing. We have to trust him because we can't understand what he is doing or why. When the scientist makes a claim, it is expected that he at least believes it to be true. If he is deliberately lying, he destroys that trust between the lay public and his profession. It boils down to a professional responsibility.

As I have said elsewhere, it's ok for a scientist to have fun with science fiction. Carl Sagan did a great job with his Si-Fi book "Contact". But Dr. Sagan knew right where that line of professional responsibility was. He used science to discover and tell the truth, and he never crossed the line. He walked right up to it on his fantastic series "Cosmos", but he never crossed it. If Dr. Sagan told me there were "billions and billions" of stars just like ours, I'd believe him without question. If Dr. Kaku told me the same thing, I wouldn't know if it was true, or just entertainment. Dr. Kaku is no Carl Sagan.

As I've said before, I'm not going to get too bent out of shape since Dr. Kaku had "Si-Fi" in the show title. But most scientists probably believe that Dr. Kaku has stepped over the line of professional responsibility. Please understand, this is not elitism, it is a simply a matter of professional ethics. In science, there is a responsibility to tell the truth, even if it doesn't support your theory. That's often painful and the temptation is always there to falsify data to get the funding that should rightly go to a more deserving project. Once scientists begin stepping over that line, scientific progress will grind to a halt and the progress we have achieved, like ending small pox and exploring the surface of Mars, will grind to a halt with it. If you know someone who bears that burden of professional responsibility, like a doctor or lawyer or engineer or even a professional scientist, talk to them sometime about their burden. Every single one will have had a crisis of ethics where they could have made more money or had an easier time of it if they had just compromised their principles.

Well, that's just my own humble opinion. If you disagree with it, that's your right. But the next time you go to the doctor to get a critical procedure done, let's just hope it's not another Doctor Kaku planning to inject you with negative matter just to see what happens. OK, that was extreme. I apologize.

40. **anon**
December 3, 2009

> Again, there was plenty of controversy, but if any of the major physicists of the era regarded the theory as crazy, I'd be VERY interested in getting citation of the source.

Well, according to Heisenberg, Schroedinger kept on saying that Einstein's photons were absurd, and that he would quit being a physicist if photons were true, until as late as 1925 or so.

41. **Tom Whicker**
December 3, 2009

Right now we have a generation of college-age people who typically believe that WATER is a fuel and that the oil cartels killed Stan Meyers, and killed the Genepax car (ran on pure water and had water as exhaust). There is a wide-spread belief that the concepts of thermodynamics and conservation of energy are "old school" if not an outright conspiracy by big oil to hide the existence of all types of over-unity power machines. Dr. Kaku is no doubt a hero of this audience…

42. **Zac**
December 4, 2009

The show is doing it's job. It's meant to be informitive, and drum up interest in the subject, and it's doing both. Are his argument's iron clad? Not by a long shot, but considering the word "Sci-Fi" is in the title and mearly the subject of theoretical physics is in itself, well, theoretical, I can give him a slight pass. You can extend that pass even further when you remember there is a time limit, and editing that he doesn't have control of.
Do I wish there was more science to the show itself? Yes, I do but I understand that he would much rather have the show air then it end up on the cutting room floor.
So it might seem a bit blasphemous but I know of 3 people who expressed interest after watching, and 1 of them went out the next day and bought a few books. So if Kaku needs to be the Elvis of Physics, then so be it if it means even one more person takes true intrest.

43. **Simple Mind**
December 4, 2009

maybe crazy wasn't the propper phrase to describe the folks i mentioned , well at least a few of them. however my point is, it sometims it takes and outlandish person to come up with some outlandish ideas, that later turn into something real and believed in. sure his ideas of a light saber my seem far fetched, and they are. but his thearetical science may later lead to the discovery of something far more profound that might be the "next big thing". i agree with what someone above me just said. I paraphrase: "sure his science may not be the most accurate, but i might inspire people". if a show like this, that deals with the theoretical science of Sci-Fi of the popular culture, can inspire just a few people to take science, physics, mechanics, and any number of other types of avenues seriously, one of them may come up with the "next big crazy idea". The next major life saver, the next major wepon that can keep our troops safer or that wild secret to the cosmos. I think it's a great show, he has a excellent personality and he has a way of makeing the impossible not seem so difficult. It's entertaining. If someone can take a subject such as theoretical physics and make it entertaining, i'd call him a genious. that subject will generally put people to sleep. I will continue to keep watching the show, because it's entertaining. hower, i do keep in mind that he's dealing with sci-fi, not sci-reality.

I enjoy reading the comment on this page, and enjoy reading the ones that make me realize how much i don't know. I appreciat a forum where no one is attacking each other and calling names. i'm glad i found this place.

44. **Grétar Amazeen**
December 4, 2009

I thinks shows that put the emphasis on proper science and the truth inspire people much more to become scientists that what Kaku is doing. How many people became scientists because of Sagan or Attenborough? Their programs were, and are, proper science and try to display a sense of exitment for grasping the truth, not far fetched fiction.

just my 2 cents…

45. **Robert L. Oldershaw**
December 4, 2009

Jacob Bronowski's "The Ascent of Man" was a remarkable televised science series that celebrated science, art, literature and culture in an intelligent way. A good example of how it can be done right.

46. **Arnaud**
December 7, 2009

To Peter, about his reply to DZS on Dec 2:

This may be where physicists get it wrong w.r.t. PR, IMHO. I would like to compare that with a more salient side of science to normal people, i.e. climate modelling, and of course climate change.

As I'm sure you're aware, there are huge issues going on in the public representation of Earth science given the massive political impacts. As a result, this particular scientific community has reacted by engaging massively with the public and expending a significant amount of time in public forums relentlessly exposing the quacks, denalists and other lobbyists who tend to repeat the same lies and create a travesty of the scientific method. They may (and do) feel sometimes that's it is hopeless, but I believe it has had a very positive impact.

Now, in one way what you are doing through this blog is similar in the field of particle physics and string theory, although, fortunately (?) for you, it seems there are no powerful lobbies on either side of the debate, just overdimensioned egos, quantum-level bank accounts, and faltering careers…

But my point is, in an information-driven society, I think it is not enough to show the truth (in the scientific meaning of the term) and debate in specialised forums. One also has to expose lies and combat them through generic public debate. But I guess this isn't a thing theoretical physicists are interested in, as that appears a thankless and idiotic task (which I can wholehartedly understand).

Are we on the edge of a "New Middle Age" as a French writer recently wrote? I don't know, but I do think scientists of the 21st century should be prepared to fight their corner for rational thinking (if not rationalism) against New Age & populist claptrap, a bit like scientists of the 16th to 18th century sometimes had to fight it against religious and political censorship.

Keep this in perspective, though: The price to pay for upholding reason now is addressing idiotic comments in the blogosphere rather than being burned at the stake. That's gotta be an improvement 🙂

A.

47. **changcho**
December 9, 2009

"…Jacob Bronowski's "The Ascent of Man" was a remarkable televised science series…"

Which of course influenced Sagan tremendously when doing his Cosmos series; Sagan was a big Bronowski fan.

For the most part, Kaku is shamelessly promoting pseduo-science; another thing altogether.

48. **ABProduction**
December 12, 2009

Could all of you really claim your vocation hasn't been a little bit influenced by sci fi? Does the true science, which have been developped all along the 19 and 20 th century, not benefit from the pop culture of sci fi. I am sure it has a great part in your own motivations. Of course every one here ask by himself questions about nature, the sci fi yields the idea that science is enough powerful to change the world. I don't know a lot of kids who decided by themselves to become the creator of a new method in analysis. Why so much space scientist in united states and russia? (and more why so much space scientist?) Why every one loves astrophysics and nuclear reactions, and just few people love condensed matter or atomistic? Because of an insane imagination. I was in a GR course looking the potential for the schwarzschild solution, and I suddenly wondered why last year I wasn't so much in love with potential of di-Hydrogen. The curves are the same in essence (I mean they are potential that's all). Now I explained myself why, I still prefer the schwarzschild one, that is not a crime.
Methods are austere, motivations are passions. (applause, cry, so beautiful).
Sorry for english, I used to love it before I realized I was a piece o…

I have too add to the text just above that carl sagan is just frozen, I definitely don't like him and his talk about universe and universal and so and so.

50 Years of Nobel Memories in High Energy Physics

December 4, 2009
Categories: Uncategorized

Over the past two days, CERN has been hosting a program consisting mostly of talks by Nobel prize winners in high energy physics, under the title 50 Years of Nobel Memories in High Energy Physics. It has been a while since anything Nobel Prize worthy has been discovered in HEP, so the speakers of necessity are all getting on a bit in years. The talks pretty much all seem worth paying attention to. Many of them are now on-line, and of the few I've had a chance to look at, the comments by Burt Richter about the ILC/CLIC issue were notable, as well as Veltman's explanation of the possible significance of not finding a Higgs.

I started watching the webcast towards the end of David Gross's talk, in time to hear him give his usual praiseworthy defense of physics against anthropic pseudo-science. Weinberg's talk by video-conference was unfortunately cut short, since he thought it would be an hour long, but it was just scheduled for half an hour.

CERN DG Heuer ended the program by thanking everyone, and looking forward to the first run of LHC collisions at reasonable intensity with the detector magnets on (although only at 450 GeV), which is now scheduled for Saturday.

Update: Videos of the talks are now available here and I've watched a few of them. One interesting thing I noticed was Frank Wilczek's talk about QCD, where his response to a question about AdS/CFT was "I'm not as impressed as I should be."

Comments

1. **Thomas Larsson**
   December 4, 2009

   Gall et al's (or is it al et Gall?) observation about the Nobel prize singulariaty is quite on the spot.

2. **Domenic Denicola**
   December 4, 2009

   Newbie question after reading Glashow's talk: he says that "Furthermore, the Higgs mechanism per se cannot fully explain electroweak symmetry breaking." What is meant by this?

3. **Cormac O'Raifeartaigh**
   December 4, 2009

   Re 'it has been a while since anything Nobel Prize worthy has been discovered in HEP, so the speakers of necessity are all getting on a bit in years'
   it seems the time gap between theory and experiment gets larger the deeper down we go. Sad to think whole careers come and go in this timeframe e.g. if supersymmetry is observed at the LHC, almost none of the pioneers will be around to see it (except Zumino)

4. **Peter Woit**
   December 4, 2009

   Domenic,

   I'm not sure what Glashow had in mind. There are various problems of principle with introducing an elementary scalar Higgs field (it's not asymptotically free, cosmological constant), there's the hierarchy problem, then there's the basic problem that you lose all ability to predict particle masses, since they are given in terms of arbitrary Yukawa couplings to the Higgs.

5. **Ricci Pieces**
   December 4, 2009

   http://insti.physics.sunysb.edu/~siegel/parodies/sam/sam.html <– Check out the section called Nobel Prize Singularity.

6. **Ralph**
   December 4, 2009

   The schedule for the weekend (http://lhc-commissioning.web.cern.ch/lhc-commissioning/news/LHC-news.htm) is interesting – 450GeV collisions mixed with ramps (presume to 1.18TeV).

   Hopefully if all goes well, they might just tweak the schedule a bit to collide at the higher energy as well…

7. **Shantanu**
   December 4, 2009

   Peter, I don't see a link to the videos of talks. Could you(or others) point me to it?
   Thanks
   shantanu

8. **Peter Woit**
   December 4, 2009

   Shantanu,

   I watched some of the talks on the live CERN webcast site. Presumably the videos will be made available later, but I don't think they're up now.

9. **zhaphod**
   December 5, 2009

   I don't understand why time would be an issue and they have to cut Weinberg's talk in the middle. It is a singular opportunity to preserve for posterity the talks by these great scientist. I think CERN should do more in this regard.

10. **dan**
December 6, 2009

So are there any seriously considered alternatives to higgs (simple scalar or composite?)

11. **Peter Woit**
December 6, 2009

dan,

The general assumption is that, to get electroweak symmetry breaking, one needs to add some sort of new fields to the fermions and gauge bosons of the standard model, with dynamics such that either an elementary or composite field gets a vacuum expectation value that breaks the symmetry. The most popular ways to do this are an elementary Higgs scalar, or a new QCD-like sector, with pions playing the role of the Higgs field (technicolor). I don't know much about other ideas, the prejudice seems to be that they end up being equivalent to one of these two alternatives.

It wouldn't surprise me though if it turns out that electroweak gauge symmetry breaking is a much more subtle business, with some currently unsuspected way of making it work. Hints from the LHC about this would be most welcome…

12. **dan**
December 6, 2009

Thanks for replying,
I know that SUSY is the proposed solution to simple scalar higgs fields, the other is fine-tuning, but do technicolor models (i.e top color assisted technicolor) or composite higgs field also suffer from the hierarchy problem, and need SUSY or fine-tuning to remedy them?
Is there a reason SUSY seems preferred to fine-tuning?

13. **Peter Woit**
December 6, 2009

dan,

Other than the problems with elementary scalar fields, it's not clear to me that there really is a hierarchy problem. One has no evidence for a GUT scale, nor an understanding of quantum gravity, so the smallness of the electroweak scale relative to these may not be of any particular significance.

14. **dan**
December 6, 2009

Thanks, just to clarify, if there is no GUT or planck scale, then Higgs large radiative contributions do not apply?

15. **Van**
December 6, 2009

Hi Dan,
The large radiative corrections do apply, even if there is no GUT or planck scale. I presume that what Peter has in mind is that there is some 'subtle' property of QFT that is currently not recognized which would make these corrections small. I presume he applies the same logic in his idea that electroweak symmetry breaking will not involve a Higgs-like mechanism.

16. **Peter Woit**
December 7, 2009

dan,

The "large radiative corrections" problem is a problem with having an elementary scalar field. It's just one of the reasons for not being happy with this way of implementing electroweak symmetry breaking.

17. **dan**
December 7, 2009

Are there serious proposals for breaking electroweak symmetry breaking that do NOT involve elementary scalar fields and is also consistent with current evidence such as W-W scattering?
thx in advance

18. **Peter Woit**
December 7, 2009

dan,

I don't think current data about WW scattering constrains much of anything, my understanding is that this is something interesting to look at at LHC energies. Technicolor and its variants are the most well-known alternatives to scalar fields, long ago I had a guest blog entry here from Robert Shrock about the state of constraints on such models, see here:

http://www.math.columbia.edu/~woit/wordpress/?p=614

A Black Future

December 5, 2009
Categories: This Week's Hype

Tom Siegfried, the editor of Science News, seems to have decided to join with Michio Kaku in the science-fiction as science business. He marks the startup of collisions at the LHC with A Black Future, an article about how "the Large Hadron Collider might help humans explore the cosmos". Here "exploring the cosmos" doesn't mean understanding how the cosmos works, it means building an interstellar spaceship to travel across it.

The argument seems to be that the LHC will produce black holes, and a recent paper by Crane and Westmoreland suggests that black holes can be used to power a space-ship. Siegfried somehow manages to drag Steven Weinberg and supersymmetry into this, with a claim I don't understand that the Crane-Westmoreland idea "may be realistic only if cosmic physics incorporates a mathematical framework known as supersymmetry."

Comments

1. **Chris Oakley**
   December 6, 2009

   The Crane-Westmoreland paper is listed under "gr-qc" (General Relativity and Quantum Cosmology) on arXiv. Personally, though, I think they should create a new category "bs" for this kind of thing – maybe they have not because it would get too crowded.

2. **J. E. Connett**
   December 6, 2009

   Hi Peter,

   This is a bit off-this-specific topic, though maybe it does relate to hype –

   There is a web commentary group called the Hydrino Study Group
   Forum (HSG),

   http://forum.hydrino.org/index.php?sid=f5b283266ad2a24080ac110d43cc9087

   which is devoted to examining the theory and experiments of Randell L.
   Mills, MD, and his company, Blacklight Power (which has attracted $60M
   in venture capital funding). Mills has published over 70 papers in
   peer-reviewed journals.

   One of the regular posters to the HSG Forum, an electrical engineer
   named John Barchak, frequently cites your blog as evidence that
   quantum mechanics is hopelessly wrong. I wonder if you could clear
   the air on this a bit –

   Do you think QM is hopelessly wrong?

   Are you aware of Dr. Mills' work and his 1000+ page book, "Grand Unified
   Theory of Classical Physics" ? What is your view of this?

3. **Peter Woit**
   December 6, 2009

   J.E. Connett,

   I don't know who John Barchak is, but citing anything I've written on my blog as evidence against QM is complete nonsense. Quantum Mechanics is in a very real sense the best scientific theory we have. It is a beautiful, fundamental theory, closely intertwined with the deepest concepts in mathematics. It has been tested with an accuracy and completeness that nothing else in science can match.

   As for Mills and his hydrinos, I see no reason to believe any of it, encourage others to ignore this kind of pseudo-physics, and to avoid trying to discuss it here…

4. **DZS**
   December 6, 2009

   Peter Woit,

   You write a lot about the Multiverse mania.
   What's your take on Many Worlds Interpretation of quantum mechanics?
   There are atleast as many dogmatic proponents of it as there is of string theory, amongst the worst: David Deutsch, Max Tegmark and I think Michio Kaku is too.

5. **Peter Woit**
   December 6, 2009

   DZS,

   My take on Many Worlds is that I'm not very interested in something which is purely an "interpretation" of QM. If it's fully equivalent operationally to other "interpretations", arguing about which is better doesn't seem to be a worthwhile activity. There is an interesting issue about the "interpretation of quantum mechanics", that of understanding how classical physics emerges from a fundamental quantum mechanical theory, but I don't see that Many Worlds has anything useful to say about this.

   As far as I can tell, despite some people's attempts to mix up the two, Many Worlds has nothing to do with the multiverse hypothesis.

   Sorry, but this is an off-topic issue, one that lots of people want to debate. It's not one I'm expert on or interested in moderating a debate about, so please find somewhere else to discuss this.

6. **DZS**
December 7, 2009

Sorry,

It's just MWI bothers me atleast as much as String Theory.
A lot of parallels when you look at it from a sociological view, with it's dogmatic proponents etc. but I understand this is a place to discuss String Theory.

Thanks for your opinion though

7. **Arnaud**
December 7, 2009

Chris O,

Are you referring to factual errors in that paper, or to their overall subject? I have to say myself I can't comment on the facts but from a cursory glanced of the paper it sounded like an interesting read.

Such papers are obviously not meant to advance the fields of physics with new insights, and maybe the paper would be better published in an astronautics journal, for instance.

But this works reminds me of the work of this past NASA group who was looking into "advanced" propulsion concepts and such like. Not useful currently, but keeps your mind open, as long as the science is right, of course.

After all, the works of Tsiolkowsky when published were probably a similar level of anticipation about technological steps needed for a given application, i.e. space travel. In fact one can argue today we have yet to realise his vision fully, but his insight into potential developments of space travel were astonishing.

A.

8. **mark**
December 7, 2009

Hi,

I also noticed some time ago:

http://www.physorg.com/news174293159.html

another idea for the LHC and insterstellar travel. Good that there is a way to experimentally test this idea right now…

9. **Chris Oakley**
December 7, 2009

Arnaud,

I have no reason to believe that there are factual errors in the CW paper *per se*. But the tone is highly misleading. *If* we had a quantum theory of gravity (we don't), or had stumbled upon artificial black hole production by chance in the laboratory (we haven't), then it might make sense to talk about the practicality of making a propulsion system based on the latter. But since neither is the case, the authors are in reality in no better a position than the scriptwriters for *Star Trek* in working out the feasibility of such a scheme. This is a paper for gullible journalists, not scientists, and providing equations and references serves merely to confuse the issue.

10. **Tim vB**
December 7, 2009

I considered myself warned after reading this in the introduction: "The conclusion we reach is that it is just on the edge of possibility to do so, but that quantum gravity effects, as yet unknown, could change the picture either way."

I'm not sure anymore if papers like this one are supposed to be a joke or not.

11. **Adam Helfer**
December 7, 2009

The CW paper is serious science of a highly speculative but appropriate sort (on the question of whether human interstellar flight is possible within certain parameters). The authors clearly don't expect their analysis to be definitive, but aim to stimulate work leading to a fuller understanding of the issues.

I think the authors' tone would be understood and not misconstrued by anyone in the field, and given the intended readership (gr-qc) I don't see a problem. Of course, anyone who is not in the field should be cautious about her or his understanding of the paper's context, the likelihood its arguments are correct, and its implications.

That the authors are aware of the potential of quantum gravitational effects to alter their conclusions is a strength rather than a weakness. There are plenty of papers on related issues whose authors seem unaware that on dimensional grounds quantum gravitational effects could be large enough to change their results.

12. **Peter Woit**
December 8, 2009

Adam,

Physicists posting wildly speculative papers about space travel and black holes to the arXiv isn't unusual or surprising. Science News publishing an article claiming these have something to do with the LHC is…

13. **Adam Helfer**
December 8, 2009

Peter,

I agree. The point I was making was that just as some of those not in the field should be cautious of forming a Crane-Westmoreland-LHC-SUSY-Weinberg amalgam, so equally should others be cautious about the sorts of criticisms they make of Crane and Westmoreland.

14. **schof**
December 9, 2009

I feel as if there might be another subject which regularly assumes the existence of certain results or axioms that are only true in some cases, or have yet to be shown.

Mathematics rings a bell…

15. **Louis Crane**
December 10, 2009

Dear sir,

I completely agree that that sentence in the Science News article is misleading. We did not use supersymmetry in our calculations. I am very skeptical about supersymmetric theories.

If LHC surprises us and produces black holes, all the calculations in our paper will need redoing, and the project will be much easier than it now seems.

On a personal note, I do not understand why contributors with no actual points to make think it appropriate to curse at us in public. I do not think the internet justifies the end of civility.

16. **Chris Oakley**
December 10, 2009

Hi Louis,

Thanks for dropping in.

This is the abstract of your paper:

> We investigate whether it is physically possible to build starships or power plants using the Hawking radiation of an artificial black hole as a power source.
> The proposal seems to be at the edge of possibility, but quantum gravity effects could change the picture.

As I do not need to tell you, an artificial black hole has never been produced. There is, I believe, recent strong evidence for the existence of black holes as astronomical objects, but since the supporting experimental evidence for GR is entirely in cases of a weak gravitational field it is entirely possible that the Schwarzschild solution does not apply to such objects. What is more, the densities of such objects are probably such that one could not ignore quantum effects. As I also do not need to tell you, we do not currently understand gravity at the quantum level. Thus our understanding of black holes from both the theoretical and experimental standpoint is extremely poor. Despite this, using semi-classical arguments Stephen Hawking was able to demonstrate that if such objects exist according to the laws of GR, then they must radiate. However, since we do not really know what is going on here, there could also be a myriad of other effects, one or other of which could making Hawking radiation irrelevant. We will not know for sure until we have a workable quantum theory of gravity.
So, if one substituted, "The proposal seems to be at the edge of possibility, but quantum gravity effects could change the picture." with, "The proposal assumes that one can produce black holes artificially – something that has never been done, and that Hawking's semi-classical model suffices to describe their behaviour – which seems highly unlikely," then it would be less likely to confuse journalists.

17. **Tim vB**
December 11, 2009

Adam Helfer, Lois Crane,
my apologies if what I said came out wrong.
IMHO the paper we talk about clearly states what is assumed and clearly states what the current status of these assumtions is, so I don't think it should cause any confusion in the physics community.
What Tom Siegfried wrote however seems to be an unjustified blend of ideas in order to attract the attention of a lay audience,
which is what motivated Peter Woit to blog about this in the first place, as he already pointed out.
However: I suspect that a highly speculative paper about harnessing black holes to propel spaceships will
look like a result of some playfully spent idle time to most scientists outside the field, which is what I meant when I said "is it a joke?" (I did not intend to imply that the paper is ludicrous, sorry for the imprecision.)

18. **Robert Frost**
December 11, 2009

Perhaps arxiv.org needs a new category:

"hep-pseudoscience [toy ideas, fantasies, untestable speculations].

Just a thought.

19. **RM**
December 14, 2009

Perhaps one way to put it is this: when physicists who normally publish meaningful physics, sometimes take a detour into the bizarre, its probably ok – and maybe even worth reading. However, if the bizarre becomes routine, one feels like revoking the tenure system. I don't know enough about general research published by Crane etc so would not like to comment on this particular piece.

But K(a)ukoo-land is quite another matter…!

Spreading Wild Rumors

December 7, 2009
Categories: Uncategorized

One effect of Nature's embargo policy is to encourage the spread of wild rumors. It's almost part of the mission statement of this blog to participate in this, so I feel I must link to this.

Update: Nature unequivocally denies that they will be publishing a CDMS paper on the 18th. The collaboration does plan to reveal the results of their latest run on that date. The wild rumor that they have seen WIMPS and will reveal all on the 18th remains in force…

Update: There's now a statement on the CDMS web-site, saying that there will be two talks on December 17, and plans to submit a paper to the arXiv before the talks.

Comments

1. **Low Math, Meekly Interacting**
   December 7, 2009

News From the LHC

December 8, 2009
Categories: Experimental HEP News

Just saw this from Tommaso Dorigo, which made me realize that I should get to work and write a blog posting before the CERN press office people wake up. The big news today is that the first collisions at a record energy higher than that of the Tevatron have occurred, marking a first step into new territory past what has been the energy frontier in HEP for a very long time. Two beams of two bunches each were successfully ramped up to 1.18 TeV, and although one of the beams was lost after a while, before that point some collisions at a total energy of 2.36 TeV were observed. An event display from ATLAS is here.

Over the next few days, the main objective of the beam commissioning team is to try and increase the intensity per bunch and provide a large number of collisions at 450 GeV/beam to the experiments. They'll also continue tests in which they ramp up the energy to 1.18 TeV/beam, and if all goes well should be able to provide the experiments with an equally large number of collisions at that energy. The experimenters are gleeful about finally having real data to play with. CMS has publicly announced the re-discovery of the pi-zero, and I assume that by now they're working their way through the 1950s, already rediscovering kaons and other particles with strange quarks. If they manage to get a significant amount of data at 2.36 TeV, there must be some sort of cross-section they can measure at an energy that just beats out the Tevatron, although with this size of a collision sample, it won't be one that anyone cares much about…

Beam commissioning work for 2009 should end on December 16, and the accelerator complex will be shut down over the holidays, re-starting January 4. During January the LHC will go back into hardware commissioning mode, with a month-long plan to commission the new quench protection system in all sectors, allowing operation at 3.5 TeV/beam. The injectors are supposed to restart on February 5, LHC beam commissioning restarting on February 8. The way things have been going, they may have at least some 7 TeV collisions happening quite quickly after that.

Update: This morning again a pair of 1.18 TeV beams were stored and brought into collision at the LHC. This time CMS as well as ATLAS is publicly saying that collisions were seen, with event displays here. CERN's twitter feed is saying over a million collisions at 900 GeV, 50,000 at 2.36 TeV. Still no press release from CERN gloating about how they now are doing physics at higher energy than Fermilab.

1. **Steve**
   December 8, 2009

   Hi, Peter. Could you explain what it means for a beam to be "lost"? I've heard that term used few times, but I don't understand the relation between that and just dumping the beam. Is there some sense in which the beam is "lost" but still circulating and waiting to be shunted to the dump system?

   Cheers,
   -Steve

2. **Peter Woit**
   December 9, 2009

   Steve,

   I think in this context "lost" means more "lost control", presumably the operators could tell you what happened to the beam particles. When a beam is "dumped", that's a controlled shutdown of the beam, by directing its particles to a safe location to be stopped.

   There are all sorts of instabilities than can disrupt a particle beam and lots of complex mechanisms for stabilizing the beam and controlling it. When it's "lost" I think this normally means that there was some sort of failure leading to a destabilization and loss of control of the beam.

3. **Nobody**
   December 9, 2009

   It appears that the beams were never declared as "stable" (neither they were intended to collide); does this mean that ATLAS keeps his detector switched on even when the beam is not under complete control and can do weird things?

4. **Peter Woit**
   December 9, 2009

   Nobody,

   My understanding is that in this situation the detector is not fully operational, with some parts switched off for protection. But enough of the detector is working to see the evidence of a collision that ATLAS showed.

5. **jks**
   December 10, 2009

   Vistars Op comments at 02:01:01 on 11-12-2009: "FIRST HIGH INTENSITY STABLE BEAMS". Looks like five bunches each in B1 & B2 (@ 450 GeV) with the FBCT (fast beam current transformer) intensity saying about 6e+10 with a slow rolloff to 4e+10 and hour and 1/2 later. Nice.

6. **a quantum diaries surivivor**
   December 11, 2009

   Hi Peter,

   thanks for the link 🙂
   Yes, you assume well. Atlas and CMS are working their way through the fifties, literally.

   By the way, when the beam is lost it is indeed what you explained. There are so many components in a proton synchrotron that may cause the beam to get progressively out of sync and lost, there is not much to explain.
   As for stable beam: LHC is indeed producing stable beams, and in fact the data that ATLAS and CMS are analyzing come from those short periods of time when machine operators take their hands off the controls and go for a coffee. Normally, they try to study the beams and by doing so the conditions are not suitable for data taking.

Cheers,
T.

7. **a quantum diaries surivivor**
December 11, 2009

Oh, and just before I forget: you might want to read my latest posting on the events of this week. Not really releasing any insider information, but I hope I have given the flavour of what is going on at CERN these days.

Various and Sundry

December 13, 2009
Categories: Uncategorized

- The proof of the fundamental lemma by Ngo has made it onto Time magazine's list of the top ten scientific discoveries of 2009. Ngo will be visiting Columbia in the near future, and I might even end up understanding what this is about. He's giving the Ritt lectures here later this week, and will be Eilenberg visiting professor for the Spring 2010 term, giving a series of weekly lectures.
- The collaborative work on the Density Hales-Jewett theorem initiated by Timothy Gowers on his blog has made it into today's New York Times magazine's survey of the "Annual Year in Ideas".
- Tony Zee's book Quantum Field Theory in a Nutshell will be coming out in a second edition next year, featuring some new material covering recent advances in computing scattering amplitudes in gauge theory. The new preface is available here and has some interesting comments from Zee about the book and about QFT books in general. It also contains a response to those Amazon reviewers described as "nuts who do not appreciate the *Nutshell*". I suggest that Zee get a blog, it gives one an excellent way to respond to nuts who misunderstand and don't appreciate one's book…
- Last weekend there was a meeting held at Rutgers in memory of I. M. Gelfand, with some materials available here.
- A couple weeks ago there was a very good article in *Science* magazine by Adrian Cho about recent discussions of the possibility of a muon collider. Since muons are much heavier than electrons, one can in principle use a storage ring to collide them without the problem of synchrotron radiation loss that limits the energy of electron-positron rings to the LEP energy scale. The fact that muons are unstable and decay fairly quickly is a huge problem. Besides making it difficult to use the "cooling" techniques needed to produce a usable beam intensity, the decay products create a very challenging environment for a detector to operate in, as well as producing neutrino intensities so high they are capable of causing problematic levels of radiation wherever they emerge from the earth.
- C. J. Mozzochi has a page here with links to many of his wonderful photographs of mathematicians, mostly in action at various conferences or lecture series.

Update: One more. Last night I watched a spectacularly bad Sci-Fi movie, Annihilation Earth, brought to the world by the Syfy channel. I don't think it's a movie that really can be spoiled for you, so here's a plot synopsis: three supercolliders in Geneva, Orleans and Barcelona are providing power for Western Europe. Scientists who designed them realized that in a certain configuration the critics were right, and the Higgs field would get out of control and form a black hole that would destroy the earth. Evil Arab terrorists hack into one of them and reconfigure it to self-destruct. The remaining two are all that is keeping the Higgs field from expanding exponentially and causing the black hole that will annihilate everything. One of the scientists refuses to believe the other when he explains this to him, because of the color of his skin and the fact that he's an Arab too (although he doesn't look it). So, in the final scene he shuts down one of the remaining super-colliders and the Earth is annihilated. I guess the film-makers should be congratulated on this innovation in sci-fi film-making, ending the film with the scientists not saving the Earth but destroying it.

Comments

1. **Ricci's Pieces**
   December 13, 2009

   Wow, I am pleasantly surprised that Ngo's work is being recognized by Time magazine. Certainly this is huge for the Langland's Program.

2. **Tim vB**
   December 14, 2009

   Time magazine chose Edward Witten as one of the most influential personalities of the year (or the decade or the century, I don't remenber) some years ago.
   They must have a mathematician or physicist in their editorial staff.
   This kind of recognition is of course great news to the whole math/physics community, not only to the Langland's program (either the reader already knows about Langland's or (s)he will have forgotten about it seconds after reading the article :-).

3. **Arun**
   December 14, 2009

   I suggest that Zee get a blog, it gives one an excellent way to respond to nuts who misunderstand and don't appreciate one's book…

   But moderating the comments is a painful chore, not to be wished upon even one's worst enemy….. 🙂

4. **sfjp**
   December 14, 2009

   About "Earth annihilation": that's why, by backward causation, the LHC will fail before producing any Higgs….:-)

5. **D R Lunsford**
   December 14, 2009

   Ok Peter, so why are there beekeepers in this flick? Maybe they are B-meson keepers. Huh?

   -drl

6. **John Baez**
   December 15, 2009

   … but for some reason backwards causation did not prevent people from making this movie.

7. **John**
   December 15, 2009

   Hi Peter,

   I was thinking of purchasing Zee's book to start learning some quantum field theory: do you have any specific suggestions regarding the work and/or beginning qft texts?

   Regards,
   John

8. **Chris Oakley**
   December 15, 2009

Annihilation Earth at least has the positive feature of making the public think that particle accelerators contribute to the electricity grid rather than being a massive drain on it.

9. **Peter Woit**
December 15, 2009

John,

I like Zee's book a lot, but the problem I see with it is that if you're just beginning in the subject it doesn't really have the kind of technical detail you need to be able to do computations yourself. It might be best used as a supplement to one of the standard, more computational texts (I like Pierre Ramond's book since it is concise, but it doesn't address lots of topics, a more comprehensive book with details is Peskin-Schroeder). Another recent QFT book I like a lot is V. P. Nair's.

10. **D R Lunsford**
December 15, 2009

Peter, I had the same complaint about Kaku's book (which, believe it or not, is eminently sane). A fairly recent book that I have is by Michele Maggiore – very good, sort of a Sakurai for modern times. For relativistic QM the book "Advanced QM" by Schwabl is excellent.

-drl

11. **srp**
December 15, 2009

Re the muon collider: I always hear these gee-whiz statements about how neurtrinos are sooo hard to detect because they don't interact with anything and they can go through the Earth without noticing it, etc. Now you tell me that the measly decay products from an accelerator are intense enough to cause radiation issues? I demand a popular science refund!

12. **Steven Colyer**
December 15, 2009

Thank you for the excellent textbooks, Peter. I also own "Nutshell" as Zee refers to his book, and find it as others do a book than likely began in intent as a non-technical popular overview of humanity's greatest 20th century achievement, QFT, then morphed somewhere along the way into a "near"-textbook without quite achieving true textbook status.

As a fine introduction to those who have mastered the Mathematics of Quantum Mechanics, I enjoyed "Quantum Field theory Demystified, a Self-Teaching Book", by David McMahon, available in bookstores and targeted to the very intelligent layperson.

As early as page 3 he makes mention of the Klein-Gordon equation with its obvious flaws, and moves quickly into the Dirac Equation. On page 4 he explains that while "x-carat" is considered an operator and "t" a parameter in QM, and one would expect the promotion of "t" to operator status in QFT, that instead "x-carat" is considered a parameter as well, and McMahon goes on from there through its slim but lovely 261 pages.

13. **Coin**
December 16, 2009

They call it "science fiction" but so much of the time the message seems to be "science is evil and will kill us all".

14. **Tim vB**
December 16, 2009

@John on QFT books:
I completly agree that you should definitly read the nutshell, it's a great exposition of many beautiful concepts, but you need a supplement that gets you calculating.
Try Voja Radovanovic: "Problem Book Quantum Field Theory" (consisting of standard problems and solutions on an introductory level).

15. **andy.s**
December 16, 2009

The problem with the "Demystified" series is that the publisher seems to have cheaped out on providing a proof reader. Did you know that the charge on the strange quark is +2/3? Me neither!

Little goofs like that are all throughout the text.

16. **Haelfix**
December 16, 2009

I loved Zee's book. Actually after quantum mechanics, I recommend a pedagogical introduction to particle physics (alla Griffith) to learn Feynman diagrams and how to compute various quantities like cross sections. Then read Zee, but don't do any of the exercises.

From there, Peskin and Schroeder is the standard field theory textbook and the one where you should spend time doing exercises and all the funky integrals. From that point on where you go depends on preference and what you are going to do in physics. I like Weinberg, b/c he goes over the whole material from scratch in a logically cohesive way and by that point you should be good enough to follow it without too much of a hitch.

17. **Gphillip**
December 16, 2009

I suspect fans of HEP and the LHC probably laughed all the way through the Annihilation Earth Si-Fi show, if they made it all the way through. I tried to watch, but failed to make it to the end. Thanks for the summary, now I don't have to watch the rest of that silly stuff. Oh well, at least they didn't have a real Physics PhD playing the lead.

18. **Coin**
December 18, 2009

I have an open-thread kind of question. Would anyone be able to recommend any current science books which would be a good Christmas gift for someone? I was thinking about something that would serve as kind of an introduction to the things the LHC might be looking for, and so was thinking of Oerter's "The Theory Of Almost Everything" which is sort of an intro to the standard model, but that book is like two or three years old and I don't know if something more appropriate or explicitly LHC-centric might be out by now. (Also it's cheap now so I was wondering if I could find something to pair it with.) I should note the person I'm thinking of giving this gift to has like a master's in earth sciences so it's safe to give something math-heavy (or even just about math, if there are any math or math-history books worth recommending that came out this year).

19. **Steven Colyer**
    December 22, 2009

    One book I would NOT recommend is the recently released "String Theory for Dummies" by Andrew Zimmerman Jones (which many here would say is the most appropriately named book of all time), because of its rather heavy PRO-strings bias, and its obviously heavy influence by Leonard Susskind. Peter, have you reviewed that book yet?

    On the positive side, I would start with journalist Louisa Gilder's The Age of Entanglement, which covers the Quantum 11 (I include Weyl) from Planck through Dirac and on into the 21st century (with stops along the way with Feynman and Bohm) in novel form. Reads like a novel, and is vastly entertaining and inspirational, albeit math-free.

    After that, Peter's own Not Even Wrong is excellent. I call attention to the middle so-called "hard parts" in the middle which are a brilliant example of expository writing regarding the development of Quantum Field Theory beginning with Weyl and ending with Atiyah. Of course the whole book is great but those are my favorite bits. Again, no maths, but that's the joy, to tell such a story in prose form.

    I would then move on to the 2009 Revised Edition of The New Quantum Mechanics by Tony Hey and Patrick Walters, with the briefest introduction to the mathematics involved. My one flaw with the book is a mere 2-1/2 pages devoted to Quantum Gravity because they only mention String Theory. Peter would probably say 2-1/2 pages is the appropriate proportion to devote to QG in a 200+ page book about QM. 🙂

    Finally, for the Math buff, there's The Road to Reality by Sir Roger Penrose. Although Sir Roger speculates quite a bit, he is polite enough to warn you ahead of time that he's doing so. It is chock full of Math and his introduction to spinors is a classic.

20. **AlBme**
    December 23, 2009

    Regarding "Annihilation Earth": The Sci-Fi channel started out with great promise, but badly deteriorated over the years through poor management — with some notable exceptions like "Battlestar Galactica". When the Sci-Fi Channel changed its name to SyFy, it became one of the worst network name changes in television history. It was so appropriate to learn from my Polish friends that "syfy" in polish is the plural for "a dirty mess" — but, dirty in the way feces is dirty.

    There's good sci-fi and bad sci-fi. This movie doesn't have enough 'sci' to even qualify as bad sci-fi.

String Theory and Heaven

December 16, 2009
Categories: Uncategorized

I hadn't heard much about Dinesh D'Souza since the Reagan era when for some mysterious reason his views were widely promoted in the media. He has continued since then to play the role (supposedly according to the New York Times Magazine) of "one of America's most influential conservative thinkers." His last book was *The Enemy at Home: The Cultural Left and its Responsibility for 9/11*, and he has a new one out called Life After Death: The Evidence. In a recent magazine interview he explains the main thesis of the book, that string theory has vindicated Christian theology by proving the existence of heaven and hell (they're out there in the multiverse somewhere).

> **How might science explain heaven and hell as places that could exist?**
>
> Scientists now posit through string theory the presence of multiple realms, multiple dimensions. One of the implications of the big bang is that space and time had a beginning, and that space and time are properties of our universe. If that's true, then outside our universe or beyond our universe, there would be different laws of space and time, or no space and no time.
>
> The idea that our universe may not be the only one and that there may be other universes operating according to different laws is now coming into the mainstream of modern physics. So the Christian concept of eternity, which is God outside of space and time, is rendered completely intelligible. It opens up possibilities that would have seemed far-fetched even for science fiction a century ago.

Update: Here's the link to the interview: String Theory and Heaven.

Comments

1. **Pawl**
   December 16, 2009

   Boldly going where angels fear to tread.

2. **andy.s**
   December 16, 2009

   Of course Christianity posits only 3 universes, ours, Heaven and Hell(*). This is more parsimonious than 10^500, making Christianity more likely than string theory.

   I wonder what the vacuum state for hell is?

   ——————————
   (*)Limbo and Purgatory being submanifolds of Hell proper.

3. **point**
   December 17, 2009

   You'd better behave yourself, Peter, or you might get sent to a universe with branes, supersymmetry and a negative cosmological constant.

4. **Geoff**
   December 17, 2009

   It is completely obvious from reading scripture that the vacuum state for heaven must be calculated using the Bogolubov transformation. As any self respecting Christian will tell you, Bogolubov is Russian for God's love. It is equally obvious that the vacuum state for hell is ill defined since hell is clearly expanding and thus creating new damned souls 🙂

5. **Rutger**
   December 17, 2009

   There is nothing new about claims like this, see the 'physics vs eastern philosophy' craze a while back. Further, I bet there are people who have written that the standard model proves there is no god/1 god/many gods. To suggest that string theory is the only theory to fall foul of these types of wild extrapolations is not quite fair (not fair and balanced? :)).

6. **Francois Vanderseypen**
   December 17, 2009

   It's good to have a laugh 🙂 The tragedy is the influence some people have and give an aberrant picture of reality. Very often, not the truth matters but the perception of things.

7. **Bob Levine**
   December 17, 2009

   " …So the Christian concept of eternity, which is God outside of space and time, is rendered completely intelligible."

   What I find bizarre is that D'Souza seems to think that the existence of multiple subuniverses, corresponding to all those different vacuum states, somehow implies that the contents of at least some of those universes are exempt from causal relationships ('outside of space and time'). Is there any reason whatever to believe that string-based models of the 'landscape' include such oases of noncausal being?

8. **Alejandro Rivero**
   December 17, 2009

   The main difference between Kaluza Klein and Modern String Theory is that the former is a theory of "needed extra dimensions", while the later is a theory of "wasted extra dimensions". Given that there is no role for the extra dimensions in string theory, this proposal is as good as any other. Any conceptual vacuum, g-d fills it.

9. **andy.s**

December 17, 2009

Damnation : i.e. |Mortal Sin>, is one of the eigenstates of a person's wave function (which layman refer to as a 'soul').

Other eigenstates: |Original Sin>, |Grace>, |Venal Sin>.

10. **Stephen**
December 17, 2009

All this may sound ridiculous, but I find the following sentences meaningful:

"outside our universe or beyond our universe, there would be different laws of space and time, or no space and no time."

"So the Christian concept of eternity, which is God outside of space and time, is rendered completely intelligible."

One may argue about the word "completely", but the line of reasoning is actually showing that a concept which was very mysterious in theology, becomes illuminated by modern physics in a beautiful way.

However this is not new, and it has nothing to do with string theory but just with other concepts, such as general relativity and the possibility of having theories with coupling constants which take different values from the ones that we observe.

11. **Chris Oakley**
December 17, 2009

andy.s,

Not to be pedantic, but what you say is only true in the Heisenberg Picture as

$|\text{Mortal Sin}\rangle = \exp(iH' t)\ |\text{Original Sin}\rangle$

where H' is the unperturbed Hamiltonian plus a deviation towards wickedness (obviously t = Day of Judgement here). In the Schrödinger Picture, they are the same ket, measured at different times.

12. **Yatima**
December 17, 2009

Sounds like a schizophrenic is free-associating on the couch. Charming.

Dante has been in that general vicinity a long time ago anyway, with his universe a 3-sphere, hell at one end, and heaven at the opposite end:
http://dx.doi.org/10.1119/1.11968

13. **h**
December 17, 2009

As any Hindu can tell you, you are all (not even?) wrong.
The world is flat, and is supported on the back of a turtle,
which swims in an infinite sea, which resides in … the multiverse?
http://en.wikipedia.org/wiki/Turtles_all_the_way_down

Why be Christian and die only once?
As a Hindu you can have multiple lives and visit the entire multiverse!

14. **Barry Cunningham**
December 17, 2009

This just reflects the fact that even the flat-earthers have noticed what many others have known for a long time: string theory is a religion. The only wrinkle is that since they believe there is only one true religion, they think it must be theirs.

15. **Scerny**
December 17, 2009

Sorry Peter, this will be totally off topic, but of interest:

Does anyone know what happened to Lubos Motl's blog? Currently it's down, blogspot saying the blog can not be found.

Scerny Pvrizek

16. **Tim vB**
December 17, 2009

You can justify Christianity by conventional physics, you don't need string theory:

The-Physics-of-Christianity

One thing I don't understand is: Do the authors expect every Christian to get a physics Ph.D.? Or may true believers just believe without understanding anything of the scientific foundations of their religion?

17. **Koray**
December 17, 2009

If physics tells us that there may be other universes, it still doesn't render "God outside of space and time" completely intelligible just as "outside of Houston, Texas" doesn't mean somewhere else in Texas, or the US, or the earth.

18. **Hal Porter**
December 17, 2009

As a non physicist, does string theory posit an immortal soul that wafts off to another universe after we shuffle off this mortal coil?

And what are the implications for the trinity, the virgin birth, and the rising of the dead after the great shout.

Rattle my bones and tie them together with strings!

19. **anon**
December 22, 2009

D'Souza has published a book after "The Enemy At Home" and before "Life After Death". It was called "What's So Great About Christianity". I read it, and I thought it was very good, and I don't even believe Christianity. I also don't have the same political views as D'Souza; mine are libertarian, which D'Souza rejects. Dinesh D'Souza is a very serious thinker, and it is unwise to discuss him dismissively. I haven't read "Life After Death", but my concern is that Woit's original entry might not accurately describe the main thesis of the book.

20. **Bob Levine**
December 22, 2009

"Dinesh D'Souza is a very serious thinker, and it is unwise to discuss him dismissively. I haven't read "Life After Death", but my concern is that Woit's original entry might not accurately describe the main thesis of the book."

Anon, just look at the content of what D'Souza says in the passage Peter quotes. The theory that D'Souza explicitly refers to, and which he takes to be synonymous with 'Science', is, like all other physical theories, a statement of a set of constraints on dynamical variables defined in terms of space and time. The 'multiple universes' D'Souza alludes to are just those possibilities which conform to those constraints. And D'Souza believes that among the members of this set of possibilities conforming to those constraints, there will be at least one which is subject to NO constraints on (entities definined in terms of) space and time, since there supposedly is *no* space or time in this member of the set of universes. Serious or not, what kind of thinking is involved here?

21. **Peter Woit**
December 22, 2009

anon,

I've added the link to the full interview of D'Souza, which I forgot to include when I originally wrote this posting.

As to questions like that of whether D'Souza is a serious thinker or an idiot, my preference is to let people read for themselves what he has to say, and make up their own minds. To me personally, this seems like an open-and-shut case…

22. **luny**
December 22, 2009

A cursory reading of the bible shows God is not "outside space and time". He creates the world, messes around all kinds of people to "test them" (Adam+Eve,Job,Abraham,…), realizes humanity is going to the dogs, floods the world after arranging an ark, and finally sends his son to save humanity.
He might be on a different brane, but his timeline is the same as ours

23. **anon**
December 22, 2009

I think it's a mistake to underestimate D'Souza's intellect, or to describe him in a mocking or dismissive way, but I suspect that you, and many other physicists, will be predictably hostile to D'Souza without even doing a serious reading of his work. There are, however, two factual errors in the blog post. One is about which book was his last one. The second is about the "main thesis" of his newest book. The publisher's description is:

"Drawing on some of the most powerful theories and trends in physics, evolutionary biology, science, philosophy, and psychology, D Souza shows why the atheist critique of immortality is irrational and draws the striking conclusion that it is reasonable to believe in life after death. He concludes by showing how life after death can give depth and significance to this life, a path to happiness, and reason for hope."

The main thesis of the book is that it is reasonable to believe in life after death. Using ideas from string theory to defend that main thesis is only a small part of the book's contents.

24. **Peter Woit**
December 22, 2009

anon,

My apologies about any inaccuracies. I haven't read the book, but I did read the full interview with D'Souza that I linked to and quoted from. He goes on there in a way that makes clear that he has no understanding at all of what he is talking about. That he has written a book claiming that the "cultural left" is responsible for 9/11 just seems to me additional evidence that he's an idiot. Maybe he's only an idiot on some days, a serious intellect on others. Those who believe this are welcome to investigate the rest of his writings.

25. **anon**
December 22, 2009

I've read "The Enemy At Home", and it isn't his best book, but it's not a complete joke either. It had some parts I found convincing, others not so much. The title they chose for that book is not a very good one, and not very representative of the contents of most of the book. Regnery often has a lot of input about the books they publish and how they are marketed, and I suspect that it might have been their choice of title, perhaps to help sell the book to consumers of an "anti left" political persuasion. I certainly have many disagreements with D'Souza, but I don't regret reading his books. I doubt you'll read his book, but none of his books that I've read are simple or bad enough to warrant a quick ad-hominem dismissal.

26. **David H. Miller**
December 23, 2009

Peter wrote:
>Maybe he's [d'Souza] only an idiot on some days, a serious intellect on others.

Peter, I've followed his career for a long time: let's just say he is no dumber than Limbaugh.

Seriously, I've seen him give a good speech (on C-SPAN), good timing, some funny lines. And, being an ignoramus on science is probably par for the course for political pundits (cf. Gore's comment on the earth's core temperature).

The country is full of guys with emphatic political or cultural opinions who have broad public platforms (Tom Friedman, Deepak Chopra) but who are not exactly experts (or even literate) in any real field of scholarship. To give a recent example, CNN a couple weeks ago had Bill Nye "the Science Guy" on as an expert on global warming (for whatever it is worth, Nye believes in global warming, although he could not say anything coherent about the actual science).

D'Souza may be no worse than the others.

Dave Miler in Sacramento

27. **David H. Miller**
December 23, 2009

anon wrote:

Please contact Dinesh's publisher and offer that comment as a blurb for his next book.

Dave

28. **Eric Baird**
December 25, 2009

If a "broad" interpretation of Multiverse theory allowed Heaven and Hell to be out there somewhere, then presumably it'd also have to allow Valhalla, Zeus's Great Hall atop Mount Olympus, the Elysian Fields, Samsara, Tian, and every other religion's special places.

So the mainstream Christian idea that there's only one true God, and only one way to get salvation, would be kinda broken.

29. **Tim vB**
December 26, 2009

When I read the interview Mr. D'Souza lost me with the very first point he tried to make: The concept of hell contradicts Freud hypothesis that religion may be explained by wishful thinking. Nobody likes the concept of hell? If there is a life after death, what happens with all the bad guys that lived rich and happy lives on earth? Surely you want them to be punished?! So of course you need a concept like hell if you want to sell your idea of a live after death!
Mr. D'Souza may have oversimplified his ideas, after all it is an interview – but he failed to convince me that he has anything interesting to say about religion or

Life in the Multiverse

December 17, 2009
Categories: Multiverse Mania

The latest Scientific American features a cover story on Life in the Multiverse: Could the strange physics of other worlds breed life? The magazine earlier this year fired a third of its staff and replaced its editor (the new editor has a column this month about the Multiverse and Star Trek).

I don't think one can blame the new editor for this though. Over the last few years, Scientific American has made multiverse pseudo-science stories a staple of its coverage of science. See for instance Parallel Universes, The String Theory Landscape, The Great Cosmic Roller-Coaster Ride and Does Time Run Backwards in Other Universes?

Update: Alejandro Jenkins and Gilad Perez, the authors of the Scientific American piece, pointed out to me something that I really should have made clear in this posting, that their arguments about the possible implications of a multiverse are of a different nature than those in previous Sci Am articles. They are arguing not for or against a multiverse, but against some popular anthropic arguments that try and explain the values of fundamental constants as being necessary for life. Anyway, my apologies to them for not making this clear, and here's something they sent me explaining in more detail their point of view:

> The title of our article in the current issue of Scientific American –as well the first bullet for the "Key Concepts" — might give the impression that our work argues for the reality of the multiverse, but this isn't really the case.
>
> Our research suggests skepticism about the usefulness of anthropic selection arguments when applied to particle physics (see the references below). The anthropic argument seems reasonably convincing when applied exclusively to the cosmological constant, as Weinberg did in 1987. But our own work shows that the parameters of the strong and weak interactions could be significantly different from what they are, without there being any obvious obstruction to the evolution of organic life. This means that the anthropic principle might not be enough to explain the microscopic laws of particle physics. In this sense, then, our story counter-balances the claims made previously by other experts about many of the parameters of the Standard Model being obviously "fine-tuned for life" (and therefore admitting an anthropic explanation).
>
> Our work is simply based on varying the parameters of the Standard Model and trying to understand how things would change from what we see in our world. It is true, though, that this intellectual exercise is motivated in part by the expectation from inflationary models (and from certain speculative proposals for the physics at the Planck scale) that the fundamental physics might produce many distinct universes besides our own.

Comments

1. **Tim vB**
   December 17, 2009

   The logic about the "anthropic principle" applied to blockbusters is sound. Harrison Ford as Dr.Kimble in the Fugitive didn't have luck, his story is the logical consequence of the fact that all the parallel Kimbles didn't make it to the theaters (would you watch a movie called "catched after 5 minutes"? See?).

2. **Pawl**
   December 17, 2009

   I notice the Parallel Universes link (referring to an article by Max Tegmark) contains the header

   > Not just a staple of science fiction, other universes are a direct implication of cosmological observations.

   I don't know if Tegmark himself makes this claim. (You have to pay to read the article, and, given that header, I'm not inclined to do so.)

3. **srp**
   December 18, 2009

   I read the Tegmark article when it was new, I think. It actually performed the service of distinguishing among the many versions of multiple-universe thinking at different levels of theory. One of them, if I recall, was pretty funny–a simple combinatorial argument about the number of atoms and possible arrangements versus the size of the observable universe that essentially applied the pigeonhole principle to show that everything should be duplicated somewhere in this universe.

4. **Belizean**
   December 22, 2009

   I think we need to distinguish between

   1) the multiverse postulated to resolve a conceptual problem in elementary quantum mechanics (for which there is abundant experimental confirmation), and

   2) the multiverse proffered to excuse the dearth of explanatory power in string theory (for which there is no experimental confirmation).

   You really need the original multiverse to explain how a quantum computer can perform a quantity of parallel computations that exceed the number of particles that comprise it (or even exist in our universe), or to make any sense out of quantum cosmology.

2010 LHC Schedule

December 17, 2009
Categories: Experimental HEP News

The LHC shut down yesterday for an end-of-year break after a very successful initial period of beam commissioning at beam energies of 450 GeV and 1.18 TeV. Tomorrow at CERN there will be public reports about the state of the LHC and the initial results from the experiments. I gather that by now all sorts of particles have been rediscovered, including kaons and lambdas, here are some details from Jim Pivarski.

There's now a tentative schedule 2010 out. Hardware commissioning of the new quench protection system, allowing beam energies up to 3.5 TeV, will begin on January 4, and be completed by February 15. A new checkout to prepare for beam commissioning will take place Feb. 17-19, and next injection of a beam into the LHC should be around February 20. Commissioning of 3.5 TeV beams and some pilot physics runs at that energy should take a month or so, with the first regular physics runs at 3.5 TeV/beam beginning around March 25. A tentative month-long shutdown to reconfigure the machine to run at higher energy (up to 5 TeV/beam) is scheduled for May 3-June 2.

From January 25-29 machine experts will meet in Chamonix to discuss whether to try and run at 5 TeV/beam in 2010, and how to implement this if it seems feasible. Plans will also be made for the late 2010-2011 shutdown. This will require deciding what to do about all the problematic splices in the machine in order to allow operation at the design energy of 7 TeV/beam, as well as understanding how much retraining of the dipoles will be needed in order to get to that energy. Current plans call for a "long shutdown" in 2013-4 to begin some upgrades of the LHC, and this is another topic that will be discussed.

While news coverage of the LHC in science magazines like Science News has been a mixed bag, often focussing on extra-dimensional speculation irrelevant to the actual science that will get done there, there's a quite good new article here, in a surprising location: Vanity Fair. The LHC has become a real celebrity…

Comments

1. **Ralph**
   December 17, 2009

   Which is more important – Increasing energy or increasing luminosity?

   There seems (a) there is a pretty good likely-hood of seeing interesting physicals already at 3.5TeV/beam, (b) seeming new physics at any energy is likely to require significant luminosity.

   So wouldn't it be sensible to push luminosity rather than energy for now?

   [Especially if one were parochial, and say, wanted to ensure beating tevatron to seeing the Higgs]

2. **Chris W.**
   December 18, 2009

   The author of the *Vanity Fair* piece, Kurt Anderson, is a novelist and journalist and host of the public radio program *Studio 360*, of which I'm quite fond. It nominally focuses on the arts, including architecture, but is very wide ranging, and almost always interesting.

   Somewhat off-topic: See this interview with Vanessa Gould, the director of the film *Between the Folds*, which was recently shown on PBS.

3. **Chris W.**
   December 18, 2009

   PS: From Vanessa Gould's statement about her film:

   > As a documentary project, this film has been less about telling a story and rather about finding an idea—layers of ideas. Everyone involved in this project has been incredibly energized by the challenge of making a documentary film about ideas. All along, we knew its central themes would speak to different people in different ways, as any film about ideas should. Therefore, it was of great importance that its themes were presented subtly and flexibly, so that every viewer could experience the film in ways that were both universally resonant and personally meaningful.

4. **Bill K**
   December 18, 2009

   "Which is more important – Increasing energy or increasing luminosity?"

   Depends on what you're looking for. In the case of a low mass Higgs (115 – 140 GeV) go for luminosity. You're actually better off running at reduced beam energy for this since the QCD background increases more rapidly with increasing energy than the signal. To search for more exotic things you obviously need enough beam energy to produce them in the first place.

5. **Steven Colyer**
   December 29, 2009

   Frank Wilczek gave an interview to the New York Times here. In in, he mentions experiments will be run at the LHC regarding Quantum Chromodynamics, for which of course he won the 2004 Nobel Prize in Physics.

   Also interesting and of note is a novel he is working on his spare time regarding four people who discover something significant, but Alfred Nobel's will (I think it was Nobel's will, if not it's just policy) allows for only three winners for any one award.

   Although the article doesn't mention it, could that reflect on Frank's award? Although he won the 2004 NPP along with David Gross and David Politzer, I'm curious if any of you know how close t'Hooft and Sid Coleman were considered for the same award. Thanks in advance.

   And darn it if that article doesn't make me want to explore the latest work in Axions. How's that going?

6. **NP Nonwinner**
   January 3, 2010

   Alfred Nobel's will was vague on details. Click on the link "excerpt of the will" (with English translation) http://nobelprize.org/alfred_nobel/will/index.html

See also Wikipedia, which quotes the paragraph, in English
http://en.wikipedia.org/wiki/Nobel_Prize

The full text of the will (English translation) is here
http://nobelprize.org/alfred_nobel/will/will-full.html

The details about the prizes were vague, so it took 5 years to sort out the legalities.
Nobel's will said nothing about "three people" and indeed it said "in the previous year" and it is says "benefit to mankind" (like confinement and asymptotic freedom in QCD?).
So …
a) the "previous year" business was set aside from the start
b) "benefit to mankind" was interpreted loosely. Mostly the Nobel Prizes are awarded for academic research. Thomas Edison contributed probably more benefit to mankind than any scientist, but he never won a Nobel Prize. (But Marconi won the NP.)

t'Hooft – it was known by all that he also derived the negative slope of the beta function in QCD (leading to confinement) but
it is also recognized that
– he did not make the connection to the (known) expt results on deep deep inelastic scattering (he did not pursue the consequences of the minus sign much)
– he already had a Nobel Prize (in 1999)

Sid Coleman? — do not know.

Has Dark Matter Finally Been Detected?

December 17, 2009
Categories: Experimental HEP News

No.

The CDMS experiment today reported the observation of two events, with an expected background of .8 events (I gather this is a 1.5 sigma result, but there is no arXiv preprint yet). Based on this, the Guardian [reports](#) that "Hunt may well be over for mysterious and invisible substance that accounts for three-quarters of mass of universe" and Science News has [Experiment Detects Particles of Dark Matter, Maybe](#). Science News quotes Craig Hogan as saying the results are "potentially very exciting", and the Guardian has "If they have a real signal, it's a seriously big deal." Unfortunately they don't have a real signal, so it's not a seriously big deal.

I just noticed that the [New York Times](#) is also covering this, but more soberly, describing the results as "faint hints". They do quote Gordy Kane, who describes the mood at the KITP in Santa Barbara as "a high level of serious hysteria", which he then embodies by claiming "It seems likely it is dark matter detection, but no proof."

For those unfamiliar with the terminology experimentalists use to characterize signals of various statistical significance, here's a summary:

5 sigma: discovery

3 sigma: observation

1.5 sigma: noise

Update: Scientific American gets it right [here](#).

Update: The paper is [here](#). It includes the information that "Reducing the revised expected surface-event background to 0.4 events would remove both candidates." There really literally is no signal here.

Update: Ethan Siegel's [blog posting](#) about this explains the appropriate scientific response to the news that two events were observed when .8 were expected:

> Well, La-dee Frickin' Dah!

Adrian Cho at Science has an excellent piece about the story: [Wimpy Evidence for Dark Matter Particles](#). He quotes two experimentalists who explain the significance of this (Richard Gaitskell: "Nobody should be attempting to say that this is evidence" for dark matter, and Edward Thorndike: "Absolutely not" an observation of dark matter). There's also this comment from theorist Joseph Lykken:

> Even so, Joseph Lykken, a theorist at Fermilab, says he's relieved that CDMS has finally seen something. WIMPs are predicted to exist by theories involving a principle called supersymmetry, which posits a heavy partner for every particle currently known. Had CDMS continued to see nothing, the results would have undermined those theories. So seeing something is better than seeing nothing, Lykken says.

Lykken seems to be ignoring the fact that the new CDMS results, two events and all, rule out yet more of the supersymmetry parameter space. For an explanation of this, written when the last CDMS results came out, already causing problems for supersymmetry, see Tommaso Dorigo's posting [SUSY more unlikely by the new CDMS II results](#).

Comments

1. **Van**
   December 17, 2009

   Actually, I think the correct answer to this question is 'maybe'. The events could be from dark matter, it's just not possible to say this definitively. However, considering the null results up to this point, these results are tantalizing and of interest. We'll have to wait a short while for better statistics, but it's very encouraging to be this close.

2. **Phil**
   December 17, 2009

   umm, " … three quarters of mass of universe … " ?
   That IS a sigma 5 observation the Guardian is making for the dark matter proportion in the universe isn't it ?

   p.s. – Sorry about overstepping bounds in a previous post, Dr. Woit.

   Thanks

3. **Amitabha**
   December 18, 2009

   I guess observation was ruled out as soon as Nature denied they would publish anything by CDMS today.

4. **Martin**
   December 18, 2009

   Oh well, the excitement is over. I had actually hoped for a bit more.
   Peter, do you know what caused these impatient scientists to publish a paper with such a low significance value?

5. **David B.**
   December 18, 2009

   Dear Martin:

   In experimental physics, you publish what you have. If a search comes out empty, you set new limits on detection, if you have some partial information, it could be noise or real signal. Either way, it must be reported. The grant agencies process can not let people wait for discovery before an announcement.

   And by the way, they were not impatient. The data is from a run starting on 2007, and they waited two years to see the events in the corresponding window where detection was possible. They did a blind analysis: they set up the complete analysis of systematics etc on the control region before opening the data in the discovery region. As far as I can tell they did a great job and presented it the right way.

6. **Peter Woit**
   December 18, 2009

   Martin,

   David B. is right, this is not a case either of impatient scientists, or of a paper that shouldn't have been published. Null results and somewhat better bounds on dark matter are very much worthwhile science.

   The only odd thing going on here is anyone portraying this as something other than a null result.

7. **SpearMarktheSecond**
   December 18, 2009

   Not quite a true null result… a true null result would be another zero, like (more or less) their previous 3 results.

   There are two good events in their signal box, which was defined blindly on calibration data. About a 23% chance the background fluctuated up. That summarizes the situation better than more qualitative things like `discovery' `observation' etc which is a terminology that has only started being used in the past few years, and are by no means universally accepted in particle physics.

   Obviously rumors leaked out that there were good events in the signal region this time. Given the importance of this experiment and result, it is easy to understand the excitement. Frankly, this excitement was more justified than all the excitement during the past 30 years about SUSY and string theory; at least this was a real experiment, carefully done.

   The paper is scientifically perfectly correct. Don't blame the authors for the excitement… the excitement arose naturally and actually is a sign that people still want real data and not mere mathematical virtuosity.

8. **Peter Woit**
   December 18, 2009

   SpearMarkII,

   Actually this is a null result. The two events go away if you tighten the cuts to the point where you don't expect any events (i.e. from .8 to .4 expected events).

   I'm all in favor of excitement over experimental results, be they negative or positive, and happy to have helped spread the unfounded rumors that led to some of this excitement. But when an experiment finds no evidence for something, having people going on about how it might really be something is not a good idea. Same as when a theoretical idea doesn't work out and having it promoted as still a possibility isn't good either…

9. **Coin**
   December 18, 2009

   So if more events are seen at the same point, then this will constitute evidence in favor of a dark matter particle?

   In the hypothetical situation where the results are not statistical noise, will having seen this negligible number of events now– and thus "knowing where to look"– aid CDMS or LHC researchers in any way by allowing them to conduct their experiment in a way that will ensure further signals at that point are not overlooked? (Alternately, is there risk that there will be an effect where since CDMS or LHC researchers "know to look there", they will be subconsciously more likely to commit experimental error that would reinforce the idea there's a dark matter particle there?)

   Even though the balance of the evidence is against the detection being real, is there value in theorists checking now to see which models are compatible with a dark matter particle at that mass, in case more events are seen?

10. **Gphillip**
    December 18, 2009

    I am excited and I can't help it. I'm excited people are interested in real physics. I'm excited we are debating real experimental results instead of multiverses and dreamworlds. I read three papers on multiverses this week and all three proposed different mechanisms and not any of them had any way to test their conjectures. Hats off to the CDMS team for conducting real science and reporting their results honestly.

11. **Peter Woit**
    December 18, 2009

    Coin,

    There's not much point in running the same apparatus much longer, you'd have to do this for quite a few years to get significantly better statistics than they already have. Better to put the time into building a more sensitive detector, and that's what they are doing ("SuperCDMS").

    I don't think the observation of these two background events helps one know what a real dark matter event would look like. All it does is tell you more about what the difficult to handle background looks like. Theorists have studied intensively the question of which models are compatible with the null results of this experiment and others. For more, see the old Tommaso Dorigo posting I linked to.

12. **SpearMarktheSecond**
    December 18, 2009

    Peter, hard to say. 2 events when 0.4 is the expected background is 2.3 sigma or so (single sided). Doesn't quite qualify as null. This experiment is in the uncomfortable in-between region, and folks want to editorialize one way or another. Rick Gaitskell is on a competing experiment (LUX), and Ed Thorndike at a LUX institution (Rochester). Lykken is at a CDMS institution. They all fall into line. You, Peter, are averse to excitement in the string theory community.

13. **Peter Woit**
    December 19, 2009

    SpearMarkII,

You have the numbers wrong, look at page 4 of the paper. The two events correspond to cuts with expected background of .8 +-.1 +- .2. They go away and there are zero events if the cuts are tightened and the expected background is reduced to .4

14. **Physicsphile**
December 19, 2009

SpearMarkTheSecond,
The CDMS paper says
"the probability of observing two or more background events is
23%"
In this case the distribution is not Gaussian so it doesn't strictly make sense to talk about sigma. But it is interesting to compare to the canonical Gaussian experiment of an assumed mean and standard deviation, sigma.
Then one says, OK if this was the true distribution and we took a sample, what would be the probability of drawing a sample with a value a greater distance from the mean than the observed one. If the probability is small, this leads you to start doubting the model. In this gaussian case, if you have drawn a sample 1.2 sigma away from the mean then there would be about a 23% probability of drawing a sample a further distance from the mean. So as a useful shorthand you can call a 23% chance of your data coming from background events as 1.2 sigma result. You may think its better to just stick to probabilities and that is fine but when you start talking about 3 sigma you are already talking about a probability of about 0.0026 which is starting to get a bit hard to visualize and once you start getting down to such small values you probably have a lot of data which means, by the central limit theorem, your distribution is probably pretty close to Gaussian anyway.

So you may say "well 23% thats less than 50% so it is a hint". But bear in mind there are lots of experiments looking for any one thing, so if you have 20 experiments, one of them is going to get a 2 sigma (5%) result on average. Also, it is generally not possible to eliminate systematics to beyond about a sigma so a two sigma result could easily be a one sigma result. So I think it really is worth having some reasonably strict criteria to when you are going to start taking an experimental detection seriously. I think a lot of theorists are too eager for new results though and that's why you get some fairly unwise comments in cases like this.

15. **SpearMarktheSecond**
December 19, 2009

Peter, I was responding to your statement that at 0.4 expected backround, the two events are cut. They are just barely cut, so if the cut is at 0.4001 or so, two events remain. Had the cut been placed there, this could have been a >2 sigma result.

The cut variations are all unfair, however, Peter, mine just above and yours. Your argument that tightening the cuts cut the events and therefore it is a null result is as bogus as my response that had the cuts been tightened to a point just before the two were cut it would have been >2 sigma.

My original point is what I stick too: it is not a null result (because 2 events in the signal region were seen) but not a significant result because 23% chance of background fluctuating. All the rhetoric of words is BS here. From my perspective, this one experiment is more valuable than all the theory of the last 20 years, however.

Physicsphilie, of course, but everyone translates from confidence levels to sigma because that is established shorthand, whether gaussians apply or not. And I think the real reason the field has come to demand 5 sigma etc is that we don't really trust our confidence interval calculations. In reality 3 sigma is just fine if we trusted the underlying understanding of the statistics. That we demand 5 sigma is a technique like in the very old days `multiplying by pi' to get a more conservative limit.

16. **Peter Woit**
December 19, 2009

SpearMarkII,

Where in the paper does it say that the two events remain at an expected background of .4001? You seem to just be making up numbers.

One other number that is in the paper is what happens if you loosen the cuts: no new event appear until an expected background of 1.7.

These numbers all correspond to exactly the sort of thing you expect to see if there is no real signal.

17. **Michael**
December 19, 2009

A statistical significance of 23% is very little, to be sure, and one could not call this "evidence" for a signal. Even if one supposes that the experimenters were conservative in they way they interpret their results (ie, with systematics, background estimates, etc.), this result is far from what one could designate to be a signal.

Are one or two of those two events actual dark matter scattering events? There is no way to tell at present. The only way to make progress is to take more data! Happily for all of us, the Xenon experiment will have relevant data rather soon, so we don't have to wait until SuperCDMS is ready and able to record new data.

So – if some of us think this is a null result, while others want to see a signal – what are the *predictions* for Xenon? 😉

18. **Peter Woit**
December 19, 2009

Michael,

Good point, someone should start circulating rumors about Xenon100, which may be reporting results in "early 2010", and is supposed to be an order of magnitude more sensitive than CDMS.

I don't know if they'll see anything, but, if they're 10 times more sensitive than CDMS, my prediction is that they won't see the 20 events you'd expect if the two CDMS events are real…

19. **teaser**
December 19, 2009

From the Xenon100 experiment page:

"A WIMP search in the current XENON100 will be first performed in 50 kg fiducial target with 40 live-days of exposure, to reach a WIMP-nucleon spin-independent cross section at 6 x 10-45 cm2 for 100 GeV/c2 WIMPs"

Is the expectation of a dark-matter candidate mass at 100 GeV/c2 based on cosmological estimates of "missing mass"? Also, is there a theoretical expectation for the cross section and is it possible that it's lower than what we think? If so, is there any way to know if we will ever detect a WIMP?

20. **Anon**
December 19, 2009

Unrelated to the post, but I think you'd find this comic funny:

http://xkcd.com/171/

21. **teaser**
December 19, 2009

I just read the CDMSII abstract and answered one of the questions I posted previously on cross-section:

The upper limit (based on current and previous data) for cross-section is 3.8 x 10 ^-44 cm2 for a WIMP mass of 70 GeV/c2. Is there any chance that the dark matter candidate has a mass greater than 100 GeV/c2 or is the lifetime to short to interact with other particles?

22. **Rien**
December 20, 2009

teaser: the mass can be both lower or higher, and the cross section can vary by orders of magnitude depending on what model for dark matter you're considering. Look at Fig 4 in the new CDMS paper. The colored area represents different parameters in the MSSM, so even within the MSSM the WIMP can have very different properties depending on in what part of parameter space you are.

23. **SpearMarktheSecond**
December 20, 2009

That the events are cut very suddenly at an expected background of 0.4 is in Lauren Hsu's talk at FNAL, see http://cdms.berkeley.edu/hsu_091217_FNAL.pdf , page 41. Still, the point is that the cut they used was determined blind and represents the fair value. Peter, your observations about loosening or tightening are hindsight and statistically biased.

Forgive me if I question your expertise, Peter, concerning what to expect about the behavior of a real signal. I doubt you've ever had to stand up and announce a new experimental result before a skeptical audience. Certainly your assertion that I make up numbers belies your noobility.

Michael… follow the impurities in Xenon100's LXe… doubt they're gonna get the sensitivity they advertise.

And if all the money spent on string theorists salaries and grants over the past 20 years had been spent instead on initiatives like CDMS, Xenon, LUX, Coupp, etc, science would have advanced one heck of a lot further in this area…

24. **Peter Woit**
December 20, 2009

SpearMarkII,

I have no idea who you are, although am quite willing to believe your expertise in this area is much greater than mine.

On the other hand, I think I have more than enough expertise to understand the numbers put out by this experiment. I don't question the accuracy of the numbers or the huge effort and expertise they represent. It's quite clear though what it means when an experiment looks for a signal that will revolutionize physics, expects one background event, instead sees two, and the two events go away when the cuts are modestly tightened (I don't see how the graph you point to has both events going away exactly at .4, but, whatever….).

25. **point**
December 20, 2009

They had a few little detectors? Why didn't they just have bigger detectors, and more of them?

26. **Peter Woit**
December 20, 2009

point,

money.

27. **jpd**
December 20, 2009

reminds me of a fellow grad student
TAing a lab class. one of his student
did an experiment with two data points
and wrote something like
'this proves the linear relationship'

28. **SpearMarktheSecond**
December 21, 2009

One event is cut at an expected background of about 0.35 and the second at an expected background of about 0.18, according to Lauren Hsu's plot. I suppose the neutron background should be added in, which probably raise those to about 0.43 and 0.26. Had CDMS chosen a tighter cut prior to unblinding, they easily could have ended up with a >2 sigma result, but not a >3 sigma result. Or, if they had chosen an expected background of 0.1, they'd have had a null result. They chose what they chose based on an optimization of their sensitivity that was done with no knowledge of their actual signal events… shown in some of the other CDMS talks this week. Very fair and very correct.

Then the unblinding of this CDMS exposure returned a result between null and significant. We all used to discuss, in the pre-blinding days, how results like this simply wouldn't get published… there was a strong publishing bias favoring true null results or truly significant results. Luckily blinding has helped allow the community to accept results in this in-between region.

Sure some people got too excited. Now other people are getting too cynical. I think the right way is to say, well, there is a 23% or so chance the background fluctuated, and so the CDMS results are interesting but not conclusive and not null either.

29. **chris**
December 21, 2009

Dear Peter,

amongst all the 'hype bashing' you do in this blog, i find the bashing of this particulat CDMS result as the most necessary piece. really.

it might seem as legit advertisind of the CDMS people to blow their result slightly out of proportion. well, this is how we (the trained scientists) react to it. 1.5 sigma is nothing. you don't have to say much more.

but the general public: oh my! you know, they trust us (scientists). and if these people go around telling their story about how they found 'dark matter' but there is a 25% chance that is was not dark matter, then guess how an average intelligent person reacts to that: oh, 75% chance that it was DM. and you know what: they are right. 1.5 sigma taken literally mean there is a 3:1 chance that this is the discovery of the century. i would get freakin' excited by that, too if i didn't know better.

if you think i am nitpicking or so, i am not. really. i spent a good part of the weekend trying to explain to laypeople why they should not get excited about a 75% chance of DM detection. and yo know what: almost nobody understood. and you know what's even worse: the people supporting me in this discussion were the 'einstien was wrong' nutcases and the 'all research is bad' types. the laypeople seriously interested in physics didn't follow me at all. and why? because they rightly invoked that these CDMS people know much better than i what they were doing and if they claim 75% chance, then this is so.

i am so depressed. seriously. i mean, what have we come to? where is the rigour of past days, where you would have to fight a steep uphill battle against an extremely conservative established opinion that you could only win with the correct theory as your companion.

i have somewhat accepted that nowadays you can claim multiverses, backward causation and all that experimentally unsupported nonsense if you include the small cautionary note that it is speculative. but it seems that this constant flow of the 'excitement' drug to the public has spoiled their perception so much that even hard-fact data based experimentalists can't resist the urge of pumping up their non-results instead of humbly reporting that they set better limits on DM. don't they see that in the long run this undermines the credibility of science? aren't they afraid about the long term effects of their claims, once DM limits have moved by a factor 10 and shown their results to be a fluctuation at the 5-sigma level? what do they say to joe the plumber then when he asks them about the 75% certainty they claimed?

i really hoped that experimentalists by their very nature would be cautious against hypes. i am really depressed about this.

30. **point**
December 21, 2009

point says: They had a few little detectors? Why didn't they just have bigger detectors, and more of them?

Woit says: money.

point: Hmmm, so I wonder what their approach would be to try to attract more money.

31. **Peter Woit**
December 21, 2009

SpearMarkII,

Your interpretation of that plot from the talk is in direct contradiction with the unambiguous statement in the paper on page 4 which I've quoted here earlier and pointed out to you:

"Reducing the revised expected surface-event background to 0.4 events would remove both candidates while reducing the WIMP exposure by 28%."

32. **no point**
December 21, 2009

Whatever detector one builds, it will always be `little' by the standards of the next generation.
I imagine that CDMS-II was not little when it was designed.
As I understand CDMS-I was at Stanford ('very little'?)
One demonstrates that the design and experimental concept are fundamentally sound (fundamentally WIMPY?)
and proposes a next-generation experiment.

33. **Physicsphile**
December 21, 2009

Chris, as far as I am aware the CDMS have not been hyping their result, that's been done by others not related to the experiment.

SpearMarktheSecond, usually in statistics you have the null hypothesis and the alternative hypothesis. You assume the null hypothesis and if your data are sufficiently badly fit you can interpret this as evidence for the alternative hypothesis. So in the CDMS case the null hypothesis is that there was no detectable dark matter (ie either dark matter does not have the properties to be detected by this experiment or there simply was no dark matter passing through this experiment) and the alternative hypothesis was that there was detectable dark matter. Assuming the null hypotheses one gets a 1.2 sigma result. Such a fit to the null hypothesis is not considered bad, the usual convention being that a 5 sigma or greater result is needed to refute the null hypothesis. Perhaps if it was 3 sigma I think you would be justified to refer to this as "CDMS results are interesting but not conclusive". I think it is more accurate to say the CDMS results are consistent with the null hypothesis that dark matter does not have the properties to be detected by this experiment.

34. **SpearMarktheSecond**
December 21, 2009

No Peter, it is an issue of significant figures (0.4 was quoted, not 0.40 or 0.400, meaning 0.3 to 0.5), consistent with not giving ultra-precise information so as to give the illusion of false precision and tuning of the cuts.

Physicsphile, sure, you're right, CDMS could not reject their null hypothesis. We can agree to disagree about whether 2 events in the signal box is interesting. Perhaps after Xenon, LUX, and Coupp have reported we'll know (assuming they can solve all their purity and discrimination issues)… all sorts of early observations are kept track of for years in the lore of experimental particle physics.

35. **dan**

December 21, 2009

Is the present non-detection of CDM at various detectors a problem for DM models, based on expected flux, probability, distribution, sensitivity?

36. **graviton383**
December 23, 2009

Dan, the answer is 'No'. Even in the somewhat limited supersymmetric DM model with neutralino LSPs the new limit from CDMS hardly makes a dent in the allowed parameter space. It only really starts to do so if the limit get about 1000x stronger..but that will be years from now. In the meantime the LHC will have a lot to say about most models with DM partcle candidates & is more likely to compress their parameter spaces if nothing is seen.

37. **dan**
December 23, 2009

thanks for replying. It sounds like LHC timetable won't be collecting statistically meaningful data for another 6-10 years out.

Until that time, isn't there time to build several thousands of these detectors?

Would increasing the size of the detectors, or increasing the number of detectors around the world, improve sensitivity? Would say having a null result from a couple thousand of these detectors all around the world, shielded from cosmic rays, neutrons, ground radioactivity, constrain it?

38. **Peter Woit**
December 23, 2009

dan,

I think the LHC time-table is shorter than this, with them collecting a significant amount of data at or near their design energy in 2012.

The cost of reproducing these detectors by the thousands, as well as installing and operating them around the world would be prohibitive. New, better detectors are being planned and built now, but the way they achieve higher sensitivity is by making the detector larger, not building a lot of smaller ones. Given the lead time necessary to design and build these things, the competition for the LHC is going to be those that are already being built and close to or already in operation.

39. **dan**
December 23, 2009

PW, thanks for replying. I was also thinking in terms of luminosity and collecting enough collision events to be statistically meaningful, say 3 bar. LHC by 2012 will have collection enough data by 2012 to discover DM and/or Higgs?

I understand that building larger detectors improves sensitivities, and I understand it is expensive and time consuming. What I had in mind is that other countries would pay for it, i.e 10+ built in Japan, Korea, China, India, Germany Britian, Italy, France, Russia, Mexico, Australia, would be paid by those respective countries.

Is there a reason that specifically the DM candidate neutralino has not been found in Tevatron? Is it that Tev lacks energy or luminosity?

40. **Peter Woit**
December 23, 2009

dan,

I think those countries aren't interested in spending more on this. Britain is planning on cutting spending on this kind of research, not increasing it.

The luminosity and energy you need to discover the neutralino depends on your model (supersymmetric theories have lots of extra undetermined parameters, and for different parameters you get different experimntal signatures). From what I can tell, immediately after the CDMS result was released, phenomenologists started writing papers calculating what the experimental signature would be for their favorite models, putting out almost half a dozen papers/day on the arXiv this week. It's a complicated business, consult those papers for the latest news on this topic.

41. **Stephen**
December 24, 2009

Already 9 papers on the arxiv on the cdms results…

42. **pushmepullyou**
December 31, 2009

Hey Woit,
Get back to work!

I'm kidding, and I'm too ignorant to comment on the subject matter here, but I enjoy reading NEW.

Best Wishes and I hope you aren't troubled by illness or sadness.

Two Books by Bloggers

January 3, 2010
Categories: Book Reviews, Multiverse Mania

The holidays are coming to an end, so expect a return soon to the usual somewhat irregular posting frequency.

Over the past week or two, one thing that I did was get a chance to read new books by two of the most prominent physics bloggers around: Chad Orzel (who has been blogging since 2002, now at Uncertain Principles), and Sean Carroll (since 2004, now at Cosmic Variance).

Orzel's new book is entitled How to Teach Physics to Your Dog, and he has a website with all sorts of material about the book here. I guess it's generally agreed that a cute dog improves just about any sort of material. While Brian Greene in his *Elegant Universe* Nova special introduced general relativity by trying to discuss it with a dog, concluding that "No matter how hard you try, you can't teach physics to a dog", Orzel takes a very different tack, structuring his book around conversations with his dog about quantum mechanics. The dog ends up with a solid intuitive understanding of quantum physics and presumably the idea is that the reader should be able to do as well as the dog. The book is a quite good, non-technical, exposition of some of the paradoxical aspects of quantum mechanics, emphasizing the subtleties of the relationship between the quantum and classical views of reality. His expertise in experimental atomic physics gives him an excellent understanding of these issues, and he does a good job of conveying some of this to the reader.

Among the best features of the book are enlightening treatments of the quantum Zeno effect, quantum tunneling, entanglement and quantum teleportation, as well as careful treatment of some crucial subtleties of the subject. If you want to go beyond the usual explanation that the uncertainty principle is about how measurements must change the state of a system, and find out how one can use quantum mechanics to measure a state without changing it, this is a good place to start.

By the end, I observed myself ending up in a linear combination of two possible states describing my feelings about the dog thing: about equal amplitudes for charming and annoying. Even now that we're in a different decade, I haven't yet collapsed into one state or the other.

The other new blogger-book is Sean Carroll's From Eternity to Here, which has its own website here. I confess to being somewhat mystified by this book, and a bit surprised by its contents. Carroll is a very smart guy, with a serious dedication to making the wonderful science of his professional field (cosmology and particle physics) accessible to the general public. Given this, my expectation was that the book would be mainly devoted to telling the conventional scientific story of some part of our current understanding of these subjects, with perhaps a more positive take than mine on the possibility of exciting new discoveries in the near future. I also expected him to include some material on his highly idiosyncratic ideas about the arrow of time.

It turns out though that this rather long book is heavily oriented towards making the case for unconventional claims about physics, with essentially no discussion at all of what is happening on the experimental side of the subject. The LHC appears only in a footnote explaining that it won't destroy the earth, and there's virtually nothing about the hot topics of dark matter, gravitational waves, or the cosmic microwave background. In a final footnote, Carroll explains that he decided not to write about these experiments because

> it's very hard to tell ahead of time what we are going to learn from them, especially about a subject as deep and all-encompassing as the arrow of time.

Carroll's problem is that the questions that he has chosen to highlight in the book may be "deep and all-encompassing", but they're of a sort one might describe as "philosophical" rather than scientific. Much of the book is devoted to arguing that in order to understand the local (in time) question of why entropy increases, one must understand the global puzzles pointed out by Roger Penrose associated with gravitational entropy, the Big Bang and inflation. More succinctly, the explanation for why an omelet doesn't turn into an egg somehow involves understanding the Big Bang.   Even after reading the book, I remain unconvinced that the global problem has to be solved to explain the local problem, and unfortunately there's no scientific way to resolve my difference of opinion with the author. No conceivable experiment can provide evidence one way or another about which of us is correct.

After making the case that one needs to understand the low entropy of the early universe to understand everyday physics, Carroll goes on to propose his own theory, the "Ultimate Theory of Time" of the book's subtitle. It's a version of the usual "multiverse" argument: one explains some mysterious distinctive feature of the universe by positing that we live in a multiverse without this distinctive feature, which just occurs as a dynamical accident in our particular universe. The problem is that this particular explanation is not a conventional scientific one, since it is immune to experimental investigation, and, as far as I can tell, few physicists take it seriously. Carroll's one scientific paper on the subject, (written in 2004 with his graduate student Jennifer Chen) received a lot of publicity on the internet and in Scientific American, but doesn't seem to have yet been published, despite being listed on his CV as submitted to Phys. Rev. D.

The book seems likely to get a lot of public attention, but I'm not sure this is a good thing for the public understanding of science. It raises fundamental issues in physics, which naturally attracts people's interest, but then addresses them in a rather post-modern yet pre-scientific manner, avoiding contact with either mathematics or experiment. Probably the best way to think of *From Eternity to Here* is as an extended essay in the philosophy of science, and as such I'd be curious to hear what philosophers expert in the subject make of it.

Update: Scientific American has an interview with Carroll, in which he addresses objections like mine as follows:

> The following statement is very true: To understand the second law of thermodynamics, or how the arrow of time works in our everyday lives, we don't need to ever talk about cosmology. If you pick up a textbook on statistical mechanics, there will be no talk about cosmology at all. So it would be incorrect to say that we need to understand the big bang in order to use the second law of thermodynamics, to know how it works. The problem is, to understand why it exists at all requires a knowledge of cosmology and what happened at the big bang.
>
> Once you assume that the universe had a low entropy for whatever reason, everything else follows, and that's all we ever talk about in textbooks. But we're being a little bit more ambitious than that. We want to understand why it was that way—why was it that the entropy was lower yesterday than it is today?
>
> To understand why the entropy was lower yesterday really requires cosmology. And I think that if you sit down and think about it carefully there is absolutely no question that that is true, yet a lot of people don't quite accept it yet.

After having sat down to think about it carefully, I still don't quite accept it…

Comments

1. **wolfgang**
   January 3, 2010

   >> It raises fundamental issues in physics, which naturally attracts people's interest, but then addresses them in a rather post-modern yet pre-scientific manner

   I would think this is true of (almost) all popular books about physics (including your own)? They are not research papers but rather more or less interesting stories about science.

2. **Domenic Denicola**
   January 3, 2010

   Although I haven't been through Carroll's blog posts on arrow of time recently, I do recall them being pretty sensible and agreeing with the general consensus at the time that I read them. That is, it's general accepted that you need to explain why entropy was low at the beginning of the universe: the Second Law of Thermodynamics alone does not suffice, without the addition of a Past Hypothesis. There's a neat argument showing this that involves phase space that I'm sure you've seen?

   Maybe you could explain more what kind of statements you found unlikely? (Apart from the multiverse "ultimate theory," of course.)

3. **anon**
   January 3, 2010

   > but doesn't seem to have yet been published, despite being listed on his CV as submitted to Phys. Rev. D.

   See arXiv:gr-qc/0505037.

4. **Franca**
   January 3, 2010

   Peter,

   thermodynamics books say that entropy is a concept defined for physical systems. A system is a set of matter enclosed in a boundary. But is the universe really a physical system? Many say yes, but is this really so? I remember a friend saying that Weinberg's opinion is that the concept of entropy is not applicable to the universe. If that is true, all discussions on the topic are not serious. What is the the "official" view on this topic?

5. **Adam Helfer**
   January 3, 2010

   I haven't read Carroll's book, but I don't see that the arrow of time enters in explaining why omelettes don't turn into eggs. That would be going from a larger to a smaller region of phase space, which is improbable unless either the dynamics or the initial conditions are very special, no matter *which* way one moves in time. (Maybe there's another idea here I'm not appreciating, though.)

   The mystery of the arrow of time (in this context) is rather why there are eggs (very low-entropy objects) in our common experience. Basically, that implies that there must have been still lower entropy in the past. That does indeed lead back to questions about the early Universe. It also inevitably leads to global issues.

   In the standard hot big bang, of course, the material degrees of freedom are thermalized. But the degrees of freedom corresponding to gravitational radiation are almost entirely unexcited — in fact, it is precisely this which is required for the homogeneity and isotropy of the Universe. Thus while the matter is in a high-entropy state, potential gravitational radiation is in a very low entropy state, and this very low entropy is moreover what provides the entire Friedmann–Robinson–Walker background (on which the evolution of galaxies, stars, chickens and eggs is described).

   Notice that the global character of the conditions — the homogeneity and isotropy — is intimately bound up with the low-entropy character of the gravitational degrees of freedom. This is contrary to what happens in more familiar thermal situations, where a homogeneous system is typically a high-entropy state. The difference is due to the attractive nature of gravity.

   (I know this is a bit lengthy, but the question is an involved one.)

6. **Tom O'Bulls**
   January 3, 2010

   "More succinctly, the explanation for why an omelette doesn't turn into an egg somehow involves understanding the Big Bang."

   I haven't been able to get hold of the book yet, but I'd be amazed if it contains any such claim, because that would directly contradict SC's numerous explicit statements to the contrary in his blog postings. There he says that the usual probabilistic arguments explain why high entropy states [almost] never evolve into low entropy states. *But* if you accept this, then you are obliged to explain where low-entropy states observed in our universe came from. The answer, of course, is that they came from something about the big bang that we don't yet understand.

   As for whether physicists take SC's ideas seriously: you have to take into account the *extremely* mysterious fact that physicists are apt to get very emotional about this issue; and I'm not just talking about cranks like Lubos Motl. Many people get upset when told that something as basic as the second law of thermodynamics is not fully understood. Partly this is due to "cosmology envy" — some people working at the more boring end of physics resent the idea of those pointy-headed cosmologists muscling in on their territory.

   Anyway, it is certainly not the case that SC's ideas are rejected because they challenge some orthodoxy; there *is* no orthodoxy on this matter. Common sense tells us that the second law implies that the universe must have begun in an extremely low-entropy state, and that this has to be explained if we are to make any sense of early-universe cosmology. But most people just don't want to think about this.

7. **Peter Woit**
   January 3, 2010

   anon,

   The preprint you mention is a 5 page non-technical essay for the Gravity Research Foundation essay competition.

   Domenic (and others),

   I don't disagree that to understand cosmology you want to explain the low entropy at the Big Bang. I just continue to not see why this explanation, whatever it is, is necessary to explain the 2nd law of thermodynamics. I'm not the only one (the book's introduction contains another example), and the problem seems to me to be that questions like this inherently can't be adjudicated by any conceivable experiment. Arguing about them thus tends to be a rather pointless activity. We're really in the realm of philosophy of science here, not science.

   "Tom O'Bulls",

   From your IP address it seems likely you're one of the people on the very short list of physicists known to have some sympathy for Carroll's arguments about the multiverse. I really wish you and others would use your real names here, especially if you intend to make arguments about what your colleagues think of all this.

8. **Peter Woit**
January 3, 2010

For those asking for an explicit example of a statement from Carroll that I disagree with, a good one is his Facebook summary of the book's argument:

"You can turn an egg into an omelet, but not an omelet into an egg. This is good evidence that we live in a multiverse. Any questions?'

9. **Ricci's Pieces**
January 4, 2010

Hi Peter,

As a mathematician, I am extremely uncomfortable with some of the multiverse claims by Sean Carroll. I think his textbook is marvelous, it was the first textbook I used to learn General Relativity, but I find the multiverse concepts meta-physics at best and it is a bit disheartening to see, let's face it, one of the more popular physicists so die hard about it.

10. **Bee**
January 4, 2010

I find it interesting to lead a discussion in a book rather than scientific papers that are (for one or the other reason) inaccessible for most people. As long as it's clear to the reader which part is backed up by solid science and which is speculation. It's a much less constrained medium that offers more freedom. Didn't read either book though, so can't say much.

Does it really bother you that the paper didn't get published?

Btw: Happy New Year 🙂

11. **Lee Smolin**
January 4, 2010

I look forward to reading Sean's book, but I am confused by some of these accounts of the issue. Even if the entropy of the universe as a whole can be defined (which I am confused about) and increases over all, the important thing for eggs, chickens and cooks is that nevertheless there are large regions far from equilibrium today.

This is in turn due to the fact that there are stars with cosmological life times, which pour hot photons into cold space. The existence of stars is due to both some fine tuning of the parameters of the standard model and the fact that gravity is universally attractive and long ranged so that gravitationally bound systems have negative specific heat.

The fact that stars exist is likely not due to the extreme homogeneity of the early universe, were the initial density fluctuations quite a bit larger I suspect there still would have been stars, possibly a higher density of them, and sooner.

Nor is there a simple thermodynamic argument that applies to gravitationally bound systems or the gravitational degrees of freedom. The canonical ensemble cannot be applied to systems with negative specific heat such as gravitationally bound systems. It can also be shown, given only that matter has positive energy, that gravitational radiation cannot come to thermal equilibrium within any finite time, nor can it be contained by any material within a finite volume. So it is unclear that equilibrium thermodynamics is ever relevant for the gravitational degrees of freedom.

Thanks,

Lee

12. **Adam Helfer**
January 4, 2010

Peter,

I think there is an issue which is physics (whatever its implications for philosophy), that is, to explicate the Second Law and its relation to the arrow of time. I also think that while it is wise to be wary of discussions which cannot lead to experimental verification, what we're doing at this stage is rather trying to clarify our understanding of some of the theory. Hopefully a deeper understanding will suggest experiments.

Let me begin with two possible formulations of the Second Law:

1. Systems tend to move from smaller volumes of phase space to larger ones (or tend to spend more time in larger volumes than smaller ones);

2. Over time, entropy increases.

The point I want to make is that the first one admits a time-symmetric interpretation (indeed, the form in parentheses is explicitly time-symmetric), while the second does not. Thus the first is insensitive to the arrow of time, but not the second; they really reflect slightly different concepts. The second form captures something that the first form misses, precisely because it does implicate the arrow of time.

I would also say that the first statement is plausible and largely an intuitive statement about probabilities. (Of course, subtle questions about issues like coarse-graining are hidden in its implicit assumption that we have selected certain phase volumes.) So I would contend that the thing to be explained about the Second Law is the "something extra" which is added in passing from the first to the second version.

What has been added is brought out most forcefully by viewing the movie backwards: going backwards in time, we find entropy decreases. That is what is puzzling. So the puzzle of the Second Law is why the initial entropy was so low. And this is a cosmological issue.

I appreciate that it seems that there is a considerable leap between everyday thermodynamic phenomena and the early Universe, and I think this is perhaps why their linkage seems hard to accept. However, this is really because we are highly prejudiced about what we consider to be "everyday thermal phenomena." Had the Universe been a more "random," average (from the phase-space view) one, it would look nothing like ours. Stars and galaxies would probably not exist (or would be rare). The fact that we can build heat engines and refrigerators (and, more spectacularly, that chickens and eggs — the original points of discussion — exist) is really due to the low entropy we still have available to us to exploit, and this ultimately came from earlier — cosmological — times.

13. **H-I-G-G-S**

January 4, 2010

This is too funny. Peter "my credentials don't matter" Woit is drawing conclusions about a commenters views on physics based on their IP address.

HNY
PH

14. **Peter Woit**
January 4, 2010

Bee,

I don't know why the the paper hasn't been published, so it's unclear what the significance of that is. I am curious though what the reaction to it is from experts in the subject. The book does acknowledge that some of what is in it is not widely accepted by other physicists, but doesn't really explain why.

15. **Adam Helfer**
January 4, 2010

Lee,

I agree with most of your points. You'll notice that I have phrased things in terms of phase-space volumes and not (except for small systems, and a reference to the conventional treatment of the hot big bang) in terms of thermodynamic entropy and equilibrium. I acknowledge that this means dodging or postponing certain questions — but that's often what allows one to make progress.

16. **anon**
January 4, 2010

A rather trivial comment, just for the record. As someone else once pointed out in this blog, turning omelettes into eggs is almost as trivial as the inverse process. Just finely chop the omelettes and feed a hen with them, she will turn them back into eggs, increasing the overall entropy of the barn with heat and waste in the process…

17. **Peter Woit**
January 4, 2010

Adam,

I understand the argument, but it just doesn't seem to me to provide a significant coupling between the global cosmological problem and the local physics problem. According to that argument, whatever the solution to the global problem turns out to be, it's not going to affect in any way our understanding of the local physics, and no possible local experiment is going to help solve the global problem.

By the way, the contrast to Penrose is interesting. Penrose has been pointing out the big bang entropy problem for a long time, but, unlike Carroll, it leads him to speculative ideas that do directly affect local physics (modifications of quantum theory with potentially observable local consequences).

H-I-G-G-S,

I've been repeatedly struck by how much lower the level of discussion is on physics blogs than on mathematics blogs. One major difference is that serious mathematicians participate in blog comments using their own names, and I think this has a lot to do with the problem (and you're a good example of it….)

18. **Christine Dantas**
January 4, 2010

What is Carroll's definition of gravitational entropy? Under which constraints is it extremized?

If one goes back to the very basics of gravitational relaxation from the point of view of statistical mechanics, several issues arise, as mentioned by Smolin, which I fully agree. [A brief review (with relevant references) can be found, e.g., in section 4.2 of astro-ph/0604544.] The point is: those issues arise in a very well-studied subject.

[There are in fact open questions. For instance, if one goes back to the very basics, as my paper above points out, mesoscopic energy constraints may be operating during gravitational relaxation. This has been discussed previously by other authors, like e.g. Kandrup et al. If it turns out that this effect is confirmed in observations, then it is just an example of why one should be careful concerning gravitational entropy and so on.]

Given that there are still down-to-earth issues that still must be elucidated in this beautiful area of real physics, it is not clear to me the logic to adhere to speculations such multiverses in order to reach whatever conclusions about whatever.

19. **neo**
January 4, 2010

Somewhere, out there in the multiverse, someone or something is turning omelets into eggs, as we speak.

20. **Bee**
January 5, 2010

The second law of thermodynamics does not say the entropy (of an isolated system) increases, but the entropy does not decrease.

Peter: Is Sean's book well written? Like in: worth reading or will catch dust?

21. **Thomas R Love**
January 5, 2010

Peter wrote:

"I've been repeatedly struck by how much lower the level of discussion is on physics blogs than on mathematics blogs."

Some how almost everyone feels qualified to comment on current physics, but few feel qualified to discuss mathematics. I saw this happen in an undergraduate course on The Philosophy of Science during a discussion of quantum mechanics. After some very wierd comments were made by several members of the class, I asked the class to raise their hands if they had taken a course on QM. Mine was the only hand raised. Not even the instructor had taken QM. But they were more than willing to discuss topics about which they were ignorant.

22. **Adam Helfer**
January 5, 2010

Peter,

Yes, Penrose deserves a great deal of credit for bringing the cosmological problem forward (and I know what I've written here is certainly influenced by his ideas). One used to hear cosmologists talking about the high entropy of the early Universe, with no mention at all of the gravitational degrees of freedom. I haven't read Carroll's book, but I believe that in the past he has acknowledged Penrose's influence.

I agree also that Penrose's speculations about links to observational physics are very interesting. While I do feel that there is an argument that cosmology does call for some reconsideration of the usual notion of experimentation (one cannot expect to produce, much less reproduce, phenomena on truly cosmic scales), one should approach this very cautiously, since one risks throwing out the foundation for scientific progress. I think something like Penrose's Weyl Curvature Hypothesis is an excellent example of an idea which could in principle be testable but nonetheless have cosmological implications.

Bee,

You are right, that is the standard formulation; I probably should have phrased it that way to avoid confusion. (But the distinction has no effect on the argument. Also it is arguably mathematical hair-splitting, since: no real system is perfectly reversible; the entropy is perfectly well-defined as a precise real number only under idealized assumptions which do not hold for real systems; etc.)

23. **Peter Woit**
January 5, 2010

Bee,

The book is well-written, and people may find lots of the various things discussed useful. My problem is just with the main thesis that the book is structured as an argument for.

24. **Peter Woit**
January 5, 2010

Thomas,

That's part of the problem. But there's a further problem with physics blogs that a significant number of the informed people with reasonable credentials who post comments have decided to do so anonymously. Cloaked in anonymity, people tend to take a lot less care about what they write…

25. **Bee**
January 6, 2010

Adam: In what sense does the whole universe conform to your idea of a "real, not idealized system?"

26. **Bee**
January 6, 2010

Peter: Thanks. I think I'll put it on my reading list. There is a nonvanishing chance I'll open it before the end of the century.

27. **Adam Helfer**
January 6, 2010

Bee,

The Universe is certainly a real system. The sense of "idealized" which is relevant here is whether the entropy can be well defined. The Universe is certainly not a system in thermal equilibrium, so it's certainly very far from "idealized" in the usual sense one wants for such a definition.

The arguments I gave earlier are based on using (logarithms of) phase-space volumes as substitutes for entropy. But that doesn't really sharply define entropy, because of the question of just where to cut off the phase-space cells (the coarse-graining issue). Only in certain idealized limits does this ambiguity in the phase-space approach contribute zero uncertainty to the definition.

28. **Bee**
January 7, 2010

Adam: What I was aiming at is that unlike all other systems the universe is perfectly isolated. Yes, you have to coarse-grain. But is that fundamental?

29. **Adam Helfer**
January 7, 2010

Bee,

Since we don't really have a really firm idea of how to define the entropy of the Universe, I don't think we're in a position to talk about what is fundamental. For the purposes of the arguments I was giving, some sort of coarse-graining is essential, because one needs to decide when two different states count as macroscopically the same.

It's true that one might try to consider extending the idea of entropy so as to treat the entire Universe in some "fundamental" sense. However, this is a very big problem, and it's not clear that it would have a solution. In fact, it's hard to see how one would define the entropy of an ordinary (say classical mechanical) system which was not in thermal equilibrium.

30. **Bee**
January 8, 2010

Adam: If the problem is not fundamental, why is it worrisome? What you say is exactly what I meant: you have to decide what different microstates count for the same macrostate, that determines your entropy (leaving aside all other problems for the moment). This notion stems from thermodynamics and that's where it has its use, but what's its use for the whole universe, a system that by definition is all there is and exists once in exactly one microstate?

31. **Adam Helfer**
January 8, 2010

Bee,

I'm not sure what your point is. If you are arguing that entropy is not a useful concept in its application to the entire Universe, that's pretty much my point of view. If you are asking about why concerns about the Second Law are fundamental, I'd say that the arrow of time is a fundamental issue — but I'd add that understanding the link between the Second Law and the arrow of time may well take us beyond the bounds of the strict applicability of the concept of entropy and ordinary thermodynamics.

32. **Bee**
January 9, 2010

Adam: Yes, is what I'm saying. I think we agree anyway.

33. **Maynard Handley**
January 10, 2010

Here is, I think, a more precise way of stating Bee's point.
Entropy, (IMHO) carefully defined, is a property of probability distributions (or, if you prefer) measures.
We can connect it to physics because, for blocks of space containing certain fields and subject to certain boundary conditions, we can construct an argument for what the PDF of the system should be, and we can calculate the entropy of that PDF.
(This requirement, well-defined PDF as a property of a few variables is also why we need thermal equilibrium. If you're going to have a non-equilibrium system, in theory you COULD define/assume/calculate an associated PDF, and this might even work for something like turbulence, but good luck doing it for a general situation. We can get away with this for the most part because when you're dealing with a steam engine or whatever, the number of coherent degrees of freedom is so small compared to the number of incoherent degrees that treating the system as in equilibrium basically works OK.)

When you expand this argument to the entire universe it basically falls apart. What is the PDF of states of the universe? What are even the allowed possible states, let alone a claim regarding what probabilities to assign to each possible state?
But if you don't have a PDF, you don't have an entropy.

Untangling String Theory

January 7, 2010
Categories: This Week's Hype

The Times of London recently sent one of its reporters out to a pub to learn about string theory from Michael Green, with results available on-line here. Green does a good job of trying to explain some physics over a few beers, and admits that:

> I think, historically, when there has been a big change in a theory there is usually some qualitatively new phenomenon which will distinguish the theory. This has not happened for string theory, which is one of the reasons some people wonder whether it is real physics.

There's an associated slide show that supposedly gives a step-by-step guide to string theory. It explains that there are ten extra dimensions of very small size, necessary because:

> Beautiful as the idea sounds, when string theory is applied in the ordinary three spatial dimensions it doesn't work mathematically, predicting the wrong numbers for constants such as pi and the speed of light. It also predicts that the whole Universe should disappear.

I do wonder what string theory's prediction for the value of pi is…

According to the Times, the LHC has something to do with all of this, since:

> Scientists hope that the smashing together of particles at the Large Hadron Collider may reveal hints of the strings lying within them.

Over at the Los Angeles Times, Steve Giddings somehow neglects to mention string theory while arguing that the LHC

- "could open new frontiers in understanding space and time"
- "might produce dark-matter particles so we can study their properties directly and thereby unveil a totally new face of the universe."
- "might also shed light on the more predominant 'dark energy,' which is causing the universe's expansion to accelerate."
- "may reveal … the existence of a completely new type of dimension — what is called 'supersymmetry'".
- "may find evidence for extra dimensions of a more ordinary type, like those that we see — still a major revolution."
- "could produce microscopic black holes."

In case all of these discoveries seem a bit abstract and useless, there's the possibility of

- new energy sources, means of space travel or communication, or amazing things entirely unimagined.

Over at Uncertain Principles, some of the Giddings arguments about spin-offs leave Chad Orzel rather grumpy.

Finally, also on the nothing-to-do-with-string-theory front, New Scientist has an article about this paper from Science, where the authors find some sort of relation I don't understand between a representation of E8 and some phenomenon at the critical point of a quasi-one dimensional Ising ferromagnet.

> Although E8 does show up in string theory calculations, observing the symmetry in magnetic crystal experiments does not provide any evidence for string theory itself, Konik says.
>
> "The fact that you see this particular symmetry in this spin chain doesn't say anything about string theory per se," he says.

Comments

1. **anon**
   January 7, 2010

   your link to the times article gives a 404 error page

2. **Peter Woit**
   January 7, 2010

   The London Times first link sometimes requires a reload to work properly for me, and the second link sometimes doesn't work at all (but it's a pop-up which can be found on the main story page, if you can get to that…)

3. **Ignatz Thugg**
   January 7, 2010

   Is it worth $15 to read the Science article?

4. **Peter Woit**
   January 7, 2010

   Ignatz,

   I very much doubt it, unless you have very specific and unusual research interests in quantum criticality and no other way of getting access to a copy of Science.

5. **Bee**
   January 8, 2010

   "We observe only three spatial dimensions in everyday life, but what if, on the subatomic scale, there are tiny, curled up, extra dimensions, deeply embedded within space, and so small that they can't be seen? What if there were ten of them?"

   The explanation is badly formulated, but I believe "them" in the last sentence refers to "dimensions" and not "extra dimensions." They don't say one needs 10 **extra** dimensions of very small size as you write.

6. **Paul Wells**
   January 8, 2010

If you define pi as the ratio of circumferance of a circle to its diameter and if the space is non-Euclidean I can see why this comment might make sense – especially in the context of a popular article where you might not want to go into details of space-time curvature etc.

7. **Tim vB**
January 8, 2010

@Paul Wells
Sure, but that would be a phenomenon of non-euklidean geometry resp. of general relativity, this has nothing to do with string theory.
And of course the definition of pi is and stays to be the "ratio of circumferance of a circle to its diameter in euklidean space time", if you insist on a geometric definition (cumbersome).
If you leave out the "in euklidean space time" you don't get the definition of a constant.
I think the author needed another "constant" beside the velocity of light to get the rhetorical figure "enumeration", and pi was the first "constant" that came to mind, from the remnants of highschool.

8. **Steve myers**
January 8, 2010

Since it is common in checking smoothness of a fixture table by comparing circumference to diameter of several "circles" it is best to treat pi as a constant defined by something like 4 * Integral (0 to 1) of dx/(1 + x^2). I guess I never realized the power of string theory — it can change math constants. Is Euler's number next? (Note: we also check the eccentricity of rolls of material by seeing how close the ratio approaches pi.)

9. **Will Orrick**
January 8, 2010

The E8 work was inpsired by A. Zamolodchikov's results on integrable massive perturbations of conformal field theory. One of the simplest conformal field theories is the minimal model M(3,4) which corresponds to the critical point of the two-dimensional Ising model (or an equivalent one-dimensional quantum spin chain). What the authors have apparently done is to realize such a spin chain experimentally. There are two integrable perturbations of M(3,4), one of which corresponds to moving away from the critical temperature, the other of which corresponds to turning on an external magnetic field. Zamolodchikov discovered a connection of the latter to E8 which can be used, for example, to compute the mass ratios of the fundamental excitations in the massive theory. I have not yet read the Science article, so I'm not sure what aspects of this picture the experimentalists were able to measure.

10. **Anonymous**
January 8, 2010

"I do wonder what string theory's prediction for the value of pi is…"

Perhaps this might help:

http://arxiv.org/abs/0903.5321

11. **petergreat**
January 8, 2010

I think arXiv needs to add a rating system like in Youtube, so papers like this will be discouraged.

12. **Bob Levine**
January 8, 2010

"I think arXiv needs to add a rating system like in Youtube, so papers like this will be discouraged."

@petergreat: this is a terrific bit of *satire*. Look at the footnotes:

[11]I could have checked the original references, but it was
easier to look everything up on Wikipedia.
[12][And who isn't? (with the passage in text footnoted as [12] reading, 'Inspired by string theory[12]'…

Reread it for what it is: a great spoof on the kind of efforts that we're always reading about on Peter's blog…

13. **Tim vB**
January 8, 2010

ROFL!
(The author missed the pi=3 statements from the bible.)
It's very telling that
a) someone wrote this and uploaded it to the arxiv,
b) I would add here that someone did not notice that it is a parody, but I'm not so sure: @petergreat, did you perhaps mean you wanted parodies to be discouraged?
c) someone felt the need to point out that this is indeed a parody.

You know, it's really up to you if you get angry, cry, run away or laugh. I'm glad that some people out there chose to laugh.

14. **The Lone Haranguer**
January 9, 2010

(The author missed the pi=3 statements from the bible.)

He was wise. See http://www.math.ubc.ca/~israel/bpi/bpi.html, On The Rabbinical Exegesis of an Enhanced Biblical Value Pi, of where the author shows that a value of 3.1415094…, accurate to 3 parts in 200,000 can be derived.

15. **Tim vB**
January 9, 2010

Interesting! Finally some numerology that makes sense.

I may be a sceptic of numerology, espacially since I read the novel "Foucaults Pendulum" by Umberto Eco, but in this case I believe it.

So let me correct my statement and say: The author should mention the Hebrew value of pi according to verse 1 Kings 7:23 of the Bible.

16. **Thomas Larsson**
January 9, 2010

    April 1st 2009 was a Wednesday. Why did he upload already on Monday?

17. **Chris Oakley**
January 9, 2010

    Thomas,

    If he posted it from a computer travelling close to the speed of light, or close to a Black Hole, it may have been April 1st in his frame of reference.

    Who knows – maybe there are frames of reference (near a cosmic-scale superstring?) where it is always April Fool's day.

18. **Thomas Larsson**
January 9, 2010

    Chris, I think the explanation is simpler than that. IIRC, the deadline for submission to the arxiv is midnight GMT. If Scherrer made his submission between 0 and 6 am GMT on March 31, it would be received and time-stamped at Cornell on March 30, but appear in the April 1 listing in Germany.

19. **Chris W.**
January 9, 2010

    NPR has some coverage of the research described in that *Science* paper.

20. **Bob Scherrer**
January 11, 2010

    Papers need to be submitted a day early in order to appear on Apr. 1. If you look back for several years previously, you will see that several spoofs get published on the arXiv every Apr. 1. The arXiv administrators are obviously aware of this and have tolerated it thus far.

Simons Foundation News

January 8, 2010
Categories: Uncategorized

The latest AMS notices has the [news]() that the Simons Foundation is now spending about $40 million/year in mathematics and related theoretical fields. This is being done under a program being run by David Eisenbud at Berkeley, and the first initiative has been the funding of [new postdoctoral fellowships]() (there's an earlier posting about this [here]()). How the rest of the money will be spent remains undecided, with a request going out for suggestions.

This fall the program will fund 15 mathematics and 10 theoretical physics 3-year postdocs, as well as 9 2-year postdocs in computer science. A similar number of new positions will be funded next year. The postdocs will pay very well, at 70K/year for the mathematics ones, 65K/year for those in physics and "gauged to attract the highest caliber of applicants" for computer science.

The departments chosen for the postdocs have not been officially announced, but a little googling turns up the following ones that have job ads specifically mentioning the Simons fellowship.:

Mathematics: Berkeley, Cal Tech, Cambridge (UK), Columbia, Harvard, Michigan, MIT, Northwestern, Stanford, Texas (Austin), UCLA, Yale

Physics: Berkeley, Cal Tech, Chicago, MIT, NYU, Santa Barbara, Texas (Austin), Yale

Computer Science: Carnegie Mellon, Cornell, MIT, Princeton

The job market for the usual sort of teaching jobs at academic institutions has not been doing well recently, especially at US state universities facing budget problems. On the other hand, the job market for mathematics and theoretical physics, at least at the post-doctoral level, may do better than that in some other disciplines. We may be returning to an eighteenth-century model where this kind of research is supported not by public universities, but by the great private fortunes of the day, those being produced in dominant new industries such as finance (Simons) and telecommunications (Lazaridis).

Comments

1. **John Armstrong**
   January 8, 2010

   Oh sure, the market for math postdocs improves *after* I've been squeezed out…

2. **Abhijnan Rej**
   January 9, 2010

   I think the Simons Postdoc at Northwestern starts from the academic year 2011!

3. **chickenbreeder**
   January 9, 2010

   The eighteenth century model of private sponsorship may turn out to be the better one. The current model is that the government collect all taxtpayers' money and give it to NSF/DOE, allowing a small number of like-thinking program managers to run the show. This highly centralized model not only leads to lack of diversity but also bureaucratic waste. This can be reverted by giving private foundations big tax break if they devote themselves to sponsorship of science.

   If 20 super-rich people do as Simons and Larzadis do, it may be enough to change the landscape of science research in the U.S.

4. **Arun**
   January 9, 2010

   2010 Federal Budget:
   National Institutes of Health $30.8 billion
   FDA $0.51 billion
   Centers for Disease Control $6.4 billion
   DOE Office of Science $1.6 billion
   NSF $7 billion

   20 Simons foundations: $0.8 billion

   Even if government spending is 10 times less efficient, it would take more than 200 Simons to match it.

5. **anon**
   January 10, 2010

   "…the job market for mathematics and theoretical physics, at least at the post-doctoral level, may do better than that in some other disciplines. We may be returning to an **eighteenth-century model where this kind of research is supported not by public universities, but by the great private fortunes of the day,** those being produced in dominant new industries such as finance (Simons) and telecommunications (Lazaridis)."

   Did pencils and paper cost fortunes in the 18th century? I can understand certain experiments costing fortunes, but not theory…

6. **Peter Woit**
   January 10, 2010

   Arun,

   Large scale experiments are still beyond the financial resources of almost all of the largest fortunes (although, extrapolating trends of the past couple decades, that may not be true in the future). But $40 million/year is a significant fraction of US government support for pure math and theoretical physics, and it's less than 1% of Simons's wealth/year.

7. **Tim vB**

January 11, 2010

@anon
Don't forget that other parts of society need talented people, too. If you put too much money into mathematics and theoretical physics you will cause a brain drain elsewhere 🙂

8. **Kay zum Felde**
January 11, 2010

Hi,

I don't know, if it is good, that money is now spent by the industry. They decide how the money is used. Physicists should decide, how they use their money.

9. **SteveB**
January 11, 2010

anon,

How much theoretical physics is done with only pencil and paper today. I would expect that a significant fraction of the "theory" work done today uses computational models to extract information and big computers do not come cheap — ~$1M to purchase and several $100K per year to power, cool, and support.

SteveB

10. **Peter Woit**
January 11, 2010

SteveB,

Very few theoretical physicists use that kind of computer power, in almost all cases a workstation or server that costs only a few thousand dollars is all that is needed. For mathematics and theoretical physics, what is costly is people, not equipment.

11. **Mitch Miller**
January 11, 2010

Is there a specific reason why the math ones pay a bit more?

12. **Peter Woit**
January 11, 2010

Mitch,

I wondered about that myself. Maybe Simons likes mathematicians more… I believe the math Simons fellowships involve teaching one semester course/year, possibly this is not true for the physics ones, and that has something to do with the difference

13. **Eric Baird**
January 11, 2010

Well, IAS Princeton was founded by a department store owner, the Perimeter Institute was set up by the Blackberry guy, and the Nobel Prize was founded with a bequest from an arms manufacturer.

14. **Arun**
January 14, 2010

OK, American Mathematical Society:
http://www.ams.org/notices/200807/tx080700809p.pdf

"Federal support for the mathematical sciences is slated to grow from an estimated US$468.59 million in FY 2008 to an estimated US$516.8 million in FY 2009, an increase of 10.3 percent."

so Simon is adding 10% to that. Significant but it doesn't change "the landscape of science research in the U.S", only that of mathematics and theoretical physics.

And on the other hand, the very same document tells us

> According to the Science and Engineering Indicators, 2008 Edition, in FY 2006, only 34.6 percent of full-time mathematics faculty, having doctoral degrees, received federal research support.

So non-federal government sources fund most math. faculty. Simon is one more.

15. **Peter Woit**
January 14, 2010

Arun,

The fact that 34.6 % of math faculty receive federal research support doesn't mean that the rest get non-federal research support. Most of them probably get no research support.

Also, keep in mind that Simons is supporting pure math research, not applied math research, and the federal support for that is a lot less than the total of about $500 million (maybe half?, NSF DMS is about $250 million). In addition, he is funding mathematics in other ways, e.g. the Simons Center, for which he gave $60 million to start the thing up two years ago.

Unless there's a mountain of money around that somehow I've never heard about, at the moment there is no other private source of funding for pure math research in the US on anything like the scale of the new Simons Foundation activities.

The Entropy Decade

January 11, 2010
Categories: Multiverse Mania

We're only a week and a half into the new decade, but already I'm seeing a trend…

A few days ago Sean Carroll's book From Eternity to Here came out, promoting the idea that understanding time and cosmology is all about understanding entropy. The same day saw Erik Verlinde's arXiv preprint On the Origin of Gravity and the Laws of Newton, which argues that

> Gravity is explained as an entropic force caused by changes in the information associated with the positions of material bodies.

Verlinde is a well known string theorist, and the paper is somewhat of a repudiation of the motivating idea for string theory unification, that string theory predicts gravity since it has a spin two massless state. But even with the main motivation gone, all is not lost for string theory, since

> The presented ideas are consistent with our knowledge of string theory, but if correct they should have important implications for this theory as well. In particular, the description of gravity as being due to the exchange of closed strings can no longer be valid. In fact, it appears that strings have to be emergent too.

This is discussed in blog postings here, here and here, and yesterday even made it to Slashdot.

Today, it's yet more entropy, with The Entropic Landscape by Bousso and Harnik, which propounds the Entropic Principle, that:

> the number of observers is proportional, on average, to the amount of entropy produced.

and claims that this principle quantitatively predicts six important aspects of cosmology.

While much of physics in the last century was dominated by a highly successful program to identify fundamental degrees of freedom of nature and understand their dynamics using increasingly deep and sophisticated mathematical formalisms, now the trend appears to be very different. Many of the most well-known theorists are pursuing research programs with the remarkable features that:

- You don't need to have any idea what the fundamental degrees of freedom are.
- You don't need any fundamental dynamical laws either.
- You can do everything with high school mathematics.

The last century was a hugely successful one for physics, whether this new order will be equally successful remains to be seen.

Update: More analysis of the Verlinde paper here, and Verlinde now has a blog and a twitter feed about it.

Update: Verlinde is adding explanations of points in his paper and conducting a discussion of it on Lubos Motl's blog here. He now says that, to explain quantum gravity

> I am not sure that string theory is the way to go.

Even though under his new framework string theory explains nothing about any fundamental physics, Verlinde refuses to give up on it, arguing that:

> It should also be emergent, and it is nothing but a framework like quantum field theory.
>
> In fact, I think of string theory as the way to make QFT in to a UV complete but still effective framework. It is based on universality. Many microscopic systems can lead to the same string theory. The string theory landscape is just the space of all universality classes of this framework. I have more to say about it, but will keep that for a publication, or I will post that some other time.

Comments

1. **zanzibar**
   January 11, 2010

   "I have one word for you son… biology!"

   The future of physics lies where experiments will be done, or where data is already awaiting analysis. Interpolation, not extrapolation.

2. **Chris W.**
   January 11, 2010

   Erik Verlinde's paper should arguably be regarded as a review article providing an accessible overview of some fairly well-known work done by others over the past 15 years. In particular, his references include the following:

   [7] T. Jacobson, "Thermodynamics of space-time: The Einstein equation of state," Phys. Rev. Lett. 75, 1260 (1995)
   arXiv:gr-qc/9504004

   [14] T. Padmanabhan, "Thermodynamical Aspects of Gravity: New insights," arXiv:0911.5004 [gr-qc], and references therein.

   Padmanabhan has developed these ideas in several papers.

   In addition, see the papers of Ariel Caticha, including the following:

   "The Information Geometry of Space and Time"
   arXiv:gr-qc/0508108 [26 Aug 2005 (v1)]

   "From Entropic Dynamics to Quantum Theory"
   arXiv:0907.4335 [24 Jul 2009 (v1)]

   I would also offer the general comment that arguments from thermodynamics and statistical mechanics played an extremely important role in arriving at an understanding of the microscopic dynamics of matter in the early 20th century. I think it is eminently reasonable at this stage to suppose that explorations of the deep interconnections of thermodynamics, entropy, and gravitation will play an equally important role in arriving at the *unified* understanding of the dynamical underpinnings of gravity and quantum fields that we don't yet possess.

3. **Peter Morgan**
January 11, 2010

The definition of entropy is hyperplane dependent, as is its thermodynamic dual, temperature. That's a problem. [As a matter of definition, something that is not hyperplane dependent would not be entropy, although clearly it is conceptually possible to introduce "measures of randomness" that are not associated with phase space. The vacuum state of QFT on Minkowski space is Lorentz and translation invariant, and introduces Gaussian fluctuations that are hyperplane independent, but quantum fluctuations are distinct from thermal fluctuations (which, again, are not Lorentz invariant).]

As far as empirical success is concerned, SR, GR, and QM were all inspired by empiricist approaches, of different kinds, but at least partly inspired by the 19th Century epitome, thermodynamics (in contrast to statistical mechanics). The descent back into model-building realism, particularly since 1950, say, is questionable (Chad Orzel has an IHE article in which he characterizes Physics as being about models — I imagine Pierre Duhem is turning in his grave). The descent into Platonic realism about mathematical models is even more questionable. So, the great successes of the 20th Century could be said to be more rooted in the 19th Century, and a return to an updated empiricism might be a good thing.

4. **Chris W.**
January 11, 2010

Peter, your link to Chad Orzel's IHE article seems to be null. Could you post a follow-up with a correction?

5. **Chris K.**
January 11, 2010

In the context of mentioning Padmanabhan, he also had an attempt to refute the massless spin-2 in "From Gravitons to Gravity: Myths and Reality" http://arxiv.org/abs/gr-qc/0409089 to which Deser cared to reply recently http://arxiv.org/abs/0910.2975

6. **Hans-Peter**
January 12, 2010

Peter, your irony is honest, but some of it may be a little bit misplaced.

You don't need to have any idea what the fundamental degrees of freedom are.

Of course, this attitude is wrong. We need to know the fundamental degrees of freedom. Not looking for them is a way to avoid solutions; you are right on this.

You don't need any fundamental dynamical laws either.

This point is more delicate. If macroscopic dynamics, such as space-time curvature, is a statistical effect, there is a certain independence from the fundamental dynamics. So this point may be an acceptable one, at least partly or temporarily.

You can do everything with high school mathematics.

This point is also delicate. "everything" is surely too much. But Verlinde's paper is, in large part, the non-relativistic version of Jacobson's. And nonrelativistic gravity is done, as we all know, with high-school maths. What is wrong here? There is only one thing that is wrong: that since 1995, when Jacobson wrote his paper, almost nobody was interested in his result. Both Jacobson and Verlinde show that, independently of the specific microscopic degrees of freedom, gravity results from their statistical properties. This is an old idea, going back to Smolin and others.

You are right to say that this cannot be the end of the story: we need to find the underlying degrees of freedom. But there are many people who do not even think that such degrees of freedom exist. For them, Jacobson and Verlinde are good: they make them start thinking.

Besides, there should be something about Jacobson and Verlinde that you should really like: these arguments are very much 3+1-dimensional. Verlinde talks about string theory as well, but in fact everything is 3+1-dimensional. (Jacobson, for example, does not mention string theory at all.) In fact, their work is discretely pulling the rug under the idea of higher dimensions. I at least, was very much astonished to see a string theorist like Verlinde writing this, because this means that he is slowly, but definitely leaving string theory – even though he does not yet admit it.

7. **Andrew Thomas**
January 12, 2010

If we are considering the fundamental level of reality, and asking the most fundamental questions about dynamics, we come up against the question "What decides how things change?" At this fundamental level, the physical laws can seem somewhat arbitrary (for example, the amount of charge on an electron). In fact, at this most fundamental level, the only principle which seems likely to describe dynamics seems to come from mathematics not physics: a system will have many more possible disordered states than ordered states, so a system which changes state randomly will most likely move to a more disordered state.

While the second "law" of thermodynamics is "just" a statistical principle, it is a mightily powerful statistical principle! This is because the basis of the second law – that "disorder will increase" – seems so obvious, and seems to appeal to a fundamental, platonic principle of mathematics. For this reason, the second law manages to appear even more fundamental and unbreakable than the other physical laws, which seem rather arbitrary in comparison. Hence Arthur Eddington's famous quote: "If someone points out to you that your pet theory of the universe is in disagreement with Maxwell's equations – then so much the worse for Maxwell's equations. If it is found to be contradicted by observation – well, these experimentalists do bungle things sometimes. But if your theory is found to be against the second law of thermodynamics I can offer you no hope; there is nothing for it but to collapse in deepest humiliation."

At the most fundamental level, I would just imagine physical dynamics are described by change of entropy – I can't imagine any more fundamental principle which could possibly describe change.

The award winning 2004 Ph.D. dissertation of Tamara Davis from University of New South Wales (P.C. Davies on her committee) Figs 1.1 & 5.1 are very relevant to this discussion. The dark energy density we detect in our past light cone is the inverse area of our future event horizon in our future light cone. Therefore, it's our future event horizon that must be the hologram screen acting retro-causally in the sense of Wheeler-Feynman's total absorber. Indeed the increase in area of our future horizon from inflation to its asymptotic constant de Sitter value in the causal diamond of our observable universe (defined by T. Davis) explains why the thermodynamic arrow of time is in same sense as the cosmological arrow and why the entropy of the early universe is so relatively small at the moment of inflation.

(I found Chad Orzel's most recent IHE article; I'm not sure it's the one Peter Morgan had in mind.)

10. **Peter Morgan**
January 13, 2010

Hans-Peter, you react fairly strongly against Peter's "You don't need to have any idea what the fundamental degrees of freedom are", but I think this is a significant aspect of a statistical approach.

We can achieve an empirically adequate model with effective degrees of freedom, whereas at some point in the future we will need to introduce a model that has different DOFs to achieve empirical adequacy to updated experimental data. Although it is possible that there is an endpoint to this process of refinement, there is no guarantee that there is.

Chris W., sorry about the link problem. I had in mind the IHE article referred to in Chad's "Uncertain Principles" blog post, http://scienceblogs.com/principles/2010/01/dog_physics_and_academic_blogg.php.

January 13, 2010

I would be more inclined to suggest that this is the entropy century!

Entropy is critical because of its relationship to inference. We are finding that the "laws" of physics are rules that tell us how to make the best inferences given our current states of knowledge. Probability and entropy are central to this point of view since probability is a measure on the space of logical statements that one can make about a system, and dually, entropy quantifies (not technically a measure) the relevance of questions one can ask about a system.

There is nothing physical about entropy. This has led to great confusion in the past. Entropy quantifies the amount of information one would need to know the particular details about a given model.

Similarly, the idea that information drives a system is faulty. Deriving laws based on probability and entropy does involve information that the one performing inference possesses, but ultimately the system is merely "driven" in the most probable direction. The fact that we get the right answer doesn't mean that the information is driving the system. It means that we took into account all of the relevant information in making our predictions, and that this relevant information was sufficient to make an accurate prediction.

The result is that we don't get a theory of *why* something evolves the way it does. Instead we get a theory telling us which is the most probable scenario.

I have been pursuing these ideas for the last decade now along with Ariel Caticha and others, and am astounded at what the community involved in this research has uncovered. This new perspective of physical law as inferential reasoning brings a unity and utility that previous interpretations lack. My belief is that these ideas will break through the stagnation that theoretical physics saw in the last century and propel us to new heights.

12. **capitalistimperialistpig**
January 13, 2010

The only substantial clue we have as to the link between quantum mechanics and gravity is black hole thermodynamics, so entropy looks like a sensible place to start. Many of the deepest ideas in physics (Faraday's field concept, Einstein's relativity) came not out of sophisticated math but careful analysis of the foundations of physics.

13. **Chris W.**
January 13, 2010

See Erik Verlinde's latest post (13 January), scroll down to the following paragraph, and read from there:

> If the previous papers [Jacobson, et al] had made the emergence of gravity so clear, why are people still regarding string theory as the final theory of quantum gravity? Somehow, not everyone was convinced that these similarities mean something, or at least, people had no clear idea of what they mean.
>
> …… … … …

14. **Tim vB**
January 14, 2010

Verlinde states that he does not believe that string theory is a fundamental theory any more, because gravity is not a fundamental force, but he also states that string theory has a right to exist as a UV completion of QFT, and as a tool that gives valuable hints.
So his statement is a repudiation of string theory as the most fundamental theory, but not of string theory as a unification of the four forces (note that we have to drop the ubiquitous "fundamental" here).

I'll pick just two examples of the many points that confuse me, maybe someone likes to fill me in on Verlindes intentions:

First point:
"Many physicists believe that gravity, and space-time geometry are emergent. Also string theory and its related developments have given several indications in this direction."

This comes as a surprise, because in my naive understanding of string theory I always thought that the existence of spacetime is one of the axioms/starting points of the theory, so that an emergent spacetime is excluded from the very start. Was that a misconception?

Second point:
Verlindes talks about space to be emergent, but supposes microscopic dynamics including the existence of "time". If you start from GR, then this is impossible: Either you have space and time or you have none. Spacetime itself describes causal relationships, i.e. relationships of events, and this requires both notions. How does one reconcile GR with having time at a microscopic level and space as an emergent macroscopic phenomenon?

On a side note I don't quite understand the amount of attention this paper receives. What's so fascinating about it?

15. **Chris W.**
January 14, 2010

Tim vB,

I'm not the best person to respond to your queries, but I'll take a stab at it.

Point 1: In string theory's original formulation, a background spacetime was indeed assumed, but as work has pointed towards a deeper, non-perturbative formulation (M-theory) it has become doubtful that this can be maintained. Edward Witten has been fairly explicit recently that spacetime must ultimately be emergent. Exactly what this means, and what such a theory should look like, has remained obscure.

Point 2: "If you start from GR…" Well, you don't necessarily start from GR. Your starting point may be something that incorporates some primitive notion of time or causal ordering, which is applied in describing the evolution of some sort of pre-geometric system, out of which spacetime arises as a sort of coarse-grained or "mean-field" approximation to the underlying structure. Again, no one is sure whether, or exactly how, this can work, although a number of provocative ideas have been under investigation for quite a few years. Causal set theory is one example.

Why all the attention? Interest in the deep interconnections of entropy, thermodynamics, and gravity goes all the way back to the 1960s, when the so-called 4 laws of black hole mechanics were formulated, essentially as theorems in general relativity. Ostensibly they simply described the geometry of balck holes, but it was quickly noticed they bore a striking resemblance to the laws of thermodynamics. As a graduate student of John Wheeler, Jacob Bekenstein decided to take this analogy seriously and conjecture that they were in fact the laws of thermodynamics in a geometrical guise. He drew out some of the implications of this, and his conjecture was soon vindicated by Stephen Hawking's discovery that a semiclassical analysis of quantum fields near the horizon of a black hole implied that the black hole had a finite temperature measured at a distance (asymptotically), confirming Bekenstein's suspicions. This intimate 3-way relationship between general relativity, quantum field theory in curved spacetime, and thermodynamics has been widely regarded ever since as a key guidepost towards a theory of quantum gravity. This has been reinforced in the last years by the work of Ted Jacobson and others (see earlier comments). Erik Verlinde's prominence as a string theorist, and his remarks in the paper and on his blog about string theory in this context, suggest a significant shift in outlook on his part with respect to string theory and quantum gravity in general. (He goes out of his way to make this clear.) Of course this shift is not definitive, but we're in a revolutionary phase in fundamental physics; little if anything can be taken for granted.

16. **Mark**
January 14, 2010

"This comes as a surprise, because in my naive understanding of string theory I always thought that the existence of spacetime is one of the axioms/starting points of the theory, so that an emergent spacetime is excluded from the very start. Was that a misconception?"

To TimVB,
You should watch the talk by Moshe Rozali on "Backgound Independence in String Theory" at Loops 07:

http://www.matmor.unam.mx/eventos/loops07/

Or read the corresponding paper:
http://arxiv.org/abs/0809.3962

17. **D R Lunsford**
January 14, 2010

quote "Entropy, thermodynamics and gravity go back to the 60s…"

The first widely accessible book on GR was R.C. Tolman's "Relativity, Thermodynamics, and Cosmology" from the mid 30s.

-drl

18. **Chris W.**
January 14, 2010

DRL,

That quote was taken out of context. I wasn't talking about understanding and applying thermodynamics in astrophysics and cosmology, where gravity and special relativity (relativistic energies) are important. I was talking specifically about the discovery—in the 1960s—of the unexpectedly thermodynamic character of a particular class of solutions in classical general relativity.

19. **John Baez**
January 14, 2010

Hans-Peter wrote:

"…since 1995, when Jacobson wrote his paper, almost nobody was interested in his result."

I guess I'm almost nobody. But seriously: everyone in loop quantum gravity was very interested in Jacobson's result; the problem was figuring out something to do with it!

20. **Tim vB**
January 15, 2010

Chris W., Mark,
thanks for the answers, that was very helpful.
At this moment I have not digested all of the offered material, so I will refrain from asking more questions with one exception:

Chris W. wrote:
"Well, you don't necessarily start from GR. Your starting point may be something that incorporates some primitive notion of time or causal ordering, which is applied in describing the evolution of some sort of pre-geometric system, out of which spacetime arises as a sort of coarse-grained or "mean-field" approximation to the underlying structure."

It makes much more sense to me to understand Verlinde in the way you suggest: If he talks about the microscopic dynamics and it's concept of "time", then it is not the macroscopic notion of time connected with the emergent spacetime, but a different concept like the "causal set structure" that you pointed out.
But I'm not sure if that's what Verlinde means, because he mentions "space", and space only, as an emergent concept.
And he uses "time" to denote the causal structure of the microscopic dynamics, which made me think that he rolls back the unification of space and time of relativity theory.
Maybe this is a simple misunderstanding caused by my overly pedantic interpretation of his use of language.

21. **Chris W.**
January 15, 2010

From Tim vB: *And he uses "time" to denote the causal structure of the microscopic dynamics, which made me think that he rolls back the unification of space and time of relativity theory.*

The unification of space and time in relativity has come to be viewed in a somewhat different light as a result of the study of the dynamical structure of general relativity ("geometrodynamics"). You should find out more about the ADM formalism.

The meaning and status of time in general relativity is a vexed subject, that has received much attention from physicists and philosophers of physics. How it will all shake out is not at all clear, of course (notwithstanding my own biases 🙂).

22. **drme**
January 15, 2010

Wow! Verlinde posting in Lubos' blog?? Is Lubos still considered an important voice in the field? Amazing!!

23. **Chris W.**
January 17, 2010

Verlinde's Jan. 15 post is now on his blog. It appeared first on Lubos' blog.

Also, although the linked titles on his main page don't work, the three posts can be accessed as separate files:

15 Jan: Entropic forces and the 2nd law of thermodynamics
13 Jan: Essential points of the paper
12 Jan: Logic of the paper

24. **Mark Wallace**
January 19, 2010

I enjoyed Verlinde's paper. I was not familiar with the earlier work he references by Jacobson, so of course it really got me thinking. It immediately raised the following questions for me:
(1) If you accept that gravity is emergent, then what is wrong with the Standard Model? Why do strings need to be added to all the QFT that makes good experimental predictions?
(2) Having spent most of my life working with computer codes, I am intuitively comfortable with ideas like the holographic principle. Similar types of information constraints come up all the time in algorithms I work with, so it does not seem surprising to see something similar in nature. However, starting with the holographic principle doesn't seem quite right when the author claims 3 dimensional space as an emergent phenomena. I am willing to go along and follow the logic of deriving spatial dimensions as emergent phenomena, but there wasn't enough in Verlinde's paper to suggest a good route. I was kind of expecting a derivation of spatial dimensions based on information-theoretic type arguments, but I could not find it.
(3) On the other hand, time was taken as a given. I was surprised, since I would have expected for entropy based arguments that time would be one of the (many) emergent phenomena, and that 3d space and the holographic principle would be the givens.
One way or another, I liked the paper and think I may have learned something. One we start down the route of saying Newton's equations are like the ideal gas law, we need to be very careful, in any given context, to say what is a "given" and what emerges. The logic can get very confused if, in the process of a single argument, the author is not perfectly consistent about the givens.

25. **Chris W.**
January 20, 2010

The New Scientist article that Verlinde said was in the works is now on the website. (See Verlinde's Twitter feed.)

The author, Martijn van Calmthout, avoids dealing with some muddled aspects of the story, but overall the article isn't bad.

The muddle is inherent in the opening paragraphs:

> WHAT exactly is gravity? Everybody experiences it, but pinning down why the universe has gravity in the first place has proved difficult.
>
> Although gravity has been successfully described with laws devised by Isaac Newton and later Albert Einstein, we still don't know how the fundamental properties of the universe combine to create the phenomenon.

This skates right by the fact that the only forces—in a Newtonian sense—in general relativity are the non-gravitational forces that take particle trajectories away from geodesics in spacetime. So strictly speaking, talk of an entropy *force* must be replaced by another locution if one is to properly understand the connection of "the flow of entropy" to geodesic deviation, ie, to spacetime curvature.

This is just one aspect of this very provocative line of thinking that could use some clarification in accounts aimed at a general readership. Ted Jacobson's original paper avoids this problem, at the cost of using some relatively dense technical argumentation, and no explicit use of the holographic principle.

26. **Chris W.**
January 20, 2010

PS: Actually, footnote 5 in Jacobson's paper makes the following reference to the holographic principle:

> Another argument that might be advanced in support of the proportionality of entropy and area comes from the holographic hypothesis[6, 7], ie, the idea that the state of the part of the universe inside a spatial region can be fully specified on the boundary of that region. However, currently the primary support for this hypothesis comes from black hole thermodynamics itself. Since we are trying to account for the occurrence of thermodynamic-like laws for classical black holes it would therefore be circular to invoke this argument.

Iranian Theoretical Physicist Assassinated

January 12, 2010
Categories: Uncategorized

An Iranian theoretical physicist named Masoud Alimohammadi was assassinated in Teheran Tuesday. Alimohammadi's publication list indicates that he began his career specializing in conformal field theory, and more recently had been working on questions in general relativity. Initial news reports inaccurately characterized him as a "nuclear physicist" and speculated that he was assassinated because of his association with the Iranian nuclear program, but there seems to be absolutely no reason to believe this.

Comments

1. **John Armstrong**
   January 13, 2010

   This sort of misunderstanding is disturbingly common. A friend of mine was almost disallowed from boarding her flight in Seattle because she had in her backpack an introductory quantum mechanics textbook.

2. **Thomas R Love**
   January 13, 2010

   It seems much more likely that he was assassinated because of his association with the Iranian political opposition.

3. **obvious**
   January 13, 2010

   Umm, JA, obviously the Iranian government knew what kind of physicist he wasn't when they decided to assassinate him.

4. **Chris Oakley**
   January 13, 2010

   I do not think there are any misunderstandings. See here for example. Either the Iranian government itself or an extremist group supporting the official line but not under their direct control (LUnatics But supporters Of the System – LUBOS for short) carried out the attack to eliminate an opposition supporter and thereby intimidate others. Ali Mohammadi was a convenient choice because they could then blame Mossad or the CIA. He of course could not have made any significant contribution to Iran's nuclear programme, but the public are not going to know that, are they?

5. **ManyMe**
   January 13, 2010

   Actually Lubos wrote about this too.
   But I am a bit confused about what he is trying to say.
   Does his contempt for murder depend on the number of string theory citations somebody has on spires?

6. **Alejandro Rivero**
   January 13, 2010

   For a contrary to Armstrong comment: I was allowed to follow by French Police after finding that my only possession was a book onC-* algebras.

   I was running, wearing black sport clothes, during a rainy night in an isolated area. So police stop me, asked to produce an ID card, which I had forgotten, and only after I show the contends on my backpack, the springer yellow book was proof enough that I was a mad scientist and not a burglar.

7. **Tim vB**
   January 13, 2010

   ManyMe,

   that's not how I understood Lubos, it's just that he was not sure if the victim could be of use to Iran's nuclear program – and that stopping that program, the assasination of the scientists who contribute could be a better alternative than, say, declaring war on Iran.
   His statement is a bit odd, because
   a) I agree with you that – given the papers the victim published – it is pretty clear that he was not involved in applied nuclear research and
   b) I sincerily hope that there are alternative approaches that will succeed to stop Iran developing nuclear weapons, without hurting or killing anyone – and I would never say that "assasination of certain people might be the most human way" to achieve anything.

   All in all the interpretation Chris Oakley cites is obvious enough, let's hope that the Iranians don't fall for the lies of their government.

8. **Serifo**
   January 13, 2010

   Well , you don`t have to be an expert on nuclear physics to work on a nuclear program ! Have you forgoten the Manhatan project ? Pure mathematicians (e.g. von Neumann) and theoretical physicists (e.g. Richard F.) all worked on the project…

9. **Tim vB**
   January 13, 2010

   Serifo,
   no, of course I have not forgotten that. And of course I cannot be sure if what I said is right, but given the information I have I think it is likely to be right.
   John von Neumann did work on hardware design of computers, too, and was successfull, because he was a pioneer. Today you would have to beat thousends of specialists with many years of experience to make a significant contribution: Very unlikely that you are able to do that as a theoretical physicist!
   During the 19th century you could make groundbreaking discoveries in chemistry on your attic. That time is gone.
   And I think it is similarly unlikely that someone interested in quantum gravity or the like would even be asked to help with a nuclear weapons program, or be assasinated if he did help.

(And yes, I know that there were plans to kill Heisenberg during world war II because some people were afraid he could succeed in developing a nuclear weapon – and that he never came close to do so, although he tried).

10. **Bob Levine**
January 13, 2010

@Serifo

"Have you forgoten the Manhatan project ? Pure mathematicians (e.g. von Neumann) and theoretical physicists (e.g. Richard F.) all worked on the project…"

Theoreticians and mathemeticians were necessary to the work of the Manhatten Project because the question of whether an explosive chain reaction based on specific materials and mechanical configurations was even possible had not been established—that was what Trinity was all about: an existence proof. Theoretical modeling was crucial to determine what kind of engineering was necessary. Generating a spherical shock wave via an explosive lens around a plutonium core to get around the predetonation problem, for example, was a novel idea that only emerged, courtesy of Seth Neddermeyer, after extended discussions based on considerable mathematical extrapolation. Things couldn't be more different now—the possibility of such processes has been proven far too often; the major engineering stages and corresponding components are known. You probably need mostly high-level nuclear engineers at this point to build a deliverable fission device, at least. The *last* person you need is a GR theorist.

11. **Simplicio**
January 13, 2010

Chris's explanation seems overly clever. A pro-gov't group assasinated Alimohammadi both because killing an reformist supporter would intimidate other members of the opposition, and because people would think Mossad/CIA/etc were behind it? So people are supposed to think the CIA is killing reformists? That doesn't make much sense.

Plus, he didn't seem to be particularly well known for his support of the reformists. You'd think the gov't would choose someone a little more high-profile if they're trying to intimidate.

Maybe he just owed money to a loan-shark or somethng.

12. **Chris Oakley**
January 13, 2010

> A pro-gov't group assasinated Alimohammadi both because killing an reformist supporter would intimidate other members of the opposition, and because people would think Mossad/CIA/etc were behind it? So people are supposed to think the CIA is killing reformists?

Not quite correct. Read *The Independent* article. The story put out by the Iranian government and media (they do not have free speech, remember?) is that Al Mohammadi is a loyal son who was brutally murdered by foreign agents who thought that he was part of Iran's nuclear weapons program.

13. **Serifo**
January 13, 2010

Tim v B , Bob Levine

" And I think it is similarly unlikely that someone interested in quantum gravity or the like would even be asked to help with a nuclear weapons program, or be assasinated if he did help. "

Unlikely but possible !! There are a lot of theoretical physicists (string theorists in particular) working on wall street , most of them had to perhaps learn some economics in order to apply their capacity of buiding abstract models for real world purposes ! A good nuclear program will always require good technical assets , theoretical physicists and mathematicians (even as assistants to calculate or build abstract models) are excelent assets ! In fact even if not needed directly in a nuclear program , because of their mathematical background , theoretical physicists and mathematicians may help the army generals in their strategic plans.

As for the assasination of Mr. Alimohammadi :

If it is a CIA – Mossad job (most likely Mossad) , then the main goal is clearly to eliminate any techinical asset that may be involved in Iran`s nuclear program. By " eliminate " I mean killing important assets , or scare other assets to leave (or not be part) of the nuclear program !

If it`s Iran`s internal job , then the main goal is to diverge the attentions of the Iranian people from the internal political and economic problems. Blaming the " zionist " and CIA is very appealing to Iranian people !

14. **Tim vB**
January 13, 2010

Serifo,
again, I cannot know if I am right…
I graduated in theoretical physics, started working as a software developer – and could easily make (a lot) more money if I accepted one of the job offers by EADS, on several weapons programs (e.g. developing software that steers rockets).
I wouldn't even have to move, I could stay right where I am now!

So I think I know what you mean 🙂
It's just the combination of several facts that make me think that your theory is less likely (it's not necessary to repeat what these are, is it?).
In the case of Iran the CIA could have invested massive amounts of money to turn around the elections.
They did it in the past in other countries, several times, with success. Such a story would have better chances to convince me.

15. **Simplicio**
January 13, 2010

@Chris

I think you're missing my point. Your explanation gives the theorized gov't allied assasins two motivations for killing the Professor which are contradictory. That they targeted him both so that reformist intellectuals will know they're willing to murder people and be intimidated, and that since he's a professor they can tell the public he was killed by Mossad to keep him from working on nuclear projects.

But who's going to be intimidated away from supporting reformists if they think he was killed for his nuclear work?

16. **Mike**
January 13, 2010

Simplicio ,

No, I think you're missing the point. They tell the world that the US and Israel did it because he was a physicist — it's what a lot of people want to believe anyway. Of course, that doesn't work internally, with their own people — they know better (at least the opposition does) and they are already taking it as a warning.

17. **Simplicio**
January 13, 2010

Maybe, but that's what I mean by it being overly clever. The plan is dependent on one group of people seeing through one dastardly ruse to a second, deeper contradictory plan to try and interpret out a vaguely threatening message. I just don't think actual people make plans like that, especially the types of people who use random violence and murder as a form of intimidation, a tactic which doesn't exactly profit from subtlety. YMMV, of course.

Plus, as I said, the Professor seems a poor target as far as intimidating reformers, even without the layers of obsfucation. While he was a supporter, he doesn't appear to have been terribly vocal about his support, possibly signing a petition and stating that the gov't should treat student protesters with less violence (which I imagine is a pretty common sentiment amongst Iranian professors).

18. **Chris Oakley**
January 13, 2010

Simplicio,

I have no idea who carried out the attack. But if it was a loan shark or other local criminal I doubt that the Iranian media would have made such a big deal of it. It will not have been the CIA or Mossad – even they are not stupid enough to see this guy as a threat. So what are you left with?

19. **JK**
January 13, 2010

The Iranian state has a long record of terrorising opposition through random murders, not claiming responsibility and often disguising them to look like crime. There are many cases where the truth has never come out. Presumably the idea of the random pattern is to increase the effect of terror. (For an example where a section of the security service went out of control and the truth was exposed google chain murders.)

Killings have fallen back a bit in recent years, but with the new upsurge in opposition I would be surprised if murders didn't start to rise.

As for blaming it on the Americans / Israelis / British that is what the Iranian state always does in every circumstance, regardless of truth or plausibility (and of course there have been some foreign interventions in Iran that are not too popular with the people there, giving the accusations some resonance – but I won't take the blog any further away from physics.)

20. **Peter Woit**
January 13, 2010

I'm shutting off comments here, since the signal to noise ratio seems to have hit zero (if not gone negative).

Please all: stop submitting comments if you don't actually know anything about the subject of the posting.

Templeton Foundation News

January 15, 2010
Categories: Uncategorized

The Simons Foundation isn't the only one announcing funding opportunities in math and physics. The Templeton Foundation's list of funding priorities for 2010 is here, with applications opening February 1. In math and physics the topics they want to support research in are:

- Quantum Physics and the Nature of Reality

and

- Foundational Questions in the Mathematics Sciences

At least for 2010, they seem to have lost interest in the Multiverse.

Templeton is also supporting a member of the Harvard Math Department in a big way, with a grant of $10 million to math professor Martin Nowak to fund a program in Foundational Questions in Evolutionary Biology.

Comments

1. **Marcus**
   January 15, 2010

   In the grant description, I'm curious what this means:
   ==quote==
   "missing knowledge problems", such as in the origins of biological creativity, the deep logics of biological dynamics and biological ontology, and understandings of teleology and concepts of ultimate purpose in the context of evolution.
   ==endquote==

   Here's the grant description link that Peter gave:
   http://www.fas.harvard.edu/~fqeb/
   It links to a page on the principal recipient Martin Nowak:
   http://www.ped.fas.harvard.edu/people/faculty/

2. **Peter Woit**
   January 15, 2010

   Marcus,

   I think the next sentence elucidates the meaning:

   "These specific kinds of knowledge are directly relevant to a wide range of philosophical and theological discussions and debates."

   or roughly translated:

   "If I can relate my specialty of the mathematics of dynamical systems applied to biology somehow to theology, there's 10 million bucks in it…"

3. **Yatima**
   January 15, 2010

   Hmmm… "teleology and ultimate purpose in the context of evolution". Well, that river opens up into cargo cult ocean. Looking for purpose in evolution is like looking for a sculptor in a limestone cave.

   Seriously though, hasn't Arthur C. Clarke or NewScientist been all over that problem already?

4. **neo**
   January 15, 2010

   IMO, this is something best judged by results rather than intent. And if the money is wasted (the results are bogus), too bad for science, but it is Templeton's money to waste (except for the tax deduction).

5. **Low Math, Meekly Interacting**
   January 17, 2010

   Perhaps the most significant aspect of Darwin's achievement was to make the make the absence of the need for teleological arguments virtually irrefutable. This in the mid-19th century. Resuscitating teleology is about as progressive as bringing the luminiferous aether back to explanations of Lorentz transformations.

6. **Anonymous P**
   January 17, 2010

   There may be room for disagreement about the value of Martin Novak's research, but I've looked at it, and it certainly falls under the category of real science. the reference to teleology appears to be misleading here.

   P

7. **The Baron**
   January 18, 2010

   The class I took from Professor Nowak was probably the most fascinating one I've ever enrolled in. The interdiscliplinary nature of the scholarship coming out of the Program for Evolutionary Dynamics is simply stunning, as is Professor Nowak's intellect. A well-deserved award.

Particle Theory in Midtown

January 17, 2010
Categories: Uncategorized

Particle theory is about to have a significantly higher profile in midtown Manhattan, with the launch of two new programs this spring:

- The CUNY Graduate Center at 34th St. is starting up an Initiative for the Theoretical Sciences, with a program of colloquia, workshops and public lectures in various areas of theoretical science. In early April there will be a workshop on Emerging problems in particle phenomenology.
- A few blocks away, at the 27th St. Stony Brook Manhattan campus, the Simons Center for Geometry and Physics will start having seminars February 12 under the title Simons Center Seminars in Manhattan.

Comments

1. **Thomas R Love**
   January 17, 2010

   The three speakers at the Simons Center Seminars in Manhattan are all string theorists. Surprise, surprise, suprise!

2. **Peter Woit**
   January 17, 2010

   Actually, they might all be better characterized as "ex-string theorists", with McGreevy recently working on condensed matter physics, Komargodski on supersymmetry breaking and Cachazo on qft scattering amplitudes.

   This reflects pretty well the "hot" topics in particle theory: string theorists are fleeing the failed program of trying to get unification or even quantum gravity out of string theory, and moving into other subjects, sometimes hoping to find a use for methods that grew out of their earlier string theory research.

3. **Mike**
   January 23, 2010

   What I found interesting w.r.t. the Simons seminar announcement is that no title of the talks, let alone abstracts is posted. Why should people attend, then?

4. **A.J.**
   January 23, 2010

   Mike,

   I suspect the organizers will post the titles and abstracts when they get them from speakers.

Big Think

January 18, 2010
Categories: Uncategorized

A little while ago I did an interview for Big Think, and they just put it up here today, with some editorial comment here.

I really don't like watching or listening to myself, so I'm not about to go through the interview and see exactly how what I tried to say came out and later got edited. If I said something unclear or nonsensical, perhaps someone will let me know. Regular readers of this blog are unlikely to hear anything they haven't read before. Big Think has their own commenting system, and you can comment there if you wish.

Comments

1. **Tim vB**
   January 18, 2010

   Did not spot anything unusual – but if you really want to show off, here's a little hint: The s-t-combination in German is usually pronounced as sh – t (sh like in hush), so Einstein is more like Ein-sh-tein and less like Ein-s-t-ein 🙂

2. **Bee**
   January 19, 2010

   43 minutes? Forgive me for not watching it. At least the first minute the video is out of synch with the audio. (Or maybe the speed of sound just changed by some orders of magnitude?)

3. **Bob Levine**
   January 19, 2010

   There's a written transcript of the interview provided as well. Peter's comments seemed quite good-natured and—at least as far as personalities went—non-judgmental, while still making the relevant points about the dead-end nature of string theory. And the comments about the Higgs, and why in some sense one doesn't really want the Higgs field to be the source of particle massiveness, was nicely done, I thought. The only problem with the interview that I could see was that in some places the editing seemed a bit spotty….

4. **GVF**
   January 19, 2010

   You talk much too fast for a recording.

5. **Eshan Shah**
   January 19, 2010

   Mr Woit, could you simply sum up the arguements for why string theory is not a 'scientific' theory?

6. **D R Lunsford**
   January 19, 2010

   Interview is OK but the streaming content is very badly done – unsynced audio and video and high CPU usage. Oh well.

7. **Peter Woit**
   January 19, 2010

   Eshan Shah,

   I don't claim that string theory is not a scientific theory. "String theory" refers to a wide range of different activities, many of which are completely scientific.

   The controversial part of string theory is the speculative attempt to use it to produce a unified theory. I would claim that such an attempt is scientific, the problem is that it has conclusively failed. What is unscientific is the attempt to evade this failure by invoking the "anthropic landscape". That's not science since it can't predict anything or even in principle be tested.

8. **Chris W.**
   January 19, 2010

   An example of that spotty editing:

   "Why do they all have different masses? We don't understand why the electron has a certain mass, **quartz** has other masses."

   Hopefully they'll make another pass on editing the transcript.

9. **Thomas R Love**
   January 20, 2010

   I watched the whole thing, in three sessions, after all they break up the 43 minutes in to 6 segments. Like you said, Peter, nothing new. But it is nice to review once in a while.

10. **David Levitt**
    January 20, 2010

    Peter,

    I am a long time fan of your blog and book, but have not commented previously. I am commenting now because of the rather bland nature of the above comments. What is wrong with giving you some applause and support? I thought it was a great interview – very fair, informative and focused. I would recommend it as a very concise summary of the current situation. I doubt it could be improved on.

11. **petergreat**
January 20, 2010

Indeed nothing new in it. I'm under the impression that no one has anything new to say about HEP. Not until LHC starts to give results.

12. **neo**
January 20, 2010

I found it very interesting and informative, although the disconnect between the video and audio was disconcerting. And BTW Chris W., Peter said quarks not quartz.

13. **Chris W.**
January 20, 2010

"Peter said quarks not quartz."

I know; I was blaming it on the transcriptionist. (I've seen some other sloppy "phonetic" transcripts recently.)

14. **Peter Woit**
January 20, 2010

Thanks David!

Actually, I'm glad that some of the conflict over string theory has died down, and Peter Woit attackers and supporters are no longer fighting in the streets (or the blogs…)

A combination of exhaustion and waiting for the LHC has put a lot of these debates into a state of suspended animation. This has now been going on for a while, and may continue for quite a while longer, which has its pluses and minuses. Anyway, I'm glad to every so often have the opportunity to restate a point of view on these issues which I've always thought is actually a fairly mainstream one in the physics community, even though for many years it wasn't getting much public attention.

15. **Paolo**
January 21, 2010

To date, I'm still failing to see what's the point of this war against string theory. Let's suppose for the sake of argument that those scholars are all completely and fully wrong and that the "theory" (I know Peter probably doesn't consider it a theory at all) doesn't make sense: so what? Don't we have better things to do than spending some of our precious time attacking those poor chaps? Like, for example, working on better ideas in the same area, or just enjoying the life and doing something completely different? Really, I do not understand. Probably I never will.

16. **Peter Woit**
January 21, 2010

Paolo,

Actually, sure, string theory is a theory, just one that doesn't work as a unified theory…

I'm glad I took the time to write the book, and to have some effect on causing there to be a needed debate about what was going on with string theory. But at this point, personally I'm taking your advice, spending very little time on string theory, instead working on better ideas and enjoying life. Arguably I'm spending too much of my time enjoying life and not enough working…

17. **Ryan Budney**
January 21, 2010

I'm another long-time follower of your blog. I thought the interview was excellent. You were clear and measured. You qualified your statements but didn't sound too much like a politician. 🙂 Very nice.

On my end your voice wasn't quite synced with the image but that's a purely technical issue of production.

Various and Sundry

January 21, 2010
Categories: Uncategorized

- The latest New Scientist has an article about Erik Verlinde's "entropic gravity", with enthusiastic remarks from Robbert Dijkgraaf and Stanley Deser. Gerard 't Hooft expresses pleasure at seeing a string theorist talking about "real physical concepts like mass and force, not just fancy abstract mathematics". According to the article, the problem with Einstein's General Relativity is that its "laws are only mathematical descriptions." I guess a precise mathematical expression of a theory is somehow undesirable, much better to have a vague description in English about how it's all due to some mysterious entropy. There's even an editorial about this:

> Now we could be closing in on an explanation of where gravity comes from: it might be an emergent property of the way objects are organised, much as fluidity arises as a property of water…. This idea might seem exotic now, but to kids of the future it might be as familiar as apples.

In a new preprint, Lee Smolin uses Verlinde's work in a very different way, to show that Newton's law of gravity must emerge from the microscopic quantum gravity approach Smolin favors, that of loop quantum gravity.

- Also on the New Scientist/entropy front, there's a review by Craig Callender of Sean Carroll's new book. I'd been wondering what philosophers of science would have to say about the book, and the reaction to Carroll's multiverse explanation of the arrow of time was about what I suspected it would be:

> Daring to speculate in the absence of well-confirmed theory, Carroll jumps from clue to clue, from black hole physics to string theory to the holographic principle, until he arrives at his destination: an eternal "mother space-time" from which a multiverse of baby universes are continually bubbling up and pinching off. The mother space-time is a high entropy vacuum that gives birth to universes like our own, some of which we can expect to begin with low entropy. Problem solved, says Carroll, because that is natural.
>
> Carroll seems slightly embarrassed by the many leaps of faith he asks of his reader in proposing this solution, and the prose of Part IV sometimes reads like the pitch of an honest used-car salesman: "This car is a dream! True, the tyres are bald, brakes unsound and transmission sticky, but you'll love it!"
>
> Carroll and other peddlers of multiverses make us an offer: we will explain the unexplained if you add vast unconfirmable matters of fact into your ontology. In this case that includes a host of disconnected baby universes, an eternal mother universe entirely unlike ours, and half a dozen unknown mechanisms to get all this working. Assuming this explains the low entropy past – and with so much unknown it is hard to be sure another conspiracy isn't lurking within – is this a good deal?
>
> In most cases I don't think so. Why is Manchester United perennially a good soccer team? Surely most solutions of the laws of physics don't have them winning so much. How unnatural (and unfair) those initial conditions are! Nonetheless, a frothy sea of baby universes tempts no one. We shrug and say, that's just the way it is. Sometimes it is best not to scratch explanatory itches.

- Witten now has a long preprint out about his beautiful recent work on analytic continuation of Chern-Simons theory that I wrote about here last fall.
- My colleague Johan de Jong has been working for a few years now on what he calls the Stacks Project, which aims at a detailed, foundational exposition of the theory of algebraic stacks, beginning with the necessary algebraic geometry. He has structured this along the lines of an open source software project, encouraging contributions to the project from other algebraic geometers. The latest addition to the project is a blog.
- The filmmakers who brought us What the Bleep Do We Know? have recently completed a new film, entitled Ghetto Physics: Will the Real Pimps and Ho's Please Stand Up!. According to Cornel West "This intelligent and intelligible film is a must-see for all of us." There may be a theatrical release this year.
- A huge proportion of the mathematics research literature is now controlled by the publishing company Springer Science + Business Media. Last April there were reports that the owners of the business had it up for sale for about \$2.9 billion. The CEO denied these reports, stating "We are not for sale, there is no truth in Springer being sold". Last month came the announcement that Springer was being sold, to two private equity firms from Sweden and Singapore. The price was about \$3.4 billion, with the new owners also taking on \$2.9 billion of the company's debt.

It's not clear if there are any implications for mathematics publishing, with this perhaps just a transfer of control of the mathematics literature from one group of private equity firms to another.

- In the next couple months Princeton University Press will publish a short new popular book on string theory, Steve Gubser's The Little Book of String Theory. It is only 184 pages long and appears to be somewhat similar to efforts like The Complete Idiot's Guide to String Theory, String Theory Demystified, and String Theory for Dummies, but less technical, with less graphics, and a lot shorter.

According to the promotional material, the author

> describes efforts to link string theory to experimental physics and uses analogies that nonscientists can understand. How does Chopin's Fantasie-Impromptu relate to quantum mechanics? What would it be like to fall into a black hole? Why is dancing a waltz similar to contemplating a string duality?

and

> After reading this book, you'll be able to draw your own conclusions about string theory.

The introduction is available here, and ends with this description of recent debates over string theory:

> I don't aim to settle any debates about string theory in this book, but I'll go so far as to say that I think a lot of the disagreement is about points of view. When a noteworthy result comes out of string theory, a proponent of the theory might say, "That was fantastic! But it would be so much better if only we could do thus-and-such." At the same time, a critic might say, "That was pathetic! if only they had done thus-and-such, i might be impressed." in the end, the proponents and the critics (at least, the more serious and informed members of each camp) are not that far apart on matters of substance. everyone agrees that there are some deep mysteries in fundamental physics. nearly everyone agrees that string theorists have mounted serious attempts to solve them. And surely it can be agreed that much of string theory's promise has yet to be delivered upon.

- For two wonderful but very different short memoirs by mathematicians about aspects of their research work, see William Stein's Mathematical Software and Me: A Very Personal Recollection, and Michael Harris's A Mathematical Dream and Its Interpretation.

Update: The Onion carries the news that World Physicists Complete Study of Physics. The quote from a physicist is:

> Yeah, that about does it for physics. All done. Math can pretty much take it from here.

Update: Robert Helling gives his take on the Verlinde paper here. It reminds him of a certain proof that reaches an unreasonable conclusion using the rules "time=money" and "money is the root of evil". I noticed this via an arXiv trackback. Funny, for some reason there are no trackbacks to my postings on this topic

Comments

1. **Ricci's Pieces**
   January 21, 2010

   I get a sense that you are not so into the entropy/gravity connection, but I think it's going to be a very fruitful area for mathematical General Relativity in the coming years. There have been about a dozen mathematical papers on the subject, most of them coming from the viewpoint of Perelman's entropy functional, Ricci Flow and all those things. It may not be Perelman's entropy functional, maybe a modified entropy functional, but this is one of the most mysterious areas in geometric analysis right now.

2. **Coin**
   January 21, 2010

   I wonder if it's a sign of trouble when you one has to specifically brag that one's work is "intelligible".

3. **D R Lunsford**
   January 22, 2010

   That piece about math software was really entertaining! I still have my working HP-71B from student days and still use my TI-92+ to do algebra in spacetime on the bus and train. I'm sort of surprised he never used Derive, which I find incredibly useful – a sort of LISP dialect that is specifically for math – the array processing is magnificent and better even than APL, and of course it handles the complex domain effortlessly.

   I heartily endorse the SAGE project, which is both fun in itself and very useful as well.

   -drl

4. **wolfgang**
   January 23, 2010

   I do not find Lee Smolin's argument very convincing.

   Verlinde considers the change in entropy dS for displacements dx assuming a holographic principle. But in his calculation he implicitly assumes the geometry of a smooth and indeed flat geometry.

   There is of course nothing wrong about that, but if Lee Smolin wants to use this argument, then he has to first show that there is a reasonable limit of loop quantum gravity, which reproduces this smooth and (almost) flat spacetime and I dont see that.

5. **John Rennie**
   January 23, 2010

   I think you're being a bit harsh when you say:

   I guess a precise mathematical expression of a theory is somehow undesirable, much better to have a vague description in English about how it's all due to some mysterious entropy.

   No-one is suggesting the existing mathematical models should be abandoned. The point being made is that the entropic approach may give us some physical insight into those mathematical models.

6. **Thomas Larsson**
   January 23, 2010

   Lubos has decided that Verlinde's paper is junk, cf http://motls.blogspot.com/2010/01/erik-verlinde-why-gravity-cant-be.html . While I don't have neither the energy nor the motivation to check his arguments, they agree with my own prejudice.

   To my embarrassment I must confess that I often find a lot of sense in what Lubos writes – in many ways, he is often expresses an extreme caricature of my own opinion.

   (I once knew how to make anonymous links to Lubos' site, but I have forgotten how.).

7. **Thomas Larsson**
   January 23, 2010

   Just copy the link into your browser's address field and you should get there.

8. **Frank**
   January 23, 2010

   Peter is right to criticize that the entropic formulation by Jacobson and Verlinde is not deep, because describing space-time as a thermodynamic limit does not tell (almost) anything about the microscopic constituents.

   When Bernoulli deduced the ideal gas law from atoms, he was able to show that gases are made of atoms whizzing around. But as suggested by many, almost any microscopic degree of freedom at Planck scale will give the proper thermodynamic limit: loops, ribbons, etc. all yield a limit that then leads to Jacobson's and Verlinde's argument.

   It is highly probable that the Jacobson/Verlinde argument is not able to distinguish between different microscopic models of quantum gravity. There is one exception though: the argument eliminates all theories with higher dimensions. In my view, the only conclusion about new physics that can be drawn from the Jacobson/Verlinde argument is: space-time is emergent and is made of microscopic degrees of freedom that fluctuate in 3+1 dimension.

   Quantum gravity people will say: we knew this since (at least) 15 years. And they are right. However, if the exploration of quantum gravity were the right path to find the microscopic degrees of freedom, they would have been found long ago. In fact, quantum gravity does not allow to deduce much about the microscopic degrees of freedom.

   The paper by Verlinde does not change the situation at all. Except that it confirms that superstrings are not the right microscopic degrees of freedom, because they do not live in 3+1 dimensions. But Peter would not call this a new result 🙂

9. **Frank**
January 23, 2010

I think that Lubos is wrong. Unruh's proportionality between acceleration and temperature implies that gravity can be seen as an thermal/entropic effect. There is little doubt about it. If you want to get rid about the gravity-entropy relation, you must get rid of Unruh radiation – and that is impossible.

On the other hand, this does not tell anything new, as I argued in my previous comment. The reason that Lubos is against the connection between gravity and entropy is clear: he understands that the Jacobson/Verlinde argument undermines string theory, because it excludes higher dimensions. Worse, through Verlinde's simplification for Newtonian gravity, EVERY physicist now understands that higher dimensions are out! This is Lubos' nightmare: a simple argument that suggests that string theory is wrong. Even worse, the argument is made by one of the world's most distinguished string theorists! We can all guess what will happen: Lubos will start discrediting the argument with the same anger with which he discredits global warming. Watch the show.

10. **Peter Woit**
January 24, 2010

Unfortunately, whenever I mention the Verlinde business, it's all anyone seems to want to comment on. I get dozens of comments (most of which I delete) submitted by people who want to discuss their own ideas about how the fundamental problems of physics can be solved using simple ideas from thermodynamics and high school math. Moderating these comments depresses me, so please stop doing it. Unless you have something really new, interesting, and very directly related to the Verlinde story, please don't post comments on the subject here.

11. **Roger Schlafly**
January 25, 2010

So do you agree that the more serious string theorists are not far apart from you on matters of substance? And that you are not far apart from them?

12. **Rhys**
January 25, 2010

Frank, which part of Verlinde's argument singles out 3+1 dimensions? I have just been going through the early parts of the paper to try to get a better feel for his argument, and no part of it seems to depend on the dimensionality of spacetime.

13. **Peter Woit**
January 25, 2010

Roger,

I don't see any disagreement with most serious string theorists about whether string theory now gives a viable unified theory (it doesn't). Where we disagree is on the question of whether to be optimistic or pessimistic about prospects for the future of this idea. I haven't seen anything in recent years that changes my pessimistic take on the situation, and I think even the more optimistic string theorists would agree that nothing learned recently adds to the case for optimism. Other than a small number of people who believe the landscape is serious physics, the majority of string theorists recognize that it's a disastrous end-point for the idea of unification via string theory.

14. **Lee Smolin**
January 25, 2010

Dear Wolfgang,

From your comment you misunderstand the argument I make. I begin the conclusions by saying: "It is important to emphasize that I have not shown here that classical spacetime emerges from loop quantum gravity, as we have assumed that there is a classical spacetime in the exterior region where we make measurements. What has been shown is that if there is a classical spacetime that emerges then Newton's law of gravity is necessarily satisfied. " Perhaps you will find the actual argument, which is to that limited conclusion, more convincing.

Lee

15. **wolfgang**
January 26, 2010

Dear Lee,

>> What has been shown is that if there is a classical spacetime
>> that emerges then Newton's law of gravity is necessarily
>> satisfied.

but this includes several assumptions which you make on p. 9 and p.10, for example
".. the excitation is moving in a classical spacetime. We assume that then it can be described as a particle."

Later on the same page you assume a specific value for a fudge factor f to actually reproduce Newton's law.

Since I do not immediately see that all these assumptions follow naturally from l.q.g. (obviously I know much less about it than you), I did not find the argument very convincing.

16. **Frank**
February 9, 2010

Rhys, the whole Verlinde argument only works in 3d. There are many ways to see this. One is to check Jacobson's original argument, which only works in 3d; another is to recall the relation between 3d and the "square" in 1/r^2.

As I predicted, Motl is fighting with all his energy. Now Verlinde is already a "crackpot". It seems that this attitude is shared by many. (It makes Jacobson a crackpot as well.) I can only shake my head in dismay. Even Seiberg, some time ago, has written a long paper on emergent space-time. It is now obvious since 15 years that space and gravity are due to some microscopic degrees of freedom, and now that there is a simple argument to show this, many dismiss it.

Wheeler spoke of "space-time foam" long ago. Then came the string theorists, and they replaced foam by compactified 11d space. But they were wrong. Wheeler was right. That is the simple truth. Space-time foam exists, and its thermodynamics produces gravity. Space-time is not a compactified 11d space.

17. **Peter Woit**

February 9, 2010

Frank,

Sorry, but I'm with Lubos on this, and I don't believe your argument that this only works in 4d. You can hope (as Seiberg does) to get space-time to "emerge" from a higher dimensional string theory, or from "space-time foam", from bits, from all sorts of things, with all sorts of different possible dimensions "emerging" at different distance scales. But by assuming just thermodynamics + some version of holography, you are starting with almost zero input. From this you will get almost zero output, not stringent limitations on the nature of the fundamental theory, for instance on its dimensionality.

Physics of the Universe Summit

January 26, 2010
Categories: Uncategorized

The New York Times today reports on a *Physics of the Universe Summit* held a week or so ago in LA. According to the Times, participants stayed at "a Hollywood hotel known long ago as the 'Riot Hyatt,' for the antics of rock stars who stayed there." Talks were a couple miles south at the SpaceX factory, Larry Page of Google was there "handing out new Google phones to his friends", the magician David Blaine performed card tricks, and Bob Dylan's son Jesse showed some sort of film about the LHC. The only other information about this that seems to be available on the web is Sean Carroll's blog posting here, where he gives a link to the slides of his talk.

Optimist Gordy Kane claimed that the LHC will soon discover supersymmetry, making physics on the verge of seeing "the bottom of the iceberg". Lisa Randall (who evidently has a new book planned about science and the LHC) argued instead for focusing on less grandiose small problems. She was skeptical about supersymmetry, pointing out that we should have seen various evidence of it by now, and that the "wimp miracle" of a stable superpartner explaining dark matter doesn't work well "without some additional fiddling with its parameters." Joe Lykken summarized the situation as:

> We're confused, and we're probably going to be confused for a long time.

Comments

1. **willman**
   January 26, 2010

   "less grandiose small problems" – does this mean that Randall has given up hope for finding evidence of large extra dimensions?

2. **Bee**
   January 26, 2010

   Gosh, if the meeting was as fuzzy and content-free as the article, it was a total waste of time and money. Always the same people telling each other always the same things. Avoid groupthink? Figure out what it is to begin with.

3. **Harrison**
   January 26, 2010

   unreal, the nyt reporter offers virtually zero insight from a meeting he spent days covering.

4. **Peter Woit**
   January 26, 2010

   Harrison,

   I disagree completely. The article seemed to me to do an excellent job of capturing the mood and discussions of this kind of meeting (for example, that people spend time arguing "is this subject depressing right now or not?"). It even included a reasonable explanation of some of the more technical arguments, for example Randall on the problems of supersymmetry.

5. **Michael**
   January 26, 2010

   If anything proves that we need new data, the quoted statements from this "conference" do!

   The hubris of trying to replicate a speech by David Hilbert with a conference called "The Physics of the Universe" is a bit too much for my taste. Staging contending camps of optimists and pessimists to duel on-stage is rather contrived. Have some of these people simply been to too many conferences and are no longer stimulated by the usual discussions among experts of concrete problems and puzzles?

   One could also complain about some very sloppy statements – CMS is not Maria Spiropulu's detector, and the LHC experiments have only looked at a few thousand min-bias events at 900 GeV. This is a far cry from "recapitulating much of the physics of the 20th century." This is hyper-hyperbole.

   Lisa Randall's comment is the most interesting one, given that her fame comes from some very big and bold ideas. It would be nice to know what are the small problems that interest her – I guess we will see.

   I am most grateful for Mark Wise's reminder that we have no reason to be depressed given the accomplishments of the Tevatron program and the turn-on of the LHC. Hopefully only a few people will be blasé about that. I can think of a few hundred, or even a few thousand experimenters who are very excited to finally get a chance to probe physics at much higher energy scales. Who knows – maybe conferences next year will focus on the interpretation of those data rather than on overblown big questions…

6. **M**
   January 27, 2010

   by the way, why the NYT journalist always writes about Maria Spiropulu?

7. **John Baez**
   January 27, 2010

   Physics "of the universe"? As opposed to what?

   I thought all physics was supposed to be about the universe. But I guess I'm just old-fashioned.

8. **Peter Woit**
   January 27, 2010

   John,

As opposed to “physics of the multiverse” I suppose…

9. **A quantum diaries survivor**
January 28, 2010

   Michael, agreed – cms is not Maria’s own, and it has not recapitulated much of last century’s physics! But neither “few thousand minimum bias collisions” is a fair description. Not even the “50,000” that Dennis reported about in his NYT piece.
   Cms collected, as you know, over 500,000 good collisions. This is nothing compared to what is in store for this year, of course, but it is enough to keep us busy with not totally irrelevant physics measurements. W and Z bosons will have to wait, but misrepresenting the situation one way may be as nocuous as misrwpresenging it the other way.
   Apart from that, I share much of your feelings.
   Cheers,
   T.

LHC Update

January 27, 2010
Categories: Experimental HEP News

Those responsible for the LHC machine are having their yearly meeting this week in Chamonix to discuss the state of the project and plans for the future. Last week a subgroup met to discuss plans for beam commissioning to 3.5 TeV/beam, starting next month. The current schedule envisages beam commissioning to restart around February 19, and best estimate is that it will take about a month to establish safe, stable 3.5 TeV beams and begin extended runs for physics purposes. There's a plan for a big media event when first collisions are achieved at 3.5 TeV/beam, something that may require discouraging experiments from announcing observation of high-energy collisions that happen before the planned moment (evidently this is what occurred last year, when Atlas saw 1.18 TeV/beam collisions before they were supposed to…).

This year's schedule includes a possible one-month stop mid-year to increase the beam energy from 3.5 to 5 TeV, but based on the discussions at Chamonix, this looks very unlikely. The most serious problem with the LHC remains the bad splices which are known to exist in the machine, as well as sectors where definitive measurements of all the splices have not been possible (they would require warming up the sector, causing delays of months). The current knowledge of the splices leaves no room for error, even at 3.5 TeV, and going to 5 TeV would require warming up parts of the machine, something which cannot be done during a 1-month stop.

Discussions are beginning about how long a stop for repairs should be planned for after this year's run ends in November. To be able to run at 5 TeV/beam will probably require keeping the machine off until May 2011 to fix splices. Going to the design energy of 7 TeV may require even more extensive work on the splices, work that could keep the machine off for all of 2011, with startup again in 2012. To get above 5 TeV, work also needs to be done on retraining the magnets through repeated quenches. Not much of this would be needed to get to 6.5 TeV/beam, but to go all the way to 7 TeV, problems that are still not understood with magnets from one manufacturer will have to be addressed.

Update: From the Chamonix summary talk, there are two main scenarios now being considered. In the first, the energy of the machine would stay at 3.5 TeV/beam this year and next, with .1-.5 fb^{-1} integrated luminosity in 2010, 1 fb^{-1} in 2011, then a year-long shutdown in 2012 to fix all splices before moving to 6.5-7 TeV/beam. In the second, splices would be fixed in stages, running for only 5 months in 2011, at 5 TeV/beam, 1 fb^{-1} integrated luminosity.

There will be a summary session at CERN next Friday.

Comments

1. **Coin**
   January 27, 2010

   Peter, thank you, this blog really did at some point become the best source of LHC updates I've found anywhere.

2. **Amos**
   January 27, 2010

   One question I've had about all of this since Resonaances first broke the "one manufacturer's splices" part of the story — these things under warranty?

3. **Peter Woit**
   January 27, 2010

   Amos,

   I'm pretty sure that these things come with no warranty. They're extensively tested before being put in the tunnel, but I'd guess there's no warranty after that.

4. **Ralph**
   January 28, 2010

   6 to 12 months to repair splices sounds pretty pessimistic – warm-up about 1 month, cool-down about 2 months, so that's about 3 to 9 months of actual work?

   If it really is that major, then putting the work off until other planned work (e.g., the 2014ish upgrade of the inner triplets?) is carried out, would sound attractive. There's plenty of interesting stuff that can be done at 3.5TeV/beam at the mean time (especially if working at a lower energy allows being more aggressive with the beam current).

5. **Michael**
   January 28, 2010

   Let me try to balance the somewhat gloomy cast of Peter's post by pointing out Ralph Heuer's (Director General of CERN) new set of goals for the 2010-11 run: there should be 500 pb-1 delivered to each experiment at high energy (which is expected to be close to 10 TeV, ie, maybe 9 TeV) and one considers even 1 fb-1. With such a data set, the LHC experiments could surpass the achievements of the Tevatron experiments, both in terms of standard model measurements and searches for new physics.

6. **Peter Woit**
   January 28, 2010

   Michael,

   Thanks for pointing this out. The splice problem directly affects the possibility of increasing beam energy, but not the prospects for increasing luminosity. Beam commissioning went very well last year, and the same may be true this year.

   For the most relevant Chamonix presentation about the effects of the splice problem on prospects for 5 TeV/beam, see

   http://indico.cern.ch/getFile.py/access?contribId=2&sessionId=0&resId=1&materialId=slides&confId=67839

   My reading of it is that going to 5 TeV/beam will require warming up sectors and is not going to happen in 2010. There are ideas discussed that could be implemented with a 1 month stop, but it looks like they would only allow an increase to 3.8-4 TeV/beam.

   Ralph,

   I think the fundamental problem is that there are 24000 splices in the LHC main circuits, and if something has to be done to a significant fraction of them, that's a time-consuming job.

7. **PhilG**
January 28, 2010

It will be very hard to hide the fact that they have collided at 3.5 TeV unless they cut public access to most of the status displays and logs.

8. **Tom Rizzo**
January 29, 2010

You must have a magic wand for reading technical slides..I couldn't find those 2 run plans in the Chamonix summaries at all…inside info?? 😉

9. **Peter Woit**
January 29, 2010

Look at Mike Lamont's talk on integrated luminosities, and the summary Steve Myers talk.

10. **Ralph**
January 29, 2010

On splice fixing, I just noticed the following from http://indico.cern.ch/getFile.py/access?contribId=8&sessionId=2&resId=1&materialId=slides&confId=67839 :

Conclusion: For safe running around 7 TeV, a shunt has to be added on all 13 kA joints

In other words, it looks like its not just a matter of fixing a limited number bad splices, they're going to put an additional copper piece around every single high current splice between magnets.

(Thankfully they don't seem to be talking about the splices inside the magnets also – presumably the protection diodes give extra margin there).

11. **robert**
January 30, 2010

i have one question why they have down till february ? what is that for

12. **Peter Woit**
January 30, 2010

robert,

Last year the new quench protection system was not yet fully operational, but they decided to go ahead and start beam commissioning at lower energy (1.18 TeV). This month they're finishing commissioning the quench protection system, and getting things ready to operate at 3.5 TeV. They should be ready to start beam commissioning again sometime in February.

Are There Cosmic Microwave Anomalies?

January 28, 2010
Categories: Uncategorized

No.

The WMAP team has just released a new set of papers based upon seven years of data from their experiment. For a summary of how this new data has sharpened some of their previous results, see the Cosmological Interpretation paper. They have also gone over claims by many groups to have found deviations from the standard cosmological model in their earlier data sets (for example claims to have found "the unmistakable imprint of another universe" which "points to string theory being on the right track.") In a paper entitled Are There Cosmic Microwave Background Anomalies, the WMAP team reports:

> In most cases we find that claimed anomalies depend on posterior selection of some aspect or subset of the data… We examine several potential or previously claimed anomalies in the sky maps and power spectra, including cold spots, low quadrupole power, quadropole-octupole alignment, hemispherical or dipole power asymmetry, and quadrupole power asymmetry. We conclude that there is no compelling evidence for deviations from the LCDM model

They give a humorous example of the problem that plagues typical claims to have found such anomalies, showing that the CMB sky map clearly contains the initials of Stephen Hawking, "aligned neatly along a line of fixed Galactic latitude."

Update: For the WMAP team's summary of its new results for the public, see here.

Comments

   January 29, 2010

   Coincidentally, I used the SH in the CMB example in my recent post Is physics cognitively biased?.

2. **Robert**
   January 29, 2010

   The only question I have is why the aliens don't know that Steven's initials are SWH, at least according to his email address.

3. **Christine**
   January 29, 2010

   A simple search in the arxiv with "cmb" and "anomalies" gives 110 hits. Several have been published in peer-review journals.

   I have read none of these, thanks to my skeptic-meter, which is becoming exponentially more severe with time, or specially when other people's skeptic-meter goes down in the opposite direction.

4. **Low Math, Meekly Interacting**
   January 29, 2010

   However, there have been no sightings of the Virgin Mary in the CMB (yet), which is somewhat encouraging.

5. **neo**
   January 29, 2010

   No virgin mary, but an axis of evil (the devil?) has been sighted.

6. **Nige Cook**
   January 29, 2010

   "… clearly contains the initials of Steven Hawking …"

   Typo: it's spelt "Stephen": http://www.hawking.org.uk/

   You escaped 5 points on item 8 of the index of Prof. Baez, since he only credits you if you misspell Hawking's surname, see: http://math.ucr.edu/home/baez/crackpot.html which gives

7. **Peter Woit**
   January 29, 2010

   OK, typo fixed. I tend to get this wrong because my brother spells it the other way…

8. **Luca Signorelli**
   January 30, 2010

   While I've always suspected most of the claimed anomalies weret at best wishful thinking, I can't help being disappointed – the "void" looked really as some interesting mystery to study…

9. **Jeff McGowan**
   February 2, 2010

   OK, question from a mathematician. I was looking at the WMP results page that Peter links to, and found it quite interesting. I'm confused however by the neutrino result, they say the WMP data give you 4.34 \pm .87 species of neutrino, and the standard model gives you 3.04, so it seems to me the WMP data is indicating there is a problem with the standard model, no?

10. **Peter Woit**
    February 2, 2010

Jeff,

Not really. See
http://www.math.columbia.edu/~woit/wordpress/?p=2597
for an explanation of the signficance of an experimental result being 1.5 standard deviations away from the expected value.

11. **Jeff McGowan**
February 2, 2010

Peter,

Thanks, I was assuming the \pm was more like 3 standard deviations, silly me 🙂

Jeff

12. **steve newman**
February 6, 2010

hi-
what do you make of this article which appeared a week ago?

has this been,/ will it be/, responded to by anyone??

it seems like a serious questioning of whole map, and therefore
of all the conclusions drawn from the map.

———————————————————————

"A remarkable inconsistency between the calibrated differential time-ordered data (TOD) of the Wilkinson Microwave Anisotropy Probe (WMAP) mission, which is the input for map-making, and the cosmic microwave background (CMB) temperature maps published by the WMAP team is revealed, indicating that there must exist a serious problem in the map making routine of the WMAP team. This inconsistency is easy to be confirmed without the use of WMAP map-making software. In view of the importance of this issue for cosmology study, the authors invite readers to check it by themselves."

I'll make an exception and give Peter 5 crackpot points anyway. He can afford them.

LHC Update, More

January 29, 2010
Categories: Experimental HEP News

According to [John Conway](), the decision coming out of Chamonix is to go with the first of the two scenarios described [here](): stay at 3.5 TeV/beam, then a long shutdown to fix all the splices. The idea is to run at 3.5 TeV during 2010 and 2011, stopping for shutdown either when 1 fb^{-1} has been accumulated, or end of 2011, whichever comes first. The LHC will thus be off throughout 2012, coming back in 2013 for a run at or near the design energy of 7 TeV/beam.

With the Tevatron counting on having around 12 fb^{-1} of data at 1 TeV/beam by October 2011, it should remain competitive with the LHC for many sorts of searches, including the search for the Higgs, for much longer than expected. This should be true for more than 3 years from now, until after the LHC has accumulated a significant amount of data at full energy in 2013. The current planning is for Tevatron operation only through FY2011, I wonder whether this will change…

Update: Science has a story from Adrian Cho [here](). The D0 co-spokesperson says the decision on running the Tevatron in 2012 "won't have to be made for several months." CERN experimenters are quoted as saying that they will still be searching for supersymmetry and extra dimensions. I haven't seen any studies of exactly what 1 fb^{-1} at 7 TeV will make possible in terms of doing better than Tevatron limits on such processes and on the Higgs.

Comments

1. **DB**
   January 29, 2010

   The LHC won't even be runnng when the Aztec calendar ends in 2012? There goes one doomsday theory! 🙂

2. **Teva**
   January 30, 2010

   "The current planning is for Tevatron operation only through FY2011, I wonder whether this will change…"

   Let's bear in mind that many particle accelerators became famous (or perhaps I should say many significant HEP expt discoveries were obtained) for reasons completely different from why they were proposed. Pre-WW2 machines didn't usually have names, but post-WW2, the Bevatron was designed to produce the antiproton (it did, and a physics NP), but it really became famous for Luis Alvarez and the bubble chamber and finding many resonances. The AGS proton synchrotron at BNL was built to reach higher energies, but nobody anticipated the 3 NP winning discoveries it produced (J of J/psi, CP violation, 2 types of neutrino species) — there was also the Omega- (Eightfold way). The AGS runs to this day (as an injector for RHIC). SPEAR? Nobody really expected the psi of J/psi, nor the tau lepton (although the idea of a charmed quark had been floated). The SLAC linac and deep inelastic scattering? The PS at CERN was a proton synchrotron of comparable energy to the AGS, and discovered weak neutral currents (Gargamelle bubble chamber), while the SPS at CERN was again a higher-energy proton synchrotron, but it really made history as a p-pbar collider. The muon g-2 storage ring at CERN indeed stored muons and gave a high-precision value for (g-2)_mu, but after that it was used for ICE (Initial Cooling Experiment) to demonstrate the feasibility of stochastic cooling.

   The Tevatron? It has produced the top quark, although the existence of the top was predicted as soon as the b quark was discovered (1977), albeit without a precise prediction for the mass. So … if the Tevatron finds a signal (or possible evidence for a signal … this is very subjective), then indeed the funding profile of the Tevatron will change. Why not?

3. **Pietro**
   January 31, 2010

   Nobel Prize winner Veltman (who won the Prize on issues around the unification of the weak interaction) thinks that the Higgs does not exist, and says so in each of his talks, citing a paper of his from 1991 which he wrote with his daughter. He predicts that there are some subtle changes in longitudinal W and Z boson scattering, but nothing else to be discovered at energies of a few TeV.

   If he is correct, both machines will see very little new physics. It will be fantastically interesting to see who is right: the majority or the "lonely" researcher Veltman.

4. **Ralph**
   February 2, 2010

   Re: "The current planning is for Tevatron operation only through FY2011, I wonder whether this will change…"

   My guess is that the only thing that is certain is that plans will change, the question is how 🙂

   If we get to the end of 2011 and it looks like something interesting is in sight, it might make sense to run LHC at 2*3.5TeV through 2012 also and aim for many fb^{-1} at that energy – in which case keeping Tevatron running would be pretty much irrelevant?

5. **Anon**
   February 4, 2010

   The "rule of thumb" is that you need ~3 times more luminosity at 7 TeV center-of-mass energy to get the same sensitivity as at 10 TeV center-of-mass energy. This is approximate and depends on production mechanism and the mass of the thing you're trying to discover and the backgrounds which can scale differently. Keeping this in mind there's a write-up from last year with some interesting information at:

   https://espace.cern.ch/acc-tec-sector/Chamonix/Chamx2009/papers/MFL_9_01.pdf

   and

   https://espace.cern.ch/acc-tec-sector/Chamonix/Chamx2009/talks/MFL_9_01_talk.pdf

   You should bear in mind that most of the these studies were done quickly making assumptions about how things scale with energy, rather than full simulation.

   In short for Higgs, LHC will overtake Tevatron in sensitivity at high masses but will struggle to be competitive at low masses with 1 fb-1. It seems the Tevatron will not discover a low mass Higgs at the 5 sigma level, but may see evidence for a low mass Higgs with 10-12 fb-1 of data. For SUSY and exotics, LHC should be in new territory.

In reply to the comment about Veltman, there are many people who have studied theories without a Higgs, he may have been the first, but it's an entirely conventional avenue of research now. In many ways the most exciting discovery would be one that nobody has thought of, and discovering nothing would also be enormously important since the whole Standard Model would need a re-think.

Particle Theory Job Market

January 29, 2010
Categories: Uncategorized

Erich Poppitz has updated his statistics on the high energy theory job market to include data from 2009. He counts hirings to tenure-track faculty jobs, using data from the Theoretical Particle Physics Jobs Rumor Mill. For 2009, out of 12 hires listed on the Rumor Mill, he counts 9 as in high-energy theory, 3 as cosmologists. Of the 9 high energy theorists, he counts 7 as in phenomenology, 2 as in string theory. I'm not sure exactly who he is counting as a string theorist, probably Easson (string cosmology) and either Elvang (now working on QFT amplitudes) or Shih (supersymmetry breaking). It appears that it is now essentially impossible to get a permanent job in a physics department if you're working on the more formal end of string theory (or string phenomenology, for that matter). You pretty much have to work in cosmology or phenomenology to have some sort of job prospects.

The academic job market in general in the US is in a terrible state, and this is reflected in the change from an average of around 20 hires per year in recent years to 9 in 2009. It looks like the situation won't be any better for 2010. The imbalance between the large number of new PhDs and postdocs, and very few permanent jobs is quite remarkable. According to the postdoc rumor mill, this year already 8 people have accepted postdocs in Princeton, at the university and the IAS, making this small segment of the community large enough to fill almost all the available permanent jobs.

The US economy remains on its knees due to the economic crisis triggered by the blow-up of debt instruments, especially those designed by quants often coming from a physics background. Luckily for physics PhDs who now have no hope for a job in academia, what I hear from my financial industry friends is that, unlike the rest of the economy, their companies are doing quite well, embarking on new rounds of hiring.

Comments

1. **Tony Smith**
   January 29, 2010

   Peter, you said "… The US economy remains on its knees due to the economic crisis triggered by the blow-up of debt instruments …"
   and
   also that you "… hear from … financial industry friends is that, unlike the rest of the economy, their companies are doing quite well …".

   Have your friends explained how it is that the financial industry, where "the blow-up of debt instruments" occurred,
   has avoided being "on its knees" and is instead "doing quite well"?

   Tony Smith

2. **Peter Woit**
   January 29, 2010

   Tony,

   This is one of the great mysteries of the modern world, but for informed discussion of it, I suggest you frequent one of any number of blogs devoted to the issue. I'd like to stick to math and physics here.

3. **Robert McNees**
   January 29, 2010

   A number of people who have worked on strings (or stringy topics) are responding to this by looking for jobs at Universities and Colleges that don't show up on the Rumor Mill. These are positions at good schools, with reasonable teaching loads and lots of time for research. Yet many of us never hear about them in grad school.

   The last few years really have been bad if you go by the Rumor Mill, but the picture isn't _as_ bad if you consider the full range of jobs that are out there. Though frankly, with the number of PhDs that are being produced, it's hard to imagine a market that could produce enough jobs to keep everyone happy.

4. **neo**
   January 29, 2010

   Fascinating how these accelerative cycles work. In Economics, it was game theorists. Game theory was hot and every department was clamoring for game theorists. New PhDs responded accordingly and became game theory specialists. For a while it was good, but then departments became top heavy with game theorists, especially when the discipline turned more empirical. But the game theory train had too much momentum. The system kept churning out game theorists. Is the same thing now happening with string theorists in Physics?

5. **Erich Poppitz**
   January 29, 2010

   In response to the post and one of the comments: I treat particle theory, phenomenology, and cosmology as one group, and string theory and lattice as the other two. In cases such as those mentioned, I allow myself to assign fractions of a person to different groups (some subjectivity definitely creeps in then; also, I notice the 2009 percentages don't add up to 100, my apologies, will fix). As for looking at jobs not on the rumor mill my only response is that these are very hard to track.

6. **Mesa**
   January 29, 2010

   Well as someone involved in said industry, I can tell you that it wasn't the design of the instruments that was particularly the problem, but the leverage with which they were applied. The decisions to lever up the exposure to these instruments were made by MBAs, not PhDs. IE bankers not quants.

7. **Francois Vanderseypen**
   January 30, 2010

   Did my PhD 15 years ago and it took me two years to find a job thereafter. There is life outside the academic world but it takes a while to make the shift. I have compassion with all those who finish their PhD in math or hep these days and cannot stay in research; it's not fair. The commercial world does benefit from all these smart people but it's sad for hep and there is much hidden (personal and/or psychological) pain underneath all this.
   Even without the economic factor, the whole publish or perish atmosphere is a destructive element on the long run. The current state is the result of an incorrect perception

about what 'research' is, I think. Probably it'll take a long time before the hep community has made a shift again.

8. **whaddyagonnado**
January 30, 2010

Not all phds apply to be postdocs. Many people start a phd with no intention of a career in academia. So it's not such a great problem that there are so many phds being churned out.

A bigger issue is the proportion of permanent/faculty jobs compared to postdoc positions, because once you've started a postdoc you're committed to the academic path. You can still get out of course, but it's more painful than when you're fresh out of grad school.

9. **Michael**
January 30, 2010

Just a piece of information: there is a major decline in the number of jobs for experimentalists in particle physics, too, based on the data posted at http://www.freewebs.com/heprumor/index.html . There appear to be 9 openings in 2009-10 compared to 16 in 2008-9, 31 in 2007-8 and 24 in 2006-7.

10. **Bob Levine**
January 30, 2010

Several years ago a rather chilling essay appeared in PHYSICS TODAY, whose author laid out a number of quite reasonable (and deliberately optimistic) assumptions about the future demand for physicists in the U.S., based on retirement rates, expansion prospects for academic programs, employment patterns in the private and military/government lab sectors, and several other parameters, and then worked out what the rate of Ph.D. production would have to be just meet these requirements. It's been a while, but as I recall, he concluded that if each senior faculty member currently employed in a university with a doctoral program in physics turned out, on average, *two* Ph.D.s over a whole career, that would be about right to meet all the need for physicists—academic, industrial, military—for the next generation at least. The obvious problem was, he noted, that no graduate program in physics in its right mind would throttle back its doctoral graduation rates to that level.

And this was *way* before the current economic implosion we're going through….

11. **Thomas Larsson**
January 30, 2010

In a steady-state situation, each advisor will on average give birth to one new advisor in the next generation. So if each advisor on average produces 10 PhDs over his career, 90% of them will not become advisors themselves.

I don't understand how that can be a surprise for anybody.

12. **Paul Wells**
January 30, 2010

Sorry -but regarding the comment " I have compassion with all those who finish their PhD in math or hep these days and cannot stay in research; it's not fair." I don't agree. I don't think there is an entitlement to work in the fields of particle physics or any other area. The current funding "crunch" (= rationalization) in particle physics has been obvious for many years. Experiments cost too much and theorists have been delivering too little on their former promises. Nine sounds about right for particle physics theory new-hires.

Physics is a fantastic field and great training for many fields. Just look at number of Physics grads working in electronics and computer areas.

If particle physics is going through a lean period – change to solid-state ! Or even consider going into industry and help the U.S. economy.

BTW I have a PhD in Physics. Left academia years ago and wish I had done it earlier.

13. **Frederik Denef**
January 31, 2010

Things are a little better than what the rumor mill suggests. Last year, three of our own string theory postdocs got faculty jobs: one in Alberta, one is Austin and one in Milan. All three are doing mathematically oriented string theory. There have been several fairly recent string hires in Europe, places like the Simons center will end up hiring quite a few too, and the hiring freezes at places in the US will not last forever.

14. **Robert McNees**
January 31, 2010

Frederik: At least one of those jobs was in a Math department, right? Was that job listed on the Rumor Mill? I'm curious about the number of jobs over the last few years that support stringy stuff, but weren't on the Rumor Mill.

15. **Peter Shor**
January 31, 2010

Thomas Larsson says:

> In a steady-state situation, each advisor will on average give birth to one new advisor in the next generation. So if each advisor on average produces 10 PhDs over his career, 90% of them will not become advisors themselves.
>
> I don't understand how that can be a surprise for anybody.

This makes the quite unreasonable assumption that the **only** jobs that a PhD physicist is qualified for is tenured professorships in PhD granting institutions. If this is the case, it's quite clear we're teaching the wrong stuff in our PhD programs.
For one thing there are lots of non-PhD granting colleges who need to hire faculty to teach physics to undergrads. The requirement for these faculty is generally that they be PhD physicists (and some of them at the better colleges are actually incredibly good PhD physicists). There are also lots of jobs for PhD physicists in industrial labs, which also don't grant PhDs.

So I would guess that the steady-state number is at least 3 or 4, and the distribution should be biased towards PhDs at top universities.

On the other hand it seems quite likely that we are granting too many degrees in physics.

16. **Thomas Larsson**
January 31, 2010

What???
I never claimed that PhD physicists were unfit for anything but professorships at PhD-granting instutions. On the contrary, 90% better be qualified for other jobs, in industry, government, education or academia. Note that I used the word "advisor" rather than "professor", thus excluding professors at non-PhD granting institutions.

17. **Arun**
January 31, 2010

Some 40% or more of graduate students in physics in the US are(? – definitely used to be) from overseas. Assuming that Asian universities are staffing up, and economic growth continues there, some number will be taken up there.

18. **anonymous**
January 31, 2010

I can also vouch for the market being far better than this suggests. Three present/former postdocs I know from Stanford got faculty jobs last year: one at Heidelberg, one at DESY, and one at Ecole Normale Superieure in Paris. (Not to double count the one who Frederik mentioned who is now in Milan). So if you're out there thriving in your research and this message stream panics you, relax.

19. **anonymous**
January 31, 2010

Oops, I should have stressed: two of those can only be called string phenomenologists, and the third does very formal mathematical string theory. [The one now in Milan, who should not be double-counted, also does very formal mathematical string theory].

20. **Peter Woit**
January 31, 2010

It's interesting to hear that the job situation is better in Europe (at least on the continent, one hears lots of bad news from Britain). At some point things presumably will pick up again in US physics departments, but in the meantime, it sounds like those looking for a job in this field need to learn a foreign language (German, French, Italian, or mathematics…).

21. **Garbage**
January 31, 2010

I think there are 2 points here. 1) Whether string theorists should be learning a new language/field (or returning home); 2) Whether we should tell PhD students (and postdocs) in universities other than Harvard, Princeton, Stanford, etc. (very short 'etc.' indeed according to Poppitz), they should seriously consider life outside academia.

On the other hand, this year postdoc jobs was unusually good (although arguably bleak for string theorist.) Not sure whether this will be a trend or not, only the future will tell…

22. **ObsessiveMathsFreak**
February 1, 2010

There are probably lots of interesting jobs and research programs outside of theoretical particle physics which in fact result in things that are actually useful. Not to be too blunt about it, but the field of particle physics—and theoretical physics in general—has not made leaps and bounds in recent years.

There are countless unsolved problems and phenomena in low temperature physics, astronomy, optics, fluid mechanics, etc. There were the bread and butter problems of physicists in days gone by and perhaps the world would be better served by young minds researching in these fields rather than adding yet more impenetrable papers to the hep-th heap?

23. **Trent**
February 2, 2010

I'm surprised to see that nobody mentioned the obvious: having lots of PhD's and few jobs is good for competition. Only the best people will get hired and in order to end up with the best one needs to start from a large pool. Exactly how things are right now. Problem?

24. **Arun**
February 2, 2010

"…having lots of PhD's and few jobs is good for competition. Only the best people will get hired and in order to end up with the best one needs to start from a large pool. Exactly how things are right now. Problem?"

Yes, the field becomes much less attractive, and good people will do something else. Over time the field is impoverished.

25. **Christine**
February 2, 2010

Trent wrote:

(…) Only the best people will get hired (…)

Define "best". Sometimes merit is undervalued against one's social capital and other interests, as science is a social activity after all. With time, too strong a competition may probably "naturally select" not the honest-type of scientist but the more aggressively ambitious-type (namely, that who aims at success and power above all).

26. **Francois Vanderseypen**
February 2, 2010

From an evolutionary point of view the idea that natural selection picks out the best, Trent is right. In the same fashion, World Wars also help nature in selecting (according to some dictators) the 'better' ones. So, the key issue in all this is the criteria you handle in this process. What is 'better' or 'best'? What is the norm? I think often criteria are used (to pick out PhD's) which are very subjective and politically loaded. The criterium 'creativity' or 'deep/visionary' is usually irrelevant.
Most of all, perceiving this (selection) process in this way disposes the fact that science is a human activity and PhD's have feelings, families, responsibilities, dreams… Discarding this dimension of life (and doing research is part of life, no?) is ignoble as far as I'm concerned.

27. **Paul Wells**
February 2, 2010

U.S. PhD takes too long. In U.K PhD takes 3 years. IMHO this is better for society and makes it easier to transition to non-academic career.The issue might be that U.S. PhD is too long and too narrow. Being cynical PhD students are just being exploited as cheap labour.

28. **babel**
February 2, 2010

"The criterium 'creativity' or 'deep/visionary' is usually irrelevant."

True, because you can't quantify it. How would you select people based on creativity, or vision? You'd just create more opportunity for corruption and bias.

Do you think the great Renaissance artists were hired based on some vague criteria like the above? No, they were hired based on previous works. And at the sole discretion of the employer. It was a free market of art. That's how you get masterpieces.

Not by imposing or saying hey more jobs should be available or whatever. Or that this and that should be the criteria. If a university wants to be competitive, it will be in its own interest to hire the most capable. Eventually natural selection will provide the best criteria. No one forced anyone to get a PhD, so no one should be issuing any sort of demands or expectations. If it's anyone's fault, it's the fault of everyone who encouraged students to get a phd in the first place.

I do agree however that getting a phd should be harder, as should getting an undergrad degree. Giving them out is bad for everyone. If you pick a random bum of the street and give him a phd, he'll still be unqualified for advanced work, but he won't lower himself to flipping burgers anymore either. Since he has a phd and all.

Yet people complain that too few people have access to higher education. Make up your mind.

Best,
A future phd student in mathematical string theory.

29. **Me**
February 2, 2010

"Eventually natural selection will provide the best criteria."

natural selection doesn't provide best criteria, only sufficient ones for survival. That's all.

30. **Trent**
February 2, 2010

Christine and others,

Imagine you are sitting on a hiring committee. You need to decide who to hire from 50 applicants and you have 3 jobs to fill. You will surely rank the candidates according to some criteria that you think is the most reasonable. Naturally you will pick the 3 best candidates. So, naturally, you will have the definition of 'best'. It will the definition that you think is the most appropriate.

Would you prefer to have the criteria given — or dictated — by somebody? Would you be happier if somebody told you who to hire?

I'm sure the answer to both questions is no. If *you* are on a hiring committee *you* will define 'best'.

This is exactly the current system, there are no uniform guidelines dictated or suggested by somebody outside the decision makers, each university, each department, each hiring committee and each member of the hiring committee makes up his/her mind and defines what is 'best'.

Christine, you wrote,

"
With time, too strong a competition may probably "naturally select" not the honest-type of scientist but the more aggressively ambitious-type (namely, that who aims at success and power above all).
"

Do you have any facts to back this claim up? Factual, quantifiable facts I mean.

Trent

31. **martibal**
February 3, 2010

To Trent

"I'm sure the answer to both questions is no. If *you* are on a hiring committee *you* will define 'best'."
So don't call it "the best", call it "the one that at instant t and place x best serves my interest". And it could be the one who seems to produce the most interesting papers, or the cutest one with whom I am sleeping and is supposed to marry me (but will left me as soon as he/she is hired), or the one that will help me in my administrative task, without challenging my scientific ideas.

"Would you prefer to have the criteria given — or dictated — by somebody? Would you be happier if somebody told you who to hire?"
Yes, I would be happy that the committee makes its decision on clear and public criteria. "the best" is an empty word. Clear criteria need not to be dictated from the outside.

When you are in hiring committe, do you take the time to really study the applicants' papers ? I guess no because you are very busy and it would take several days/weeks to fully study the work of 50 candidates. And of course one week of a hiring committe member (who, by the way, has been at some time pointed out as "the best", hence considers himself that his opinion needs not to be justified) is worth more than the work-lifetime of 50 candidates.
The most honnest thing I have heard on hiring committe is from a professor explaining that, once a short list is made, all the candidates would fit the position. The process is then totally random, and it would not be less fair to just throw a dice.

32. **Thomas Larsson**
February 3, 2010

Natural evolution selects the fittest. Fittest is the person that was selected.

33. **Peter Woit**
February 3, 2010

Please, enough mounting of hobbyhorses about the fairness/unfairness of how hiring decisions get made.

34. **sourgrape**
February 3, 2010

If Peter Woit can get a job, why can't I get one?

35. **Peter Woit**
February 3, 2010

sourgrape,

I suspect you have a job. And, life is unfair…

36. **Alexey Petrov**
February 3, 2010

Very strange study — looks to me that the data is not accurate — even if we consider Particle Rumor Mill as a source (note that some particle jobs were also listed on the Nuclear Rumor Mill).

For example, in 2001, when I got my job, there were 31 openings in the US with 21 first-time hires — that is according to the Rumor Mill. Erich lists only 19 — why? Not to mention that my job does not exist according to page 2 of his study…

37. **Alexey Petrov**
February 3, 2010

To add to my post above — there were 6 new hires advertised on the Nuclear Rumor page that went to particle theorists (if you consider QCD theorist as particle theorist). And there is also Astro rumor page that aslo lists cosmology jobs. So the studies are at least not accurate… yet it is clear that the number of faculty jobs in particle theory went down quite a bit compared to some years ago…

38. **Erich Poppitz**
February 4, 2010

In response to Alexey's comments: yes, there is an inherent inaccuracy stemming from use of Theory Rumor Mill data only. I have now put the disclaimer on top of the page. On his concrete questions about the memorable 2001: yes, indeed there was an omission, and the correct number is 20, so we split the difference (as for his job, it was listed on p.2, which I have made clearer now).

39. **Doug Natelson**
February 5, 2010

I can't comment on high energy hiring in particular, but having served on and chaired search committees, I can talk about hiring in more general terms. Regarding martibal's comment above…. If the search committee has done its job well, then yes, you would hope that everyone on the short list is "above the bar", so to speak. By that, I mean that everyone on the short list would (a) stand a reasonable chance of research success (as much as anyone does; there is some luck involved, after all); (b) not be an embarrassment in the classroom (and ideally would be an excellent teacher and clear communicator); (c) not have major problems getting along with colleagues; and (d) be able to interact well with students; not necessarily in that order.

That doesn't mean that choosing among the short-listed people is random. After a visit (with individual conversations w/ faculty members) and (in our department's case) two talks (one to the whole department and one about research plans to the search committee), it becomes clear that the different short-listed candidates bring different strengths to the table. One might be a more dynamic, interactive person; one might be more creative or visionary in terms of research; one might fit very well into the perceived research needs of the department. At this point, it's a matter of the search committee really refining what they want and need, having seen the choices before them.

For what it's worth, in my limited experience I think in general that hiring practices in academia are certainly no worse than in other professions. Committees may tend not to be bold or adventurous, but at least there's a process, as opposed to the whims of a HR department + keyword search of resumes. The ratio of applicants to academic positions makes the process painful from the applicant side far more than the hiring process itself.

40. **Chris Oakley**
February 6, 2010

Here is one possible job opportunity: teaching string theory to Anne Hathaway.

41. **martibal**
February 6, 2010

Is this a tenure track, or just a 1+1 year postdoc ?

42. **Chris Oakley**
February 13, 2010

Martibal,

You would have to check with her agent.
Another female celebrity who might be into it is Courtney Love.
She apparently likes "watching quantum physics videos on YouTube".
I must admit that I did not know there were any, but now I will check it out.

Various and Sundry

- Now that the plan for running the LHC over the next few years is in place, one can start to get an idea of what new physics might emerge from it between now and 2013. For the question of the Higgs, Tommaso Dorigo does some analysis here, going back to 1999 Tevatron projections to see how reliable they were. He concludes that the 1999 projections were accurate for the mass range above 135 Gev. Below that, they depended on assuming a silicon detector upgrade that never was funded. His bottom line is that he sees the Tevatron as ultimately able to rule out the Higgs at 95% confidence level over the entire relevant mass range, but unable to come up with convincing evidence of its existence if it is in the lower part of this mass range. For this, the LHC will be required, but this will have to be after the move to higher energy in 2013:

> The LHC experiments will be unable, in my opinion, to make up in two years of data taking, and with the 3.5 times larger energy, for the 8-year advantage in running time of the Tevatron. The Higgs boson will be unlikely to be discovered before 2013, and it will probably be a sole LHC business; however, until then the Tevatron will retain the better results as far as the mass exclusion range is concerned.

- Operating on a different reality plane is Michio Kaku:

> "We're beginning to test string theory with the large Hadron collider outside Geneva, Switzerland, costing ten billion euros, the most expensive machine that science ever created. That's what I do for a living," said Kaku in a recent conference call interview from New York.

This is from a story mainly about Kaku's new TV show on the Discovery Channel, accurately entitled Fact or Fiction? Physicist Dr. Michio Kaku blurs the line between science and science fiction.

- NPR has recently started up a project called 13:7 Cosmos and Culture. It's a blog "set at the intersection of science and culture." Unfortunately, NPR's conception of the intersection of physics and culture is occupied by Stuart Kauffman, who has a series of posts arguing that the physical universe cannot be described by physical laws (see here and here). In the most recent one, Kauffman takes up the complicated subject of decoherence and the emergence of classical behavior in quantum systems, and claims to have (inspired by Karl Popper) an argument based on special relativity showing that decoherence cannot be described by any fundamental law of physics. This is supposedly experimentally testable:

> As it happens these ideas may have testable consequences, for they should be more marked as the relative velocities of the event A and one or two receding detectors increase toward the speed of light. And, since quantum decoherence is easier if the quantum processes in the "environment" are locally abundant, they should be more visible in that case. These are testable consequences of Popper's original idea and my use of it with credit.
>
> I hope the experiments are done.

For more about all this, Kauffman refers to his article here from the Edge web-site, where he argues that that the brain is "quantum coherent", and:

> Reversibility of the coherent to decoherent-classical to recoherent quantum states are essential to my hypothesis for I wish the brain to be undergoing such reversible transformations all the time.

He gets around problems with time-scales by noting that:

> The time scale of neural activities is a million times slower, in the millisecond range. But it takes light on the order of a millisecond to cross the brain, so if there were a dispersed quantum decohering-recohering mind-brain, reaching the millisecond range is probably within grasp of a quantum theory of the mind-brain system.

I suppose it is true that it might take light a millisecond to cross one's brain, if one's brain were about 200 miles across…

- Normally I don't think I can ethically post gossip about mathematician's love lives here, but once it has already appeared in the media…
- Some ex-colleagues from here at Columbia are among those launching the Journal of Unpublishable Mathematics. From what I hear, they haven't yet published anything, but have had nominations.
- Last week the algebraic geometer Eckart Viehweg passed away at the age of 61. His wife Helene Esnault is also an algebraic geometer, and recently posted an article on the arXiv based on joint work, with a heart-breaking abstract.

Comments

1. **Peter Shor**
   February 6, 2010

   Kauffman's right (in some sense). Decoherence cannot be described by any fundamental law of physics, as it is an emergent phenomenon (presumably fully explained by the fundamental laws of physics, although I don't believe we completely understand it yet).

2. **Peter Woit**
   February 6, 2010

   Peter Shor,

   That's not the argument Kauffman is making. He's not saying that decoherence can't be "described" by fundamental laws, he's saying that it can't be entailed by fundamental laws (it doesn't "emerge" from anything):

   "Since Newton we scientists, particularly physicists, have believed that all that unfolds in the universe is entailed by the fundamental laws of physics. I believe this view is false and its implications deeply alter our world view, heal the breech between science and the humanities, much of it discussed in my book "Reinventing the Sacred"."

   His argument is that relativistic causality implies this, and that this argument has experimental implications which can be tested. I don't see enough detail to figure out what these supposed experimental implications are.

3. **anon.**
   February 6, 2010

   I suppose it is true that it might take light a millisecond to cross one's brain, if one's brain were about 200 miles across…

   Well, light does take longer to cross a medium with a high index of refraction. I have little trouble believing that Kauffman's "mind-brain" is so incredibly dense that the speed of light within it is reduced by a factor of a million.

4. **Chris Oakley**
February 6, 2010

Kauffman could be referring to [Marvin, the paranoid android](), who, apparently, has a "brain the size of a planet".

5. **John Romeo Alpha**
February 6, 2010

Maybe he means that light traveling the same twisted path as regular neural activity would take a millisecond, so that this "dispersed quantum decohering-recohering mind-brain" could accomplish something in a millisecond which is not possible with a real brain and its pokey neural activities.

6. **Abhijnan Rej**
February 6, 2010

Hi!

Eckhart's death is really sad… I knew Helene and Eckhart for some time now, and both of them had the German algebraic-geometric community in place, with their common sense, sharp remarks (I remember seeing Helene stop Pierre Cartier short!) and just good will for people starting out!

BTW, their work on surface singularities is completely nontrivial!

Obi

7. **Bee**
February 7, 2010

I skipped over most of what Kauffman wrote, but in a nutshell he seems to be saying (correct me when I'm wrong), if decoherence happens on a hypersurface of simultaneity then this surface is observer dependent, meaning if you boost high enough in some frame it will not be simultaneous. That's hardly a new observation is it? Besides that the detector does provide a reference frame and thus I cannot see any fundamental problem with SR, I frankly don't quite get why this means it cannot be described by "physical law." Unfortunately, Kauffman's essay isn't really insightful, and it's quite unclear what he wants to observe and conclude. It might be it's just in principle unobservable, or eventually an empty statement. I mean, consider the usual EPR type setting, with an entangled pair of spins. You measure one in a detector, what happens to the spin of the other particle? Or, more importantly here, when does it happen? Problem is, it's entirely irrelevant what happens to the other particle if you don't measure it. Well, I guess what I'm saying is I don't know what he's saying.

8. **Ulla**
February 7, 2010

Kauffman talks of 'order for free' or self-organization in biology. self-organization is done by an entropy minimizing process, seen as instanse in the formation of virus shells and protein-folding.
[http://www.edge.org/3rd_culture/kauffman06/kauffman06_index.html]()

The automized process demands an earlier input of entropy, as an information or a codex, though, so this is only seen as a delayed response in my eyes. The order is there implicitly, and the folding makes it explicit.

Physical forces outside fundamental forces would peak in the direction – a Universe created by God, or the creationist wiev. This seems not be the case.

So the question is of the emergence of the Universe or not, the emergence of information. The same as Verlinde spoke of and Lubos discuss in
[http://motls.blogspot.com/2010/02/entropy-information-and-mixed-states.html#more]()

And that is not outside the fundamental laws at all.

Interesting though that he speaks of new biology 🙂

9. **Peter Shor**
February 7, 2010

Hi Peter,

I know that's not the argument Kauffman is making. I just found it ironic that he could be right (in one sense) and totally wrong at the same time.

10. **Peter Shor**
February 7, 2010

I should have remembered that irony (like entanglement) cannot be transmitted over the Internet.

11. **Bill K**
February 7, 2010

"Some ex-colleagues from here at Columbia are among those launching the Journal of Unpublishable Mathematics. From what I hear, they haven't yet published anything, but have had nominations."

Of course not, Peter. The actual publication of a paper which cannot be published would create a logical paradox.

12. **mathphys**
February 9, 2010

Testing string theory at the LHC oustide Geneva, the most expensive machine that science ever created, is an honorable way to make a living. I'm touched by Prof Kaku's modesty.

13. **Coin**

February 13, 2010

Peter wrote:

> I suppose it is true that it might take light a millisecond to cross one’s brain, if one’s brain were about 200 miles across…

Are you accusing Stuart Kauffman of having a big head?

> Some ex-colleagues from here at Columbia are among those launching the Journal of Unpublishable Mathematics. From what I hear, they haven’t yet published anything…

Just as you’d expect, given the title. Perhaps our library can afford this one.

Expanding Crackpottery

February 9, 2010
Categories: Uncategorized

Lubos Motl is getting rather concerned (yes, I know about what pops up when I link to his blog…) about recent trends in theoretical physics, especially the implications of recent work (discussed here) of well-known string theorist Erik Verlinde. He claims that many other string theorists share his concern:

> The people whose knowledge and opinions about physics are close to mine are finally beginning to realize the worrisome trends affecting the quality and character of the research in theoretical physics. I have a significant number of e-mail exchanges with these folks – and let me assure everyone that you're not alone.

In many ways I also share Lubos's concern. Like lots of people, over the years I've been deluged with examples of what I'll call "unconventional physics", in a spectrum ranging from utter idiocy to serious but flawed work. Much of it shares the all-too-common feature of making grandiose claims for new understanding of fundamental physics, based on vague ideas that often use not much more than a few pieces of high-school level physics and mathematics. The beautiful and deep physical and mathematical ideas that go into the Standard Model are ignored or thrown out the window. In many cases, it's hard not to suspect that the authors have decided that they can replace modern physics, without bothering to take the trouble to learn what it is. This kind of thing is pretty easy to quickly identify and decide to ignore, and it ends up having no impact on the scientific research community.

In recent years though, some theorists who definitely understand and have made contributions to modern physics have started promoting research which looks depressingly like the typical sad examples of "unconventional physics". Many of the products of the ongoing multiverse mania fit into this category. Lubos is getting quite worried to see that a very talented and well-known leader of the string theory community, Erik Verlinde, seems to be engaging in this sort of research, and getting positive attention for it. Within a month of its appearance, Verlinde's "Entropic Force" paper has already generated a dozen or so preprints from other physicists on the same topic. It could easily end up being the most influential (in the sense of heavily referenced) paper of 2010. Seeing this coming from a string theorist he admires is worrying Lubos and his correspondents.

While I agree with Lubos that this is something worth worrying about, his interpretation of the problem is characteristically irrational. In his posting, he argues that this is all due to the influence of the "notorious crackpots" Lee Smolin and Peter Woit. I don't see how I'm supposed to be responsible for prominent string theorists taking up dubious lines of research I strongly disagree with, other than perhaps having some responsibility for driving them over the edge. In any case, Lubos concentrates his attack on Lee Smolin, arguing that he's the one mainly responsible for this, an idea which is completely absurd. While Smolin is surely more sympathetic than I am to research like that of Verlinde, he's a serious scientist and not one with a lot of influence over Verlinde and the string theory community. Lubos's argument that this is all a left-wing plot organized by the far-left radical hippie Smolin is just laughable. One merciful thing about the string wars always was that positions people took were uncorrelated with their political ideology, keeping politics out of it.

Unlike Lubos though, I'm not convinced that I understand what the source of the problem is. My diagnosis of the current state of the field remains what it was when I wrote my book quite a few years ago: the lack of relevant experimental data coupled with the faddish pursuit of a failed idea about unification has led to a disturbing situation. In a very deep sense though, I just don't understand why talented physicists react to this by engaging in things like anthropic string landscape research, or vague arguments about "entropic forces". Lubos is right to notice that this situation has recently become more disturbing. A debate about the causes of this involving people more sober than Lubos would be a good idea. Twenty-some years of string theory hype in the scientific literature and popular press did a lot of damage, and if this gets replaced by hype of ideas even more dubious than string theory unification, things will go from bad to worse. Maybe the LHC will save us, but if this is what it takes, it looks like we're stuck for a few more years.

Comments

1. **Daniel de França MTd2**
   February 9, 2010

   This story of relating general relaitivty , to holography and thermodynamics, is god-know-how-many-years-old. There are several papers concerning this matter by Raphael Bousso which has between 100-500 citations. It was intensively used as tests to know if black holes of higher dimensions in SUGRA had the correct entropy. And this not counting just relating GR with thermodynamics, which is even older. Jacobson had papers about this 16 years ago.

   Now, I don't get is what all this fuzz is all about since Verlinde merely made a paper about a super simplified case, using Newtonian gravity…

2. **capitalistimperialistpig**
   February 9, 2010

   My guess is that Lubos has done more damage to the reputation of string theory than you and Lee combined. It hardly improves the credibility of your science if a practitioner behaves a lot like the crazy guys on the street corner talking about the end of the world.

3. **capitalistimperialistpig**
   February 9, 2010

   I have to say, though, that your snide remarks about the entropy work remind me a lot of what I heard about black hole radiation and Beckenstein's entropy back when – and yes, I am that old.

4. **Bee**
   February 10, 2010

   Well, if you believe Lubos, Lee is single-handedly responsible for every evil in this world. It's quite funny actually. Unless you're Lee I suppose.

   Anyway, you know what disturbs me about this isn't even Verlinde's paper. I don't really know what to make out of it, but he has evidently put work into it, it's thought through, maybe he has a point to make, I don't know. I don't get it, but maybe it shouldn't be dismissed too easily. It probably took quite some courage to put this out. But thing is, I'd usually have ignored it. What I find disturbing is how quickly people are jumping on the topic. I mean, look at this, it's a matter of weeks! The thing goes through the blogs, is in New Scientist, and so on, and so on. I mean, really, what's this? The-Making-Of the topic for 2010? After we had Horava-Lifshitz and Unparticles (and whatever happened to that?). I take some comfort of living in a relatively hype-free North European country (there is one person here who reads blogs! No really! But he didn't know about Cosmic Variance. And he didn't read your book either. And some other guy read your book but thought Lee wrote it. Or the other way round, forgot.) Now guess what I found on the printer yesterday. Yes, that's right, Verlinde's paper 🙂

5. **QED**
   February 10, 2010

Verlinder did nothing wrong! He has every right to publish
his results. If you get angry it is your problem. I don't see
the moral level of our physics community is evidently lower
that in 70's or 60's. There are always some very interesting
papers, some less interesting papers, so nothing worths
making fuss about.. In this regard, Verlinder's paper is
much better than many not-even-wrong papers.

6. **Per**
February 10, 2010

Hi Peter (if I may)

You are way to negative!

Sure, perhaps the Verlinde paper is nonsense, but as Bee said, he did 1) put serious work into it 2) he has atleast prior to this proven he is not an idiot (no matter what one think of string theory) 3) those two facts combined, it wouldn't really make any sense if he put something really stupid out.

Of course, it could happen, but this off hand dismissal just because it has a totally novel approach I find somewhat, hmm, unscientific.

7. **fh**
February 10, 2010

I'm with bee, the hype is disconcerting. BUT I think the paper itself is refreshing, at least compared to the myriads of conceptually trivial papers that are mathematically sophisticated this is a paper that tries for come real conceptual discussion. And it doesn't come out of nowhere Ted Jacobson, Black Hole Entropy, holography, etc.. This paper is in good company.

No the problem isn't with this paper but with the fetishisation of highly technical calculations (not Maths most of the time mind you, just calculations) that add no insight whatsoever. Philosophy is considered a derogatory term (see Polchinskis rant against "word ideas"), and as a result conceptual discussion is automatically labelled crackpot.

It can be. Crackpottery often pretends to be conceptual discussion (though not always, see the Bogdanov affair), but it can be distinguished from genuine, measured, precise debate. Fundamental physics just has forgotten how preferring instead to focus on more "objective" measures like technical skill.

(BTW, since somebody will misread this, technical skill is absolutely highly important, but it seems to me it is emphasized to the detriment of everything else, including, BTW sound mathematical reasoning)

8. **Michael Varney**
February 10, 2010

@capitalistimperialistpig

Lubos is pretty much not taken very seriously by many string theorists I know. They recognize him because of his blog, political leanings and his attacks on others more than for any recent physics contributions.
I would worry little about any damage to the reputation of string theory due to Motl. Many consider him to be traveling the road to becoming a crank.

This is pretty obvious from his post moderation, and his contention that people take his blog more seriously than peer reviewed papers. =)

9. **Peter Morgan**
February 10, 2010

There are reasons why people are getting onto Verlinde's paper. Partly it's his prestige, but it's also partly because there *are* previous works that are mathematically interesting that people are pointing out, and links into other research directions will be developed progressively. Verlinde has definitely not walked into a vacuum. I imagine that 't Hooft and others who have been working with stochastic or random fields will watch developments with interest, as I shall. We'll find out in a few years (or decades) whether Verlinde has marred his reputation or pointed out a path that becomes interesting and empirically relevant as it becomes increasingly thought through, both mathematically and philosophically.

Although I take your point that "The beautiful and deep physical and mathematical ideas that go into the Standard Model are ignored or thrown out the window", I think it's a little too much. A new approach to Physics has to pick *something* that it can do in an interesting way, then it has to construct a Correspondence Principle between itself and QM/QFT/the standard model that is mathematically elegant and that works well enough to be useful. The second step is very difficult to do well enough, the more so as the conceptual distance is greater. Lee Smolin's valley has to be crossed. If you had held Planck or Bohr to your standard, we might never have got from classical Physics to QM, since, emphatically, none of that work reconstructed all of classical Physics. The new QM more-or-less solved the Correspondence Problem with classical Physics in the late 1920s, but we still live with the slight failings of our understanding of how that works precisely.

Despite these reservations, good post!

10. **joel rice**
February 10, 2010

Maybe it just makes more sense to put heavy theorizing on hold
until the LHC can weed out the unproductive paths .

11. **Peter Woit**
February 10, 2010

joel,

I think that has been a lot of people's attitude for nearly a decade (at one point the LHC start date was 2005), and it hasn't worked out well. Right now, if everything goes according to plan, it seems likely that significant new information from the LHC won't come until data from the 2013 run is analyzed and released, possibly in 2014. So, best case scenario is four more wasted years. And then, what if the LHC data just agrees with the Standard Model?

12. **Fabio**
February 10, 2010

Its not just formal theory that is having quality control problems. A large portion of the phenomenology community spends it's time shamelessly chasing the statistically insignificant experimental anomaly du jour. Some phenomenologists I know have privately indicated disgust at the situation. I'm not sure exactly how Lee Smolin can be blamed for this, but there must be a way, because he is the devil. But citations for crappy papers are better than no citations for crappy papers not written, so it will continue to get worse before it gets better.

13. **johan couder**
February 10, 2010

Perhaps the source of the problem is identified in your book: "It is also true that there are no alternatives to superstring theory that one can easily learn and quickly start doing research into. Other ideas remain very little developed, and many of them require dealing with a whole slew of different mathematical ideas that are not part of a physicist's normal training." (p. 269 in my copy). "…, since readable expository material about much of modern mathematics is sorely lacking.", why spend (waste?) years of learning exotic mathematics, if high-school math(s) will do for the time being?

14. **Peter Woit**
February 10, 2010

Per,

I'm not critical of the Verlinde paper because it is "totally novel" (which it isn't), but because I read it and don't believe you can get a serious scientific theory of the gravitational force from what he starts with (thermodynamics + vague ideas about holography + high school mathematics).

As I wrote in my posting, I don't understand why a smart, capable scientist is putting out this sort of paper, just as I don't understand why a lot of other smart, capable people pursue multiverse pseudo-science.

15. **F**
February 10, 2010

There are a number of instances where simple 'high school' calculations can provide significant insight and/or lead to significant advances in a subject. The Jones polynomial for knot invariants can be derived using elementary ideas in geometry (basically three Reidemeister moves) and some trivial algebra. See Kauffman's work for an easy introduction. However, before the Jones polynomial was discovered in the 80's, mathematicians toiled with the Alexander polynomial for over 60 years by studying a very formal branch of mathematics dealing with the fundamental group theory of the complement space of a knot embedded in 3-space. I recall it took me a whole semester and about 100 pages of formal theory to just arrive at a rigorous understanding of the Alexander polynomial knot invariant. And despite all this effort, it can't tell the difference between the trefoil and its mirror image!! (something the Jones polynomial can). Despite its simplicity the Jones polynomial is connected with deep mathematical ideas.

Is this the fate of string theory??

In any case, one can slave away for decades on a highly sophisticated and formal subject that is considered 'acceptable' for academic research – and make progress – but if an an alternative idea comes along wrapped up in some simple 'high school' mathematics, we shouldn't be so hasty in rejecting it as 'nonsense', especially when there are deep physical insights underlying the arguments….

16. **F2**
February 10, 2010

I don't really see what's the trouble here. Why would I complain about someone investing his or her (private!) time in a new approach? If the Higgs ect. is there, then good for the core Standard Model physicists. This model works quite well for what it should do and of course people like that. If one wants to go beyond that in any way – why do other people have a problem with someone who thinks about something not semi-containing the old theory? If it doesn't work out, I guess it was worth a try still. If it's just high school mathematics, as you say, then people won't stick to it like to the string theory unification approach caus then people understand it and understand that it won't work. I think it's a bigger problem, that some physicists don't want to share their last two or three decades of lifetime with something that might seem far fetched, because they learnt something else, the past three decades. old story.

17. **Peter Morgan**
February 10, 2010

"I read it and don't believe you can get a serious scientific theory of the gravitational force from what he starts with (thermodynamics + vague ideas about holography + high school mathematics)." So should we have told Einstein not to worry his little head about a trivial, vague thought experiment that compared and contrasted acceleration and gravity, and not to look for a mathematics that makes that intuition into something powerful and useful? Of course not every intuition comes to anything, but, even if you might be right about Verlinde, you're sounding a little testy here. We can celebrate Verlinde's voyage even if he might sink. It's a strange, troubling sport to see you make this particular common cause with Lubos.

To me, the holography is inessential, but the thermodynamics maps directly to geometry, suggests Poincaré's "Science and Hypothesis", chapter IV, published in English in 1905, which then, I think, can go beyond high school mathematics. So yes, not so new. On the other hand, string theorists might find Poincaré's conventionalism a little indigestible.

18. **Peter Woit**
February 10, 2010

Peter Morgan,

Personally I find comparing Verlinde's "entropic force" paper to Einstein's GR papers just absurd.

In this case, I think Lubos's evaluation of this sort of research is accurate, and most of the theoretical physics community likely feels the same way. Maybe the ideas Verlinde (and you in your comment) are promoting represent where theoretical physics is headed, but if so I don't think that's a good thing.

19. **Thomas Larsson**
February 11, 2010

There are only two kinds of physicists today – those with bad ideas, and those without ideas. Crackpots vs. mediocracy.

Lubos proves that these sets have a non-vanishing intersection.

20. **P**
February 11, 2010

Standard model is very successful but IMHO it has already reached it's limits and all attempts to extend it further will fail. I also doubt LHC will find any new physics though it also likely won't find Higgs or SUSY neither.

It is however not true that there are no experimental observations which need explaining, there are plenty of deep foundational questions which are still unanswered, like: what aspect of physical reality is captured by wavefunction? what is described by fine structure constant? why SM parameters have the values they have? and many more…

I believe such questions have to finally be answered if we are to see further progress. They cannot however be answered in the framework of SM (or the answers would have been found by now), they require a novel approach based on different foundations. And this approach will likely look like crackpotism to those accustomed to SM at first.

This is why I believe unconventional thinking is good and the ideas like ones proposed by Verlinde should be encouraged even if they turn out to be wrong. Wrong ideas can still be beneficial if they inspire others or at least inform them that such and such approach does not work for following reasons.

This doesn't mean however that anything is worth exploring, speculations which cannot be tested even in principle like multiverse are still worthless and should be discouraged.

Finding successor to SM certainly won't be easy, it may very well be the most difficult task ever faced by physics what is really unfortunate is that those who chose to work on it face not only technical difficulties but also sociological barriers. Many in physics not only actively avoid foundational questions they also associate such work with crackpots and tend to shun those who try to work on them. This combined with publish or perish attitude makes such work very problematic for young researchers who are most likely to find solutions missed by their predecessors.

All this may significantly delay progress and could also mean that eventual breakthrough will have to come from outside mainstream physics.

21. **ObsessiveMathsFreak**
February 11, 2010

> In a very deep sense though, I just don't understand why talented physicists react to this by engaging in things like anthropic string landscape research, or vague arguments about "entropic forces".

Well, what's their alternative? They could spend another 20 years of their life battering their heads against the rock of modern particle physics with very few results and recognition to show for it; or they could produce and almost as substantial document about "entropic forces" in a hundredth of the time nd for ten times the press. It's a no-brainer from a game theory perspective at least.

Of course there's option 3, which is to research in some less grandiose, but no less worthy, branch of physics, e.g. battery research, and produce results potentially of great and immediate worth to mankind. However, this may be quite difficult to do after living in a dreamworld for 30+ years.

22. **Marcus**
February 11, 2010

I think this whole thread is unfair to physics. Key people in the entropic force business are Ted Jacobson and Jerzy Kowalski-Glikman. Both have solid integrity, neither show any interest in publicity, both are clearly guided by genuinely serious scientific consideration. The cynicism of some of these comments is shameful.

If you want a good quick overview of the thermodynamics of geometry, read Jerzy K-G's 5-page February 2010 note:
http://arxiv.org/abs/1002.1035
I think there is no better source if you want to know what is going on in that area. Among other things he offers specific fundamental degrees of freedom as called for in Verlinde's heuristic.
It is appalling that people badmouth Verlinde's paper merely because he does not offer specific tangible degrees of freedom to carry the temperature and entropy he talks about. His paper is a valuable and courageous opening game. Tangible details will be and already are forthcoming.

23. **Christine**
February 11, 2010

Peter,

What do you think about Padmanabhan's line of research? (See summary, e.g., here). He has been working on a thermodynamical interpretation of gravity for quite some time now. Do you consider his line of research as dubious as Verlinde's? If not, why? If yes, why?

Thanks.

24. **Peter Woit**
February 11, 2010

Christine,

My interest in arguments about quantum gravity that say nothing about particle physics or unification has always been limited, so I haven't followed closely research like Padmanabhan's. He appears to be engaged in a serious investigation of some of the puzzles raised by the relation between thermodynamics and event horizons in GR, and that's a perfectly legitimate area of research. His recent Verlinde-like claims to derive GR purely from considerations about entropy strike me as likely to be rather circular, or just dimensional analysis, but I haven't looked into this carefully. In any case, just saying "gravity comes from entropy" seems to me a rather empty and useless statement. Unless you have some idea how to use this to say something new about physics, testable at least in principle, few people are going to be interested (unless you're a well-known string theorist promoting the idea…).

25. **Daniel de Franca MTd2**
February 11, 2010

Peter,

That seemed to be a qualitative work, and Verlinde did cite Jacobson in his paper, so this is not like he is coming from nowhere. The follow up papers did seem to get the idea and produce things with much higher quality of math. So, it doesn`t seem that the overly simplified approach from Verlinde was any kind of barrier to development.

And just to reinstate what I said before. This links of gravity to thermodynamics are not a new topic, rather, they are quite common and involve several hundreds of papers. Take a look at the cite count of Bousso`s papers and you will see the ones involving gravity, holography and thermodynamics approaching 500 citations, most of them by string theory, or sugra papers.

Speaking of simplicity, I downloaded his 1st paper on general covariant entropy the day it was out on arxiv and printed because it was extremely simple, and it was one of the very few things I could understand from arxiv.org, being on the 2nd semester of my course.

I guess what is catching people`s attention it is that this paper it is that this concept is starting to be widely cited used outside string theory.

26. **Bee**
February 12, 2010

"The important thing in science is not so much to obtain new facts as to discover new ways of thinking about them." ~Sir William Bragg

27. **German guy**
February 20, 2010

If physicists were sophisticated enough to have a sophisticated vocabulary, like mathematicians, then it wouldn't be a problem, bro. For example, if "conjecture" was required usage in the physical sciences, then people could conjecture all day long, and over a period of years the good conjectures would rise to the top.

As it is, you moron physicists use a binary vocabulary where everything is science of some sort (speculative, etc.), or it's crackpottery. And we know why that is, don't we? Because physicists are supposed to be smart like mathematicians, but yet the state of modern experiment for the glory physics doesn't allow many conjectures to be fleshed out, thus no glory with a tight vocabulary, which is completely unacceptable for those seeking glory. Thus the loose definitions used.

But you're not doing a thing to fix the fundamental problem, so keep on licking those big black boots to maintain establishment acceptability, and I'll keep on doing the important things I do.

28. **Mihai Pomarlan**
February 24, 2010

irt. the Bragg quote:

"you should keep an open mind, but not so open that your brain falls out" – Richard Dawkins.

I see several commenters rushing in to defend Verlinde's paper, and for all I understand of those comments, they defend it because it's a new approach.

As if that in itself is a justification. The plethora of "new approaches" is precisely the problem these days, because most of them are junk. If this one is new, why is it worth it? Does it explain some new and puzzling obervation?

Or if it's not new, as references to similar and much older papers are present, then why the fuss?

And can anyone explain it to someone with an Engineering background like me?

(loose quote) "if you can't explain it in an undergraduate-level course, then you don't understand it" – Feynmann.

LHC Update

February 11, 2010
Categories: Experimental HEP News

A new schedule for operation of the LHC is out. It has sector tests of injection into the LHC starting the evening of Feb. 17, circulating beams again around Feb. 22, about 6 weeks for beam commissioning, then physics starting April 5. On October 18 the LHC would be stopped for two weeks to set up ion beams, which would then run for four weeks, with an end-of-year stop starting Nov. 29.

Last year there there was an estimate of about 10 days to establish collisions at 3.5 TeV/beam, but the latest estimate is more conservative, about 25 days. So, at the earliest, probably about March 4, more likely around March 19. Complicating the matter is CERN's plan to have first collisions broadcast worldwide on LHC First Physics Day, which is supposed to be a mid-week day announced a week in advance. So, the beam commissioning team is going to have to first get to the point where collisions are possible, then spend the next week of work being very careful to avoid stray collisions that one of the experiments might pick up and someone might blog about…

CMS collaboration members were asked for their best estimates of when first collisions would occur, with results plotted here. Lots of optimists voted for around March 1, the date that got the most votes was April 1.

Comments

1. **neo**
   February 11, 2010

   "…the date that got the most votes was April 1."

   Clearly some CMS members have a good sense of humor.

2. **PhilG**
   February 12, 2010

   They will be able to spend that week doing something useful at lower energy such as increasing the number of bunches

3. **Bill K**
   February 12, 2010

   "On October 18 the LHC would be stopped for two weeks to set up ion beams, which would then run for four weeks, with an end-of-year stop starting Nov. 29."

   Is it known at what energy the ion beam run will be conducted?

String Theory for Undergraduates at Brown

February 11, 2010
Categories: Uncategorized

A few years ago various US universities decided it was a good idea to offer a course on string theory for undergraduates (see here), but in recent years most of these seem to have been dropped from the curriculum. Brown University is going in the other direction, offering Physics 1970C, String Theory for Undergraduates, this semester. A report from a Brown undergraduate on Lubos's blog gives me some encouragement to continue blogging:

> Life is carrying on naturally. In fact, if I hadn't been reading eg woit's blog, I would've suspected we're still in the middle of a stringy revolution! We even just started a new string theory course for undergrads, and I and quite a few other undergrads held a string theory seminar. Interest in stuff like LQG is completely zero. So in the press you have woit, smolin blahblahblahing, ok. But in the meantime, you have ads/cft, and the whole twistor reformulation of yang mills in terms of contour integrals over grassmannians (inspired by twistor string theory). Even condensed matter physicists accept string theory as one of the greatest things that happened to physics.

The undergraduates at Brown have a String Theory Study Group, Facebook group here.

Update: The undergraduate string theory courses are now facing some competition. LSU is offering an undergraduate Introduction to Loop Quantum Gravity.

Comments

1. **Paul Wells**
   February 11, 2010

   I am not a great fan of superstring theory but I am also not sure this course is a bad idea.

   I think it is good for students to be exposed to the fact that Physics is an evolving lively subject that is often controversial.

   How about a course with basic ideas from three different approaches to quantum gravity – LQT, strings and maybe Dynamic triangulation ?

   Lets face it – the standard model is -well- pretty standard. I think there should be some courses in a Physics degree that excite and risk being wrong.

2. **Peter Woit**
   February 11, 2010

   Paul,

   The main problem with teaching undergraduates about proposals for how to quantize classical GR is that to even understand what the problem is, they first need to understand classical GR as well as how to quantize a classical field theory. The number of undergraduates who understand GR and QFT is quite small, and they would be best off in graduate courses.

   Encouraging undergraduates to do coursework on the various controversies over quantum gravity that haven't led anywhere interesting in recent years, before they have the background necessary to appreciate the crucial technical issues, seems to me to be a bad idea.

3. **Max**
   February 11, 2010

   I've been a long time reader of this blog, this is my first comment.

   I'm in this class! I'm a senior at brown. The class about 5 undergrads and 3 grad students, taught primarily by a postdoc (Ari Pakman) and by prof. Antal Jevicki when he is available.

   I'll answer anything you want about it, if you have further curiosities. I'm personally rather skeptical of string theory , but only based on what I consider to be second-hand information. I've never sat down and tried to understand the maths. I thought this class would be good to not only close that gap.

   Where did you find that quote?

4. **Peter Woit**
   February 11, 2010

   Max,

   The quote is from "gigel", commenting at Lubos's blog on his recent posting about "expanding crackpottery" that I blogged about here.

   Good luck with the course, I'm sure you'll learn something from it (although I think students would be much better off learning quite a bit of quantum field theory before tackling string theory).

   The only real textbook I know of at this level is Zwiebach's, so I'm a bit curious to hear if some other source is being used as a text for the course.

5. **Max**
   February 11, 2010

   The source is indeed the zwiebach book. I'm sure that most people in the class are going to have holes in their physics fundamentals, but it is being taught in a manner that will hopefully have a chance to address those shortcomings. I don't expect to have a robust understanding of string theory or ads/cft at the end of the semester, but I'm excited for the chance to learn first-hand what everyone is getting so worked up about; I might not get another chance.

6. **Peter Woit**
   February 11, 2010

   The problem I see with trying to teach AdS/CFT at this level is that students don't even know what the CFT is, and giving them that kind of background is not going to be possible in a course like this.

AdS/CFT is an interesting topic, but, like much of string theory, it is surrounded by vast amounts of hype. Enjoy, but don't believe everything you hear…

7. **gigel**
February 11, 2010

Hi Peter,

I think quite a few of the undergrads in the course do know both qft and gr, so this seemed like a decent opportunity to build on both.

You can't deny that string theory has been pretty useful in all sorts of places. I don't even think that the whole unification bit is the most amazing (possible) feature of string theory. You can take it as a tool to solve condensed matter problems, or just a new framework to test your undergrad knoweldge of lagrangians. I'm not sure where doubt has any room in this.

The two topics in the quote above are just a few examples where string theory did prove useful. Can you possibly deny this in any way?

8. **Peter Woit**
February 11, 2010

gigel,

On its main selling point (unification), string theory has been an abysmal failure, something which Zwiebach's book doesn't really acknowledge.

Sure, string theory is an interesting exercise in how to quantize an infinite dimensional classical system. The problem is that it is really a quite difficult exercise (due to the infinite-dimensional invariances of the system). Zwiebach covers some of this, but it seems to me that most people's time would be better spent first understanding more physically relevant QFT examples. If Brown undergrads really do understand QFT at the appropriate level, they should be ready for a graduate-level course.

The use of AdS/CFT as a tool to solve condensed matter systems is a hot research topic, but it remains very unclear how powerful it is. Your claim that "condensed matter physicists accept string theory as one of the greatest things that happened to physics" is pure hype and nonsense.

9. **petergreat**
February 11, 2010

String theory as a tool to solve condensed matter systems? As far as I know, this topic has become hot among particle theorists, but has not had any real impact on condensed matter physics. Until condensed matter physicists think AdS/CFT has solved problems that they can't solve before, and until AdS/CFT becomes an essential part of condensed matter physicists' tool set, this is just another speculative research direction.

10. **gigel**
February 11, 2010

Ok I was obviously hyping that part.

Peter, people sometimes are eager to see research or more "fun" topics before they reach 30 and complete their phd. Following the standard courses very often drives people away from physics. Finding about Noether's theorem in grad school? Finishing your SB in physics and not knowing what the weak and strong forces are (ie, about half the forces in physics)?

It happened that many undergrads here were interested in the topic, so the university offered the course. No one attempted to brainwash us or drag us into the bottomless pit of string theory research. It was student requested.

11. **Trent**
February 11, 2010

Slightly off topic, but Peter, how is your research going on BRST?

You said something like a year ago that by the summer of 2009 you will have publishable results, at least a preprent, what happened to that?

Cheers,
Trent

12. **Pawl**
February 11, 2010

It's certainly good when people try to learn about the issues. On the other hand, learning what string theory *is* (while difficult enough) is not the same as getting the right background to assess its prospects. For that one needs understanding of general relativity and quantum field theory at a deep — really, a foundational — level.

Very few physicists work at such a level. There are many really excellent physicists, but virtually all work is done on problems which are solved by technical acumen within existing frameworks, or modestly extended ones. So it is very hard to point a student to someone or some reference which would help with a critical foundational assessment of string theory (beyond the semi-popular literature).

I should point out that a main tenet of string theory has been that gravity *can* be quantized by a modest extension of existing framework (getting a quantum field theory over strings, rather than over points). (This is not "modest" within the class of quantum field theories, but it is extremely modest from the point of view of what might potentially be involved in reconciling quantum theory and gravity. That might be something entirely different from quantum field theory.)

13. **petergreat**
February 11, 2010

I second Trent's concern. I do hope Dr Woit will publish more papers. Both this blog and the related book have been excellent, and the world has already received the message. Maybe it is a good time to move on.

14. **gigel**
February 11, 2010

Pawl, you are forgetting about holography. It might turn out that the better definition of string theory and quantum gravity comes from ads/cft. There are many possibilities, not just the old "everything is made of tiny vibrating strings singing along".

Whichever way you put, ads/cft is just to remarkable to brush off. At least that's what I think. Typical unification pales in comparison.
I mean, on the one hand, what, everything is not made from point particles, but from strings. ok. On the other, you have two completely different theories living in different spaces and being equivalent. That's the real wow.

15. **Pawl**
February 11, 2010

Gigel,

As duality between quantum field theories, holography is interesting; as a statement about gravity, is on far shakier ground.

In fact, the history of the subject is something of an object-lesson in the point I was making. It was originally introduced by particle theorists who wanted to regard black holes as just another species of particle — and showed little awareness of the differences in the causal structure of black-hole space-times from others. This led to misunderstandings which persist to this day, and also made the physical basis of the theory fuzzy.

Its recent manifestations are still rather fuzzy. (There is, for instance, the over-arching question of what the entropy really is and whether one can meaningfully speak of the entropy of a general gravitational configuration. There are also serious technical problems.)

Some good might come out of it, but what I am arguing for here is the necessity of an assessment which fairly faces up to the problems. Its proponents would do well to demonstrate their own critical awareness by bringing these forward.

16. **gigel**
February 11, 2010

And besides, the theory really encourages you to look at many different topics, including in mathematics. I'm not sure why anyone would call that "wasting time". Mathematics is useful to anyone studying anything, and I mean anything, not necessarily science.

I'm pretty sure you can put all the math and techniques to good use in other places if string theory were to somehow fail (though there's no way that could happen since it's intrinsically related to YM, in at least two vastly different ways).

Pawl, I'm a very big fan of being critical and pointing fingers at the problems. But no one is hiding them, like some people would say. I mean, most papers have a dedicated section at the end on remaining open problems. In fact, that's probably everyone's favorite section of a paper. What more would you want?

Sure, you probably won't hear what the difficulties of ads/cft are in popular press, if that's what you're referring to. But people do know about them. And how do you get people to solve them? You obviously don't hold a talk and start with "so we have this thingy, but man it has so many problems! so, any volunteers to help us out?". You would probably want to say something like "ok we have this thing, we could use it for this and this and this. who wants to develop it further?" Notice the difference?

I think this is pretty much valid in all fields of science. Think of eg quantum computing, which would be the extreme example.

The "publish or perish" thing probably isn't helping much either. If people need to put out a few papers per year, they don't really have much time left to tackle the truly formidable conceptual problems. A "we rederive the relations of aaa et al using absolutely nothing new" still sounds better than "ya, i thought really hard about this for a couple of years, I even asked some friends, but didn't get anything. sorry. next time, I promise". But of course everyone knows about this. Not an easy to solve issue.

In the meantime, what's wrong with some undergrads having fun while they still can 😛 . Either they'll like it and be happy to have found something worth their time and effort, or they'll smell something fishy and cross out a potential research topic early on. It's not like we're learning something completely useless. The majority of people in het are still into strings, so it's sensible to prepare undergrads for the outside world accordingly. As in absolutely any other field.

17. **JC**
February 11, 2010

On a slight tangent, are there any universities which officially offer a regular undergraduate course on quantum field theory?

I suppose if such an undergraduate course on qft is offered, the easiest way to do it would be to do canonical quantization of the scalar fields with tree level and 1-loop calculations of phi^3 interactions in 6 dimensions.

18. **Pawl**
February 12, 2010

Gigel,

You bring up a number of points.

(1) Sure, mathematics is useful. It's not the same as foundational physics, however.

(2) You want to be "a big fan of being critical," but you also would, it seems, view it as a surprise if string theory "somehow turned out to be wrong;" you cite connections with Yang-Mills. This is mixing mathematical results and fundamental physics. The math is reasonably secure; the idea that we have reason to be less than skeptical of string theory as a fundamental physical theory is not supportable.

I really have to underline how gross this is. It is extremely hard to get physics right in (for example) an energy regime which is half an order of magnitude beyond what has been experimentally investigated; there is, for example, no consensus at all on what results will emerge from the LHC. We're usually simply not clever, or imaginative, enough to guess; nature surprises us. If (as in string theory) one aims to describe the Planck scale — well, it's good to be ambitious, but simple experience shows that it is far more likely one will get it wrong — and seriously wrong — than right. Any claims of naturality of beauty that string theory has are no defense here: beautiful theories are (to borrow a phrase of Haldane's) slain by ugly facts all the time.

I've limited myself to generalities which would apply to *any* speculative fundamental theory, but I could also list specific reasons for being especially dubious about string theory.

(3) Yes, papers mention open problems. It's the problems they *don't* mention which I'm concerned about. I don't think the authors have any conscious intent to conceal; it's rather that they're unaware of the problems, or of how serious they are.

(4) I was not referring to difficulties with ADS/CFT, but to two other things. The first were the original arguments (ca. 1993?) about holography and black holes, which depended heavily on supposing CPT invariance held but didn't take into account that the time-reverse of a black hole is a white hole. (This mistake is still being made in somewhat different contexts.) The second was the cavalier assignment of entropy to regions in space-time.

(5) It's important to be quite frank with students (whether research students or undergraduates) about the chances of success (in the sense of progress on fundamental physics), and not just to be a cheerleader.

    February 12, 2010

    No study of string theory is complete without reading the introduction to [hep-th/0204131](hep-th/0204131), in particular subsection 1.6. And keep in mind that the author is the founder of the string theory group at Rutgers.

20. **Anonymous**
    February 12, 2010

    With reference to "some encouragement to continue blogging", I follow your blog and Jester's for the great "executive summaries" you both provide of what's going on in high energy physics.

21. **Paul Wells**
    February 12, 2010

    Peter,

    I take you point – but how are you going to attract people to people with just the same old courses on Electrodynamics, Optics and Thermodynamics ?

    After my first degree i had no exposure to GR, weak interaction etc other than what I read for myself.

    I think that there is a need to compromise academic rigor here against the need to give people some education about what the cutting edge of Physics is about.

    Otherwise people might end up going into Engineering or (gulp) even Biology…

    I get frustrated when I see Physics taught as if it were Ancient Greek rather than a lively active discipline.

22. **Paul Wells**
    February 12, 2010

    [sorry meant people to Physics of course]

23. **Peter Woit**
    February 12, 2010

    Trent, petergreat,

    What I'm working on is still the idea outlined in toy-model form in

    http://www.math.columbia.edu/~woit/brstdirac.pdf

    I haven't finished that paper since I'm still not quite clear on where it is going and I want to understand this better before finishing it. The next step is to understand the case of affine Lie algebras, and the relationship to what people have done in geometric Langlands. I've been learning a lot about this, especially about the D-module approach to representation theory, and this has given me a new perspective on this material. I'm quite excited about this, but still in the middle of it, hope to have an updated and maybe final version of the paper this spring, we'll see…

24. **Peter Woit**
    February 12, 2010

    gigel/Paul,

    I'm in no way opposed to teaching material beyond 19th century physics to undergraduates. If they graduate without being exposed to some version of Noether's theorem (i.e. that symmetries imply existence of notions of energy, momentum, angular momentum, charge… and their conservation), that's educational malpractice.

    Also not against fun. There are a lot of ways though to choose interesting and challenging material about modern physics to try and explain, without picking a 40 year old set of speculative ideas that haven't worked out and are in the process of being abandoned by the community. If you want to present something cutting-edge that is going to get ambitious undergrads a jump on hot topics in current research, string theory is a peculiar choice these days.

25. **joel rice**
    February 12, 2010

    It might be fun and useful to have a course on
    "what is screwed up with the Standard Model".

26. **gigel**
    February 12, 2010

    Pawl,

    It would be very hard to believe that all the results from ads/cft and twistor string theory are just mathematical coincidences. It is much more likely there is something going on which we still have to uncover completely. The fact that ads/cft is a complete equivalence really does say you can't kill string theory.

    But also, you can't really make the distinction between "mathematical" connection and "physical" connection as you suggest. The Standard Model is also just a mathematical connection with nature. It's a model, a translation of nature to our own language. It's good because some calculations you do with it turn out correct. String theory might be a different translation of Yang Mills. In one of its manifestations.

27. **Pawl**
    February 12, 2010

    Gigel,

    You seem determined not to distinguish between mathematical and physical successes. While physics is indeed cast in terms of mathematics, there is a huge difference.

Physics makes testable connections with the world in ways which are as precise as possible. String theory — as a fundamental physical theory — has no successes at all in this regard.

The position you have been taking is indeed one which has at times existed within the string-theory community. However, it amounts to an abandonment of the basic goals of physics, and the motivation for this radical step is nothing more than aesthetic attachment to a “theory” with no phenomenological successes!

28. **Peter Woit**
February 12, 2010

Pawl, Gigel,

Please, enough of the tired pro/anti-string argumentation, unless someone has something new to say.

29. **CWJ**
February 12, 2010

I don’t know what other advanced elective courses Rutgers offers, so it’s hard to put this in context.

As a physics professor in a small department, I occasionally get students coming to me expressing interest in string theory. Tellingly, they are rather intellectually incurious about the steps before they get to string theory. They’ve heard of GR, maybe even taken a class in it, but they haven’t really heard of quantum field theory (due to budget cuts we can’t offer such a course), and they certainly haven’t heard of gauged field theories. And they seem completely uninterested in such topics; they seem to view gauged field theories, not as the theoretical triumph that they or, not as a rich field of ongoing investigation, but as a pesky inconvenience on their way to becoming the next Einstein. There’s no real intellectual curiosity; they just want to be the next Einstein.

I can see string theory (or LQG) as being part of a more general survey course, which would include QFT, the standard model and gauged field theories, and ending with quantum theories of gravity. And if Rutgers or LSU do this but call it a “string theory/LQG for undergraduates” to draw in more students, more power to them.

30. **JC**
February 12, 2010

CWJ,

This has been going on for more than 20 years. Back when I was in grad school, it was common to find grad students (and some highly motivated undergrads) who had the mentality that quantum field theory, gauge theories, classical GR, etc … were pesky “inconveniences” in their quests of being the next Einstein. I remember a few students who didn’t even bother taking the quantum field theory courses, and went straight to studying stuff like string theory papers (various Schwarz lectures), and later the Green, Schwarz, Witten superstring theory books.

31. **Paul Wells**
February 13, 2010

Well Peter, my undergraduate degree didn’t cover Noether’s theorem. The address is University of Cambridge, Cambridge, U.K if you want to sue them for educational malpractice :-).

I think universities in general do a lousy job of keeping the interest of their students in Physics. I don’t believe final year undergraduates can’t cope with the basics of GR, Higgs mechanism etc. The details can wait for grad school.

Most undergraduates don’t become Physics professors. I think it is a disservice not to give them at least a flavor of Physics developments after 1915. Maybe things have improved since 1985 when I graduated but I doubt it.

By the way I think the (well-deserved) success of your book and others like it show there is a huge demand for this kind of course. I know Feynman tried it with QED. Maybe not strings but at least a few Feynman diagrams and an outline of the standard model.

32. **JC**
February 14, 2010

Paul Wells,

Several of my former colleagues have taught undergraduate particle physics courses using the Griffiths textbook on elementary particles. Their courses typically covered tree level calculations in the Standard Model, along with whatever background stuff that was needed to understand such calculations (ie. Higgs mechanism, SU(2) and SU(3) groups, Dirac equation, etc …). They didn’t bother going extensively into renormalization, other than the simple minded approach taken in the Griffiths book.

In the end, it was essentially a course in calculating Feynman diagrams by being given the Feynman rules, without going through much of the quantum field theory formalism. Not entirely satisfactory, but it was the least they can do without making the course too difficult.

33. **Chris Oakley**
February 14, 2010

Paul,

You may be talking about Cambridge specifically as the Physics course you did is embedded in the Natural Sciences Tripos which -even if you take all the physics options – has a lot of non-physics stuff in it, giving you less time to (e.g.) study the Higgs mechanism. In the first year of any physics course one has to do a lot of calculus, linear algebra and other mathematics, plus thermodynamics, electromagnetism and classical mechanics. I don’t see how one can avoid that. In the second year, one needs to study quantum mechanics, atomic physics, nuclear physics, statistical mechanics, solid state physics, special relativity, more electromagnetism and optics. Again, I don’t see how one can avoid that. So – maybe in the third year, bearing in mind that all the lab work will be a commitment throughout – one could get more up-to-date. At Oxford the particle physics 3rd year option (at least in 1980) got us pretty up-to-date, but it was an experimentalists course as relativistic QM and QFT were not taught. Neither was GR. I am in two minds about teaching GR to undergraduates, but certainly think that the theory of continuous groups should be taught – and preferably before even one starts on quantum mechanics. One should know what SU(2) is before studying angular momentum in QM. Noether’s theorem? I am not sure. That would have to be embedded in a QFT course – and to do that in sufficient depth would require cutting out a lot of important other stuff.

34. **Trent**
February 14, 2010

Peter, I can’t believe you said this:

”

February 14, 2010

> Noether’s theorem? I am not sure. That would have to be embedded in a QFT course – and to do that in sufficient depth would require cutting out a lot of important other stuff.

Noether’s theorem appears first in classical mechanics. It can be explained in 5 to 10 minutes to students who already have studied cyclic coordinates and their relation to conservation theorems. Proving it requires only a chain-rule differentiation and takes just one line.

I’ve always wondered why textbooks like Goldstein or Landau and Lifshitz do not even mention Noether’s theorem, whereas they spend a lot of space on much more abstruse topics with many fewer practical applications.

36. **JC**
February 14, 2010

anon,

re: Noether’s theorem

We were given Noether’s theorem as a homework problem in an undergraduate Lagrangian mechanics course.

37. **JC**
February 14, 2010

Chris Oakley,

Maybe I should have went to Cambridge for undergrad. 😉 Back when I was an undergrad, it felt frustrating not doing any modern physics stuff earlier in the curriculum.

For example, we didn’t do any quantum mechanics until the tail end of junior year (ie. third year). That junior year quantum course basically covered modern physics topics (ie. Planck, de Broglie, Bohr, etc …) and some simple solutions to the Schroedinger equation (ie. free particle, square well, Heisenberg inequality, etc …) at the end of the course.

For most of the first three years of physics undergrad, it was largely classical physics done in successive courses with more mathematics added in each year. So by the time we took that first quantum course in junior year, we already had taken: 2 courses in classical mechanics (ie. with and without Lagrangian mechanics), 1 course on electromagnetic theory (ie. solving Laplace’s equation), 1 course on complex analysis (ie. resides, Cauchy’s theorem, etc …), 1 course on partial differential equations, 1 course on physical optics (ie. solving Maxwell’s equations, etc …), and 1 course on classical thermodynamics + heat transfer (without any statistical mechanics).

I suppose learning all that mathematics and classical physics stuff in extensive detail before ever doing quantum mechanics, does take some of the “deus ex machina” out of quantum mechanics. (For example, the analogy between Poisson brackets and the commutators of operators in quantum mechanics). But unfortunately it didn’t leave much time for the more modern courses like particle physics, nuclear physics, solid state, etc … By the time we were able to take the particle and/or nuclear physics courses in senior year (4th year), it was the last semester before we graduated. We all had a bad case “senioritis” by then. 😉

I remember several former classmates I knew in my freshman undergraduate year who decided to transfer to another university, because our university didn’t do any “cool” modern physics stuff in sophomore or junior year (2nd and 3rd years). They were very impatient for the most part, and wanted to do quantum mechanics early on. Years later I found out a few of these same former classmates who transferred out, were also into string theory years later. They were the same ones who thought that it was a brilliant idea to skip the quantum field theory and general relativity courses, and go straight to reading string theory papers.

I ended up taking the particle physics course (along with the nuclear course) in the last semester of senior year. It was largely an “experimentalist” course, where quantum field theory and relativistic quantum mechanics were not covered at all. At the time it seemed kind of disappointing.

38. **changcho**
February 16, 2010

“If they graduate without being exposed to some version of Noether’s theorem (i.e. that symmetries imply existence of notions of energy, momentum, angular momentum, charge… and their conservation), that’s educational malpractice.”

Well, I didn’t see that as an undegrad; had to wait to become a grad student to see Noether’s theorem.

39. **Amos**
February 16, 2010

Peter, on the BRST point: You said here, and I’ve seen a few other references that seem to track your language, something along the lines of, that BRST “comes close” to explaining why there are fermions. Could you explain what you mean by that? I’ve been trying to understand it, but its clearly far deeper into the math than I’ve been able to penetrate.

40. **Tom**
February 17, 2010

@JC says: “On a slight tangent, are there any universities which officially offer a regular undergraduate course on quantum field theory?”

IIRC, Caltech offers Ph205 (?) which I’m told is basically a QFT course.

Undergrad physics majors who stayed the course — ie, didn’t change majors halfway through their years — and kept pace on their math courses, would be taking Ph205 in 4th year.

Ph205 was nominally a graduate course, but beginning graduate courses were also populated with 3rd/4th year undergrads.

41. **JC**
February 17, 2010

Tom,

When I was in grad school, it was not unusual for highly motivated undergrads to take graduate level courses. When I took quantum field theory in grad school, there were several undergrads enrolled.

With that being said, what I was asking in my previous question is whether there was an undergraduate course on quantum field theory which was not cross-listed with the graduate qft course.

Now that I thought about it more, I suppose such an "undergrad qft" course could in principle cover quantum electrodynamics done using canonical quantization. What I had in mind was Sakurai's "Advanced Quantum Mechanics" book.

42. **DaveB**
February 18, 2010

When I was at UMIST in the mid 1990s we touched on qft in the 2nd year, and there was an optional particle physics course in the 3rd year.

43. **Me**
February 18, 2010

Now that I thought about it more, I suppose such an "undergrad qft" course could in principle cover quantum electrodynamics done using canonical quantization. What I had in mind was Sakurai's "Advanced Quantum Mechanics" book.

Thats what I had in my 4th year of undergrad. Renormalization was done using dimensional regularization. Almost no loops but we had some SM stuff.

44. **JC**
February 18, 2010

Me,

We never got around to renormalization in senior year undergrad quantum mechanics. The furthest we got was Dirac's equation and various solutions (ie. plane waves and hydrogen atom).

45. **Peter Woit**
February 18, 2010

Amos,

On a very vague level, one can speculate that, since we use fermionic fields (valued in the Lie algebra of the gauge group) to deal handling gauge symmetry (a la BRST, or Fadeev-Popov), physical fermionic fields might also have an interpretation as a means for dealing with some symmetry. The natural symmetry to consider is diffeomorphism symmetry, or local translations. These fields though are spinor valued, which makes them rather different. I've played with various ideas for trying to do this, have some new ones I'm working on in the context of the BRST=Dirac cohomology framework. The fact that I still don't completely understand this is one thing keeping me from finishing the BRST-Dirac paper.

46. **Me**
February 18, 2010

JC,

My degree was a 5 year degree late previous century so this wasn't even in my senior year. (though for some people it was).

We barely did renormalization but I sure remember dimensional regularization and people being baffled about integrating in d+e dimensions where d is an integer an e->0.

We did basic QED and some SM. Mainly calculating tree-level approximations to weak-force related events.

It wasn't QFT as we later studied since things were motivated from Dirac's equation and then upwards and not starting from a Lagrangian and QFT and deriving the rules. Things were very heuristic.

I didn't like it very much but we certainly did some long calculations…

47. **Dave Nott**
February 21, 2010

Does anybody have web references for the twistor reformulation of Yang-Mills in terms of contour integrals over Grassmannians?

48. **Peter Woit**

Completely Off-Topic

February 12, 2010
Categories: Uncategorized

I'm heading off to New Orleans tomorrow morning, will be there for Mardi Gras, back next Wednesday. Light to no blogging for the duration.

Since I'm already off-topic, I can't resist promoting my friend Alexei Karamazov (aka Mark Ettinger)'s show, which opened last night here in New York at the Minetta Lane theater. The Flying Karamazov Brothers travel the world with a wonderful show that could best be described as demented vaudeville featuring some of the best juggling around. They're here in New York City for the first time in many years, through March 7. For one of the first reviews, see here. Some of their previous shows featured references to string theory, this one doesn't. Go to their web-site to learn more, then go buy tickets and help me recoup some of the money I put up as an investor to help make this happen…

No Comments

The Little Book of String Theory

February 21, 2010
Categories: Book Reviews

Back from New Orleans, and there are now three books I've read recently that I'll try and write reviews of. The first is The Little Book of String Theory, by Princeton's Steve Gubser. The author has a web-site for the book here, and the introduction is available.

While trying to cover a huge amount of complicated material, the book is quite short, with 162 pages of text, in a small format. Gubser has chosen to deal in a radical manner with the problem of deciding whose work to reference, and whose name to mention in connection with various discoveries. There are no footnotes or end-notes, no bibliography of any kind, and no mention of the names of any string theorists, or any living physicists at all for that matter. The history of the subject pretty much only appears in a few of Gubser's comments about early parts of his own career.

To somehow counterbalance its main focus on a highly sketchy treatment of an intricate and very abstract subject, the book periodically introduces some very concrete and explicit numerical computations, starting with a first chapter devoted to explaining in detail the equation $E=mc^2$. Unfortunately, none of these calculations have anything at all to do with the topic of the book, string theory. The central section of the book, about branes and duality, contains no such concrete calculations, but instead largely consists of page-long paragraphs recounting in words the intricate structures that occur in this subject. I find it hard to believe that anyone not already familiar with this topic will get much out of this kind of discussion.

Gubser intensively uses analogy to try and convey some understanding of the material, and has a fondness for analogies based on his mountain-climbing experience. Here's an example, based on a climb to the Aiguille du Midi:

> The ridge we climbed is famously narrow, heavily trafficked, and snow-covered. For some reason everyone seems to climb it roped up. I've never quite approved of the practice of climbing roped when no one is tied to a solid anchor. If one person falls, it's hard for the others to avoid being pulled off their feet. Usually I think it's better to trust yourself and climb unroped, or else anchor and belay. But I'll admit that I climbed the ridge roped up to my climbing partner like everyone else. My partner was a very solid climber, and the ridge isn't really that tough.
>
> In retrospect, I think that roped teams climbing a narrow ridge provide a good analogy to the Higgs boson, which is one of the things LHC experimentalists hope to discover.

The point here is that the top of the ridge is supposed to be like the unstable maximum at zero of the Higgs potential, but it seems to me that few are likely to get much real understanding out of this kind of analogy. Similarly, the chapter on GR and black holes opens with a chilling story about a fall while climbing near Aspen, but it's hard to see how it adds much to the reader's understanding of the subtleties of the modern understanding of gravitation.

The book is advertised as "a non-technical account of string theory and its applications to collider physics." The last chapter is about recent attempts to use AdS/CFT as an approximate calculational technique in heavy-ion physics. This is Gubser's specialty, and he does a good job of giving a hype-free explanation of the state of the subject, for instance:

> The second reason why it is tricky to compare a prediction of the gauge/string duality with data is that the string theory computations apply to a theory that is only *similar* to QCD, not to QCD itself. The theorist has to make some translation between one and the other before he or she has a definite prediction to give an experimentalist. In other words, there's some fudge. The best attempts to handle this translation honestly lead to predictions for the charm quark's stopping distance that are either in approximate agreement with data, or perhaps as much as a factor of 2 smaller. A similar comparison can be made for viscosity, and the upshot is that the gauge/string duality produces a result that is either in approximate agreement with data, or perhaps a factor of 2 away from agreement.

While giving a reasonable account of the heavy-ion collision story, the description of the relation of string theory to the much more interesting question of what happens in proton-proton collisions at the Tevatron or LHC energy frontier is actively misleading hype. What he is really describing is supersymmetry, and while he begins with the arguable:

> Supersymmetry predicts many other particles, and if they are discovered, it would be clear evidence that string theory is on the right track.

he then goes on to claim that:

> What is exciting is that string theorists are placing their bets, along with theorists of other stripes, and holding their breaths for experimental discoveries that may vindicate or shatter their hopes…
>
> If it is found, many of us would take it as confirmation of superstring theory

There's no discussion of the issue of the supersymmetry breaking scale, or acknowledgement of the fact that string theory does not at all require this scale to be low enough for superpartners to be observable at LHC energies. The fact of the matter is that string theory makes no predictions at all about what the LHC will see, and Gubser's claim that string theorists have some sort of LHC prediction they are betting on is just not true. There is no bet here that string theorists can possibly lose: if superpartners are found, they are likely to trumpet this as "confirmation of string theory", but if not, they'll fall back on the accurate statement that string theory predicted nothing about this.

Throughout the book, Gubser is on the defensive about the issue of string theory's lack of predictivity, invoking highly strained and dubious analogies as excuses. One chapter begins with a discussion of Roman history and its effects on our present-day culture. He then argues that our many centuries remove from this history is somehow like the way string theory makes predictions at high energies, not low energies. I don't see the analogy (we have lots of evidence for Romans, none for strings), and in any case the problem with string theory is not that it can't predict what happens at low energies, but that it can't predict anything at any energy. In another chapter he compares current string theory unification models to the BCS theory of superconductivity, noting that the BCS theory doesn't work for high-temperature superconductivity. I'm not sure what to make of this analogy, since BCS is a successful theory, string unification models aren't. The only point of it seems to be the hope that something new will be discovered experimentally (analog of high temperature superconductivity), and some unknown version of string theory will describe it.

Like pretty much all of his colleagues at Princeton, one thing Gubser wants nothing to do with is the multiverse and the anthropic string theory landscape. While he explains the moduli-stabilization problem, the landscape and the multiverse are not discussed, and anthropic argumentation is dismissed with:

> Altogether, I find myself unconvinced that this line of argument is useful in string theory.

In the next posting, I'll write about another new popular physics book, one that I think is much better and much more readable, although it takes the West Coast multiverse interpretation of string theory as gospel, ignoring the views of Gubser and his Princeton colleagues.

Comments

1. **DaveB**
   February 22, 2010

   The idea of travelling on a ridge roped up with no anchors is simple. If one person falls off the ridge then the other is supposed to somehow find the willpower to jump off the other side, leaving both mountaineers hopefully alive but dangling a few metres below the ridge line. It isn't very good for ropes or nerves.

   I'm not sure if that has any relation to particle physics, but modern climbing ropes can hold strong forces, and are thin enough to be stringy…

   February 22, 2010

   Peter, I wrote this in a previous thread but maybe you missed it, I'm genuinely interested:

   Peter, I can't believe you said this:

   "
   Please, enough of the tired pro/anti-string argumentation, unless someone has something new to say.
   "

   What?!? Using this argument you could close your blog!
   If you mean the above genuinely why don't you fold the tent?
   I'm kinda confused.

   Trent

3. **Peter Woit**
   February 22, 2010

   Trent,

   Much of the blog is not about the string theory controversy, and I'd be quite happy if the fraction of postings on this topic went to zero. Unfortunately, there continues to be a very active campaign by string theorists to mislead people about the subject, and I think there's a continuing need for some sort of response to this. If someone else wants to take on this job, or if string theorists decide to stop the hype, I'll stop writing about this and will stick to other subjects (including the more positive aspects of the string theory story).

   In the meantime, I'll just keep doing what I'm doing, which is not to continually bring up this tired subject for no reason, but to respond to string theory hype as it appears.

4. **Tim van Beek**
   February 22, 2010

   What is the intended audience of this book? The author writes on his homepage that his book is supposed to be a non-technical account for the layperson, but in the introduction we find statements like

   "An example of an anomaly is that if there were particles similar to neutrinos, but electrically charged, then certain types of gravitational fields could spontaneously create electric charge."

   Or

   "When heavy ions collide head-on, it is even more chaotic than a proton-proton collision. it's believed that protons and neutrons melt into their constituent quarks and gluons."

   Aren't people who don't have a degree in physics scared away by this introduction?

5. **Peter Woit**
   February 22, 2010

   Tim,

   The level of knowledge expected of the reader is very uneven throughout the book, with an explanation of scientific notation one place, explanations that require a sophisticated knowledge of physics to understand in others.

   Note that I don't necessarily think this is a bad thing. I certainly did some of this in my book, and see nothing wrong with different parts of a book being accessible to different audiences, with some parts of the audience only able to follow parts of the book. In general, I think the best philosophy is to make explanations as simple as possible, but no simpler. For example, explanations that use analogies that are so over-simplified that they don't capture much at all of what the true story is seem to me a bad idea (the Higgs mechanism analogy I quoted in the post is an example).

6. **milkshake**
   February 22, 2010

   The problem with using such analogies in popular writing is that the people who are specialists in a highly technical field but are trying to explain it to the general public have hard time gauging the usefulness of their analogies and the clarity of their expose (because it is difficult for them to correctly approximate the thinking of a person within the intended audience). Then there is a normal problem with vanity, or the author gets carried away in a chapter that deals with his favorite subject, etc.

   Years ago when I was reading the "Elegant Universe" – a book that was generally agreed to be a good piece of popular writing – I remember that I was at times put off by what I felt was too verbose and even somewhat condescending explanation of simple stuff like photoelectric effect or curled dimension – but when the analogies and more detail would have been actually helpful in the esoteric later parts dealing with branes, holographic principle, dualities and M-theory, the expose became suddenly very sparse and reverted to "here is what was found" or " the current thinking is that".

   A specialist writing a popular science book – especially when he is new to this business – should at least distribute the manuscript copies to his friends and colleagues from other departments (including humanities) and ask them to participate in anonymous poll that would, for example, correlate the level of readers technical training level and professional background with their assessment of what they got out of the book, so that one could maybe re-adjust the detail level in particular chapters or rethink the used analogies. Of course working with a competent editor also helps.

February 23, 2010

I’m afraid that at some point the reason for these shortcomings becomes: “It’s just not that easy, I don’t have time for this, the book is getting too long, we have to stick to such-and-such a publication date, …”

It doesn’t help when the majority of one’s colleagues take a dim view of taking time away from professional activities to write books for a general audience.

A serious effort to write accessible material on these topics should be collaborative, so no one person has to take on too much of the job. Ideally, that would be happening in a medium like Wikipedia. Unfortunately, there is reality to contend with.

That said, perhaps the best reason to keep writing such books is that it sends the message that people in the field care enough to try, and thereby inspires young people (one hopes) to keep going into the field, or at least care to support it as taxpayers.

The Edge of Physics

February 22, 2010
Categories: Book Reviews

The second book about physics or math that I finished reading recently is Anil Ananthaswamy's The Edge of Physics: A Journey to Unlock the Secrets of the Universe. The author has a blog devoted to the topic of the book, as well as a web-site, which includes some wonderful photos of the experiments discussed.

The bulk of the book is devoted to the author's description of his travels to visit experimental projects around the world devoted to learning more about cosmology, particle physics, dark matter and dark energy. These include CDMS at the Soudan Mine in Minnesota, the Lake Baikal neutrino telescope in Siberia, the Very Large Telescope at Cerro Parranal in Chile, Mauna Kea in Hawaii, the Square Kilometer Array in South Africa, BESS at McMurdo Bay and IceCube at the South Pole in Antarctica, as well as the LHC and Planck satellite. Ananthaswamy is a quite good writer, and does an excellent job of describing the settings of the experiments and what they are trying to measure, as well as the scientists who are working on them.

Unfortunately though, he doesn't stick to the impressive experimental story going on, but wraps everything in a heavy dose of string theory/multiverse hype. None of the experiments he visited actually are capable of saying anything about string theory or the question of whether or not there is a multiverse. Most of them are investigating subjects like dark matter, which are of great potential interest, but have nothing at all to do with string theory or the multiverse. The only one for which there have been claims of such relevance are cosmological measurements of the spatial curvature of the universe, with Susskind claiming a prediction of the sign (but not the magnitude, experimentally it seems to be zero). This "prediction" actually doesn't work, see this paper.

It's too bad that among the string theorists Ananthaswamy interviewed, none included the many prominent ones such as Gross or Witten, or pretty much anyone at Princeton (see for example the book by Gubser reviewed in the previous posting) who could have explained to him the actual situation. So, if you're interested in what's going on at the experimental frontiers of this subject, this is a good book to read, as long as you skip all the parts about theory…

Update: Ananthaswamy describes here how decided to deal with the problem of writing about experiments, yet wanting to address string theory.

Comments

1. **neo**
   February 23, 2010

   Thanks for the reviews. I am always in the market for science books, so the info is useful. Sounds like Ananthaswamy's book is good for its descriptions of these mega-research projects, and I ordered it for that reason. I am used to skipping over string-multiverse hype–you have to do it every day reading the science press.

2. **a quantum diaries surivivor**
   February 23, 2010

   Hi Peter,

   If I recall correctly, Anil interviewed me for two hours over the phone three years ago… It was the beginning of the "new scientist – economist" higgs cry-wolf crisis. I tried to explain things to him but later saw them misreported. I do not know whether it was because he wanted to give more emphasis to the excess CDF was seeing or what.
   Of course, this says nothing of Anil's ability as a journalist. Just for the record…

   Cheers,
   T.

The Quants

February 25, 2010
Categories: Book Reviews

The third book I recently read that has some math or physics content is Wall Street Journal reporter Scott Patterson's The Quants: How a New Breed of Math Whizzes Conquered Wall Street and Nearly Destroyed It. It's a very lively and entertaining telling of a story which features quite a few mathematicians who have gone on to make (and then sometimes lose) absurd amounts of money using mathematical models to try and exploit market inefficiencies. Jim Simons and his large group of mathematicians and other Ph.D.s at Renaissance play a significant role, and among other mathematicians who make an appearance is Neil Chriss, co-author of Representation Theory and Complex Geometry, one of the most well-known books on geometric representation theory (now available as a "Birkhauser Classic").

Patterson's story emphasizes heavily the relationship to gambling. He writes extensively about Ed Thorp, who developed the theory of card-counting, did well with this at casinos, then moved on to the hedge fund business. Just about everyone profiled in Patterson's book is described as having read and been inspired by Thorp's 1962 book on card-counting (*Beat the Dealer*). Many of them are serious poker players, and the book opens by describing the scene at the one of the recent Wall Street Poker Night Tournaments. These are yearly events (Chriss and Simons are among the organizers) that bring together quants and professional poker players to play high-stakes poker, with proceeds donated to Math for America.

The subtitle of the book puts the blame for the financial crisis on this kind of activity, but there's not much evidence given to justify this. Most of the book is about various hedge funds, and the stories of failure are pretty much the same old story of Long Term Capital Management's failure back in 1998. Finding some sort of market inefficiency and exploiting it tends to work for a while, but sooner or later either others start doing the same thing or patterns change, sometimes very quickly. If one has gotten greedy and started using too high levels of leverage, one can get in trouble fast. The best-run hedge funds (for instance, Renaissance) managed to stay out of trouble, others didn't. How much of a public problem all this is remains unclear. To a large extent the failures just lead to some rich people (and universities like Harvard) becoming less rich, while some hedge-fund owners and employees see their income go down but get to keep the fees earned while they were taking too much risk. It's very clear why a lot of mathematicians and physicists go into this.

None of this though seems to have had a determining part in the disastrous financial crisis of recent years and its ongoing effects. The book has little to say about a more significant failure that involved a different group of quants, those responsible for the bad mathematical models used to justify the mortage securitization business. From what I can tell, there the story is that if there's a lot of money to be made creating a financial instrument carrying large risks obscured by complexity, it's not hard to find people willing to help you sell it by creating bad mathematical models of its behavior.

The story of *The Quants* is a remarkable one, whether or not the people described have some responsibility for the current state of the financial industry and the dangers still embedded in it. While reading the book I couldn't help thinking that it would be a good idea if the best of them would play a little less poker and take on another pro bono task, that of coming up with a good understanding of the current pathologies of the financial system, and models useful in the task of figuring out how to change it to something more socially desirable.

Comments

1. **milkshake**
   February 25, 2010

   …when you have good understanding of the current pathologies of the financial system, the natural thing is to try to make money from it for your fund.

   Do you expect people from Renaissance to go public with their models – or to complain to the regulators that certain trading schemes shouldn't be allowed?

2. **chris**
   February 26, 2010

   very well said. this pretty much sums up the defect of our current system.

3. **Frank Quednau**
   February 26, 2010

   @milkshake
   What do you mean by "the natural thing" ? Altruism is also a "natural thing". "Socially desirable" would be to expose those pathologies to work towards a system that does *not* only work for a few and leaves the major part of roughly 7bn. people in its wake.

4. **AJ Scruffles**
   February 26, 2010

   I'm waiting for the paperback to come out in England – but what i'm interested in is the implication/accusation that quantitative analysts were responsible for the crash.

   I recall a recent television program on the crisis that used NASA's imperial/metric mistake as a framing analogy before cheekily adding that some of the people who had designed these faulty financial products were themselves rocket scientists. You wonder if there are moves to scapegoat the quants or whether it's just an interesting angle.

   Also, you allude to the social value of this kind of work. In the UK the most common destination for science graduates (in applicable fields) is banking. The discrepancy between employment opportunities and starting salaries in the financial sector to any other is (or was) mind boggling. I've never really seen this issue raised in the mainstream media. Perhaps it's less apparent in the U.S. but it's surely indicative of a wider social problem.

5. **Anonymous**
   February 26, 2010

   @above: Indeed I've seen many people graduating in math, material science, neuroscience, biology and so on getting into banking. I'm simply amazed at how banking in the UK is such a large industry that absorbs a considerable proportion of all science graduates.

6. **mathphys**
   February 27, 2010

   "Representation Theory and Complex Geometry" is based on lectures that V Ginzburg gave as a visitor at the U of Chicago before he eventually became a professor there. N Chriss was a graduate student who took lecture notes that formed the basis of the book.

7. **Chris Oakley**
February 27, 2010

LTCM blew up because they started getting into products (e.g. merger "arbitrage" and gilt swap spreads) that they did *not* have a mathematical model for worth the name. In the end it turned out that the LTCM math PhDs – despite having larger genitalia (financially speaking, of course) – were *less* good at the seat-of-the-pants trading done by the other market players.

I agree with Peter that the quants who did the *real* damage were not these (relative) small-time gamblers, but those whose models gave AAA ratings to horse-excrement sub-prime mortgage bonds. These were sold in the trillions to pension funds, insurance companies and sovereigns like Iceland, and the fallout from their crash will be felt for decades to come.

8. **george harrison**
February 27, 2010

like string theory, is not the problem that the mathematical models are incapable of prediction, but only capable of wealth transfer?

9. **Peter Woit**
February 27, 2010

George,

I don't think the situation is at all like string theory. Mathematical models in finance make very definite (although statistical) predictions. The problem with many of the bad models wasn't that they didn't predict anything, but that they made specific predictions about levels of risk that were just wrong.

String theory isn't a very effective means of wealth transfer, typically transferring rather puny postdoc salaries to a bunch of people, more substantial senior faculty salaries to a few. On the financial industry scale though, all these numbers would be rounding errors…

10. **Haelfix**
February 28, 2010

I have a few quant friends, and the story I heard was a little different. Contrary to media reports, most of the models were *not* wrong. Including some of the highly publicized ones. Many of these were optimized for rather short timeframe corrections.

Instead they were really very accurate, which is a large part of the problem and caused a bit of a selffulfilling prophecy. The models had a number of fallbacks to prevent catastrophic loss. They also had well defined regimes of applicability where the model was supposed to be valid.

What happened was within the span of about a week, the market entered a phase where one by one, the fallbacks of the models triggered (not necessarily a big deal at first glance), and then the regimes of applicability were passed.

At that point, you had firms that had been basing a large percentage of their forecasting and risk assessment on these things, all of a sudden lose complete predictive power. This caused a panic, which triggered more rapid selling and more models to trigger selloffs (too much redundancy on systems that are too similar).

Economically, the panic occurs not necessarily on fundamentals, but b/c the computer all of a sudden returns negative infinity within a timespan that is much too quick for rational human activity and assessment. In short, what should have been a much more gradual correction, instead turns into a near world destroyer.

But I think the point is, its not the computers or the programmers fault really. The CEO's just didn't listen to the fine print, nor did they appreciate just how herdish wall street really is. Moreover the best models arguably saved their companies millions of dollars by getting the firms to remove their money or rethink their risk exposure before the real selloff's took place.

11. **Peter Woit**
February 28, 2010

Haelfix,

Thanks, although this "the model was fine, people using it just needed to read the fine print which said there was a significant probability it might blow up in their face" argument sounds a lot like someone covering their ass ex post facto.

From what I can tell, there were a wide range of models in use, some of which did what they were supposed to (Renaissance's Medallion fund doesn't seem to have done too badly). Others seem to have been just absurdly bad, including those used to create many AAA-rated mortgage backed securities.

12. **SteveM**
February 28, 2010

LTCM collapsed primarily because they were massively overleveraged and because they had way too much faith invested within a piece of solvable stochastic analysis that is emperically wrong since markets are not perfectly Gaussian. It is also ironic that Merton and Scholes were harsh critics of the Kelly propertional betting criterion, which is essentially a compromise between optimization of gains, relative to a given edge, while minimising risk. Ed Thorp on the other hand used the Kelly criterion as a guide when he played blackjack so that he would not overbet and wipe out his edge. If you have $2000 in liquidity or capital at the blackjack table for example, you can't bet more than $20 a time or else volatility or negative fluctuations can wipe you out and ruin the player edge from card counting–its true for a modest blackjack bankroll and its true for a massive hedge fund portfolio. Thorp's hands-on experience in blackjack seemed to have made him very risk adverse when he subsequently ran his successful hedge fund. Simons and his crew did'nt actually build the Medallion fund at the heart of Renaissance: this masterpiece was constructed by the brilliant Elwyn Berlekamp and Berkeley number theorist, the late James B. Ax–hence "Axcom Trading"–both of whom I guess vastly underestimated its power when they sold everything off to Simons. Interestingly, Kelly, Thorpe and Berlekamp are all very closely associated with Claude Shannon of Bell labs, the father of information theory.

13. **SteveM**
February 28, 2010

Haelfix, the quants who constructed debt instruments like mortgage-backed securities have to take some blame for the current mess but only some since they were still quite a way down the "food chain". But regardless of how good the models might have been, in reality there was simply no way to check the quality of hundreds of thousands of mortgages in these pools or whether the reality behind that triple-A mortgage rating on a six-bedroom luxury villa was that it had been sold to a Walmart's shelf packer. The people who pushed these insane subprimes also have to take a lot of blame as is everyone in the mortgage-backed securities chain. I guess sheer greed just got in the way.

A huge part of the mess is also due to the "American Dream" mentality: the average American (and European) consumer living way beyond their means on credit, fuelling a lifestyle and standard or living they had'nt actually earned but which they thought they were entitled to almost as a birthright. Asset bubbles, especially real estate ones, are always due to too much credit so also blame Alan Greenspan for adjusting interest rates and flooding the system with easy money/credit and creating the credit superbubble in the first place; of course, one reason for doing that was the fear that markets would collapse following the meltdown of the aforementioned LTCM. Also when LTCM got bailed out others realized they could also take massive risks and also get bailed out if it all went wrong–a win-win situation for them and the start of the "too big to fail" mentality. Also, Clinton's financial advisers in the late 90s, who helped dismantle the Glass-Steagall banking act of 1933 to "free things up".

The US is now in such a crushing black hole of debt it has forever past the "horizon" of ever returning to a vibrant free-market economy–all is can do now is default on its debt or inflate/hyperinflate it away, with dire consequences. And then there is Greece and the Euro and of course China…OK I won't rant on:) But this giant Ponzi scheme of moving money, printing money, credit, selling debt, buying debt, stimulus packages, massive bailouts and TARP is now the ultimate bubble and it simply can't be sustained–the worst is probably still to come.

14. **Chris Oakley**
March 1, 2010

> LTCM collapsed primarily because they were massively overleveraged

Agreed.

> and because they had way too much faith invested within a piece of solvable stochastic analysis that is emperically wrong since markets are not perfectly Gaussian

Not agreed. Let us take the case of merger arbitrage – one of the things that killed LTCM. Company A decides to buy company B, exchanging x shares of B for a share of A. That means that if the share price of company A is pA, then the share price of company B should be pA/x, right? If it is not then there should be a free lunch: if it is lower then buying B and shorting A will give you money for nothing and if it is higher then buying A and shorting B will give you money for nothing. This is merger arbitrage, and it is not rocket science. The problem is this: what if they change their minds about the ratio before the deal goes through? Mathematical models will not help you here (eavesdropping on board meetings would, but that is illegal). The other major thing that killed LTCM was gilt swap spreads. The 5-10 year interest rate for interbank loans in sterling was historically much too high relative to the 5-10 year interest rate for UK government debt (gilts) and did not reflect the relative credit quality. LTCM, along with everyone else, knew that this difference had to come down (this difference was determined by markets, and more specifically by the fact that many investors were only allowed to buy government debt, forcing gilt prices up and therefore yields down). LTCM were right – eventually the spread did reduce, but not quickly enough, and in the meantime their convergence trade helped to bankrupt them. Unless they could have known what every player in that market was doing, and going to do, they could not only guess when the convergence was likely to occur. Mathematical models, again, would not have helped.

15. **Gene Caldwell**
March 1, 2010

I think part of the problem was that the input parameters to the models representing assumptions about risk were provided to the modellers by the business and finance people.

16. **Eric Dennis**
March 1, 2010

I think it must be satisfying to some people to speculate that quant finance models — whether for algorithmic trading or mortgage securitization — have the power to cause the kind of economic upheaval experienced over the last two years. In fact, they don't have that power. They were a secondary factor in it.

The manifest proximate cause of the contraction was too much bad debt, especially mortgage debt. Models didn't generate this debt. The bad debt was assumed because the prices for it, known as interest rates, were too low. Interest rates were too low because the Fed decreed them to be so (negative, in real terms) for an extended period after the dotcom implosion (itself a previous iteration of the same scenario). It would be valid to impugn the macroeconomic models consulted by the Fed in making their decisions, but these models are really just an impotent formal rationalization for the back-of-the-envelope Keynesian/Monetarist guesstimates that actually drive monetary policy.

Securitization was simply a new mechanism by which the excess green paper printed by the Fed (i.e. created out of thin-air when the Fed bought securities in "open market operations") was goosed into the larger economy. The new mechanism made the process easier, but it didn't create all the bogus liquidity. The Fed did. It is true that models used by the ratings agencies to declare a lot of this garbage debt perfectly safe are also nonsense, premised on naive assumptions of macroeconomic stability. That certainly didn't help things. But everyone knew these models were nonsnse to begin with. That's what you get from quants (or anyone else) working for the ratings agencies, which are more creatures of government than of Wall Street due to their special status as an oligopoly mandated by federal regulation.

17. **MBS Quant**
March 3, 2010

There is a fundamental misunderstanding here. The reason the bond market blew up (and have since recovered) was mainly because of a massive "depricing" (spread widening) during the crisis across the board, way over and above fundamentals (which MBS quants concentrate on).
Structuring 101: Suppose you have a 1000 subprime mortgages, each at 10% interest and $100,000 original balance. Your model tells you that at worst 30% of these loans will eventually default. Now you create two $50 millon bonds A and D backed by these loans. You structure the bonds so that A will pay the buyer 500 of all 1000 cashflows (principal and interest) that come in every month, and bond D gets the remaining of the cashflows each month. If your model is right, as far as A is concerned defaults do not matter, you have a low risk bond, since it would take more than 50% of the loans defaulting for this bond to lose a penny. This is how you shift collateral default risk from bond A to bond D. Yes the collateral is garbage but statistically only half or less of it, and that is key. Based on this risk profile bond A gets an AAA rating and since it is paying a nice 10% interest, it trades at a premium. Bond D, on the other hand, holds all the collateral risk and it gets (say) a D rating. D trades at a very low price (high yield) and is bought by "savvy" investors who (1) want the very high yield and/or (2) are betting on their belief that your model is too pessimistic (i.e., they believe they have a better default model).
Now the housing market tanks and many of the 1000 loans start defaulting at a high pace, looking like you will indeed get 30% or maybe even 50% defaults. Note that unless defaults reach 51%, bond A will receive the same cashflows. What happened next was that bonds like D got crushed, as they should, but the market dumped all MBS bonds, and bonds like A (and all bonds for that matter) got also crushed in the process, because of supply and demand. Nobody wanted to hold any of these things. Since then, the market, specially for bonds A-like, has greatly recovered. A lot of hedge funds loaded up on A-like bonds when they got spectacularly cheap, priced way below their fundamental value.
MBS bond prices come from 4 factors: cashflow structure, modeled losses, modeled prepayments, and a fourth factor which is a "technical spread" (or how much investors are willing to (not) pay for the perceived un-modeled risk, liquidity, demand/supply of the bond). MBS "quants" concentrate on modeling the first 3, the fourth one was historically contained and this time it blew out (dragging down bonds like A) because of unprecedented market panic and hysteria (spiraling as institutions were forced to mark(price) to market their bond portfolios). Yes, default models are based on history, and it is true that modelers now understand that the fourth component can blow out and bonds may trade like stock, regardless of the fair value of the underlying cashflows, making modeled prices at that point irrelevant. Your car that gets you to work every day may not be worth a dime after all, if nobody wants to buy it. Can one say that A bonds should be rated F because they are backed by sub-prime loans and lost so much market value at the bottom of the crisis? Well, the hedge funds may certainly hope so, because they would be buying AAA cashflows being sold for dirt all day long. What programs like TARP (initially) and banks tried to do was to warehouse these bonds and hold them to maturity (realizing their cashflows) or until the market returns from trading bonds like they were GM stock…

18. **Sigge**
March 4, 2010

Here a presentation from Professor Philip Jorion (aka MR Value-at-Risk) that gives an interesting discussion about what caused the financial crisis. There is one example that may be particularly interesting where you can see that a tranche of a CDO security was giving credit rating AAA when a more appropriate assumption about the default correlation for the underlying loans would give BBB.

19. **Edward K. N.**
March 4, 2010

The LTCM predictive models did not account for the collapse of the ruble. It is not likely that exogenous variables can be incorporated into any useful model.

Nassim Taleb discusses the limitations of statistical theory in his "Black Swan."

The recent books about the crash have disclosed that senior management were clueless about the methods used by the quants and therefore did not comprehend the extent of the risks.

20. **anon**
March 5, 2010

> The LTCM predictive models did not account for the collapse of the ruble. It is not likely that exogenous variables can be incorporated into any useful model.

The influence of the ruble on the real estate market in the US is a subject that has just begun to be explored.

Now that water has been found on the Moon, maybe real estate markets will stage a spectacular rebound. Watch out for a huge surge in the price of subprime mortgages.

21. **Tim van Beek**
March 5, 2010

In case you did not notice, Scott Patterson was on the Daily Show on March 4th.

22. **Chris W.**
March 5, 2010

… coming up with a good understanding of the current pathologies of the financial system, …

The fundamental question might well be this: If the agents participating in the system use models to guide their actions, and worse yet, if they use models as a selling tool —eg, to provide bogus justifications for rating bonds as triple-A, while the underlying assumptions are being invalidated by the actual behavior of market participants— can models *ever* be expected to be reliable guides to the actual behavior of the financial system?

I seriously doubt it……

23. **Geoff**
March 8, 2010

Hi Peter –

Thanks for book review since I probably would have missed it. What I found interesting (page 115) is that Renaissance employs a number of people who originally worked on speech recognition and are clearly well versed in Shannon information. Achim Kempf was published a series of papers utilizing some of the same technology but in a completely different context – quantum gravity.

"Information-theoretic natural ultraviolet cut-off for spacetime"

http://arxiv.org/abs/0908.3061

A perimeter seminar can be found here and Susskind can be heard asking questions.

http://pirsa.org/09090005/

I'm curious whether you find the approach promising.

24. **Peter Woit**
March 8, 2010

Geoff,

Yes, that's an interesting insight into the kind of thing Renaissance is interested in.

Personally I don't find the kind of approach to quantum gravity you mention very promising, for various reasons. One is that I don't see that throwing out geometry in favor of information theory really buys you anything, but mainly I'm skeptical that "quantum gravities" that don't have anything to say about unification will ever be testable or useful for anything.

LHC Update

February 27, 2010
Categories: Experimental HEP News

Beam commissioning has started for 2010, with beam back in the LHC starting early Sunday morning. The plan is for roughly a month until colliding beams at 3.5 TeV/beam.

For the latest news, see here and here.

Update: Please, everyone, stop e-mailing me and posting comments here with the "news" (e.g. here or here) that the LHC will shutdown for a year or more in the future to fix bad splices. This is not news, it was announced by CERN back in January (see here).

Comments

1. **lhc**
   March 2, 2010

   It is curious that there is so much verbosity on "Quants" etc and so few comments on the various LHC update posts. Kudos to PW for diligently staying up-to-date and spreading the word on the LHC commissioning. You see now (I hope!) the difficulties of the reality of bringing a state-of-the-art superconducting collider to fruition. May I suggest for your further reading two articles (Part I and II actually) directly connected with the same subject, viz the problems and ultimate failure of the ISABELLE superconducting collider at BNL in the 1970's. (Today RHIC occupies the old ISABELLE tunnel.)

   Parts I and II
   http://www.springerlink.com/content/r114825754r38578/
   http://www.springerlink.com/content/824344k282615438/

   Well worth reading. You may need a journal subscription. Crease is a professor at Stony Brook and the resident historian of BNL. The consequences of the ISABELLE demise affect the US HEP community to this day. It is a lesson in leadership as well as pure physics. Don't complain if the CERN management is cautious about the LHC.

2. **DaveB**
   March 3, 2010

   The BBC will be broadcasting a programme about the last year at the LHC this evening.

   http://www.bbc.co.uk/programmes/b00qvpb9

   It will probably be available for download after being broadcast, although it may be restricted to UK IP addresses.

3. **Bill K**
   March 3, 2010

   "Don't complain if the CERN management is cautious about the LHC."

   More frequently I've heard the opinion that the previous CERN management showed a lack of caution, and that now the LHC is headed on a prudent course. To be fair, the pressure from all sides has been intense, to produce results in the form of papers, theses and press releases.

   The present plan of 1/fb at 3.5 TeV seems reasonable. But note that along with the reduced energy, this is well below the design luminosity of 10/fb/year. One should realize that finding the Higgs with only 1/fb of data is unlikely, and that any new results will primarily be more mundane measurements in b quark and t quark physics.

   In addition to the other problems, an underlying concern is the unknown effect that prolonged operation will have on the solder connections.

4. **SpearMarktheSecond**
   March 5, 2010

   I've heard the LHC collaborations will focus on J/Psi physics in their early studies. Yippie, back to Spear circa 1974!

5. **PearsAnjoutheThird**
   March 9, 2010

   It's a calibration. When LEP II was pushing to sqrt(s) in excess of open W production, still they stopped at sqrt(s) = M_Z0 first to calibrate the detectors at the start of a run.

First Hint That the Multiverse Really Exists

March 3, 2010
Categories: Multiverse Mania

Multiverse mania rolls along, with New Scientist this week running a cover story entitled Touching the Multiverse. They advertise the story by claiming that "we reveal the first hint that the multiverse really exists".

It turns out that this is a promotional effort for the work of Raphael Bousso, with the first hint that multiverse really exists a paper of his from more than 3 years ago that purports to "predict" the observed value of the cosmological constant. This in some way improves on Weinberg's 1987 anthropic argument, which to this day remains about the only piece of evidence backing up multiverse mania. The New Scientist article also reports on his more recent attempts to better justify the 3 year-old calculation with this decade's buzz-word ("entropic principle") as well as that of the last decade ("holographic").

Comments

1. **MyrtleParker**
   March 3, 2010

   Uhm, you insinuate that the guy went back and revisited his old paper to update it with new buzzwords when the original three year old paper's title is, "Predicting the Cosmological Constant from the Causal Entropic Principle?"

   You positing some form of new time travel theory here?

2. **Peter Woit**
   March 3, 2010

   MyrtleParker,

   You're right, Bousso had the "entropic principle" buzzword several years ago, before other people. It's the addition of "holographic" buzzword to the story that seems to be more recent.

3. **Bee**
   March 4, 2010

   I guess one could say the first hint that the multiverse exists is that the universe exists? 😉

4. **Dave Buettner**
   March 4, 2010

   I recently bumped into a couple of theorists I know. They were jubilantly celebrating a recent victory after a long and arduous effort. Using string theory, they were able to calculate the precise number of universes in a non-infinite version of the multiverse. Their work is yet to be published because, although they believe peer review will be a breeze, an embarrassing imaginary term appeared which they have yet to account for. However they believe they can work around it by adding another dimension. Anyway, the correct number (real part) of universes is 7,477.

5. **MyrtleParker**
   March 4, 2010

   Dave, I heard something similar although the details are a bit different. I heard that the team had used string theory to determine that the number of universes in the multiverse was in fact finite. However, they could not determine the exact number. Rather different starting assumptions lead to a landscape of finite values numbering near 10^500. Definitely finite though. So there is that.

6. **Peter Woit**
   March 4, 2010

   The notion of "counting the number of universes" in string theory is completely ill-defined. There's no reason to believe that the various constructions of "string vacua" known now are the only ones. Some of these constructions give an infinite number of vacua. The only hope of getting finiteness is to put in a cut-off at a certain scale, beyond which you expect the approximate calculation to be wrong anyway. Any numbers you get depend on the arbitrarily chosen scale.

7. **MyrtleParker**
   March 4, 2010

   Peter, I should have put tags around the post above 🙂

8. **MyrtleParker**
   March 4, 2010

   Err, should be 'sarcasm' tags.

9. **Peter Woit**
   March 4, 2010

   MyrtleParker,

   This is a subject where it's very hard to tell what's a joke and what is supposed to be serious science….

10. **MyrtleParker**
    March 4, 2010

    Indeed… that's what makes it so painfully funny.

11. **neo**
    March 4, 2010

    Infinite, schminfinite. Can we even know whether the set of possible universes is a countable set?

12. **Jeffrey McGowan**
    March 4, 2010

    Physicists know what countable means, really? 🙂

13. **Amanda Gefter**
    March 5, 2010

    Hi Peter,

    While I can't speak to the way the article was marketed, I was really writing about Bousso's paper from last year, Complementarity in the Multiverse (arXiv:0901.4806), which argues for a duality between a global picture of the multiverse and a local causal patch measure that only considers what a single observer could see. I found this really interesting, because if it holds it circumvents the problem of unobservable universes. It would allow you to do multiverse physics without reference to anything unobservable beyond your own horizon. I thought this was an intriguing new spin on the debate about whether the multiverse can be considered science.

    Anyway, I always love to hear your opinions on these matters! Thanks for mentioning the article.

    Cheers,
    Amanda

14. **Peter Woit**
    March 5, 2010

    Hi Amanda,

    Thanks for the further explanation, I should have been a lot clearer in my posting. I just don't see how this helps in terms of testability, since it doesn't change Bousso's original CC calculation or make any other testable predictions as far as I can tell. So, not much of a new hint…

    I should have also noted that you start the article describing George Ellis's skepticism about the multiverse. That there are skeptics about this, probably in a large majority, doesn't always get mentioned. Glad to hear you enjoy the blog!

15. **Ron Macken**
    March 6, 2010

    Maybe this is too basic a question, but what is leading physicists towards a multiverse model? I'm familiar with the anthropic principle, but am not sure if there are any other logical arguments for a multiverse.

16. **Peter Woit**
    March 6, 2010

    Ron,

    What is leading string theorists to multiverse models is not logic, but desperation. If your theory can't predict the value of X, you can try and explain this away by invoking a multiverse, with the value of X a random artifact of our particular universe. With string theory this gets taken to an extreme: the theory predicts nothing, but instead of giving up on it, some string theorists are trying to invoke a multiverse as an explanation for not predicting anything.

17. **neo**
    March 6, 2010

    But doesn't chaotic inflation theory also lead to a multiverse, independently of string theory?

18. **John Baez**
    March 6, 2010

    Jeffrey writes:

    Physicists know what countable means, really?

    Yes, but different physicists use different definitions, depending on how high they can count.

19. **Peter Woit**
    March 7, 2010

    neo,

    The idea of "eternal" inflation leading to a multiverse has been around for a long time, independent of string theory. It didn't get a lot of attention though, since it was (and is) untestable. By itself, it doesn't say anything about observable physics (except perhaps, could be used to justify the anthropic CC argument). There were initial hopes that the string theory version of the idea would be able to predict something (e.g. whether supersymmetry breaking scale is high or low), but that has not worked out.

20. **Zathras**
    March 8, 2010

    Jeffrey McGowan says:
    March 4, 2010 at 6:42 pm

    Physicists know what countable means, really?

    Well, since irrational numbers aren't observable, strictly speaking, a Physicist would say it doesn't matter!

21. **Michael T.**
March 8, 2010

@Ron. It seems that the main argument in support of the multiverse is not so much scientific but philosophical. That is it can neatly side step the fine tuning argument invoking theism.

22. **noel**
March 8, 2010

It still seems that the multiverse explanation is better than fine tuning. Anthropic principle always > theistic principle. So it's not like we're not making progress..
What's better, assuming that our solar system has 9 planets and that other systems might have a different number, or that our system has 9 because it's somehow unique and special? It's always good to expect that not everything we see around us has a particular reason for being the way it is. Accidents do happen.

The issue is not more philosophical here than anywhere else. For example, who predicted that the standard model will be described by gauge theories? No one. We just assume a priori that this works, and it does work, and you can make predictions from there. Similarly, who can predict which of the vacua describes our universe? No one, but if we find the right one in there, it might turn out that it works, and we could make other predictions from there.

I'm not a fan of the multiverse, I'd like all parameters to be predicted from a simple principle, but nature doesn't give a s*** about what I like and hope. Similarly, I'd like there to be a reason why gauge theories work, in the form of a very abstract and general no-go theorem. If people can't come up with something like that, I'm not very sure we should be expecting a selection principle for the vacua. It's the same problem, just different names.

23. **Peter Woit**
March 8, 2010

noel,

Personally I think the reason gauge theories work is that they embody a very deep truth about the relationship between mathematics and physics, one that we only partially understand.

But, that reason is not the reason gauge theories are a successful physical theory. They're successful because if you look at some of the simplest possible gauge theories, described by a small number of parameters, you get a consistent theory that makes an infinite number of very non-trivial predictions, and every one of these that can be tested comes out exactly right, on the nose. From a small input, you get a huge non-trivial output.

The string theory landscape is just completely different. There, the simplest examples don't look like the real world. You have to make your constructions more and more complicated in order to evade contradiction by experiment, until you have something so complicated that you can't predict anything. This is exactly the kind of thing you expect to happen when you pursue a wrong idea.

Sure, we don't know a priori whether a fundamental theory exists that is more predictive than the standard model. Based on past history, pursuing the search for such a thing seems likely to work out. But, no matter what kind of theory you want to pursue, if you're going to do science you need some way of testing your ideas against the real world. The utter failure of the string theory landscape to meet this kind of Science 101 standard is very telling. Comparing it to the situation with gauge theory is just absurd.

24. **Giotis**
March 9, 2010

Well you can't test everything. There are physical and technological limitations. It's just the way things are. People don't do Physics of the 19th or 20th century anymore. This doesn't mean of course that is forbidden to construct theories for certain regimes; you must keep making progress at all fronts and push the limits of knowledge. There are other ways to evaluate a theory i.e. Its Mathematical and theoretical consistency, its explanatory power and the lack of better alternatives.

25. **Peter Woit**
March 9, 2010

Giotis,

The problem with string theory is not that you can't test everything, it's that you can't test anything at all, because it predicts nothing. Arguing that you're going to replace experiment by mathematical consistency doesn't help here, since you don't have a mathematically consistent theory (you don't what string theory is non-perturbatively, can't even write down conjecturally what the theory is that's supposed to be producing the landscape).

All arguments like this about the string theory landscape that I've seen are just attempts to excuse what is an obvious failure. This is a really bad idea.

26. **Christine**
March 9, 2010

push the limits of knowledge

You can only push the limits of knowledge if nature validates back. Otherwise, it is not knowledge that you are gaining, but only the ability to construct good (?) hypotheses.

There are other ways to evaluate a theory i.e. Its Mathematical and theoretical consistency, its explanatory power and the lack of better alternatives.

That is a distortion of the scientific method. What you describe is a working hypothesis, not a theory. Only when the hypothesis offers predictions and/or effectively explain observed phenomena is that you have a *theory which describes that phenomena*. Such a theory evidently may only be valid at certain regimes and be eventually generalized or revised or an entirely new theory be formulated in its place. This is what pushing the limits of knowledge is about. And it happens exactly because of the scientific method.

Well you can't test everything. There are physical and technological limitations.

We all acknowledge that. So perhaps it is time to acknowledge the difference between speculation, hypothesis and theory as well.

27. **Giotis**
March 9, 2010

"The problem with string theory is not that you can't test everything, it's that you can't test anything at all, because it predicts nothing."

Peter, the problem (?) with string theory currently is not that it predicts nothing but that it predicts everything.

This “everything” though has explanatory power and that’s important. You can’t just close your eyes to that fact.

28. **Peter Woit**
March 9, 2010

Giotis,

Predicting everything and predicting nothing are the same thing.

A theory that predicts either nothing or everything has no explanatory power at all.

29. **neo**
March 11, 2010

Peter,

Predicting everything correctly is definitely better than predicting nothing. I do not follow you.

neo

30. **Bob Levine**
March 11, 2010

@neo

‘Predicting everything’ in this instance means predicting *anything*. If no what what the situation is, your theory predicts that it’s one of the possibilities—if it’s compatible will anything at all—then that theory makes no predictions, because it rules nothing out.

Top Cites 2009

March 8, 2010
Categories: Uncategorized

Travis Brooks of SLAC's SPIRES database has a blog posting today announcing the availability of various lists of the high energy physics papers most heavily cited during 2009. A full matrix of links to this data is here, data broken out by arXiv subfield is here.

It's hard to over-emphasize how much the particle theory parts of these lists are dominated by classic papers on AdS/CFT, in particular Maldacena's original 1997 paper. It now has over 6600 citations and during the next year or so should pass Weinberg's 1967 paper as the most heavily cited particle physics paper of all time. One remarkable thing about this paper is that in recent years the number of citations of it has increased to new highs, reaching 731/year in 2008. Even at the height of theoretical activity surrounding the Standard Model back during the late 1970s, none of the classic papers of that subject (such as Weinberg's) reached even half the citation rate of the Maldacena paper. Similarly, during the explosion of interest in string theory after 1984, none of the papers from the first superstring revolution reached half the Maldacena rate.

Among the top 25 entries in the 2009 overall top-cite list, the leading theory papers are 97-98 AdS/CFT classics at positions 3, 8 and 9, as well as Randall-Sundrum extra dimension papers from 1999 at 14 and 20. Among the top 50 entries, there are only two hep-th papers that are not from the last millennium: at number 33 one of the papers on superconformal Chern-Simons/supergravity duality, and Horava's Lorentz-breaking gravity proposal at number 38 (there's a very recent article about this at FQXI).

Looking just at the articles cited in hep-th during 2009, gauge-gravity duality is again completely dominant. The top 3 are AdS(5)/CFT(4) classics , the rest of the top 9 are about the lower dimensional AdS(4)/CFT(3) case (except for an AdS/CFT review article). To find something not about gauge-gravity duality, one has to go down to number 10, the KKLT paper that set off the landscape craze.

Taking a look at recent hep-th lists of postings, there seems to be no let-up in the AdS/CFT dominance. The only recent paper on another topic that seems likely to make the top ten of the 2010 listings is Erik Verlinde's January paper on entropic gravity, which two months later already has 40 citations.

Comments

1. **top50**
   March 8, 2010

   Very many of the top 50 in 2009 are astrophysics papers. (WMAP figures promimently ~ good for WMAP!) I suppose that's an indicator where the new physics is. As for Maldacena v. Weinberg, I suppose this is an indication of publication inflation? (Substitute favorite deragatory term if so desired…) There was no arXiv in the good old days, quite likely many of the citations are to arXiv postings, also there are many more conferences/symposia/whatever these days (and easily available online), so there are overall many more publications these days. Not a uniquely string theory phenomenon.

2. **Roger Schlafly**
   March 8, 2010

   I am surprised that Witten only has 2 papers in the top 50. I thought that his papers were very widely cited.

3. **Peter Woit**
   March 8, 2010

   Roger,

   Witten has written many highly influential papers, but there is no single one that stands out, and they tend to be on the mathematical end of the subject, where fewer papers are published. In these days of all AdS/CFT, all the time, very little that is not AdS/CFT is getting heavily cited in hep-th. It's not surprising that the Witten papers that show up are his AdS/CFT-related one and one other.

4. **neo**
   March 8, 2010

   It is not hard to understand why Maldacena's paper is so widely cited. It is a striking and tantalizing conjecture that attracts string theorists and particle theorists alike.

5. **fernighan**
   March 9, 2010

   It is not hard to understand why Weinberg's paper is so widely cited. It is a striking and tantalizing THEORY OF NATURE that attracts string theorists and particle theorists alike.

6. **anon.**
   March 9, 2010

   It's a bit silly to compare citations to Weinberg versus citations to Maldacena. In any field there is a body of accepted knowledge that one doesn't bother to cite. No one cites Weinberg for the Standard Model any more than they would cite Feynman, Schwinger, Tomonaga or Dyson to justify doing quantum field theory, or Einstein to explain relativity. It's fully integrated into the infrastructure of the field. This is far more important than any number of citations.

   (I imagine that at some point people will stop explicitly citing the original AdS/CFT papers and just assume that it's known, but — maybe just because they're already there in the TeX code everyone recycles, maybe because it isn't in a standard textbook yet — so far it looks like everyone will keep doing it.)

7. **Peter Woit**
   March 9, 2010

   anon,

   I was comparing the citation rates for Maldacena and Weinberg during comparable periods, about a decade after they were written, at a time when research in HEP was dominated by the topic that they started. Weinberg's 1967 paper (after getting no citations in the first few years, but that's another story…) reached a high of 351 citations/year 13 years later, in 1980. Maldacena's 1997 paper may not have hit its highest point yet, but was at 731 citations/year 11 years later, in 2008. This increase of more than a factor of two is partly explained by an increase from 1980 to 2008 in the number of papers written in HEP, but I think also reflects the historically very unusual domination of hep-th by research into one particular set of ideas.

The other comparison one can make is just the integrated number, where Weinberg is about to lose out, despite a 30 year head start. The future is hard to predict, but it seems just about certain that the Maldacena paper will be the most heavily cited HEP paper written during the 20th century, and may very well end up being the one most heavily cited during the 21st.

8. **dan**
March 9, 2010

re Maldacena – Is there any experimental evidence or empirical evidence that would suggest this level of citation is bad for HEP?

9. **Peter Woit**
March 10, 2010

dan,

In and of itself, I think the high citation rate is historically unusual, but from that you can't conclude it's "good" or "bad". Personally, I think the way the field is dominated by one very specific research topic is a reflection of an unhealthy situation. Many would argue though I think that this is the way it is just because AdS/CFT is the only good idea out there that has not been fully investigated.

10. **M**
March 10, 2010

it would be interesting to renormalize to the total number of citations in the field per year

11. **N**
March 10, 2010

That requires an index of inflation, to be able to state a baseline "the comparisons (of Maldacena and Weinberg?) are in constant 1990 citations". What of the citations of the papers of Albert Einstein (the statistics must be available somewhere) … how to compare? Pre-WW2 physics was "small science" and a comparison of citations based on inflation-adjusted numbers would still be impossible to formulate meaningfully. I do not doubt that in the decades to come things will get much worse.

12. **Peter Woit**
March 10, 2010

M and N,

It would be interesting to normalize these statistics, if anyone has good data on the yearly size of the HEP literature I'd be interested to see it. The comparison between the peak Weinberg and current Maldacena numbers is from 1980 vs 2008. There was a huge historical expansion in the size of physics research employment during the 60s, at least in the US. I'd suspect that there has been an increase from 1980 to 2008, but not as large, and concentrated outside the US and Western Europe.

More relevant may be that the Weinberg and Maldacena papers are not comparable because the Weinberg one was of much wider relevance, getting cited by phenomenologists and experimentalists as well as whatever the 1980 equivalent was of hep-th.

13. **piscator**
March 10, 2010

I think it would be interesting also to normalise by the number of citations per paper. When I read older papers I never see the long{recent work on the Buggins model includes [1-55]} reference lists that often occur in the current literature. Maybe that is because with the arxiv people are more aware of the literature, with electronic texts it is easier to cut and paste references, and there are also more people to be offended if you don't cite them.

There is also an unhealthy herd effect on citations when it comes to fashionable topics that seems particularly prevalent in hep-ph but is also present in hep-th.

As mentioned by others the comparison of absolute citation numbers between Maldacena and Weinberg doesn't mean very much, any more really than the relative price of a Hershey bar in 1998 compared to 1967.

In the period I have been in the field, which is not so long, I've noticed that the size of the topcite percentage bins in the SPIRES playground has grown by around 50%. Acording to SPIRES close to 1 paper in 5 is a topcite now. Glad to see we're all doing high impact work then 🙂

14. **M**
March 11, 2010

hi Piscator. Dividing by

N(t) = (average number of citations per paper) = (average number of references per paper)

allows to remove the effect of longer citation lists, which is mostly a consequence of informatics (easier to ask for citations, easier to say yes, easier to access papers).

But also the number of papers per author increased, in part because computers allow to write more useless papers, in part because the field expanded.

To remove both effects of informatics one should therefore divide by the average number of references per author per year.

15. **Haelfix**
March 12, 2010

Citation count (at this level) is usually not a good indicator of what a paper means to our understanding of nature. There are plenty of stringy papers that are far less cited, and ultimately more important.

Instead citation count here is a sort of combination of luck factors and sociological ones. For instance, if your paper is the final word on the subject, and is part of the way nature work, you will get a lot of citations, but not nearly as much as if you only discover a portion and leave questions unanswered.

Likewise, sometimes it turns out that a research direction is too technically challenging, and you hit a lot of brick walls. Consequently, less people will be inclined to take the plunge.

AdS/CFT hits that perfect middle ground, where its not too hard to work in and spawns fruitful research, yet is by no means perfectly well understood.

16. **SpearMarktheSecond**
March 15, 2010

Perhaps unheralded is the tendency to truly bury contributions in experimental particle physics. Talented young people first get their contributions buried under the collaboration, where first-authorship for the prime movers has been largely abandoned. Second, the papers get rolled up into the Review of Particle Physics.

So for me, the true source of who does what in experiment is the record of doctoral dissertations and internal collaboration notes, where the latter is generally not public. Perhaps those notes should become public, say, 1 year after they are written. The public pays for them.

There has been some discussion by theorists that it is hard to get young LHC researchers interested in new ideas. There are at least two ways to view this… on the one hand, the system discussed above gives little recognition to the people who do the work. On the another hand, the theory community has lost touch with real experiment in their 30 year or so journey through string theory, and suffers cognitive dissonance now when they look at how experimental collaborations make their sausages.

Short Items

March 9, 2010
Categories: Uncategorized

- Bill Thurston teams up with Issey Miyake for their fall ready-to-wear collection based on the Geometrization Conjecture (via Quomodocumque). Youtube video here.
- Why String Theorists Should Switch Fields to Quantum Computing.
- This month's AMS Notices has an interview with last year's Abel Prize winner, Mikhail Gromov. This year's Abel prize will be announced March 24, see here for the committee making the choice. Also to be announced soon is the winner of another million dollar prize, the Templeton Prize.
- Yet more string theory in popular culture.
- From UT Austin, various interesting new lectures in their GRASP series. These include a nice expository talk by David Ben-Zvi on the Fundamental Lemma. Ngo is lecturing about this weekly here at Columbia. In the fall he will move to Chicago and take up a permanent position there.
- This year's Talbot workshop will be on one of my favorite topics, Twisted K-theory and Loop Groups. At MIT there's a preparatory seminar here, and a page for the workshop here.
- This has been mentioned here before, but one can't stop marveling at the Math Overflow phenomenon.
- There's an interesting interview with Alan Sokal here.

Update: Some helpfully just pointed me to this review of a new novel by Ian McEwan in which

> characters mention M-theory, Nambu Lie 3-algebra and coincident M2-branes

Looks like something I'll have to read when it comes out here in a couple weeks.

   March 27, 2010

A side issue you may find interesting, is that Garrett Lisi's theory seems to be in trouble: see [here]() or at the [Arxive]().

Strings 2010

March 11, 2010
Categories: Strings 2XXX

Strings 2010, this year's version of the big annual string theory conference, will be held next week in College Station, Texas. There's a university press release about this here. Normally the conference is held in the summer at places like Rome, Madrid, Paris, Kyoto, etc. and attracts about 4-500 string theorists. This year's time and location may keep attendance down (although College Station is a lot cheaper place to stay than Rome…).

Unlike most years, there have been no promotional public lectures arranged. It also appears that there is no summary talk scheduled. In recent years, these have often been given by David Gross (who won't be talking this year) or by Robbert Dijkgraaf (who is busy with another project, video here, for which he might want to recruit help from fellow string theorist Lubos Motl). Many of the talk titles are now available. In the past, sometimes the hot topic was mathematical and mathematicians were in attendance, but this has no longer been true for a while now. This year the hot topic is condensed matter physics, with several talks scheduled on attempts to apply AdS/CFT techniques to superconductors.

It turns out I'm going to be relatively nearby, but a week later, giving a talk for the public the evening of March 24th at Collin College in Plano.

Starting up this week and continuing through May, the KITP is hosting a string phenomenology program entitled Strings at the LHC and in the Early Universe. The program blurb somehow neglects to mention that string theory doesn't actually predict anything at all about LHC physics or cosmology. To get a good idea of the topics that researchers in this field are discussing, online talks are here, starting with two rather general discussion sessions, one led by Blumenhagen, the second by Ovrut. As far as connecting to real physics goes, the state of the art seems to be much like it was a quarter century ago, with people struggling to find ways to come up with string theory-motivated constructions that are not in obvious disagreement with experiment. To achieve this requires going to ever more complicated models, which often contain various particles not in the Standard Model. In terms of making LHC predictions, one has no idea if this is a good or bad thing.

Update: The Strings 2010 talks will be web-cast. There's now a participant list. With 192 participants, this will be the smallest Strings XXXX conference in many years.

   High Tc Superconductor is already a hot field for many many years, now with string theorists joining…

2. **Sam**
   March 12, 2010

   Looks like you're coming to my neck of the woods – I live in Collin County and Plano is very convenient.

   From the press release

   http://www.ccccd.edu/news/PressReleases/2009-2010/20100310distinguishedSpeaker.html

   the lecture is open to the public. I'm going to try to attend.

3. **George H.**
   March 16, 2010

   "Robbert Dijkgraaf (who is busy with another project, … for which he might want to recruit help from fellow string theorist Lubos Motl)."

   Funny!

   It would surely make Patrick Michaels happy.

4. **lun**
   March 17, 2010

   As a heavy ion physicist with an interest in AdS/CFT, the presentations I saw absolutely shocked me.

   The tone of the speakers, and I am talking about the leading lights of string theory, was essentially "we learned everything there is to learn about heavy ions, so we are not interested in it anymore, let us do condensed matter physics".

   While AdS/CFT was, and still is, a promising field, its "objective" impact to understanding the system created at RHIC is zero: I mean, there are neat calculations of highly idealized models, but there is no evidence that these models actually apply to the real world. Worse than that, there was very little effort to _look_ for this evidence. For the string theorists to now behave as if the job is finished, and they can concentrate on something else, is simply preposterous. It would be bad enough to admit failure (its premature, this approach has potential!), but they behave as if it was an unqualified success (and surely enough, PR annoucements will continue to claim this). Heavy ion phenomenologists (not to speak of the experimentalists) have every right to be extremely annoyed at this attitude.

   No idea how the condensed matter community will receive this interest. The people I know working on high-Tc superconductivity and related problems (a sample of ~5) have either never heard of AdS/CFT, or are dismissive of it. From my admittedly naive outsider perspective, the models described in the talks are largely too "artificial" to teach us anything we do not know already (in comparison the heavy ion models are actually pretty simple and natural, something I have in the past found very attractive), so it looks very much a repeat of the heavy ion performance: A few technical calculations of models that "look like" the system they claim to rapresent, little phenomenological effort, and a lot of PR.

   Honestly, if this is the best the field can offer, we are in deep trouble.

5. **Shantanu**
   March 25, 2010

   Peter and others, see this talk by Stanley Deser on overview of quantum gravity
   http://online.kitp.ucsb.edu/online/colloq/deser1/rm/flashtv.html

Around 40th minute there is some discussion of string theory.

LHC Update

March 12, 2010
Categories: Experimental HEP News

There's now a tentative date set for first high energy (3.5 TeV/beam) collisions at the LHC: it's March 30th.

Comments

1. **nessuno**
   March 12, 2010

   I don't know where you got this info. If it is from where I believe, it is followed by a (TBC) (TuBerCulosis? To Be Confirmed ?). Of course everyone is hoping that the moment comes as soon as possible; but perhaps, as history has shown, to start putting a lot of mediatic emphasis on things that cannot really be planned so precisely is not the best strategy.

2. **Peter Woit**
   March 12, 2010

   nessuno,

   That's why I described it as a "tentative date"… I agree that there's a good chance it will change.

3. **Bill K**
   March 13, 2010

   "… perhaps, as history has shown, to start putting a lot of mediatic emphasis on things that cannot really be planned so precisely is not the best strategy."

HEPAP Meeting

March 12, 2010
Categories: Experimental HEP News

HEPAP is now meeting in Washington, presentations available here. Like the rest of science, HEP has been doing very well in the federal budget, including a temporary increase due to the stimulus program. Excluding stimulus money, the president's FY2011 request has total DOE HEP funding up 2.3% (theory is up 3.8%) over FY2010. This is about 10% over the FY2007 level. At the NSF, the proposal is for a 2.8% increase in physics research spending in FY2011, up 20% since FY 2007.

The NSF will be funding several "Physics Frontier Centers", with five-year renewable awards of 1-5.5 million $. Pre-proposals are due in August.

The DOE has been emphasizing Early Career Programs, with 14 "Early Career Awards" to tenure-track physicists made in HEP in FY1010. Six of these went to HEP theorists, pretty much all in phenomenology, with funding for string theorists not popular these days it seems.

With the particle theory job market a complete disaster, particle theorists somehow managed to convince the DOE that the answer to the problem is to produce more particle theory Ph.Ds. There is a new program of HEP Theory Fellowships funding (with two-year fellowships) an additional five students this year, five more each year in the future. So I guess, steady-state, the idea is to add 10 more theory Ph.D.s/year, into a job market where the total number of permanent jobs/year is about 10.

Update: Science magazine has a story here about budgetary problems of the DUSEL project.

Comments

1. **Joseph Smidt**
   March 12, 2010

   Well, even without the extra DOE fellowships there would be a steady stream of particle theorists. They seem pretty set on going into particle theory, money or not.

   For instance, here at UC Irvine there is a constant scare among the particle theory grad students that if there isn't enough TA positions in the coming quarters, they may have no source of funding at all. (At least, this is what they tell me. They always TA and have been warned there might not always be enough TA slots for everyone.)

   However, even with the realization that they may have to be a grad student with no funding at all, including no TA position, at some point in their grad career, there is always a steady stream of people who sign up and say "Well, I didn't become a physicist for the money."

2. **Anonymous**
   March 12, 2010

   I'm starting a PhD in string theory. Is it possible to switch to phenomenology for postdoc, if the job market continues to favor phenomenology? I don't like this trend. What they call "phenomenology" is stuff that is as speculative as string theory, yet somehow they convinced everyone that it is down-to-earth physics. Yeah LHC is going to produce results soon, lets focus more on phenomenology! And do lots of "model building" out of nowhere to predict what will happen! I won't object to this trend if LHC has really found something very interesting that needs investigation, but such "warming up" before LHC results is not very rational, and is not fair for more formal theorists.

3. **Avidan**
   March 12, 2010

   What is the logic of supporting tenure-trackers if they have a job, while those whose research the DOE should really be supporting, are people without a tenure-track and that, despite them not doing string theory, are forced out of the system to do finance ?

4. **Peter Woit**
   March 12, 2010

   Avidan,

   One justification for creating these well-funded grants to tenure-track physicists is that a lot of the money will go to their employers (mostly universities, sometimes government labs), encouraging said employers to turn these tenure-track positions into permanent ones, and/or create more tenure-track ones.

   Put differently, if this grant program didn't exist, there would be six more tenure track theorists without a grant, in danger of not getting tenure (with one permanent particle theory job disappearing), and six institutions that would think twice before agreeing to another tenure-track line in particle theory.

5. **David B.**
   March 12, 2010

   Dear Peter,

   This complaint is very unfair to both theorists and the DOE.

   The past few years have seen a steady erosion of the support in individual grants, to the point where many theorists can not pay to support students any longer. The salaries of students and researchers has gone up, and the grant amounts have been steady or declining.

   The fellowship program is to remedy somewhat that situation. It is competitive and will be similar to some extent to the NSF graduate fellowships.

   Also, the early career award is the new name for what used to be the OJI awards. These are the Junior Investigator grants that the DOE has been awarding for many years past under a new name.

6. **Peter Woit**
   March 12, 2010

   David B,

   The idea of the OJI/Early Career grants seems like a good one to me. Anything that supports more tenure-track or permanent positions is helpful.

On the other hand, the huge imbalance between the number of particle theory Ph.Ds awarded and the number of permanent positions has always seemed to me very unhealthy for the field. If the trend is that DOE/NSF money and university budgets are tighter and able to support fewer permanent faculty in particle theory, they should also be supporting fewer graduate students.

Among the various problems that the field of particle theory suffers from, too few Ph.D. students being trained for the available permanent positions is not one of them. I understand extremely well that from the local point of view of any particular faculty member at any particular university, more Ph.D. students in their subject is a good thing. That doesn't mean it's a good thing globally.

7. **A String Theorist**
March 12, 2010

Agreeing with the first comment about the steady stream of particle theorists:

On our graduate admissions committee there has been an ever-increasing pressure to try to throttle back the number of HET students we admit, but it never works (mostly, because of people who write an ambiguous statement of interests, or who simply lie about what they want to work on.)

This year we tried a quota of three for the HET group, but now we are hearing back from admitted students and at least eight of them have listed HET as their first area of interest. Meanwhile the various (condensed matter, astro) experimentalists in our department are in serious trouble because they can't attract enough students to staff their equipment.

So, there is still huge demand for particle theory Ph.Ds. Apparently, despite the hype, young people still recognize the discovery of string theory as one of mankind's greatest intellectual achievements.

P.S. I also certainly agree with Anonymous 1:37 — I distinguish between "hard" and "soft" phenomenology, the former comprising actual data analysis and Monte Carlo coding, while the latter is not only more speculative than string theory but also significantly less useful.

8. **Paul Wells**
March 15, 2010

I think it is unhealthy that the state of Physics seems to depend so much on LHC results.

What if LHC just discovers the Higgs with a mass of 120 GeV ?

What are all those LHC experimentalists and string theorists going to do next ?

I think there should be a better balance with areas such as dark matter searches, LIGO, condensed matter, low temperature physics, neutrino physics etc.

In addition I am not sure that an experiment with thousands of PhDs provides good training for those PhDs.

9. **Peter Woit**
March 15, 2010

Paul Wells,

Unfortunately, prospects for progress in HEP and thus for it remaining a healthy scientific field, do depend strongly on LHC results. This is an unavoidable aspect of the science and of how difficult it is to do experiments at the energy frontier.

In the US, funding for LHC research is a relatively small part of the reseach budget, with a lot of attention going to the subjects you suggest.

10. **Paul Wells**
March 15, 2010

Point taken – but at some point building larger accelerators is just impractical.

In addition neutrino measurements are pretty much guaranteed to give useful data for theorists.

Maybe accurate neutrino masses /mixings would give a clue as to why there are 3 generations of leptons ?

I think this might be more profitable than building bigger and bigger accelerators that may not discover anything interesting.

11. **Peter Woit**
March 15, 2010

Because there is no viable way to compete with the LHC at the energy frontier, US HEP is already putting its emphasis on the kind of neutrino experiments you suggest (Fermilab's next generation "Project X" is being designed largely to produce an intense neutrino beam).

If there really is nothing interesting at LHC energies, and surprises in neutrino physics, maybe this will work out very well for the US…

12. **Per**
March 15, 2010

It's a nice thing that the current administration at least live up to one of its promises…

13. **Peter Woit**
March 15, 2010

Per,

Yes, but note that this recent increase in science spending is taking place in the context of large increases in all federal spending to fight the recession. As (and if…) the recession ends, there will have to be significant budget cuts in coming years to bring down the current large deficits. It's when decisions have to be made about what to cut that we'll find out how dedicated the administration (and the Congress) is to science spending…

14. **Markk**
March 17, 2010

"I think it is unhealthy that the state of Physics seems to depend so much on LHC results."

What ever gave you that idea? Most of the physicists and most of the papers and most of the work done in physics wouldn't even notice if the LHC imploded tomorrow. Well they would notice and be sad but it wouldn't directly affect their work. It is only High Energy Particle Physics and its theorists which depend on LHC. That is literally a small fraction of physics. Typical of the attitude of many science newspeople though to really focus on that area alone.

15. **chris**
    March 18, 2010

    Markk,

    actually (and naturally) it is really the HEP-experimentalists. a sizeable fraction of us HEP-theorists are doing perfectly fine without LHC.

Millennium Prize to Perelman

March 18, 2010
Categories: Uncategorized

The Clay Mathematics Institute announced today the award of the Millennium Prize to Perelman for the proof of the Poincare Conjecture. The award was made based on the rules set up when the prize was created: a Special Advisory Board (Donaldson, Gabai, Gromov, Tao and Wiles) made a recommendation to the CMI Scientific Advisory Board (Carlson, Donaldson, Margulis, Melrose, Siu and Wiles) that was accepted.

On June 8 and 9 Clay will host a conference to celebrate at the Institut Henri Poincare.

The initial press release says nothing about the question many have been wondering about for years: who will get the million dollars? Does all of it go to Perelman? Did he accept it?

Update: According to alexbellos on Twitter, Carlson says that Perelman has been informed of the award of the prize, but there has been no response yet from him about whether he will accept it.

Comments

1. **Nigel**
   March 18, 2010

   Since he declined the Fields Medal in 2006 despite two days of fruitless attempts to make him accept, maybe they'll take the easy option and mail him the check for the Millennium Prize?

2. **David Rysdam**
   March 18, 2010

   Why have many been wondering about the million dollars? Are the rules unclear or something?

3. **Dr.Kathrine Martinez-Martignoni**
   March 18, 2010

   I am really very happy for him.
   Will be Prof. LOUIS DE BRANGES the next one to receive this "premium" for his demonstration of the Riemann hypothesis?
   I hope so.
   Best,
   dr. kathrine (Switzerland).

4. **literalman**
   March 18, 2010

   There's a question about the $1,000,000 because Perelman refused the Fields previously — see
   http://en.wikipedia.org/wiki/Grigori_Perelman#The_Fields_Medal_and_Millennium_Prize

5. **Peter Woit**
   March 18, 2010

   Kathrine,

   There are very specific rules governing the Millennium prize, including a process that begins when a complete proof has been written down and refereed according to the standards of major journal or its equivalent. In this case, Clay helped fund the book written by Morgan-Tian to make sure that this was done. In the de Branges there is no such refereed paper.

6. **Roger Schlafly**
   March 18, 2010

   What took them so long? Perelman posted his proof 7 years ago, and it was published in a peer-reviewed journal 4 years ago. The Clay rules say only to wait 2 years.

7. **John Baez**
   March 18, 2010

   Yay! That's great news! He deserves it. Whether he wants to take the money or not, that's up to him…

8. **neo**
   March 18, 2010

   Recognition of his great accomplishment is all that matters. Whether or not he wants to accept it is up to him.

9. **Chris Oakley**
   March 19, 2010

   > Yay! That's great news! He deserves it. Whether he wants to take the money or not, that's up to him…

   It could be that the Clay Mathematics Institute, under pressure to cut costs, is now only allowed to award prizes to those who are not likely to accept them.

10. **Sakura-chan**
    March 19, 2010

    Hamilton should get some of that too.

11. **Ricci's Pieces**
    March 19, 2010

    Just leave him alone. Why can't people understand, he feels like accepting these prizes are beneath him. It's almost sad at this point. Everyone knows he completed Hamilton's Ricci Flow program. I'm even more stunned that Gromov was on that committee; the one person I thought understood Perelman.

12. **Peter Woit**
    March 19, 2010

    Ricci's Pieces,

    The task of the committee Gromov was on was mainly to get experts to go through the proof and make sure that it is a valid proof of the claimed theorem. Checking the proof is important and requires experts like Gromov. I see no rational reason Perelman should object to this activity, quite the opposite. He should be pleased that other mathematicians are working hard to understand his ideas and their implications.

    As for the decision to award him a $1 million prize, the thing may be beneath him or not, but once the prizes associated with problems were set up, when one of the problems is solved, that must be acknowledged. That's what Clay has now done. If Perelman wants to either ignore them or reject the award, he's free to do so.

    I'm struck actually by how low-key this announcement was. There appears to have been no effort to get this wide distribution in the media, and the $1 million is not mentioned at all in the press release.

13. **Simplicio**
    March 19, 2010

    @Ricci's: I don't see how they can not at least try and award him the prize. It was set up to go to whomever proved Poincare's conjecture, and that was Perelman. Its not like the Field's medal where its more of a judgement call.

    Will be interesting to see if he takes the money though. A million bucks is a lot to turn down, especially since he's now reportedly unemployed.

14. **capitalistimperialistpig**
    March 19, 2010

    Einstein once described Dirac as living on the knife edge between genius and insanity. Guys like Perelman and Groethendieck seem a bit over that edge. I don't think that their motivations can be interpreted in conventional terms. It would seem sad, at least to me, if Perelman, like Groethendieck, has lost interest in mathematics

15. **Ricci's Pieces**
    March 20, 2010

    When I mentioned Gromov, I meant much more in the sense of politically and not mathematically. I know a lot of Gromov's work was used in Perelman's work and naturally you would ask someone like Gromov to check the work or parts of the work. However, in Gessen's recent book on Perelman, it was very apparent that Gromov supported Perelman's stance on the Fields Medal situation. On the other hand, I guess Clay has their hands tied; they have no choice but to award it to Perelman.

16. **amateur**
    March 20, 2010

    I think there is a difference between recognition and fame. If Perelman has stated he wanted recognition, I think that is a very different thing than being famous.

    I would argue that Perelman's refusal to accept the Fields medal and apparent refusal to accept the Clay prize has nothing to do with those things being "beneath him". I think he his trying to make a statement about purity of math, and any exchange of money effectively cheapens math and makes a mathematician look like a prostitute. Although that might not be the precise way to phrase it, I can see it as a principled position and I suspect it is one that is closely aligned to Perelman's.

17. **professional**
    March 20, 2010

    > and any exchange of money effectively cheapens math and makes a mathematician look like a prostitute.

    More than a principled position it seems to me juvenile, if not downright childish. Nobody thinks of Euler as a prostitute, even though he worked for Catherine the Great, and the Clay institute is certainly not a brothel.

    I very much doubt you're accurately representing Perelman's ideas.

18. **amateur**
    March 20, 2010

    Perhaps your right, I humbly submit my apology if I caused offense.

19. **Soarer**
    March 20, 2010

    Uncertain of its validity, yet some russian media's indicating that perelman has declined the award.
    http://english.pravda.ru/society/stories/19-03-2010/112643-perelman-0

20. **professional**
    March 21, 2010

    Come on amateur, we're just discussing ideas, no need to apologize. Prof. Perelman certainly has a very uncommon, and maybe extreme, view of the mathematical community which probably very few people, aside from him, fully understands. I just don't think your rather simple interpretation of his behavior could possibly reflect his way of thinking.

21. **martibal**
    March 22, 2010

    I guess there is not so much money in Russia for science right now. Would it be so "impure" to take the money to help other young (or less young) mathematician in his country ?

22. **amateur**
March 22, 2010

I have read several articles and a few books, and they all seem to say basically the same thing. He really just wanted his work checked, he was upset that some competing mathematicians tried to claim his work as their own, and he feels isolated from the broader mathematical community. I think if my suggestion that accepting money might make him feel like a prostitute is childish, it would seem to fall in line with some of his behavior already. However, just because one might perceive such behavior as childish, I would argue that because of his apparent situation of being exceptional at math, he probably has never fully developed strong personal skills, simply because there are probably fewer than 10 people in the world he can have discussions with about the type of math he's interested in (probably less if you consider the language barrier). I think under those situations, a person would behave very childishly, particularly when you consider that a few of the people he can converse with behaved equally childishly and tried to take claim for his work.

23. **professional**
March 22, 2010

From what I've read, I think one of the things Perelman is reacting to is his perception that sometimes positions, prices, and credit are given for political reasons, whereas often talented and deserving people don't get the credit (and money…) they deserve because they are not well connected politically.

If so, his attitude of withdrawing from mathematics could not be more wrong. He's just leaving a vacuum that will be filled by others, perhaps less deserving.

I fully agree with you that he should have accepted the price and use the money to help young people who lack support to develop their careers as mathematicians. Even more, if he had accepted the Fields medal he could have used the prestige and political influence that comes with it to try and change some of the things he thinks are wrong with the community.

24. **andreask**
March 22, 2010

..as far as I understood it should be well-known that Perelman was far from being that stereotyped lack-of-personal-skills-mathematician, it seems quite clear he never visited any new-age-manager-seminars on 'development' of 'personal skills and potential', but his love for literature, including Dostojewskij and Tolstoj is one of his few personal convictions that made it through the media and seem to have been, in fact, directly initiated by Perelman himself. Possibly those are some of the few hints Perelman gave to mathematical community, knowing that the ones that he aimed at would understand and the ones he did not aim at, would refuse to understand. One could call this childish, but in Dostojewskij's perception of reality (compare 'Notes from the underground', 'The Idiot' etc.) characters similar to that one being 'performed' by Perelman were the great and unrecognized heroes of the Russian society during the 19th century.

25. **Common Sense**
March 22, 2010

> One could call this childish, but in Dostojewskij's perception of reality (compare 'Notes from the underground', 'The Idiot' etc.) characters similar to that one being

I would like to suggest to Prof. Perelman a much more effective course of action, though definitely less literary.

Accept the prize, and donate the money to the children of Haiti, or whatever needy place you like. There's no lack of starving children in the world that could use a million dollars worth of food.

Then, with a few thousands of dollars of the prize money, publish and ad in a large newspaper saying: "Dr. so-and-so, president of whatever mathematical institution, is a corrupt asshole".

Mind you, that message would reach very far and would be heard loud and clear by millions. After that, he can go back to his favorite cave with the pleasing satisfaction of a job well done.

26. **Peter Woit**
March 22, 2010

I'd be very interested to hear from anyone who actually knows something about Perelman and his thinking on the prize issue. But most of the comments here seem to be pure speculation, informative perhaps about the commenter, but not about Perelman. Enough.

27. **jester**
March 23, 2010

here is the link. it seems he refused the money (or prize).

http://www.dailymail.co.uk/news/worldnews/article-1259863/Worlds-cleverest-man-turns-1million-prize-solving-mathematics-greatest-puzzles.html

28. **amateur**
March 23, 2010

29. **Joseph**
March 23, 2010

Being a mathematician myself, I doubt in his situatin I would have refused the prize, acting on moral high ground, as Common Sense suggests, or otherwise – but he gets all my respect for mocking the lusts of this world.

30. **Eugene Stefanovich**
March 23, 2010

Take a look at two video clips on http://www.lifenews.ru/news/18018

In the first one a reporter talks with Perelman on the phone and asks if he decided to take the Clay prize. Perelman's response is that he has not decided yet. If he is going to accept the prize the Clay Institute will be the first to know. The clip is dated March 23, 2010.

The second clip shows Perelman walking to a neighborhood grocery store. A (different) reporter is stalking him trying to ask questions. And Perelman is doing his best to avoid the annoying encounter.

31. **Richard**
    March 23, 2010

    Good grief, that obnoxious “news crew” behaving more like paparazzi probably does nothing but drive him further underground. He should have wasted some of the food he bought on the camera’s lens.

32. **D.**
    March 23, 2010

    The site linked directly above is a fascinating microcosm of another culture. Fully half the women commenting are proposing to bear his children. I am fairly certain that recent US Fields medalists did not inspire this response in the general public.

33. **a**
    March 24, 2010

    “Even more, if he had accepted the Fields medal he could have used the prestige and political influence that comes with it to try and change some of the things he thinks are wrong with the community.”

    I don’t think you could be more wrong about this. Perelman gets little if any prestige or political influence from the Fields medal, especially in the mathematical community, unless it’s the kind of influence that he doesn’t want in the first place. On the contrary, it’s he who would give prestige to the medal.

34. **amateur**
    March 24, 2010

    I think the media should just leave him alone.

35. **student1729**
    March 25, 2010

    If Diogenes was around today walking with his lamp in Saint Petersburg looking for an authentic, honest human being he would actually find one.

36. **Chris**
    April 4, 2010

    Come on, what’s a million dollars these days? Peanuts. It wouldn’t buy you an apartment in London (or just a tiny apartment, perhaps). And I hear that Moscow is the most expensive city in the world, which is probably where Grigori Perelman would like to buy an apartment. Big deal. They should increase the prize to a 100 million USD.

High Energy Beams at the LHC

March 19, 2010
Categories: Experimental HEP News

At 5:23 am in Geneva this morning, for the first time the two LHC beams were ramped up to high energy, the 3.5 TeV/beam that they plan to run at for the next two years. These are the highest energy (per particle) beams ever created by human beings, significantly surpassing the value at which the Tevatron operates (.98 TeV/beam) as well as the record achieved last fall (1.18 TeV/beam) during the early stages of beam commissioning.

From now on, work will continue on preparing the machine to operate at higher intensity (for now they are using low-intensity pilot beams). For the next week or two, one of the challenges will be to carefully avoid any interesting collisions between particles in the two beams, since a major media event is being organized around the first collisions, and the event is tentatively scheduled for March 30.

Update: CERN press release is here.

Update: CERN has confirmed in a press release that first collisions will be attempted on March 30.

Comments

1. **amateur**
   March 19, 2010

   Its a very exciting moment in human history, it is sad that so few understand how important it is.

2. **Dr. E**
   March 20, 2010

   Awesome!

   I heard this news while flipping through the AM dial last night!

   They were talking about it on some conservative radio talk show, instead of health care and politics.

   Science is a great uniter and exalter, and hopefully the LHC will inspire us to focus on all those greater things we have in common–the mystery of physical reality–rather than those things that divide us.

   Does anyone know the general odds that people are laying for and against the LHC finding new science?

3. **Bill K**
   March 21, 2010

   Dr. E says: Does anyone know the general odds that people are laying for and against the LHC finding new science?

   A certain online betting site quotes these odds for finding the Higgs:
   by 31 Dec 2010 – 11 percent
   by 31 Dec 2011 – 17 percent
   by 31 Dec 2012 – 22 percent
   by 31 Dec 2013 – 29 percent

   Of course these are way too optimistic. "Finding the cause of electroweak symmetry breaking by 2015" would be a good bet.

4. **SteveB**
   March 22, 2010

   It appears they got a short circuit today. "Cycling the machine/ Short-circuit detected on the main circuit in SPS – under investigation/More news asap."

   It does not say if this is serious, or a normal, every-day, minor glitch. I cannot judge.

5. **Peter Woit**
   March 22, 2010

   SteveB,

   A bit later : Short circuit in SPS has been identified and problem solved… Beam should be back in half an hour.

   With this kind of huge and incredibly complicated apparatus, finding short circuits may be a not uncommon occurrence.

6. **Barzin**
   April 3, 2010

   I heard the news too, but I don't know what they understand from that test? does it solve any problem in physics? or not yet!!

7. **Peter Woit**
   April 5, 2010

   Barzin,

   Not yet! It will take a year or so to accumulate enough data to start to be interesting, probably several years and an upgrade to full energy in 2013 to get results that will answer the questions we're most interested in, about the Higgs mechanism.

More Prizes

March 26, 2010
Categories: Uncategorized

As far as I can tell, it's still unclear if Perelman will accept the $1 million Millennium prize awarded to him last week. This week brings news of two more million dollar prizes:

- John Tate is this year's winner of the Abel Prize, worth 6 million Norwegian Kroner, which is a bit more than $1 million. Tate is now 85, recently retired from UT Austin (he spent much of his career at Harvard). He is a major figure in the development of algebraic geometry and number theory during the second half of the last century. His Princeton Ph. D. thesis, which pioneered the use of Fourier analysis on the adele group in the study of number theory, could easily be the most widely read and used doctoral thesis in mathematics.
- The 2010 Templeton Prize, worth 1 million British pounds, or about $1.5 million, was awarded to biologist Francisco Ayala. Remarkably, the Templeton Foundation describes the prize-winner as someone who has "vigorously opposed the entanglement of science and religion". I had thought that the main goal of the Templeton Foundation WAS "the entanglement of science and religion", so this is a bit surprising. Ayala has done admirable work over the years refuting creationism and intelligent design.

There was a bit of a kerfuffle over the fact that the announcement was made at the National Academy of Science (Ayala is a member), with Sean Carroll quoted as:

> Templeton has a fairly overt agenda that some scientists are comfortable with, but very many are not. In my opinion, for a prestigious scientific organization to work with them sends the wrong message.

Science magazine has an article here about the award and about what some scientists think of Templeton's activities, including the following:

> Even those who are put off by Templeton's mission agree that the foundation does not attempt to influence the outcomes of the research and discussions it sponsors. "I am not enthusiastic about the message they seem to be selling to the public—that science and religion are not incompatible; I think there is real tension between the two," says Steven Weinberg, a Nobel Prize–winning physicist at the University of Texas, Austin, who has been an outspoken critic of religion. "But for an organization with a message, they are pretty good at not being intrusive in the activities they fund. I don't wish them well, but I don't think they are particularly insidious or dangerous."

Comments

1. **Sakura-chan**
   March 26, 2010

   They should have given Tate the money when he was younger so that he could enjoy it more.

2. **Anonymous**
   March 27, 2010

   @Sakura-chan:

   First, there *was* no Abel Prize when Tate was (much) younger, since it only exists since 2003.

   Second, the Abel Prize is not the only prize around. Overall, you might say that we now have the Fields medal for young mathematicians, the Abel prize for older ones, and the Wolf prize (which Tate got as well) for people somewhere in between. So what's wrong with that?

   Third, I doubt money was in any way a motivation for Tate to do the work he got the prize for.

3. **yota**
   March 27, 2010

   >>>*the Abel prize for older ones*

   There will be competition between the Abel prize and the Chern medal : http://www.mathunion.org/general/prizes/chern/details0/

   Chern medal will be awarded during International Congress of Mathematicians like the Fields medal.

   What do you think about this new prize ?

4. **Vince**
   March 28, 2010

   I am pretty sure for $1.5 million atheistic scientists will find good reasons why Templeton is not so bad after all.

5. **tytung**
   March 28, 2010

   As long as the scientist need it and they provide him with the money, I don't think there is any problem with it. Who knows, maybe the next Einstein will turn out to be a templeton funding beneficiary?

6. **ninguem**
   March 28, 2010

   @Sakura-chan: I believe Tate has had a very happy and trouble-free life and, especially after taking up the Chair he had at Texas, no money worries. One could argue that the money could be better spent elsewhere but prizes like this add visibility to math. I don't think the press would have taken this much notice if the amount was, say, 100K. But I confess to have mixed feelings about these huge prizes.

7. **Peter Shor**
   March 28, 2010

   One million-dollar prize will get a lot more publicity then ten $100,000 prizes, and so this is a lot better for the donor. I'm not sure that it's better for the field, even though mathematics publicity is good in general.

8. **chris**
March 29, 2010

i don't really get it why Templeton money is thought of as untouchable by some. just imagine, if you had a hundred million bucks to spare, and you would really like to know what science has to say about religion. would it be so unreasonable and bad if you just set up a foundation to fund people who want to find out by doing some research?

sure, it might be all politically motivated. but you are free to turn away from it the moment this becomes obvious.

i personally find Templeton-like money to be about the 'cleanest' possible source of funding nowadays. it seems to be spare money donated by someone who really would like to know. this is what science is all about after all. now think of the other funding sources: DoE, NSF, DoD – and their equivalent counterparts in other countries. don't they have an agenda? or is it so much cleaner than Templetons?

as a grad student, i was financed by the DoE nuclear stockpile stewardship program. nowadays i get grant money by basically promising that we can beat other countries in supercomputer applications and give ours a competitive edge. maybe many of the readers here are much closer to the true spirit of fundamental science in their funding sources, i don't know. but for me, i feel that I have no right really to despise Templeton-funding.

9. **Diz**
March 30, 2010

i don't really get it why Templeton money is thought of as untouchable by some. just imagine, if you had a hundred million bucks to spare, and you would really like to know what science has to say about religion. would it be so unreasonable and bad if you just set up a foundation to fund people who want to find out by doing some research?

The concern is mostly that they do not in fact "really want to know", but rather are trying to push a foreordained conclusion, i.e. compatibility between science and Christian doctrine.

Most detractors would put very long odds on a Templeton award being presented for findings that the two are incompatible, or that modern science vindicates Hinduism or Zoroastrianism or the worship of Marduk, however compelling a case was made.

Go John!! Woohooooooo!!!

First High Energy Collisions at the LHC

March 29, 2010
Categories: Experimental HEP News

Current schedule is for first 7 TeV center of mass collisions tomorrow (Tuesday) at 9:17 am Geneva time. Injection of the beams will take place after 2 am, ramp up to 3.5 TeV/beam from 3-4 am. For more details of what has been going on recently at the LHC, see here. The schedule for tomorrow is here, a link to the planned webcast is here.

CMS e-commentary is here, ATLAS control room blog here.

Update: I just woke up, a couple minutes after first collisions were observed, 12:57 Geneva time. Collisions are going on now.

Comments

1. **Michael**
   March 30, 2010

   I tried to post a digest of Mike Lamont's talk on the commissioning of the LHC machine at Collider Blog.

   Last night there were non-colliding beams, and CMS and some of the other experiments were able to measure the position of the beam using the tracker – the position was within 1 sigma of the correct position.

2. **Eudox**
   March 30, 2010

   In my country the local media says that the LHC collisions is recriating the Big-Bang. Is that true or just another hype?

3. **Peter Woit**
   March 30, 2010

   Eudox,

   It's hype. The conditions created at the LHC are not those of the big bang, and the questions we hope it will answer have little to do with the big bang.

4. **Sakura-chan**
   March 31, 2010

   Electro-weak symmetry breaking sounds so unsexy to the media.

5. **Paul Wells**
   March 31, 2010

   Well, I don't think "recreating the big-bang" is a bad analogy.

   Presumably it refers to (possibly) creating a Quark Gluon Plasma in ALICE.

   Science Journalists don't have an easy job and I think it is better to give a distorted picture than no picture at all.

6. **a quantum diaries surivivor**
   March 31, 2010

   Paul, I have to concur in general. However, there are ways to convey the importance of what the LHC is doing that have nothing to do with the big bang (which, by the way, is deceiving, since we are doing particle physics and not cosmology down here).

   The LHC is "studying what breaks the symmetry of subatomic force carriers." The LHC hopes to "produce new so far unseen particles that may teach us more about the organization of the world at its tiniest distance scales". The LHC will "collide protons at an energy never achieved so far by Man". The LHC will "allow physicists to prove their conjectures on the origin of mass". The LHC might "permit us to discover a new world of subatomic bodies, symmetric to ours but so far undiscerned".

   All of the above is still hype, but slightly more informative and more sober. It took me thirty seconds, and I did a rather sloppy job. I am sure journalists could do that too.

   Cheers,
   T.

7. **Christine**
   March 31, 2010

   Unfortunately, the most part of the world population has no idea whatsoever about what each of these means:

   – "breaks the symmetry" (symmetry? Is that an illness or something? Is there a way to repair it?)

   – "subatomic" (don't know even what an atom is, much less what a "sub" means)

   – "force carriers" (who are these strong guys?)

   – "organization of the world" (the politics of our planet?)

   – "protons" (what?)

   – "mass" (ah, weight)

   – "subatomic bodies, symmetric to ours" (esoteric!)

This is not a criticism at your attempt, which is better than connecting to the big bang (something that most people recognize as — "see? The scientists are just getting close to what religion already said"). There is a lot of deep ignorance out there. The best to be done, perhaps, would be:

"The scientists are colliding one type of tiny particle against another to see what is inside them; this is the strongest collision ever attempted, and they hope to learn from it something about these and other particles that make up everything around us".

8. **SteveB**
March 31, 2010

I agree we should not be too critical of the media. And I do not think we need to denegrate the general public.

Everyone must have experienced the frustration of having to dumb down your explanations and using less than perfect analogies to try to convince even very smart people on a subject, if they are outside of your own speciality. I know I have had to use some statements that are not quite correct because I did not have the 10 minutes (or 2 pages) I needed to do it right. I think science reporters are in an especially tough role because they have to try to write to both scientists in other fields and also to the general, educated public.

I do not think the uneducated public typically chooses to read the science reporting, just as I do not choose to read Hollywood gossip. With something as news worthy as the LHC, the reporters *do* have to broaden their audience a bit. Not easy.

I think Peter did an excellent job explaining difficult material in his book and I have been trying to keep his methods for approaching complex issues in mind when I present in my own specialty.

I will also mention (with a bit of pride) that my 14 year old daughter is really enjoying the Sean Carroll Dark Matter, Dark Energy, Teaching Company Courses lecture series. She doesn't quite get how space-time can be expanding, but otherwise is following the material quite well. She also reads New Scientist every week. So, I might suggest you think of the "public" as having many smart, educated people in it, rather than dwelling on the not-so smart and not-so educated portion.

SteveB

9. **Arun**
March 31, 2010

It is better to let the reader know that they definitely don't understand something than to mislead them with wrong words and wrong analogies.

10. **Tim van Beek**
April 1, 2010

In Germany, in the news headlines, the LHC was called the "big-bang machine" (the name LHC was mostly left out), telling the audience that "scientists reacreate the big bang and that, for god's sake, the first collisions proove that the machine does not destroy the earth".
And I'm pretty sure that even this description was too boring for most people.
My favorite anecdote about science literacy is this: Someone with a Ph.D. in computer science asked me about the LHC, and as a little check I first asked back "what is the difference between velocity and acceleration?".
Answer: "There is none, if I want velocity and/or acceleration, I hit the gas pedal."
True story.

11. **a quantum diaries surivivor**
April 1, 2010

We could discuss what is the best way to communicate to the public what the LHC is and what it does for decades without reaching a consensus.

My two cents are that there are maybe 85% of people in our planet who we will never reach with our science talk; and an additional 14.5% who is reachable and receptive. We should invest on reaching that 14.5%, by telling them true facts, as hard as they may be.

So I think Arun summarized it best.

Cheers,
T.

12. **milkshake**
April 1, 2010

Do you think there is a chance of observing events that produce a massive particle from the dark sector? Because if you tell a curious kid that the majority of stuff in our galaxy probably is of some weird type that we know almost nothing about – and we hope to produce this thing and watch its disappearing act, I think the kid is going to be awed by the idea more than by some vague hype about big bang. Its almost like finding out that two thirds of your own family is actually populated by aliens.

13. **John Baez**
April 2, 2010

The LHC is "studying what breaks the symmetry of subatomic force carriers."

I'm afraid I have to agree with Christine that this would mean nothing to most people. You could say the LHC is "studying what rotates the electricity of nuclear momentum particles" and it would make just as much sense.

14. **Arun**
April 4, 2010

Dennis Overbye in the New York Times (Week in Review) has this
http://www.nytimes.com/2010/04/04/weekinreview/04overbye.html
"A Primer on the Great Proton Smashup".

Pretty good, I thought. In particular:

"Physicists suspect that the laws of physics evolved as the universe cooled from billions or trillions of degrees in the first moments of the Big Bang to superfrigid temperatures today (3 degrees Kelvin) — the way water changes from steam to liquid to ice as temperatures decline. As the universe cooled, physicists suspect, everything became more complicated. Particles and forces once indistinguishable developed their own identities, the way Spanish, French and Italian diverged from the original

Latin.

By crashing together subatomic particles — protons — physicists create little fireballs that revisit the conditions of these earlier times and see what might have gone on back then, sort of like the scientists in Jurassic Park reincarnating dinosaurs. “

Short Items

April 2, 2010
Categories: Uncategorized

Planning on getting back to writing some longer postings, but for today, here's a collection of quick news and links:

- I hear from number theorists that Princeton's Manjul Bhargava has some breakthrough results on the ranks of elliptic curves. I was out of town and missed his colloquium talk here, reports were that it was quite impressive. Here's the main result, from the talk abstract:

> There is a standard conjecture, originating in work of Goldfeld, that states that the average rank of all elliptic curves should be 1/2; however, it has not previously been known that the average rank is even finite! In this lecture, we describe recent work that shows that the average rank is finite (in fact, we show that the average rank is bounded by 1.5).

- There's an intriguing new paper out from Frenkel, Langlands and Ngo, describing some tentative new ideas about how to prove functoriality using the trace formula. I gather that this combines ideas from Ngo's proof of the fundamental lemma, ideas of Langlands about "Beyond Endoscopy", and ideas originating in the geometric Langlands program. The paper is clearly largely written by Langlands (one hint is that it's in French, be grateful it's not in Turkish…).
- Besides this new work, Ed Frenkel also has a new film coming out, entitled Rites d'Amour et de Maths. Here's the plot summary from IMDB:

> Is there a mathematical formula for love without death? The film 'Rites of Love and Math' is a sprawling allegory about Truth and Beauty, Love and Death, Mathematics and Tattoo, set on the stage of Japanese Noh theater. About the directors: Edward Frenkel is Professor of Mathematics at University of California at Berkeley and one of the leading mathematical physicists in the world. Reine Graves is a talented French filmmaker who has directed a number of original and controversial films that have won prestigious awards. Having met in Paris, Frenkel and Graves decided to create a film showing the beauty of mathematics. But how to do this without getting bogged down in technical details of the subject that could scare away non-specialists? Looking for the right metaphor, they came across the idea of making the tattoo of a mathematical formula. What better way to show the beauty of the formula than by letting it merge – literally – with beautiful female body! They found the aesthetic language for expressing this allegory in the enigmatic film 'Rites of Love and Death' (a.k.a. 'Patriotism') by the great Japanese writer Yukio Mishima, which had a very unusual and mysterious history of its own (banned for over 40 years, it came out on DVD in the Criterion Collection in 2008). The exquisite imagery of Mishima's film and the original idea of Frenkel and Graves have led to the creation of 'Rites of Love and Math.'

- Harvard finally has a female tenured math professor: Sophie Morel.
- This week's Science Magazine has an article about Sabine Hossenfelder's work (also see her blog posting here) purporting to show that you can't get linear terms in deformed Special Relativity, making deviations from standard Special Relativity unobservably small. Personally, this is the sort of thing I don't know enough about to offer an informed judgment on, but I'm curious to hear what experts think.
- Nature has an article about social scientists studying the LHC project.
- The KITP is now running a program on Strings at the LHC and in the Early Universe, which is a bit odd, since string theory predicts nothing at all about either topic. They've had promotional Blackboard Lunch talks by Cvetic and Brandenberger claiming otherwise (Brandenberger's title was "Testing String theory with Cosmological Observations"). Taking a look at them, I don't see anything at all that corresponds to a "test of string theory".

Update: One more. See here for Jester's summary of what particle theory came up with during the noughties, which has to have been the most depressing decade for the subject in a very, very long time.

Update: There are two new papers (see here and here) on the arXiv this evening that address Sabine Hossenfelder's arguments about DSR (she also has a new paper summarizing her argument, here). In one of these, Lee Smolin argues that, at least in some cases, the paradoxes pointed out by Hossenfelder can be eliminated if one studies wave-packet propagation instead of classical propagation.

Update: There's another unusual paper on the arXiv this evening, by Longo and Witten, entitled An Algebraic Construction of Boundary Quantum Field Theory. It's an algebraic QFT paper, written in a rigorous mathematical style, quite out of character with typical papers from Witten.

Comments

1. **Egads Itwerks**
   April 2, 2010

   "Harvard finally has a female tenured math professor: Sophie Morel."

   Honestly, Peter, who cares about Harvard anymore? Columbia is more important, as are most other Universities. Harvard isn't to be faulted for hiring Lubos, no, they lost cred the day they gave George W. Bush a Masters degree. No rational person can respect them now. The once proud institution gives new meaning to "yesterday's newspaper."

2. **Li Shenjang**
   April 2, 2010

   According to the new 2010 NRC rankings (yet to be released to the wide audience), Harvard is not even in top 5 anymore. So the answer to the obvious question "would it hire S. Morel if she were a he" is probably a resounding "yes".

3. **Peter Woit**
   April 2, 2010

   Li Shenjang,

   What's going on with the NRC rankings? I remember that already several years ago they were late being released…

   And, Egads, Harvard still has a great math department, whether or not it's in the NRC top 5.

4. **Bob Levine**
   April 2, 2010

   The NRC ranking are due to be released late this spring, at last report. My understanding is that the format will be somewhat different; rather than a strict order on departments, graduate programs will be grouped into tiers. It does seem a bit more sensible, doing it that way.

5. **Shantanu**
April 3, 2010

Peter, what do u think about Deser's talk at KITP? Looking forward to your comments. I think Brandenberger's talk was about String gas cosmology(an alternative to standard inflationary model)

6. **M**
April 3, 2010

The social scientists write about CERN "its two restaurants live up to their reputation for offering some of the best food of any physics canteen in the world."

This is more irrealistic than the CERN airplane invented by Dan Brown

7. **Bee**
April 3, 2010

Hi Peter,

Thanks for the link. Since I just saw that Lubos commented on my recent paper, I hope you will kindly host my reply to him since I know it's pointless to leave it at his blog.

It is of course complete bullshit that this recent paper, or any of my previous papers, is the result of communication with Lubos. I did indeed have an email exchange with Lubos about DSR at some point. I have repeatedly, and fruitlessly, tried to tell him that the model I've been working on does not have an energy-dependent speed of light. [That model dates back to 2003] as one can easily see from my publication list. Lubos has failed all the years to grasp this simple fact. His misunderstanding is documented on various of my and his blogposts. This isn't the place to explain what's behind my model, but who is interested can check out [this blopost]. Up till today I don't know if Lubos really didn't understand that or if he just pretended to so he had a reason to proclaim I'm dumb.

To address another particularly nonsensical remark in Lubos' blogpost: Neither Lee Smolin nor anybody else has ever "pressured" me to write a paper. That I started writing papers on DSR after I went to PI is obviously because I started to get more interested in the topic. I first tried to figure out what the relation is to my model, documented [here] and [here]. I then wrote two papers about what I think are the biggest problems of DSR, the so-called [soccer-ball problem] and [the formulation in position space]. The latter paper was a precursor to the more recent paper.

Even though I've thought an energy-dependent speed of light to be incompatible with observer-independence (which is why I didn't consider the option in my 2003 paper) it wasn't so easy to show after all. Sometimes I thought it might work, but then again it didn't make sense, then I tried something else, that didn't work either, then I thought I might have missed something, etc.

It adds to this that I'm not particularly happy poking holes in other people's models, I'd rather have something more promising to offer myself. The recent paper actually came about because I was trying to figure out if there is a way to distinguish deformations of Lorentz-invariance from breaking of Lorentz-invariance by taking measurements in two different frames (say the Earth and a satellite), but I ran into some problems there. I wrote up my notes on that and dumped them on the arXiv. I frankly didn't expect them to get this attention, in particular not since the problems with locality had been pointed out previously by Unruh and Schützhold (and in my earlier paper). It's just that nobody ever put the numbers in. That's what I did. Turns out the nonlocality is far larger than even I expected it to be. So it seemed worth writing up.

Best,

Sabine

8. **Chris Oakley**
April 3, 2010

Bee,

If you insist on taking Lubos seriously, Peter does have a "Censored Comments from the Reference Frame" entry which I think still accepts comments:

http://www.math.columbia.edu/~woit/wordpress/?p=412

Although it is an old post, new comments will show up in the right-hand column here.

9. **Peter Woit**
April 3, 2010

Bee,

Thanks for the further explanations of this.

Chris,

The current configuration of the blog shuts off comment threads after some predetermined length of time. I'd rather people don't respond here to Lubos's rantings, unless it's on-topic (as Bee's comment very much was).

Shantanu,

Deser seemed to me to be saying nothing new or surprising.

10. **hv**
April 3, 2010

«It adds to this that I'm not particularly happy poking holes in other people's models, I'd rather have something more promising to offer myself.» Lubos' offer is simply the plain old Lorentz invariance. His point often being, if there's nothing reasonable and/or justified to offer, then don't! And pointing holes in models should be compulsory in any theoretical science, especially if you know they're there! It makes issues in science less foggy. Is Lubos harsh in his discourse? Yes, he his! But afaik his points are correct. Mind you, Nature isn't polite either.

11. **Peter Woit**
April 3, 2010

hv,

The problem with Lubos is not just that he's impolite. He's a fanatic, and like all fanatics is devoted to misunderstanding and ignoring facts that disagree with his preconceptions. The rudeness makes it extremely unpleasant for anyone who tries to take on the task of correcting something he is wrong about, and the fanaticism ensures that he'll never acknowledge error.

Enough though about Lubos. It's depressing to put up postings mentioning a range of interesting topics, then find that all people want to discuss is Lubos the minute some reference is made to him.

12. **Sacre Bleu !!**
April 3, 2010

> what particle theory came up with during the
> noughties, which has to have been the most depressing decade
> for the subject in a very, very long time.

The idea being, I gather, that any progress in particle
physics (say, advances in jet algorithms or QCD perturbative
computations) is extremely boring, whereas any incremental
result in some obscure subfield of number theory is
fascinating, especially if it has been written in some
Quartier Latin's dialect of French.

13. **Lubos Motl**
April 3, 2010

An anonymous unfriendly person – a reader of yours, Peter – has sent me a link to your blog, Peter. I haven't heard about the blog for years but it's good to see it's still alive. But not too good. 😉

Interesting conversation. Concerning your frustration: Well, let us admit that I am by far the most interesting topic you have ever discussed on your blog, so the mindless zombies who keep on visiting your crappy website even years after it's been shown that you are just a grumpy dishonest crank are unsurprisingly excited by this topic. Get used to it. You owe everything to me.

The whole point of this collapsing website has always been to poison people and slander physics and physicists. The whole point was to claim that there was nothing interesting or valid going on in theoretical high-energy physics – which mostly means string theory. The whole point was to make people frustrated, bored, upset, and misled.

So it is pretty surprising to hear that you think that you are offering "interesting topics". You have never offered any interesting topics or ideas in your whole life, Peter. Even the most hardcore mujahideens who still keep on visiting this site know that which is why they're trying to discuss the only remotely relevant interesting topic which just happens to be myself at this point (although I would surely modestly disagree that I am the most interesting topic – but among the topics that are accessible to limited people who have been brainwashed by your stupidities for 6 years, I probably am). 😉

[arguments/threats directed at someone else deleted]

14. **Bee**
April 4, 2010

hv:

The thing is that what's "reasonable" and "justified" is not an objective criterion. Different people may have different opinions on that, and these opinions will typically differ depending on the context of their work and their interests. One of the key motivations to consider the particular type of deviations from Special Relativity that my paper comments on is that Special Relativity does not respect the invariance of any (finite, non-zero) energy scale. If you believe the Planck mass is a physically meaningful UV regulator, then it should be the same in all restframes, so the argument. You can't do that with usual Lorentz-transformations. Thus, you need a modification of Special Relativity to achieve the invariance of the Planck scale.

Now I've argued (in one of the papers I mentioned above) this is not the right way to think about the invariance of the Planck scale, but then I do not think it's an "unreasonable" motivation either to examine such deviations from Special Relativity. Best,

B.

15. **Ricci's Pieces**
April 4, 2010

It is ridiculous to say that Harvard is not important anymore. They have Jacob Lurie! I'm not a category theory person, but it cannot be denied that what Jacob Lurie is doing is ground breaking work. Yes, Columbia has some impressive people, but Harvard is still one of the best math departments in the nation.

16. **anon.**
April 4, 2010

One of the key motivations to consider the particular type of deviations from Special Relativity that my paper comments on is that Special Relativity does not respect the invariance of any (finite, non-zero) energy scale. If you believe the Planck mass is a physically meaningful UV regulator, then it should be the same in all restframes, so the argument.

On the contrary. Lambda_{QCD}, or maybe 4pi Lambda_{QCD}, is a UV scale if you're talking about pion physics. And it's not Lorentz invariant. Is this a problem? Of course not; it's only if some *invariant* quantity is larger than Lambda_{QCD} that it's sensitive to the UV completion (QCD). It's true that this is simple field theory, not deep and mysterious quantum gravity, but I don't see why the fact that quantum gravity is deep and mysterious should lead you to conclude that all the rules have to change.

17. **anon.**
April 4, 2010

To clarify, my "it's not Lorentz-invariant" means "it's not Lorentz-invariant if viewed as a cutoff *energy*." The point, of course, being that the cutoff is not in energy but in invariant kinematic quantities.

18. **anon.**
April 4, 2010

I now recall that I made the same point on your blog several years ago, Bee. I'm not sure if I'm failing to convey the point or if you have some argument I've missed.

19. **?**
April 5, 2010

Somebody must ask this: the 1st female math professor at Harvard is there because she was the best candidate, or because Harvard now has a radical feminist president and a lot of $ for "diversity efforts"?

20. **Peter Woit**
April 5, 2010

?,

Morel is an excellent mathematician, not at all out of place among the list of other Harvard senior faculty. One could also note that she started her career with admission to the ENS in Paris, which is by competitive exam. If one is going to try and make the case that affirmative action is a problem at American universities, she's not a helpful example.

21. **willman**
April 5, 2010

Anon,
Bee's conclusion, as I understand it, is that the Planck energy does not in fact need to be an invariant of Lorentz boosts (see p. 18 of her "Box-problem" article); thus, I don't see any actual disagreement between you and her on this point. Bee also claims that the Planck scale needs to be observer-independent if this scale is truly fundamental; but I'm not sure why this claim is any more controversial than the idea that taking the velocity c of light as fundamental involves taking c to be observer-independent.

It would be helpful if someone were to put together a post discussing in detail this issue of the observer-dependence of the Planck scale, and the different sides of the question.

Solar

April 5, 2010
Categories: Book Reviews

Ian McEwan's new novel Solar is now out, with a plot featuring Michael Beard, an aging theoretical physicist. Beard won a Nobel prize early in his career for the "Beard-Einstein Conflation", which supposedly involves some unexpected coherent behavior in QED, based on the discovery of a structure in Feynman diagrams that involves E_8. An appendix of the novel reproduces the Nobel presentation speech, evidently it's the work of physicist Graeme Mitchison (see here).

As the novel opens in 2000, Beard is in his fifties, having spent quite a while coasting on his Nobel Prize. He's director of an alternative energy research center, and one of the activities there employs postdoc theorists to evaluate unconventional ideas that are sent in, largely by cranks:

> Some of these men were truly clever but were required by their extravagant ambitions to reinvent the wheel, and then, one hundred and twenty years after Nikola Tesla, the induction motor, and then read inexpertly and far too hopefully into quantum field theory to find their esoteric fuel right under their noses, in the voids of the empty air of their sheds or spare bedrooms – zero-point energy.
>
> Quantum Mechanics. What a repository, a dump, of human aspiration it was, the borderland where mathematical rigor defeated common sense, and reason and fantasy irrationally merged. Here the mystically inclined could find whatever they required and claim science as their proof.

The postdocs have little interest in the old history of Beard's discovery about QED, but instead baffle him by making "elliptical references to BLG or some overwrought arcana in M-theory or Nambu-Lie 3 algebra." McEwan seems to have gotten this from Mike Duff, who is thanked in the acknowledgments. There's the obvious problem though that Bagger-Lambert-Gustavsson, a hot topic while the book was being written, dates from 2007, so is anachronistic as a topic of discussion in 2000. Beard's reaction to what the postdocs work on is:

> Some of the physics that they took for granted was unfamiliar to him. When he looked it up at home, he was irritated by the length and complexity of the calculations. He liked to think that he was an old hand and knew his way around string theory and its major variants. But these days there were simply too many add-ons and modifications. When Beard was a twelve-year-old schoolboy, his math teacher told the class that whenever they found an exam question coming out at eleven nineteenths or thirteen twenty-sevenths, they should know that they had the wrong answer. Too messy to be true. Frowning for two hours at a stretch, so that the following morning parallel pink lines were still visible across his forehead, he read up on the latest, on Bagger, Lambert and Gustavsson – of course! BLG was not a sandwich – and their Langrangian description of coincident M2-branes. God may or may not have played dice, but surely He was nowhere near this clever, or such a show-off. The material world simply could not be so complicated.

To some extent, *Solar* is an entertaining comic novel of physicists and the alternative energy research business. The dominant theme though is a topic not all will find interesting: Beard's personal life, which involves five failed marriages over the years. At the end of the book, Beard is in his sixties, a fat, unpleasant slob, with two younger women fighting over the possibility of being number six on the list.

Comments

1. **Nigel**
   April 5, 2010

   Second sentence:

   "… based on a the discovery of …"

   You need to decide whether it is "a" or "the" discovery.

   "… a topic not all will find interesting: Beard's personal life … At the end of the book, Beard is in his sixties, a fat, unpleasant slob, with two younger women fighting over the possibility of being number six on the list."

   I suppose it would be interesting why two women would fight over such a person … if it wasn't just fiction.

2. **Peter Woit**
   April 5, 2010

   Thanks Nigel, fixed.

   The phenomenon of attractive younger women throwing themselves at much older unattractive and unpleasant men is one that seems to have been exhaustively dealt with in literature. Whether it correlates to anything statistically common in reality, I have no idea. To be fair to McEwan, in this book, one of the two women is portrayed as unattractive herself…

3. **roland**
   April 5, 2010

   I think no "real" physicist would think of a primary school exam that features non integral solutions when confronted with some new theory that he thinks is too messy or complicated or whatever to be true.

4. **Kea**
   April 6, 2010

   So all crackpots are men? Phew, that let's me off the hook.

5. **cormac**
   April 6, 2010

   Hi Peter,
   I just finished 'Solar' too! I must say I thought it was a very good book indeed, in many ways.
   First and foremost, I thought the description of the main character utterly plausible, and most impressive for a non-scientist. I also thought McEwan's antihero a much more complex character than you imply.
   There were several other themes I liked – the conversion from gw sceptic to convictee was very convincing. Also the tension between genuine believer and later

commercial interest was very well done – a theme that few scientists seeem to be aware of.
Re personal angle, well it is a novel! It's a book I look forward to reading a second time..

6. **Peter Woit**
   April 6, 2010

   Thanks Cormac,

   I'm afraid I was rather unfair to the novel in limiting my remarks about the non-theoretical physics parts of it to some easy snark. I agree to some extent with your comments and hope they go a ways to giving a better idea of the rest of the book.

7. **Andrew L.**
   April 6, 2010

   First off,big fan of your blog,Peter. A second year graduate student in pure mathematics at Queens College and The City University Of New York Graduate Center.
   Never read the novel under consideration-sadly,literature,once a great love of mine,has long since been back seated to my personal life. But to answer your question from my own limited experience, attractive younger women are attracted to fat old slobs of questionable character for one very simple motivation that takes a myriad of forms: riding the storm.They feel attaching themselves to such a man who's regarded as an eminent person will share that eminence with them and increase thier importance in society's eyes. It's why rock stars marry 20 something models who they are old enough to be grandfather to,why Anna Nicole Smith married a 90+ year old billionaire,and why half the Senators,lawyers in Cambridge and doctors on Park Avenue have second wives younger then thier daughters.It's not really just about wealth,although that's the simplest and most obvious example.It's about hooking thier car to a train everyone gathers around to watch when it pulls into the station.

8. **Jen**
   April 8, 2010

   Aw, like some people (including yourself) the non-science stuff is reviewed rather harshly.
   I found it quite an intriguing novel, also because of the science involved. I'm a senior EE major/ philosophy minor at the U of southern calif (at the moment at the ETH in Zurich, switzerland, which – by the way – is a waaaay cool university) and I love my physics classes and ever since my friends heard of that, all presents I'm getting for birthdays etc involve physics in some way or other. Solar was one of them.

   anyhew, the main reason why I'm writing a comment is that I'm one of those 20-something women involved with an older, not always pleasant to others guy, and that I MUST protest! Our relationship is not even a publicly known fact, so I'm NOT doing it to get some glory or money or whatever.
   you know, love can sometimes be even harder to describe than the laws of physics. and people sometimes fall in love completely irrationally, creating really bad matches. but what's a mere mortal to do?

9. **Jen**
   April 8, 2010

   haha, sorry for the unfinished sentence there! of course, it's supposed to say
   "like some people, including yourself, wrote …"

   sorry! tired me produces half-way sentences. brain thinks, fingers too tired to keep up.

Freaky Physics Proves Parallel Universes Exist

April 6, 2010
Categories: Multiverse Mania

Fox News has decided that some recent experimental atomic physics work showing that quantum mechanics works as expected (for a sane discussion of the science, see here) proves that parallel universes exist and that time travel may be feasible. In an article entitled Freaky Physics Proves Parallel Universes Exist, Fox News writer John Brandon develops this idea with help from Sean Carroll and Fred Allan Wolf (aka Dr. Quantum):

> The multi-verse theory says the entire universe "freezes" during observation, and we see only one reality. You see a soccer ball flying through the air, but maybe in a second universe the ball has dropped already. Or you were looking the other way. Or they don't even play soccer over there.
>
> Sean Carroll, a physicist at the California Institute of Technology and a popular author, accepts the scientific basis for the multi-verse — even if it cannot be proven.
>
> "Unless you can imagine some super-advanced alien civilization that has figured this out, we aren't affected by the possible existence of other universes," Carroll said. But he does think "someone could devise a machine that lets one universe communicate with another."
>
> It all comes down to how we understand time.
>
> Carroll suggests that we don't exactly feel time — we perceive its passing. For example, time moves fast on a rollercoaster and very slowly during a dull college lecture. It races when you're late for work . . . but the last few minutes before quitting time seem like hours.
>
> **Back to the Future**
>
> "Time seems to be a one-way street that runs from the past to the present," says Fred Alan Wolf, a.k.a. Dr. Quantum, a physicist and author. "But take into consideration theories that look at the level of quantum fields … particles that travel both forward and backward in time. If we leave out the forward-and-backwards-in-time part, we miss out on some of the physics."
>
> Wolf says that time — at least in quantum mechanics — doesn't move straight like an arrow. It zig-zags, and he thinks it may be possible to build a machine that lets you bend time.

Update: Matt Springer has a more detailed analysis of the Fox News article entitled The Worst Physics Article Ever. For some reason his critique skips over the multiverse part, implying that that's the one part of the article that makes sense…

   This is.. not even wrong.

2. **milkshake**
   April 6, 2010

   The time-bending machine from Dr. Quantum + Fox News: It would be lot more feasible to build a machine that bends the public perception of reality… Wait, it already exists.

3. **Chris Oakley**
   April 6, 2010

   Reminds me of graffiti scrawled in one of the men's toilets in college in the Einstein centenary year (1979):

   Space is straight, Einstein was pissed

   [NB: pissed (Brit. sl.) = drunk]

   Underneath, someone had then written

   No, space is bent: God was pissed.

4. **Matt Leifer**
   April 6, 2010

   Wow, this is an incredibly garbled article. I sort of expect it from Dr. Quantum who often produces stuff that skirts the edges of quantum flapdoodle, but I would have expected Sean to be more careful (or at least more highly attuned to to possibility of an out of context quote).

5. **hasan**
   April 9, 2010

   I know jack shit about physics, but when i saw the article was from fox i immediately suspected bullshit. That suspicion was confirmed when i googled for more stories on the subject and couldn't find any. God, i wish google would stop linking to Fox "News" Pieces. I was so excited about the parallel universe thing too.

$2 Million For The Nature of Time

April 6, 2010
Categories: Uncategorized

FQXI has just announced that it will be awarding another series of large grants, of size \$50K-\$100K, totaling about \$2 million. These grants will be targeted at research into "The Nature of Time." Initial proposals are due June 14, grants will start January 2011. For more details, see here and here.

At this point, I'm a bit curious about where the FQXI money is coming from. They started up in 2006 with a seed grant from the Templeton Foundation of about \$8.8 million, and that grant was supposed to finish at the end of last year. Going forward, I haven't seen any indication of whether they're still operating on the seed money, or have new money from Templeton or other sources.

   April 6, 2010

   I received their bulk email about this, even though I asked to be taken off their mailing list years ago. Anyway, I submitted a proposal, because it was easy enough, but I doubt it will get past the admin people … an institution is required.

A Tear at the Edge of Creation

April 6, 2010
Categories: Book Reviews

There's a new book out this week by Marcelo Gleiser, entitled A Tear at the Edge of Creation. Gleiser blogs at the NPR site 13.7, and that site also has a review of the book from his fellow blogger Adam Frank.

Gleiser started out his professional life as a string theorist, enchanted by the prospect of finding a unified theory, and for many years that motivated his research:

> Fifteen years ago, I would never have guessed that one day I would be writing this book. A true believer in unification, I spent my Ph.D. years, and many more, searching for a theory of Nature that reflected the belief that all is one.

Over the years he began to become disillusioned with this quest, not only with string theory, but also with other closely associated ideas (e.g. GUTs and supersymmetry) about how unification is suppose to happen. Hopes that GUTs would give predictive theories of inflation or proton decay have fallen by the way-side, and about supersymmetry he is "very skeptical":

> The fact that the particle has so far eluded detection doesn't bode well. To make things worse, results from the giant Super-Kamiokande detector in Japan and the Soudan 2 detector in the United States have ruled out supersymmetric GUT models, at least the simpler ones, based again on the proton lifetime. If SUSY is a symmetry of Nature, it is very well hidden.

About string theory itself, Gleiser refers to my book and Lee Smolin's, and comments that:

> Responses from notable string theorists were of course highly critical of the books and their writers. Some were even offensive. I find this sort of dueling pointless. People should be free to research whatever they want, although they should also reflect responsibly on whether their goals are realistic.

Ultimately, Gleiser came to the point of view that all hopes for a unified theory are a misguided fantasy, and explaining this point of view is the main goal of the book. In an interview on his publisher's web-site, he says:

> After years searching for a "final" answer, as a scientist and as a person, I realized that none exists. The force of this revelation was so intense and life transforming that I felt compelled to share it with others. It completely changed the way I think about Nature and our place in it.

In his book, he argues repeatedly against the fundamental nature of symmetries in our understanding of physics, seeing the failures of GUTs and supersymmetry as a failure of the idea of getting unification out of larger, more powerful symmetry laws. For him, symmetries are always just approximations, never exactly true principles. He claims to be more interested in asymmetries, in failures of symmetry laws, seeing in asymmetry a fundamental explanatory principle about the universe and humanity's role in it.

Personally, I find myself in strong disagreement with him about this, and don't see much evidence in the book that the abandonment of the search for symmetries that he advocates leads to any positive route to greater understanding of the universe. I agree with him about the failure of the most popular ideas about how to use symmetry to get beyond the Standard Model, but disagree with him about the implications of this.

The problem with both GUTs and supersymmetry is that one posits a new symmetry only to be faced immediately with the question of how to break it, with no good answer. To be successful, any new symmetry principle needs to come with a compelling explanation of how it is to be realized in fundamental physics. A repeated lesson of the development of the Standard Model was that major advances came not only from coming up with new symmetry groups, but through coming up with unexpected ways of realizing them (e.g. spontaneous symmetry breaking and confinement in gauge theory). I don't believe that the gauge symmetries of the Standard Model are approximations, but rather that they are among our most powerful and fundamental physical principles, and that much work remains to be done to understand their full implications. The failures that have discouraged Gleiser have also discouraged many others, and a resulting abandonment of symmetry-based attempts to find a better, more unified, fundamental theory would be a shame.

Comments

1. **Claire**
   April 7, 2010

   Hi Peter,

   there is another option, between the idea of Gleiser and yours: that the known gauge symmetries are exact, but that no higher symmetries exist. So far, experiments point more in this direction.

   After all, Gleiser's experience is not that unification is misguided, but only that supersymmetry-based unification (thus with this particular higher symmetry) does not work.

   Claire

2. **James**
   April 7, 2010

   "Gleiser started out his professional life as a string theorist, enchanted by the prospect of finding a unified theory, and for many years that motivated his research."

   This does not appear to be a true statement, as can easily be checked by looking at Gleiser's papers on SPIRES. It seems that he has worked in cosmology most of his 30 year career and did not start out as a string theorist as you have claimed. It would seem that you have simply asserted this in order to find yet another way to throw mud at string theory.

3. **Peter Woit**
   April 7, 2010

   James,

   To quote from page 149 of the book:

   "Together with my Ph.D. advisor, John G. Taylor, I even wrote one of the first papers on how superstrings could explain the Big Bang, back in 1985."

I don't think I've mischaracterized Gleiser's attitude toward string theory at all. He's quite critical of the whole general idea of trying to find a unified theory, including the specific approach of string-theory based unification, and that's a subject he has worked on and thought about.

4. **DaveB**
   April 7, 2010

   Off topic, but I noticed that your posting about the Paul Dirac biography isn't listed in the book reviews section.

5. **Peter Woit**
   April 7, 2010

   DaveB,

   I only started using the "book review" tag relatively recently. Will add it to the Dirac bio posting, others as I notice them.

6. **jpd**
   April 7, 2010

   is that "tear" as in cry a tear? or a tear in my shirt?

7. **Peter Woit**
   April 7, 2010

   jpd,

   tear as in my shirt is my guess. For one thing, the cover of the book features a torn photograph.

8. **younghun park**
   April 7, 2010

   Hi Peter
   Could you explain the reason why you believe that gauge symmetry is perfect?

9. **Giotis**
   April 7, 2010

   My understanding is that the very nature of the Big Bang itself forces us to search for a unification scheme above a certain energy.

   Regarding symmetries Susskind says pretty much the same with Gleiser in this interview:

   http://www.closertotruth.com/video-profile/Why-do-we-Search-for-Symmetry-Leonard-Susskind-/1493

   But when he talks about symmetries he is referring to global and not gauge symmetries. He doesn't consider gauge as real symmetries in the strict sense. At least this is what I understood.

10. **rrtucci**
    April 7, 2010

    I don't get it. Why is it called 13.7 ? I thought all NPR radio stations in the US are by convention near 90FM. 1/137 ?

11. **theoreticalminimum**
    April 7, 2010

    rrtucci: 13.7 as in 13.7 billion years, estimated age of the universe.

12. **Peter Woit**
    April 7, 2010

    Giotis,

    I don't see how the Big Bang has anything to do with it.

    yonghun,

    Adding gauge-non-invariant terms to the Standard Model action is believed to ruin fundamental consistency properties of the theory such as unitarity. There's also neither any experimental evidence for such terms, nor any theories of them viable enough to motivate people to even bother to look for such effects.

13. **Giotis**
    April 7, 2010

    Peter, what do you mean when you say that the Big Bang has nothing to do with the unification of forces?

    This is pretty much conventional wisdom. To see what I mean check this article in Wikipedia for example regarding the evolution of forces during the Big Bang.

    http://en.wikipedia.org/wiki/Timeline_of_the_Big_Bang

    Or maybe you mean something else?

14. **Signs of the Times**
    April 7, 2010

    The era of "shut up and calculate" is long gone. Now it seems to be
    "Don't compute, just blather on"

15. **Peter Woit**

April 7, 2010

Giotis,

What we can observe about the Big Bang just doesn't give us any useful information about unification and Beyond Standard Model physics. What gets a lot of attention is that people have been hopeful that we might observe things like monopoles or cosmic strings that were remnants of BSM physics produced at early stages of the Big Bang, but nothing like this has ever been seen. All our observations of the Big Bang are completely consistent with the SM. Nothing we see about the Big Bang is helpful for understanding LHC energy physics, much less higher energies.

16. **Peter Morgan**
April 7, 2010

As an empirical matter, I take an observed symmetry as a starting point: to say that a real object is circular or square starts a discussion in terms of a particular mathematical object, after which we can introduce more subtle measures of how close the real object is to being an ideal circle or square. If we start with a real object that is close to being a circle, it's relatively natural to use representations of the rotation group to express how close the object is to being a circle. When we later discover that an object is close to being an ellipse, it may become relatively natural to introduce other, different measures of how close the object is to being an ellipse.

In the more abstract arena of correlations between observables at time-like separation, which have traditionally been discussed from a starting point of a Hamiltonian or Lagrangian presentation of a free quantum field dynamics, it is relatively natural, and quite empirically effective, to introduce gauge-invariant deformations of that type of presentation, while keeping the CCRs undeformed. That is by no means true if we adopt a different mathematical starting point for discussing correlations at time-like separations, or if we were to decide, more radically, that it is worthwhile to discuss something other than correlations, expected values, and other statistics as a universal representation of empirical data.

The idea of representations of a symmetry group that act (linearly or non-linearly) on a representation space is sufficiently general as a way to organize calculation that it seems likely to be part of at least the next generation of mathematics that is used to describe what mathematical object the world is like, and how close the likeness is, just as a matter of correspondence. But in the more removed future we might have to say that some more abstract mathematical concept has taken over from "symmetry" as the label du jour.

Gleiser, I suppose, has to some extent given up the quest to find some mathematical object that is more like the way the world is, in a tractable and useful way, than what we currently have.

17. **Bill K**
April 7, 2010

All our observations of the Big Bang are completely consistent with the SM. Nothing we see about the Big Bang is helpful for understanding LHC energy physics, much less higher energies.

One of the most important observations from the Big Bang is inflation, and the hypothetical particle which causes this, the inflaton, is not a part of the Standard Model.

18. **John Baez**
April 7, 2010

Peter wrote:

> All our observations of the Big Bang are completely consistent with the SM.

What about the evidence widely believed to support the inflationary cosmology? I don't think inflation can be explained using only Standard Model physics.

19. **neo**
April 8, 2010

So is the search for symmetry and unification a good approach to doing physics, or not? In some cases, the search for them has led to profound discoveries. In other cases, they have proved a wild goose chase and wasted productive years by great scientists. In still other cases, symmetry and unification were the result but never the motive.

20. **Kea**
April 8, 2010

Peter, classical symmetries rely on the classical concept of spacetime. Do you not think there is a good chance that the non local formulation of the SM (which must exist according to the evidence from twistor theory) might employ distinct, albeit necessarily deeper, principles?

21. **Frank**
April 8, 2010

John,

there is *no* observational evidence for inflation. As explained in the wikipedia article you cite, there is evidence for flatness, homogeneity, a specific fluctuation spectrum, etc., etc.. But many cosmological models gives those same results, also models without inflation. (This is not mentioned in the wikipedia article, but any cosmologist will confirm this.)

To claim that cosmology provides any evidence beyond the standard model is wishful thinking!

22. **Peter Woit**
April 8, 2010

Bill K and John,

My comment about SM and the Big Bang was perhaps slightly too strong. The problem with inflation is that it gives us very little extra to go on, basically something like "there's some kind of other physics, which can be crudely modeled by an inflaton with an effective potential we have some very minimal information about". The original hope was that this inflaton would correspond to a particle that fit into the GUT scenario, and that then inflation would be experimental evidence for unification, but this has not worked out.

Kea,

Twistor theory is a very good example of a different way of realizing symmetries, one that could turn out to have deep significance for unification.

23. **Physicsphile**
April 8, 2010

Cosmology very strongly points towards the existence of dark matter which cannot be explained by the SM.

24. **Peter Woit**
April 8, 2010

Physicsphile,

The main evidence for dark matter comes not from cosmology but from observations of relatively nearby galaxies. As with inflation, what we know about the Big Bang gives us only very minimal information about dark matter and what sort (if any..) of non-SM physics it might come from.

My point remains that, despite a lot of hype promoting the idea that the way to get information about unification is to study cosmology, this hasn't really worked out.

25. **Physicsphile**
April 8, 2010

Peter,

The rotation curve of galaxies is an important piece of confirming evidence for dark matter but by itself it does not show that the dark matter is not a SM particle.

To do that you need Cosmic microwave background data or a combination of galaxy survey data and big bang nuclear synthesis data.

26. **Remus**
April 8, 2010

> combination of galaxy survey data and big bang nuclear synthesis

I'm pretty ignorant on these matters, but nucleosynthesis falls squarely within the SM of particle physics. In fact, it is pre-SM physics, since it was first developed before the SM was even formulated.

27. **Thomas R Love**
April 8, 2010

Gleiser's statement:

'After years searching for a "final" answer, as a scientist and as a person, I realized that none exists.'

This is classic sour grapes. He is saying that he failed to find such a theory and since he is so smart, no one else can either.

Conservation laws are the foundation of physics and conservation laws follow from continuous groups, therefore groups form the foundations of physics.

28. **Paul**
April 8, 2010

Personally I don't see symmetry as fundamental to unification. Symmetry is an important property but it is just an abstraction forming only part of a proper description of any object.

SM is mostly based on guesswork and since it is much easier to guess a symmetry then to guess all the other details of a description symmetry has played an important role. But now that we know all the relevant symmetries the task is to elucidate all the other details of description of fundamental physics.

29. **chris**
April 9, 2010

a highly esteemed colleague once said that all of particle physics is mislead by the higgs mechanism. most people expect the symmetry to increase by going to higher energies, where actually experience tells us that it is exactly opposite. in solid state physics you can plainly see this. and also in high energy physics it is to be expected: the modern view of renormalizability has told us that no matter what happens at the high scale, at low energies we will end up with the SM lagrangean with only the few renormalizable terms that it contains.

it would be very strange in my opinion, if this symmetry generating mechanism, that is already discovered, would be unused by nature and instead of a proliferation of terms we would see them thinning out at high energies. to me, this scenario seems strongly disfavoured by the renormalizability of the SM.

30. **Physicsphile**
April 9, 2010

Remus,

big bang nuclear synthesis data indicates that baryons only make up about 5% of the energy density needed to close the Universe. Redshift surveys indicate that non-relativistic matter makes up about 30%, so 25% of this is inferred to be non-baryonic matter.

Independently, the CMB can constrain both quantities. Some assumptions are needed to do this in each case, as with all science. If you combine more data sets you can then reduce the number of assumptions.

31. **Remus**
April 9, 2010

Physicsphile,

I agree with you that Big Bang nucleosynthesis predicts an amount of baryonic matter that, when compared with the matter needed to explain astronomical observations of gravitational effects, turns out to be just about 5% of the mass/energy density of the universe.

But nucleosynthesis is a collection of purely SM processes. In fact, since the synthesis of nuclei occurs at typical energy scales of tens of MeV, it is pretty insensitive to the high energy structure of the SM, or its extensions. For example, nuclear synthesis occurs in the Sun all the time, and it's quite independent of the precise value of the top mass.

Chris,

the SM has a larger symmetry group than any of its lower-energy effective theories. At a scale of, say, 1MeV, particle physics looks like QED + Fermi model + nuclear physics. At the electroweak scale, it's all just a single gauge theory (with a product group, so not unified yet). So, at least in this case, higher energy leads to more symmetry. Which comes to show that the RG-flow point of view you are taking does not prohibit that from happening.

By the same token, it might well happen that at 1TeV particle physics looks like the SM + a bunch of effective interactions, which are all derived from a single theory with an even larger symmetry group at some higher scale. Or it might well be that something else happens…

32. **JC**
April 10, 2010

I took a look through this book earlier this evening. It consists of a lot of short chapters about stuff unrelated to particles, cosmology, strings, etc …

Overall it reads a bit like a rambling monologue, with some nuggets about his change of heart about unification and the "eureka moment" which led to it.

33. **Bill K**
April 10, 2010

Remus,

A moment spent googling 'big bang nucleosynthesis' will help clear up your confusion. Yes, it's true that the nuclear reactions are low energy. However the net yield of light isotopes produced (particularly deuterium) is sensitive to the temperature curve of the cooling big bang, and this in turn is influenced by whether you use the standard model or one of its extensions. So the amount of primordial deuterium that one observes has a direct bearing on particle models.

34. **Remus**
April 11, 2010

Bill, there's no confusion at all. Element abundances in the Universe depend on nucleosynthesis rates and on the thermal history of the Universe. Nucleosynthesis data do not disagree with the SM. The thermal history of the Universe is another story, to which I made no reference in my posts.

35. **Physicsphile**
April 12, 2010

Remus,

I never claimed BBN was not explained by SM processes.

36. **Chris W.**
April 12, 2010

An interview with Marcelo Gleiser is here.

He may have a case to make, but judging from this interview it isn't much of one.

Three Mysteries

April 13, 2010
Categories: Favorite Old Posts, Uncategorized

There's a well-known list of high-profile problems in fundamental theoretical physics that have gotten most of the attention of the field during the past few decades (examples would be the problems of quantizing gravity, solving QCD, explaining dark energy, finding a model of dark matter, breaking supersymmetry and connecting it to experiment, etc.). Progress on these problems has been rather minimal, and in reaction one recent trend has organizations such as FQXI promoting research into questions that are much more "philosophical" (for instance, they are now asking for grant proposals to study "The Nature of Time"). In this posting I'd like to discuss a different class of problems, ones which I believe haven't gotten anywhere near the attention they deserve, for an interesting reason.

The three problems share the characteristic of being apparently of a purely technical nature. The argument against paying much attention to them is that, in each case, even if one were to find a satisfactory solution, it might not be very interesting. It's possible that all one would discover is that the conventional wisdom about these problems, that they're just "technical" and thus not of much significance, is correct. The argument for paying more attention is that the technical problem may be an indication that we're doing something wrong, that there is something of significance about the Standard Model that we haven't yet understood. Achieving this understanding may lead us to the insight needed to successfully get beyond the Standard Model. At the moment all eyes are on the LHC, with the hope that experiment will lead to new insight. Whether this will work out is still to be seen, but in any case it looks like it's going to take a few years. Perhaps theorists with nothing better to do but wait will want to consider thinking about these problems.

Non-Perturbative BRST

The BRST method used to deal with the gauge symmetry of perturbative Yang-Mills theory does not appear to generalize to the full non-perturbative theory, for a rather fundamental reason. This was first pointed out by Neuberger back in 1986 (Phys. Lett. B, 183 (1987), p337-40.), who argued that, non-perturbatively, the phenomenon of Gribov copies implies that expectation values of gauge-invariant observables will vanish. I've written elsewhere about a different approach to BRST that I'm working on (see here), which is still at a stage where I only fully understand what is going on in some toy quantum-mechanical models. My own point of view is that there's still a lot of very non-trivial things to be understood about gauge symmetry in QFT and that the BRST sort of homological techniques for dealing with it are of deep significance. Others will disagree, arguing that gauge symmetry is just an un-physical redundancy in our description of nature, and how one treats it is a technical problem that is not of a physically significant nature.

One reaction to this question is to just give up on BRST outside of perturbation theory as something unnecessary. In lattice gauge theory computations, one doesn't fix a gauge or need to invoke BRST. However, one can only get away with this in vector-like theories, not chiral gauge theories like the Standard Model. Non-perturbative chiral gauge theories have their own problems…

Non-perturbative Chiral Gauge Theory

Since the early days of lattice gauge theory, it became apparent that chiral symmetry was problematic on the lattice. One way of seeing this is that naively there should be no chiral anomaly on the lattice. The problem was made more precise by a well-known argument of Nielsen-Ninomiya. More recently, it has become clear that one can consistently introduce chiral symmetry on the lattice, at the cost of using fermion fields that take values in an infinite dimensional space. One such construction is known as "overlap fermions", which have the crucial property of satisfying relations first written down by Ginsparg and Wilson. This kind of construction solves the problem of dealing with the global chiral symmetry in theories like QCD, but it still leaves unsolved the problem of how to deal with a gauged chiral symmetry, such as the gauge symmetry of the Standard Model.

Poppitz and Shang have recently written a nice review of the problem, entitled Chiral Lattice Gauge Theories Via Mirror-Fermion Decoupling: A Mission (im)Possible? They comment about the significance of the problem as follows:

> Apart from interest in physics of the Standard Model — which, at low energies, is a weakly-coupled spontaneously broken chiral gauge theory that does not obviously call for a lattice study — interest in strong chiral gauge dynamics has both intensified and abated during the past few decades. From the overview in the next Section, it should be clear that while there exist potential applications of strong chiral gauge dynamics to particle physics, at the moment it appears difficult to identify "the" chiral theory most relevant to particle physics model-building (apart from the weakly-coupled Standard Model, of course). Thus, the problem of a lattice formulation of chiral gauge theories is currently largely of theoretical interest. This may or may not change after the LHC data is understood. Regardless, we find the problem sufficiently intriguing to devote some effort to its study.

In a footnote they compare two points of view on this: Creutz who argues that the question is important since otherwise we don't know if the Standard Model makes sense, and Kaplan who points out that if there is some complicated and un-enlightening solution to the problem, it won't be worth the effort to implement.

You can read more about the problem in the references given in the Poppitz-Shang article.

Euclideanized Fermions

Another peculiarity of chiral theories arises when one tries to understand how they behave under Wick rotation. Non-perturbative QFT calculations are well-defined not in Minkowski space, but in Euclidean space, with physical observables recovered by analytic continuation. But the behavior of spinors in Minkowski and Euclidean space is quite different, leading to a very confusing situation. Despite several attempts over the years to sort this out for myself, I remain confused, and can't help suspecting that there is more to this than a purely technical problem. One natural mathematical setting for trying to think about this is the twistor formalism, where complexified, compactified Minkowski space is the Grassmanian of complex 2-planes in complex 4-space. The problem though is that thinking this way requires taking as basic variables holomorphic quantities, and how this fits into the standard QFT formalism is unclear. Perhaps the current vogue for twistor methods to study gauge-theory amplitudes will shed some light on this.

On the general problem of Wick rotation, about the deepest thinking that I've seen has been that of Graeme Segal, who deals with the issue in the 2d context in his famous manuscript "The Definition of Conformal Field Theory". I saw recently that he's given some talks in Europe on "Wick Rotation in Quantum Field Theory", which makes me quite curious about what he had to say on the topic.

For some indication of why this confusion over Minkowski versus Euclidean spinors remains and doesn't get cleared up, you can take a look at what happened recently when Jacques Distler raised it in related form on his blog here (he was asking about it in the context of the pure spinor formulation of the superstring). I'm not convinced by his claim that the thing to do is to go to Euclidean space-time variables, while keeping Minkowski spinors. Neither is Lubos, and he and Jacques manage to have an argument about this that sheds more heat than light. It ends up with Lubos accusing Jacques of behaving like Peter Woit, which lead to him being banned from commenting on the blog. While this all is, as Jacques describes it "teh funny", it would be interesting to see a serious discussion of the issue. Since it in some sense is all about how one treats time, perhaps one could get FQXI funding to study this subject.

Update: Lubos Motl has immediately come up with a long posting explaining why these are all non-problems, of concern only to those like myself who are "hopeless students", "confused by many rudimentary technicalities that prevented him from thinking about serious, genuinely physical topics." If I would just understand AdS/CFT and Matrix theory I would realize that gauge symmetry is an irrelevance. Few in the theoretical physics community are as far gone as Lubos, but unfortunately he's not the only one that thinks that concern with these "technicalities" is evidence that someone just doesn't understand the basics of the subject.

Comments

1. **Interested**
   April 14, 2010

   "Others will disagree, arguing that gauge symmetry is just an un-physical redundancy in our description of nature, and how one treats it is a technical problem that is not of a physically significant nature."

   Interesting. Please elaborate on that argument.

2. **Trent**
   April 14, 2010

   Peter, you write,

   "More recently, it has become clear that one can consistently introduce chiral symmetry on the lattice, at the cost of using fermion fields that take values in an infinite dimensional space."

   This is complete rubbish. Fermions in the overlap formulation have exactly the same number of components as for example fermions in the Wilson formulation. At each space time point they have 4 Dirac indices and 3 color indices.

   What you might be confusing with overlap fermions are domain wall fermions. However domain wall fermions do not solve the chirality problem exactly, there is a residual breaking. In the limit when the residual breaking goes to zero one recovers overlap fermions, which have, as stated above, the same number of components as conventional Wilson fermions. No surprise there, because overlap fermions are based on Wilson fermions, only the Dirac operator is not the Wilson matrix, but a function of it (related to the sign function, if someone was curious).

   Trent

3. **Trent**
   April 14, 2010

   You mentioned Distler's blog, where I also commented and pointed out that the initial assertion of Distler is incorrect. He also admits this, so this issue is very clear and there is no confusion. All of this happened before Lubos entered the scene though 🙂

   Basically, Distler was claiming that in Minkowski space \eta_\mu^\mu = d – 2 whereas in Euclidean space \eta_\mu^\mu = d so he thought there was a problem somewhere.

   But actually there is no problem at all, as I pointed it out to him and he admitted to being wrong, since also in Minkowski space we have \eta_\mu^\mu = d and there is no minus 2 anywhere.

   This is basically elementary linear algebra or vector calculus or whatever you want to call it, at any rate part of QED 101 material. I was surprised to see Distler getting confused about such simple things, but good thing is he quickly admitted to being wrong. Gentlemanly, one could say.

   This is also my take on your issue. What is exactly wrong with Wick rotation and analytical continuation once it's done properly (with positivity constraints)? In lattice gauge theory the constraint is called "reflection positivity". Please state a specific problem or specific quantity one can not calculate in a Euclidean setting. Things like "oh, it's so mysterious" doesn't count 🙂

   Trent

4. **Peter Woit**
   April 14, 2010

   Trent,

   Apologies for the imprecise statement about the overlap formalism and the other ideas about how to deal with chirality that it grew out of. For a detailed explanation by an expert of the point I was referring to, see Neuberger's hep-lat/9808036, where his summary of the situation goes:

   "At the base of this progress lies a world consisting of an infinite number of fermions, all but one having very large masses. This infinity is fully under control and consequently can be completely eliminated."

   As for the Wick rotation question, I should make it clear that this "mystery" is of a different nature than the two others. It's not that there's a well-defined problem of non-existence of a needed non-perturbative construction (at least in flat space-time). It's rather that I just don't see a clear explanation of the relationship between the QFTs in Minkowski signature and Euclidean signature, especially when dealing with chiral fermions. What I'm looking for is something that treats the spinor geometry in a coordinate-invariant way, so would make sense even in a curved background. Maybe such a thing exists and I'm just unaware of it, but the literature I've looked at doesn't seem to contain such a thing. The discussion between Lubos and Jacques indicates that maybe I'm not the only one confused by this topic.

5. **Peter Woit**
   April 14, 2010

   Interested,

   This is a complicated topic. Two quick points about it are:

   1. In principle, you are supposed to be able to get rid of the problem of gauge symmetry by working just with gauge-invariant variables. The problem with with this argument is that the (gauge-dependent) space of connections (gauge fields) is a linear space that we know how to quantize, and with coordinates that are local and transform simply under Lorentz transformations. If you try to eliminate the gauge degrees of freedom, go to the "reduced space" and quantize this instead, you lose all these nice properties and encounter intractable "technical" problems.

   2. In a Hamiltonian formalism, you should be able to deal with gauge symmetry by just looking at states invariant under the gauge group. However, something more subtle is going on when you actually try and implement this. Complexifying, there are no gauge-invariant states, so the standard Gupta-Bleuler trick is to impose invariance only under half the gauge symmetry. BRST deals with this issue in a trickier and very interesting way.

6. **Trent**
April 14, 2010

Peter, you write

"What I'm looking for is something that treats the spinor geometry in a coordinate-invariant way, so would make sense even in a curved background."

Such a thing certainly exists and is well-known, it's called the spinor bundle of a Riemannian manifold. The metric can be curved or flat, doesn't matter. The spinor bundle is defined as long as a certain Stiefel-Whitney class is zero and the various choices are parametrized by another Stiefel-Whitney class. So there is no mystery at all, in my opinion, around defining spinors for a curved manifold.

Trent

7. **Peter Woit**
April 14, 2010

Trent,

Of course I know how to define the spinor bundle on a curved manifold. The problem is Wick rotation or analytic continuation.

To have the usual notion of analytic continuation, relating sections of spinor bundles over a Riemannian signature space and over a Minkowski signature space, it seems to me you need to represent the two spaces as subspaces of a complex manifold of twice the (real) dimension, and the spinor bundles as restrictions of a holomorphic bundle. This is why I mentioned the Grassmanian and twistor theory. There you have exactly this, and even better, the (half)-spinor bundle is just the tautological bundle over the Grassmannian.

This is all just a story about classical fields, and what you really want is a quantum field theory. That's where I start to get confused….

8. **anonymous**
April 14, 2010

Just to point out a recent progress towards resolving the Neuberger problem done in http://arxiv.org/pdf/0710.2410 and http://arxiv.org/pdf/0812.2992 . Though it is true that the Neuberger problem is a technical problem (just for the lattice), they want to resolve it to do proper simulations then – the same motivation as to have chiral gauge theory on the lattice: to do non-perturbative computations for QCD in a practical way.

9. **Interested**
April 14, 2010

Thanks Peter.

My impression of your post was that you were explaining that guage symmetry doesn't have a physical basis.

On something a little unrelated, I would just like to let you know my impression is that, outside particle physics, nobody cares about a theory that doesn't make experimental predictions. As such shouldn't it be called the String Hypothesis (hypotheses??)?

So keep fighting the good fight.

10. **Interested**
April 14, 2010

Sorry

My impression is that *others* believe guage symmetry doesn't have a physics basis. I am aware (If I remember your book/blogs correctly) that you think that symmetry is the key to making progress.

11. **Peter Woit**
April 14, 2010

Interested,

I don't think the term "has a physics basis" is very well defined, but it's true that I think properly understanding the implications of gauge symmetry will give deep insight into fundamental theory. Others think it's a technical device that can in principle be ignored.

Yes, calling string theory a "theory" has led to all sorts of confusion and trouble. But, that's far off-topic, please try and keep this posting string-free unless strings have something to do with one of these three problems.

12. **CKK**
April 14, 2010

What Lubos describes is in fact one of the great achievements of modern physics – the realization that problems too hard for conventional methods may always be solved by psychology – all one has to do is convince enough peers that the problem is a non-issue, a technicality, a shortcoming of mathematics which has nothing to do with real physics, and the problem will simply go away.

This clever method has been very successful recently, particularly in string theory, where it is by far the most popular technique with a large number of devoted fans.

13. **ijc**
April 14, 2010

I sometimes appreciate what Lubos has to say, but his reaction to these issues betrays his disappointingly un-mathematical character. The issues are technical matters, but that does not make them less important, unless we are to be satisfied with doing only calculations according to symbolic replacement rules, without any definition a meaning for the formal objects.

At no point did you (Peter) even attack the un-rigorous establishment in theoretical physics, perhaps you accept it as necessary ever since Newton introduced calculus without defining it, and yet Lubos' reaction is quite defensive. He really does seem to prefer physicists who are so intoxicated by their own egomania that they just consider their mastery of the replacement rules to suffice for understanding:

LM: ” More experienced and powerful physicists have no trouble with the formalism and they can instantly penetrate it and get to the actual physics.”

That’s right, LM and his powerful friends have no concern over writing nonsense such as complex measures on function space; not only do they have no concern, but they judge anyone who wants to properly contextualize these “analytic continuations” into a mathematical space as a bad student. More powerful physicist have no trouble with replacement rules like “t – > i T”, and they KNOW that these kinds of rules are as complete and total of an understanding as there could ever be.

14. **Peter Woit**
April 14, 2010

ijc,

Historically I think there is good reason for the standard prejudice amongst physicists to just charge ahead and not worry about what appear to be technicalities. You may get somewhere this way that you wouldn’t have gotten to if you had got hung up thinking about something that didn’t turn out to be really necessary.

After 30 some years though of charging ahead and getting nowhere (or farther and farther from anywhere one would like to be), this may be an unusual historical moment in which it would be a good idea to go back and take a closer look at those things one doesn’t completely understand, even if someone has a plausible sounding argument about why this is likely to be a waste of time.

15. **mathphys**
April 14, 2010

When I try to read Motl’s post, my browser comes up with a warning message that says “To protect your security, Internet Explorer blocked this site from downloading files to your computer. Click here for options…”.

I think he puts so many ads and so forth on his web pages it’s impossible to read now.

16. **Peter Woit**
April 14, 2010

mathphys,

For the past couple days, Lubos’s blog has been hanging and crashing one of the browsers (the gnome browser, epiphany) on the Linux machine I use at work. In this he joins Jacques, whose blog for a year or so has been giving an error message when you try to connect to it with epiphany. Firefox does still work on both of them.

A week or so ago, I noticed a loud noise at home periodically, finally realized that it was occurring whenever I had a browser window open on Lubos’s blog. Turns out it was the processor fan on my Windows machine, which started cranking at top speed to keep the processor cool as it tried to deal with Lubos’s web-pages…

17. **N. Nakanishi**
April 14, 2010

Peter,
I would like to point out that non-perturbative covariant BRS-quantization of gauge field theory was formulated in a satisfactory way more than thirty years ago. For reviews, see

T. Kugo and I. Ojima, Prog. Theor. Phys. Suppl. 66 (1979) 1.
N. Nakanishi and I. Ojima, Covariant Operator Formalism of Gauge Theories and Quantum Gravity (World Scientific, 1990).

The trouble of Gribov copies is nothing more than a defect of the path-integral approach, just like the doubling problem of fermion poles in the lattice theory. The path-integral approach cannot give a complete quantum field theory, because in its own framework one cannot prove the unitarity of the physical S-matrix. The path-integral approach induced such inadequate notions as instantons, axions, etc. It is generally inconsistent with field equations, and therefore violates the Noether theorem, because of the use of T*-product instead of T-product. This fact induced incorrect appearance of various anomalies such as gravitational anomaly, FP ghost-number anomaly, etc.

18. **Peter Orland**
April 15, 2010

N. Nakanishi

Many people have noticed that the Gribov problem occurs in Hamiltonian quantization of non-Abelian gauge theories – not just in path integrals. The problem of copies means there is an essential difficulty in solving Gauss’ law, for most gauge conditions. Gribov copies are not an artifact of any particular formalism. The only way to avoid the problem is not fixing the gauge. This is fine for some purposes (strong-coupling lattice, Monte-Carlo), of course.

19. **Spivak**
April 15, 2010

Lubos wrote an article regarding three mysteries you suggested, I am very much interested to hear your counterargument.

20. **A.**
April 15, 2010

Agree with Peter W. that nonperturbative BRST is an important problem, esp. in regard to Gribov and the difficulty of quantising on the reduced space of gauge fields. As already illustrated by the opposing opinions, here, of whether Gribov is relevant nonperturbatively, this is a hard topic to make progress in. Also agree with Peter O. that the copies are in no way attached to a particular formulism. It’s easy to find examples in the literature which make no reference to the path integral approach.

One issue which makes this area difficult to persue is the reluctance of large parts of the community to care about it — I’ve found that the average reviewer is typically very hostile to any paper which tries to make a point of the importance of Gribov. Often the reaction is just “go to the lattice” and everything will ultimately be fine (even when the reviewer admits that there are still copies on the lattice).

21. **abc**
April 15, 2010

Hi,
As rightly pointed out by A., Gribov copies do exist on the lattice too (e.g. Recently, Gribov copies are fully classified on the lattice though for a ‘toy’ model http://arxiv.org/pdf/0912.0450). Their effects on the gluon propagators on the lattice is an active research area mainly being done by several groups in Germany, Australia and Brazil. And many issues need to be settled down there.

Best,
abc

April 15, 2010

Firefox with NoScript, Adblock Plus and WOT (not Woit): Lubos' page loads rapidly and without problems on both Ubuntu and Windows, even on a old machine.

24. **Peter Woit**
April 15, 2010

Spivak,

Responding to Lubos in detail would be a full-time job, but here are a few other comments:

1. On the Wick rotation issue he's mostly arguing with Distler, not me. I think we agree that this is a crucial part of QFT, with QFTs not well-defined in Minkowski space. Exactly how this works for chiral spinors, non-perturbatively, in non-flat backgrounds, seems to me to be something still not completely understood. Lubos just asserts that it works without providing a reference to where one can find the details.

2. He claims that these problems are just lattice artifacts, that some other non-perturbative formulation of gauge theory won't have these issues. The problem is that there is no such thing as a completely well-defined non-perturbative definition of chiral gauge theory outside of the lattice framework. The lesson of many years of work on understanding the problem of chirality on the lattice is that it's not a lattice artifact, but something inherent in the use of a cut-off, some version of which is needed to make sense of the QFT. His comments about the problems of supersymmetry on the lattice are irrelevant, this is a question about a non-supersymmetric theory.

3. The general criticism he and others make of anyone trying to work on these issues, that they're just second-raters working on uninteresting technicalities, unable to, like real men, work on AdS/CFT, I think I've dealt with in the posting and earlier comments.

25. **Chris Austin**
April 15, 2010

Hi Peter,

What is your opinion on Peter Hirschfeld's paper "Strong evidence that Gribov copying does not affect the gauge theory functional integral," Nuclear Physics B 157 (1979) 37-44, which he wrote whilst an undergraduate at Princeton, with advice from Curtis Callan, if I remember correctly?

Best,
Chris

26. **Peter Woit**
April 15, 2010

Hi Chris,

I'd never seen that paper, just took a look at it. Peter O. is more of an expert on this question, and maybe he knows if there is a problem with this Peter H. paper, and if so what. From my quick look, there are several things to worry about in his argument (non-compactness of the gauge group, existence of the kind of coordinates he wants, whether the intersection number he gets is zero…). In any case, if his claim is that one can just ignore the contributions of Gribov copies, that seems to conflict with the large amount of later work on the subject.

27. **F**
April 15, 2010

"Non-perturbative QFT calculations are well-defined not in Minkowski space, but in Euclidean space, with physical observables recovered by analytic continuation."

Peter, your comment above is not quite correct. Euclideanization is ONE way to handle non-perturbative calculations in QFT, but not the only way. Light cone quantization of quantum field theories is a standard tool that can be used to obtain non-perturbative solutions without a Wick rotation of the time coordinate. In this way, one can avoid a lot of the subtle issues you mention arising from changing the space-time signature of a theory.

28. **anon.**
April 15, 2010

Just to be precise about the issues of BRST and Gribov problems — they don't affect the nonperturbative definition of the theory since, as you say, the lattice can always calculate gauge-invariant quantities. They are relevant when people want to investigate, e.g., the "nonperturbative gluon propagator" in some particular gauge. But there's no deep reason to think such things are good physical quantities to study.

Similarly, the Gribov problem exists for many gauges in the continuum (e.g. Landau gauge), but not for others (Weinberg's book, for instance, skirts the problem by using axial gauge).

So I think really the only problem is that one cannot write down an action that is simultaneously *manifestly local*, *manifestly Lorentz-invariant*, and *gauge fixed* without running into Gribov problems. (Although Zwanziger has a formalism attempting to do this by adding more auxiliary fields, which I've never fully digested.)

Whether one things these problems are interesting is a matter of taste — I find them somewhat interesting, but I doubt they hold the key to a more solid nonperturbative understanding of QCD, since any such understanding should be expressible in terms of only gauge-invariant quantities.

29. **Peter Orland**
April 15, 2010

anon.

The reason Gribov copies are interesting is the following. The physical configuration space of Yang-Mills theories are gauge orbits, not gauge fields. A gauge orbit is an equivalence class of gauge connections, the equivalence relation being gauge-equivalent.

If you don't want to find coordinates on the space of orbits, then you don't have to worry about the Gribov problem. If you do, then you do have to worry.

So whether or not it is important depends on how you want to study gauge theories. In perturbation theory, you can ignore copies, which correspond to large gauge transformations. If you study gauge-invariant functionals (like Wilson loops) and somehow have a calculational scheme avoiding gauge fixing, you can bypass the issue altogether. Unfortunately, no one has such a scheme for QCD.

The Gribov problem is present in axial gauges as well, though open boundary conditions (instead of periodic boundary conditions) ameliorate the situation considerably.

30. **N. Nakanishi**
April 15, 2010

Peter Orland,
Please give me a reference, if any, which shows that the Gribov problem is relevant to the operator formalism of the
BRS-quantized gauge theory. I note that in the operator formalism, of the BRS-quantized gauge theory, c-number solutions to the gauge fixing condition are totally unnecessary; the canonical quantization can be carried out exactly in the same way as in the non-gauge theory.

31. **Peter Orland**
April 15, 2010

N. Nakanishi,

Respectfully, I don't have to give you a reference. The Gribov issue is very general, and it isn't my problem whether the methods you advocate are right or wrong. That is for you to work out.

Anyway, Peter W. insists this is not a physics discussion board, so I will just say this:

You need to show that large gauge transformations are properly taking into account in your formalism (that is how copies arise). Everything I have seen on BRS (except Herbert Neuberger's work) deals with infinitesimal gauge transformations. For example, how do you handle the Gribov horizon, where the Fadeev-Popov determinant vanishes?

32. **N. Nakanishi**
April 15, 2010

anon,
You claim "one cannot write down an action that is simultaneously manifestly local, manifestly Lorentz-invariant, and gauge fixed without running into Gribov problems".

Such a theory does exist! It is the Kugo-Ojima theory (see,
Prog. Theor. Phys. Suppl. 66 (1979) 1-130).

33. **N. Nakanishi**
April 15, 2010

Peter Orland,

It seems to me that you do not understand the fundamental nature of quantum field theory. In quantum field theory, symmetries are described by Lie algebra but not Lie group; that is, I mean that only infinitesimal transformations are
relevant. To recognize this point is particularly important in supersymmetry, because there is no "supergroup". The same is true for the local gauge symmetry: finite-size local gauge transformations are irrelevant to the quantum gauge theory. The c-number gauge trasformation is a purely classical concept; in quantum gauge theory, there exist only the BRS transformations. So, it is totally unnecesary to take account of the Gribov copies in the proper framework of quantum field theory. The FP determinant is a consequence of the path-integral formalism; it is a misleading notion based on the classical gauge theory.

34. **Peter Orland**
April 15, 2010

N. Nakanishi,

Yes, call me a dummy. Other people have said worse.

Only infinitesmal transformations are relevant? Not so. Global properties of symmetry groups are important, even in the theory of spin.

The Fadeev-Popov determinant, can be derived from the Haar measure of a lattice theory. There is nothing misleading about it. Is the lattice theory just a classical concept to you (or a misleading notion)?

35. **Peter Orland**
April 15, 2010

Anyway, I will not comment further on this thread. I am sure Peter W. is tired of insults flying around.

36. **N. Nakanishi**
April 16, 2010

Peter Woit,

Since Peter Orland does not wish to continue the discussion, I would like to have your opinion. Do you still assert that the non-perturbative BRS-quantization of gauge theory is not yet formulated?

Peter Orland's comments provide no logical basis for claiming that the Gribov problem is relevant to the operator formalism of the BRS-quantized gauge theory. What he commented are nothing more than his feelings. (Reply to his question: The lattice gauge theory is essentially based on the path integral. There is no BRS-formulated lattice theory.)

37. **Z**
April 16, 2010

Hello, I find the subject of gauge symmetries very interesting but also very confusing, I tried asking Lubos about some of the details of his argument about gouge symmetries being just technicalities but without luck so far, perhaps someone here could be more helpful, here is what is bothering me:

On one hand Lubos argues that gouge fields represent unphysical degrees of freedom and it agrees with what I've read generally. But on the other hand it is also said that gouge bosons mediate interactions, for example a photon is a gouge boson associated with U(1) symmetry. Isn't that a contradiction? Photons are certainly physically real, so why are they modeled by gouge fields which should only describe unphysical states?

Lubos also claims and Peter seems to (at least partly) agree that one can reformulate the theory without any gouge degrees of freedom but if that is indeed the case that what will happen to the photon and other gouge bosons in such a description? What will mediate forces?

Finally the gouge symmetry associated with photons – U(1) represents quantum phase and while there may be no way to directly observe this phase is not really unphysical as it does affect experimental outcomes (position of interference fringes in in double slit experiments or Aharonov Bohm variants for example).

So are gouge degrees of freedom completely unphysical or do some of them describe physically real phenomena?

38. **Peter Woit**
April 16, 2010

anon,

While it's possible to argue that one can just ignore problems with handling gauge symmetry in vector-like theories like QCD (not that I'm convinced, one may very well learn something important by taking these problems seriously), this is not at all the case for chiral gauge theories (like the Standard Model…).

Nakanishi,

Yes, I'm afraid I agree with Peter Orland. I don't believe the operator formalism for QCD is now well-defined in the sense that the path integral formalism is through lattice gauge theory. The lattice formalism gives a completely well-defined calculational set-up that one can even put on a computer (although the calculation may not be practical). A possible addition to my list of mysteries would be that of the relationship between the operator formalism and the path integral formalism. This is much trickier than often assumed and working out details of this might be very interesting.

Z.

gauge fields include both physical and gauge degrees of freedom. In some sense the problem is that there is no clean way to separate them.

39. **anon.**
April 16, 2010

Peter Orland, I don't understand your comment "If you study gauge-invariant functionals (like Wilson loops) and somehow have a calculational scheme avoiding gauge fixing, you can bypass the issue altogether. Unfortunately, no one has such a scheme for QCD." What about the lattice? Or do you just mean a continuum scheme?

40. **anon.**
April 16, 2010

I think the strongest hint that the Gribov problem might be relevant comes from evidence that at least in some gauges, configurations like center vortices that should be relevant for confinement (based on arguments that don't depend on a choice of gauge) are localized on the Gribov horizon. There seems to be something interesting and poorly understood lurking there.

41. **Peter Orland**
April 16, 2010

anon.

I meant a non-numerical (i.e. analytic) scheme, lattice or not.

42. **Z**
April 16, 2010

Thanks for the answer Peter.

43. **Rondeau**
April 16, 2010

"The same is true for the local gauge symmetry: finite-size local gauge transformations are irrelevant to the quantum gauge theory."

In perturbation theory, in principle, only infinitesimal gauge transformations are relevant because finite gauge transformations are just compositions of infinitesimal ones. But globally, not just locally, there are obstructions to that naive approach to gauge transformations.

But even in the perturbative quantum theory there is at least one finite gauge transformation that is crucial: the one connecting unitary gauge (in which the theory is manifestly unitary), to a suitable covariant gauge (in which the theory is manifestly renormalizable). Without that transformation there is no consistent quantum theory.

44. **N. Nakanishi**
April 16, 2010

Peter Woit,

You confuse the existence of the formalism and that of the method of numerical calculation. The former is a fundamental theoretical problem, while the latter is merely a practical one. The existence of the satisfactory formalism is very important as physics even if one cannot solve it. Indeed, the covariant operator formalism of the non-Abelian gauge theory clarified various theoretical problems (e.g., formulation of the condition of color confinement, resolution of the dilemma between the Higgs mechanism and the Goldstone theorem
in the manifestly covariant theory, proof of the charge universality in the electroweak theory, etc.). On the other hand, I think that the lattice theory cannot show even the angular-momentum conservation law. The lattice theory discusses quark confinement but not color confinement.
Anyway, you should read a review of the covariant operator formalism of BRS-quantized gauge theory. If you give me your mailing address, I am willing to send you a copy of my book.

Rondeau,

You confuse the problem at the operator level and that at the representation level. Since the path integral does not discriminate them, the people working only in the path-integral approach often misunderstand this point. The finite-size c-number transformations are not well-defined at the operator level. They are often recovered at the representation level; the physical equivalence (but not unitary equivalence!) of unitary gauge and covariant gauge can be shown after the representation space (i.e.,state-vector space) is introduced.

45. **Peter Orland**
April 16, 2010

OK, against my better judgement, I will jump back in. I am already regreting it.

Mr. Nakanishi, stop telling other people they are confused. It does not make you look knowledegable. It just shows you have an agenda.

So here are the issues:

1) The lattice formalism does not require numerical simulation. It is just a gauge-invariant regularization of gauge theories. I repeat – numerical issues are irrelevant. Go and read Wilson's paper from 1974. He does no simulations in that paper.

2. It is not true that the lattice implies the use of the path integral. There is a Hamiltonian (Kogut-Susskind) lattice formalism where the same issues arise (in solving Gauss' law).

3. Let me say it again – the Gribov problem occurs in the Hamiltonian formalism too.

4. The issue of large gauge transformations has nothing to do with one formalism (path integrals) or another (Hamiltonians). In the Hamiltonian approach, as I said before, it arises in the measure on the space of states. States are singlets under gauge transformations. ALL gauge transformations, not just infinitesimal ones. There is still the issue of large gauge transformations.

This is fundamental to gauge theories and you can't invent any formalism to avoid it. If you say some method removes it, the method is plain wrong (or at least, your interpretation of the method is wrong). For example, there will be no theta vacua in any formalism of gauge theories ignoring large gauge transformations. Different n-vacua are large-gauge transformation-equivalent to a pure gauge. That is how theta vacua arise. Once again, this is just as true in a Hamiltonian as a path-integral formalism

5. Though one does not need to path integral in these arguments, why you dismiss path integrals mystifies me. I suggest you look at the books by Simon, Glimm and Jaffee on the subject. These people actually proved theorems about quantum mechanics and field theory, using path integrals.

6. Now in this forum, I can't prove any of this to you. All I can say that it has been generally known since the seventies. The blogosphere is not a good teaching environment. I am not able to prove it to you without our actually working through the math together (and I am pretty sure you would not be willing to do that anyway). So instead of repeating your pronouncements, you should read and understand some of the literature (not just the literature you are promoting).

6. Last and most important. I don't know if you are still doing research in this field. If you are, listen! I am saying something you should hear, even if you don't want to.

46. **N. Nakanishi**
April 17, 2010

Mr. Orland,

In this forum, discussions should be scientific ones. OK?

1. It is Peter Woit who emphasized the importance of numerical aspect of the lattice theory.

2. & 3. May I understand that what you call Hamiltonian formalism is the formulation in the Schroedinger picture? The Schroedinger picture is good in quantum mechanics (because of von Neumann's theorem), but very bad in relativistic quantum field theory. The Schroedinger picture not only violates manifest covariance but also suffers from the difficulty of vacuum polarization. Even worse is the fact that it is unclear what representation is adopted.

4. The covariant operator formalism of gauge theory is formulated in the Heisenberg picture. It is BRS invariant. It is not invariant under local gauge transformations. Hence the Gribov problem is totally irrelevant to it.
The theta vacuum is a pathological consequence of the path-integral approach. What is physically sensible is the variation of the action but not the action integral itself.

5. I know that path integral was used in the constructive field theory, but the models treated there are such simple ones as scalar field theory. The trouble with path integral arises in more realistic theories such as quantum gauge theory and quantum gravity. The path-integral approach cannot be a complete theory because within its own formalism one cannot prove the unitarity of the physical S-matrix. The hermiticity of the action cannot be defined in it.

6. Non-scientific.

47. **Thomas**
April 17, 2010

> The theta vacuum is a pathological consequence of the path-integral approach.

So there is no strong CP problem, theta vacua are just an illusion?

48. **Anon.**

April 17, 2010

"The covariant operator formalism of gauge theory is formulated in the Heisenberg picture. It is BRS invariant. It is not invariant under local gauge transformations."

Typically, one starts with gauge invariance, and then gets to BRST as a way to handle gauge invariance when quantizing. If you take the gauge-fixed BRST theory as the definition of your theory, then yes, there is no ambiguity. You are essentially truncating your definition of the theory at that level.

As long as non-perturbative effects are hard to test experimentally, your theory might survive, I don't know. Conceptually though, it sounds like you have no notion of a non-perturbative definition. You are just ignoring the unknown. Taking gauge invariance seriously all the way has lead to correct ideas in the past, eg.: Aharonov-Bohm effect, which is intimately tied to monopoles, theta angles and such.

"The theta vacuum is a pathological consequence of the path-integral approach. What is physically sensible is the variation of the action but not the action integral itself."

That cannot be entirely true because we know (experimentally) that tunneling exists in quantum mechanics.

More generally, path integrals are extremely natural from a lot many points of view. Anomalies, renormalization group, lattice gauge theory etc. are all most natural from a path integral viewpoint.

49. **Peter Woit**
April 17, 2010

Nakanishi,

Thanks for the offer of a copy of your book, but I already have bought one, several years ago. It and Henneaux-Teitelboim are the only two books I know that address the issue of treating gauge symmetry via BRST, beyond Feynman diagrams. Henneaux-Teitelboim I think I understand quite well, your book much less so. Henneaux-Teitelboim try and connect the Hamiltonian and path integral formalism, but do so using (like others who try and do this) phase space path integrals that are ill-defined.

Despite some effort, I still haven't completely understood exactly what the assumptions are that go into the covariant operator formalism. I started my career working on lattice gauge theory, so one virtue it has for me is familiarity, but the other is that it is precisely well-defined (independently of its use in numerical calculations). One thing I learned by doing numerical calculations is that setting them up on a computer forces you to make sure you understand very precisely what you are doing, there is no room at all for ambiguity.

The lattice approach to QCD is precisely defined, even if you can't prove things about it. If the covariant operator formalism for QCD is as well-defined, and gives different answers, this would be very interesting. One problem you would have then is that as far as I know, no lattice computation that can be compared to experiment has given anything incompatible with what is observed. If you claim there are no theta-vacua, one thing you have to explain is the success of Witten's argument for the eta-prime mass.

There is conventional wisdom about how the path integral and operator formalisms are supposed to be two ways of treating the same theory, in principle compatible. If someone could sort out carefully what is going on here, that would be very interesting.

50. **Peter Orland**
April 17, 2010

In any case with no theta vacua, the U(1) problem in QCD has no solution.

By the way, there is a formulation of unitarity within path-integral lattice gauge theories. It is called reflection positivity and was first considered in gauge theory by Osterwalder and Seiler.

Whether or not one takes the Kugo-Ojima formulation seriously, I don't believe that it forbids theta-vacua, unitary gauges or Gribov problems. If it does, it is purely perturbative. A formulation which does forbid such things is not going to be unitary, except in perturbation theory. An analogy is to treat the double-well Hamiltonian perturbatively, ignoring tunneling. The result for the spectrum is going to be wrong, unless tunneling (a nonperturbative process) is taken into account.

51. **Peter Orland**
April 17, 2010

Sorry to have prolonged this discussion Peter.

52. **Rondeau**
April 17, 2010

"Witten's argument for the eta-prime mass."

This is probably a stupid question, but wasn't that 't Hooft's argument?

"Sorry to have prolonged this discussion Peter."

I'm sure I'm not the only one who found it interesting.

53. **Peter Woit**
April 17, 2010

Rondeau,

't Hooft showed that the argument that the eta-prime should have low mass is ruined by the anomaly. Witten actually gave a formula for the mass, arguing from the 1/N approximation. I guess Veneziano did this independently, it is known as the Witten-Veneziano mass formula.

54. **N. Nakanishi**
April 18, 2010

Thomas,

That is right. The non-existence of strong CP violating term is confirmed by the non-existence of neutron's electric dipole moment. Axions are also non-existent.

Anon,

The Kugo-Ojima formalism provides us the manifestly covariant formulation of the Standard Theory. It is important to recognize that local gauge transformation is a classical concept, because it contains arbitrary functions, i.e., functions chosen by human being. Quantum field theory is the fundamental theory; it must be independent of human will. The quantum version of local gauge invairance is nothing but BRS invariance. Local gauge invariance is recovered in the sense of gauge independence of the physical S-matrix.

The AB effect establishes experimentally that gauge potential is the fundamental quantity. Monopoles and theta vacua are merely hypothetical things.
Tunneling exists in quantum mechanics. But this does not imply that instanton is physically sensible in quantum field theory. The reasoning used here is no more than analogy. Can you prove the conservation of total probability in the process in which transition via instanton really occurs?

"Natural" is merely your feeling. You must logically show why. Path integral is no more than the generating function of Green functions. Anomalies, renormalization group, lattice theory, etc. can be considered also in the framework of operator formalism, because Green functions can be defined in it.
What I am emphasizing is that it is quite dangerous to make physical considerations based on the path integral beyond the extent justifiable by the operator formalism.

Peter Woit,

Thanks for buying a copy of my book; please read it. The Kugo-Ojima formalism is nothing but a natural extension of the manifestly covariant formalism of abelian gauge theory (QED and Higgs model) to the non-abelian gauge theory. Nothing is conceptually difficult.

I think that the lattice approach is an important tool for QCD. What I stress is that the lattice gauge theory cannot be a fundamental theory because the angular momentum conservation cannot be proved within its own framework (Remember the importance of partial-wave analysis.).
I don't know much about the problem of eta-prime's mass, but it is a matter crucially dependent on approximation method. What I assert is the matter of the fundamental principle of the theory. Field equations and canonical commutation relations are independent of a constant term of the action. This is a completely non-perturbative statement.

Path integral and operator formalism have some delicate differences. If you are interested in this problem, please see the following paper:
M. Abe and N. Nakanishi, Perturbative or Path-Integral Approach versus Operator-Formalism Approach, Prog. Theor. Phys. 102 (1999), 1187.

Peter Orland,

There is no strong CP violation; there are no axions.

To repeat, the Kugo-Ojima formalism is non-perturbative, manifestly covariant, unitary, and totally irrelevant to the Gribov problem.

Tunneling is possible in quantum mechanics, because the representation is unique. In quantum field theory, there are infinitely many representations. It is impossible to tunnel to different representations.

55. **Peter Orland**
April 18, 2010

I never said their were axions and did not comment on strong CP violations. But a theta-term is possible to add to the QCD action.

As I said, if the Kugo-Ojima formulation has the properties you say, then it is wrong (but I don't believe your statement that it does have such properties).

Tunneling is present in field theory (and not just gauge theories); provided the WKB factor is non-zero.

56. **Rondeau**
April 18, 2010

thanks for your answer

57. **N. Nakanishi**
April 18, 2010

Peter Orland,

If you claim that my assertion is wrong, you must point out where and why it is so. It is non-scientific to claim "wrong" merely based on your feeling.

58. **Peter Woit**
April 18, 2010

Nakanishi,

It is difficult to prove things in 4d lattice gauge theory, but you can do computer calculations and check whether what you get satisfies properties you expect. In particular, as you take the coupling to zero, you can check whether the breaking of rotational symmetry introduced by the lattice disappears as expected. My understanding is that this is what happens.

The reference you give to a discussion relating the covariant operator formalism and path integral formalism is for a 2d theory. The divergence structure of 2d QFT is quite special, and, especially in the context of conformal field theories, there is quite a bit known about the operator formalism and its relation to the path integral (this is a beautiful subject mathematically). However, the 4d divergence structure is quite different and much worse. I don't see evidence that you are able to explicitly construct operator algebras and representations with the properties that you expect to have. The advantage of the lattice version of the path integral is that it is an explicit construction, and you can check that it has the properties you want, analytically in a few cases, numerically in others.

59. **Peter Orland**
April 18, 2010

Actually I have no obligation to point that out. It is you who is making claims that the conventional view on gauge theories is wrong, so it is you who has an obligation to prove it.

The very loaded term "non-scientific", in its simplest form means making assertions without evidence. I have evidence that I what I am saying is true. You claim to have other evidence. Only doing the mathematics can say who is right.

My research is in field theory, and I have some confidence in my assertions. I do my best to be careful in what I do. I make mistakes, but after a lot of checking and reworking, I try to fix them. Though I am not perfect, I work hard to understand the issues. If I am sure something is true after reading well-written and convincing papers and my own hard calculations, why should I believe someone who says it is all wrong?

Perhaps I can best express my reaction to your assertions though quoting the following:

http://xkcd.com/675/

60. **N. Nakanishi**
April 19, 2010

Peter Woit,

I am not concerned with the matter of expectation or hope based on a finite number of numerical calculations. What I am saying is that the angular momentum conservation must be exactly established if the theory is fundamental.

Thanks for quick reading of my paper. The subject of this paper is not to discuss the divergence problem but to clarify concretely the pathological aspects of the perturbative or path-integral approach in 2d quantum gravity.

The original topic which you proposed is non-perturbative BRS. I don't understand why you adhere to lattice approach so much. There is no BRS-formulated lattice theory!

Pete Orland,

I have never said that your work is wrong, because I don't know your work at all. Probably, it is better to stop the discussion with you.

61. **Peter Orland**
April 19, 2010

I was not talking about my own publications. But OK, you are right, this
has gone on too long.

62. **D R Lunsford**
April 19, 2010

This topic has been one of the best in the history of this blog. I wish there were more sane discussion on the net.

-drl

63. **mathphys**
April 20, 2010

Dear Nakanishi san and Peter Orland,

Please continue the discussion. I personally found it instructive as I didn't realize there were any controversies in these matters. There must be a way to talk about these things without getting all worked up.

64. **N. Nakanishi**
April 21, 2010

mathphys,

If you are interested in my point-of-view, please read the following paper:
N. Nakanishi, Method for solving quantum field theory in the Heisenberg picture, Prog. Theor. Phys. 111 (2004), 301-337 (Invited paper).

As for Orland's opinion, please ask him.

65. **Peter Orland**
April 22, 2010

D.R. and mathphys

I will not succeed in doing these topics justice, but I will try to give a summary below.

The first person to compute the effects of tunneling in gauge theories was Polyakov, who studied the problem for QED on a Euclidean lattice in 1975 (Physics Letters B), and in the O(3) Yang-Mills theory broken to a U(1) symmetry in 1977 (Nuclear Physics B). The lattice case was studied in the Hamiltonian formulation in

Qed On A Lattice: A Hamiltonian Variational Approach To The Physics Of The Weak Coupling Region.
S.D. Drell, Helen R. Quinn, Benjamin Svetitsky, Marvin Weinstein, (SLAC) . SLAC-PUB-2122, Jun 1978. 64pp.
Published in Phys.Rev.D19:619,1979.

So the path integral is absolutely and most definitely not essential.

Attempts to do full-fledged calculations of tunneling between n-vacua in four-dimensional Yang-Mills (instantons) are highly suggestive, but inconclusive, mainly because classical conformal invariance leads to infrared divergences. Some progress was made in the 2-dimensional O(3) sigma model, but even there the result is problematic (I am actually working on this problem some of the time).

Gribov worked in the continuum, but the Gribov problem is present in the Hamiltonian, as well as the Euclidean lattice formulations. The gauge fixing problem can be thought of as a spin-glass. If you think of minimizing TR A^{2} with respect to gauge transformations, the result is Lorentz gauge (on a 4D lattice) or Coulomb gauge (on a 3D lattice). This problem is finding the minimum (or classical-ground-state) energy of a spin glass, with a non-Abelian spin-space. The gauge field plays the role of the spin-glass frustration. Such problems are well-known not to have a unique minimum.

There is a lot more to say, but I hope this will give you some idea of what the problems are about.

66. **Chris Austin**
April 22, 2010

Hi Peter W,

Thanks for the reply on Peter H's paper.

What specifically were you thinking of, halfway down the Older Comments page, where you said, "The lesson of many years of work on understanding the problem of chirality on the lattice is that it's not a lattice artifact, but something inherent in the use of a cut-off, some version of which is needed to make sense of the QFT"? Is there some other non-lattice kind of short-distance cut-off that causes fermion doubling, quadrupling, etc., in simple treatments?

Best,
Chris

67. **mathphys**
April 22, 2010

Peter O,

Thank you for recalling these classic papers. Great works.

68. **Peter Woit**
April 22, 2010

Chris,

Besides the lattice, I don't know of any simple ways to write down a cut-off gauge theory non-perturbatively.

What I had in mind with that comment is that (take a look at the Neuberger paper about the chiral fermion problem) the anomaly is really a topological problem, one that can be reduced to a problem about how you count states in the spectrum of the Dirac operator. Any kind of naive discretization of the Dirac operator will somehow run into trouble with the anomaly, with doubling one possibility.

Exactly how species multiply to cancel the anomaly depends on what one does. If you do something like Kogut-Susskind fermions, another way of thinking about what you are doing is that you are discretizing differential forms, not spinors, and for these there is no anomaly, and you expect to get spinors with multiplicity given by the dimension of the spinor space. Always seemed to me that what one should look for is some formulation that inherently involves the geometry of spinors, not that of forms, but I've never had a good idea along those lines…

69. **Chris Austin**
April 22, 2010

Thanks Peter

70. **younghun park**
April 24, 2010

Hi Peter
Your book "Not Even Wrong" and your blog have made me
think about the future of physics.
I have read your book several times.
As you point out, Standard Model is the successful theory
which needs to be improved the more.
But I think Anyone doesn't know how to improve this theory.

Maybe, String theory is suggested as the alternative to
Standard Model with the difficult problems.
I feel you believe that String theory is the failed theory.
You and your fans have confidence that String theory can't
be the alternative to SM and that is not the true science.
I agree to your idea.

But, what is alternative to SM?
Is there any good idea to improve SM?
The insight to be ontained from researching for the improved
Gauge theory makes this situation better really?

I want to ask these questions of you and many visitors to this blog.

My thought is that physics can't go ahead any longer
as far as it is confined in the concept "Field".

"Field" is the good concept to explain the electic and magnetic
phenomena. Dirac and high energy physists developed this "Field"
as abstact concept to describe the particle creation and annihilation
in sub atomic world.

In fact, several problems in SM are relevant to Field concept.
The infinity appeared in the caculation is not irrelevant to using the Field.
Lattice gauge theory also be made for escaping from the infinity appeared
in the caculation with using Field.

Is there any concept alternative to Field to describe the High-enery physics?

I feel that theorists must begin to think what is the alternative to Field.

How about my thought?

71. **N. Nakanishi**
April 24, 2010

Younghun park,

The concept of quantum fields is very successful, so it is too hasty to give it up. Learn from history! Newtonian mechanics was very successful, but to formulate quantum mechanics it was essential to rewrite it into analytical dynamics, which was achieved by treating spatial coordinates and conjugate momenta on an equal footing. Likewise, to formulate general relativity it was essential to rewrite special relativity into the four-dimensional tensor analysis, which was achieved by treating space and time on an equal footing.

Now, quantum field theory unified the concept of particles and that of forces. Next, we should proceed to unifying the concept of fields and that of spacetime. That is, I suggest that we should rewrite quantum field theory by treating quantum fields and spacetime on an equal footing, before a possible breakthrough is found.

The symmetry between quantum fields and spacetime was found to hold in the BRS-formulated manifestly covariant formalism of quantum gravity in the de Donder gauge. There is a 16-dimensional supersymmetry IOSp(8;8) on the basis of of the supercoordinates consisting of spacetime coordinates, gravitational B field, FP-ghost and FP-antighost, though, of course, most of the generators of this supersymmetry are spontaneously broken, and the graviton is one of Nambu-Goldstone bosons.

72. **Peter Woit**
April 24, 2010

yonghun park,

This discussion really has nothing to do with the topic of this posting, and I don't want to run a general physics discussion board here.

73. **tbs**
April 24, 2010

Hi,
Firstly, thanks to Peter Woit to write this post. All of them are seriously under-investigations by the field/ theorists. Sometimes making serious research public does help, although many times don't! Anyway, I am not writing this to discuss those social science issues. I just wanted to point out some efforts to obtain a BRST-formulated lattice theory, mainly by evading the Neuberger's 0/0 problem. Firstly it was Testa's paper http://arxiv.org/pdf/hep-lat/9803025 which tried to restore BRST symmetry on the lattice. Meanwhile, Schaden and Baulieu showed that gauge fixing was a Witten-type TQFT http://arxiv.org/pdf/hep-th/9601039. Schaden then went on used this important interpretation to restore BRST symmetry on the lattice using coset space construction http://arxiv.org/pdf/hep-lat/9805020.
There were some other efforts too e.g. http://arxiv.org/pdf/hep-lat/9709154, but Neuberger had counter argumented http://arxiv.org/PS_cache/hep-lat/pdf/9801/9801029v2.pdf . I don't know the current status of this approach.
Using Curcci-Feerrari gauge, in http://arxiv.org/pdf/0807.0480, it was also tried to evade the Neuberger problem.
Very recently, the Neuberger problem seems to be evaded using redefinition of the gauge-fixing on the lattice in http://arxiv.org/pdf/0710.2410 and http://arxiv.org/pdf/0812.2992 (someone has already mentioned these papers above). The current research is to do simulations with this BRST-formulated lattice theory. The Kugo-Ojima theory is indeed appreciated in many of these papers.
It should be noted that relatively 'low no. of citations' to Neuberger's original papers should not be taken as low interest in this problem. But rather as a difficult problem to be addressed.
If you are interested in some debates on relavant issues on these topics, there is a blog http://marcofrasca.wordpress.com/ where the author sometimes do discuss about these topics – though the blog seems to be inactive for the past few months. Note that I am not the blogger of that blog nor actively involved in this particular research nor here to defend/offend any of the above approaches. But closely watching and eager to see the progress.
Hope this helps.
tbs

74. **Marco Frasca**
April 25, 2010

Dear tbs,

Thank you very much for citing my blog as a reference for people working in the field. This blog is inactive for the simple reason that, in my place of work, has been installed Websense and a lot of sites that could be helpful for this activity are no more accessible. E.g. I can read this blog but not the one from Backreaction. Last but not least, I cannot see pictures, photos and formulas making the management really involved and restricted in a small range of time in the day that is generally not available for other reasons. I am able to put down these lines from my home computer.

I think that this is not the right place to cite my blog for the simple reason that me and Peter have had some questioning last year about my work. A couple of formulas of mine appeared in Wikipedia and Peter intervened to get them removed. This produced some fuss here and and in the blogosphere concluded with an intervention by Terry Tao. Curiously enough this was beneficial to my work and, now, I should say that Peter helped me to make things work.

Marco

75. **N. Nakanishi**
April 25, 2010

tbs,

I think that Neuberger's 0/0 problem is simply caused by his erroneous assumption. There is no reason for assuming that the BRS-invariant measure is a trivial one with respect to the
FP-ghost and antighost variables, that is, it may contain c-bar c terms.

Of course, the existence of the BRS-invariant measure is merely an assumption. In exactly solvable models, we often encounter the BRS anomaly in the path-integral approach, but not in the operator-formalism approach.

Tevatron vs. LHC

April 20, 2010
Categories: Experimental HEP News

The news from Fermilab is that the Tevatron has set a new luminosity record, with a store last Friday that had an initial luminosity of 4.04 x $10^{32}cm^{-2}s^{-1}$, or, equivalently, 404 inverse microbarns/sec. For more about this, see a new posting from Tommaso Dorigo, where someone from Fermilab writes in to comment that they're not quite sure why this store went unusually well.

Over in Geneva, commissioning of the LHC continues. There, the highest initial luminosity reported by ATLAS is 2.3 x $10^{27}cm^{-2}s^{-1}$, or 200,000 times less than the Tevatron number. I haven't seen a recent number for the total luminosity delivered by the LHC to the experiments so far, but I believe it's a small number of hundreds of inverse microbarns. The Tevatron is producing more collisions in one second than the LHC has managed in the three weeks since first collisions.

The current plan for the LHC is to devote most of the rest of 2010 to increasing the luminosity of the machine, with a goal of reaching something somewhat lower than the Tevatron luminosity (1-2 x $10^{32}cm^{-2}s^{-1}$) by the end of the year. Then the plan is to run flat out at this luminosity throughout 2011, accumulating data at the rate of about 100 pb^{-1}/month, and ending up with a total of 1 fb^{-1}. The hope is that this will allow them to be competitive for some measurements with Fermilab, the lower luminosity compensated by the advantage of a factor of 3.5 in beam energy that they now enjoy.

The Tevatron has already produced over 8 fb^{-1} of data, and the current plan is to run the machine through the end of FY 2011, reaching at least 10 fb^{-1}, and then shut it down for good. The LHC is supposed to go into a long shutdown throughout 2012, not coming back into operation until 2013. Even if all goes well, it likely will not have accumulated enough data to decisively compete with the Tevatron until late 2013 or 2014. Under the circumstances, it's hard to believe that there aren't plans being proposed at Fermilab to keep the Tevatron running for several more years, until 2014. The machine should then be able to end up with a total of 15-20 fb^{-1} worth of data, which could be enough to allow them to see evidence of the Higgs at the 3 sigma level over the entire possible mass range.

Shutting down the Tevatron as planned would free up funds for other experiments, and free parts of the accelerator complex for use by neutrino experiments. It will be interesting to see whether instead of this, the decision gets made to go for a bid to outrace the LHC to the Higgs and other high energy frontier physics over the next few years.

Update: The integrated luminosity seen by the ATLAS detector for the current run so far is about 400 inverse microbarns, 350 at CMS (where they have 300 worth of recorded data).

Update: This morning the LHC has started delivering collisions with stable squeezed beams to the experiments, initial luminosity 1.1-1.2 x$10^{28}cm^{-2}s^{-1}$.

Update: Integrated luminosity delivered to each experiment at the LHC is now up to around 1000 inverse microbarns.

Comments

1. **Verified Armonyous**
   April 20, 2010

   Do you think the comparisons of instant luminosity you make are in any way significant?
   I think you can make your point on the need to run Tevatron longer (with which I fully agree) without trashing the LHC.

2. **Peter Woit**
   April 20, 2010

   I'm not in any way trashing the LHC, which is undeniably the long-term future of the field and is moving forwards towards fulfilling that role. What I'm doing is trying to put out the best numbers available about the current situation and what can be expected from the two machines over the next few years as well as noting the obvious questions these numbers raise.

3. **milkshake**
   April 20, 2010

   It is worth to point out that Tevatron is not obsolete yet, and it is not unfair to make a direct comparison because LHC promise of delivering breakthrough results soon has been over-publicized and meanwhile Fermilab has had hard time with funding…

4. **luminosity**
   April 20, 2010

   "The Tevatron is producing more collisions in one second than the LHC has managed in the three weeks since first collisions."

   LEP ran from 1989-2000. One good weekend in 1994 produced as much integrated luminosity as the whole of the 1989 run. See the chart at bottom of page for integrated luminosity at DELPHI for LEP-I ("Z0 factory")
   http://hepunx.rl.ac.uk/~adye/thesis/html/node9.html

   See also here for LEP-II integrated luminosity 1994-2000
   http://accelconf.web.cern.ch/Accelconf/e00/PAPERS/TUOBF101.pdf

   It is a matter of history that 70% of the integrated luminosity of LEP was delivered during its last three years of operation. All of this merely underscores the *enormous* technical challenge of commissioning and operating a (large) new accelerator. The Tevatron itself ran for years with instant luminosities of approx 1E30. So LHC delivers 2.3E27 now? Perhaps the right viewpoint is that 2.3E27 is better than zero.

5. **Paul Wells**
   April 21, 2010

   From a global perspective I think it would be more efficient to shut down Tevatron now.

   LHC will find the Higgs eventually if it exists.

   This reminds me of SLC and LEP competing to find the number of neutrinos from the width of the Z.

Why not shift resources now to neutrino work ?

Is this just a matter of ego ?

6. **eff**
April 21, 2010

Who is to define "efficiency" ?
SLC and LEP — again a too-narrow focus on HEP expt (# neutrinos and Z width) and neglect of accelerator technology. SLC also pioneered a new acceleator principle/technology, that of a linear collider. These are not "turnkey" operations that one can buy off the shelf nor can they be designed "on paper" with computer simulations.

7. **Peter Woit**
April 21, 2010

Paul,

By the same argument, any piece of scientific apparatus should be shut down as soon as there's a viable plan for something better. That's not the way science is done, for good reason. It's not because of ego, but because actually getting results is important, so you don't just stop before you have them when you think someone else will have a better shot in the future.

In this case, no one knows how long it will actually take the LHC to reach the point of producing data that makes the Tevatron irrelevant. The history so far is that things have taken significantly longer than planned.

In addition, for some sorts of measurements, higher center of mass energy is not so crucial. For example, for a low mass (115 GeV) Higgs, my understanding is that the higher energy of the LHC doesn't really help.

It's also true that having multiple confirming observations of something is quite valuable. If a Higgs is seen, it's going to be a difficult signal, and seeing it at four different experiments will help confirm it is really there.

The argument for shutting down the Tevatron is not the LHC, but that once it has collected a certain amount of data, it's not worth spending a lot more money to collect only marginally more data.

8. **Dr.Kathrine Martinez-Martignoni**
April 21, 2010

Peter,
do you think that americans feel themselves a little bit "frustrated"
to constate that LHC has already surclassed Tevatron in the mass
media propaganda?
Dr.Kathrine M.

9. **Peter Woit**
April 21, 2010

Katherine,

I don't think this is a nationalistic issue. Among Americans, most non-physicists don't know or care about the question, and most physicists are quite excited by the fact that the LHC is finally getting into operation and very much looking forward to what it will find.

Tevatron vs. LHC is not exactly a hostile competition, since the experimentalists involved on both sides are often the same people (many work on both the Tevatron and LHC detectors). It's also not much of a nationalistic competition, since many European physicists work on the Tevatron experiments, many Americans on the LHC experiments.

10. **Verified Armonyous**
April 23, 2010

There you have it. Now people have started quoting your unfair comparison, akin to comparing your reading skills with those of a three month baby.

11. **nessuno**
April 23, 2010

Armonyous,
I don't think the post is an "unfair comparison"; rather, it is a representation of the real current situation. By the way, I found a similar post some days ago (http://blog.vixra.org/2010/04/10/lhc-needs-more-luminosity/). But if you want to compare, Tevatron is like an old 8 tons truck running at its best and delivering stuff to the customers. LHC is like a brand new 40 tons truck, but only tested with a 4 grams load. And the plan to increase the load is, for the time being, unpredictable. So, if the customers think it is still useful to get some stuff within a predictable delay, they should keep the old truck running. Only when the new one delivers what it has promised, the old truck can be dismissed. After all SLC was not stopped before LEP produced decent luminosity.

12. **Verified Armonyous**
April 23, 2010

Sure, I'm fully convinced and in favor of keeping Tevatron running for much longer. Still I believe the wording of the comparison was not very fortunate and was certainly unnecessary to make the point. Only a theoretician could speak like that.

13. **th**
April 23, 2010

A true blue theoretician wouldn't mention the LHC or Tevatron at all. Everything could be deduced from pure Platonic intellectualism (like strings?). I am much impressed by PW's diligent efforts to present up-to-date reports on the progress/status of LHC and Tevatron (also RHIC, as with the private donation of funds by Simons to keep the machine running in 2006).
http://www.math.columbia.edu/~woit/wordpress/?p=328

Unfair comparison? Not at all!

Kudos to PW!

14. **Coin**
April 23, 2010

Could eventually it be possible to do a single statistics analysis / bump hunt using merged data from the LHC and Tevatron?

15. **Peter Woit**
April 23, 2010

Coin,

They run at different energies, and one is a proton-proton, the other a proton-antiproton machine. So, doesn't really make sense to combine the data.

If they do both end up with some sort of marginally significant Higgs signal, there probably is some sort of statistical analysis that would quantify the improved significance of the Higgs signal taking into account the two analyses.

16. **Coin**
April 23, 2010

Interesting, thanks.

17. **Bill K**
April 23, 2010

one is a proton-proton, the other a proton-antiproton machine.

This has always left me scratching my head, for the following reason.

1) Suppose that back in 1975 or whenever, someone had said to you, "Hey, let's build a proton-antiproton collider at Fermilab." Wouldn't your reaction have been, "No, of course not, that'd be like shooting yourself in the foot. Just think how difficult it would be to generate the antiprotons and collimate them into a usable beam. You'd never be able to produce enough luminosity that way." And yet the Tevatron does so, admirably.

2) Given that success, suppose that back in 1985 or whenever, someone had said to you, "Hey, let's build a collider at CERN and make it a proton-proton machine." Wouldn't your reaction have been, "No, of course not, that would just complicate the magnet design. Look what a great job the Tevatron does using antiprotons."

3) Now suppose in 2010 someone says to you, "Hey, let's build an even larger machine." Given that both the Tevatron and the LHC are now remarkably successful — of the two designs p-p or p-anti p (never mind the other options!) do you see either of them as having a real advantage, and if so which one and why?

18. **Remus**
April 23, 2010

In the case of the LHC, I guess it *had* to be proton-proton because the same accelerator was intended to accelerate, and collide, heavier nuclei as well.

19. **Ralph**
April 23, 2010

Well, LHC just got to 1.2e28 🙂 Still a way to go to 1e34…

Of course, if Tevatron decides to make it a race, LHC might decide to play along and put off the 2012 shutdown; even one year could well be enough to increase the luminosity by a factor of ten at this stage of the LHC…

[LHC needs to do its repairs before it gets too irradiated though – I wonder if that is a constraint?]

20. **Peter Woit**
April 23, 2010

Bill K,

My understanding is that the reason the LHC is a proton-proton machine is that, as you go to higher energies, you want higher luminosity since cross-sections of interesting processes are falling off with energy. So the LHC design luminosity is 10^34 cm^-2s^-1, and there's no way to get to this kind of luminosity with anti-protons. The Tevatron luminosity is very much limited by the ability of the accelerator complex to accumulate and store anti-protons in a beam.

It looks like, as Ralph mentions, this evening they've had significant success, producing stable colliding squeezed beams of higher intensity, so getting a significant increase in luminosity.

21. **pbar**
April 24, 2010

Bill K ~ "1) Suppose that back in 1975 or whenever, someone had said to you, "Hey, let's build a proton-antiproton collider at Fermilab." Wouldn't your reaction have been, "No, of course not, that'd be like shooting yourself in the foot. Just think how difficult it would be to generate the antiprotons and collimate them into a usable beam. You'd never be able to produce enough luminosity that way." And yet the Tevatron does so, admirably."

We need a serious history lesson here! The idea of colliding proton-antiproton beams WAS FIRST PROPOSED AT FERMILAB IN 1976, using stochastic cooling to increase the phase-space density of the pbar beam to a useable level (i.e. sufficient luminosity in collisions), and the Fermilab management KICKED THEM OUT.

The proponents of p-pbar colliding beams were Carlo Rubbia, David Cline and Peter McIntyre. See for example Peter McIntyre's home page
http://faculty.physics.tamu.edu/mcintyre/

"In 1976 Prof. McIntyre was the first to propose the possibility of making colliding beams of protons and antiprotons using the large synchrotrons at Fermilab and at CERN. This work led to the discovery of the weak bosons at CERN in 1982."

McIntyre says "Fermilab and CERN" but is was Fermilab that they turned to first. The Fermilab people openly laughed and told them that stochastic cooliing violated Liouville's theorem, etc., much as Bill K says above.

So Rubbia and Cline went to CERN, which was hungry for a Nobel Prize, and CERN was willing to try the stochastic cooling idea (which idea had been invented by Simon van der Meer who was a CERN engineer in the first place). CERN converted the SPS into the SppbarS, it worked and produced the W and Z and led to the 1984 Nobel Physics Prize for Rubbia and van der Meer.
http://nobelprize.org/nobel_prizes/physics/laureates/1984/

All of this is well-documented. A book which describes the history of these events is "Nobel Dreams" by Gary Taubes
http://www.amazon.com/Nobel-Dreams-Deceit-Ultimate-Experiment/dp/1556151128

The Tevatron did not yet exist in 1976. It would have been necessary to convert the Fermilab Main Ring synchrotron into a p-pbar collider (as CERN did with the SPS). Pbar beams were first circulated at Fermilab in 1985, and the Tevatron became operational around then.

Why were Rubbia etc kicked out by the Fermilab management? At least part of the reason is that Robert Wilson, who was then the director of Fermilab, had devoted significant resources to Rubbia's expt at FNAL, leading to the high-y anomaly (go look THAT up on your own!) which was later debunked by CERN. This followed on from the "alternating neutral currents" fiasco, also perpetrated by Rubbia at his expt at FNAL (go look THAT up on your own, too!). Rubbia had a history of bogus grand claims leading to embarrassment at FNAL. The high-y anomaly business broke in 1977. When in 1976 Rubbia came up with yet another hair-brained (hare-brained?) scheme — it was obviously a very speculative and difficult idea — and was obviously no longer focusing on high-y, to which Wilson had devoted significant resources, Wilson realized that Rubbia was again off on another tangent. Robert Wilson lost his temper with Rubbia and kicked him out. It is a matter of history and irony that Robert Wilson, despite his many talents, gave priority to the high-y anomaly (which was a false phenomenon), and rejected the pbar stochastic cooling idea (which led to a Nobel Prize).

The SSC was proposed as a proton-proton collider for precisely the same reason that the LHC is a proton-proton collider, exactly as PW says — it is difficult to produce antiprotons in sufficient quantity (and phase-space density) to attain adequate luminosity. The disadvantage of a proton-proton collider (RHIC, LHC) is that one needs two rings instead of one. This doubles (approximately) the cost of the final ring in the accelerator complex — LEP was a single ring — but it simplifies the beam production, storage and acceleration process. So there are trade-offs.

But never doubt that the idea of colliding proton-antiproton beams was first proposed at Fermilab, which famously rejected the idea. Wilson resigned as director of FNAL around 1977, and Leon Lederman became the director. There was the famous "Armistice Day" meeting at Fermilab in Nov 1977, where everyone was invited to speak openly, and Lederman decided as a result that FNAL would not attempt to compete/race with CERN to make and collide pbar beams. It is a tribute to Robert Wilson's foresight that he left enough space in the Fermilab Main Ring tunnel to build a second ring — he visualized the two rings as a p-p collider — but the Tevatron instead became a single-ring p-pbar collider. But Wilson also kicked out Rubbia for proposing stochastic cooling and p-pbar collisions instead of focusing on the high-y anomaly.

Bill K #2 — "Given that success, suppose that back in 1985 or whenever, someone had said to you, "Hey, let's build a collider at CERN and make it a proton-proton machine." Wouldn't your reaction have been, "No, of course not, that would just complicate the magnet design. Look what a great job the Tevatron does using antiprotons.""

Understand first the history of the Tevatron. Understand the history of the idea of colliding p-pbar beams.

Rubbia and the bogus grand claims – after discovering the W and Z, the UA1 collaboration went on to discover supersymmetry (monojets) and also the top quark (44 GeV). Remember those?

CERN punished Rubbia for these transgressions by making him the DG. Bogosity pays!

22. **a quantum diaries surivivor**
April 24, 2010

Hi all,

although I do not share pbar's rather negative view of Carlo Rubbia (who after indeed several fiascos and some dangerous politicking to steer the labs into financing his endeavours, hit on the right idea and over the course of a winter became the world's expert of antiprotons, becoming the engine that brought the SppS to existence) his reconstruction is rather accurate.

Regardless of neutral currents, y anomalies, monojets and top quarks, every ounce of Rubbia's Nobel prize for showing the world that W and Z bosons were there is well-earned.

Cheers,
T.

23. **pbar**
April 24, 2010

My intent was really the history of p-pbar collisions and Fermilab, and Rubbia got more mention than I intended.

BTW "surivivor" –> survivor (unless it's deliberate?)

24. **P**
April 25, 2010

Thanks for a very interesting history lesson.

25. **Paul Wells**
April 28, 2010

Peter,

Do you have a reference to what the LHC luminosity optimizations actually are and what future optimizations are planned ?

Naively one would think a proton proton collider should have a huge advantage over a antiproton proton collider since protons are easier to make than anti-protons…

Thanks
Paul

26. **Peter Woit**
April 28, 2010

Paul,

There are lots of sources of up-to-date info online at CERN about plans for what needs to be done to increase the LHC luminosity towards the ultimately planned design luminosity. I'm not linking to them since there's an unfortunate history of CERN shutting off access to such information sources after seeing links from blogs.

The main issue for luminosity increases this year at the LHC is the machine protection system. They're starting to enter into a regime of "unsafe beams", where a loss of control of the beam could lead to very serious damage to the machine. Because of this they plan to be very careful and go about this slowly, being sure they completely understand and control the behavior of the machine at one luminosity level before moving to the next.

Podcasts

April 26, 2010
Categories: Uncategorized

In case you're tired of reading me going on about the same topics and instead would like to listen to me going on about such topics, there are now two new options:

- A couple weeks ago I did a podcast with the folks at the Rationally Speaking web-site, talking to Massimo Pigliucci and Julia Galef (their podcast site is here, direct link to my segment here). In the near future they'll be doing a different podcast on the topic of the Anthropic Principle. Pigliucci is a philosopher of science and comments on this here.
- Last month I visited Collin College in Texas, and they have a podcast up from an interview I did there. The site is here, link to interview here.

Comments

1. **milkshake**
   April 26, 2010

   I liked the podcast from Collin College better – the interviewer must have had the structure of the interview planed out in advance, she kept the questions short and to the point and she was not plugging her own observations. One of signs of professional interviewer is that she/he is patient and leaves most of air in the room for the guest.

   I had impression that it was harder to get your points across clearly in the Rationally Speaking conversation. Debates can be quite messy to follow when the subject is philosophy and there are several participants some of which are more eager to listen to themselves than to others.

2. **Peter Woit**
   April 26, 2010

   milkshake,

   They're just different. The Collin College one was basically just an interview, with questions discussed in advance, so I could just make points I wanted to make that I thought would be accessible to as many people as possible. The Rationally Speaking one was intentionally more of a conversation, and I think got into some more of the subtleties of the issues. It was recorded after we had dinner together and talked quite a bit, so ended up, for better or worse, being somewhat of a continuation of that conversation.

   Because some of these debates about string theory end up getting into significant questions about the philosophy of science, I'm always interested to hear what professional philosophers of science think about the debate. In this case, Pigliucci is a philosopher who has thought a great deal about these issues, and I was enjoying discussing them with him, not just putting out my own point of view.

3. **milkshake**
   April 26, 2010

   The Rationally Speaking debate felt a bit like split-screen pundits on CNN competing for limited air time, a style which made it harder for anyone involved in that debate to make their basic points across in a concise way, and then to elaborate them in more detail before getting cut off. It was somewhat ineffective format not because the ideas were discussed in more depth but because not everyone involved seemed willing to stop and listen what the others had to say, then formulate a good reply.

   By the way, philosophy of science is not such a inaccessible field, it has to do with practical usefulness of an idea and the scientific integrity, these are concepts that anyone can understand.

4. **Joe Joe Bob**
   April 28, 2010

   I prefer to read.

   Get to work, slacker. Hunt up interesting information and make more of a contribution to the market place of ideas, understandable or otherwise, provacative or mundane, original or mere reporting. With a kickback job like yours, having hours to ponder the deep and mysterious in your ivory tower office, surrounded by your yellow library of Springer textbooks and monographs, there's no excuse for you turning into a slacker.

Dark Matters

April 28, 2010
Categories: Uncategorized

Initial 2010 data from the Theoretical Particle Physics Jobs Rumor Mill indicates that the particle theory job market remains as trend-driven as ever. This year, it seems that if you want a tenure-track job in the US, you must be working on phenomenology. And not just any sort of phenomenology, your work has to be about dark matter. Of the seven theorists offered tenure track jobs so far, no less than 6 are phenomenologists working on dark matter. The seventh is Davide Gaiotto, who has been working with Witten and others at the IAS on mathematically quite interesting topics that use N=2 and N=4 supersymmetric gauge theory. His offer is from Stony Brook, where much of the funding comes from Jim Simons of Renaissance Technologies. Simons is putting profits from the world's most successful hedge fund to work keeping alive the idea that the intersection of mathematics and physics is still worth pursuing, so not everyone has to become a dark matter phenomenologist.

(By the way, the rumor mill seems to indicate that Kachru and Silverstein are leaving the KITP, heading back to Stanford. Is that right?)

If you're a young theorist who wants to remain in the field, you better get to work on dark matter phenomenology. I'm afraid that this blog won't be of much help, you should carefully follow Resonaances, which has the latest news and rumors.

Update: It seems that my point about the dominance of dark matter hiring has even more backing than I thought, since Sergei Dubovsky evidently has an offer from Stony Brook (and other places). So, that makes it seven out of eight for dark matter so far this year.

   April 28, 2010

   Woit writes:
   "If you're a young theorist who wants to remain in the field, you better get to work on dark matter phenomenology."

   That makes no sense. If you want to remain in the field then stay in the field. If you want to do phenomenology, then you go ahead and work on dark matter and other venues.

2. **graviton383**
   April 28, 2010

   Shamit & Eva will be back in Stanford-land this Fall.

3. **Avidan**
   April 29, 2010

   M, what you say makes no sense:

   How do you suggest non-dark-matter people will stay in the field (which I define as academic high energy theory) if they have no job ? Fill out a lottery card ? get a day job as a software engineer ?

   You know, physicists also usually eat, pay bills, and even (maybe to some extent rarely) have families…

4. **Rien**
   April 29, 2010

   Of course, it could be because dark matter is where there is something interesting going on at the moment, what with recent and coming data. There is only so much you can do while waiting for LHC.

   Some people, as weird as it may sound, still think physics is related to experiments.

5. **Peter Woit**
   April 29, 2010

   Rien,

   I won't argue against the idea that dark matter is a hot topic for good reason. This doesn't mean it's a good idea for US physics departments to only hire people working on the latest, hottest topic. They've been doing this now for a very long time, and this has a lot to do with the sad current state of the field.

6. **M**
   April 29, 2010

   What I mean is that you should follow what you like, not what is trendy. Your research topic should not be dictated by what is popular. If you have gained the basic knowledge in physics to understand the current problems then you ought to be able to come up with a few ways to tackle at least one of them. Then you try to solve the problem and in the end you should learn something: why your thing worked or why it did not. These problems do not live in the academia. They are free for anyone to try.

   If you want to get an academic job, then you have to play the game and do cartwheels. That game changes every year / decade / generation / etc. The situation is nasty; the lottery ticket summarizes it well. Nothing is fair in life. But if you want to understand something you actually like, surely you do not need to be in the academia. Just follow the rules of the scientific method and you should be able to stay away from crackpotery.

7. **Rien**
   April 29, 2010

   Peter, of course I agree that this trend-following is not good. I believe one should try to hire smart people foremost. But actually, many of the people on the list are not working on only dark matter but phenomenology in general.

8. **Theorist**
   April 30, 2010

Peter, have you considered that you might be confusing causation and correlation? Is it possible that the people hired are simply the best candidates and the reason that dark matter is a hot topic is (in part) because the best young people are working on it?

I know part of the theme of this blog is to expose the shadowy conspiracy that is high energy theory, but it is possible that the dark overlords don't control every hire.

9. **Peter Woit**
April 30, 2010

Theorist,

I didn't say anything about dark overlords or any conspiracy, I'm well aware of how the hiring systems in both physics and math work. What's happening is a lot of people with the same point of view independently making the same decision about priorities. And sure, the decisions of the best young people about what to work on and of the older people doing the hiring are both part of the picture.

What I was pointing out is the end-result of the whole process: virtually everyone working on the same topic. I think there's a good case to be made that this end-result is not a healthy one, that people should be acknowledging this and thinking about what can be done about it. I take it that your conclusion is that nothing's wrong, there's no reason to be concerned about this kind of pattern, it's just the result of everyone making the best possible decisions. Others may disagree…

10. **Anonymouse**
April 30, 2010

However, Rien's point is valid — if you look at the phenomenologists you classify as 'working on dark matter', I would have to concede that every one of them has a paper on the subject. However, less than half of them have worked for, say, 50% of their career (measured in publications) on the subject, and several of them not in the past year or two. What makes for a dark matter theorist? Or even virtually everyone working on the same topic? I also find the faddishness unfortunate, but I'm not seeing more than a vague trend here.

I think it is fair to say that phenomenology remains more attractive to search committees than more formal work, as has been true for a few years now. Dark matter is an important component of phenomenology in general. Particularly given the slow start-up of the LHC. Wanting a general phenomenologist is not being faddish, it's being smart in the sense that someone with a track record of being able to follow interesting results is, long term, a much better investment.

Also let me point out that at least three of the jobs listed on the HEP theory rumor mill (Carnegie Mellon, Case Western, and Oregon) state they are looking for someone specifically with interests in cosmology. That pre-selects them for dark matter and away from HEP theory. It may be that this just shows they were more organized about following a fad than other places, but I doubt it.

11. **Peter Shor**
May 1, 2010

Maybe the question should be not: why do Physics departments hire only people working on the latest trendy fad but: why do Math departments avoid hiring based on the latest fads? From what I've seen of other disciplines, in many of them hiring is significantly more tilted to hot areas than it is in Math departments. There may be something in the mathematics culture that discourages this.

Of course, from a personal perspective I probably should be asking: How can we make quantum computing the hot topics in Physics departments?

12. **Peter Woit**
May 1, 2010

Peter Shor,

Yes, mathematics does seem to avoid excess faddishness, it would be a very good idea for particle theorists to think about why this is and whether they could learn anything from it. My own speculative ideas about the sources of the difference are:

1. The ratio of people to jobs is better in math. In particle theory there are more people with excellent credentials then jobs, so hiring committees can add the criterion of working in what they see as the most promising area. In math if you tried to add this criterion, you'd typically end up not being able to hire the best people.

2. For 40 years 1. has been true, so the permanent faculty now consists completely of people chosen using the criterion of having made their career by working on the latest hot topic. Not unreasonably, they take the attitude that the best people are the ones who work on the hot topic, those not doing so are those that just can't cut it.

3. Particle theory now has a well-developed ideology about what speculative ideas (supersymmetry, extra dimensions, GUTs) are promising, limiting the attention of those in the field to a relatively narrow range of ideas.

4. Mathematicians have a culture which values expertise, and the idea that really understanding a particular subject is very difficult and requires many years of work. When a subject all of a sudden becomes hotter, say after Wiles or Perelman's work, you see some more activity in it, but people from other fields don't jump into the now hot one, since they don't believe they can do it successfully, and others would tend to not take them seriously. Particle theorists often have a much more arrogant attitude, convinced that they can jump into something they don't know about and a couple months later be writing useful papers on the subject. Witten can do this, lots of other people think they can….

13. **Peter Shor**
May 2, 2010

Peter Woit,

In addition to your points, there may be another factor in play. In mathematics, you can expand the boundaries of mathematics in many directions, all of which are potentially worthwhile. In physics, there's only one "right" answer, so some directions of exploration are preordained to be blind alleys. This can be used to justify the attention to hot topics; historically, at any time there have only been a few directions of research which led to the next step in discovering the laws of nature. (Of course, these weren't always the "hot" topics at the time, but with hindsight this is easily forgotten.)

14. **theorist2**
May 2, 2010

I think Peter Shor makes an important point. However close the ties between physics and mathematics are, they are fundamentally different disciplines. Research in each field is carried out in very different manners. Given that there is only one universe, unless we digress into multiverse discussions, there is only one "right" answer. Whether a theorist's best guess is correct or not can only be judged by experiment. While some ideas are more promising and more mathematically compelling than others, which in turn creates trends in high energy theory, if in the end of the day the ideas are falsified by experiment then they are ultimately wrong. Therefore, it might not be wise to take clues from Mathematics departments as far as hiring practices are concerned.

It would be hard to compare the "faddishness" of dark matter or phenomenology hires to string theory or "formal" theory hires. What are the most interesting experimental results, or those ideas which have the most interesting experimental consequences, will presumably always drive the field to a large part as it always has. That is of course when there are interesting experimental prospects or results (outside of those times who knows what the best guide should be). A number of questions could be relevant: Does HET do worse as far as results go in the long term compared to other areas of theoretical physics? Is hiring in HET that different than in other fields of theoretical physics? How different are hiring practices in more related disciplines like Biology and Chemistry(rather than Math)?

15. **Peter Woit**
May 3, 2010

Peter Shor,

It's true that this kind of physics is different in that ultimately there will be just one correct better theory. But, it's quite likely that there are multiple possible ways to get from here to there, and the current situation is that we don't know at all what the right direction to go is. In such a situation, focusing on one particular highly speculative direction and making anyone who works on anything else jobless is probably not a good idea.

One reason particle theory is so faddish is that (in the distant past…) fads were driven by experimental results. When a ground-breaking unexpected experimental result arrives, there's a very good reason to focus on it and what it means. Unfortunately, I think what is going on now is experimentally-driven faddishness with no significant experimental results. If someone actually had a dark matter signal, that would justify what is going on, but there is no solid evidence for such a signal out there right now, and the idea that it is just around the corner remains quite speculative.

16. **Remus**
May 3, 2010

> historically, at any time there have only been a few directions of research which led to the next step in discovering the laws of nature. (Of course, these weren't always the "hot" topics at the time, but with hindsight this is easily forgotten.)

Maybe to easily… One can turn the question around, and ask how many laws of nature were found that way.

General Relativity? QED? QCD? Electroweak Theory? Antimatter?
Renormalizability of the SM? Asymptotic freedom?

As far as I know, none of them was a hot topic immediately before they were discovered. They became a hot topic afterwards, and no further natural laws were found in those directions.

17. **Peter Shor**
May 3, 2010

Peter Woit,

My post seems to have been misinterpreted. I didn't mean to say faddishness was a good idea. What I meant to say is that there are reasons why over-confident physicists who think they know where the next breakthrough is coming from think it's a good idea. Remus understood exactly what I was trying to say.

18. **Verified Armonyous**
May 5, 2010

Why do you count Dubovsky for DM ?

19. **Peter Woit**
May 5, 2010

Because:

1. That's how my source, who was very well-informed about Dubovsky and his work, counted him.

2. Of his last 5 papers, only one isn't about phenomena that involve dark matter candidates.

20. **Verified Armonyous**
May 6, 2010

I would say exactly the opposite, that only one among his last 5 papers deals directly with DM.

21. **Anonymouse**
May 6, 2010

Here are my take on the stats, listing the person with the offer on the rumor mill, number of papers about dark matter, total number of papers, and a paper about dark matter in the last 12 months (yes or no):

Chang: 6 dark matter, 22 total, Almost 100% DM this year

Dubovsky: 6 dark matter, 52 total, Yes to DM this year

Gaiotto: 0 dark matter, 46 total, No DM this year

Graham: 4 dark matter, 14 total, Yes to DM this year

Kong: 4 dark matter, 32 total, Yes to DM this year

Papucci: 4 dark matter, 22 total, yes to DM this year

Schuster/Toro: 4 dark matter, 13 total, yes to DM this year

Toro's papers are complete subset of Schuster's (Schuster has 4 more, 2 of which are dark matter), so I listed them together. Also, it amused me to do so.

I was strict in choosing papers about dark matter, meaning I did not accept work on other aspects of cosmology as a dark matter paper. In a couple cases I also avoided articles that had dark matter in the title but were clearly about collider physics (but only a couple like that). You can quibble about what was meant by various comments made above, but given the over-all discussion I believe that this is fair. I did not separate out published from unpublished, which does represent an over all bias of some kind.

I draw a very different conclusion from these data: forget working on dark matter, just get Arkani-Hamed or Dimopoulos to support you. Particularly if your CV is on the weaker side. I understand that numbers do not capture impact or any number of other important metrics by which research should be judged, but I feel I know the individuals well enough to judge them that none of them clearly deviates by huge amount in terms of impact that would substantially change the picture the numbers is painting. The two who impress me the most as scientists actually have the largest number of publications independently of that fact.

To reiterate: I don't see a huge jump on a dark matter fad this year. Dark matter is interesting, and there is data available, questionable in interpretation though it may be. A large number of phenomenologists worked on dark matter in the last two years (amny of whom already had faculty positions, and still more who did not receive one), and I believe this is just intelligent people following interesting results.

22. **A Phenomenologist**
May 6, 2010

The phenomenologists who got jobs this year are all highly deserving candidates and their work extends way beyond "Dark Matter". It is extremely silly to label these people as "dark matter phenomenologists". In particular, Peter Woit's counting of Dubovsky's last five papers and labeling four of them as Dark Matter papers is just plain asinine. Perhaps's Peter Woit's illustrious publication record of five papers in the last 20 years makes it difficult for him to count papers and understand their content.

It is high time that young people who are either guided by data, or whose work leads to new experimental probes of physics are rewarded with faculty positions. In fact, I find it very odd that people whose work explicitly deals with theories that cannot possibly describe the world or involve dualities between worlds that are also not our own world continue getting jobs. They ought to find themselves positions in a dual world.

23. **Peter Woit**
May 6, 2010

"A Phenomenologist",

You seem to be rather upset that even one out of eight of these jobs is going to a non-phenomenologist.

It's interesting to see that now that phenomenologists have vanquished their enemies and successfully won the political fight in HEP theory, at least some of them have adopted the arrogant and juvenile attitude that in the past so endeared many string theorists to their peers.

24. **noname**
May 9, 2010

I'm surprised that you haven't corrected your wrong statement about Dubovsky.

25. **Anonymouse**
May 9, 2010

I guess there are many scarred people out there on both the phenomenological and "non" (in all forms) sides. I think saying phenomenology has won is not accurate. Winning at the moment, to be sure, but that particular pendulum has swung back and forth at least twice in my memory.

Add Johannes Walcher to the list of faculty positions, not dark matter and not phenomenology. And Chris Jackson, phenomenology and some dark matter component.

Without the polemic of "A Phenomenologist", which I think is pointless, I am also surprised that Peter Woit is not interested in the debate as to whether his assessment that dark matter earned people jobs this year is accurate. He seems to studiously avoid it, which may be because I think the facts just don't bear it out. Which is his choice, but he is the one who made the pronouncement to begin with.

Phenomenologist: Even among the people getting jobs in your camp this year, are you really sure they are at all relevant for the real world? Despite the upswing in phenomenological positions, there is still very very little representation in the past ten years for people who do work on the Standard Model. People seem to be happy reward inventing unlikely or baseless theories for how nature could be, but the work of studying how it is seems to get very little attention.

26. **Peter Woit**
May 9, 2010

Anonymouse,

I haven't responded to your arguments partly because I've been out of town, but mainly because I just don't have anything significant to add. Yes, the world is complicated and "the people getting jobs are dark matter phenomenologists" is an over-simplification of a complicated situation. On the other hand, I still believe that the point I was making in the posting is quite valid: particle theory hiring is often very faddish, and this year the fad is phenomenology, with an emphasis on work relevant to dark matter.

Some other people's arguments I haven't responded to just because long experience has shown it's a waste of time trying to have an intelligent discussion with people who want to carry on a hostile argument from behind the cover of anonymity.

27. **Anonymouse**
May 9, 2010

That's fair enough.

28. **Eric**
May 9, 2010

I only have one thing to add, which is that hiring choices are frequently determined by which candidates are considered to have the best chances of bringing in grant money. Research topics which seem to have the best chance of getting funding are frequently those which some consider to be faddish.

Bohmian Spat

Here's a story from the boundaries of conventional physics of the sort I normally try to resist paying any attention to, but couldn't quite help myself this time:

Last week I noticed amongst the e-mail from Jack Sarfatti that clutters my (and many other people's) mailbox some forwarded messages about a kerfuffle involving the withdrawal of a conference invitation to Brian Josephson. Josephson is a Nobel Prize winner but, on the other hand, he seems to think that [this sort of thing] makes sense. In one of the messages, I noticed that Josephson defends himself by pointing out that his talks often don't involve paranormal phenomena, giving as example a recent [Hermann Staudinger lecture] in Freiburg (Staudinger was a chemistry Nobelist, also my great-uncle).

This mini-scandal has now made it to a [Times Higher Education story] today, which starts off:

> An extraordinary spat has broken out after a Nobel prizewinning physicist was "uninvited" from a forthcoming conference because of his interest in the paranormal.
>
> Details of the conference in August for experts in quantum mechanics sounded idyllic. Participants were due to discuss "de Broglie-Bohm theory and beyond" in the Towler Institute, which is housed in a 16th-century monastery in the Tuscan Alps owned by Mike Towler, Royal Society research fellow at Cambridge University's Cavendish Laboratory.
>
> Last week, any veneer of serenity was shattered. Conference organiser Antony Valentini, research associate in the Theoretical Physics Group at Imperial College London, wrote to three participants to say their invitations had been withdrawn.

The current situation seems to be that Josephson, David Peat and Jack Sarfatti were un-invited, but now Josephson and Peat have been re-invited.

I had never heard of the [Towler Institute] before, but it sounds like a beautiful place, which physicist Mike Towler has admirably made available as a site for hosting small meetings and conferences. From the information on its web-site, this looks like the kind of place I'd find it very difficult to turn down an invitation to, no matter what the conference topic.

The [conference] at issue will be held at the end of the summer, and deals with what is known as "de Broglie-Bohm theory". One can read about this many places, including this [site] of Mike Towler's. The conference summary itself refers to the de Broglie-Bohm theory's "fringe nature in modern physics", and for more about why it is controversial see Towler's lecture [Not even wrong: Why does nobody like pilot-wave theory?].

After spending a little time learning about it many years ago, I quickly decided that I personally didn't like pilot-wave theory, partly because it seems to me that it throws out all the deep, amazing and experimentally verified links between modern physics and mathematics that motivate what I love about the subjects, getting nothing much in return. I don't see a good reason to believe that research in this area is going to lead to something interesting, but those who do have every right to keep trying. As they do so, they face serious problems in distinguishing crackpot from non-crackpot efforts, as this story makes very clear. Note that I have no intention of putting any time into this problem myself, so in this case I'm adopting a uniform policy of just deleting all comments arguing for or against de Broglie-Bohm. If that's a topic you like to argue about, do it elsewhere.

There's more [here] from Chad Orzel.

Comments

1. **willman**
   April 29, 2010

   Just to get a little clarification/enlightenment, I'll try a question: do you dislike the GRW approach to quantum mechanics (and related "spontaneous collapse" approaches like Philip Pearle's) as much as you do the de Broglie-Bohm approach, or do you find GRW's work more palatable than that of pilot-wave theorists (and if so, why)?

2. **Anonymous**
   April 29, 2010

   I remember hearing a talk given by Brian Josephson on "Mind Matter Unification". After the talk a student challenged Josephson with the question whether his theory is experimentally falsifiable. Josephson thought for a while, and answered, "The energy of the Universe may be different when mind is taken into account". According to people who know him, Josephson lost interest in conventional physics soon after (or even before) he was awarded the Nobel prize, but he is a very smart person and he's still doing integrals in his non-conventional research.

3. **Stephen**
   April 29, 2010

   The abstract of Brian Josephson's paper (i.e. "this sort of thing") starts "A model consistent with string theory is proposed for so-called paranormal phenomena such as extra-sensory perception (ESP)…". Is there a hint of irony here?!

4. **Peter Woit**
   April 29, 2010

   willman,

   In general I'm not much of a fan of attempts to modify the basic structure of quantum mechanics in order to deal with the measurement problem (precisely because this basic structure fits so well with basic structure in mathematics). From the little I know of them, the "spontaneous collapse" models have more modest goals and are less about replacing the whole QM formalism with something that I find radically less appealing, but I know very little about this.

5. **Bob Levine**
   April 29, 2010

   There seems to be a bit more to this story than the impression conveyed by the initial reports, on the basis of which Orzel asks the entirely reasonable question, what were the organizers thinking? A big part of the answer seems to be contained in Towler's long post in response to the THE story and attendant correspondence—specifically, that Josephson and Sarfatti were NOT formally invited. According to Towler, they 'they asked me if they could attend, which is very different.' Indeed it is. A bit more information about what *actually* happened is probably warranted before any conclusions are drawn from all this.

6. **willman**
April 29, 2010

Thanks, Peter.

7. **milkshake**
April 29, 2010

They got worried about being lumped together with Esalen… I feel sorry for the organizers, they seem generous. Maybe they should look into bringing in younger people instead; summer workshop would be also a less conspicuous way to invite someone with fringe ideas

8. **Alex R**
April 30, 2010

The comments following the Times Higher Education story are not to be missed, for entertainment value at least, containing comments from Sarfatti, Josephson, and Towler among the usual anonymous suspects…

9. **John Baez**
April 30, 2010

That paper by Josephson may have been moved from the hep-th section of the arXiv to the general physics section — see his complaints here.

10. **Phil Warnell**
May 1, 2010

Dear Dr. Woit,

As Antony Valentini was himself fated to existing for years outside the protected walls of the Ivory Towers, it is indeed curious to find him at the centre of all this. I would be the first to say such bickering as being completely unnecessary and yet also would insist that transparency should not be forsaken in situations where an opinion is rendered, by citing any which others may have to express as being irrelevant in respect to the topic.

Sincerely,

Phil

11. **Antony Valentini**
May 2, 2010

I would like to make a public statement about this.

The fuss stemmed from a private email that I wrote to Prof. Brian Josephson on the 19th April 2010, regarding a conference (about the de Broglie-Bohm interpretation of quantum mechanics) which I am co-organising with Dr. Mike Towler. The matter has recently erupted into the public domain with the publication of a rather misleading article in Times Higher Education.

Conference organisers are sometimes required to make difficult judgements, and of course mistakes can and do occur. The email I wrote was an attempt to deal with a difficult and complex organisational problem internal to the conference. It was not intended as a literal statement of my views about the scientific status of research into the ‘paranormal’. Nor did the wording accurately convey the nature of Prof. Josephson’s early association with the conference.

For the record, and contrary to what many are claiming: I am not in principle opposed to the careful and scientific investigation of alleged anomalies, whatever they may be. This view seems to me entirely obvious and uncontroversial.

Some will ask why I wrote an email apparently ‘dis-inviting’ a participant. Normally, such a step would of course be a regrettable breach of basic etiquette, and the recipient could reasonably complain strongly (and in private) to the organisers. However, as many will have learned from Dr. Towler (who started planning the conference before I got involved), certain alleged ‘invitees’ were in fact never formally invited.

Even so, some may ask why certain people became associated with a conference that is outside their domain of expertise, and which was never intended to be about the paranormal. Others feel driven to suggest that I was forced to write the email by a sinister power, and attempt to portray this episode as a bigoted attempt to suppress radical ideas. Some have simply concluded that there were probably good (if obscure) reasons for my writing the email, while others have seen fit to make comments without knowing the full (and private) facts behind the case.

In my view, if I may say, these matters are the business of the conference organisers and not of anybody else.

Prof. Josephson took the regrettable step of posting my email, in full and with author signature, on his website. (The author information and some of the text has now been removed.) This act encouraged a storm of protest from some of Prof. Josephson’s associates, partly in the form of a large volume of misleading emails sent to all the conference participants as well as to dozens of others (including journalists) and partly in the form of postings on various websites, including one that by any reasonable standard can only be described as deliberately defamatory.

Private correspondence (whether by conventional or electronic mail) should be treated as private, and should not be placed in the public domain without the author’s consent. The internet is an evolving medium, and one can query the suitability of standard constraints in this context. However, I suggest that we all take a deep breath, and ask ourselves if it is wise to blur the distinction between private and public correspondence in this way.

It is my view that a private matter between Prof. Josephson and myself has been brought into the public domain in a manner that is inappropriate and improper, as well as unhelpful and deeply misleading.

Some will regard my attitude as old-fashioned. For the other side of the argument, I can recommend a book by Lee Siegel, whose title speaks for itself: ‘Against the Machine: Being Human in the Age of the Electronic Mob’.

12. **csrster**
May 4, 2010

That’s a shame as the conference otherwise sounds like a Bohmian Rhapsody.

13. **Janne**
May 4, 2010

Theoretical physicists seem to have this strong paranormal ability to assess the mental health status of people they haven't even met.

14. **M. Wang**
May 5, 2010

Dr. Woit, can you elaborate on "all the deep, amazing and experimentally verified links between modern physics and mathematics that motivate what I love about the subjects"?

15. **Peter Woit**
May 5, 2010

M. Wang,

I'm referring to the close relationship between between representation theory and quantum mechanics, and the still not well-understood issue of how these work in the case of gauge symmetry and qfts like the Standard Model.

16. **Dave Miller**
May 7, 2010

Peter,

I've been interested in Bohm-de Broglie theory since my undergraduate days (alas, more than three decades ago!).

I share your aesthetic feelings that Bohm-de Broglie is unlikely to really give fundamentally deeper insight into the nature of QM. However, even granted that, I have always found it interesting that there does exist this mathematically consistent theory that reproduces all the results of standard QM. I think that this is worth exploring from the viewpoint of foundations, even if, as I suspect, it will not in the end, replace standard QM.

I have also followed both Valentini's and Sarfatti's work over the years. Valentini's work is normal physics: e.g., mathematical results are proved from clearly stated assumptions, etc.

I think I can honestly and diplomatically say that a different characterization would be needed to describe Sarfatti's work (Jack himself might even agree).

These guys are engaged in different activities, very, very different activities. Trying to include those activities in the same conference would be like holding a joint conference on superstrings and digital signal processing (and I hope I didn't just start a new string subfield!).

All the best,

Dave Miller in Sacramento

Oy vey

Categories: Multiverse Mania

Last Friday City College held a symposium here in Manhattan celebrating physics at City College. I was able to attend just the morning session, which began with a quick rescheduling of Anton Zeilinger for David Gross, who had overslept. Gross finally did make it and gave a talk on "The Frontiers of Particle Physics". He says he's taking bets in favor of supersymmetry being seen at the LHC, with 50/50 odds, and expects first evidence for supersymmetry within a year or two. By the time he got to the part of his slides about string theory he was over time, so he bypassed them, flipping ahead several slides at once.

Unfortunately I seem to have missed the real fireworks, which were at a panel discussion that afternoon. There's a report at Scientific American, entitled [Star physicists trade barbs over cosmological model](). Alan Guth was there, promoting the multiverse and the anthropic explanation of the CC. Gross was having none of it:

> "In reaction to that last talk—oy vey,"…
>
> Gross called Guth's concept of eternal inflation somewhat speculative, noting that if other universes do exist, they are causally disconnected from ours—"every goddamn one of them." As such, Gross added, talk of other universes "does bear some resemblance to talking about angels."

1. **Nathaniel**
   May 1, 2010

   Hmm…Gross says that Guth's multiverse bears some resemblance to talking about angels…huh, what about string theory? Seems like both theories are speculative unless there is some experimental evidence behind either of them. Kind of like the pot calling the kettle black.

2. **Mantis**
   May 1, 2010

   +20 sanity points for Gross.

   Nathaniel, string theory was supposed to describe our Universe but failed and it's this failure that prevents it from making testable predictions. Multiverse OTOH is all about things unobservable even in principle and from the very start, so even if it works perfectly it's still completely worthless untestable speculation.

   Multiverse ideas are a complete waste of time and resources, a pathology, a nonsensical fashionable crap which doesn't deserve to be associated with physics of natural sciences in general.

   Science is based on empiricism, if something cannot make a connection to experiment even in principle it is not science, it is theology.

   And I don't mind people studying theology but I do mind theology masquerading as physics especially if it's consuming funds which society devoted to physics.

3. **Verified Armonyous**
   May 3, 2010

   Mantis, although I share your point of view regarding landscapism, I was not aware that string theory has failed.

   Perhaps one could say that string theorists have failed so far in delivering what they had promised. In spite of that, I think string theory is too good not to have anything to do with physical reality and it's just a matter of time that this will be proven to be the case.

   Then one can debate about how much manpower should be devoted to this enterprise
   and other sociological issues but the shear revolutionary potential of string theory is beyond doubt.

4. **Peter Woit**
   May 3, 2010

   VA,

   It's not "string theory" that has failed (that term now applies to so much that it is becoming meaningless). What has failed is the speculative idea of starting with string theory in the critical dimension (10) then finding a consistent "string vacuum" that keeps 4 dimensions large and somehow deals with the other six. 25 years of work on this have provided strong evidence that this can't provide a predictive framework (leading to the multiverse nonsense as a desperate way out). Going to M-theory just makes things worse by providing even less predictivity.

   Anyone who wants to claim that this speculative idea has not failed needs to provide a plausible scenario in which it can be salvaged and turned into a success. I think the only way this can be done is through arguments of the sort "the general idea of string theory is so wonderful that there must be some unknown new insight into it which will come along and save the situation." These are more wishful thinking than science.

5. **Austin**
   May 3, 2010

   Peter Woit said,

   "Anyone who wants to claim that this speculative idea has not failed needs to provide a plausible scenario in which it can be salvaged and turned into a success."

   Correct me if I am missing something, but I see no problem with the following scenario: like any other physical theory, you use observation to constrain the free parameters of the theory, then you can make predictions. Technically difficult, but plausible I think.

6. **Peter Woit**
   May 3, 2010

   Austin,

You need to explain why no one has done this so far, and provide a plausible scenario for how this is going to change in the future.

The state of the art is that in various "string vacua" you can calculate very crude things like number of generations, but find that you can get any number you want. And you don't even know if you want 3 or 4 (maybe there's a fourth higher mass generation??).

For some more detailed numbers, like fermion masses, as far as I've ever been able to tell, the state of the art is that you can't compute these reliably and accurately (say, to better than 1 %). There also seems to be no reason to even try, since the evidence is that even if you could do this for any specific string vacuum, among the 10^500 possibilities you could get whatever number you wanted.

In other cases (vacuum energy), people working in this area have explicitly given up. Generically computations give something wrong by absurdly large numbers of orders of magnitude, leaving the only way out the one Gross describes by "Oy vey!".

7. **Austin**
   May 3, 2010

   I don't know why no one has done this, but it's a plausible scenario, I think.

   "…among the 10^500 possibilities you could get whatever number you wanted."

   Yes, but most or all of those 10^500 are at odds with observation. Thereby observation can cut the 10^500 possibilities down to fewer (perhaps zero).

   Regarding vacuum energy: I thought (admittedly I'm not familiar with this technically) that various string vacua allowed different values of the vacuum energy, (just like fermion mass and number of generations) some of which are negative, some of which are positive but too large ("by absurdly large numbers of orders of magnitude"), and some of which may be in the experimentally allowed range.

   Still it's just a plausibility argument, I assume that actually making this work technically would be beyond difficult.

8. **Fabien Besnard**
   May 3, 2010

   Mantis said : "Multiverse ideas are a complete waste of time and resources, a pathology, a nonsensical fashionable crap which doesn't deserve to be associated with physics of natural sciences in general."

   This is a rather dogmatic point of view. MWI interpretation of QM is in some sense "saner" than wave function collapse. More generally, science is full of entities that can't be observed but are theoretically useful, so one must keep an open mind.

   As I see things, the problem is more with anthropic explanation than with multiverse theories. Saying that something is anthropically explained amounts to saying that it happened merely by luck, so it is equivalent to say that there are no reason for it. It is fine if there really is no reason, but this means we gave up explaining that thing, it does not mean that we explained it.

   So adopting a multiverse theory for the sake of anthropic reasoning is not a good deal. But if you have other, compelling reasons, to adopt a multiverse theory, and that theory says something (like the cosmological constant) is environmental, then it is ok for me.

9. **Peter Woit**
   May 3, 2010

   Austin,

   You should think carefully about the significance of numbers like 10^500. Say you are wildly successful, and you manage to calculate the 20 or so parameters of the standard model each to 1 % accuracy. You'd expect each such achievement to cut out 99% of the possible vacua. Doing all 20 calculations successfully and imposing the results, you expect to have 10^460 viable possibilities left.

   There are very good reasons most particle theorists have given up on this, whether or not they're willing to use the word "failure" to describe the situation.

10. **Peter Woit**
    May 3, 2010

    Fabien,

    The kind of cosmological multiverse motivated by the string theory landscape that Guth is promoting and Gross is "Oy vey"ing about is something different than the multiverse of the MWI interpretation. They're two quite different things.

11. **Austin**
    May 3, 2010

    Peter Woit said,

    "Say you are wildly successful, and you manage to calculate the 20 or so parameters of the standard model each to 1 % accuracy. You'd expect each such achievement to cut out 99% of the possible vacua."

    I don't follow this reasong. "1% accuracy" is not the same as "1% of all possibly allowed values" and therefore is not the same as cutting out 99% of them.

    I'll try a simple counterexample to clarify what I'm saying. Take some free parameter of the standard model, say unit charge e, that theoretically can have any real positive value. Measuring the value of e even to 50% uncertainty eliminates a fraction of the previously allowed values that is arbitrarily close to 100%. See what I mean?

    10^500 is a huge number, but (as far as I know) before observational constraints, the standard model allows uncountably infinite possible values for its free parameters. In light of this, calling 10^500 big is a bit like a black hole calling the kettle black, isn't it? At least 10^500 is finite.

12. **Peter Woit**
    May 3, 2010

    Austin,

    One can make pointless arguments about things like finiteness of the number of string theory vacua all day, but the bottom line is that the LHC is starting up and despite more than a quarter century of intense effort by thousands of smart people, string theory has led to no predictions at all about what it will see. If you actually spend time understanding string vacuum constructions and how they work (or don't), the reasons for this become apparent. If you want to claim that this situation is not a failure, you need to come up a plausible explanation for why things have not worked out so far, but will work out in the forseeable future.

13. **Fabien Besnard**
May 4, 2010

Peter said :
"The kind of cosmological multiverse motivated by the string theory landscape that Guth is promoting and Gross is "Oy vey"ing about is something different than the multiverse of the MWI interpretation. They're two quite different things."

I know, but Mantis was saying that any multiverse theory was junk, on the ground that other universes are unobservable. I replied because it's a rather common point of view, which I think is completely misguided.

14. **Verified Armonyous**
May 4, 2010

Peter said :
"Anyone who wants to claim that this speculative idea has not failed needs to provide a plausible scenario in which it can be salvaged and turned into a success."

I'm not a string theorist myself and there are people better qualified than me to defend string theory. But as far as I know string theory is by far the only serious game in town when it comes to quantizing gravity, which is a notoriously difficult and non trivial task.

It also seems clear that much much more work will be needed to make definitive progress in proving that this theory has something to do with the real world.

At this point, what do you propose to do? To abandon the most serious candidate we have to solve this problem, simply because you're not patient to wait longer? I don't think your position on this is very serious. Some dose of criticism on the string community might even be healthy but you shouldn't throw the baby out with the bath water.

15. **Bill K**
May 4, 2010

At this point, what do you propose to do? To abandon the most serious candidate we have to solve this problem, simply because you're not patient to wait longer? I don't think your position on this is very serious. Some dose of criticism on the string community might even be healthy but you shouldn't throw the baby out with the bath water.

String theory has been looking for a baby for 25 years, but it is all bath water.

Neither "abandon" or "wait" has anything to do with the way research is conducted. When a theory runs into a dead end, as string theory has, you don't abandon it, but you do put it aside temporarily. And you don't wait, you just try to find something that's more productive.

Witten has been quoted as saying that string theory was ahead of its time, and maybe that's the problem. Maybe we just need to take things in the proper order, and after understanding what comes after the Standard Model we'll be better able to appreciate what, if anything, string theory is good for.

16. **Pawl**
May 4, 2010

VA,

At the risk of repeating old arguments (but yours are old too):

(a) "String theory is by far the only serious game in town when it comes to quantizing gravity" is inaccurate.

(b) The sense in which string theory was a hopeful approach to quantizing gravity was that it seemed to be an approach along the lines that quantum field theorists were familiar with which looked like it might tackle the problems which seemed most bothersome to quantum field theorists. It was far less convincing to relativists even in its heyday — something which is only fair to take into account in assessing its strengths.

(c) If we're going to make progress on quantum gravity we need to have a hard-headed assessment of when to give up on poor approaches. At some point the argument that one approach is "the best thing going" becomes a weaker one than the judgment that that approach seems to have little going for it and quite a lot against it: it becomes an error not to cut one's losses and reconsider the question and the entire approach.

(d) We are likely to make little progress on quantum gravity until the right breakthrough occurs. It is very hard to figure out what sort of steps the field as a whole could take to try to hasten this. But the first thing would be to set a standard of examining carefully and fairly the strengths and weaknesses of different ideas.

17. **Verified Armonyous**
May 5, 2010

Bill K, make up your mind. Either string theory is bath water or ahead of its time. Let me trust Ed on this one.

"Neither "abandon" or "wait" has anything to do with the way research is conducted."

Exactly. And when you stumble on a theory ahead of its time you don't wait to be ready to deal with it. You jump on it and devote all your effort to understand it. Taking things in its proper order is for bureaucrats, not for curious scientists eager to find the right theory behind Nature.

Pawl, it's fine for arguments to be old as long as they are right. Your (a) is not even an argument but simply an statement. Without further qualifications it's useless.

(b) hahaha

(c & d) The breakthrough will come from more work, not from your clear definition of when to give up or how to precisely weight the worth of different ideas.

18. **jpd**
May 5, 2010

a)
arxiv search for "quantum gravity" AND NOT "string"

returns:
Your query resulted in too many hits, only 1000 hits are being displayed. These are not necessarily the 1000 most recent papers. We recommend that you try a more specific search.

b) “hahaha” isn’t even a statement

19. **Verified Armonyous**
May 5, 2010

jpd

a) Oh, you convinced me! Now it’s clear to me that there are much better ideas out there on how to consistently quantize gravity. Just with one click! I’ll use your insightful method in the future!

b) Sure it is.

20. **Peter Woit**
May 5, 2010

VA,

Excellent job of driving the intelligence level of a discussion down to zero. Enough.

String Vacuum Project 2010

May 3, 2010
Categories: Multiverse Mania

I've written before about the String Vacuum Project (back in 2006 and 2008), and there was a story about it in Nature. This week they are having an SVP 2010 Spring Meeting at the KITP, talks available here.

A proposal to the NSF for funding of the String Vacuum Project was first made five years or so ago, but I had heard that this and later versions hadn't been successful. In recent years perhaps the main proponent of the project has been Keith Dienes of the University of Arizona, who organized its last meeting in Tucson two years ago. Dienes started work as a program manager at NSF last fall. Maybe it's just a coincidence, but the SVP now has funding through an NSF grant for $150K this year, with the grant paying for bi-annual meetings (of which I guess the KITP one is the first). While "the PIs are proposing a String Vacuum Project (SVP) network with eight geographic nodes", the grant sponsor is the University of Arizona, where the co-PI for the grant is Shufang Su, a phenomenologist who doesn't seem to have any history of working on string vacua.

Well, at least stimulus funding is helping get the SVP off the ground…

Update: After looking through some of the workshop talks, it's very unclear to me what the "String Vacuum Project" actually is. At this point it appears to just be a mechanism for getting the NSF to fund three graduate students working on string phenomenology. From the talk by Michael Douglas you learn that it's very unclear what a string vacuum even is. It appears to involve an intractable large unknown space (including e.g. "all six manifolds"), with an unknown effective potential on it, with disagreements among practicioners about whether the effective potential is a sensible thing to look at.

Not surprisingly, the discussion session about what the project should be doing was a sad thing to watch. One of the main topics was the SVP Wiki, which people hope to improve. Maybe it's been moved somewhere else, but the only address I know for it (here) has been down for quite a while.

Update: More discussion showing the current level of understanding (nil) of string vacua here.

Update: There is now a new String Vacuum Project web-site.

Comments

1. **Coin**
   May 3, 2010

   From a physics outsider's perspective the SVP certainly *sounds* like the kind of thing the string theory community ought to be encouraged in. If the landscape is unavoidable then we ought to at least make some sort of effort to determine what it looks like?

   The thing that interests me about the SVP is the attempt to do that census or sampling of string vacua. The NSF grant says they will be funding students to work on that? I'm not sure I can see much sign of that particular effort in the SVP talk descriptions but I don't think I'd know what to look for. I wonder, are they still planning on making that online database of vacua they've analyzed?

2. **Peter Woit**
   May 3, 2010

   Coin,

   The problem is that there has already been a great deal of effort put into looking at string vacua, with discouraging results. Most string theorists acknowledge this, and don't work on this sort of thing.

   When the SVP started many years ago, part of the plan was to try and gather enough data to make statistical predictions of some sort. The initial hope was that you could at least tell whether supersymmetry breaking was likely to be at high or low energy scale. That failed and people seem to no longer believe statistical predictions are possible, so I don't see what you would do with an accumulated database of string vacua. It's rather unclear to me what the specific plan of the SVP project is now, it will be interesting to see what comes of their discussions at the KITP this week.

3. **Dave**
   May 4, 2010

   Indeed surely a coincidence, since NSF program officers abide very strictly by conflict of interest regulations.

4. **Fabio**
   May 4, 2010

   I've just completed the CPP (Cubic Polynomial Project). I've enumerated every cubic polynomial with complex coefficients, and have created an online database of results which is integrated into Wolfram Alpha. Just go there and type in a polynomial, it will show you the results of my analysis. Now I am applying for NSF funding to do the same for quartic polynomials.

First Results From XENON100

May 4, 2010
Categories: Experimental HEP News

The XENON100 dark matter experiment now has a paper out reporting their first results, from a test run of 11 days. They claim a 90% confidence level exclusion of 50 GeV WIMPs with a spin-independent elastic cross-section above 3 x 10^{-44} cm^2, which one can compare with the recent CDMS limit of 3.8 x 10^{-44} cm^2 at similar mass (70 GeV). At the time of the CDMS result many seemed to believe that the two events seen were not background (see here), with Gordon Kane claiming “it is likely it is dark matter.” The New York Times has an article today, with Kane now commenting on XENON100 “if they see a signal, it will be unambiguous”, by which I presume he means that their full data will conclusively show whether the CDMS events could have been a signal. Given that they are seeing nothing at all now, at 10 times greater sensitivity later, they may very well see an ambiguous signal…

The XENON100 result also appears to rule out claims from the DAMA and CoGeNT experiments to have seen some sort of signal. For more on this, as always in dark matter issues, Resonaances has the best coverage of the story.

Update: Physics World reports on objections to the XENON100 claims from a CoGeNT physicist and others, see this arXiv preprint.

   May 4, 2010

   “It’s the strongest statement about dark matter today and it reads: we have looked here and there and over there but didn’t find nothing,” Rafael Lang of Columbia University, wrote…

   I guess Columbia doesn’t teach remedial English.

2. **Anonymouse**
   May 5, 2010

   Ics:

   Rafael Lang is a postdoctoral researcher. Columbia didn’t teach him anything, in that he never took a course there. He works there.

   Oh, and he is German. Sorry that some people have less than perfect English… for it being at least his second language, I would say he does reasonably well…

3. **John Baez**
   May 7, 2010

   Suppose XENON doesn’t see WIMPs even when it reaches the maximum sensitivity that people have planned for it. What would this tell us? What kinds of WIMPs would be ruled out as a plausible explanation of the amount of cold dark matter that we seem to see? And roughly when would this happen?

4. **Bill K**
   May 7, 2010

   By definition, a WIMP interacts with nucleons via the weak nuclear force, implying an elastic cross section of the order of 10^-44 cm2. So already an order of magnitude improvement in the experimental limit would start to make things uncomfortable.

   On the other hand, there’s so much uncertainty surrounding the properties of dark matter, and so much interest, that a sequence of much larger experiments beyond XENON100 (LUX 300 kg, XENON1T 1 ton, LZS 1.5 tons, LZD 20 tons) have been studied/ planned/proposed. So my guess is the search for WIMPs will go on for another 5 years at least.

5. **Anonymouse**
   May 9, 2010

   WIMPs may have originally meant “weak nuclear”, but that is a strong version of the definition compared to the way the term is used today. Call it more “roughly weak nuclear” or even “sub-weak nuclear” more accurately.

   Xenon100 will start to become sensitive to backgrounds at roughly one year of running. So end of this year, expect their big jump in improvement. It will take a bite out of, say, MSSM parameter space, but not one that will make SUSY practitioners uncomfortable.

6. **Bill K**
   May 10, 2010

   Anonymouse, my understanding is that the observed abundance of dark matter particles as thermal relics of the Big Bang implies that their self-annihilation is of the order of the weak nuclear force. And hence they are usually considered to be WIMPs in the strict sense (the so-called ‘WIMP Miracle’) This conclusion holds regardless of whether they arise from supersymmetry or something else.

7. **Anonymouse**
   May 10, 2010

   Bill K,

   We sell the WIMP miracle as a pretty picture, but it is far from encompassing the spectrum of possibilities for dark matter or WIMPs. That said, I think it is likely to turn out the WIMP miracle does explain the relic abundance of dark matter.

   However, when one gets precise, the thermal abundance actually requires “sub-Weak strength” interactions. Literally weak stength leads to a cross section which is too large, causing the WIMPs to stay in equilibrium longer, and they are depleted in the Universe by too much (e.g. there is too little dark matter to match observations). So in fact if we take the WIMP miracle seriously, defining WIMP to be “weakly interacting” in the strict sense is in fact excluded by measurements from WMAP and other experiments.

It’s true that none of this requires supersymmetry, but my hope is that my answer above provides context which is useful to someone like John Baez, who asked what Xenon100 can do and on what kind of time scale

LHC Update: Bing Bang Machine Could Confirm or Disprove String Theory

May 5, 2010
Categories: Experimental HEP News, This Week's Hype

Today's CERN LHCC meeting had a wide-range of reports about how the machine is doing (1 nb^{-1} now, 10 nb^{-1} over the next 5 weeks), what the experiments are seeing (charm, Ws), and what physics might be possible with the 2010-11 run (limits on some supersymmetric and other more exotic scenarios).

Reuters this evening reports on the meeting, headlined with the typical delusional nonsense about string theory and the LHC which we're in for several years of {"Could confirm or disprove string theory").

Update: This story has made it to various media outlets, including one that has it as Collider on Track With Bing Bang Research. Title of posting edited appropriately.

Comments

1. **Interested (I guess I'll keep that moniker)**
   May 6, 2010

   Can you clarify something?

   The link you provided quotes an LHC director stating they may find "large extra dimensions, string balls and heavy slow-charged particles".

   Do string theories have as precise definitions of those things listed as the particles the Standard Model predicted? My impression is that if the definitions are loose or even if they just come up with another thousand guesses they will eventually 'find' something.

2. **Peter Woit**
   May 6, 2010

   Interested,

   String theory doesn't predict anything about what the LHC will see, but it is consistent with all sorts of things in an infinitely long list of exotic non-standard model possibilities. That's what is being referred to here.

3. **unreuters**
   May 6, 2010

   At least Reuters reports on the thing at all.
   Let's not complain about *everything*.
   It's overall a good article, there's no need to quibble about a few extra dimensions here and there.
   For example:

   "The CERN collisions, some 200 million since March 30, in the 27 km (16.8 mile) LHC tunnel are recreating on a miniature scale what happened within nano-seconds of the Big Bang 13.7 billion years ago that created the galaxies, stars — and life."

   This is not bad at all. Quite good, some might even say. Why not? And this —

   "Six ultra-sophisticated detectors around the LHC record how the particles behave after being smashed together, transmitting the data for analysis to laboratories at CERN and in other research centres around the globe.

   Already the machine has identified many elements included in the so-called Standard Model that physicists created during the 20th century for how they believed the cosmos should and does work, said CERN scientist Andrei Golutvin.

   ……..

   "To me, it is a miracle that the LHC is detecting the particles we expected from the Standard Model so early in this experiment. It shows just how well the LHC is functioning," said Golutvin, spokesman for the LHCb."
   .

   Really that is all quite good.

   Once upon a time, in a land not so far away, the Daresbury lab invited reporters on a tour, showing them their sychrotron and their van-de-Graaf generator (which was the world's tallest). An article subsequently appeared on the "world's tallest synchrotron." Eh …

   As for the LHC and the Big Bang, it was not so different for the SSC and the Big Bang. Indeed, I once was asked by some high school students in (near) Chicago, "We are confused about the reports on the SSC. It says the SSC will reach temperatures not seen since the Big Bang." So I replied "Yes." "But," said the students, "the SSC is a *superconducting* machine. It operates at *cryogenic* temperatures close to absolute zero. How can it possibly reach the temperatures of the Big Bang?"

   Oy double vey … ?

   I said the first thing which popped into my head, which was "Why me?"

4. **Peter Woit**
   May 6, 2010

   Unreuters,

   Typically, as with this one, the article itself isn't bad, but it's sitting under a headline of ludicrous hype about string theory. Most people read the headline, don't read the article.

5. **unreuters**

May 6, 2010

That is true of very many things besides string theory. Reuters is a business, and it has to sell, and the headline has to attract attention, and Reuters is not alone in this. There are many misrepresentations of things much worse than string theory, typically political subjects … but I drop the subject here.

6. **Robert**
May 6, 2010

   Typically the headlines are not even formulated by the same people as the article.

7. **Paul**
May 7, 2010

   "The CERN collisions, some 200 million since March 30, in the 27 km (16.8 mile) LHC tunnel are recreating on a miniature scale what happened within nano-seconds of the Big Bang 13.7 billion years ago that created the galaxies, stars — and life."

   This is not ok, the claims that LHC is a "Big Bang machine," or studying Big Bang are pure BS. There is no scientific reason to link it to the hypothetical Big Bang, the collisions recreated are ubiquitous in the Universe and the results won't tell us anything about the Big Bang itself.

   The conditions nanoseconds after the hypothetical Big Bang were completely different as the Universe was squeezed to an incredibly tiny fraction of it's current size and we have no idea how dark matter, dark energy, visible matter or other as yet undiscovered mass and energy types behave in such conditions. And invoking hypothetical inflation breaks the link to Big Bang even further.

   The link to Big Bang is nothing but a publicity stunt, the LHC is not studying Big Bang and won't tell us anything new about it, claiming that it will is ensuring that the public will see it as a failure.

8. **kumar**
May 7, 2010

   An answer would be very welcome for the long awaiting physics community. But the real question, if LHC results are against string theory, whether will it be sufficient enough to convince the string theorists?

9. **a quantum diaries surivivor**
May 7, 2010

   Stop it, people. We insist with our century-old mistake – we give the same old image of a snotty-nosed set to whomever cares to read our mutterings. Let us instead start trying to offer the media with images that are as sensationalistic as they need them, but correct.

   Much harder than criticizing, ain't it ?

   Cheers,
T.

10. **Joao Leao**
May 7, 2010

    BING Bang? Is this in homage to Bing Crosby or did Microsoft buy the naming rights to the Big Bang? (With editors like this who needs copywriters?)

11. **John Baez**
May 7, 2010

    Yes, it's "Bing Bang".

    Sing along with me: Uh Eeh Uh Ah Ah Ting Tang Walla Walla Bing Bang!

12. **Yatima**
May 7, 2010

    Next: Rappers rapping about the "Bling Bang". Ok, this is silly. Back to work.

13. **thomas**
May 7, 2010

    unreuters: awwww that hyschool studence story is so cute ^____^

14. **Claver**
May 7, 2010

    Might it not be a 'bling-ing' bang? It wouldn't just 'bling' would it? Or, maybe a 'blings' bang?

15. **Chris Oakley**
May 9, 2010

    BLING, from the Urban Dictionary:

    > As of 2007, commonly used to designate expensive new compact electronic accessories. Best examples are: 1) small, feature-packed cell phones. 2) small, high-megapixel digital cameras with huge RAM and bright LCD displays. 3) High-end MP3/video players. 4) Particle accelerators.

16. **Eric Baird**
May 14, 2010

    So if the LHC is now "Bling", where do we attach the big gold chain?

Applying String Theory to Quantum Information Theory

May 10, 2010
Categories: This Week's Hype

There's a remarkable article by Mike Duff in this month's CERN Courier, arguing the case that string theory does too have important applications: in Quantum Information Theory. The claim seems to be that since the same algebraic structures appear in black-hole entropy calculations in string theory and in the analysis of certain cases of the entanglement of qubits, this provides an application of string theory to Quantum Information theory. There's some remarkably obscure algebra involved, from exceptional structures such as E7, the octonions and the Fano plane to Cayley's nineteenth century work on hyperdeterminants. Besides the very complicated mathematics and physics, what I don't understand about this is the claim that if the same classical algebraic structure gets used to do a calculation in string theory and in subject A, it means that string theory is being applied to subject A.

While the mathematical physics story Duff tells may be of some interest (to learn more about it, there are review articles here and here), unfortunately he can't resist the temptation to shanghai it into service in the string wars. He gives a less-than-honest description of the problem with string theory:

> The partial nature of our understanding of string/M-theory has so far prevented any kind of smoking-gun experimental test.

The problem with string/M-theory is not that it is missing a "smoking-gun experimental test", it is that it is missing any kind of experimental test whatsoever, which is rather different. He defends the failure of string theorists to come up with any experimental test after more than 25 years of work by thousands of physicists writing tens of thousands of papers with a comparison of the situation to that of the time lag between the 1935 Einstein-Podolsky-Rosen paper and J.S. Bell's work 29 years later. One obvious difference is that, before Bell, hardly anyone tried to come up with such a proposal, unlike the case of string theory, where the issue has been the central one in the field since 1984.

Under the heading "Further Reading", one is referred to Duff's 2007 debate with Smolin, which I posted about here, based on second-hand reports from those in attendance. Until now I don't think I'd seen the transcript of the debate, which is available here. I notice that Duff sums up his argument as follows:

> The trouble with physics ladies and gentleman is that Lee Smolin and Peter Woit having lost their case in the court of science, are now trying desperately to win it in the court of public opinion. Thank you.

It seems to me that Duff, having lost his case in the court of his physicist peers, where string theory unification is widely seen as a failure and young string theorists are just about unemployable, is now trying desperately to win it with tendentious argumentation in the court of popular opinion (well, at least in the pages of the CERN Courier…).

Update: Lubos seems to mostly agree with me about this:

> So the role of the qubits, or the arguments of the hyperdeterminants, are "physically" completely different.
> …
>
> A superficial similarity of one aspect is very far from a full-fledged mathematical equivalence.

Update: John Baez's latest TWF has an explanation of some of the mathematics involved here.

Comments

1. **bohm (not)**
   May 10, 2010

   EPR and Bell – actually I think it was David Bohm – remember him? -who (re)formulated the EPR paradox in terms of spins, which were easier to visualize. This was done approx 1952(?)
   http://www.ge.infn.it/~zanghi/DJB.pdf

   EPR formulated their gedanken experiment using positions and velocities, but all(?) the expts use spins. Much simpler.

   EPR 1935, Bohm c. 1952, Bell 1964, Aspect 1982, GHZ 1989
   Progress takes place approx every 10-15 years (on average?).

2. **sf**
   May 10, 2010

   If these really are "important applications" then you'd think that us quantum information theorists would have heard about them…

   Maybe we're just incapable of understanding them.

3. **kevinfp**
   May 11, 2010

   It just happens that you and Lubos agree with each other. Does it mean that the two of you are necessarily right?

4. **Trent**
   May 11, 2010

   Peter,

   You continue to be the funniest person ever 🙂

   You write,

   "It seems to me that Duff, having lost his case in the court of his physicist peers"

   What exactly makes you say that?

   "where string theory unification is widely seen as a failure"

Any data to back that claim up? And even if true, let's suppose string theory unification doesn't work, how does that make string theory as a whole a failure? If there were 1000000000000 other true applications of string theory in other subjects, would you still claim that string theory is a failure just because it didn't fulfill it's original goals?

"and young string theorists are just about unemployable"

And you conclude what from that? 10 years ago string people were very much employable while hard phenomenologists were "just about unemployable". Same goes for loop quantum gravity (and not just in the last 10 years but they are pretty much unemployable even today). Would you have said that this is a signal that phenomenology or loop quantum gravity is a failure? Aren't you taking a superficial metric heavily influenced by fashions and trends (employability) and judge a whole field based on it if it suits your objectives (as in string theory) and do not do the same thing when it doesn't (as in phenomenology and loop quantum gravity)?

"…. now trying desperately to win it with tendentious argumentation in the court of popular opinion"

Are you really comparing yourself to Duff? Please check the archive how many scientific arguments does Duff make and how many do you make. Then do another piece of homework and check how many blog posts and other activity that is designed to effect public opinion does Duff make and how many do you make. See, this is one of the reasons I find you very funny 🙂

Cheers,
Trent

5. **Peter Woit**
May 11, 2010

Trent,

I didn't write that "string theory is a failure", specifically because "string theory" now refers to very many quite different things, some of which have had successes. However, the idea of using string theory in higher dimensions to get a unified theory has failed, and most physicists are aware of this. If physics departments thought that string unification was still a promising research program, they would still be actively trying to hire young people in the subject.

Duff knows the subject is in trouble, but instead of acknowledging failure and moving on, he's trying to evade the consequences of this failure with over-hyped and misleading claims. If he can't even get Lubos to defend them, you know he's gone way too far…

6. **pwlub**
May 11, 2010

"It just happens that you and Lubos agree with each other. Does it mean that the two of you are necessarily right?"

To borrow from George Carlin –
If PW and Lubos agree with each other in the middle of a forest and there is no woman around to hear them, are they both still (not even) wrong?

7. **Peter Woit**
May 11, 2010

kevinfp and pwlub,

Lubos isn't exactly a reliable source, but if he won't defend a certain piece of string theory hype, you're going to have trouble finding anyone who will.

Similarly, if he ever starts acknowledging global warming, I suggest you immediately head for higher ground…

8. **John Baez**
May 11, 2010

Personally I think it's almost a waste of time worrying about whether this counts as an "application of string theory". String theory is obviously in deep trouble when it comes to making any sort of contact with experiment, and at this point I've decided to take pity on that severely wounded horse and stop beating it. There's a lot of cool math in string theory, and there's a lot of cool math in Duff's work regardless of whether one considers it "string theory".

While Peter may consider it "remarkably obscure algebra", the 56-dimensional representation of E7 is a beautiful thing. I've discussed it [here](). I explained how it's related to a certain 57-dimensional manifold, the lowest-dimensional manifold on which E8 acts nontrivially. I also explained how it's built up from two copies of the exceptional Jordan algebra and two copies of the real numbers (56 = 27 + 27 + 1 + 1). It's called the "Freudenthal algebra" and it's been studied quite a lot. It's great to see new things being done with it – there's a nice introduction by [Bianca Cerchiai and Bert van Geemen](). To my mind, when it comes to beautiful structures like these, arguing about their possible "applications to physics" is far less enjoyable than actually learning about them.

9. **Trent**
May 11, 2010

Peter,

You continue beating your favorite dead horse. So I ask again, more sharply this time, so that you will perhaps not avoid responding:

Who cares if string theory does not work as a unified theory of the 4 forces?

Let's assume string theory has 1000000000000 fruitful applications outside of its original goal (unification), but does not work for its original goal (unification). Who cares?

If I set up a theory to prove the Poincare conjecture (never mind about Perelman for a second) but eventually end up proving the Riemann conjecture with it, do you think mathematicians will go around writing blogs about me being a sucker and all my efforts were in vain because I could not prove the Poincare conjecture using my methods, which was my original goal?

So, is this clear what I'm trying to say? If not, I'll clarify, but it seems to me you understand me perfectly well, you just don't want to answer or reply or comment on this very point because it's inconvenient for you.

"If physics departments thought that string unification was still a promising research program, they would still be actively trying to hire young people in the subject."

Again, what's your point? You argue by authority and majority but science is neither based on authority nor is democratic. By the same argument you would have concluded 5 years ago that string theory is the best thing in town. Or by using the same argument you would have concluded in year X that the best research program in that year is the one which gets the most hires. How sensible is that?

On another issue in my post you did not respond either. You countered the claim that you are courting public opinion instead of doing research by saying that Duff is doing exactly this. I gave you and your readers 2 homework assignments: (1) check the amount of noise you and Duff did in the past 3 years that can be considered "courting public opinion", call these N_W and N_D (2) check the amount of research results you and Duff had in the past 3 years, call these R_W and R_D. I'm pretty sure everybody will find

N_W >> N_D
R_W >> R_D

In other words, the situation of Duff and you is completely different, can not be compared.

10. **Trent**
May 11, 2010

I've just seen John Baez's reply and I fully agree.

The point is, who cares if string theory does not work as unification or does not make contact with experiment? It does lots of other great things, things for which it was not invented. Is that a bad thing?

11. **Trent**
May 11, 2010

Ooooops, my inequalities got mixed up.
Correctly, they are:

N_W >> N_D
R_W < < R_D

Cheers,
Trent

12. **Peter Woit**
May 11, 2010

John,

There's no necessary contradiction between your claim that this sort of algebra is beautiful and mine that it is "remarkably obscure".

Trent,

Once string theorists give up writing popular articles designed to mislead people about what string theory is and what it isn't, I'll stop pointing this out. The unwillingness of influential string theorists to own up to what has happened is a continuing source of damage to the subject.

The reason I pointed out that string theorist's colleagues have decided to stop hiring them is that you asked for evidence that physicists believe string theory to be a failure. That the latest fad is now dark matter phenomenology is not necessarily a reason to believe it will be any more fruitful than string theory. The sort of thing I personally have the most hope for, "formal" QFT research, is far more unpopular than either string theory or phenomenology.

String theory does do some interesting things, and I'm in favor of people investigating them and writing intellectually honest articles about them. In the case of what Duff is writing about, I don't actually see string theory doing anything, just a lot of hype on his part.

Duff's summation against Smolin and myself was not that we're not doing research, but that, within the physics community, the arguments for doing string theory had won out over those against the subject. That may have been true before the past half dozen years or so, but now the shoe is on the other foot. Instead of making an honest technical argument for string theory research that could convince his now-skeptical colleagues, Duff has decided to write a misleading semi-popular article, exactly the sort of behavior he wanted to accuse Smolin and me of.

13. **CWJ**
May 11, 2010

Trent writes,

"If I set up a theory to prove the Poincare conjecture (never mind about Perelman for a second) but eventually end up proving the Riemann conjecture with it, do you think mathematicians will go around writing blogs about me being a sucker and all my efforts were in vain because I could not prove the Poincare conjecture using my methods, which was my original goal?"

But that's a sloppy analogy. Suppose, having successfully proved the Riemann conjecture, you then went around saying, 'This suggests that the Poincare conjecture is true, too.' That's what string theorists often imply–that the success of their methodology in another area means that string theory–as applied to particle physics–is correct. And they have totally failed to establish the latter.

It's perfectly fine that the math invented from string theory is applied to other areas. That's great. But that establishes *nothing* about the hypothesis that strings are the fundamental constituents of matter.

14. **Peter Woit**
May 11, 2010

cwj,

I agree, but it's also important to note that what Duff is talking about is NOT math discovered by string theorists. There are a few examples where you can make the case that string theory research has uncovered important new ideas in mathematics. This isn't one of them.

The contrast between this reality and the string theory partisan argument "first assume string theorists prove the Riemann hypothesis" is rather striking.

15. **Roger Schlafly**
May 11, 2010

Trent, there is no need to clarify. Your argument consists of absurd hypotheticals and ad hominem attacks. If string theory had some merit that you wanted to promote, then you would address those merits.

16. **Coin**
May 11, 2010

“Suppose, having successfully proved the Riemann conjecture, you then went around saying, ‘This suggests that the Poincare conjecture is true, too.”

And this Duff article is clearly suggesting this. I mean, look at it. After four paragraphs about QIT he suddenly jumps in with “Strings, branes and M-theory: If current ideas are correct, a unified theory of all physical phenomena will require some radical ingredients in addition to supersymmetry”. He is clearly here not arguing string theory is an interesting mathematical tool potentially leading to technical advances in various areas. He is talking about M-theory as a physical model of the universe: string theory the hypothesis, not string theory the mathematical toolset. The following [dense] section where he lays out the mathematical similarities between QIT and string theory is specifically named “Falsifiable predictions?” and says “Nevertheless it cannot be denied that such a prediction in string theory would be welcome” before launching into his math dump. It seems like a not mathematically inclined person (or even someone mathematically inclined but not able to follow his argument– which honestly I can’t, I understand the article up to the “falsifiable predictions?” header fine and then everything that follows flies completely over my head) would look at that section introduction, see a bunch of dense mathematics and walk away assuming that he had just presented an argument that the string theory hypothesis falsifiably predicts [something to do with 3-bit entanglement]. Actually, I’m not totally certain he _isn’t_ trying to argue this. (He does back off to “so the esoteric mathematics of string and M-theory might yet find practical applications” at the end of the section, but if that’s the goal then why the big header talking about falsifiable predictions of M-theory?)

Overall I guess it seems weird to complain about Peter attacking the “dead horse” of string theory unification but not seem so worried about theoretically more-significant publications such as the CERN Courier publishing articles supporting that same “dead horse”.

17. **Kea**
May 11, 2010

Perhaps instead of bickering like stupid little boys, you could all spend some time reading, for instance, the papers of Levay, who is mentioned in Duff’s article. Sure, Duff is deluded about strings, but he has done some cool stuff here and if it turns out that the QI is in fact at the foundations of QG, then it will be relevant. And won’t you want to know something about it?

18. **John Baez**
May 11, 2010

Peter wrote:

> John,
>
> There’s no necessary contradiction between your claim that this sort of algebra is beautiful and mine that it is “remarkably obscure”.

True. I was trying to say, not only that it’s beautiful, but that it’s not “remarkably obscure”.

There’s a tiny smidgen of algebra that’s extremely well-known: the stuff people are forced to learn in math grad school, and the stuff theoretical physicists use all the time.

Then there’s a bunch of algebra that’s a bit less well-known, but still actually quite famous to people who care about algebra: stuff like E7, the octonions, the Fano plane, and Cayley’s hyperdeterminants. (I don’t know what Cayley’s hyperdeterminants are, but I keep running into people talking about them, so I don’t call them “extraordinarily obscure”: I just say I haven’t learned about them yet! The mere fact that they were discovered by a famous dude like Cayley means they aren’t all that obscure.)

Then there’s a vast amount of algebra, about 100 times as much, which has been worked out by mathematicians we’ve never heard of, and can be found in papers that sit largely unread in math journals. *That’s* the really obscure stuff: the kind of thing where merely citing an example would instantly multiply by 1000 the number of people who’d ever heard of that thing. Okay, I’ll give an example: 3-PAPLs. I’d call those fairly obscure.

Anyway, none of this is very important. I just wanted to say: you’ve got enough justifiable complaints against Duff without labelling his algebra “extraordinarily obscure”. In fact he’s studying quite famous algebraic structures, and apparently doing cool stuff with them.

19. **PhilG**
May 12, 2010

All Duff says is “While string theory and M-theory have yet to make readily testable predictions in high-energy physics, they could find practical applications in quantum-information theory.” and “So the esoteric mathematics of string and M-theory might yet find practical applications.” Notice the “could” and the “might”. There is no definite claim, just an intriguing idea that he is trying to get people interested in.

The maths behind this is very cool and yet not fully explored. It is just the kind of thing that mathematical physicists should be interested in. There are connections between hyperdeterminants and cohomology theory for example. The 2x2x2x2 hyperdeterminant is a degree 24 polynomial and this is connected to the “mysterious” appearance of this number in the theory of elliptic curves and bosonic string theory. Binary codes appear when the hyperdeterminants are extended to invariants of E8. This raises many questions about what else could be going on here.

Woit says that string theory as a unified theory has failed while others like Duff say that it has not suceeded yet. Half full or half empty? take your choice. Duff is just promoting the idea that there could be a fundamental connection netween M-Theory and quantum information theory that could answer some questions about both. He does not know enough yet to make a definite claim but he thinks it is worth mentioning. How can this justify such an attack?

20. **mathematician**
May 12, 2010

Wow, I hadn’t realized they were doing so much string theory in the 1800’s!

21. **Trent**
May 12, 2010

Peter,

Okay, let’s look at formal QFT. It’s been a subject that has been around for at least 30 years, but let’s say 25.

Can you please explicitly state what has been the original motivation 25-30 years ago?

And can you please explicitly state what has been achieved from these original goals? And what has been achieved as a byproduct or accidental result?

Cheers,
Trent

22. **Trent**
May 12, 2010

Coin,

"
Overall I guess it seems weird to complain about Peter attacking the "dead horse" of string theory unification but not seem so worried about theoretically more-significant publications such as the CERN Courier publishing articles supporting that same "dead horse".
"

The CERN Courier is not a research journal. Scientific discussion is done in peer-reviewed research journals. So it's okay for CERN Courier to talk in lay-man terms and in hyperbole. As far as actual science is concerned this is pretty much irrelevant just as Peter's blog is irrelevant. This is what Peter is missing, he is doing science journalism about science journalism. See, he is 2 steps away from real science. 1 step is science journalism. Writing popular postings about science journalism is 2 steps away from actual science.

He completely lost perspective, which is not surprising because he himself is not doing any actual original research, the only thing left for him is popular science journalism, but he insists on calling it scientific activity.

When you are far from a certain topic it's hard not to lose perspective. Example: Peter frequently complains about the multiverse. I actually agree, this multiverse business is pretty silly, but if you actually look at the archive and see how many papers there are on the multiverse you will quickly find out that it's a fringe minority. So why bother? Lee Smolin and Peter wants to let people choose their research topics independently and free from pressures. So why not let some weirdos choose esoteric topics such as the multiverse? I personally think it's silly but who cares? It's a fringe minority and what is important some of these people already proved that they are capable of doing real research (such as Linde) so who are we to tell them what to do? Similarly, 't Hooft already proved that he is good, so who is entitled to instruct him that he should not be working on his crazy weirdo deterministic quantum mechanics stuff?

Cheers,
Trent

Cheers,
Trent

23. **Peter Woit**
May 12, 2010

Trent,

By formal QFT I just mean the investigation of the structure of QFTs, often using mathematical methods. This has been going on not for 25 years, but since the invention of the subject back in the 1930s. An example of success would be Veltman-'t Hooft's work on the quantization and renormalization of gauge theories, which was crucial for the Standard Model. Current ideology is that we understand completely gauge theories, that formal theoretical work on their structure is a waste of time. I disagree.

Your comments about the CERN Courier make exactly my point about Duff now doing what he was criticizing Smolin and me for 3 years ago.

I may be beating a dead horse, with the particle theory community completely in agreement with me about the multiverse and string theory unification. I do find some encouragement to continue when I see that instead of just boring people and making them go away, it continues to upset some who want me to stop interfering with the continuing production of hype like Duff's. It's also interesting to note that while half the criticism I get is that I should be ignored since I'm a marginal figure who doesn't know what he is talking about, the other half seems to be that I should be ignored since I'm just saying well-known things that almost everyone in the community agrees upon.

24. **responsible outreach**
May 12, 2010

"So it's okay for CERN Courier to talk in lay-man terms and in hyperbole. As far as actual science is concerned this is pretty much irrelevant just as Peter's blog is irrelevant."

It is far from irrelevant and far from okay (well, lay-man terms are okay, but not hyperbole). Science may not be "done" in the New York Times or the CERN Courier, but it still matters what they say about it because it is the de facto medium through which it is explained to the people who are paying for it. Billions of dollars are spent on projects like the LHC and if we are going to make up bogus feel-good stories about how it may soon verify string theory or how possible applications of string theory in quantum information bolster its potential as a theory of everything, then this amounts to something like fraud.

If we're going to accept that, we should spend the money on something else, perhaps a subsidy for science fiction writers which may get us a better story for far less money. We should also be prepared to butt out and shut up if the Pentagon tell us that things are going well in Afghanistan or BP tells us that the oil spill is under control and not their fault. After all, what do we lay people know that they don't? Do we have better ideas of what to do?

We expect the public media to take seriously their responsibility to report things as accurately as they can. Scientists in turn have a responsibility to help them in this process when it comes to reporting science, whether it is through direct contact with journalists or outreach publications like the CERN Courier. It does not matter that the people reading it know less than you do, do not have better ideas, or do not participate in the science itself.

25. **Trent**
May 12, 2010

Peter,

I thought you mean algebraic field theory. Okay, so let's stick to basic questions about QFT in general. As an example let's take your example, 't Hooft and Veltman. And let's look at the time frame of string theory: let's say past 20 years.

Question 1: What was achieved in the field of "basic QFT structures" in the last 20 years that is comparable to 't Hooft and Veltman?

Question 2: If the answer is "not much", then would you conclude that the field of "basic QFT structures" is dead, because if anything could be achieved, this would have been done in the last 20 years?

Please answer both questions specifically.

You write

“Your comments about the CERN Courier make exactly my point about Duff now doing what he was criticizing Smolin and me for 3 years ago.”

It seems you didn’t get my point which I illustrated with inequalities as well. These two things are not the same: (1) Duff says “Woit is just producing misleading popular science journalism and should be ignored” (2) Woit says “Duff is just producing misleading popular science journalism and should be ignored”. Again, these two things are not the same, although you might lump them together superficially.

Why?

Because Duff is actually doing original research and you don’t. This is not an ad hominem attack, but a factually correct description of reality. So, if we completely ignore Duff as a whole we lose lot of good research and perhaps miss some irrelevant popular science journalism. If we ignore you, on the other hand, we only miss out on irrelevant popular science journalism and nothing else. I hope it’s clear why the situation is not symmetric and it’s perfectly legitimate to have different points of views on you and Duff, although superficially it might look like both of you are doing similar things.

You also write,

“I may be beating a dead horse, with the particle theory community completely in agreement with me about the multiverse and string theory unification.”

You don’t understand my point about the dead horse. The particle theory community is not in complete agreement with you. Reason being is that you think string theory is bad for particle physics and popular science as well. The particle theory community, on the other hand, simply doesn’t care about the multiverse and string unification, because the multiverse business is a fringe topic practiced by a handful of people and whether string unification works or not, is completely irrelevant, nobody cares. If it works, great, if it doesn’t, who cares, something else will work and string theory is useful anyway for other things.

Please note again: you are not in complete agreement with the particle theory community, for the above reason.

You also enlightened us with

“It’s also interesting to note that while half the criticism I get is that I should be ignored since I’m a marginal figure who doesn’t know what he is talking about, the other half seems to be that I should be ignored since I’m just saying well-known things that almost everyone in the community agrees upon.”

You are definitely a marginal figure who doesn’t know what he is talking about, because you are beating a dead horse 🙂 You think string unification is so central to particle physics that all that is good or bad with the subject has to do with string unification. Your interpretation of the social aspects of particle physics is also wrong, if there are no surprising and striking experiments for 20 years, it’s natural that people will move to more formal and mathematical things, such as string theory. Now with the LHC string people get hired less, which is very natural, because new experiments demand new phenomenologists. This phenomenon has nothing to do with the hype, promise, originality, scientific merit, etc, of string theory. In fact, this could have been predicted easily:

no experiments -> more string theory (and other formal stuff)
new experiments -> less string theory (and other formal stuff)

It’s very simple. This is the major reason Lee Smolin and you are both wrong about the social aspects of the particle theory community (not to mention that Lee Smolin is as far removed from experiments as any string theorist).

I hope it’s clear why the two reactions from the particle community to you are compatible: (1) Woit should be ignored because he doesn’t know what he is talking about in general (2) Woit should be ignored because he attributes an enormous amount of importance to well-known things, which are however not very relevant.

Cheers,
Trent

26. **Peter Woit**
May 12, 2010

Trent,

I don’t know who you are, or why you are so obsessed with me and how I choose to spend my time. You’re quite right however that I should be spending more time on my research, so will now do so and stop responding to you, since doing so has been a complete waste of time.

27. **Quantum Information Theorist**
May 12, 2010

Kea says:

Sure, Duff is deluded about strings, but he has done some cool stuff here and if it turns out that the QI is in fact at the foundations of QG, then it will be relevant. And won’t you want to know something about it?

On several occasions when I have tried to suggest to string theorists that quantum information theory might have something to do with the foundations of QG, I have been laughed out of the room.

28. **A String Theorist**
May 12, 2010

Trent says:
“and whether string unification works or not, is completely irrelevant, nobody cares. If it works, great, if it doesn’t, who cares, something else will work…”
Are you nuts? Must of us work on String/M-theory because we sense that it WILL work out and is Fundamental Real Physics. Nice that it is useful elsewhere, but if it were not our best candidate for Unification, it WOULD be a monumental waste of talent and time as far as HEP is concerned.

31. **Geoff**
May 17, 2010

This is completely off topic as I was unsure where to post it. For those that appreciate wildly inaccurate headlines, you might appreciate this article from Pravda about Perelman:

http://english.pravda.ru/society/stories/07-05-2010/113310-perelman-0

32. **Coin**
May 17, 2010

Geoff: Perhaps I shouldn't pick at this, but do I read this correctly that their source for the entire part on page 2 is some random person who posted on their web forum who claims to know Perelman? I'm particularly fascinated by the bit about the crosses and rosaries and how his "apartment is heavily decorated with icons". That's the apartment he shares with his mother, isn't it? Isn't Perelman's family Jewish?

I showed this article to a friend and they suggested that maybe Pravda was trying to lure Perelman out of hiding by printing an article so intentionally inaccurate that he was provoked to step forward to correct it.

33. **Andrew Zimmerman Jones**
May 18, 2010

In regards to Peter's comment:

> *I didn't write that "string theory is a failure", specifically because "string theory" now refers to very many quite different things, some of which have had successes. However, the idea of using string theory in higher dimensions to get a unified theory has failed, and most physicists are aware of this.*

When I was writing ***String Theory For Dummies***, one of the string theorists who was performing a technical editor role (not Daniel Robbins, who was co-author on the book) claimed that the majority of string theorists *never* claimed that it would unify physics under a single "theory of everything," which I found odd, of course, since most string theorists who talk about it in the public forum use precisely this sort of terminology.

Despite this, the string theorist in question did claim that string theory would still work to unify the four forces under QFT … so I was never particularly clear on his real complaint. I think he just fundamentally didn't like the phrase "theory of everything" itself.

This particular string theorist seemed to take personal affront to a lot of phrasing choices, though. For example, he strongly objected to the suggestion that Richard Feynman received the Nobel Prize for the creation of Feynman diagrams, despite the fact that both the Nobel committee and Feynman himself specifically discussed Feynman diagrams when discussing the work that brought him there.

Toward the end of the editing process, I began to think that he was just looking for reasons to complain. (And no, it was not Lubos. 🙂

34. **Anonymous**
May 19, 2010

In my opinion it may be true that most string theorist are already disillusioned about the prospect of unification, as claimed by Trent and Jones. Hardly any string theory professors I met are fanatic about string theory. One of them teaching a course on string theory openly makes it very clear to students that string theory may have nothing to do with unification, but still it is worth studying for various other reasons. The PhD students doing string theory, as far as I can tell, don't have much faith in string unification either, although when asked about what they are doing by some non-physicist, they always answer they are trying to unify nature's forces.:-) Actually they choose this route simply because they want to get into formal particle theory, and given the current environment it does seem to be a natural choice for someone whose interest lies in this area.

35. **srp**
May 19, 2010

Slightly off topic of QIT, but I would be interested in our host's opinion about this:

http://www.scientificamerican.com/article.cfm?id=simple-twist-of-fate

36. **Peter Woit**
May 19, 2010

srp,

The SciAm article is a bit behind the times, with the string theory/twistor ideas from seven years ago. More recently, there have been quite interesting uses of twistors, but in QFT, not string theory, see some comments here

http://www.math.columbia.edu/~woit/wordpress/?p=1705

37. **Kea**
May 20, 2010

Actually, the SciAm article refers to some recent progress on Hodge's diagrams, although it does not do a good job of explaining this.

Short Items

May 25, 2010
Categories: Uncategorized

- Beam intensity at the LHC continues to increase with successful collision this morning of beams containing 13 bunches of protons, producing an initial luminosity of about 1.5 x $10^{29}cm^{-2}s^{-1}$. This is about a factor of 1000 below the goal for later this year, 2000 below typical luminosities at the Tevatron. The current plan is for proton-proton collisions this year until November 1, then a shift for a while to heavy ions. Integrated luminosity is about 10 nb^{-1}, see a graph here.
- Last week this result (also see here) from DZero got a lot of attention in the press, including a front page story in the New York Times. The claim is of observation of a CP-violating effect not predicted by the Standard Model, with a significance of 2-3.2 sigma, depending on exactly what numbers you look at. If I had to bet, I'd bet that this, like lots of other purported violations of the SM over the last 35 years, will ultimately disappear. Unfortunately, it seems that CDF is unlikely to be able to confirm or disconfirm this. For blog postings from people who actually know something about this, see here and here.
- There's an interesting interview with Shing-Tung Yau at Discover. This fall he has a new book coming out: The Shape of Inner Space.
- My colleague Brian Greene is keeping very busy, with the World Science Festival here in New York next week, and filming a four-part NOVA series based on is book *Fabric of the Cosmos*.
- If I weren't planning a trip to South America to see another eclipse in July, I'd probably be trying to find an excuse to go to Paris that month, and ICHEP 2010 might do the trick. Now, it seems even physics conferences have blogs.
- Herbert Neuberger has a very nice survey here, based on a colloquium talk, of our understanding of non-perturbative QCD.
- Frank Quinn has a long essay here which has quite a few interesting things to say about mathematics, mathematics research, mathematics education, and relations to physics. Quinn is a topologist who has interacted with physicists since the late 80s, in the context of topological quantum field theory. I learned about this from a posting at the n-Category Cafe, where some illustrious commenters have an interesting exchange about TQFT.
- For a long time now, particle theory has been divided up between phenomenology and string theory, with formal QFT an increasingly marginalized subject. At the same time, more and more mathematicians have been studying QFT long enough to become quite expert at it. In the future it seems conceivable that this will ultimately lead to new discoveries about QFT coming out of math, not physics departments. For an indication of how things are going, take a look at the recent MSRI workshop in honor of Alan Weinstein. Videos of some of the talks are supposed to be available at some point. I'm most looking forward to seeing what Graeme Segal has to say about Geometric aspects of the positivity of energy in quantum field theory, and curious to know what Reshetikhin had to say about Hamiltonian structure of gauge theories (it appears that video of that talk will not be available). Next week Reshetikhin is teaching a master-class on gauge theories in Amsterdam (web-site here), and he taught a course on QFT there last fall

Updates:

- See Resonaances for some news that makes the DZero supposed SM violation look less likely. Some support for the claim came from earlier data showing similar SM violation in another channel, but the latest from CDF is that, with more data, this has gone away.
- Latest from the LHC is that on Tuesday morning a peak luminosity of about 2 x $10^{29}cm^{-2}s^{-1}$ was reached. Integrated luminosity is now about 16 nb^{-1}.
- Nature has an interview with Brian Greene about the new orchestral work from Philip Glass inspired by his recent children's book.

Update: A more skeptical report on the DZero result from Adrian Cho at Science Magazine is here.

Comments

May 25, 2010

   Where are you heading to to see the eclipse? I'll be in Chile at the time visiting some groups in Santiago but might see if I can go see the eclipse. That would make the last three in a row!

2. **Peter Woit**
May 25, 2010

   Hi Jonathan,

   I'll be with a group going down to Patagonia from Buenos Aires. In Patagonia the eclipse will be happening near sunset, and the probability of clouds is high, so the plan involves getting on a chartered plane to get above the clouds at eclipse time. Not cheap, but cheaper than the other South American way of seeing the eclipse, which would be to fly to Easter Island and see it there. But those flights, and any place to stay on the Island, are quite expensive.

3. **Coin**
May 25, 2010

   "The current plan is for proton-proton collisions this year until November 1, then a shift for a while to heavy ions"

   So I'm not sure I understand what the heavy-ion searches are about.

   The proton collisions, as I understand, the point is to probe the particle spectrum. This will likely require a long, high-luminosity run before anything "new" can be found, because a large number of events have to be logged in order to establish a background which interesting events can be distinguished against.

   The heavy ion collisions though as I understand have nothing to do with the particle-spectrum search, and the goal there is to create a quark–gluon plasma (which I assume, like the exotic particles in the proton searches, will last only a short amount of time and be analyzed only by the particle spray it leaves behind?). Will the heavy ion experiments have the property the proton experiments have, where the machine has to run for a very long time in order for any conclusions to be drawn at all?

   Is there somewhere that would be a good source for learning about how the quark gluon plasma analysis works and exactly what we are hoping to learn from it?

4. **Peter Woit**
May 25, 2010

   Coin,

   Good questions. I've seen very little about what people will be looking for in heavy ion collisions at LHC energies. Maybe there's a knowledgeable reader out there…

5. **Tim van Beek**
May 26, 2010

> In the future it seems conceivable that this will ultimately lead to new discoveries about QFT coming out of math, not physics departments.

Is it a coincidence that this statement is similar to the closing words of the (draft of the) preface of “Mathematical Foundations of Quantum Field and Perturbative String Theory” that you can read [here](#) ? (Last paragraph on the page, right above the “authors” list).

6. **Bill K**
   May 26, 2010

   Why, recreating the conditions of the Big Bang, of course. 🙂

   Knowledgeable I’m not, but I can point you to a good summary of what they’ll be looking for:

   http://www.bnl.gov/npp/docs/Hunting%20the%20QGP.pdf

   And I have some opinions. Under the constraints that the LHC is currently operating, I think ALICE is much more likely to produce new and interesting physics than the other experiments. And I think the two months they’ve allocated for it is far too little. Switching over to lead will be more than just flipping a switch – another lengthy tuning process will be needed.

7. **Peter Woit**
   May 26, 2010

   Bill K,

   I’d be curious to see something more LHC-specific. What will the LHC see that RHIC can’t? What will this tell us? Are their predictions of AdS/CFT and other methods that will be tested?

8. **Anonymous Grad Student**
   May 27, 2010

   I attended the MSRI workshop. Forgot I had made some sketchy notes of Graeme Segal’s talk. Here are some scans to tide you over till the video is posted. (No notes for Reshetikhin’s talk, sorry.)

   http://i46.tinypic.com/2s6pjs7.jpg
   http://i46.tinypic.com/r8ukid.jpg
   http://i46.tinypic.com/e9c2md.jpg

9. **Anonymous Grad Student**
   May 27, 2010

   Also, there were no results in Reshetikhin’s talk. He gave the impression that he’s still in the process of learning gauge theory, and just gave some examples of them. I think the talk even ended with “Results: to come”. Possibly why the video isn’t being posted.

   Should have mentioned, take the notes above with a grain of salt. I’m sure there some misrepresentation in there, especially towards the end 🙂

10. **Adam Helfer**
    May 27, 2010

    AGS,

    Your notes look interesting, but I couldn’t tell specifically what was going on. Was Segal trying to look at properties of Hamiltonians of quantum fields in curved space-time? If so, in the case of generic space-times (no timelike Killing vector), these Hamiltonians are pathological, even for linear quantum fields. They’re not only non-positive, they’re unbounded below (this is an ultraviolet problem) and they do not exist as self-adjoint operators, but rather in the weak sense.

11. **Peter Woit**
    May 27, 2010

    AGS,

    Thanks a lot for the notes and the report!

    Adam,

    I think what Segal is interested in is trying to make sense of “Wick Rotation” for a curved space-time. Euclidean signature methods are needed in the path integral formulation of QFT, so having an appropriate notion of how to analytically continue from Minkowski to Euclidean signature is crucial. Even in flat space this is an interesting question which I’m not convinced is resolved when one has spinor fields.

    One could imagine thinking about this by complexifying space-time, and looking at holomorphic objects, but Segal is doing something different. He’s taking a fixed space-time manifold and complexifying the space of metrics on it. From what I can tell, he has some good understanding of what happens in d=2, which is interesting for 2d QFT and string theory, not sure what he has for d=4.

12. **JE**
    May 27, 2010

    Surely off-topic and not really sure of its significance, but just in case… news reports broke in Spain announcing that Professor Francisco Santos of the University of Santander has disproved the Hirsch Conjecture.

13. **Coin**
    May 27, 2010

    JE, that is very interesting… Wikipedia’s “Hirsch Conjecture” article seems to have some information on this already (they link a blog post by Gil Kalai who noticed this as early as May 10):

    > The result is to be presented at the conference 100 Years in Seattle: the mathematics of Klee and Grünbaum… a counter-example was found, using a 43-

dimensional polytope of 86 facets with a diameter of more than 43.

The conference starts July 28, the abstract for Santos' paper is here.

14. **Adam Helfer**
May 27, 2010

Peter,

Thanks. I suppose I should wait for MSRI to finish posting the video before going too far in discussing this, but if one doesn't have some very strong link between the physical metric and whatever the auxiliary structure is (in this case, apparently the space of complexified metrics), it's hard to see what the physical content of the mathematics is.

On the issue of Euclideanization (or, to put it in more physical terms, the pseudo-Lorentzianization) of Minkowski space, I don't know if this comment helps, but the two two-component spinor spaces, that is, the primed and unprimed spaces, have well-defined analytic continuations. What changes is the way these spaces are related to the relevant sense of choices of orientation. In each case, the two spin spaces essentially correspond to the two eigenspaces of the duality operator on two-forms. In the Lorentzian signature, the eigenvalues are plus or minus i, and the spaces are conjugates of each other, and neither is preferred (without more information). In Euclidean signature, however, the eigenvalues are plus or minus one, and so there is an invariant distinction.

15. **Researcher**
June 3, 2010

Another, very sad short item: Vladimir Arnold, a great Russian mathematician, passed away today in Paris, France.

16. **Anonymous Grad Student**
June 9, 2010

Just a heads up. The video for Graeme Segal's talk (along with others from the conference) is now available.
http://www.msri.org/communications/vmath/VMathVideos/VideoInfo/4666/show_video

I couldn't get the streaming video to work, but the download link works fine.

More Quantum Information Theory From String Theory

May 27, 2010
Categories: This Week's Hype

Claims made recently in the CERN Courier that string theory can be applied to Quantum Information Theory (see here) are being followed up with a new paper entitled Four-qubit entanglement from string theory which appears to claim that, despite what some might think, string theory is falsifiable since it makes experimentally testable predictions about Quantum Information Theory:

> Falsifiable predictions in the fields of high-energy physics or cosmology are hard to come by, especially for ambitious attempts, such as string/M-theory, to accommodate all the fundamental interactions. In the field of quantum information theory, however, previous work has shown that the stringy black hole/qubit correspondence can reproduce well-known results in the classification of two and three qubit entanglement. In this paper this correspondence has been taken one step further to predict new results in the less well-understood case of four-qubit entanglement that can in principle be tested in the laboratory.

Previous papers along these lines about the three-qubit case involved some algebra that I referred to as "remarkably obscure", a comment that "was like waving a red flag in front of a bull" as far as John Baez was concerned, leading him to some expository comments about the subject in his latest This Week's Finds in Mathematical Physics. About the string theory claims he comments:

> Unfortunately, Duff gets a bit carried away. For example, he says that string theory "predicts" the various ways that three qubits can be entangled. Someone who didn't know physics might jump to the conclusion that this is a prediction whose confirmation lends credence to string theory as a description of the fundamental constituents of nature. It's not!

Unlike the three-qubit papers, this latest one sticks to mathematics that is not particularly obscure. The mathematics invoked is the quite beautiful subject of the classification of nilpotent orbits in a Lie algebra. I've been trying to learn more about some related topics in recent months, having to do with the role of nilpotent orbits in representation theory. Part of this story involves what are now known as "finite W-algebras", and these have a BRST definition. I've been curious about the relation of this to the BRST/Dirac Cohomology relationship I've been working on.

The mathematical problem at issue here is that of classifying $SL(2,\mathbf{C})^4$ orbits on the four-fold tensor product of $\mathbf{C}^2$. For an exposition of this problem aimed at mathematicians, see these lecture notes by Nolan Wallach. In the new paper, the authors claim that the Kostant-Sekiguchi theorem implies that this classification is the same as that of orbits of SO(4,C) on its Lie algebra, and this latter classification also classifies certain sorts of black holes in supergravity, but I haven't checked the details of this. It's a complete mystery to me why the use of the Kostant-Sekiguchi theorem to relate the straight-forward mathematics used in QIT to a black hole classification problem is going to somehow turn string theory into falsifiable, experimentally testable science.

Comments

1. **from CERN**
   May 30, 2010

   Despite the paper on CERN Courier, the seminar at CERN was attended almost only by some string theorists

2. **anonymous**
   June 2, 2010

   Pete, sorry if OT. From the June 2010 Scientific American issue:

   http://www.scientificamerican.com/article.cfm?id=interactive-12-events

3. **Peter Woit**
   June 2, 2010

   anonymous,

   The one of the SciAm 12 "events that will change everything" that has to do with particle theory is the possible discovery of extra dimensions, that is assigned a probability of 50% by 2050. It's true that would be a huge event in the history of science, but I think most theorists would put the probability one or more orders of magnitude below 50%.

   The article mistakenly claims that supersymmetry requires 10 dimensions, mixing up supersymmetry and string theory (string theory isn't mentioned at all).

   There's a quote from Arkani-Hamed:

   "So while extra dimensions would be a terrific discovery, at a deeper level, conceptually they aren't particularly fundamental'.

   In some sense I agree, although perhaps with a different point of view. Extra dimensions don't solve any fundamental problem that we care about, much more interesting would be a conceptual breakthrough that would solve such problems.

4. **Bill K**
   June 2, 2010

   Extra dimensions are the last thing we need. It's hard enough trying to explain the existence of the first four!

5. **Confused Student**
   June 3, 2010

   Does the inverse scattering transform method for kdV equation make falsifiable predictions from the Schrodinger equation and hence validate the basic equation of quantum mechanics? Is this the major success of quantum mechanics?

6. **anonymous**
   June 3, 2010

   Thanks for your answer, Pete.

Althought the article must be judged by its genre (journalistic science counterfactual forecasting?) when reading it i had the impression that present physics much more open than i think it is.

For instance the 50% issue: i´m not even sure that to assign probabilities to such (or similar) events is correct. If it is, 50% must be interpreted as if we had not any information about if the universe has 3+1 dimensions or more, but as you say “most theorists would put the probability one or more orders of magnitude below 50%”. This issue is not a fair coin, it´s clearly biased !

On the other hand despite Arkani-Hamed comment I still find highly unsatisfactory that SM is compatible with extradimensions, if only for parsimony.

In any case, congratulations for your blog!

7. **bane**
   June 4, 2010

   @anonymous.

   The assginment of probabilities to those events is perfectly foundationed interpreting them as Bayesian probabilities incrorporating whatever theoretical prior beliefs. The biggest difficulty is that (assuming that if extra dimensions exist they will be detectable by 2050) it seems almost all relevant physicists either believe theories that say there are extra dimensions with a tiny chance of being wrong, or that there aren’t extra dimensions for parsimony reasons with a tiny chance of being wrong. So all this probability really represents is what the writer (Sci Am, Peter) thinks the relative proportions of the two groups is.

8. **Pawl**
   June 4, 2010

   bane,

   The problem is not just prior theoretical prejudices. It is that the “large extra dimensions” scenarios are not at all developed theories, but guesses about what might possibly be achieved if somehow the apparently enormous problems involved in developing theories to support the scenarios might be overcome.

   Any reasonable estimate of their chance of being true must take into account: (a) the magnitude and complexity of these difficulties; and (b) the odds that, even if those are overcome, the original guesses will turn out to have been pretty much correct — something which is hardly assured given the depth of the unresolved problems.

   The 50% figure is preposterous from this point of view.

9. **anonymous**
   June 8, 2010

   bane,

   It is not that i want to revive the probabilities interpretation debate, but i´m classical or ortodox on this: let the probabilities for real or theoretical systems which fit into Kolmogorov axioms.

   On this sense the posibility of asigning probabilities to such “universe property events” as the number of dimentions seems tied to the belief either on some kind of multiverse or sequential toss, on which 50% of the universes have extradimensions and 50% not. This makes no sense if the universe had unique properties (i.e. the universe properties are always the same after every sequential or parallel universe toss).

   On the other hand the sentence “I think most theorists would put the probability one or more orders of magnitude below 50%” seems clear enough.

- Several blogs have now pointed out the wonderful snarXiv site, which automatically produces random plausible-sounding hep-th entries. It's something along the same lines as the famous Postmodernism Generator. For entertainment, you can try playing snarXiv vs. arXiv.
- HEPAP is meeting in Washington today, presentations here
- At Fermilab, the User's Meeting continues today, talks here.
- Last week was Brookhaven Forum 2010, talks available here.
- Talks by Michaels Atiyah and Green at the Young Researchers in Mathematics 2010 meeting are available here. Atiyah reminisces about his early career and offers a lot of helpful career advice for young mathematicians. For the future, he's betting that topology and symmetry will remain crucial themes in mathematics, with solitons continuing to be interesting since they live in the intersection. Green gives a very standard promotional talk on string theory. For some reason he explains to the young mathematicians the story of the string theory anthropic landscape explanation for the CC, then remarks that he personally finds it to be a cop-out.
- The Edge web-site has a wonderful discussion with my Columbia colleague Emanuel Derman, covering his early career in particle physics, his days as a Quant, and thoughts about the current state of the finance business.
- From Fabien Besnard, the news that Vladimir Arnold died today in Paris.

Where Do They Go?

June 6, 2010
Categories: Uncategorized

HEPAP has had a Demographics Committee since about 1999, charged with gathering data on what happens to young people in the US who enter the field of High Energy Physics (both theory and experiment). The latest report from the committee is here, but it contains more questions than answers. The data gathered show that only 10-20% of HEP graduate students end up with permanent tenured positions at HEP institutions, and the other 80-90% in some sense "leave" the field.

The committee seems to have had very little success at finding out what happens to the "leavers", perhaps because its data-gathering method is based on questionnaires filled out by one person at each institution. Very typically, once someone "leaves" academia for a different career track, within a few years their ex-colleagues no longer know where they are or what they are doing. On the other hand, in the age of Google and Facebook, tracking people down has become rather easy, so it's unclear why an effort hasn't been made to do this, if not for everyone in the database, than at least for a randomly chosen statistically significant sample.

I'd certainly be curious to see some real data, but based on my personal experience I'd guess that the 80-90% number sounds right, with "leavers" going into a wide variety of different careers. The financial industry may be the most popular, but I also know many who have gone into the computer or telecommunications industries, as well as other fields in academia.

By this count, I and others who have ended up in mathematics departments count among the "leavers". I'm very happy with how my own rather unusual career path has worked out, but have generally advised others that it relied too much on good luck for anyone else to try and emulate it. A few days ago I heard from someone at the Perimeter Institute who told me about a new "hybrid research/IT position" that they are trying to fill. The job listing is here, with a detailed description of what they are looking for here. They seem to be a looking for a candidate with both a research Ph.D. and IT experience, which is a somewhat unusual combination. A Ph.D. with little IT experience but the right skills (quick learner with patience, common sense, enjoys working with technology and helping others with their technical problems) who is interested in the position might want to try and convince them that most of the IT skills get picked up on the job anyway…

Comments

1. **John Armstrong**
   June 6, 2010

   tracking people down has become rather easy, so it's unclear why an effort hasn't been made to do this

   It's perfectly clear: people like me who have been cast out of the academy are apostate.

2. **Kea**
   June 6, 2010

   And the job sites are still full of ads begging for ~~exploitees~~ students.

3. **Tim van Beek**
   June 7, 2010

   > a new "hybrid research/IT position"

   That sounds familiar, the software company that I work for offers similar jobs, where you have to combine some familiarity with a field that uses IT heavily (finance, telecommunication, car producers), with some IT knowledge. You evaluate new technologies and create solutions for standard problems. In this case this could be something like "we need a programming language for a multithreading Monte Carlo simulation of lattice gauge theories"…and you would have to be able to recommend a programming language, an integrated development environment, a visualization and evaluation framework, a set of trusted pseudo random generators etc.

   (Preferably as a single download self explaining package 🙂
   It does not make any sense if everyone who needs to do a Monte-Carlo simulation looks for and evaluates pseudo random generators all by himself, and it is impossible to do that for every component you need anyway.
   Same goes for all the other IT-topics of interest to the research community.

4. **Anon**
   June 7, 2010

   Can someone clarify the Departure Table (page 7) for me? In the first column, we have HEP, Other Physics, blah blah blah. What does the HEP row mean? Does the HEP row mean that they were initially 115 students? But then how can one lose 118 students to Unknown (last row of the first table on page 7)?

5. **Anon**
   June 7, 2010

   Oops! Ignore the previous post. I just found out that departure just means change of institution or rank. So HEP is just change of institution to another one.

   June 7, 2010

   peter wrote:
   I'm very happy with how my own rather unusual career path has worked out, but have generally advised others that it relied too much on good luck for anyone else to try and emulate it.

   Writing an excellent book didn't hurt your career

7. **Peter Woit**
   June 7, 2010

   Thomas,

   I only was able to write the book because I had a permanent academic job that gave me the time, energy and people to talk to necessary to learn about, then write about, the topics of the book. Finding such a position required a certain amount of luck.

8. **D R Lunsford**
June 8, 2010

Well I never had a ghost of a chance to “stay” vs “go”, for many reasons – but I don’t feel as if I myself went anywhere – I’m still doing physics the way I learned it – but I strongly feel that academic life left me, and not the other way.

I feel much worse for engineers than I do for us physicists.

9. **Belizean**
June 8, 2010

The thing that irks me is that NSF, DoD, etc. are still funding efforts to increase the number of graduates in fields of Science Technology Engineering and Mathematics (STEM). I’m forced to mention this in just about every grant application that I write.

They should instead fund efforts to *decrease* education in STEM fields, as there is very obviously a glut.

10. **naezileb**
June 9, 2010

“Science” includes also things like biology and biotechnology. There may be a glut of graduates in HEP theory, but is there a glut across all of STEM?

As for the 80-90% “leavers” if the statistics reveal that the leavers earn three times as much as the stayers (D R Lunsford?), there may not be great incentive to advertise the fact.

11. **D.**
June 9, 2010

Compare the guy on his third postdoc to the same guy joining a hedge fund soon after his thesis defense and the multiple is more like 8, unfortunately. This doesn’t address opportunity cost etc.

The Abstruse Goose recently provided an excellent summary of how to go about learning string theory. It starts with "String Theory for Dummies", here. Tommaso Dorigo's latest say of the week is somehow relevant.

Comments

1. **ampm**
   June 9, 2010

   There's commentary on those who wish to use mathematics to study gauge theories, too.

   http://abstrusegoose.com/105

2. **Giotis**
   June 9, 2010

   He forgot to include Supersymmetry and Supergravity.

3. **Coin**
   June 10, 2010

   I would be legitimately interested in an entry-level introduction to string theory, especially if it focused on string theory as a mathematical framework rather than string theory as a physical theory.

4. **Tim van Beek**
   June 11, 2010

   @Coin: You could try "A mathematical introduction to string theory. Variational problems, geometric
   and probabilistic methods." by Albeverio, Jost, Paycha, Scarlatti.
   This is a mathematically sound exposition of the quantization of the relativistic bosonic string using the Polyakov functional integral (so it is not an introduction to "string theory", as the title implies, but only to one aspect, but mathematically rigorous).

5. **Coin**
   June 12, 2010

   Tim, thanks! I'll try to take a look and see if I can handle it…

Through the Wormhole with Morgan Freeman

June 9, 2010
Categories: Uncategorized

The Science Channel is starting up yet another show on physics tonight, with Michio Kaku's Sci-Fi Science and Into the Universe with Steven Hawking being joined by Through the Wormhole with Morgan Freeman. The topics being covered by Freeman are the usual ones: Black Holes, Aliens, Is Time Travel Possible? What Happened Before the Big Bang? etc.

The series unfortunately first starts out by bringing religion into it, with an episode called Is There a Creator?

> Did our Universe just come into being by random chance, or was it created by a God who nurtures and sustains all life?

I gather that the episode begins with speculative physics elements that include Alan Guth on the multiverse and Garrett Lisi on E8 unification, but then moves on to speculative God stuff, with a neurophysiologist followed by the "maybe we're just a simulation" business. The New York Times today has a depressing review, by a writer who wants more of the God part and less physics:

> …this opening installment, which is supposed to be about whether there's a Creator, almost immediately degenerates into theoretical yakking by scientists about unified theories of this and missing particles of that.
>
> Especially with recent news coverage of that particle accelerator near Geneva, it seems as if we'd been hearing about this type of physics for a long time, and the discussion never does go anywhere or have much practical relevance. Anybody got a particle big enough to plug that busted oil pipe in the Gulf of Mexico?
>
> Anyway, after about half an hour, Mr. Freeman's show does get intermittently interesting because it turns itself more directly to the Creator question. (Questions are pivotal to this series; future episodes include "How Did We Get Here?" and "Are We Alone?") Doesn't answer it, of course, but does check in on an assortment of scientists who have an assortment of theories.
>
> One thinks our idea of God is a kind of neuropsychological tic and plunks a ridiculous-looking contraption he calls a God helmet on research subjects' heads to try to prove it. Another suggests that we're nothing but a computer simulation created by our own descendants. If this program can stay away from same-old science and work this territory — theories that sound a little bit crackpotish, a little bit geniusy — it might set itself apart in an increasingly crowded genre.

Update: Chad Orzel weighs in here.

Comments

1. **Grétar Amazeen**
   June 9, 2010

   I don't know what is sadder, the show or the review. The world needs another Carl Sagan desperately!

2. **Garrett**
   June 9, 2010

   Sadly, I'm no Carl Sagan.

   I hope this episode isn't terrible. I've only seen parts of it. I gave the producers lots of advice, and even introduced them to the Science & Entertainment Exchange. They had their own ideas and agenda though, and did their own thing. I'm mostly just hoping I don't get What the Bleeped, or pronounced a physics prophet.

   The only thing about it that I know is good is that Morgan Freeman will talk a bit about Lie groups. That I'm happy about. The God stuff, not so much.

   And, err, there is a decent shot of me surfing.

3. **Amos**
   June 9, 2010

   How's the e8 work coming then?

4. **Garrett**
   June 9, 2010

   E8 work is going well. Short paper coming soon — probably out next week.

   (Peter, feel free to curtail any inappropriate threads if we're drifting off topic.)

5. **Mike**
   June 9, 2010

   I confess I am a mere consumer of such programming, and though I have not derived any of the force calculations referenced, I am impressed with the show. "More questions than answers" was promised, but a deeper dive than expected is the result. I will now research into Lie groups, because I really want to understand the math behind them, though I probably never will, fully. Was that really the north shore you were shot at–excellent surfing there!

6. **Chris Oakley**
   June 10, 2010

   Morgan Freeman talking about Lie groups? I just checked his wiki page and his qualifications in this regard seem to be that (i) he was a mechanic in the USAF and (ii) he has played God twice in movies. (i) requires (only) a working knowledge of O(3) and its subgroups, so I guess that he is getting in under (ii) which, I suppose would qualify him for just about anything (anything *good*, anyway).

7. **Tim van Beek**
   June 10, 2010

> The New York Times today has a depressing review, by a writer who wants more of the God part and less physics…

Well, there *has* been a lot of coverage about the LHC, all the physicists *keep* on saying the same things, the discussion *is not* moving anywhere, and, frankly, I would like a well done documentary about different notions of "God" in the world religions of the present day and the past **much** more than anybody telling the same over and over again how the LHC could detect additional dimensions.

Yes, it is depressing, but that's not the fault of the reviewer 🙂

8. **Jeff Olszewski**
June 10, 2010

Well Dr. Lisi, your comments are spot on as usual. However, while it is true that you are no Carl Sagan (yet), I wouldn't undercut the influence that your theory is having today, and will likely have in the future on physics. A buddy called me up last night and said "get to the TV now, Morgan Freeman is doing a spot on Dr. Lisi". I enjoyed the show, even the God speculation, because I'm not a hard core physicist. One thing for sure, your legend is growing, in no small part because you are likely the only world class physicist who also surfs. Remember the movie line "Charlie don't surf"? Well, "Garrett surfs" may someday be a T-shirt. Keep at it!

9. **Chris Oakley**
June 10, 2010

Jeff,

Your comment suggests a remake of *Apocalypse Now* with the String Theorists as the VC, Peter Woit as Col. Kurtz and Garrett Lisi as Lance the surfer.

E.g. Captain Willard [not sure who that would be] looking at Peter's dossier on the boat:

> At first, I thought I had wrong dossier. I couldn't believe they who they've had for their enemy! Third generation Harvard, top of his class. Numerous degrees. About a thousand prizes. Etc, etc… I mean, I know this man, or at least I think I know him better than others do, but… I couldn't connect who he was then with who is he now.
>
> He had an impressive career. Maybe too impressive … I mean perfect – Harvard, Princeton, PhD with Callan. Oh! He was being groomed for one of the top slots of the corporation. Professor, Head of Department, anything … In '04 he returned from a lecture tour and things started to slip. The report to the DoE was highly restricted. Seems they didn't dig what he had to tell them. During the next several months he made four requests for transfer back to physics. And he was finally accepted. Physics blogging? He was 44 years old, jack. Why the f-ck would he do that?

10. **Peter Woit**
June 10, 2010

The horror… the horror…

11. **MN**
June 10, 2010

"One thing for sure, your legend is growing, in no small part because you are likely the only world class physicist who also surfs."

This is so scary in so many ways.

Lisi is no "world class physicist" (he seems honest and might even agree) and the fact that surfing makes one's "physicist's legend" status grow just shows that fans such as "Jeff Olszewski" are far more dangerous to science than your average creationist crank.

Science is about describing the physical world.
Lisi made no advances on this (public at least).
Surfing and other wet dream fantastic irrelevancies such as the trash this post describes are just substitutes for the ignorant masses and these masses just keep asking for more (see the NYT review).

"The horror… the horror…"

Indeed.

12. **anon.**
June 10, 2010

There are actually a lot of world-class physicists who surf. Which way the causation goes between this and the KITP being located on a beach, I don't know.

13. **Thomas Larsson**
June 10, 2010

Hm. If KITP is located in the same building as the ITP was when I was a grad student, it is not located on the beach, but on the UCSB campus on the top of the cliffs. Now, *I* was frequently located on the beach (some of the tan still remains after 27 years), but that didn't prevent me from being the only one in my class to pass the qualifier as a freshman.

14. **Chris Oakley**
June 10, 2010

MN,

Your comment is mean-minded as Lisi is certainly a world-class physicist.

The question is more whether he is on to something or not.

Personally, I doubt it, but if unrealistic expectations have built up, then he is probably just as embarrassed as you are.

15. **Tim van Beek**
June 10, 2010

> …Lisi is certainly a world-class physicist.

I vote to make physics an olympic discipline, then we would all know who is world-class and who is only replacement bench material 🙂

16. **Anonymous**
June 10, 2010

Found this blog in a Google search for this show.
Just wanted to share my opinion:
This first episode's religious theme was a turnoff to me. I watch the Science Channel for science, not for religious BS, so I decided to skip this one. I may watch (some of?) the other episodes, but I wasn't very attracted to spending an hour watching "speculative God stuff".

17. **H-I-G-G-S**
June 10, 2010

Dr. Lisi has world-class fame as a physicist, even if no actual physics was done while achieving this fame. I'm pretty sure that is all that matters to the producers of this show.

18. **Hendrik**
June 10, 2010

Garrett, good to hear E8 is going well. Maybe I missed it, but was there an answer to:

http://arxiv.org/abs/0905.2658

19. **Shecky Riemann**
June 10, 2010

Are you sure that guy is writing for the NY Times?… sounds more like the NY Post!

20. **Risco**
June 11, 2010

"I think that's what is so fascinating with that episode especially with Lisi's theory of creation because he himself is an atheist and he totally accepts and understands that his theory can prove the existence of God and that's one of those wonderful conundrums. We wanted to explore God and science, not God versus science."

That's from the producer. Garret?

21. **Risco**
June 11, 2010

http://www.surfingtheuniverse.com/Surfing_the_Universe/Welcome.html

And, ?

22. **D R Lunsford**
June 11, 2010

Shecky, the poor guy is just the theater and TV critic – and that's the problem with these shows – they are so inchoate and filled with idle speculation that they cannot be reviewed based on any meritorious content, as could say the NOVA shows about the standard model, broadcast in the late 70s. These science shows are no better in fact than the endless stream of drivel about chucucabras, ghosts, aliens, angels etc. that also gushes from these cable networks.

-drl

23. **Ken**
June 14, 2010

I have no extensive education in physics, theoretical or otherwise. And after second year calculus, I was lost. But I must say I did enjoy this first episode of "Through the Wormhole." The theories presented were done in an interesting way without any perceived bias.

When the discussion of the origin of the universe crops up, the intelligent design debate is guaranteed to be close at hand. As Aristotle said, "It is the mark of an educated mind to be able to entertain a thought without accepting it."

I am the general public to whom I believe the series is targeted. I liked it and will watch the rest.

24. **david**
June 16, 2010

It seems obvious that this NYT writer knows next to nothing about the genre of theoretical physics. Apparently all he wants to hear is that the God he learned in Sunday school created everything on the SCIENCE channel. He denounces science based on the fact that the answers to all the questions havent been discovered in the 2 years the LHC has been working like it should be been all figured out over night. He doesn't want to hear about "theoretical yakking by scientists about unified theories of this and missing particles of that." Einstein died with this question in his head. Perhaps getting an understanding for a subject before spitting out an ignorant review on it would be a swell idea.

25. **Marc**
June 23, 2010

When Garrett says of the producers "They had their own ideas and agenda though, and did their own thing" he hits the nail on the head. There are some interesting gathering of facts, but i am quite sick and tired of pseudo science shows like "monster hunters" and "ghost investigators" and such, posing as real science to push an agenda. Unfortunately a small part of shows like these leak out as sound bites and get twisted and used. For instance, i had a discussion with a co-worker; he cited the existence of the "God Particle" to prove that scientists are forced to admit the existence of his christian god!
oh well, the world will end in a couple of years anyway…

26. **Researcher**

June 27, 2010

Just a small side note: Garrett's new preprint is already out there:

http://arxiv.org/abs/1006.4908

27. **Garrett**
June 28, 2010

Yes, this paper answers the question of whether or not a generation of fermions embeds in E8. Curiously, Distler's lengthy response came within minutes of the paper appearing on the arxiv. Getting a few days' lead on new papers is one of the perks of being on the arxiv board I suppose.

28. **Peter Woit**
June 28, 2010

Thanks Garrett,

The introductory section of that blog posting is pretty remarkable. I'm still wondering what argument the hep-th moderator uses to justify censoring trackbacks to this blog, thought maybe it was that I'm sometimes obnoxiously snide. But now, it's clear that that can't be the argument….

29. **H-I-G-G-S**
June 28, 2010

Garrett,

The time stamp on Distler's blog energy is 9:17pm. I presume this is CST since he is in Texas. ArXiv papers are available starting at 7PM CST, so that is 137 minutes, a quantity of time rarely referred to as "within minutes." I don't see any reason why he couldn't have written the post in that amount of time. After all, your recent paper in no way contradicts the results of his paper with Garibaldi.

30. **Peter Woit**
June 28, 2010

H-I-G-G-S,

Lubos is the only one in the business who can read papers and write blog articles at that length (with graphics!), that fast…

In any case, as far as I know there's no rule against arXiv moderators reading papers as they come in. If you care about this issue, you should ask Jacques himself.

31. **jpd**
June 28, 2010

"your recent paper in no way contradicts the results of his paper with Garibaldi" i agree with that, you agree with that, i even think Distler agrees with that. i am not sure why he takes it so personally. its just a question of definitions.
until a prediction comes out, both Lisi and Distler are not even wrong.

32. **H-I-G-G-S**
June 28, 2010

Peter, I don't care about it, I was simply correcting the impression left by Garrett's incorrect description of the time involved. People who are careless with the truth about small things also tend to be careless with larger things, in my experience.

jpd, it is not a question of definitions, it is a question of physics. In particular it is a question of how chiral fermions work, the difference between real and complex representations, and the physical implications of having mirror fermions or anti-generations in Distler's language. Here Distler is definitely correct and Garrett is engaging in wishful thinking.

Not In Our Lifetimes

June 9, 2010
Categories: Uncategorized

A report from one of last Saturday's events at the World Science Festival has string theorists Brian Greene and Shamit Kachru admitting that they'd be surprised to see experimental evidence for string theory in their lifetimes:

> John Hockenberry, the panel's moderator, asked Greene if he thought experimental evidence would come during his lifetime.
>
> "I'd be surprised," said Greene.
>
> "And in your lifetime?" Hockenberry asked Kachru.
>
> "…I'd be surprised," conceded the young physicist reluctantly.

For more reports about the same panel discussion, see here and here.

Comments

1. **ludwig**
   June 9, 2010

   Ludwig Boltzmann saw no evidence for the atomic hypothesis in his lifetime, underlying his work on kinetic theory, microstates and entropy and the Maxwell-Boltzmann distribution.

   And he committed suicide.

   Which is one way to guarantee that one won't see results in one's lifetime.

   A role model for the ages?

2. **Chris Oakley**
   June 9, 2010

   The moderator seems to have avoided the obvious follow-up question, i.e. "Why the f*** are you still working on it, then?"

3. **Mantis**
   June 9, 2010

   For the vast majority of theorists the fact their theories cannot be verified in their life time is a blessing!

   Only a tiny amount of theoretical ideas turn out to be correct in the end. If verification were straightforward almost all theorists would see their vacuous ideas butchered by experiments.

   The fact there is no way to separate the wheat from the chaff brought progress in fundamental physics to a halt.

4. **Wyman**
   June 9, 2010

   Boltzmann saw no evidence of the atomic hypothesis? The man pioneered statistical mechanics! Just because there was still resistance to the atomic hypothesis does not mean there was no evidence–Dalton saw evidence of the atomic hypothesis before Boltzmann was even born.

5. **Thomas Larsson**
   June 10, 2010

   I expect to see the disproof of supersymmetry, and thus indirectly of string theory, at the LHC in my lifetime.

6. **Anonymous**
   June 10, 2010

   Can we even see a *defining equation* of string theory within our lifetime?

7. **Giotis**
   June 10, 2010

   The real power of String theory is that it *explains* things in a consistent way and does not just describe them. This is essential for a TOE. If someone could give a better explanation for the origin of the field content in 4D for example then we could compare the two approaches. Until then String theory is the only viable explanation and thus it would be very interesting to see where it can lead.

8. **Peter Shor**
   June 10, 2010

   Giotis,

   I keep hearing this, and I keep asking how string theory explains the black hole information paradox (how does information get out of a black hole?), and I keep getting completely incoherent answers. Maybe I'm dumb, but it certainly doesn't explain everything to me.

9. **Bob Levine**
   June 10, 2010

@giotis:

The real power of String theory is that it *explains* things in a consistent way and does not just describe them.

While I'm not dead keen on a lot of what she says, Nancy Cartwright in one of her books notes that explanatory success accompanied by descriptive failure is a bad way to do science, at least over the long haul. Given its detachment from any observable context which could constitute an empirical test, it's hard to see any descriptive efficacy in ST. And we've yet to be given any real reason to believe that the theories in physics which *do* connect with observation fall out as theorems from ST. So exactly what is the explanatory triumph you appear to be attributing to ST which redeems its descriptive failure ?

10. **a quantum diaries surivivor**
June 10, 2010

Let me play the devil's advocate for this once.

The question involved the time the two scientists think -or are willing to state they expect- to live, together with the time before they think a first evidence for string theory will concretize. So they had to give a statement on the ratio R=T_s/T_d between the time to an evidence for string theory and the time to their death, and they both said they would be suprised if this ratio R turns out to be smaller than 1.

If you consider it this way, claiming that sihce they believe that R>1 they should work on something else makes as much sense as saying that the Tevatron should not search for the Higgs boson, given that the expected reach on the ratio R between the observable Higgs rate and the expected SM one is larger than unity…

Cheers,
T.

11. **Dave B**
June 10, 2010

Or maybe they think that we will all be eaten by a black hole before we get to the energies we need to test string theory 🙂

/gets coat & sneaks away

12. **Peter Woit**
June 10, 2010

I think that what is more relevant than specific estimates of the distance to the goal of string theory unification is the time evolution of these estimates.

1985: String theory enthusiasts were very excited, many were convinced that evidence would be found within a few years, say less than five.

2000: A typical estimate might be more like 20 years to go. See
http://www.longbets.org/12 where in 2002 Kaku and others were willing to bet money on superstring unification before 2020.

2010: Given normal life expectancies, we're now talking about more than 40 years from now as an estimate from string enthusiasts about when they will have evidence.

13. **dan**
June 10, 2010

@Thomas Larsson – how would LHC DISPROVE SUSY? If SUSY is not seen couldn't that be consistent with a breaking scale above LHC energies?

Are there genuine particles or phenomena the LHC could plausibly see, such as technicolor, or Top-quark assisted technicolor, 4 generations of SM, preons, higgless EW breaking, or the non-detection of SUSY partners such as little Higgs, that would definitively discredit SUSY?

14. **Mitchell Porter**
June 10, 2010

I spent the last month studying something out of string theory – the F-theory GUT models – because they very clearly have a chance of looking like reality. It seems inevitable either that the F-theory program will issue in the discovery of string-theory backgrounds which are completely consistent with experiment and cosmological observation, and in which all Standard Model parameters have a concrete explanation in terms of compactification, brane configuration, and various "fluxes"; or that the program will result in an impossibility theorem, to the effect that such models can't do the job after all. I'd expect one outcome or the other within a few years, and obviously it's big news either way.

So I struggle a little to understand what Greene and Kachru are thinking. But the panel discussion was about extra dimensions, so probably they were talking about direct experimental evidence for extra dimensions, such as missing energy. The F-theory models prove that you can already interpret particle physics in terms of specific higher-dimensional phenomena, so I would have thought there's a very good chance that we'll have indirect arguments for extra dimensions very soon.

15. **anon.**
June 11, 2010

I haven't followed all the latest papers, but early on F-theory GUTs ignored all moduli stabilization problems, and had at best a hand-wavy argument for preferring (fairly high-scale) gauge mediation to gravity mediation. (My experience is that gauge mediation tends to be delicate — it's difficult to stabilize all moduli and cancel the C.C. without breaking SUSY.) So there's a long chain of tenuous arguments that end up predicting — minimal gauge mediation! Which, of course, predates F-theory GUTs by many years. Seeing it wouldn't convince anyone of anything about high-scale physics, beyond the zeroth-order question of what scale SUSY is broken at.

16. **Rudigger**
June 11, 2010

I'd be surprised if string theory makes a definite prediction in my lifetime.

17. **Anon2**
June 11, 2010

Even if you can't get falsifiable *predictions* from string theory, you could still falsify some of the assumptions it is built upon. E.g. spin-2 gravitons seem to everyone to be logical and necessary and require some kind of stringy framework unlike the spin-1 vector bosons in the Standard Model, but suppose gravity doesn't conform to the expectations of Pauli and Fierz, and isn't spin-2. It's looked logical to Ptolemy to model the sun and stars daily orbiting the Earth… things did not turn out to be that simple.

Like Ptolemy's epicycles, string theory is an ad hoc mathematical explanation for a widely held prejudice which still hasn't a shred of experimental evidence behind it. Maybe we need a new Kepler.

18. **AdSCFTfan**
June 11, 2010

OK, maybe string theory has not predicted anything definite about the real world yet. But via the AdS/CFT correspondence it has made many precise predictions about some gauge theories at strong coupling, like the N=4 supersymmetric Yang-Mills.

These predictions are testable. In fact, some of them have been tested by solving for some qauge theory quantities as functions of the coupling and comparing with string theory at strong coupling. It works!

Maybe this is not enough to satisfy some of you critics, but I find this amazing.

19. **Fluffy Eschaton**
June 11, 2010

AdSCFTfan: Woit has been fairly consistent in saying that it's string *unification* he thinks hasn't panned out, not all the mathematical developments associated with string theory.

20. **Remo**
June 11, 2010

> @Thomas Larsson – how would LHC DISPROVE SUSY? If SUSY is not seen couldn't that be consistent with a breaking scale above LHC energies?

Dan, if no hint of susy were observed at the LHC it would mean, as you say, that its scale is significantly higher than 10 TeV. In that case it would lose most, if not all, of its phenomenological appeal.

21. **AdSCFTfan**
June 11, 2010

Fluffy Eschaton:
Thanks for the clarification. Why is this blog still called `Not Even Wrong' then? Them there harsh words…
Isn't it time to admit that string theory gets some things right? Hey, you never know: the real world may budge next!

22. **Mitchell Porter**
June 12, 2010

anon., what I anticipate is that a specific higher-dimensional effect may become the standard explanation for a specific unexplained feature of the Standard Model. The analogy is with SU(5) GUT explaining the weak mixing angle and supersymmetric GUTs providing exact unification of running coupling constants. For example, the F-GUT explanation of flavor hierarchies (arXiV:0906.0581).

23. **Giotis**
June 13, 2010

Dan is right. Even if LHC falsifies SUSY in 4D it doesn't mean that SUSY doesn't exist in 10 or 11 dimensions i.e. in the energy realm of string/M theory. Supersummetry is inevitable in String theory for internal consistency reasons and not because it is a good candidate for physics beyond the standard model in 4D.

So even if LHC falsifies SUSY in 4D they could always construct models that break all the SUSY in 4D upon compactification. They will have to search for a different kind of vacua that's all.

24. **dan**
June 19, 2010

@ Remo, Michio Kaku, Lubos and other string partisans have argued that it is merely a limitation of collider technology that prevents experiments above 10 TEV scale. If SUSY is broken above 10 TEV, and there were colliders that could explore this scale, wouldn't it be phenomenologically interesting? Maybe not stabilizing EW scale but perhaps DM candidates?

@ Giotis the successor to CDMS II is SuperCDMS. It evidentally has the sensitivity to detect neutralinos over its entire parameter space.

SUSY dark matter in light of CDMS II results: a comparative study for different models
Authors: Junjie Cao, Ken-ichi Hikasa, Wenyu Wang, Jin Min Yang, Li-Xin Yu (Submitted on 5 May 2010)

"(i) For each model the new CDMS limits can exclude a large part of the parameter space allowed by current collider constraints; (ii) The property of the allowed parameter space is similar for MSSM and NMSSM, but quite different for nMSSM; (iii) The future SuperCDMS can cover most part of the allowed parameter space for each model."

If the LHC does not find neutralinos, and the future SuperCDMS (and other direct and indirect dark matter detection) also fails to detect neutralinos with sensitivity to detect them over its parameter space, is there a plausible SUSY model (4D or 11D, planck-scale, etc.) that could account for both null results?

Can SUSY be a symmetry of nature broken at any scale if neither LHC nor SuperCDMS detects them?

25. **Thomas Larsson**
June 20, 2010

"Can SUSY be a symmetry of nature broken at any scale if neither LHC nor SuperCDMS detects them?"

From Frank Wilczek's [Future summary]() from 2001, p 20:

"Of course, the ultimate test for low-energy supersymmetry will be to produce some of the predicted new R-odd particles. Even in the focus point scenario, there must be several accessible to the LHC."

26. **Giotis**
June 22, 2010

@Dan

Yes of course. Supersymmetry has been well established by String theory as a theoretical concept at high energies.

Whether it would be observed at the low energies of LHC is not vital for Supersymmetry although psychologically this would be bad news for SUSY and String theory.

Moreover the vast majority (if not all) of String theory models have been constructed for N=1 SUSY in 4D so a failure in LHC would have I guess a significant impact in 4D model building.

LHC Update

June 11, 2010
Categories: Experimental HEP News

See here for a new status report on the state of beam commissioning at the LHC. About two weeks ago a peak luminosity of about 2 x $10^{29}cm^{-2}s^{-1}$ was reached, using beams with 13 bunches, but each bunch relatively low intensity. Since that time, efforts have been directed at increasing the bunch intensity towards nominal values. During this process, there has been little new physics data gathered, although the plan has been to interleave physics runs on weekends with beam commissioning during the week.

On Wednesday, this plan was changed, with the focus now completely devoted to commissioning beams with nominal bunch intensity. The hope is to have collisions of high intensity bunches in two weeks or so and then provide a 4 week period of stable running for physics during August, at luminosities an order of magnitude higher than now available. The limiting factor will be the stored energy in the beam, which is approaching Tevatron levels. To go higher will require much more testing of the beam protection systems.

This week in Hamburg there was a conference people have been waiting a long time for, Physics at the LHC 2010, the first conference devoted to the presentation of LHC experimental results. So far the results are based on very low luminosities, so are only able to check that the machine is working and rediscover various well-known features of the Standard Model. As the luminosity increases, it will start to become possible to observe or rule out various exotic particles at masses not reachable by the Tevatron, as long as the cross-sections are high.

Mostly such things are unmotivated and not expected to turn up, but one story to watch is that of supersymmetry, as the LHC becomes capable of observing strongly-interacting superpartners at masses beyond the Tevatron's reach. The MSSM includes a huge number of unknown extra parameters, so the masses of these things are unknown. Given one motivation for supersymmetry, that it is supposed to stabilize the electroweak scale, one would expect superpartners to readily show up at the new mass ranges being investigated by the LHC. The problem with this is that it's hard to understand why they haven't already been seen at the Tevatron, or indirectly in other experiments through the effects of higher-order processes. Taking current non-observations into account, even if one has faith that superpartners exist at masses the LHC can probe, it doesn't seem likely that the earliest LHC data will be able to see them (for more specific analysis along these lines, see for instance this talk).

I'm quite dubious that the LHC will ever see superpartners, but many prominent theorists claim that this is likely to happen. It would be interesting to pin them down on what LHC luminosity is needed to see what they are expecting to see.

Update: A particularly noteworthy talk is that of Mike Lamont, where he gives estimates of the progression of integrated luminosity this year. They're significantly more pessimistic than similar estimates from early this year, with about 50 inverse pb this year instead of 200, but still on track for 1000 inverse pb by late 2011.

Comments

1. **lhc**
   June 11, 2010

   It is a delicate balance, to spend time to test and commission the machine (higher energy, more bunches, etc) — which may result in possible failure of the strategy — and to run a stable machine for HEP, at a lower energy and luminosity.

   LHC and finding superpartners — I look at my marriage and I realize that finding a superpartner is indeed a very speculative notion.

2. **Geoff Brumfiel**
   June 11, 2010

   So just out of curiosity Peter, what are you putting your money on the LHC finding first then?

3. **Peter Woit**
   June 11, 2010

   Geoff,

   Unfortunately I don't see any reason to expect new strongly interacting particles, a new resonance, or anything else visible with the amount of data the LHC is likely to produce this year and much of next year. I would love to be wrong…

   By late next year possibly and more likely in 2014, they should start having the data necessary to either see a Higgs, or rule it out and maybe see something else that is responsible for electroweak symmetry breaking, that's when it seems likely that things will get interesting. An at least during next year, for the Higgs they'll be in competition with the Tevatron.

Millennium Prize Update

June 11, 2010
Categories: Uncategorized

The Clay Mathematics Institute this past week sponsored a conference in Paris devoted to celebrating the proof of the Poincare Conjecture. This included a short ceremony on June 8th awarding the Millennium prize to Perelman, which included several laudations explaining his achievement.

The question of what happens to the million dollars remains unresolved, with the following statement issued yesterday:

> The Clay Mathematics Institute has no plans for the Millennium Prize funds other than to respectfully wait for Dr. Perelman's decision. No deadline has been fixed for his decision, and nothing has been said or will be said about the possible use of the funds. Please see the text and laudations below for what is truly important: Dr. Perelman's great gift of a solution to the century-old conjecture of Henri Poincaré, and Thurston's geometrization conjecture. Their solution was celebrated at a conference in Paris held June 8-9, 2010. Those present send their congratulations and best wishes to Dr. Perelman.

Comments

1. **Syzygy**
   June 11, 2010

   Among the laudations for Perelman from several very distinguished mathematicians, I would like to bring attention to Thurston's: It is the only one to hint that perhaps what is most admirable about Perelman, even beyond his awesome mathematical strength, is his courage to stay true to his convictions and to challenge all this relentless chasing after fame and external recognition at the expense of caring for our "deeper needs". I'm glad that someone of Thurston's calibre thought to make this point clear. The other laudations, while full of praise for Perelman's mathematical heroism, do not say anything essentially fresh.

2. **D R Lunsford**
   June 11, 2010

   Peter, for you next book, I wish you would write up an historical exposition of this and related work, understandable to non-specialists with some grounding in advanced mathematics.

   -drl

3. **Fred**
   June 11, 2010

   The Institute should make public a deadline for Perelman to accept his prize. If no response, they should just give the money to charity. If Perelman doesn't want the money, this would be a perfect opportunity for him to make a tangible contribution to humanity by accepting the prize money and immediately giving it to charity. This is a million dollars here. Do you know what a million dollars could do? These people should get out of their ivory towers and look around at the world.

4. **Peter Woit**
   June 11, 2010

   drl,

   I'm afraid this is a topic way beyond my competence. There's at least a couple popular books already (by Szpiro, Gessen) and various survey articles at different levels. But the kind of geometric analysis behind Hamilton's work and the Perelman proof is way beyond me. I know just enough about it to know the kind of time commitment that would be needed to really understand it…

5. **Dr.Kathrine Martinez-Martignoni**
   June 11, 2010

   Why don`t they send this "Millennium Prize" (one millions US dollars)directly to the mother of Perelman who is living in a very poor way in St.Petersburg?
   Best wishes,
   Dr.Kathrine M.(Switzerland).

6. **Roger Schlafly**
   June 11, 2010

   It is funny how everyone says that Perelman turned down the prize when he has said nothing. It is also funny how people like Fred try to tell Perelman what to do.

7. **ghengis.khandada**
   June 11, 2010

   Perelman once said the greatest reward for proving the Poincare conjecture is the proof itself, and that the best way to honor him/his work is to re-direct our time and energy to understand the proof. Perelman gives me tremendous hope by being a purist to the end.

8. **Fred**
   June 11, 2010

   Roger,

   I just meant that as a suggestion for Perelman, that's all. If he really wanted the money/prize, he would have said something by now. He clearly doesn't want the money, so I offered the suggestion that the Institute just give the money away to charity. The other suggestion, mentioned above, is that he money go to his mother instead. If Perelman wants all this hoopla to lead to something good, then my suggestion was for him to accept the money and give it to people who need it, since he clearly doesn't want it. You can find plenty of people/causes that would benefit from the money. It's a good opportunity for him to make this happen. I don't know about you, but I think that's a good idea.

9. **BigG**
   June 11, 2010

Fred,

Given the number of needy people in the world what Perelman is doing is extremely selfish. It's really cool he's not accepting the money on principle, but he could redirect the Clay Inst. to donate the money or accept it on the grounds he will donate it. Wittgenstein did something similar and for similar reasons.

As for the other guy, why bother responding to people who obviously are not seriously interested in what you have to say? If there is no serious engagement with the issues or interest in a disscussion there's no basis for debate.

10. **Haelfix**
June 12, 2010

Alternatively the Clay inst. could just create a new question (there are many worthy ones) and have instant funding.

11. **Anonymous**
June 12, 2010

This Fred and BigG sillness reminds me of piles of angry letters Grothendieck recieved upon his decline of Crafoord Prize. The particularily absurd one was from a woman accusing him of robbing French people from Kenseyian stimulus the economy would recieve would he spend his prize money in France.

Also, Dr Kathrine, Perelman probably cares more about his mother than you do about her. I'd also like to point that Perelman recievied a few prizes in the nineties and is moderately wealthy by Russian standards.

12. **Bob Levine**
June 12, 2010

"This Fred and BigG sillness reminds me of piles of angry letters Grothendieck recieved upon his decline of Crafoord Prize. The particularily absurd one was from a woman accusing him of robbing French people from Kenseyian stimulus the economy would recieve would he spend his prize money in France.

Also, Dr Kathrine, Perelman probably cares more about his mother than you do about her. I'd also like to point that Perelman recievied a few prizes in the nineties and is moderately wealthy by Russian standards."

Well said on all counts, Anonymous!

This thread raises a question which is much more general than the question of what Perelman is going to do—namely, what is the virtue (or otherwise) of these huge cash prizes that are associated with specific prizes for scientific discovery? Does the prestige of the physics Nobel, for example, really depend on the attachment of approximately $1,500,000 US to it? Suppose the prize were reduced to $10,000, but everything else about the award were left intact—would that alter the role of the Nobel in singling out the absolutely highest level of achievements in physics and the other disciplines it's awarded for?

Suppose the answer to that one is 'No'. The next question one would want to ask would be, does the award of the Nobel actually promote achievements in the Nobel disciplines which otherwise would not be reached, or not reached until much, much later?

My impression is that Perelman's point in declining the Field Medal, and (in all likelihood) the Millenium Prize, is to forcefully express his own judgment on these questions: a sound result is the only authentic reward of scientific investigation. Everything else is, well, hype. Does anyone *really* want to argue that the opportunity to support this or that charity trumps taking and maintaining such a principled position?

13. **BigG**
June 12, 2010

It's absolutely not silly. This western idea of the lone genius can lead to extremely selfish thinking. When you have homeless and starving people who cares about your purity as a mathematician. The European enlightenment was a good thing but individual self-determination can be taken too far. It may be a long time before people like you understand this.

14. **Jack Lothian**
June 12, 2010

Turning down a prize is selfish??? While I presume accepting it isn't selfish?? That is silly. Forcing Perelman to accept the prize & donate it charity would be unethical and morally unacceptable. Yet you feel this should be done on his behave & against his wishes because it makes you feel better? While I would not make the same decision as Perelman, I respect his right to make his decision.

Truth is, his decision awes me. I wonder if maybe he sees further then me even in non-mathematical issues.

15. **Coin**
June 13, 2010

It seems to me that by not accepting the prize, Perelman is effectively donating a million dollars to the Clay Institute. This seems like a not unreasonable use of a million dollars to me.

16. **BigG**
June 13, 2010

Jack you haven't read what I said closely. No one can make him accept the money but not doing so on some principle of the purity of maths is selfish. It has nothing to do with making me feel better and by saying this your unfounded assumptions while reading become clear.

The idea that a principle of the purity of math is somehow more important than helping others is selfish. Who cares about math in comparison with relieving the suffering of others? On a personal level, the decision by itself to stand up for one's principles is admirable. But given the money and what can be done with it, there are times when a principle such as this needs to be put aside.

There are two points of view of this principle, one for himself and one for the discipline of math. Both these are less important than helping those in need. In comparison, who cares about Perelman and who cares about math. They are meaningless from this point of view.

I would also be in awe of Perelman from a personal perspective of standing up for one's principles. But there is nothing to be in awe of when you consider how much could be done.

Consider a thought experiment. His mother is sick and too poor to receive treatment. He turns down the prize because of some personal principle. Is he worthy of awe now or completely selfish? This is exactly the situation he's currently in.

You need to think about what's being said. When your perspective begins to go from me to them you will understand my point.

17. **Sansa**
June 13, 2010

For the people condemning Perelman for not accepting $1M and giving immediately to charity, why aren't you also condemning Landon Clay for not giving $7M to charity?

(Also BigG consider a thought fact: Russia has UHC)

18. **Fred**
June 13, 2010

Bob Levine:

"My impression is that Perelman's point in declining the Field Medal, and (in all likelihood) the Millenium Prize, is to forcefully express his own judgment on these questions: a sound result is the only authentic reward of scientific investigation. Everything else is, well, hype. Does anyone *really* want to argue that the opportunity to support this or that charity trumps taking and maintaining such a principled position?"

Suppose this money could be used to educate people about science in a third world country. I believe this kind of thing trumps such a principled position because holding such a position accomplishes nothing. Accepting the money in an effort to make peoples' lives better accomplishes something. It takes money away from rich people, using it in the service of others.

Here's a suggestion for the Institute. If Perelman doesn't accept the prize money in two weeks, the Institute will use the money to develop schools that educate people about science and math. Schools in countries too poor to have them.

19. **BigG**
June 13, 2010

Sansa,

I'm not condeming Perelman. You need to read what I'm saying more closely. I never used the term condem. Another simple analogy will make the point clear. If you over pay for something and I say 'you paid too much for that' there's no condemnation. That's your choice. All I'm doing is stating my opinion that you paid too much money. These words don't imply anything else.

Your comment about Russa having UHC misses my point completely. Its an abstraction from people in general to someone in particular that makes clearer how he would be selfish not to accept the money if someone needed it.

Fred seems to be the only one who understands my point. I don't care if you agree or not with me but most of those who disagree don't understand my point. As a result, when they reply they make claims that are not supported by what I wrote.

"I said he would be lonely, & he said he prostituted his mind talking to intelligent people."

20. **John Bacon**
June 13, 2010

> "Who cares about math in comparison with relieving the suffering of others?"

I do. In the end Perelman's work is far more important than the lives of thousands if not millions of humans. Certainly yours or any commenter here.

Human life is severely over-rated. Most humans are trash and contribute nothing to understand the world and advance knowledge only concerning themselves with stupid societal pursuits such as kicking a ball into a net or deceiving other people for social/financial status.

In the end Perelman's work trumps all of this trash and so does is right to refuse the prize for whatever reasons he sees fit.

> His mother is sick and too poor to receive treatment. He turns down the prize because of some personal principle. Is he worthy of awe now or completely selfish?

Both.

People who aren't openly selfish always have insidious ulterior motives that make them far more dangerous than ones that those who are selfish.

21. **Peter Woit**
June 13, 2010

Enough, the comments here reveal all too much about the commenters, but nothing at all about Perelman and his situation. Don't submit comments unless you have something informative about the topic of the posting to contribute.

22. **basic arithmetic**
June 14, 2010

To put things into perspective, $1miilion represents about 0.00001% of the USA's (annual) GDP.

23. **Tim van Beek**
June 14, 2010

At the end of the 1990ties I spent a few weeks at the institute Laue-Langevin in Grenoble, France, and got to know some scientists from Russia, they had grants and tried to save as much money as they could, because at that time you could live like a year in Russia with the money you had to spent during one month in Grenoble. They did research, too, but one told me that the main reason for him to go to Grenoble was to get French money and use that to fund his research back home.
Perelman's story reminds me of him, maybe he would have refused the million dollar price, too, if having this amount of money would mean that he could not concentrate on his research as much as he liked to, and if he did not need it because his savings were enough to survive.
I have always admired the Russian experimentalists, who were able to produce results despite their unfavorable economic situation.

24. **ML**
June 14, 2010

I live in Stcokholm, just an hours flight from St Petersburg, where
I have good friends well connected in mathematics. I wanted to invite Perelman to Stockholm as a short-term guest, with no commitments from his side. But the message from Perelman was that he was not willing to discuss anything related to mathematics.

25. **The Vlad**
June 14, 2010

I think the interesting questions are: Is he still doing math? And if so, what fantastic insights and technical advances is the academic community missing because of his reclusivity? Presumably he is documenting his putative findings in such a way that those who eventually follow him–should his work ever see the light of day–can build on that work.

26. **Pilot**
June 16, 2010

With apologies to Peter ("Don't submit comments unless you have something informative"), here is my suggestion: Perelman should accept the award, take the money and declare a million-dollar-prize of his own for his favourite problem in mathematics. Or better, award it to the next Henri Poincare. He certainly deserves at least ten million dollars and Perelman can start by redirecting his one? 🙂

27. **Arun**
July 1, 2010

http://news.yahoo.com/s/ap/20100701/ap_on_sc/eu_sci_russia_math_genius

Grigory Perelman, a reclusive Russian mathematics genius who made headlines earlier this year for not immediately embracing a lucrative math prize, has decided to decline the cash.

Perelman's decision was announced Thursday by the Clay Mathematics Institute in Cambridge, Mass., which had awarded Perelman its Millennium Prize.
….
….

Jim Carlson, institute president, said Perelman's decision was not a complete surprise, since he had declined some previous math prizes.

Carlson said Perelman had told him by telephone last week of his decision and gave no reason. But the Interfax news agency quoted Perelman as saying he believed the prize was unfair. Perelman told Interfax he considered his contribution to solving the Poincare conjecture no greater than that of Columbia University mathematician Richard Hamilton.

"To put it short, the main reason is my disagreement with the organized mathematical community," Perelman, 43, told Interfax. "I don't like their decisions, I consider them unjust."

28. **Benni**
July 1, 2010

Perelman now has officially declined the clay prize.

According to recent press articles, Perelman told:
http://www.spiegel.de/wissenschaft/mensch/0,1518,704113,00.html

Perelman thinks that Richard Hamilton deserves the prize similarly than does Perelman. Perelman says the decision of the Clay institute therefore would not be fair. As a consequence, he refused to accept the prize.

This seems to be a reasonable decision. It is always doubtful, if an achivement like this in mathematics can be attributed to one single person who can be given an avard. Often, there are more people involved in a proof than just one person.

29. **Tim van Beek**
July 1, 2010

I've read that article, too, but, oddly enough, there does not seem a link or hint to the source. Surely, no one from the spiegel online editorial staff talked to Mr. Perelman in person, right?

30. **Arun**
July 1, 2010

This version reports Perelman saying that he had as many reasons to accept as to decline the prize and that is why it took him so long to make a decision. I'm glad he considered taking the award.

Source: Tanjug News Agency

Russian mathematician Grigory Perelman decided to reject the Millennium Prize worth $ 1 million from the American Clay Mathematics Institute, the Interfax News Agency reported.

"I declined the award. **I had as many reasons to accept it as to turn it down.** That's why it took me so long to make the decision" Perelman said.

The main reason for his decision to reject the award was its "unfairness".

"I think my contribution in solving the problem of the Poincare conjecture was not greater than the one of the American mathematician Richard Hamilton."

Predictions From David Gross

June 14, 2010
Categories: Uncategorized

Video of David Gross's talk at the Physics at the LHC 2010 conference is now available. He devotes much of the talk to reviewing predictions he made back in 1993 of what would happen by 2008, and making new predictions for what will happen by 2020.

The 1993 experimental predictions that didn't work out could mostly be explained away by the SSC cancellation, which pushed investigation of TeV scale physics into the future at the LHC. In 1993 Gross predicted two light Higgs particle and superpartners (due to supersymmetry), new Z-mesons (i.e some new U(1) gauge fields) and "There will be cloudy evidence of superstrings." His 1993 predictions about theoretical developments related to string theory didn't work out very well:

> String field theory will begin to be a useful tool and will illuminate the underlying symmetries of the theory. (*not at all, he admits*)
>
> New mechanisms of string supersymmetry breaking will be discovered leading to new and definitive low energy models. (*new maybe, certainly nothing definitive*)
>
> The conceptual revolution arising from the nonperturbative formulation of string theory will be in full swing, revolutionizing the concepts of space-time geometry. ("*on its way, but it hasn't really revolutionized our concepts*")

For 2020, Gross makes one striking non-scientific prediction: The US will join CERN and there will be a joint plan to build a linear collider at CERN.

His experimental predictions include a repeat of the 1993 ones (superpartners, new Z-mesons, and the Higgs, although now he only mentions one Higgs), except that he has now given up on even "cloudy" evidence of superstrings showing up at the TeV scale. His theoretical predictions include a much scaled back version of the 1993 theoretical predictions about string theory: "If we're lucky, string theory will start to be a theory with predictions (right now we don't understand it)".

As far as supersymmetry goes, he says that he is "totally convinced that SUSY should be there, at the 50% level" and repeats his offer to take bets at 50/50 odds. One of the main motivations for this is the argument that SUSY can provide a suitable dark matter candidate, and he predicts observation of dark matter by 2020 at non-accelerator experiments.

Finally, he ends up with an attack on the anthropic explanation of the CC, and predicts that a better one will be found by 2020.

Update: See Lubos, who has a lot more energy than I do, for a transcription of Gross's predictions.

   June 15, 2010

   A linear collider at CERN? Has he ever looked at a map of the area?

6. **clic**
   June 15, 2010

   CLIC – the CERN LInear Collider or Compact LInear Collider
   homepage
   http://clic-study.web.cern.ch/clic-study/

   see also
   http://public.web.cern.ch/public/en/research/CLIC-en.html

   It is a project *by* CERN, even if the eventual location is not physically at Geneva.
   Moreover, the CLIC project has been under study for many years.

   Gross knows what he is talking about, as far as a linear collider at CERN is concerned. Whether or not the US will join CERN is a highly political question, and by 2020 is yet another question, but CERN has certainly demonstrated up to now that it (CERN) is prepared to go it alone (w/o USA), for CLIC. Whether CLIC itself will be ready (w/ or w/o USA) by 2020 is another question. A lot of course depends on the outcome from the LHC ~ the Higgs … at what mass? It may (will?) take years to accumulate and analyze the LHC data.

   not quite the same as asses

God Particles Breeding Like Bosons

June 15, 2010
Categories: Experimental HEP News, This Week's Hype

Science news in the media today is full of stories about Fermilab finding no less than five Higgs particles: God Particles Breeding Like Bosons, The 'God Particle' may exist in five forms, Large Hadron Collider's rival project finds, US experiment hints at 'multiple God particles', Fermilab Experiment Hints at Multiple Higgs Particles. The source of these stories can be traced back to this preprint, whose authors then appeared on this radio program, leading to this Symmetry Breaking story.

On May 18 D0 claimed observation of CP violation in processes involving B-mesons of a sort that could not be explained by the SM, at a significance level of around 3 sigma. For an explanation, a good place to look is Resonaances. A violation of the SM is an extraordinary claim, so it requires some extraordinary evidence, and a 3-sigma result is not that extraordinary. The case for such a violation was strengthened by the fact that D0 and CDF had seen a 2-sigma violation of the SM in a similar CP-violating process. The May 23 theory theory preprint tries to explain these SM violations with a model involving two Higgs doublets. Two days later though, on May 25, CDF reported new results: with better data, their 2-sigma SM violation had gone away (now it is 0.8 sigma, completely consistent with the SM). Again, for a good explanation of this, see Resonaances. Somehow, the disappearance of one of the main reasons for taking all this seriously didn't make it into the Symmetry Breaking story, or any of the flood of ridiculous stories that appeared today.

   There are voices about this new result, to be announced at summer conferences + press release

5. **Peter Woit**
   June 18, 2010

   Thanks Shantanu, hadn't seen those. Looks like more of the same about the landscape, a lot more about attempts to apply gauge-gravity duality to condensed matter physics.

   the broad Higgs,

   Now that's a very interesting rumor…

6. **Tona**
   June 18, 2010

   The DZero collaboration does not claim that the 3 sigma result proves asymmetry, just that it MAY point to that. The collaboration is happily waiting for CDF or the LHC to cross check its analysis.

   The CDF paper released a coupld weeks ago and mention here and in the Resonaances blog does not confirm or disput the DZero result. It is like comparing apples to oranges.

   The CDF collaboration did release a sin(2beta_s) result a few weeks ago that looked at CP violation states and found the discrepancy between the amount of particles that decayed to matter versus antimatter in line with the Standard Model, the opposite of what DZero's study found. The CDF study is an update of a 2007 meson decay analysis that both CDF and DZero conducted where both found discrepancies in the preference for decays to matter and antimatter. The recent CDF update of this analysis, which is being submitted to the scientific journal Physical Review Letters, found a smaller discrepancy than in 2007. DZero has plans to conduct its own update.

   However, comparing the updated CDF study and the current DZero asymmetry result is like comparing apples and oranges. True, both studies look at CP violation in meson decays, which can be used to search for "new physics" beyond the Standard Model. However, while the studies look at the same underlying physics, they use vastly different approaches and analysis methods that renders it impossible to draw a conclusion from the CDF study that would deny or confirm the DZero asysmmetry result, according to CDF leaders. Also, the uncertainties of both measurements more than "cover" the disagreement – so neither rules the other one out.

   What the CDF study does do is highlight the need for CDF to conduct an apple-to-apple type study of the current DZero result that would have the potential to validate or invalidate it.

   While there was some initial discussion, even among CDF collaborators, about whether CDF could perform the same search because the magnet construction in its detector differs from DZero's, CDF collaborators believe they can reach the same level of sensitivity as DZero to the decays.

   CDF conducted a similar apple-to-apple type study several years ago, but with a much smaller dataset, not enough to make a judgment either way, according to collaboration leaders. The DZero result is based on more than 6 inverse femtobarns in total integrated luminosity, corresponding to hundreds of trillions of collisions between protons and antiprotons in the Tevatron collider.

However, the success of CDF's past study, leads CDF collaborators to believe they can conduct a larger, comparable analysis, although in a slightly different fashion, than the past CDF study and the current DZero study.

The CDF collaboration announced at the Fermilab Users' Meeting in early
June that it will perform this analysis with its full data set. The duration of the study will depend on the amount of preliminary work conducted, but collaborators estimate a result in time for a presentation at the winter 2011 physics conferences if the CDF search turns out to be as competitive as DZero's.

You can read an expanded version of this at the updated symmetrybreaking post: http://www.symmetrymagazine.org/breaking/2010/06/04/could-dzero-result-point-to-multiple-higgses/

7. **Peter Woit**
June 18, 2010

Tona,

Thanks for clarifying this. However, it should be pointed out that the theory paper about the "five Higgs particles" makes a big deal about the older D0/CDF result indicating non-SM CP violation in a different process, discussing it extensively on the first page of the preprint. The bottom line in this discussion on the first page is that, combining old and new, the new D0 result is 2.5 sigma from the SM. The authors then combine this 2.5 sigma with the old 2.1 sigma deviation to argue that there is a violation at 99.9% confidence level. This argument gets blown away by the new, better CDF measurement, and I assume the authors at some point will revise their preprint to take this into account.

Even with independent 2.5 and 2.1 sigma deviations, it seems to me to be a bad idea to go on the radio trying to sell the highly speculative explanation they have. I don't know when the radio interview was, but if it was after the release of the CDF result then it was an even worse idea. I listened to the first few minutes of the interview and the extent to which the interviewer had no idea what was going on and the physicists little interest in explaining the highly speculative nature of their work made the whole thing almost comical.

Various and Sundry

June 21, 2010
Categories: Uncategorized

- Last week's symposium in Paris on Symmetry, Duality and Cinema now has talks available on-line. These include a very nice survey talk by Edward Frenkel, including some comments on his recent work with Langlands and Ngo that involves an analog of the trace formula in the geometric case. The symposium also included a showing of Frenkel's film *Rites d'amour et de maths*, and the Huffington Post has an article about the film here.
- Some notes from this year's Talbot workshop on Twisted K-theory and Loop Groups have started to appear here.
- For the last three weeks or so, the LHC has not been taking data, but instead working on commissioning the beam at higher intensity. This process should end soon, and the plan is to have physics runs this summer with up to 24 bunches/beam, getting an integrated luminosity of around 5 pb^{-1}.
- For an excellent article on the science job market in the US, see The Real Science Gap. The author quotes from this posting about 2009 particle theory hiring. Numbers for 2010 so far look similar.
- The authors of the preprint that led to the "Five Higgs" world-wide hype-fest (see previous posting) have put out a revised version of their preprint. The first version gave as major motivation corroborating SM-violating data in another channel from earlier experiments, but this has gone away in recent CDF data. The new version removes most of the discussion of this, leaving one paragraph that seems odd to me, since it refers to the recent CDF data as "strengthening the case for physics beyond the SM", although that data only disagrees with the SM at the .8 sigma level.
- In Denmark it seems that they take their quantization of moduli spaces very seriously, with the Center for the Topology and Quantization of Moduli Spaces at Aarhus now joined by a new Center for Quantum Geometry of Moduli Spaces.

Comments

1. **Researcher**
   June 21, 2010

   Just a minor quibble: the letter p in *The Real Science Gap* is not linked.

2. **Peter Woit**
   June 21, 2010

   Thanks, fixed.

3. **nbutsomebody**
   June 22, 2010

   Peter,

   I had an impression that job market in Mathematics is better than that of HEP. Partially because less number of people graduating. Please correct me if I am wrong.

4. **Peter Woit**
   June 22, 2010

   nbutsomebody,

   I don't have any good numbers, but the job market seems to be much better in math than in HEP theory. The ratio of permanent jobs at research universities to people getting Ph.Ds at the top universities is much higher in math. In very rough numbers I'd guess that typical top US universities are each producing about 5 HEP theory Ph.Ds and 10 pure math Ph.Ds, who will end up competing for about 10 permanent HEP theory positions and an order of magnitude more permanent math research positions.

5. **Andy**
   June 24, 2010

   CQGM in Arhus is a continuation of CTQM, with the same director but under a different name.

String Theory Fan

June 21, 2010
Categories: Uncategorized

One of the weirder battles of the String Theory wars became known to some as “trackbackgate”, referring to arguments over the arXiv’s policy of not allowing trackbacks to this blog. I’ve mercifully forgotten the details of the story, other than that I wasted a lot of time arguing the issue with the authorities at the arXiv and Cornell, an argument that I finally lost. If you’re interested in the history, a couple blog entries you could start looking at would be this and this.

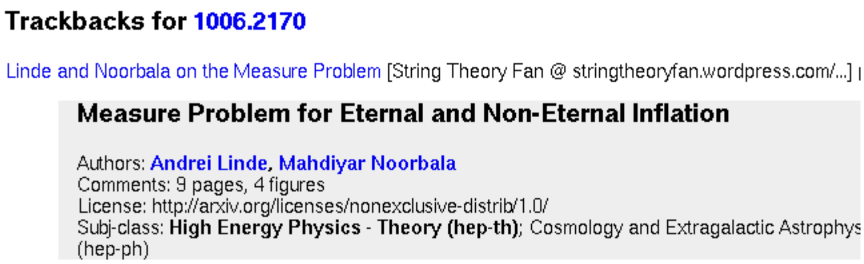
At some point the arXiv’s policy changed, and some trackbacks to blog entries here started to appear, as well as trackbacks to all sorts of media stories that linked to the arXiv. A little bit of checking seemed to indicate that trackbacks would appear if I linked to papers not in hep-th, but wouldn’t appear when I linked to hep-th papers. A recent example would be this blog entry, which linked to and discussed this paper. This made me a bit curious about what the arXiv current trackback policy might be, but from past experience I figured that trying to contact them to find this out was unlikely to get me anywhere.

One day recently it occurred to me that a way to find out something about this would be to start up another blog, write a posting linking to an hep-th paper and see what happened. It’s quite remarkable how little time it takes to start up a blog, so an hour or so later String Theory Fan was on the web, with an About section:

> This blog will be devoted to discussing the latest exciting developments in string theory, our best hope for a fundamental unified theory of particle physics and quantum gravity.
>
> The author is an academic actively studying this fascinating subject.

a first blog entry spouting hype about string theory, the multiverse and how uninformed critics were, and a second one linking to and superficially summarizing a randomly chosen recent multiverse paper.

Well, I still don’t know what the arXiv’s policy is about trackbacks to hep-th papers, but the data shows that while Not Even Wrong doesn’t seem to qualify, String Theory Fan does:



Trackbacks for 1006.2170

Comments

1. **Kea**
   June 21, 2010

   The shady activities of the arxiv are now well established. Fortunately, alternative sites such as vixra make the arxiv essentially redundant, even if professional ass kissing keeps it alive.

2. **Wyman**
   June 21, 2010

   I do hope research universities keep this in mind when Cornell comes to them begging for help paying arXiv’s server bills.

3. **Bee**
   June 22, 2010

   Well, that’s a little bit embarrassing for the arxiv admin isn’t it?

   In any case, it must be difficult for them to deal with the trackbacks. They probably want to preserve a certain quality standard so will try to avoid trackbacks to random crackpot sites. You can’t automate quality standard, so they will have to check them by hand. This inevitably brings in personal opinions and subjectivity and will occasionally cause problems. Not saying there’s a good reason to not list trackbacks to your blog in particular, I’m just saying the problem is one where such things are prone to go wrong every now and then.

4. **Stucker**
   June 22, 2010

   Peter,

   I’m usually critical of your activities, but this time, I have to admit, my hats off! 🙂

   Well done!

   Best,
   Stucker

5. **Syksy Räsänen**
   June 22, 2010

   Excellent, Peter.

6. **Anon2**
June 22, 2010

LMAO. Very funny. Their “policy” is string worship. But they probably don’t even realise how subjective they are.

7. **Fabio**
June 22, 2010

Hilarious. But you should have held out for a supportive link from Lubos before you spilled the beans.

8. **String mafia**
June 22, 2010

to proof that you are a real scientist, the next step is publishing a paper about the Multiverse with your colleague Sokal

9. **Peter Woit**
June 22, 2010

Fabio,

While Lubos approves of the string theory fanboy aspect of the blog, he’s not big on the Multiverse, so I doubt he would endorse “String Theory Fan”. To find someone willing to endorse both string theory fanboydom and Multiverse pseudo-science, it seems you need an arXiv hep-th moderator.

By the way, does anyone know why most multiverse papers like the one I linked to are in hep-th and not gr-qc? I’d have thought qc=quantum cosmology was exactly their topic, and they typically have no connection to HEP. Maybe the gr-qc moderators wouldn’t allow them…

10. **Alejandro Rivero**
June 22, 2010

Bee, the problem is that they automate quality standard, in other sense: once some decision about blocking has been evolved into code (Perl or any other matching algorithm, I dont know), it seems very hard for the next ArXiV moderators to review and remove them, specially when/if moderators and programmers change with time. For robot scans, for instance, it seems that the ban is kept ethernally. Death penalty for your IP.

11. **Peter Woit**
June 22, 2010

Alejandro and Bee,

The little information I have about this is that yesterday someone connected to the “String Theory Fan” blog from an arXiv trackback administrative page, and looked at all the “String Theory Fan” pages. Soon after that, the trackback appeared. This was definitely not automated, but I have no idea who was doing this, or what criteria they were using to decide whether “String Theory Fan” was trackback-worthy.

I’m not very surprised they found the site trackback-worthy, partly because they now seem to be operating under a very loose standard, allowing trackbacks from all sorts of postings from non-scientists (e.g. Slashdot). What is surprising is that even under this newer loose standard, my postings are still often being judged unworthy. These decisions seem to be being made manually, not automatically, but, again, I have no idea who is making them or what criteria they are using.

12. **Anon2**
June 22, 2010

“… I have no idea …”

Very tactful of you! (Surely, you don´t need top be Einstein to work out from the list of arXiv advisers, those who are old enemies of your blog.)

13. **Peter Woit**
June 22, 2010

Anon2,

I’m sure a certain member of the physics arXiv advisory board from the University of Texas has something to do with all this, but exactly what remains a mystery. Some of those who know him tell me he’s a reasonable guy, whose hands are tied by the true powers-that-be in this business. Seriously, I don’t actually have any idea what arXiv policy on this now is, or who is implementing it.

14. **nbutsomebody**
June 22, 2010

An excellent step.

15. **Roger Schlafly**
June 23, 2010

I am not sure your experiment proves much, except that a trackback can be approved quickly. Maybe someone dislikes you personally, or thinks you are a physics traitor, or thinks you are too negative about mainstream physics, or is offended that you attack sacred cows, or sees you as a threat to physics funding. It might be useful to do an experiment to distinguish these possibilities. Maybe you (or some reader) can start a blog that directly attacks the multiverse as unscientific, or says that the LHC is a big waste of money. Maybe you could throw in some Lubos-style rants.

16. **Janne**
June 23, 2010

Once again the true colors come out. Pathetic.

17. **younghun park**
June 23, 2010

Roget Schlafly

Your critic on Peter may be right.
I agree that Someone seems to dislike him and his act.

But, his writings make us think about what is true science.
Someone likes the concept of Multi-universe
and the others dislike the concept of Multi-universe.

It's not important that someone likes or dislike
that concept. The important thing is whether we are
going on the right way or not.
His blog makes us think about that question.

"Which way Now physics is going on?"
"That way is right or not?"

Maybe, it will be answered after the result of experiment
shows up through LHC.

I believe his critic on current physics will make current physics more healthy. I hope to see his active critical life.

18. **Benni**
June 23, 2010

Peter, If you want your trackbacks to appear, then make your comments at scirate.com.

This is a site where one can comment on arxiv papers. Trackbacks from that site are allowed, and any comment on a paper will automatically produce a trackback to the comment linked to the paper. (unfortunately, the comments are sometimes uninformed. For example, if someone does not like a paper, he can leave misleading claims on scirate on the article. Those rants then automatically produce a trackback that gets linked to the paper on arxiv.

19. **El Punko Rubio Herreras**
June 23, 2010

Yo, that is so el unprofessional to have done that, hombre. You will come to regret that, el mucho, grande mucho.

20. **Gphillip**
June 23, 2010

Their policy seems very clear. You are on the wrong side of the argument. You can either change the fundamental physics of the Universe, or learn to live without trackbacks. Trackbacks are so great, I'd suggest you change the fundamental physics of the Universe. Of course there are others who have been trying to do just that for decades, but I'd say you have just as much chance at it as they do. Good luck!

21. **sheldon**
June 24, 2010

Why exactly is it so important to have trackbacks from the arXiv to this blog? I am reminded of the quote by Sheldon Flender from the Woody Allen film "Bullets over Broadway"

http://www.imdb.com/title/tt0109348/quotes

Sheldon Flender: [bragging] I have never had a play produced. That's right. And I've written one play a year for the past twenty years.

David Shayne: Yes, but that's because you're a genius. And the proof is that both common people and intellectuals find your work completely incoherent. Means you're a genius.

22. **Peter Woit**
June 24, 2010

sheldon, Benni

I don't actually think it's of much importance to have trackbacks from the arXiv to blog entries here, so am not about to devote any more time to arguing the issue with them or figuring out some way around what they are doing.

But the arXiv itself is of central importance these days for the health of particle theory and several other academic fields. How they handle the tricky issue of moderation is of interest, so I thought devoting a couple hours to this test project was worthwhile. But, that's probably already more time than was sensible….

23. **Neville**
June 24, 2010

This episode is a hoot! Thanks for the entertainment.

Life is supposed to be fun.

24. **Lenny**
June 25, 2010

Peter,

While you are right that your experiment suggests that arxiv's trackbacks are not managed in a serious way, I'd join with others in agreeing that nor are they a serious thing about which to worry. Moreover, there is a danger to feeding the caricatural anti-establishmentarianism manifested by some of those on the fringe of legimitate science – there is a difference between wild, credible ideas and junk – and for the arxiv to be useful it is essential that the latter be excluded – that's not the old boy network – that's good management.

25. **Tim van Beek**
June 25, 2010

The arXiv is a central part of the hep-th community at least, so the way it is run and moderated is an important topic, certainly.

IMHO the next step would be to set up a blog like "string theory fan" and include watered-down versions of original rants, for example:

"LQG is just stupid. I know it because I once met a LQG expert, talked to him and he was just unable to understand what I said. Plus their Hilbert space is not separable."

And

"Modular localization in axiomatic QFT is plainly wrong, because it is not part of string theory, therefore I don't know what it is, which proofs that it has to be wrong. If it were right, it would be part of string theory. And it would be supersymmetric".

(In case anyone thinks that this is certainly not "watered-down": The relevant blog archives are all available online).

26. **Steven Jones**
June 25, 2010

i know this is a bit dark, and i might be wrong, or not even wrong, but sometimes i get the feeling that if we threw all the blog posts and comments and trackbacks into the trash, physics would not be harmed in any way, and may even be enhanced, as the snarky, handwaving, entrenched regimes of failure faded to naught, allowing new ideas to blossom.

never have so many insiders been paid so much to do little more than set up criterion and networks to define others as crackpots, beginning with the premise that their own non-theories, decades-old dead ends are non-crackpottery.

a little humility across the board would be a great thing, for until one comes up with a meaningful postulate and equation, how does one know that one is not a crackpot?

i suspect that this reality eats at a lot of people in modern physics.

for instance, when this is respectable research at major institutions:
http://www.amazon.com/Eerie-Silence-Renewing-Search-Intelligence/dp/0547133243/ref=sr_1_1?ie=UTF8&s=books&qid=1277494776&sr=8-1
http://www.amazon.com/Physics-Impossible-Scientific-Exploration-Teleportation/dp/0307278824/ref=sr_1_1?ie=UTF8&s=books&qid=1277494816&sr=1-1

what constitutes crackpottery?

I mean just look at the titles.

Physics of the Impossible: A Scientific Exploration into the World of Phasers, Force Fields, Teleportation, and Time Travel

The Eerie Silence: Renewing Our Search for Alien Intelligence

Imagine Einstein, Bohr, Feynman, Dirac, or Pauli having anything to do with the above titles….

27. **kevin strings**
June 25, 2010

why the above titles reflect most exalted physics!

crackpottery would be something like:

The Eerie Silence: Renewing Our Search for Phasers, Force Fields, Teleportation, and Time Travel

or

Physics of the Impossible: Renewing Our Search for Alien Intelligence

now books like these would be crackpottery!

28. **Peter Woit**
June 25, 2010

I don't think the two titles you mention are very highly thought of at most research physics departments, and their authors are not modern-day analogs of Einstein, Bohr, etc.

For a better example of something that is mysteriously highly thought of at certain physics departments (although not so highly thought of at many others), see

http://www.amazon.com/Cosmic-Landscape-String-Illusion-Intelligent/dp/0316013331

29. **Hank**
June 26, 2010

Certainly a damaging finding. I remain unconvinced that entrenched bias will lead to better science.

Summer School

June 26, 2010
Categories: Uncategorized

This is the time of the year when young particle physicists usually want to go to school, more precisely, a "summer school" held in some pleasant location. These typically have a series of survey lectures on the hot topics of the subject, aimed at the level of advanced graduate students and postdocs. These days, the lectures are often available on-line in some form, so anyone interested in learning some more about currently active research topics can do so, even if they have to miss the summer travel aspect of the school.

Here's a partial list of some of the larger such programs:

Theoretical Advanced Studies Institute in Elementary Particle Physics: String theory and its applications, Boulder, Colorado June 1-25

Summer school on structures in local quantum field theory, Les Houches, June 7-25

50th Cracow School of Theoretical Physics, Zakopane, Poland June 9-19

2010 European School of High-Energy Physics, Raseborg, Finland June 20 -July 3

Summer School on Mathematical String Theory, Blacksburg June 21-July 2

Cargese Summer School on String Theory: Formal Developments and Applications, Cargese, Corsica June 21-July 3

PASI School on Quantum Gravity, Morelia, Mexico June 23-July 3

Prospects in Theoretical Physics: Aspects of Supersymmetry, Princeton July 19 – July 30 (why Princeton as a location to travel to for the summer is a bit of a mystery…)

Cargese Summer School on Physics at TeV Colliders, Cargese, Corsica July 19-July 30

International School on Strings and Fundamental Physics, Munich July 25-August 6

PSI Summer School on Particle Physics: Gearing up for LHC Physics, Zuoz, Switzerland, August 1-7

SLAC Summer Institute on Neutrinos, Stanford, August 2-13

Clifford Johnson is blogging from the quantum gravity school in Morelia, where he's shocked to find the "totally bizarre" situation that the students there aren't very enthusiastic about string theory. He attributes this to their ignorance:

> Here's the really odd thing about all this … : While this is a school on Quantum Gravity, after talking with the students for a while one learns that in most cases the little they've heard about string theory is often essentially over 20 years out of date and almost always totally skewed to the negative, to the extent that many of them are under the impression that string theory has nothing to do with quantum gravity at all! It is totally bizarre, and I suspect it is largely a result of things that are said and passed around within their research community.. So there are a few students here and there who have some familiarity with strings, huddling together at times for warmth in a sea of miscommunication, misinformation, and strange preconceptions.

I find it extremely hard to believe that the students at this school are ignorant of claims that string theory is a unified theory including quantum gravity, more likely they're just unconvinced and more interested in other approaches.

Lubos reacts to this by noting that Clifford is finally encountering reality:

> Clifford Johnson seems to be surprised that almost all the students have been brainwashed by various anti-stringy misconceptions. Clifford has clearly been living outside the reality at least for 4 years, and so have many other serious high-energy physicists.

and then goes beyond Clifford, arguing that the problem is not just ignorance, but sub-normal intelligence:

> There's no string theory group in Mexico – another fact that shouldn't be shocking given Mexico's average IQ around 85. The IQ increment needed to go from non-stringy quantum gravity to string theory is around 20.

Comments

1. **Mantis**
   June 26, 2010

   Lubos rant is really hilarious.

2. **alfredo**
   June 26, 2010

   Hi Woit,

   you write:

   "I find it extremely hard to believe that the students at this school are ignorant of claims that string theory is a unified theory including quantum gravity, more likely they're just unconvinced and more interested in other approaches."

   I would love to agree with you on this, but I can't. It is a fact that the high energy and gravity community in Mexico is out dated and has promoted a negative attitude towards not only string theory but basically any new physics idea in the past 20 years. By this I do not mean that there has been a critical attitude (that would be nice), it is just negative as a matter of "principle".

   One of the many consequences of this (the one that I think hurts the most) is that students usually work on old and uninteresting (in the sense of the community) problems. This in turn disables them in terms of competition in the international market. In Mexico it is still relatively easy to find a position at a state University. There is no much competition.

Of course there are many other factors involved, but I do think the attitude of the old guard has been essential.

Now, regarding Lubos. I don't think you should take it to seriously when he comments on the IQ stuff. In some sense, I wish that was the problem! He likes to tease, and the you fall!! 😉

Un abrazo….

3. **Anonymous**
June 26, 2010

You have to be up to date with current literature for your ideas to be taken seriously. That's about the only difference between a crackpot and a serious scientist with a non-mainstream research interest. Even if the current literature (such as string theory) may turn out to be crap, people who think they can work on something (such as quantum gravity) without knowing the current literature is destined to reinvent the wheel again and again and make little progress.

4. **Ricardo**
June 27, 2010

Hi Peter,

Regarding Lubos comment there is a string theory group in Mexico, although small, and they even have annual meetings:

http://fejer.ucol.mx/elena/mexicuerdas/index.html

I am a grad student at UNAM, and you're right when you say there is a group of people "unconvinced and more interested in other approaches" when it comes to strings as a unifying theory, I myself am one of them. I should also mention that people working in string theory in Mexico are more geared towards duality than finding a TOE, at least in my perception.

I agree with Alfredo (Hi Fefo) that there is a tendency from the old school to resist change, but then again I know people who are working on loops, noncommutative geometry and some other less "trendy" stuff

5. **Peter Woit**
June 27, 2010

Alfredo and Ricardo,

Thanks a lot for the comments on the situation in Mexico, very interesting to hear. I'm still dubious though about Clifford's claim that Mexican students "are under the impression that string theory has nothing to do with quantum gravity at all!".

As for whether Lubos is serious, that's always hard to tell, but I do think that the ideas that string theorists are smarter than other theorists, and that skepticism about string theory indicates a lack of intelligence are among his deepest and most sincerely held beliefs.

6. **Roger Schlafly**
June 27, 2010

Why is that hard to believe? Did someone get a Nobel prize for using string theory to solve quantum gravity? Is there some scientific paper that proves that there is some relation?

7. **Bill K**
June 28, 2010

"people who think they can work on something (such as quantum gravity) without knowing the current literature is destined to reinvent the wheel again and again and make little progress."

It depends on who you are. Feynman used to say, if you read what's in the literature you'll just repeat the same mistakes they made.

8. **Cesar Laia**
July 1, 2010

Just crashed in your blog, and I am really shocked with the IQ stupid joke.

I had to see it, and rest of the text by Lubos did not help.

9. **Lee Brown Jr.**
July 2, 2010

I really enjoy this blog. I have been working independently on quantum gravity after being out of school and completely out of physics for a decade. I think I am representative of the newer generation.

One major reason why I avoid string theory, is that the best minds have worked on it for 30 years, and to what end? There is no result you can point to and say that it was a real contribution to our understanding of Nature. Not only that, there is nothing you can point to as a significant calculation.

If guys like Witten get nowhere (from an outsiders perspective), then what chance is there that a more human mind will do better? Moreover, if an idea is truly insightful and meritous, then usually it reaps rewards in fairly short order. SR, GR, Schrodinger Equation, the Dirac Equation, QED, QCD , all contributed soon after proposition.

Younger researchers are not as emotionally and professionally invested in string theory. Abandoning it for more fertile, more tractable pastures only makes sense.

10. **Valentina**
July 2, 2010

It really "amuses" me to see where the link about Lubos takes you to.
I'm Italian so I apologize for my English but, as we say in my country, I think the guy needs a good one, where one means psychiatrist.

His pretending to be some kind of superior being just testifies the huge inferiority complex he must have.

Sorry to be so rude. I'm really "intolerant" towards racist people.

July 2, 2010

I'm curious to know what the mix of students at the PASI quantum gravity school was like. Can anyone say roughly what percentage North/South American? Or what universities they mostly came from?

I'm happy that there was finally such a panamerican QG school. Already in Europe there have been several QG schools of this type—one or two weeks, for graduate students (and others) starting research and wanting an introduction to active topics. I think the first European QG school was in spring of 2007 at Zakopane ski resort in Poland. About time this practice gets a start in this hemisphere.

July 6, 2010

Ian,

The issue, ultimately, is funding. If, in industrial research, your boss offered to pay £1,000 for you to go on a conference/workshop/symposium in Barbados/Bermuda/Bahamas you would probably say, "No thanks, I'd rather have the money – then I can go to one of these places with my family and not have to sit through a whole lot of boring seminars." This option is not available in academia – no cash is on offer if you choose not to go. So think of the whole conference/summer school thing as a charity that provides exotic vacations to those on meagre salaries.

LHC vs. Tevatron Update

June 28, 2010
Categories: Experimental HEP News

Over the weekend the LHC had a first successful physics run with nominal intensity beams, in 3 bunches. A peak luminosity of about 5 x $10^{29}cm^{-2}s^{-1}$ was achieved, and the total integrated luminosity per experiment is now around 30 nb^{-1}. While this is quite a bit behind optimistic schedules of earlier this year, it may now be possible to much more quickly increase the LHC luminosity as the number of bunches is increased. The current plan foresees an integrated luminosity of about 1 pb^{-1} in July, and another 3 pb^{-1} in August.

The report about this from BBC News has the LHC's Mike Lamont trash-talking about the Tevatron:

> "It's clear that the LHC is the new boy in town, but in two years running we're going to put Fermilab out of business," operation group leader Mike Lamont told BBC News.

John Ellis is enthusiastic about the possibility of producing black holes:

> Professor Ellis added that as the luminosity increases, one of the things physicists at Cern will be looking for is a mini- black hole.
>
> "It would be absolutely, fantastically exciting if we produced black holes at the LHC," he said.
>
> "Then we would test our ideas about gravity, quantum physics, string theory. This would be much more exciting than finding a… Higgs boson or even dark matter."

Meanwhile, over in Batavia, the Tevatron has been regularly operating at peak luminosities of 3-4 x $10^{32}cm^{-2}s^{-1}$, nearly a 1000 times that of the LHC, accumulating integrated luminosity of around 50 pb^{-1} a week. They're getting the total number of collisions produced at the LHC this year about every couple of minutes. So far this year they are doing even better than planned, with over 2000 pb^{-1} of integrated luminosity in FY 2010. Last week, the Physics Advisory Committee met to consider plans to get in Mike Lamont's face, and keep operating the Tevatron past its planned closing date of end FY 2011, possibly for another three years. This would take their total data set from about 10 fb^{-1} to possibly as much as 20 fb^{-1}. With this amount of data they expect to be able to provide 3-sigma evidence for a Higgs over the entire expected mass range, as well as stay ahead of the LHC in several different measurements, including the sort of possible non-SM CP-violating effects that recently have been in the news.

Update: More about CERN's competition with the Tevatron here:

> The LHC now has to produce as many collisions as possible in the next two years in order for the various experiments at CERN to essentially prove their worth among other established particle physics laboratories.
>
> The past failures of the LHC weighed heavily on operations group leader Mike Lamont who talked about some of the criticism from the media.
>
> "The Americans in particular can be quite aggressive," he told Deutsche Welle.
>
> "It's quite clear that we're competing with the States, and we've had setbacks, and you can see journalists occasionally being aggressive about that," he said. "I mean 'You're spending taxpayers' money, and you're still messing up,' which can be a fair comment."
> …
> Only if the experiments meet their goals for collected data by 2012, Lamont said, would CERN pull ahead of the research performed at the US-based Fermilab, a particle accelerator located near Chicago, Illinois that measures 6.3 kilometers in circumference.
>
> "We've got reach in energy, but they're still sort of chasing at our heels," Lamont said. "So if we can collect enough data in 2010 and 2011, we essentially put them out of business, then we can relax in 2012 and fix the properly."

Update: The latest news (01:51) on the LHC Vistar doesn't sound good: "soon access in US15 for fire brigade". The beam was lost around 01:00, soon after beams had been ramped to 3.5 TeV. US15 is an underground service cavern next to the ATLAS detector.

Update: Not clear what that was about, but as of 4:30 things are back to normal and they're getting ready to inject another beam.

Comments

1. **VVAA**
   June 29, 2010

   Wow, you seem disappointed that things went back to normal!

2. **Peter Woit**
   June 29, 2010

   Not at all, I'm very glad the problem wasn't serious, and they're now back in business, as of a few minutes ago colliding beams at even higher luminosity. That's great.

   I hope both the LHC and the Tevatron do great physics over the next few years, in a friendly and vigorous competition…

3. **nbutsomebody**
   June 29, 2010

   It is unlikely that Elis takes the proposal of black hole production very seriously. Last time I heard him (in february) he was very critical about the idea.

4. **informed bitch**
   June 30, 2010

   Dear Peter,

   the problem of the Tevatron experiments with the Higgs search is that they will have to face degrading performances of their silicon detectors in the second part of a 20/fb dataset. Silicon sensors are sensitive to the radiation dose they get, and those of CDF and D0 were not designed to withstand such high integrated fluxes. They are currently working fine, but signs of increased leakage currents are clear, and bias voltages need to be knocked up. Signal to noise has already decreased. For a while things will not directly affect the b-tagging efficiency, but we are on untested ground to a non negligible extent.

Another issue is that the predictions that are being sold for the Higgs reach at the Tevatron are based on 2xCDF, which assumes that D0 will eventually catch up with the better sensitivity that CDF is showing in the low-mass analyses. I know how hard CDF has worked on the low-mass region, and have serious doubts that D0 will ever match CDF there, especially given the serious undermanning of D0.

In summary, the reach for the Higgs at low mass is, IMHO, not as good as it is made to appear.

Best regards,

IB

5. **Bill K**
July 5, 2010

"A peak luminosity of about 5 x 10^29/cm^2/s was achieved, and the total integrated luminosity per experiment is now around 30/nb. While this is quite a bit behind optimistic schedules of earlier this year, it may now be possible to much more quickly increase the LHC luminosity as the number of bunches is increased."

Does the luminosity go up quadratically as the number of bunches is increased? I.e. does each bunch going one way get to collide with each bunch going the other way?

6. **lumo**
July 6, 2010

Luminosity and bunches ~ typically yes.
The luminosity goes as the product of the number of particles in each bunch, divided by the cross-sectional area. For convenience assume the beams have equal cross-sectional areas, say an ellipse with rms semi-axes (sigma_x, sigma_y). Assume also the bunches collide head-on and the longitudinal axes are coincident (not merely parallel). This is all fairly typical operation. Then if the circulation frequency is f_rev, the luminosity is

L ~ N1 N2 f_rev / (sigma_x sigma_y) * (factors of pi, etc)

Hence the units of luminosity are cm^-2 s^-1.

Suppose there are B1 bunches in one ring and B2 in the other ring, then

L ~ B1 B2 N1 N2 / (sigma_x sigma_y) * (factors of pi, etc)

Typically B1 = B2. Otherwise the operation is less than optimal. Also typically N1 = N2. In practice this is only approximate because some particles are lost during the acceleration process, one cannot guarantee that the transmission efficiency is equal for both rings. But one can say N1 ~ N2.

Because the beams are proton-proton, they are in two separate rings, and collide only at the interaction points. This is all the same for LHC and RHIC.

But in a p-pbar collider, or an e+e- collider, the counterrotating bunches pass through the SAME ring, in opposite directions. Then if there are B1 = B2 = B bunches, they collide at 2B points.
This leads to unwanted collisions in the ring arcs, which disrupt the beams. So the beams have to be artificially separated where collisions are not desired.

But to answer your question ~ yes.

7. **PhilG**
July 6, 2010

The bunches in one direction do not intersect with every bunch in the opposite direction because they are in separate rings and are only brought together at the points where the experiments are housed.

The exact number of interactions per turn depends on the filling scheme, i.e how they arrange the pattern of bunches in the buckets. For large number of bunches you can assume one collision per turn per bunch. This means the luminosity increases linearly with the number of bunches, not quadratically.

8. **lumo**
July 7, 2010

Mea Culpa! I stand corrected.
You are absolutely correct that a bunch in one ring does not collide with every bunch in the other ring. FYI in RHIC for the polarized protons, the polarization pattern is ++– in one ring and +-+- in the other ring. That way one gets all 4 spin combinations (++) (+-) (-+) (- -). I don't know if there are any unpolarized bunches.

9. **Chris Oakley**
July 7, 2010

Lumo,

I assume you cannot be Lubos Motl ("Mea Culpa" is not something he would be capable of saying), but this nickname is often used by him. Can I therefore suggest that you use another to avoid confusion? Or, better still, just use your *real name!*

Perelman Turns Down Millennium Prize

July 1, 2010
Categories: Uncategorized

The Clay Mathematics Institute today announced that Perelman has turned down the one million dollar Millennium prize:

> On June 8-9 CMI held a conference in Paris to celebrate the resolution of the Poincaré conjecture by Grigoriy Perelman. Dr. Perelman has subsequently informed us that he has decided not to accept the one million dollar prize. In the fall of 2010, CMI will make an announcement of how the prize money will be used to benefit mathematics.

There are various media stories appearing about this, based on an AP report, with a bit more detail:

> Jim Carlson, institute president, said Perelman's decision was not a complete surprise, since he had declined some previous math prizes.
>
> Carlson said Perelman had told him by telephone last week of his decision and gave no reason. But the Interfax news agency quoted Perelman as saying he believed the prize was unfair. Perelman told Interfax he considered his contribution to solving the Poincare conjecture no greater than that of Columbia University mathematician Richard Hamilton.
>
> "To put it short, the main reason is my disagreement with the organized mathematical community," Perelman, 43, told Interfax. "I don't like their decisions, I consider them unjust."
>
> …
>
> Carlson said institute officials will meet this fall to decide what to do with the prize money. "We have some ideas in mind," he said. "We want to consider that carefully and make the best use possible of the money for the benefit of mathematics."

Comments

1. **Simplicio**
   July 1, 2010

   And somewhere, Hamilton is wondering why Perelman doesn't just take the money and give him half a million bucks.

2. **Sakura-chan**
   July 1, 2010

   They should distribute it to the remaining 6 problems.

3. **"Shecky Riemann"**
   July 1, 2010

   gotta love the eccentricity of so many prodigy mathematicians…

4. **Dr.Kathrine Martinez-Martignoni**
   July 1, 2010

   This Perelman is really a very strange man.
   I can write only this because it is the first time that a man
   (a genius in mathematics but anyway always a man)is so "crazy"
   to refuse one million US-Dollars.
   I am really completely fascinated by this man.
   Good luck Dr.Perelman!!!
   Dr.Kathrine M. (Switzerland).

5. **David Santo Pietro**
   July 2, 2010

   My respect for Perelman is increasing exponentially. He has his principles and he sticks to them regardless. Seriously, how many people these days could turn down a million dollars on principle. Not only that, but he does so in a classy and non confrontational way. When given the opportunity to publicly rub the prize in the noses of the establishment mathematical community, Perelman chooses to rightly give credit to Hamilton in his brief statement. This even after he has had to endure mathematicians claiming credit for his work. When people talk about Perelman they sometimes do so in a condescending way, as if he was "crazy". From everything I've seen, Perelman has the clearest state of mind of anyone in this whole saga.

6. **Deane**
   July 2, 2010

   For me the greatest tragedy is not Perelman turning down the Millennium Prize but the apparent prospect of Perelman refusing to do any more mathematics, both because he seemed to love it so much and because he has and presumably would continue to contribute so much to the field. I am still hoping that Perelman is just toying with us, and in fact he is still pursuing his passion in the subject.

7. **Daniella**
   July 2, 2010

   This bitter, wierd little man named Perelman continues to manipulate the media and the good general publics sentiment by whoring out his persona. The man is clearly so desperate for fame, notoriety and being remembered after his own death that little else matters to him.

   Instead of graciously receiving the monies from this award and doing good deeds with it – such as charitable donations, helping his own family or himself he has selfishly chosen to spit in the face of the establishment once agin.

Principled? Sure – it's just a pity that his "principles" are geared towards ensuring his own fame at the cost of everyone else. When I studied with him at University he was not well liked by anyone and to be frank this is exactly why he was universally shunned. This media attention is further fuelling his lust for fame and power unfortuantely, just as he'd hoped.

8. **csrster**
July 2, 2010

Simplicio – There is a precedent. That's what Banting did with his Nobel Prize money for the discovery of insulin, sharing it with his assistant Charles Best. History seems concur with Banting's view that Best was equally deserving of the prize.

9. **chris**
July 2, 2010

i guess the most logicl recipient of the money should now be the institute he worked for. they sure could use that money.

10. **Sam I Am**
July 2, 2010

That a man turns down a prize that seems to him exorbitant and inappropriate should be respected, and one with curiosity should try to understand his motivations.

Perelman is right (provided he really said what the newspapers have apparently quoted him as saying) that Hamilton contributed as much as he to the resolution of the Geometrization Conjecture to which Perelman's work lead – Hamilton laid out the program of using Ricci flow, and proved fundamental results showing the viability of the approach, and even identified the obstacles which later Perelman showed how to overcome.

Perelman is right that such prizes are unfair and unjust. For every mathematician who receives such a prize there are several more who do work of similar depth who receive nothing. The sociological effects of such prizes are not always positive for the mathematical community, even if they are largely positive for the recipients (they can be negative for those who do not receive, but know they could have, who sink into bitterness). Vershik wrote something along these lines in a Notices of the AMS.

The notion that Perelman should accept the prize and give it to charity, and that by not so doing he is doing something wrong, is ludicrous, based on a precious and oppressive moralizing. He has not asked for the prize, he has not wanted the prize – it is not his to decide what to do with what is not his – if one thinks that such money would be better given to a charity than to a mathematician – then one's quarrel is with the Clay Institute, not with Perelman.

11. **Zilog**
July 2, 2010

Daniella, your statement is completely unfair. He's not desperate for fame – he IS famous already. And it's his ownr right to refuse what he thinks doesn't belong to him. That charity-things are just side-effect of money-hungry nature of other people, and it's good that Perelman doesn't obey them. Narrow-minded enough (your post).

12. **Mitch Miller**
July 2, 2010

I have no problem with him turning down anything, but I wonder why he decided to put the proof on the Arxiv in the first place. It seemed like he had problems with the math community before he got the attention based on this proof.

13. **killbill**
July 2, 2010

Being weird is cool in math and physics. Erdos is the paradigmatic example, but we all know people like him among our colleauges, who like to be eccentric for the sake of eccentricity. Perelman is entirely entitled to do whatever he wants with the award, but it is silly for his admirers to insist that he does not care about fame etc. You don't get that good without having incredible ambition. He is certainly more famous than most other Field's medalists because of his antics.

Case in point: My girlfriend, who is a veterinarian and couldn't care less about math, told me today after reading the news about this "crazy genius" mathematician who doesn't want a million dollars.

Ultimately, this entire thread is silly, because the guy is of course a genius. But it is fun to psycho-analyse him anyway.

14. **Eric Habegger**
July 2, 2010

I think there might be an added element that brings a reasonableness to the mystery that is Perelman. I think it makes sense because it also fits in with his mathematical talent. I absolutely agree with his ethics but the essence of the divergence from most of us in giving up 1 million dollars is that almost all of us would weigh the two elements, our morals vs our enjoyment of the luxuries 1 million could bring, and come down on the side of the money.

I wouldn't presume to read his mind but I think when you have such a rich an inner intellectual world as he does one's outer environment isn't quite as important as it might be to most of us. At least it makes me feel better to think about him that way. I tend to think some others bitter conclusions about Perelman reflects more on their subconscious knowledge of their dependence on the outer world for their contentment.

15. **David Santo Pietro**
July 2, 2010

Daniella, are you saying that Perelman devised a plan to get famous and remembered after his death that included dropping out of the mainstream mathematical community, moving in with his mother into an apartment in Russia, stopping all contact with the outside world, working on a problem no one could solve for a century, then after he solves it not talking to anyone about it or accepting awards for it? If this was truly all part of a grand scheme Perelman devised to get remembered after his death, he is an even greater genius than we are giving him credit for.

You seem to dislike him personally, and maybe it is warranted (professional mathematicians aren't necessarily the most personable people in the world), but I don't see how you can say that someone who has almost no contact with the outside world is a "media whore".

16. **Dr.Kathrine Martinez-Martignoni**
July 2, 2010

Daniella,
in this world there are people that ,for a million Us dollars, can kill
theirs mothers …and,fortunately,there are also (few) people who can refuse 1 million Us dollars!!!

The world is so nice , so beatiful and so interessant because there are so many different people who think differently.
I think simply that you have to respect Perelman (and his decisions) even if you don`t like him.
Dr.kathrine M.

17. **Rana**
July 3, 2010

Actually, this refusal makes some sort of sense. Hamilton was the one who laid out the program, and as astounding as Perelman's solution was, Hamilton should have been awarded the Millennium as well. I wonder why the Clay institute didn't include him.

18. **Alejandro Rivero**
July 3, 2010

At least now I understand why my own solution was not acceptable. I suggested to allow Perelman to propose a new problem to be managed by Clay institution. But if he does not consider that the mechanism of prices is fair nor good to promote maths, then of course he would not like to propose any.

19. **Lee Brown Jr.**
July 4, 2010

I say give the money to his mom. She's probably earned it.

20. **Anonymous**
July 4, 2010

Perelman has won my heart by giving credit to Hamilton. That's the standard of ethics that every respectable scientist must have.

21. **Pierre N.**
July 4, 2010

Chapeau bas to Perelman! In a very different way, this is as impressive as his proof. He just earned the Field prize of intellectual honesty as only he can judge how much he owes Hamilton.

22. **altf**
July 5, 2010

I agree with rana. Hamilton has made a great contribution to solve this problem (and also generally to mathematics) by his introduction of Ricci flow. For me, Perelman is on finishing touch (although it is the most difficult part at times), but Hamilton is the real founder.

23. **nbutsomebody**
July 5, 2010

A really off topic discussion. Have you seen this
http://scienceblogs.com/principles/2010/06/the_physics_of_the_imbecile.php

it seems Kaku is going along with Deepak Chopra in a new age hype.

24. **John Baez**
July 5, 2010

I think we should force Perelman to take the money.

25. **Coin**
July 5, 2010

I'm not sure how Perelman could communicate "just leave me alone" any more clearly than he already has.

26. **JG**
July 6, 2010

Perelman was widely regarded as the best geometer of the last century, even before his proof of geometrization – see his incredible proof of the soul conjecture, for example.

27. **Will Farnaby**
July 21, 2010

Perelman is not "an eccentric": he presents Asperger's syndrome – see also Glenn Gould, for example – and, like Gould, he's made the world a better place in his own particular way.

Various and Sundry

July 7, 2010
Categories: Uncategorized

- It seems that Jean-Pierre Serre now spends his time commenting on blogs.
- For those interested in particle physics history, there's an interesting article by George Zweig here about his role in the discovery of quarks (which he called "aces").
- There's a very nice new survey article by Mikhail Shifman about QCD, especially about hopes to exploit supersymmetric models to better understand non-perturbative issues.
- Blogger String Theory Fan still gets hits from the trackback to his blog entry over there. Trackbacks to hep-th papers from here still seem to be censored, but people find out about the postings anyway. For instance, the authors of this recent paper have put out a revised version adding a reference to the earlier calculation in the math literature pointed out here.
- If you like listening to talks by Nobel Laureates, there's a whole bunch here.
- One person who is more than distinguished enough to be a Nobel Laureate but isn't one since he made the mistake of being born too late is Edward Witten. Last week he was in Europe collecting other well-deserved medals: the Lorentz Medal in Amsterdam and the Newton Medal in London. Evidently he was giving two talks, one for the public and one more technical. The public one was entitled *String Theory and the Universe* and probably not to my taste. It should appear at some point here, but for now there's a report here at Physics World. Michael Green introduced Witten with the accurate title of "Master of the Path Integral". The more technical one may have better shown off Witten's mastery; it had the fascinating title of *A New Look At The Path Integral of Quantum Mechanics*, and I'm hoping it will appear soon here (or maybe a commenter who has heard the talk in Amsterdam or elsewhere can tell us more about it…)
- While I'm not sure how strongly Witten feels about string theory these days, there's not much ambiguity in the case of Michio Kaku. He was on the Colbert Report Monday night and has a recent blog entry arguing that We Physicists Are the Only Scientists Who Can Say the Word "God" and Not Blush:

> As you know, I work in something called String Theory which makes the statement that we are reading the mind of God. It's based on music or little vibrating strings thus giving us particles that we see in nature. The laws of chemistry that we struggled with in high school would be the melodies that you can play on these vibrating strings. The Universe would be a symphony of these vibrating strings and the mind of God that Einstein wrote about at length would be cosmic music resonating through this nirvana… through this 11 dimensional hyperspace—that would be the mind of God. We physicists are the only scientists who can say the word "God" and not blush.

If you're in New York and want to help him defeat a Cyborg Army on July 16th, see this.

- As for me, I'm heading soon for Patagonia to try and see another eclipse. After that I'll be traveling in South America for a couple weeks, won't be able to help with the Cyborgs since I should be somewhere around Lake Titicaca on the 16th. Comments may get shutdown temporarily here for a while, partly because of the hundreds of spam comments coming in here each day, not all of which get caught by the spam filter, making some on-going maintenance necessary.

1. **Tim van Beek**
July 8, 2010

> Michio Kaku…was on the Colbert Report Monday night

…and he got applause for announcing the upcoming invention of invisibility cloaks and time travels, so all you physicists: Get to work! You don't want to disappoint the customers!

(But if you are a little bit like me, you might want to hide behind a nearby bush, crying).

2. **DaveB**
July 8, 2010

Good luck with the weather Patagonia.

I have been planning to go climbing or trekking there for years, but it has a reputation as one of the wettest places on the planet.

3. **Doug Henning**
July 8, 2010

W.r.t. Witten, don't you mean born too early, since experimental evidence for strings won't be found until those light-year-radius particle accelerators get built a thousand years hence?

P.S. Enjoy Patagonia. Good luck hanging out with gauchos, rheas, titanosaur bones, and assorted Nazis-in-hiding.

4. **Dave B**
July 8, 2010

Don't forget the patagonian welsh!

5. **Mark Decker**
July 8, 2010

Michio!
"Reading the mind of God" sounds dangerously close to those fanatics who "hear the voice of God." Thanks for the heads up. At least we know how grandiose your string delusion has become.
And although you can make statements like that without blushing – please know that I am embarrassed for you.

6. **Roger Schlafly**
July 8, 2010

I don't understand the Witten comment either. Has any Nobel Prize ever been given for the sort of work that Witten does?

7. **Peter Woit**
July 8, 2010

Witten's work is not just mathematical, but covers a lot of ground. The more mathematical end of it has been the most successful, but that's partly because, in the thirty-some years of his career, no particle theorist at all has had the kind of success that leads to a Nobel Prize. If Witten had been born ten-twenty years earlier, I'd bet that he would have played some sort of important role in the development of the Standard Model, of a sort that would have involved a Nobel prize.

8. **twistingthenightaway**
July 9, 2010

Witten's "new look" is all about A-branes and provides a neat explanation of some things hinted at earlier in a paper of him and Gukov. He will publish it in due time I guess. Nothing new about quantum mechanics… that is, apart from Witten's clear explanation of some of the more arcane points of path integral lore.

p.s. As it was a whiteboard talk nothing will appear on the workshop website.

9. **AK-47**
July 9, 2010

Serre just corrected an absurd misinterpretation of the word character by "Nigel" . To say that Serre now spends his time commenting on blogs is a tad hyperbolic….

10. **schieghoven**
July 9, 2010

"Witten's "new look" is all about A-branes…"

I don't quite agree. Mostly the talk (at Imperial) was about deforming path integrals into the complex domain in order to improve the convergence… the A-branes came in at the end, as an application. I thought the preceding ideas were valuable in their own right.

11. **Mitch Miller**
July 9, 2010

Witten could have had a shot at a Nobel for asymptotic freedom if he had just decided to work for Gross right after undergrad.

12. **D R Lunsford**
July 9, 2010

Don't forget to read "In Patagonia" by Bruce Chatwin. Look at the reviews on Amazon.

14. **Shantanu**
July 10, 2010

Hi, Peter or anyone else,
Does someone know of any interesting new results or blogs form GR19 conference?

15. **D R Lunsford**
July 11, 2010

How's the weather in Argentina/Chile? Looks good for Easter Island. The eclipse perfectly brackets the World Cup Final, so 2012 may be early. If the Moai start blinking, run.

-drl

16. **Anonymous**
July 11, 2010

Witten could have had a shot at a Nobel for asymptotic freedom if he had just decided to work for Gross right after undergrad.

Asymptotic freedom is great, but discovering something that others would have discovered anyway (in hindsight) doesn't make you a genius of Witten's caliber. Einstein was a genius because without him, it might have been several decades later that GR was discovered.

17. **chimpanzee**
July 12, 2010

It was raining Sat Easter Island, partly cloudy for Sunday. Eclipse was clear (some wispy clouds), cloud interference @3rd contact. D. Fischer (German science writer) had clear skies from Patagonia:

http://twitpic.com/photos/cosmos4u

Cook Islands (Mangaia) & French Polynesia (Hao atoll) had cloud issues, but some got clear skies:

Spaceweather

witten is a bit too formal for a physics nobel. but the proof of the cake is the eating … let's wait and see.

19. **martibal**
July 12, 2010

Anonymous: it seems that Hilbert was not far from discovering GR as well. And also special relativity may have been discovered, maybe not exactly in this form, by Poincare. This does not deny anything to Einstein genius, but making a great discovery is also a matter of luck, being at work at the right moment in time.
What about if physics (at least high energy physics) is just entering a period of one or two centuries without major discoveries ? This might be the case, not due to the lack of bright minds, but because nature and our current knowledge (e.g. we do not have the good experimental tools to get new information, and not the good mathematical tools to understand our current theories in a way allowing to make significant progress) may be such that there cannot be major discoveries in this specific argument before ages.
I have just read (do not remember where) that Einstein refused to be instructed in social science (and I guess biology as well ?) because he thought these were areas to well understood and there was nothing to discover here. Maybe high energy physics is to well understood at the moment and this is not the subject where big discoveries will be made.

20. **Peter Woit**
July 12, 2010

Unusually clear skies here in Patagonia, all the way down to the horizon. So we had perfect conditions and a beautiful eclipse just before sunset. Headed back to Buenos Aires, then on to Bolivia and Peru.

21. **Chris W.**
July 14, 2010

> I have just read (do not remember where) that Einstein refused to be instructed in social science (and I guess biology as well ?) because he thought these were areas to well understood and there was nothing to discover here.

I seriously doubt it. If anything, he thought that these fields were simply not amenable to the kind of theoretical understanding that he had come to admire in physics, and were therefore not to his taste. More precisely, they were replete with mind-numbing empirical detail, and lacking any examples of effective and testable unifying theoretical frameworks to make sense of all these observations.

22. **Sakura-chan**
July 15, 2010

Hi DRL,

In that paper of Zweig that you linked to, in the epilogue on page 36 he talks about his appointment to a leading university being blocked by a senior theorist. Is he talking about Chew?

23. **Charles**
July 15, 2010

You should have gone to Bariloche to do some trekking…it´s very cheap (or maybe visit el Glaciar Perito Moreno, but that is a lot more expensive).

24. **martibal**
July 16, 2010

Chris W.: well, my source may not be very reliable indeed, since this is the french wikipedia page:
“Il fait ses études primaires et secondaires à la Hochschule d’Aargau en Suisse, où il obtient son diplôme le 30 septembre 1896. Il a d’excellents résultats en mathématiques, mais refuse de s’instruire en biologie et en sciences humaines, car il ne perçoit pas l’intérêt d’apprendre des disciplines qu’il estime déjà largement explorées. Il considère alors la science comme le fruit de la raison humaine et de la réflexion.”
But this statement is not referenced, and does not seem to appear on the german or english version.

25. **Peter Woit**
July 16, 2010

Charles,

Spent the morning before the eclipse at Perito Moreno, which really is spectacular.

26. **Martin**
July 18, 2010

Judging from his website, wikipedia entry, the ever growing book no the subject and his scientific publications, Hagen Kleinert would surely think that he deserves the title “Master of the Path Integral” ;-).

27. **D R Lunsford**
July 21, 2010

Sakura-Chan, I doubt it. I have my own know^h^h^h^hopinion on who it is but will not spread rumors in public.

-drl

28. **anon.**
July 22, 2010

Hope you start blogging again soon. There is little worth reading on the internet at present.

29. **Peter Woit**
July 23, 2010

anon,

Thanks, although I seem to have chosen a good time to go on vacation. In Peru on the Amazon now, heading back home soon, at work again on Monday. Will attempt to resume your regularly scheduled programming soon after that.

New Higgs Results From the Tevatron

July 26, 2010
Categories: Experimental HEP News

Just got back from vacation this morning. Luckily I managed to be away for the blogosphere-fueled Higgs rumors, returned just in time to catch the released results which appeared in a Fermilab press release minutes ago. The ICHEP talk in Paris announcing these results will start in about half an hour, slides should appear here.

The bottom line is that CDF and D0 can now exclude (at 95% confidence level) the existence of a Standard Model Higgs particle over a fairly wide mass range in the higher mass part of the expected region: from 158 to 175 GeV. If the SM Higgs exists, it appears highly likely that it is in the region between 114 GeV (the LEP limit) and 158 GeV. The most relevant graph is here. It shows an excess of about 1 sigma over the entire region 125 GeV to 150 GeV, which unfortunately is nothing more than the barest possible hint of something actually being there.

Comments

1. **Wild Goose Chase**
   July 26, 2010

   Why is there a difference between “expected” and “SM=1” in the linked graph?

2. **bane**
   July 26, 2010

   On a different topic, one thing I’d have expected you to comment about is the recent “finding” that the proton’s charge radius appears different from that predicted by QED.

   http://en.wikipedia.org/wiki/Proton#Charge_Radius

   Presumably either the proton’s charge radius is described by something other than current QED model, or the mathematical model used to infer the charge radius from a proton+meson is wrong, both of which look like new clues about some issue in the area of field theories that you’re interested in. Any thoughts?

3. **Peter Woit**
   July 26, 2010

   WCG,

   The experiments are not seeing a signal, so the plot is of the 95% confidence level limit they can put on a signal/divided by the signal expected for a SM Higgs. The “expected” value for this is based on the expected performance of the detectors. Around 165 GeV they expect to be able to put a limit on the size of the signal below the SM value, and they do, ruling out the existence of a Higgs at that mass. Around 125 GeV they expect to only be able to get a limit about 1.8 times the SM value, so don’t expect to be able to rule out a Higgs at that mass.

   If there really were a Higgs at a certain mass, one expects that the experiments would start to see an excess above expected background, and this would make their 95% confidence level worse than expected. However, the excess they are seeing is still so small as to be quite consistent with no real signal.

4. **Peter Woit**
   July 26, 2010

   bane,

   That’s on a list of things to learn more about and see if there’s anything interesting to say. But I just got back from vacation a few hours ago….

   Update: for those who really want to discuss the proton charge radius question, this really isn’t the place.

5. **SpearMarktheSecond**
   July 27, 2010

   The q^2 employed in the old proton charge radius measurements is probably of order 1 GeV^2, while the new muonic hydrogen measurements probably have a q^2 of order the muon mass squared, or 0.01 GeV^2.

   Would it be very surprising if QCD caused evolution of the charge radius between those values of q^2?

   As for the Higgs, someday I’d like to dig out all the august testimony to Congress during the SSC days, where the leading figures of the field argued passionately for the SSC’s energy and luminosity, in order to test the Higgs hypothesis sufficiently.

   The LHC was not sufficient, they said. Of course a bunch of blurry estimates of the Higgs mass happened between then and now, and have pointed at the light Higgs and thus new physics soon. But maybe it was all Luck not being a Lady, and instead, we have a 800 GeV Higgs + some strongly interacting electroweak bosons, and now trace of new physics, and thus a desert.

6. **Eric Habegger**
   July 29, 2010

   I just watched Veltman’s video presentation about the Higgs at the Lindau Conferernce here:

   http://www.lindau-nobel.org/WebHome.AxCMS

   I thought it was an excellent presentation that gives a jargon free explanation of the search for the Higgs. It really is an outstanding talk and I came away with a much better understanding of the issues involved. I’m still digesting his final conclusion about why he thinks there is no Higgs. I’ll give a hint: It involves the corrections to the scattering amplitudes of the vector bosons that would require a Higgs particle. Second hint: the highest sigma for the Higgs is at one particular energy where there is no scattering correction required. I think he is onto something. I like the guy.

   Eric Habegger

7. **higgs**
   July 30, 2010

   Veltman has disbelieved in the Higgs since the beginning. (This despite the proof of renormalizability of Yang-Mills with SSB etc.) But does he offer any credible alternative for the gauge boson mass and their longitudinal polarization modes?

Witten Talk and Interview

July 27, 2010
Categories: Uncategorized

In conjunction with his receipt of the Newton Medal, Edward Witten gave a public talk in London (now available on-line here), and an interview (available as part of a pod-cast here).

Witten's talk was a rather polemical argument for string theory, in which he laid out his reasons for still feeling that string theory is on the right track. The video is in two parts, with the first part not especially interesting since it is pretty much word-for-word the standard arguments for string theory that he and others have been making since the mid-eighties. The second part has some more interesting content, including Witten's comments on the evolution of his own personal relationship to the subject. This started in the early eighties, before the 1984 "First Superstring Revolution", when he began studying string theory, feeling that it was an approach to unification that deserved more attention than it was getting.

A recurring theme in his talk is that "string theory" has gone through unexpected changes in perspective over the 30 years he has been working on it, with the unspoken argument being that some new change in perspective may yet make the current deadly problems of string unification go away. He takes an ambiguous attitude towards attempts in recent years to argue for a change in perspective to the pseudo-scientific "landscape", explaining the arguments of proponents while not signing on to them. In the podcast he says "I don't know if this is the right picture of the universe", in the talk it's "to my thinking we still need more clues to have a better picture whether that is the right interpretation."

It's interesting to compare Witten's pro-string theory arguments to the somewhat similar ones of his much less mild-mannered thesis advisor David Gross (see here for a posting about a recent talk by Gross). Unlike Witten, Gross is clear where he stands on the anthropic landscape, denouncing it as pseudo-science. One other crucial difference has to do with their discussion of upcoming LHC results. Here, Gross argues strongly that the LHC will see supersymmetry, and is willing to put money on the table to back this up. Witten's talk barely refers to the LHC, and while he argues that a point in string theory's favor is its relation to supersymmetry, all he's willing to say about supersymmetry or extra dimensions at the LHC is "it might happen if we're fortunate enough." The next interesting part of the string theory story may very well be what happens in 2013-4 when it becomes clear that supersymmetry and extra dimensions are not going to be seen at LHC energies. After paying off his debts, I wouldn't be surprised to see Gross take this as an opportunity to back off from the idea of string theory unification. On the other hand, in his talk Witten seems to be positioning himself for carrying on as before, by now making arguments for string theory that don't at all involve low-energy supersymmetry.

Witten ends his talk with the argument that we still know very little about what string theory is, and this implies that it remains an excellent subject for young physicists to start to work on. I suspect he sees all too well that among physicists the tide has changed, with students turning to other subjects as jobs in string theory dry up and prospects for progress on string theory unification look increasingly dismal. He's trying to counter this by restating the arguments that have continued to keep him interested in the subject.

Update: Clifford Johnson has some very interesting and accurate comments on Witten and on how others react to him here.

Comments

1. **Sakura-chan**
   July 27, 2010

   Thanks for posting this Peter! I agree, the second half is more interesting than the first.

2. **Chris W.**
   July 27, 2010

   I second those thanks.

   For me, the overwhelming impression is one of ongoing stagnation, combined with a melancholy nostalgia for the excitement that once surrounded the subject.

   I really wonder if a truly good and insightful idea in this field would be recognized as such by its current practitioners.

3. **Claude**
   July 28, 2010

   In a recent video interview, David Gross said explicitly that he would still believe in supersymmetry even if the LHC did not find it. So it seems that your opinion about Gross changing his mind if experiments contradict theory is somewhat optimistic.

   In addition, it is a pity how little string theorists are following the advice of Murray Gell-Mann, who suggested to clarify its basic principles, in the same way that Einstein clarified the basic principles of general relativity before starting calculations. A search on arxiv essentially leads to zero results.

4. **Bee**
   July 28, 2010

   Makes me wish I could have a look at the future and see what people will think about string theory in 30 years from now. Will you still be blogging then and keep us updated? 😉

5. **Theorist**
   July 28, 2010

   "The next interesting part of the string theory story may very well be what happens in 2013-4 when it becomes clear that supersymmetry and extra dimensions are not going to be seen at LHC energies."

   You don't know that. I agree that there's no reason to believe in SUSY or extra dimensions of any kind at the TeV scale (unless the latter is related to EWSB), but you make that statement with an (apparent) certainty that far exceeds what you know for sure.

   On a related note, 2014 is WAY too early to be ruling out anything that Tevatron won't have already excluded.

6. **Shantanu**
   July 28, 2010

HI Peter,
I haven't looked at the talk, as am travelling. However did Witten discuss any high energy prospects for string theory (such as proton decay, neutrino oscillations). 5 years ago, I attended [this](#) where Witten talked about proton decay predictions in some string theory model. Also I am guessing he said nothing about loop quantum gravity?

7. **Pmer**
   July 29, 2010

   after seeing the talk I am more sympathetic to string theory, since

   1. unifies gauge, diffeomorphism and super symmetries
   2. interactionns are global only, so e.g. space could be emergent 3. it is not some theory that gets quantized, but starts with both parameters a' and h (just imposing a commutator is not principled)

   these are important to the foundations of quantum mechanics

8. **Mitchell Porter**
   July 29, 2010

   "Dismissing" the landscape is itself not a scientific act. It is a question of fact as to whether string theory inherently predicts chaotic inflation; it is a question of fact as to whether we live in such a universe; and as things stand, an answer of yes to both questions is consistent with all the evidence.

   I can understand people being skeptical about anthropic reasoning – though Weinberg's argument is a good one – but you don't get to reject string theory just because it suggests that particle physics is highly contingent. Practical field theory is about model-building meant to explain observations; in the era of the landscape, so is string phenomenology. In other words, it's actually a return to business as usual, except that now you have a class of models that contain gravity.

9. **Peter Woit**
   July 29, 2010

   Theorist,

   Sure, that's my prediction, confidence level 95%…. For people who do expect supersymmetry to show up at the LHC, I'm quite curious to know what amount of data they will need to see before they admit it's not going to happen. In particular, what exactly are the terms of David Gross's bet? I was using the date 2014 based on the expectation that by then there should be about 10 inverse-fb of analyzed data at design or near design energy (6.5 or 7 TeV/beam). If no signs of supersymmetry are seen in that data set, I'd think that prospects for them showing up in 100 or even 1000 inverse fb would be slim.

   The LHC is going to be around for a long time, a very long time if you count various proposed upgrades. If those saying they are willing to bet on supersymmetry at the LHC are including the full life span of the machine with upgrades, betting with them would not be a good idea for someone middle-aged like me since I might not be around to collect.

10. **Peter Woit**
    July 29, 2010

    Shantanu,

    In the talk you refer to, Witten's conclusion is negative:

    "There is no hope of getting a real answer right now, because even if string theory is correct and even if nature is based on one of its GUT-lik realizations, there are far too many possibilities."

    He described string theory as the "only real idea about quantum gravity", which I guess was a comment on LQG (I told you the talk was kind of a polemical one…).

11. **Peter Woit**
    July 29, 2010

    Pmer,

    In Witten's talk he described the speculative hopes like the ones you mention that he still holds for the theory. I characterize his talk as polemical since he makes repeated overly-strong claims, not even mentioning the reasons for skepticism about them. I thought for a minute about examining these claims and explaining the problems with them, then realized "wait a minute, this is a complicated topic that I wrote a whole book about…"

    Mitchell Porter,

    Witten gave an exhaustive list of the reasons he thinks string theory is still worth pursuing. "String phenomenology" was not mentioned, I think for good reason.

12. **Chris Austin**
    July 29, 2010

    Hi Mitchell Porter,

    I had been under the impression that within the context of the KKLT or similar landscapes, it is not possible or practical to point to a specific model and say, "This specific model definitely has a cosmological constant small enough to be consistent with observations," the problem being that large positive and negative contributions, of very different origin, have to cancel to a precision of about 1 part in 10^{120}, and neither type of contribution is controlled to anywhere near the necessary degree of precision.

    If this is incorrect, or no longer the case, what would be a good reference to look for examples in?

13. **hmm**
    July 29, 2010

    Just a perhaps obvious remark about the previous comment by C. Austin
    :

I believe it is correct, but it is not a specific limitation of string theory.
In no current framework for theoretical physics do we have the ability
to compute contributions to vacuum energy to sufficient accuracy to claim that one would definitely reproduce today's vacuum energy to high precision.

It is important not to confuse specific problems of string theory (of which there may be many, or may be none), with general difficulties that face all theoretical models, and are not specific to one framework.
I believe the small value of the vacuum energy is in the latter category,
if one wants a normal predictive theory that explains the value, and does not want to resort to Weinberg arguments and vacuum multiplicity.

14. **Mitchell Porter**
July 30, 2010

Chris, I think you're right, but matching the observed cosmological constant is likely to be one of the last considerations in building a phenomenological model from string theory, precisely because it is supposed to arise from a complicated near-cancellation of many positive and negative contributions. Just reproducing the qualitative structure of the Standard Model in string theory is quite difficult and this offers guidance to the model builder that is far more direct. There are only a handful of ways to do it (that are known) and there are plenty of other issues to preoccupy the people working on each such possibility. At the moment I'm interested in orbifold models and there are a few papers on getting the cosmological constant there, e.g. hep-th/0603088. But it's an issue for the final stage of string phenomenology, along with particle masses and moduli stabilization.

15. **dan**
July 31, 2010

Mitchell Porter
How close are string theorists to "reproducing the qualitative structure of the Standard Model" along with such string phenomenology, along with particle masses and moduli stabilization and cc?

16. **Mitchell Porter**
July 31, 2010

I can't say. I'm a neophyte and remote from the centers of research. But from the literature I can say that what people try to do is to find string vacua which produce the "minimal supersymmetric standard model" (MSSM) or a supersymmetric GUT which reduces to the standard model. This is the qualitative part and has been done several times in several ways. Usually such models must contain extra particles that haven't been seen, and so you have to find vacua where those extra particles are heavy or otherwise undetectable at present energies.

So far as I can see, people are not yet presenting further refinements of these models in which *all* the standard model parameters are derived at once, such as the masses of the *observed* particles, but instead this final step is being tackled piece by piece. There are a lot of papers on how to get a heavy top quark, there are a few papers on how to give the up and down quarks small nonzero masses, and so on. It's all very incremental, and also framework-dependent (a mechanism for giving quarks mass in one class of model may not be transposable to another class of model), and even dependent on basic theoretical progress (e.g. arXiV:0707.1871).

17. **Bruno Galileo**
August 3, 2010

In the history of all of science, has a hunch such as string theory ever received so much attention and funding?

Truly, string theory and its handwaving ethos shped physics over the past twenty-thirty years. Even LQG adopted some of its tenor and tone, often stating in its own defense, "hey if string theory can be not even wrong then we have every right to be not even wrong too!"

One must wonder about all the lost opportunities. What physicists were shut out from the academy and funding? How many bright young minds were lead down a seemingly dead-end street? How many gained tenure not by science, but by politics?

As Witten was an undergraduate history/politics major, it would have been interesting to hear his take on how string theory politicized and polemicized science.

Best,

Bruno Galileo

18. **CNX**
August 5, 2010

As Thomas Kuhn stated in his book about Scientific Revolutions, in many cases new ideas/theories do not just replace the old ones by being more successful, but they simply outlive them: they only get established when the older generation of supporters for the one theory gradually die out and the younger generation prefers the new theory. I think this is the most likely scenario how String theory will fade out, if it does at all, and this can take a very long time(Too long for middle-aged people to witness?). However, if the theory continues to win the souls of the younger physics students, whether by its rosy prospects(?), virility(?) or career pressure from its established, influential practitioners, then it may still be able to survive many more generations. In that case, even during the entire lifetime of a younger person such as me fundamental theoretical physics may continue in its current shape, monopolized by one seemingly promising theory which does not live up to its huge expectations.

19. **horace**
August 5, 2010

> in many cases new ideas/theories do not just replace the old ones by being more successful, but they simply outlive them:

In many cases, like… what?

20. **Max Planck**
August 6, 2010

hello all,

i believe the quote you were looking for comes from max planck:

A new scientific truth does not triumph by convincing its opponents and making them see the light, but rather because its opponents eventually die, and a new generation grows up with it. –Max Planck

21. **Mark Decker**

August 6, 2010

A great collection of quotes. This single post should serve as a resource for anyone on the fence and looking for string theory opinions from scientists who haven't lost their sanity.

Getting back to the Witten topic: Everyone talks about how much of a genius he is but yet he is a string theorist. What contributions has he made that will stand the test of time when string theory eventually falls by the wayside? I'm not being a wiseguy and I'm not taking shots at Dr. Witten – I was just wondering if anyone could clear that up?

22. **Peter Woit**
August 6, 2010

Mark Decker,

I wrote extensively about Witten and his non-string theory achievements in my book.

23. **Pmer**
August 15, 2010

Witten made clear in his talk that one cannot start with a classical theory and then quantize it to get M-theory. Rather, you have to start with alpha' and hbar together.

Can anybody expand on this? What is he talking about?

24. **Peter Woit**
August 15, 2010

Pmer,

I think this is just one aspect of the fact that we don't actually have any definition of M-theory or really know what it is. We really just have a conjecture that a theory exists with certain properties.

For first-quantized string theory, you can proceed in the usual way, "quantizing" a classical theory of strings. But this can only give you interactions through a series expansion in the string coupling (expansion in the genus of the string world-sheet) one that doesn't converge. M-theory, among other things, is supposed to give a theory valid at non-zero string coupling. One doesn't know how to get M-theory by "quantizing" a classical theory and Witten suggests will be impossible. But until you understand what the theory is a lot better, I don't see how you can be sure that it might not have some formulation that could be interpreted as a "quantization" of something.

Short Items

August 4, 2010
Categories: Uncategorized

- There has been some recent progress on increasing the LHC luminosity. Recent physics fills have peak luminosities around 2.5 x $10^{30}cm^{-2}s^{-1}$, total integrated luminosity is above 500 nb^{-1}, with a goal of getting to 1000 nb^{-1}=1 pb^{-1} this week. The current goal is to get to peak luminosity of around 1 x $10^{32}cm^{-2}s^{-1}$ this year, but there are only about 12 weeks left in this year's proton run. To achieve next year's goal of 1 fb^{-1} in integrated luminosity, they will need to get to peak luminosities around 2 x $10^{32}cm^{-2}s^{-1}$.
- According to a new preprint entitled It's On, with only 70 nb^{-1} of analyzed data ATLAS has already been able to rule out some parts of the huge parameter space of supersymmetry models, beyond that already ruled out by the Tevatron. These limits come from looking for missing transverse energy.

A story at Ars Technica says:

> John Ellis was quite a bit more optimistic; he expects that we might be seeing new physics once we've obtained somewhere in the neighborhood of a trillion events, which may happen as soon as this autumn. Since the Higgs boson, the ostensible target of the LHC, is in a noisy place, in terms of the other particle decays with similar signatures, we may actually end up seeing supersymmetry first. Since the experiments are so well-tuned, it may only be a matter of hours before it's flagged, and the rumors start to filter out.

A trillion events is about 10 pb^{-1}.

If there's no sign of supersymmetry in this year's LHC data, how discouraging will this be for those who expect to see supersymmetry at this energy scale?

- Besides supersymmetry, something else that experimentalists will be looking for in the initial LHC data will be a fourth generation quark. The Tevatron has been able to put limits of 300 GeV or so on the mass of such a thing, see Tommaso Dorigo's latest posting for more about this topic.
- Capitalist Imperialist Pig has a review of a movie with the title *String Theory*. It seems that this is actually a very popular movie title, used by at least two feature-length films (here and here) as well as three shorts (here, here and here). For some reason (as far as I can tell), no one has yet used *Not Even Wrong* as a film title.
- *Colliding Particles* is a well-done on-going series of films featuring experimentalists working at the LHC. There are six of them so far, and they're available on-line here.
- While I was away Erik Verlinde made the New York Times with his "entropic" theory of gravity. There's also a talk at ICHEP available here. This week he's promoting this at SciFoo, going on at the Googleplex, see a report here:

> So far all this is just an "intuition", Verlinde says. Now he needs to find the mathematics to prove it. Then he shrugs and says perfectly matter-of-factly that this was how Einstein started out too.

I really don't get this at all….

- From David Berenstein I learned about Jonathan Rosenberg's comic series Scenes From A Multiverse (some randomly chosen examples here and here).
- Finally, from Gordon Watts, a wonderful tale of the tenure process.

Update: One more. There's a very informative long piece by Stephen Hawking here about his scientific career.

Update: See Resonaances for more about the "It's On" paper.

   August 4, 2010

   If there's no sign of supersymmetry in this year's LHC data, how discouraging will this be for those who expect to see supersymmetry at this energy scale?

   In 2010 data? Not discouraging at all. In 2011 data? Fairly discouraging. In 2014 data? Enormously depressing.

2. **DB**
   August 4, 2010

   Since supersymmetry is in a permanent state of being always "just around the corner", failure to observe it will only strengthen such convictions.

   It is a self-reinforcing cycle.

3. **Peter Woit**
   August 4, 2010

   DB,

   I think a lot of that (although not all…) has been the LHC (or SSC) being "just around the corner", which has been the story for a long time now. So, failure to find evidence for supersymmetry at the LHC when it finally is working will significantly change the environment.

4. **DB**
   August 5, 2010

   I would say that the environment for SUSY and especially for String Theory (which is umbilically bound to SUSY) has already changed very significantly since you (and Lee Smolin) launched your crusade. Failure to find SUSY will consolidate this trend.

   But the true believers have an ace up their sleeve: split supersymmettry – it knocks the ball into the next court and keeps the faith alive. However, they won't be able to claim its around the next corner anymore, more like around the next galaxy!

5. **Roger**
   August 5, 2010

   DB – Split SUSY still predicts new physics at TeV energies, eg a stable gluino.

6. **DB**
August 5, 2010

Thanks Roger, I must have been thinking of Supersplit Supersymmetry :))

7. **SpearMarktheSecond**
August 5, 2010

Energy trumps luminosity easily in the beyond the SM search business… twas ever thus. But the Tevatron is the remnant of the US HEP program, so, it gets a bit more hype than is deserved.

The light Higgs is one kinda sorta exception. Amazing the level of hype the light (<2M_W) Higgs has produced.

8. **Anonymous**
August 5, 2010

In the article Hawking says he was lucky not to do a PhD project in particle physics at that time, because the Cambridge school was in support of the futile S-matrix program, and his work would have been forgotten by now…

Maybe today's graduate students starting a project in string theory should think about Hawking's words? (Though nobody knows for sure)

9. **ozanam**
August 6, 2010

here is an excerpt from a recent article by Stephen Hawking:

"….There was an exciting period culminating in the Les Houches summer school in 1972, in which we solved most of the major problems in black hole theory.

This was before there was any observational evidence for black holes, which shows Feynman was wrong when he said an active field has to be experimentally driven. Which is just as well for M theory [a relative of string theory that involves membranes]. "

Peter, comment ?

10. **Peter Woit**
August 6, 2010

oznam,

The problem with the idea of unification in 10/11 dimensions using string/M-theory is not that it isn't experimentally driven. It's that it doesn't work.

11. **Shantanu**
August 6, 2010

ozanam,
Eventually we did find observational evidence for black holes.
Also there were many papers on proposed observational tests of black holes by Salpeter, Zeldovich etc, which had specific predictions which were later vindicated.
whereas in string theory its more than 30 years without a single prediction

12. **stan**
August 6, 2010

"The problem with the idea of unification in 10/11 dimensions using string/M-theory is not that it isn't experimentally driven. It's that it doesn't work."

What does this even mean? String theory has many solutions, embedded in 10/11 dimensions, that look essentially like our world, and that unify the gauge and gravitational interactions into a common calculable framework. The problem is that there is too much flexibility in constructing such scenarios, and hence it is not predictive (at least so far), But I have a hard time interpreting "it doesn't work" as anything more than a debating stance.

13. **Peter Woit**
August 6, 2010

stan,

In science "not predictive" = "doesn't work". This is scientific methodology 101, not a "debating stance".

After more than a quarter-century of learning more and more reasons why string theory unification can't ever predict anything, claiming that it's reasonable to believe that things are going to some day turn around and string theory unification will become predictive, now that's a debating stance…

14. **stan**
August 6, 2010

Peter,

I don't think I'm being overly pedantic by suggesting that saying"it doesn't work" is either too vague or else misleading, if the goal is to actually impart some understanding here. There are obviously huge distinctions between theories which are a) internally logically inconsistent b) make definite and wrong predictions c) make no predictions at all (by themselves). Theories of type a) or b) either have to be discarded or modified. Theories of type c) are not necessarily wrong, but they do have to be supplemented by extra information, incorporated into some other larger theory, etc. in order to be viewed as successful scientific explanations.

These are pretty basic distinctions, but I honestly don't know which of these you are driving at (or maybe you just don't care). I personally believe that string theory is correct but of type c). I think we are going to need new ideas and physical input to make progress, but that our current understanding of string theory will be incorporated into this. I guess you think I'm just an irrational, deluded, string partisan.

The analogy with QFT is often made. It is of course nice that our world is described by a fairly simple gauge group. But it's easy to imagine a world governed by some hideously complicated gauge group and matter representations, maybe even strongly coupled. In such a world it could take ages before QFT would make successful predictions. Would you say that "QFT doesn't work" in this world? This is of course more or less what many people were saying in the 1960s after failing to understand the strong interactions.

15. **Peter Woit**
August 6, 2010

stan,

I've devoted a lot of time over the years to carefully writing a book on exactly the topic of what is wrong with string theory unification (and what many people consider far too many blog postings on the same topic). If you don't agree with or understand the argument of the book or the blog postings that's one thing, but you seem to be pretending they don't exist.

The argument you make that QFT is inherently no more experimentally testable than string theory is one I've answered many times, despite the obvious absurdity of claiming that the most successful scientific theory we have is not distinguishable from one that predicts nothing. Sure, you can imagine a universe governed by QFTs of such complexity that conventional scientific method would be useless. That's not the world we live in. The currently popular idea that we live in a universe governed by a string theory with solutions of such complexity that conventional scientific method is useless is logically possible, just like the idea that we live in a simulation run by aliens, but it's not science.

You're welcome to believe, as many highly competent physicists do, that some new advance is going to come along and fix the problems of string theory unification. But you should first admit that, given our current understanding of the subject, the problems are deadly and this "doesn't work". Maybe someone will figure out how to make it work, but I don't think the last quarter century of history is at all encouraging, so there's a lot to be said for getting people to move on and look for something else.

16. **stan**
August 6, 2010

Peter,

My interpretation of your position is that you firmly believe that the true physics lying behind the Standard Model is "simple" in some sense, and so the correct theory describing it will lead to testable predictions in short order. Since String Theory has not provided any such predictions it must be the wrong theory. That's fine, but I doubt you can put forth a shred of evidence supporting this — it's an aesthetic judgement. I don't feel compelled to hurl insults at you based on this.

What are these "deadly problems" you mention that I must admit to? As I said at the start, the problem with string theory model building is that it is too flexible, allowing for too many ways of constructing worlds that look like ours, hence not being predictive (exactly the same problem faced by all existing QFT based attempts at unification by the way). Everyone agrees additional input is needed, the disagreement is whether this means that string theory is incompatible with whatever this new input is.

17. **Peter Woit**
August 6, 2010

stan,

Sure, my belief is that particle theory will continue to advance in the same way that it always has: if we find a more accurate description of nature than the Standard Model, it will be one sufficiently simple for us to analyze it and confront it with experiment in a conventional scientific manner. This isn't just "an aesthetic judgment", it's more about my understanding of what it means to do science. Claiming that string theory unification involves some new way of doing science, necessitated by the complexity of its solutions, is just a cop-out and refusal to acknowledge failure.

The fact is that string theory unification allows no reliable and predictive computations of any kind. Why this is requires a long analysis of an incredibly complicated set-up, but whatever you think the reasons for this situation are, those are the "deadly problems". Again, you may believe someone will someday make them disappear, but right now they're there and looking at the history of the subject gives no reasons for such optimism.

18. **stan**
August 6, 2010

Peter,

We're starting to go in circles here. Let me just note that if we somehow were able to determine that we lived in String Theory Vacuum X of the sort that people have studied, there would be lots of predictions we could make. You think this could never happen, either because string theory has nothing to do with our world, or because even if it does it is still inherently incapable of making predictions — I'm still not clear what your position on this is.

People will jump en masse into any new line of thought that could lead to beyond the Standard Model predictions, based on string theory or otherwise. The fact that no attempt so far has been successful in this sense is seen by some as evidence that no simple answer is lying just around the corner. I personally think that expecting to find enlightenment based on greater mathematical sophistication is a poor judgement. Since you argue based on historical precedent I will do the same: I can't think of a single example in modern physics where a testable prediction has emerged from someone pursuing a mathematically minded approach. Advances always seem to come from applying old math to deep new physical insights. It's actually quite remarkable how unsuccessful mathematicians have been in directly advancing physics. It's amazing that all of known physics can be understood using math no more complicated than basic differential geometry and simple group theory. I say all this to challenge the viewpoint promoted by your book and your blog (and to prove that I have read them, at least in part).

19. **CWJ**
August 6, 2010

stan said: *"I can't think of a single example in modern physics where a testable prediction has emerged from someone pursuing a mathematically minded approach"*

I can:

General relativity.

The Dirac Equation.

There are probably scads more.

20. **jpd**
August 6, 2010

whats so special about 'modern physics'
eg fourier and newton ?

21. **stan**
August 6, 2010

General relativity.

The Dirac Equation.

Neither of these are good examples. Riemannian geometry was at least 50 years old when Einstein used it. Everything in physics obviously uses math that was new and sophisticated at one time, but I was looking for examples involving new mathematical ideas.

Neither did Dirac use any sophisticated math. He wanted a Lorentz invariant first order wave equation, and found that he needed objects obeying anti-commutations relations. By trial and error he found that some 4 x 4 matrices did the trick. I don't think he needed to consult with mathematicians or read math papers to do this!

22. **stan**
August 6, 2010

whats so special about 'modern physics' eg fourier and newton ?

Up until one or two hundred years ago, there wasn't much distinction between a mathematician and theoretical physicist. Since then things have diverged, and mathematicians have adopted a style different from physicists. I think history shows that their style has not led to advances in the search for new physical laws.

23. **Peter Woit**
August 6, 2010

stan,

The problem with the argument that "if we could determine the string theory vacuum" all would be well is that we can't determine the string theory vacuum. The reasons for this are complicated, having to do with inherent limitations on what is calculable for each possibility in the current string theory set-up, together with the huge number of possibilities.

I have looked closely at attempts to do string theory phenomenology and to make progress on getting to something that would do what you argue for. Everything I've seen is ridiculously far from being useful. The fact of the matter is that string phenomenologists have had 20 years to prepare for the opening of a new energy scale at the LHC, it's here, and they have no predictions at all. If this isn't failure, I don't know what is. The idea that new LHC physics is going to match some string-inspired vacuum and justify string theory is so far-fetched that even most string theorists I know dismiss it as completely implausible.

You're right that my own judgment about ideas worth pursuing involves trying to get inspiration from mathematics. This has worked out sometimes in the past (e.g. general relativity), but it's true that most of the time it has not been fruitful. I'd argue that this is because historically experiments were throwing up things that disagreed with theory, and pursuing these as hints was far more likely to lead to progress than pursuing mathematical hints. The problem now is that we don't have much in the way of such hints from experiment, so may not have any choice but to try and make progress along other, more difficult lines. In any case, I think this is a time people should be trying all sorts of different approaches, since no one has good evidence that of any particular speculative approach working out.

24. **stan**
August 6, 2010

Peter,

I agree with you that it is very hard to get particle physics predictions out of string theory. Ergo, if our world is described by a complicated string theory vacuum, doing fundamental physics is going to be very difficult. The non-sequitur comes when you present this as evidence that our world is not described by such a string theory vacuum. This makes no logical sense unless you are starting from the axiom that physics should be simple, in which case the whole argument is circular.

Actually, I hope you're right, and I wished I shared your optimism.

25. **Bruno Galileo**
August 6, 2010

woit writes, "You're right that my own judgment about ideas worth pursuing involves trying to get inspiration from mathematics. This has worked out sometimes in the past (e.g. general relativity), but it's true that most of the time it has not been fruitful. "

actually, general relativity was inspired not by mathematics, but by the very *physical* reality of gravity.

you will recall that einstein hired mathematicians to figure it out.

to not take my word for it, but heed freeman dyson:

In Disturbing the Universe, Freeman Dyson writes, "Dick [Feynman] fought back against my skepticism, arguing that Einstein had failed because he stopped thinking in concrete physical images and became a manipulator of equations. I had to admit that was true. The great discoveries of Einstein's earlier years were all based on direct physical intuition. Einstein's later unified theories failed because they were only sets of equations without physical meaning. Dick's sum-over-histories theory was in the spirit of the young Einstein, not of the old Einstein. It was solidly rooted in physical reality." In The Trouble With Physics, Lee Smolin writes that Bohr was not a Feynman "shut up and calculate" physicist, and from the above Dyson quote, it appears that Feynman wasn't either. Lee writes, "Mara Beller, a historian who has studied his [Bohr's] work in detail, points out that there was not a single calculation in his research notebooks, which were all verbal arguments and pictures."

Hype or Not Hype?

August 6, 2010
Categories: This Week's Hype

The high point of my expertise in condensed matter physics was about thirty years ago, when I studied the subject in order to pass one of the general exams at Princeton. At the party after the test was graded, Phil Anderson came up to (after a fashion…) compliment me, noting that he was glad to see that even though I hadn't been able to solve one of the condensed matter problems, I had known enough to realize that the calculation I was trying to do was giving a result that couldn't be right and had written that on the test.

Since then, my little understanding of the subject has slowly decayed over the years, so I'm in no position at all to evaluate claims made about new advances. Recently there has been a lot of interest in applications of gauge/gravity duality to certain condensed matter systems, and this week there's a new article out in Science (not available on the arXiv itself, but based on this arxiv preprint), together with a press release from MIT. This has led to news stories headlined String Theory Explains Superconductors, and String theory and black holes show a possible path to practical superconductors. This latest story starts off:

> A leading candidate for room temperature superconductors is the copper compound cuprate, but no one knew how cuprates facilitated superconductivity…until some brave souls looked inside a black hole and broke out the string theory to explain how they work.

So, hoping that there might be someone expert on this out there and willing to comment, what's the verdict: hype or not hype?

Comments

1. **Professor Elephant, Ph.D.**
   August 6, 2010

   Hype. Without much doubt.

2. **Dr Ron**
   August 6, 2010

   Well, it's 30yrs since I worked in condensed state physics for my PhD, and it had pretty well lost its way back then. To my casual glance, this is the application to the condensed state of some peculiar substances of some of the well-established mathematics that has been developed in the course of studying string theory, just like we happily fiddled with Green functions way back when. Perfectly plausible. Damn all to do with String theory per se, but it makes a better headline.

3. **Peter Orland**
   August 6, 2010

   It sort of makes sense to use a new tool (i.e. AdS-string methods) to try to study as many problems as possible, and that's my impression of what is going on.

   Like you, Peter, I not a condensed-matter insider, but I try to keep up with cond-mat. In the two or three years many people have tried to use string theory in condensed matter physics, but I don't think there is a definite outcome. The big problem in high-T_c (from my ignorant standpoint) is non-Fermi-liquid behavior (in many contexts). I am not aware of any definite progress on this front using any method. I don't have any specific comment on the paper you mention, though.

4. **Peter Orland**
   August 6, 2010

   OK, I just glanced at the paper. It seems to be an attempt to describe a non-Fermi-state using anti-deSitter methods. It is not a microscopic approach, though. With no microscopic theory (e.g. a Hamiltonian for the electrons/holes) it isn't clear to me what it all means.

5. **Peter Orland**
   August 6, 2010

   I suppose one can have an effective theory (like the Ginzburg-Landau approach). I can't see whether this string-AdS model is even an effective theory in that sense, since it seems to just start with some high dimensional system. Maybe a real non-Fermi-liquid should behave the way the authors claim, but it is not clear to me.

6. **neo**
   August 6, 2010

   I don't know whether it is hype, but it seems simple to decide. Theorists need simply to show how string theory provides a single prediction about superconductivity that is not predictable without string theory but which is or eventually can be confirmed. Then everyone will pay attention.

7. **Roger Schlafly**
   August 6, 2010

   Peter, you are going soft on us. The p.r. even has Polchinski saying physicists can throw in some gauge/gravity duality whenever they cannot understand a system. Do you really think that there is some chance that black holes will explain the conductivity of rare metal compounds?

8. **Anonymous**
   August 7, 2010

   It would be interesting to find out Xiao-Gang Wen's opinion about AdS/Condensed matter. Originally a student of Ed Witten, now a professor in the condensed matter theory group at MIT, his research has spanned string theory, quantum gravity, and (NON-string related) high Tc superconductors. (Though I'm not sure whether he still follows string theory.)

9. **spin fluctuations**
   August 7, 2010

   I have recently been involved in the new iron superconductors. Judging by who gets invited to give lectures at conferences, it seems theorists who do first principles calculations have made important contribution in this field than people who study various models. There are some papers written by Sachdev, Viswanath, etc. about superconductors, but most people don't seem to pay attention to them.

In superconductors, the most important questions are what are the pairing interaction and symmetry. I don't think string theory has anything interesting to say about that and people in condensed matter theory and experiment don't seem to care about AdS/CMT correspondence.

10. **nbutsomebody**
August 8, 2010

Hype 75%
Not hype 10%
Who knows ? 15%

11. **nbutsomebody**
August 8, 2010

My previous rating was for the usefulness of AdS/CMT activity. If the question is about pairings in cuprate etc. (what peter asked) then

Hype 99.5%
Who knows ? 0.5%

12. **anonymous**
August 9, 2010

The claims are overstated in the press release, but AdS/CFT does provide an interesting handle on strongly coupled field theory at finite density, a subject that goes back several years. The MIT group's paper as well as one or two other papers in this area have found some of the hallmarks of strange metal behavior, but in models that are known not to be the correct theory for the cuprates or any other real material. The hope is that some aspects of the AdS/CFT theories can survive an extrapolation to real materials, but there has not been a concrete proposal for a systematic way to improve the AdS/CFT models to make them realistic.

13. **ab**
August 9, 2010

Not hype.

14. **Avidan**
August 9, 2010

You gotta be kidding, of course its hype. I hear numerous AdS talks on this superconductor crap and unfortunately read more on high-Tc than most of the speakers (and their advisors).

The definition of high-Tc superconductors according to string- theorists is: any gravity background, which if applied on with the correspondence, that is unlikely to work except for N=4, will produce something with funny dispersion relation.

Oh God, what has science has come to. God bless wall-street for giving these people something to do once they figure out that there are no jobs in this swindle.

15. **nbutsomebody**
August 9, 2010

ab,

Most of it is hype. Are you kidding ?

16. **Smurf**
August 9, 2010

The authors of the paper managed to construct a gravity background which seems to be dual to a system with non-Fermi-liquid-like behavior. (This is not the first paper on the subject though.) Everything else is hype, but what is not hype in today's media?

17. **nbutsomebody**
August 9, 2010

Although unrealistic the non-fermi liquid part is reasonably interesting. However any connection with cuprate superconductors and claim that gravity duals may be used to understand the high-Tc pairing mechanisim is pure bullshit !

18. **somebody**
August 10, 2010

"However any connection with cuprate superconductors and claim that gravity duals may be used to understand the high-Tc pairing mechanisim is pure bullshit !"

Its not clear to me that in high-Tc superconductors (which are strongly coupled) "pairing" is a good description because particles are an inherently weakly coupled notion. At best "pairing" can count the charge of the condensate in terms of the fundamental charge, but beyond that it is not really useful.

Anyway, the message that I draw from the holographic superconductor business is that many of the features of high-Tc superconductors are universal, and captured by gravitational systems via AdS/CFT. This is scientifically interesting. Nobody in the field is under the illusion that they have a theory for any *specific* cuprate. The problem is morally as hard as finding the standard model among the vacua of string theory.

The hype in the public media (if it exists in this context) is such an omni-present problem that I will leave that fight to braver souls.

19. **Anonymous**
August 10, 2010

AdS/QCD is remarkable because it is the *only* theoretical tool (not counting lattice QCD) which calculates quantities such as entropy / viscosity ratio. According to the MIT press release, AdS/CMT is also the *only* model that offers an explanation of the behaviour of "strange metals" such as linear dependence of resistivity on temperature. (In the article, Liu says "There's really no theory of how to explain that") If this is indeed the case, I would say they are probably on to something!

20. **Peter Orland**
August 10, 2010

Anonymous,

A strong-coupling calculation of the ratio of entropy to viscosity is found analytically (not numerically), without using the AdS correspondence in

http://arXiv.org/abs/0810.4181

21. **Peter Orland**
August 10, 2010

My point is not that one can't learn from the AdS correspondence in some contexts (I believe one certainly can). It is that it is just one tool among many (such as that mentioned above for the entropy/viscosity ratio), and is heavily oversold as solving heretofore unsolved problems. It's high time to solve some of these strongly-coupled problems, not to sell the proposed solution.

22. **anonymous**
August 10, 2010

There are already multiple ways to explain linear resistivity in the holographic setting (the one in the MIT press release, and Lifshitz theories and generalizations to name two). This may be theoretical progress, but the effective theory of real high Tc materials is an open problem, and still of great interest.

23. **somebody**
August 10, 2010

Sorry but I might be missing something. Seems to me that strong coupling expansions of the kind in that paper (0810.4181) are believable only a-posteriori. It is essentially a purely classical computation (even though naively it uses the path integral in terms of Wilson loops). It is not clear what renormlaization means here (in a theory like QCD this is not forgivable), it is not clear where the confinement-deconfinement transition is etc. The latter is essential because it is only in the deconfined phase that one can talk about viscosity to entropy ratio.

I agree it is not a worthless calculation, but to call it "another technique" seems a bit too much. Why did nobody do it until AdS/CFT? The authors quote the AdS/CFT result explicitly and one of the authors has written papers on string theory …

24. **nbutsomebody**
August 11, 2010

"Anyway, the message that I draw from the holographic superconductor business is that many of the features of high-Tc superconductors are universal, and captured by gravitational systems via AdS/CFT. This is scientifically interesting. Nobody in the field is under the illusion that they have a theory for any *specific* cuprate. The problem is morally as hard as finding the standard model among the vacua of string theory."

really ?, many features of high-Tc superconductors are universal, and captured by gravitational systems via AdS/CFT ? This is the most standard hocus-focus most AdS/CMT people will write in the introduction of their papers (well, I have to do it too :)). The whole point is that there is no reason to believe such claims.

25. **nbutsomebody**
August 11, 2010

It is undeniable that viscosity and entropy ratio calculation is a big triumph for string theory. Other applications of AdS/QCD, while not exact, are also sufficiently interesting. AdS/QCD is a standard part of various QCD and lattice literature. Most reviews contain some holographic results etc. atleast for a comparison purpose.

However the question here not so much with AdS/QCD but with AdS/CMT. Is it possible to learn something novel about condensed matter system by applying ideas of AdS/CFT ? I would like to stick with a resounding nooo…

26. **chris**
August 11, 2010

somebody,

your argument is really priceless. yes, 0810.4181 does make uncontrolled approximations – but at least it starts out with the right theory.

but well, if you think that this is far worse than some estimate in an N=4 maximally supersymmetric extension of QCD…

27. **somebody**
August 11, 2010

" many features of high-Tc superconductors are universal, and captured by gravitational systems via AdS/CFT ? This is the most standard hocus-focus most AdS/CMT people will write in the introduction of their papers … The whole point is that there is no reason to believe such claims."

Really? All you have is that ideological pronouncement?

Before AdS/CFT, how often has anyone been able to theoretically produce even the condensate curve of a strongly coupled superconductor? Getting generic (universal, if you prefer) condensates, conductivity, gap, etc. are simple via AdS/CFT. I am not repeating a talking point I read somewhere: it is simple and I know how to do it. The point is that this is still not enough in understanding any *specific* high-Tc superconductor.

To check what you call a "claim" for its veracity, you just need to open one of the papers and read beyond the "hocus pocus" in the introduction.

28. **somebody**
August 11, 2010

" … but well, if you think that this is far worse than some estimate in an N=4 maximally supersymmetric extension of QCD…"

All this is at finite temperature, so SUSY is broken. The bigger problem potentially is that N=4 SYM is conformal, whereas QCD is confining. But at finite temperature conformal invariance is broken and the deconfined phase is what we are after.

But yes, I agree that it is a matter of judgment.

29. **Peter Orland**
August 11, 2010

somebody,

We've been over this before. Yes strong-coupling approximations are not controlled approximations. But AdS/QCD is also a strong-coupling approximation.

This is a renormalization-group issue. The only correct way to make a strong-coupling approximation is to integrate out all the short-wavelength degrees of freedom. Unlike at weak coupling (near the fixed point, where the theory becomes simple), this means the effective theory is filled with irrelevant operators. Until that is done, I can't trust the claim that a lattice or stringy strong-coupling method comes from QCD. I don't know if you work on AdS/ACD, but many who do work on it, to their credit, understand this point.

30. **Peter Orland**
    August 11, 2010

    Anyway, the only reason I brought up the lattice paper on entropy/viscosity is to point out that AdS is not the *only* (claimed by one of the many Anonomouses) method for doing analytic calculations. The real problem is that there is *no* analytic method which is clearly correct.

    I think the situation is similar in condensed-matter physics. Ultimately the goal is to calculate using a microscopic Hamiltonian, not a model. Does this mean string methods are not useful? Of course not. It just means they haven't solved these problems yet.

31. **somebody**
    August 11, 2010

    Peter O., I am not sure I understand what you have in mind. For instance, it is not clear at all to me what you mean by microscopic description. From one of your previous messages it looks like what you want is to understand high-Tc superconductors in terms of a Hamiltonian for electrons and holes. Electrons and holes are useful only when the theory is close to a free limit. It is meaningless to talk about them away from it where the degrees of freedom can be completely different. If it was a UV free theory or something, there would be some meaning to saying that they *are* the true degrees of freedom (like quarks in QCD), but here we only care about the IR of the theory.

    In fact, this is the whole reason why it is not a Fermi liquid: high-Tc superconductors have charge carriers that don't behave like free particles on a fermi surface. It is a mistake to think that the microscopic Hamiltonian for superconductivity is comprised of electrons and holes: the microscopic Hamiltonian is that of the standard model of particle physics. It is indeed an unsolved challenge to see how the (dressed) electrons and phonons of BCS theory arise from the standard model. But we don't care, because that is not what we mean by solving superconductivity. What we mean when we try to "solve" superconductivity, is precisely to identify the right degrees of feedom where the problem can be understood quantitatively: we are trying to GUESS the degrees of freedom, because deriving it is impossible. This is what BCS did, for usual (weakly coupled) superconductors: they guessed that they were phonons etc. In a strongly coupled high-Tc system, if a gravitational/stringy system can be the right degrees of freedom, then that answers the problem as completely as BCS theory. Yes, a dual black hole is more dramatic than a phonon, but that is hardly an argument against it.

    Wanting to have a theory in terms of electrons and holes, as you say in a previous message is simply not the right approach, IMHO. If there is a string vacuum which can reproduce a /specific/ superconductor, then that /is/ the theory we want, and the problem is solved. I personally think it is a looooooong shot, but it does seem useful for understanding some generic features.

    PS: As a final comment, I use the word "hole" loosely, because you used it. Doping and superconductivity seem somewhat distinct to me: but I hardly know any condensed matter, so what do I know?

32. **nbutsomebody**
    August 11, 2010

    "To check what you call a "claim" for its veracity, you just need to open one of the papers and read beyond the "hocus pocus" in the introduction."

    Actually, I wrote few of them 🙂

    AdS/CMT does not produce a condensation curve which may not be reproduced by Landau-Ginzberg theory. However you are quite correct that calculation of conductivity and especially the mass gap etc. is indeed a novel result. I personally find it very interesting. However the results one gets is rather unphysical and mass gap is actually zero. It changes to a non-zero value as we shift to a non-abelian p-wave holographic superconductor. I do not want to go into more technicality as Peter does not like a lot of technical discussion in this blog. However the bottom line is quite clear that it is unclear (sorry for the pun) whether there is something generic about strongly coupled superconductors. Hence we may not say much about high-Tc etc from the study of holographic superconductors. The goal in high-Tc business is to learn about some specific superconductors. Generic results possibly do not have much role to play.

    Also look at Peter Orland's post about uncontrolled nature of whole AdS/CFT business. Another point is that here the system we are looking at is rather different than conventional superconductors. It is a lorentz invariant system, there is no lattice, it is a large-N gauge theory and the list goes on and on. The whole holographic superconductor business is actually just the study of bose condensation in a holographic context. That is why it is sometimes called holographic superfluid and has more closer relation to flavor superfluid phase in QCD phase diagram.

    To set the context correct there was no debate about the relevance of studying holographic superconductors. It is possibly interesting and relevant. Although it is unlikely that it would provide a deep insight in cuprates.

33. **Peter Orland**
    August 11, 2010

    "Wanting to have a theory in terms of electrons and holes, as you say in a previous message is simply not the right approach…"

    It's not? I thought it was the goal. Isn't that what we're supposed to do is describe phenomena in terms of the most basic theory we can?

34. **nbutsomebody**
    August 11, 2010

    Peter Orland,

    "It's not? I thought it was the goal. Isn't that what we're supposed to do is describe phenomena in terms of the most basic theory we can?"

    I think so. That is what I have been informed by my colleagues in condense matter.

35. **somebody**
    August 12, 2010

Peter O., contrary to the comments of the other somebody, there is strong experimental evidence that the system cannot be captured by a weakly coupled Fermi liquid. That is, free electrons etc. cannot be a good description in a high-Tc superconductor. (for eg. linear resistivity above Tc cannot arise from a weakly coupled description.)

I emphasize that even in the BCS theory, the degrees of freedom (not sure why you call them microscopic, they are strictly effective) were *guessed*. (Dressed) Electrons and phonons there, are effective, in no sense fundamental, and also we do not know how to derive them by integrating out some fundamental theory.

The thing about BCS that made things useful, was not that it was fundamental, but that these effective field theory d.o.f were weakly coupled.

36. **somebody**
August 12, 2010

"Actually, I wrote few of them "

So you were being disengenuous, and not ignorant. You have got me between the devil and the deep sea …

"AdS/CMT does not produce a condensation curve which may not be reproduced by Landau-Ginzberg theory."

No condensate curve can ever be /not/ produced by some Ginzburg-Landau theory. So this point is moot.

"However you are quite correct that calculation of conductivity and especially the mass gap etc. is indeed a novel result. I personally find it very interesting. …."

You seem to be going back and forth between this and the other extreme. About your other comments like p-wave etc.: the real high-Tc superconductors are d-wave, so I would say it is encouraging that a hard gap can be found by going from s to p.

But anyway, there are other problems when you get to d-wave because the spin is too high etc. My point: that some general characteristics of superfluid/superconductors can be captured by holographic methods is not bad. This already warrants further inevstigation. I am not going to do it myself pbbly, because I prefer more fundamental questions, but I am glad someone is doing it.

37. **Peter Orland**
August 12, 2010

Yes, somebody (capitalized Somebody?), we know it isn't a Fermi liquid. The disagreement is not a technical one, so there is no need for a technical justification.

Physics is supposed to explain things, as well as describing them. It's fine to derive Green's functions from a scheme, but you need to derive them from a theory. Schemes and theories are not (always) the same.

AdS methods are another tool and more power to the people who use them. The point people are making on this thread is that AdS/CMT is not enough. You have to justify it on the basis of something you know about matter. Similarly AdS/QCD needs to be justified from QCD. That, in a nutshell, is the problem.

38. **somebody**
August 12, 2010

I do not agree that the Fermi liquid issue is merely a technical point. The fact that high-Tc is a non-Fermi liquid is of fundamental significance in this discussion. You seem to want to apply the particle/hole/phonon idea in a situation where I see no reason why it should be applicable.

Also, why are you not unhappy that nobody knows how to derive BCS theory from standard model or QED? Why is BCS any more explanatory, than descriptive in that sense? Is it because you have a mental picture of a metal with free electrons etc. in it?

"The point people are making on this thread is that AdS/CMT is not enough. You have to justify it on the basis of something you know about matter."

From my side, it looks like you are just uncomfortable with the idea of a dual description, where the original degrees of freedom have re-organized (or at least re-expressed) into something completely different. You rationalize that discomfort by looking suspiciously at AdS/CFT.

Wanting a full proof of AdS/CFT is a noble thought and certainly interesting. But note that in the history of QFT it would've been a bad idea to first make the path integral rigorous. Working with it instead, was what lead to progress especially in the second half of the last century. My strong prejudice is that trying to prove AdS/CFT in a full way is a bad idea at this stage. I am convinced that AdS/CFT is correct, not just because of the specific and detailed tests, but also because the beautiful way in which too many different things (like details of gauge theories, gravity and black hole thermodynamics) tie together.

Also, this thread is really about the specific issue of condensed matter applications, not the general viability of holographic methods. I am not interested in the latter discussion because having worked with various aspects of gauge-gravity duality, I think a blog discussion is unlikely to change my opinions on it.

39. **Peter Orland**
August 12, 2010

Somebody, my discomfort isn't with dual descriptions (which I have worked on, by the way). I am not trying to cast suspicion on this idea or that idea. I am trying to cast suspicion on declarations of victory.

I and nbutsomebody (whoever he or she may be) are just trying to make a non-technical, unbelievably simple, point.

In physics we try to understand how behavior emerges from theories. No one is saying we should derive BCS directly from the standard model, which would be a very foolish thing to try to do. But B, C and S derived superconductivity from a theory of Nature (electrons and phonons). We can understand how this theory arises from QED, another theory of Nature. This in turn arises from the standard model, yet another theory of Nature. There are some mathematical gaps (the second law of thermodynamics, crystallization), but we have a pretty good picture of how it all this fits together.

Ultimately, we would like to understand non-Fermi-liquid behavior from a Theory of Matter. Phenomenological models are stepping-stones, not the answer. This is very basic to science.

Here is a better analogy than BCS. Kepler's laws are great, but they aren't enough to explain how the solar system works. A theory of mechanics and gravity is more fundamental. Maybe in the 17th Century, someone thought science should settle for Kepler's laws. Wasn't it a good thing some scientists didn't believe that Kepler's laws "explained" astronomy? I think so.

Having taught courses for non-physicists, I know that many non-technically-trained people understand this. Don't you?

40. **somebody**

August 12, 2010

"But B, C and S derived superconductivity from a theory of Nature (electrons and phonons). We can understand how this theory arises from QED, another theory of Nature."

No, we don't know how to get BCS from any more fundamental theory. This is the point. You are just comfortable with the idea that BCS *might* be derivable from QED, because the ingredients are not too exotic. The degrees of freedom are not the same as in QED, the vacuum we are working with is horrendously complicated (a metal), we really have NO idea. BCS were clever to ask the correct (effective) questions to get the correct (effective) answer.

If (a big if) holography delivers, this will precisely be the situation with high-Tc. The only difference is that the description of the system is in dual variables, in terms of black holes in AdS. It will be phenomenological, exactly to the same extent that BCS theory is. The comparison is not at all with Kepler's laws. It would indeed be great if we could derive effective theories from fundamental theories, but that is generically not possible with most mesoscopic phenomena.

In particular, it is not clear to me that the phonons etc. are somehow useful for any purported "microscopic" description.

"Having taught courses for non-physicists, I know that many non-technically-trained people understand this. Don't you?"

🙂

41. **Peter Orland**
August 12, 2010

What a lot of baloney!

Somebody, if you don't think that science uncovers deeper descriptions, then why do it?

42. **Peter Orland**
August 12, 2010

… and since you don't want to argue the real issue and prefer to hide in a smokescreen of jargon…

BCS applied mean field theory and a Bogoliubov transformation to a model of electrons and phonons. They didn't start with the answer, they derived it! BCS is not a phenomenological theory. I don't know where you came up with the nonsense above.

43. **somebody**
August 12, 2010

"Somebody, if you don't think that science uncovers deeper descriptions, then why do it?"

Its money for nothin, and chicks for free in physics. Thats why. 🙂

You will have better luck with me, if you phrased your commentaries as commentaries and not rhetorical questions. Lets not re-interpret my criticisms about specific misunderstandings you had, into some deep and profound differences in our "views" on science. Science is of course about deeper truths, what I am saying is that these deeper truths do not fit with your prejudices.

I imagine that there will be hell to pay for my glib comment above: Woit gets all politically correct when string theorists are being tongue-in-cheek. So I will be bowing out.

44. **Peter Orland**
August 12, 2010

My questions were not rhetorical. I was really curious.

You misinterpret my disagreement with you as a technical issue. It's really not technical. That's why I tried to turn the conversation to plain words, not jargon.

45. **somebody**
August 12, 2010

"BCS applied mean field theory and a Bogoliubov transformation to a model of electrons and phonons. They didn't start with the answer, they derived it! BCS is not a phenomenological theory. I don't know where you came up with the nonsense above."

Aaaaaargh, you drag me in again! 🙂

Where do you have phonons and dressed electrons in any fundamental theory, sir? QED doesn't have them! Is this so difficult to understand? What you call a derivation is what I call BCS theory already. That derivation is trivial, and one can essentially do away with it by just writing down the relevant operators once one identifies the degrees of freedom. The point is that it is forbiddingly difficult to derive it from a (microscopic) theory like QED where the degrees of freedom look different: photons, fermions, etc, are different from the phonons etc. of BCS. This is why BCS is an *effective* theory.

46. **Peter Orland**
August 12, 2010

Yes, the degrees of freedom look different. No, we can't rigorously derive electron-phonon systems from QED. But that doesn't mean we have no understanding of how they arise from QED.

I apologize if I have made you so frustrated. My friends (it's hard to believe I have any, I admit) and relatives all tell me how frustrating I can be.

There are outstanding problems in deriving certain results from deeper models. Some of us fall back on approximations, and sometimes hand-waving arguments. A small number of people try to prove propositions and theorems to make some of the connections more carefully (like how states of matter appear in more fundamental theories). I am not saying it is easy.

Your viewpoint seems to be that we can't really explain anything. Well, it's very tough, but occasionally we can.

47. **somebody**

August 12, 2010

Phew, at least we seem to be beginning to understand each other…. lol! Thanks for playing and thanks for staying honest.

Just one comment:

“Your viewpoint seems to be that we can’t really explain anything.”

Not all phenomena, just mesoscopic ones. In general I think trying to truly derive mesoscopic phenomena can be quite hard, but I am not sure thats the equivalent of surrendering. It is usually a detail thing, rather than a concept thing – or so we hope. Because usually, we in particle physics regard the low energy physics as somehow understood, even though it is not really understood. From what you say, it seems like this reductionist hope is ultimately what you vote for too.

But the interesting thing about AdS/CFT is that it is the great equalizer in energy scales: quantum gravity can be dual to things at lower energy scales. Its a bit like concept and detail are dual to each other. This reverse direction of the arrow is what is interesting from a fundamental physics point of view. A detailed explanation of high Tc superconductivity is secondary (at least to me) – no matter how interesting it might be, from a practical point of view.

48. **onymous**
August 12, 2010

Maybe an actual condensed matter expert can correct me, but my understanding is that the CM community doesn’t have even a *toy* calculable model that exhibits all the basic features of the cuprate phase diagram — antiferromagnetism, the pseudogap, superconductivity, a Fermi liquid phase at higher doping — or a good guess at the universality class of the suspected underlying quantum critical point. So *if* AdS/CMT could give a toy model that encompasses all of these phenomena, it might be of interest. My (not thoroughly up-to-date) understanding is that AdS/CMT can give toy models of critical non-Fermi-liquid-like phenomena, tunable to achieve any desired scaling behavior, and hence isn’t so close to doing this. But one could imagine it might be possible, and would count as a success.

As far as matching to *the* correct theory, though, AdS/CMT is dual to something with large N and large ‘t Hooft coupling, and thus is in the same situation as AdS/QCD; it’s a toy model that exhibits a lot of the right phenomena, but it’s *very* far from being *the* system one is interested in, and there’s little concrete hope for bridging the gap in the foreseeable future. This doesn’t make it useless, though; toy models are a worthwhile part of physics.

49. **nbutsomebody**
August 12, 2010

Somebody,

“No condensate curve can ever be /not/ produced by some Ginzburg-Landau theory. So this point is moot.”

It can be found. I am surprised that you do not know it.

50. **nbutsomebody**
August 12, 2010

“So you were being disengenuous, and not ignorant. You have got me between the devil and the deep sea …”

No I was not. It is natural in a scientific literature to speculate when it is explicitly mentioned as so. It becomes disingenuous when those speculations are advertised as a important scientific finding in the popular media.

“My point: that some general characteristics of superfluid/superconductors can be captured by holographic methods is not bad. This already warrants further inevstigation.”

Not bad and not too great either. There are various investigations going on even on less important matter. Surely it deserves some investigation and no hype.

“You seem to be going back and forth between this and the other extreme.”

I am not the center of the universe, nor are you. Just the fact I find something interesting does not mean it is extremely important.

51. **nbutsomebody**
August 12, 2010

Somebody,

“About your other comments like p-wave etc.: the real high-Tc superconductors are d-wave, so I would say it is encouraging that a hard gap can be found by going from s to p.”

Not a bad point ! I think one should write it up and I more or less know how to calculate it. Any interest of doing a “less fundamental” work?

52. **nbutsomebody**
August 12, 2010

onymous,

Very nice description. This is also my realization although I am not a CM expert. However as you have pointed out it would be nice to have model which produces all the feature of cuprates phase diagram in one place. It would be nice if some CM expert correct those speculations.

53. **Seth Thatcher**
August 16, 2010

Peter, I just discovered your blog tonight, or rather this morning and find it extremely helpful both in posts and comments to understanding the ongoing temporal battles in theoretical physics. I am a layman and must admit that I have been taken in by all the Michio Kaku’s of the world and their seeming confidence in the truth of string theory. It is only upon reading this blog that I come to realize that there is a sizable contingent of physicists who regard string theory as bunk. So now I must ask the question-What, if any, theories are there that take the place of string theory in whole or in part? That question is not meant insult. I understand that many physicists may think string theory is incorrect while not having any ideas to what might be correct given the fascinating and elusive nature of our universe. Are there competing theories? Where can I read about them? Thanks in advance and I will be visiting often even if I only understand about 1/100th of what is discussed here.

54. **Yatima**

August 16, 2010

>>What, if any, theories are there that take the place of string theory in whole or in part?

No-one knows. Indeed, is is not at all certain that we already have the mathematical tools to do it yet.

I recommend Roger Penrose's "The Road to Reality" as pretty good math-based "introduction". He doesn't refrain from proposing his own ideas in that Phone-Directory-Sized Wonder, but that's ok. One of the books that take a few years to read.

55. **SteveB**
August 16, 2010

Seth,

I recommend reading Peter's book: Not Even Wrong. Very good reading. The standard model description is good and especially how mathematicians have contributed to the physics. Peter is very reasonable about asking for some verifiable predictions from a theory. I have read Peter's book twice (so far). Also, I recommend Lee Smolin's book, The Trouble With Physics. I just finished it and it is also very good.

56. **Peter Woit**
August 16, 2010

Seth,

There are various competing ideas about how to get a quantum theory of gravity. Lee Smolin has written about some of them. There's an interesting more recent idea that a certain standard supersymmetric version of general relativity may avoid the usual arguments that standard quantum field theory can't give quantum gravity, but I haven't seen a popular exposition of that.

It remains true that there aren't any good competing ideas about unification: how to put the Standard Model and quantum gravity together. The excitement over string theory was mainly due to its promise to achieve this, a promise which hasn't worked out. So, right now we're in a situation where every known proposal for a unified theory has very serious problems. My own point of view is that this means that people should be casting a wide net to look for new ideas, and not spending more time on failed ones. But in no way do I claim that the problem is that there is some great idea about unification that is being ignored in favor of string theory.

57. **stan**
August 16, 2010

… how to put the Standard Model and quantum gravity together. The excitement over string theory was mainly due to its promise to achieve this, a promise which hasn't worked out.

Oh dear, here we go again. String theory does of course provide fully explicit and calculable solutions that unite the Standard Model and Quantum Gravity (there is admittedly some fine print here, which we can discuss if need be), and I'm sure Peter knows this. The hope was that this problem was sufficiently constrained as to admit a more or less unique solution, hence being predictive — a hope that seems not to be realized. So string theory succeeded in unifying the Standard Model and Quantum Gravity. What failed was the dream that this would be enough to make experimental predictions. Any attempt to go beyond the Standard Model has to face up to this fact. The truth is that only String Theory has been pushed sufficiently far to encounter this fact of Nature.

58. **nbutsomebody**
August 16, 2010

Stan,

It would be nice to know more detail about the string theory compactification you are talking about.

59. **Peter Woit**
August 17, 2010

nbutsomebody,

I suppose one could point out again to "stan" that the statement that string theory unification hasn't worked out is an uncontroversial one that even most string theorists agree with. But I fear that would be a waste of time…

Enough about string theory unification hype, unless someone has something new to say. Otherwise, please return to the topic of this posting, whether claims that AdS/CFT explains high Tc superconductivity are hype or not.

60. **Shawn Halayka**
August 23, 2010

"There's an interesting more recent idea that a certain standard supersymmetric version of general relativity may avoid the usual arguments that standard quantum field theory can't give quantum gravity, but I haven't seen a popular exposition of that."

That does sound interesting. I wonder if it would mean that hidden dimensions are effectively fictitious.

Do you know where to find documentation on this idea?

61. **martibal**
August 24, 2010

Well, this comment is off topic regarding AdS/CFT and high Tc superconductivity, but totally in the topic regarding "Hype or not Hype". Here is an article (in french)

http://www.rue89.com/2010/08/23/les-freres-bogdanov-exagerent-le-succes-de-leur-dernier-livre-163583

explaining how the Bogdanoff are exaggerating the success of the their new book (taking into account what they claim, they should have sold 50 000 copies in one single night !).

What could be interesting for the readers of this blog, or at least funny, is the photo at the top of the article. It is amusing to see who-you-know on one of the most renown online-newspaper in France.

62. **Chris Oakley**
August 24, 2010

Re: the photo of the Bogdanov bros. with a former Harvard Assistant Professor – who is destroying who's credibility?

63. **martibal**
August 25, 2010

Chris: good question ! It is fair to say that the photo is from 2008, and the former Harvard Assistant Professor has probably not been asked by the online-newspaper the authorization to publish the photo.

64. **Thomas Larsson**
August 25, 2010

I spent a week in Paris on vacation this summer, and noticed that the Bogdanoff's new book was among the most exposed science books.

65. **martibal**
August 25, 2010

They are pretty popular in France (mostly because of their science/ science fiction show on TV 25 years ago) and their are still very present in the medias. Some people claim this is because they are quite close to one of the son of Sarkozy (at least they pretend to have worked with him on one of their TV program). It is just completely frightening to imagine they could be some scientific counselor of the president…

Gossip

August 17, 2010
Categories: Uncategorized

As the date for announcement of the 2010 Fields Medals approaches, gossip about who the winners might be has been circulating. Math Overflow is by far the best internet site for authoritative discussion between knowledgeable mathematicians, but, unlike this site, they have a "no gossip" rule, leading to the closing of discussion threads like this one.

You can bet on who the Fields Medalists might be here. I assume there's no bet possible for Ngo since he's a sure thing…

Update: It's Ngo and Villani, also Elon Lindenstrauss and Stanislav Smirnov. For the announcement and information about the work of the prize winners, see here. Accurate rumors about this don't seem to have started circulating until the ICM announced the winners to the press late Tuesday. This information was embargoed until today, breaking the embargo didn't seem sporting…

Update: Best blog by far for following this is that of Timothy Gowers, who was on the committee that picked the Fields medal winners, and promises to tell us about Cedric Villani's outfit.

Comments

1. **Nameless**
   August 17, 2010

   Isn't it conventional to invite future recipients of the Fields Medal as speakers?

   If that is the case, we can probably rule out Cedric Villani. In fact, the only people under 40 on the list of invited plenary speakers are Avila, Ngo, and possibly one or two ladies (Dinur and Plofker) whose ages I can't readily determine. Plofker does not appear to have done anything worth a Fields, and Dinur is a better match for Nevanlinna.

2. **Nameless Too**
   August 18, 2010

   @Nameless: no, the invitations are made long before the Medals are finalized. Extra plenary slots are held open for Medalists who were not already invited. Among the 2006 laureates, only Tao was scheduled to give a plenary; Okounkov and Werner were both scheduled originally for 45-minute talks, and were moved to other slots after the prizes were announced.

   I find it telling that those three names (Ngo plus the two at the betting site) have been circulating loudly for a few months without (to the best of my knowledge) any informed suggestion to the contrary. If someone were in the position of being anointed by incorrect rumors, there might be some attempt to dispel the resulting attention. There might yet be a fourth medal as well. Anyway, we'll know in less than 24 hours.

3. **Peter Woit**
   August 18, 2010

   Much higher quality rumors are now circulating, although embargoed by the ICM until 2am tonight New York time.

   In the righteous cause of stamping out ignorance and error, right now I'll just say that rumors about Artur Avila seem to have no substance.

4. **Oisin McGuinness**
   August 18, 2010

   Manjul Bhargava was a plenary speaker at ICM 2006, giving a nice account of his 'Higher Composition Laws' (the 4th paper in this series came out in the Annals of Mathematics in 2008), and was given the AMS Cole Prize in 2008 for this. There are 5 recent (since May) preprints on the ArXiv with very deep applications of his methods (e.g., 100% of quintic fields have S_5 as Galois closure); that on the boundedness of the average rank of elliptic curves (with Arul Shankar) is particularly amazing and wonderful. (They get a bound of 1.5 for the average algebraic rank; previous results on the average analytic rank pioneered by Armand Brumer 20 years back were a) higher, b) conditional on GRH etc.) So he deserves a Fields medal. However, as noted in the discussion here last year, he will still be eligible in 2014, and these papers probably came out too late for affecting the choices this year.

   But I'll still be disappointed if he's not on tomorrow's list!

5. **Anonymous**
   August 19, 2010

   If the list of speakers' names and attendees' names at the ICM web site are accurate, that would filter out some of the candidates. Manjul's name has not been there for several weeks, so are a bunch of others. It seems that Jacob Lurie's name just appeared recently, if my memory is correct.

6. **Tooth Fairy**
   August 19, 2010

   Winners:
   Elon Lindenstrauss
   Ngô Bảo Châu
   Stanislav Smirnov
   Cédric Villani

7. **Voltberg**
   August 19, 2010

   two out of four a year ago. Not bad !!!

8. **Sasha Gantil**
   August 20, 2010

Who was on the Fields Medal Committee?

9. **Michael Thaddeus**
August 23, 2010

Laszlo Lovasz (chairman), Corrado de Concini, Yakov Eliashberg, Peter Hall, Timothy Gowers, Ngaiming Mok, Stefan Müller, Peter Sarnak, Karen Uhlenbeck.

10. **Tooth Fairy**
August 24, 2010

I don't know where else to ask, so I will ask this here. Do you think that there is a change of the type of work that is getting the fields? My impression is that the medal was given for work that finds applications to physics. (are these really needed applications from the physics viewpoint ?) Furthermore, the connection is with statistical mechanics, not string theory. Are the powers behind the math scene signaling the new direction they think math will profit to explore? Or is it part of the previous scheme of things?

11. **Peter Woit**
August 24, 2010

Michael,

Thanks a lot for finding that and posting it!

Tooth Fairy,

I don't think you can conclude that much about trends in mathematics from these choices for the Fields. I believe that any Fields medal committee would have chosen Ngo, but that another committee could very easily have chosen different people for the other three. The choice of these three reflects who is on the committee and who they're getting advice from, as they try and choose 2 or 3 people amongst maybe a dozen or so equally distinguished young mathematicians. There's a sizable randomness factor here. As far as the connections to physics go, analysis has always drawn inspiration and problems from physics, going all the way back to the beginnings of the subject, there's nothing new here.

I suppose you could draw one conclusion, that the lack of a Fields medal for any of the more esoteric string theory or qft-related topics many people are working on reflects a judgement that there hasn't been anything really dramatic coming out of that area in the last few years.

12. **math_lambda**
August 24, 2010

@Tooth Fairy: as an outsider I'd say the spirit of the prize hasn't changed, it's just that what current mathematicians do is more varied than 40 or even 20 years ago. It's still that great math prize which rewards great proofs.

Werner's medal and now Smirnov's medal are really awards for the probability side of things, the insight on brownian motion geometry. Given the wide range of math used to model physical phenomena (and, as a result, the number of exciting mathematical problems coming from physics), it's bound to happen from time to time that some medalists have results of physical significance. Same with Villani: definitely it's subtle analysis first and foremost, with delicate estimates and innovative new norms.

So I don't think at all it's a signal or anything regarding applications to stat phys v strings, it's all about recent great mathematical results.

Geometric Langlands at the KITP

August 17, 2010
Categories: Langlands

There's a very interesting program going on at the KITP discussing recent work of mathematical interest on 4d supersymmetric gauge theories (N=2 and N=4). These include various connections of 4d gauge theory to geometric Langlands uncovered by Witten and collaborators a few years ago, as well as last year's conjecture by Alday-Gaiotto-Tachikawa of a relation between 4d gauge theory and 2d Liouville conformal field theory. In his introductory talk, Edward Frenkel discusses the possibility of a relationship between these ideas and the much earlier ideas about 2d conformal field theory that were inspirational at the beginnings of research on geometric Langlands (about which he has written extensively).

Yesterday and today Witten gave two talks on some new work. The first was about the very basic problem of how you quantize a finite dimensional symplectic manifold, which he approached using the phase-space path integral. The idea was similar to that described in a 2008 paper with Gukov, where the quantum mechanical problem gets turned into a 2d topological QFT problem. The innovation here is that he does this explicitly at the level of the path integral, using the kind of techniques for complexifying the problem, using holomorphicity and choosing appropriate path integral integration contours, that he pioneered in his recent paper on Analytic Continuation of Chern-Simons Theory. The second talk applied these ideas to the case of Chern-Simons theory. The path integral there is somewhat like the phase-space sort of path integral, and he expressed it in terms of a 4d QFT. He claims to be able to thus solve a well-known problem, that of how to get a QFT that gives Khovanov homology, which is a topological invariant with Euler characteristic the Jones polynomial. Unfortunately I get lost at the end when he has to go to 5 dimensions and perform some duality transformations. I gather he'll have a paper about this relatively soon, and I'll try again to see exactly how this works then.

Perhaps a collection should be taken up to buy a new camera for the KITP. The resolution of the one they have now been using for years is such that you often can't quite read what the speaker is writing on the blackboard. Still, it's wonderful to be able to follow along as they quickly put a lot of high-quality talks on-line.

Comments

1. **Kea**
   August 17, 2010

   Well, it's great to see Frenkel introducing the categorical viewpoint so early on! What a cool talk archive.

2. **Jim Martindale**
   August 18, 2010

   Did you see Prof. Witten's notes from his 8/16 "A New Look At The Path Integral Of Quantum Mechanics" lecture at
   http://online.kitp.ucsb.edu/online/duallang_m10/witten/pdf/Witten_LanglandsQFT_KITP.pdf
   ?
   Are they any help?

3. **Peter Woit**
   August 18, 2010

   Jim,

   The notes aren't Witten's, but taken by someone in the audience. They do help with the blackboard readability problem, but by the end of a long action-packed talk, one can see that the note-taker's ability to write everything down starts to flag…

4. **Kea**
   August 19, 2010

   Hmmm, given the way the camera keeps re-focusing, I am wondering if perhaps the problem is with the eyesight of the camera person!

   So towards the end of Witten's second lecture (about getting Khovanov homology from a 5d theory, where the extra dimension came from using D branes in a IIB string theory) he concludes that (S duality for) N=4 SYM is 'universal' in a nice sense, related to Langlands somehow. And then he discusses some '6d' M theory theories, from which one can get (by a 1d reduction on a circle) (i) the Khovanov theory or (ii) another case that reduces down to Chern-Simons …

   I confess that I skipped some of the talk here. Does this mean that to understand the reduction 'Khovanov to CSFT' we need to talk about the M theory picture?

5. **oarobin**
   August 25, 2010

   peter,
   have you seen and do you have any comments on the video "String Theory for the Scientifically Curious with Dr. Amanda Peet" available at
   http://www.youtube.com/watch?v=PpQngpaHamg

   especially the Q & A section at the end.

6. **Peter Woit**
   August 25, 2010

   Thanks oarobin,

   Hadn't seen that. Quite something, I think it deserves a new edition of "This Week's Hype"…

This Week’s Hype

August 25, 2010
Categories: This Week's Hype

I’m rather busy these days with a move to a new apartment, but maybe there’s time for a quick edition of “This Week’s Hype”.

A commenter on the previous posting points to Amanda Peet’s recent talk entitled String Theory for the Scientifically Curious. In the question and answer section, she responds to someone who asks her to comment on Phil Anderson’s claim that string theory makes no falsifiable predictions. She describes this claim as “absolutely fundamentally completely utterly wrong” and says that Anderson should “be smacked around the head” for saying it. She then goes on to a vigorous and extensive personal attack on Lee Smolin.

Her argument that string theory really is falsifiable is that a paper by Distler and collaborators shows this and has been published. The paper she is referring to is this one, which started off as a preprint with the title Falsifying String Theory through WW scattering, but was only published after a forced change of title to “Falsifying Models of New Physics Via WW Scattering”. One reason for this is that there’s actually nothing about string theory in the paper. Evidently Peet just saw the preprint, not the published version. If you want to know more about this particular piece of hype, see blog postings here, here, and here.

For more Amanda Peet in action, there’s a classic video from the KITP, blogged about here.

Comments

   August 26, 2010

   that’s incredible.

   what an utter lack of respect and discussion culture. somtimes i wonder what the scientific community has come to.

2. **Felipe Zaldivar**
   August 26, 2010

   I was appalled for the level of aggression in A. Peet answers to people asking some questions after the talk. Is this really necessary? Has this field of Physics sunk to such level or is she just a “singularity” in the realm? I did not watch the whole video, but if someone is interested, see from 1:19 to 1:25 min in the video.

3. **H M**
   August 26, 2010

   She claims that Phillip Anderson has an agenda, there are not enough smart people working on superconductors and therefore he wants to attract potential string theorists (aka the smartest people in the world) towards Condensed Matter physics. Such arrogance seems very prevalent among string theorists.

4. **Fabio**
   August 26, 2010

   I’ve never known Peet to voice an opinion that didn’t come directly from one of her mentors. In this case she seems to be aping some of Lenny’s earlier personal attacks against Smolin. Of course, if you’re an insecure lesser figure in a field, loudly and publicly attacking apostates is an easy way to earn some plaudits from your peers.

5. **srp**
   August 26, 2010

   (I apologize if this double posts–there was a glitch the first time.)

   I was very confused by this post; a Google search quickly confirmed that the Amanda Peet I’ve heard of is someone you’d be very surprised to find had an opinion on string theory…

   It might be a good idea to say “Amanda Peet (not the famous actress)” just as a post about an actor named Ed Witten would be well-advised to tell the reader it was not referring to the more-famous one.

6. **Edward**
   August 27, 2010

   She’s hardly a lesser light, Fabio. That she has the same viewpoint as her supervisor and peers is, of course, a common phenomenon and not necessarily indicative of mindless parroting. As for her level of aggression, unfortunately this (and thick skin) is what is often required to succeed in physics, especially in the rarefied atmosphere of high-energy. Anderson is no less tenacious/vicious.

7. **Peter Woit**
   August 27, 2010

   Edward,

   I’ve spent a lot of time in the “rarefied” atmosphere of academia, both in high energy physics and mathematics, and I’ve never seen this kind of public behavior (except from Lubos Motl, who didn’t last long, and a bit of it from Lenny Susskind).

   There’s a reason that serious academics don’t respond (in public) to substantive arguments about science by engaging in personal attacks on those they disagree with and saying that they need to be “smacked”. Doing this makes it clear to everyone in the audience that you probably don’t have a substantive response to the argument. Doing it and adding as your only substantive response that your claim is true because it was published in a paper in Phys. Rev, when a referee explicitly wouldn’t allow that claim to appear there makes it crystal-clear what is going on.

8. **hep-ph**
   August 27, 2010

   Anderson testified to the US Congress in 1987 against the construction of the Superconducting Super Collider and does deserve a good smack in the face, regardless of his views on string theory.

9. **onymous**
August 28, 2010

I wish people would stop talking about smacking Phil Anderson. Have you *seen* the man lately? He doesn't look like he would hold up to much physical violence. But he's pretty intellectually combative, so maybe fighting with words would be more productive….

10. **anon**
August 28, 2010

Hello Dr. Woit,

Why does it matter whether or not the string theory makes falsifiable predictions?

Suppose the latest version of general relativity fits all experimental evidence, and none of its predictions are falsified. Suppose the same were true of the latest version of the standard model of particle physics.

On another blog, reference frame by Lubos Motl, I read the statement that string theory is the only mathematically consistent way to unify those theories. Suppose a correct, extensive mathematical proof of that statement is given, covering every last mathematical technicality. Perhaps it will appear soon on that blog, or maybe I missed the reference to it.

Then, wouldn't string theory be correct and a great achievement even without having any falsifiable predictions that are specific to string theory, and not to the pre existing models it unified?

If stars and particles must be made of the same matter, and if the Lubos Motl assertion is proven, then wouldn't it be logically mandatory that string theory is accepted even if it does not introduce any new falsifiable predictions?

This is probably a dumb question and I have only a basic, introductory level, familiarity with physics at this time. It's just that "no falsifiable predictions" is one of the main complaints here, but the people who promote this research don't advertise new predictions, they advertise the prospect of less contradictory models for existing predictions that already fit empirical evidence.

11. **Anon2**
August 28, 2010

anon, a lack of falsifiability is actually a BONUS to theoretical physicists, allowing them to sleep soundly at nights, safe in the knowledge that their theory CANNOT be falsified.

Woit just doesn't grasp the fact that BEING FALSIFIED is not good for business if one is a theoretical physicist wanting fashionable non-falsified research on one's CV.

12. **Giotis**
August 28, 2010

Well she may be a little harsh but she has her own unique authentic style. I like this, we don't have to do PR all the time. Our world is too hypocritical as it is and we need authentic people like Amanda Peet to speak their mind.

13. **Peter Woit**
August 28, 2010

anon,

There's nothing wrong with unfalsifiable theories, they just tend to not be scientific theories, but something else. And no, string theory at this point does not provide a mathematically consistent unification anyway.

The weird thing about the Amanda Peet attack on Anderson over the falsifiability issue is that most string theorists would acknowledge that, in its present state, string theory doesn't make falsifiable predictions. The controversy is not over this, but over the question of whether there's reason for optimism that string theory unification may someday make predictions. I see no good reason to expect this, string theorists typically are more optimistic.

14. **Peter Woit**
August 28, 2010

Giotis,

I have no problem with Amanda Peet speaking her mind if she wants to. The problem is with what's in her mind….

15. **anon**
August 28, 2010

I was under the impression that string theorists wanted a logically consistent way of getting the same predictions one already has from GR and particle physics. I thought they were concerned about GR and QM contradicting each other, not with either one of them coming up short when it comes to fitting experimental data. If GR and QM already count as scientific and falsifiable if wrong, then a model that gives the same answers as them should also.

Ad hominem responses and impugning motives are not what one is supposed to do. However people still do them. It might be a case where the audience gets only what the lecturer thinks the audience has enough background to understand.

16. **Giotis**
August 29, 2010

"I was under the impression that string theorists wanted a logically consistent way of getting the same predictions one already has from GR and particle physics."

Anonymous you are right of course but the issue here is that String theory has so many components you can manipulate that practically you can come up with any physics you want in 4 dimensions. Moreover the attempts to derive the 4D physics we know seems too contrived from string theory perspective although I would say this is a subordinate issue. In any case if there was a natural *unique* solution of String theory that would produce the 4D physics we know then of course nobody could seriously criticize String theory regardless of any new falsifiable predictions. It would be truly a triumph that no one could deny since the real purpose of a unified theory is to explain our world in the deepest fundamental level. But unfortunately this is not the case at least so far.

Note though that for many people this plethora of solutions is a blessing more than a curse. It gives for example a natural explanation to certain puzzles of nature like the small value of the cosmological constant and the presumed fine tuning of our Universe in general.

17. **chris**
August 31, 2010

reading some of the comments here i really wonder if there is not even a consensus within the physics community any more about threats of physical violence being inacceptable.

i mean seriously: we all know the game of shaping the future of research by the economic stranglehold on postdocs. so is this not enough? now physical violence comes into the game again? i am totally appalled.

"Anderson testified to the US Congress in 1987 against the construction of the Superconducting Super Collider and does deserve a good smack in the face, regardless of his views on string theory."
apart from the fact that this could have saved billions of $ from being pumped into a doomed project: what is it that you want to express with this statement? that scientists should not speak their honest opinion lest they get beaten up by the opposing mafia-gang of their peers? or that a democratic decision on science project funding is a nuisance that should be done away with?

Everything is Emergent

August 26, 2010
Categories: Uncategorized

During the past year Erik Verlinde has made a splash (most recently in the New York Times). with his claim that the reason we don't understand gravity is that it is an emergent phenomenon, an "entropic force". Now he and Peter Freund are taking this farther, with a claim that the Standard Model is also emergent. Freund has a new paper out on the arXiv entitled "Emergent Gauge Fields" with an abstract:

> Erik Verlinde's proposal of the emergence of the gravitational force as an entropic force is extended to abelian and non-abelian gauge fields and to matter fields. This suggests a picture with no fundamental forces or forms of matter whatsoever.

Freund thanks Verlinde, who evidently has much the same idea:

> I wish to thank Erik Verlinde for very helpful correspondence from which it is clear that he independently has also arrived at the conclusion that not only gravity, but all gauge fields should be emergent.

He remarks that this new theoretical idea is remniscent of Geoffrey Chew's failed "bootstrap program" of the sixties:

> It is as if assuming certain forces and forms of matter to be fundamental is tantamount (in the sense of an effective theory) to assuming that there are no fundamental forces or forms of matter whatsoever, and everything is emergent. This latter picture in which nothing is fundamental is reminiscent of Chew's bootstrap approach , the original breeding ground of string theory. Could it be that after all its mathematically and physically exquisite developments, string theory has returned to its birthplace?

It's very unclear to me why this is supposed to be a good thing. In his Nobel prize lecture, David Gross, a student of Chew's explains:

> I can remember the precise moment at which I was disillusioned with the bootstrap program. This was at the 1966 Rochester meeting, held at Berkeley. Francis Low, in the session following his talk, remarked that the bootstrap was less of a theory than a tautology…

Comments

1. **Peter Shor**
   August 26, 2010

   How can everything be emergent? To the best of my understanding, emergent laws of nature are derived by considering the statistical mechanics of the fundamental laws of nature. If there aren't any fundamental laws, you can't have any other laws emerge from them.

2. **Paul Murray**
   August 26, 2010

   So, they seem to be saying that the fundamental forces can be reduced to some other kind of thing from which they emerge. Ok … so what's new? Isn't this exactly what string theory has been hypothesising all along?

3. **Morton**
   August 26, 2010

   The preprint is just words. Compared to that, even Christoph Schiller's approach is better. He claims to deduce quantum theory and the three gauge groups from emergence, in four dimensions…

4. **Marcus**
   August 26, 2010

   Mockery by reference to that strange sometimes-very-funny Jonathan Foer book "Everything is Illuminated".

5. **chris**
   August 26, 2010

   full circle back to bootstrap theories?

   oh my, this one is completing a much larger full circle: full circle back to Aristoteles, where physical theories are suggested in vage analogies without the inhibiting rigour of mathematics.

6. **slw**
   August 26, 2010

   Okay, so there is a deeper underlying reality for which our current understanding of the universe is simply an higher-level abstraction. That's good to know, I guess. Are there any hints in the paper what the deeper, simpler reality could be? Or is this simply one of those mathematician anecdotes with the punchline "a solution exists!".

7. **Frank Quednau**
   August 26, 2010

   Looks like philosophy isn't far away now. I do have to chuckle a bit. Seems to me the whole physics body has no clue right now as how to move on in understanding that silly thing called reality.

   If you're trying to find a more fundamental explanation to features of reality, isn't it mandatory to declare those features you deemed fundamental as "emergent"?

8. **Sam**
   August 26, 2010

   Verlinde's proposal is somehow quite compelling. To say that the gravitational equations are emergent is not so different than saying that the Navier-Stokes equations are emergent. What one means is that Navier-Stokes are some equations that are derived from the macroscopic behavior of enembles of things described microscopically in quite a different way, subject to constraints like conservation of energy. The gravitational equations are not so different … at least this is what Verlinde is arguing.

The philosophizing ones are those who speak of ‘fundamental forces’ while not expressingly clearly or precisely what that means. Whatever that means, the equations describing the motion of a fluid certainly do not describe fundamental forces/laws, and the suggestion at the bottom is that we need to think of and derive the gravitational equations from a similar point of view. What’s so terribly unreasonable about that?

9. **DB**
August 26, 2010

Good news for Fritjof Capra and his Tao of Physics baloney.

10. **cyd**
August 26, 2010

Er, the Standard Model IS emergent. That’s what it means to be a renormalizable quantum field theory, and that’s the basic lesson of the renormalization group.

11. **SteveB**
August 26, 2010

I am a bit fuzzy on what the term “emergent” means in a mathematical or physics context. There are some good clues in the previous responses but is there a precise definition?

12. **cyd**
August 26, 2010

> I am a bit fuzzy on what the term “emergent” means in a mathematical or physics context.

The standard meaning of “emergence” in the physics context comes from Phil Anderson’s 1974 article “More is Different”. In the context of the Standard Model, “emergence” refers to the statement that the Standard Model is an effective field theory. This is not a free-floating claim; it arises from the renormalization group’s insights about what renormalization really means.

13. **Ricardo**
August 26, 2010

After reading the paper Plato’s theory of forms came to my mind, it very much reminded me of the long, involved arguments you had to read in high school philosophy class to determine whether they were valid or invalid.
Leaving the physics apart, I can’t even begin to see if the paper is logically correct, but the thing that really bothers me about these emergent “models” is that I fail to see what is the gain, what do they have to offer besides what we already have from supersymmetry, strings, etc,?

14. **H M**
August 26, 2010

The idea that gravity and gauge fields could be low-energy emergent degrees of freedom is FAR from new and there has already been done lots of work on this. See for example the work of Xiao-Gang Wen (http://dao.mit.edu/~wen/) or the book “The Universe in a Helium Droplet” by Grigory E. Volovik (where he shows that many features of the standard model can emerge as effective low-energy model of superfluid 3He, it is of course just a toy model).

In Condensed Matter physics emergent gauge fields and relativistic symmetries are nothing new, and has been measured in many different systems. The mechanism Verlinde proposes might of course be new (although its very hand-waving right now), but the idea of emergent standard model is not his.

@Paul Murray: No, emergence is not what string theory is about. You are confusing the fact that string theory (or another microscopic theory) should reduce to SM at long distances, with the concept of emergence (which is very different and very subtle).

15. **H M**
August 26, 2010

@Ricardo
Quote: “the thing that really bothers me about these emergent “models” is that I fail to see what is the gain, what do they have to offer besides what we already have from supersymmetry, strings, etc,?”

You have to understand the difference between emergence and reductionism. The prevalent idea in high energy physics is that everything (up to a limit) can be split apart and reduced into more and more fundamental particles (or strings). For example the proton is build out of three quarks, which again might be build out of more fundamental things.

The idea of emergence is VERY different. If a particle is not fundamental it is not necessarily build out of smaller particles, it can be a COLLECTIVE degree of freedom. There are many examples of collective phenomena in physics (specially pioneered in Condensed Matter Physics), and these “particles” cannot be described in a reductionist way. Quantum solid and liquids, are microscopically non-relativistic and build out of many-particles interacting with EM. But they can have low energy degrees of freedom which are much more symmetric, ie have Lorentz invariance and emergent non-Abelian gauge bosons.

Thus the answer to your question is that; what emergent models can offer is to describe emergent phenomena! IF gauge symmetries and gravity are not fundamental, but emergent collective degrees of freedom, they cannot be described by, say, strings. Wither the content of the standard model is fundamental or emergent is not known (though most people tend to prefer non-emergence).

16. **noel**
August 26, 2010

So we had emergent gravity, we knew about Kaluza-Klein compactification of gravity….connect the dots r serious business rite? Why exactly did he have to communicate with Verlinde about this trivial observation?

17. **Ricardo**
August 26, 2010

@H M
Ok, thanks for the clarification, but my point is this: as I understand Verlinde’s proposal is based on the holographic principle, which is based on strings, so if you use that to show that the emergent degrees of freedom are not strings, isn’t that self-contradictory or circular reasoning at best?

18. **H M**
August 26, 2010

@Ricardo

Oh I'm sorry, I misunderstood your question.

Well I don't think that the holographic principle is necessarily based on string theory, the original proposal by 't Hooft didn't as far I can know (http://arxiv.org/abs/gr-qc/9310026). But it is apparently, mostly implemented in stringy environment (I must say that I know very little to nothing about this).

With that said, it seems like Verlinde want to, as you say, put in string theory into his mechanism. This also sounds odd to me, but I need to study his papers more carefully before commenting on this.

19. **Roberto Percacci**
August 26, 2010

Quoting H M:

> what emergent models can offer is to describe emergent phenomena!

Yes, that would be useful, but much of the literature does not address the issue of constructing workable emergent models for gravity. It seems to me that those that go furthest in this direction are people that do not usually talk much about emergence. For instance, you could argue that causal dynamical triangulations is currently the most successful way of actually calculating emergent properties of gravity.

20. **Shantanu**
August 26, 2010

FWIW, Erik Verlinde's talk on his paper is online at
http://online.itp.ucsb.edu/online/joint98/verlinde2/

21. **Haelfix**
August 27, 2010

The word 'emergent' is one of those horribly loaded words in physics, that means about ten different things depending on the context.

For instance, the way I interpret the word, would be that the author of that paper claims that the gauge fields of the standard model and gravity (eg the W, Z, gluons, graviton etc) were in fact not fundamental and instead collective degrees of freedom.

The classical reply to that, is to point out the Weinberg-Witten theorem precludes exactly this scenario.

Having said that, I don't think that's what Peter Freund is saying at all, and I have no idea what to make of his paper. I think perhaps I will now associate the word 'emergent' with 'opaque, excessively verbose papers' and be satisfied to leave it at that.

22. **onymous**
August 27, 2010

It's not clear that Weinberg-Witten applies here; certainly it doesn't apply any more than it would to the original emergent gravity idea. We know that both gravity and gauge fields in AdS can emerge from the boundary theory, which has a stress tensor and conserved currents but in one lower dimension, so that the assumptions of Weinberg-Witten are evaded. (The gauge fields can either live on branes, or arise in the Kaluza-Klein manner exactly as Freund suggests.) What isn't clear is how any of this concretely works in any setting other than AdS. Verlinde proposes that gravity in flat space emerges from lower-dimensional physics (I think), in a mysterious unspecified way. If this is true, it would seem almost mundane to have gauge fields also emerge in this way.

23. **Kea**
August 27, 2010

In the UCSB talk, Verlinde takes some time to argue that gravity and gauge theories should emerge from a new kind of matrix theory that reflects the entropic screen information. This talk is not as good as the Perimeter one (although it has slightly more substance) because he tries too hard to cater to the stringers in the audience.

24. **Chris Austin**
August 27, 2010

In agreement with onymous, it seems to me that the Weinberg-Witten theorem, "Limits On Massless Particles," Phys. Lett. B 96 (1980) 59-62, does not exclude the possibility that the graviton could be a collective degree of freedom in a combinatorial system such as causal dynamical triangulations.

The assertion in H M's first two comments above, that non-relativistic condensed matter systems in the laboratory can have low energy collective degrees of freedom that behave like non-Abelian gauge bosons with Lorentz-invariant dynamics, and that such behaviour has been measured in many different systems, is completely new to me. It would be very interesting to see some references on this.

25. **Haelfix**
August 27, 2010

Mmm, terminology and loaded vocabulary! A system where dualities are present is a different type of 'emergence'. You wouldn't really say that the gravitons in ads/cft were composite would you? But you could say that the bulk was "emergent" from dynamics that lived on the boundary.

Likewise its kind of odd to call a lattice approach 'emergent'. For instance I consider lattice gauge theory the very definition of what qft means. But then its not particularly standard to say that lorentz invariance is 'emergent', even though thats explicitly what happens when you take the continuum limit of a typical qft.

In any event, playing word games doesn't increase one's knowledge of the physics, instead they're supposed to be defined by the context and the associated mathematics… Unfortunately it seems such a specific realization is considerably more difficult to produce, than currently in vogue publishing standards….

26. **Roberto Percacci**
August 27, 2010

> its kind of odd to call a lattice approach 'emergent'.

maybe so, but it's not at all obvious that by throwing together a lot of little triangles and stirring you get something that looks on average like a smooth manifold. That's why I think it is correct to use the word here.

> for instance I consider lattice gauge theory the very definition of what qft means.

As "cyd" pointed out above, the form of the lagrangian of the standard model could be said to be an emergent property: whatever nonrenormalizable stuff you started with at high energy would be enormously suppressed by the time you arrive at low energy. This is exactly the behavior that occurs in statistical systems with a second order phase transition, which is undeniably an example of emergence. And by the way, something similar could happen in the case of gravity, if it had a suitable fixed point…..

Concerning the Weinberg-Witten theorem, it does not forbid "induced gravity", which is another concrete example of "emergent gravity" (you integrate out matter fields in a background metric, and in so doing you generate an action for the metric). WW explicitly point this out in a footnote.

27. **Jim**
    August 27, 2010

    Dear Dr. Shor,

    Wheeler was the first to state Freund & Verlinde' idea clearly:

    "The only Law, is the Law that there IS no Law".

28. **Marcus**
    August 27, 2010

    I liked Percacci's two comments here, so I started a discussion thread at Physicsforums to follow up with perhaps a bit more detail:
    http://physicsforums.com/showthread.php?t=424552

29. **Norea Armozel**
    August 28, 2010

    What I find annoying by the use of the term emergence is that it dilutes its original meaning for both natural and social sciences. In both sciences, emergence means there are some laws which are fundamental, but that the resultant 'sub'-laws come about as an interplay/relationship between the given fundamental laws. This is especially true when considering sociological studies of extralegal institutions and some such (I'm not sure what would be the analog in physics or chemistry… Friction perhaps?).

    It's like emergence is the new synergy or whatever. X_X

30. **Einblick**
    August 28, 2010

    The claim that the gauge field is emergent is not new, I think. X.G.Wen has argued that the gauge field dof can be emergent from the string-net liquid. And I think that Verlinde's entropy gravity is only classical gravity, until we get to know what are the fundamental degrees of freedom and how they behave, since we don't have the notion of quantum thermodynamics, but rather quantum statistics.

31. **martibal**
    August 28, 2010

    Can anybody explain (in a nutshell) what bootstrap theory was ?

32. **John McVirgo**
    August 28, 2010

    These two great physicists, although they did brilliant work in their youth, are rather past it when generating creative ideas that have some resemblence to reality.

    Erik Verlinde is 48

    Peter Freund is… 73

    Let's wait and see what the young post docs have to say.

33. **Wyman**
    August 28, 2010

    That is an awful bit of ageism right there. Do we really want to ignore the contributions of anyone over the age of 40?

34. **Chris Austin**
    August 28, 2010

    With reference to attempts to view an Abelian gauge field as emergent from something else, perhaps it is fair to note that in 1861 James Clerk Maxwell developed a theory of magnetic lines of force as rotating vortices subject to Newtonian dynamics, with tiny particles like ball bearings separating neighbouring vortices to eliminate friction, and that this mechanical analogy apparently helped him to develop his field equations published four years later. See
    http://upload.wikimedia.org/wikipedia/commons/b/b8/On_Physical_Lines_of_Force.pdf

35. **Chris Austin**
    August 29, 2010

    With reference to the one sentence in which Freund mentions supersymmetry, perhaps a pointer to the way forward might be the papers of Cioroianu, Diaconu, and Sararu, e.g. [0903.0259](0903.0259), in which they use the Batalin-Vilkovisky apparatus to show that any theory in 11 dimensions that nontrivially couples a massless symmetric tensor, Rarita-Schwinger field, and 3-form gauge field, without altering their degree of freedom counts, must automatically be supersymmetric and coincide with the CJS theory after field redefinitions, and thus also have vanishing cosmological constant in 11 dimensions, by Bautier, Deser, Henneaux, and Seminara.

    In other words, if you could adapt the Neuberger Dirac operator to a Majorana spinor living on the links of causal dynamical triangulations in 11 dimensions, and also add a 3-form gauge field, perhaps simply as a number living on the 3-simplexes, and ensure that the system is nontrivially coupled in the infra-red, then the Cremmer-Julia-Scherk theory should automatically emerge at long distances.

If combining Neuberger and CDT turned out to require a combinatorial tangent space or vielbein, perhaps the appearance of combinatorial structures called oriented matroids in the Gelfand-MacPherson construction of combinatorial Pontrjagin classes, math/9204231, and MacPherson's subsequent theory of combinatorial differential manifolds, might provide a clue, the connection being that Pontrjagin classes are involved in the subtleties of discretized spinor fields via the Atiyah-Singer index theorem. Various types of connection between oriented matroids and M-theory have already been considered by J. A. Nieto, e.g. hep-th/0603139.

36. **Jack Lothian**
August 29, 2010

I am not sure that I am understanding "emergence". I find the discussion in this thread opaque. The group & topology theory discussion goes over my head but statistical mechanics is something that I am familiar with. So, is emergence like the stable vortexes observed in turbulent flow – it arise out of statistical averaging of complex multi-body interactions? If so, like turbulence, does this imply that our universe is in a quasi-equilibrium state? Are phase transitions possible?

I am not sure how any reporter can comment on this stuff. I have an ancient masters degree in Statistical Mechanics plus I worked my whole life in science related topics yet this discussion comes across as voodoo science to me. So what is emergence – in layman's terms? Can someone tell me?

37. **Chris Austin**
August 29, 2010

Jack,

To a condensed matter physicist, "emergent" refers to properties of large collections of atoms that have no analogue for one or a few atoms.

To a high energy physicist, "emergent" refers to the large distance or low energy properties of a model system whose microscopic definition has a simple mathematical structure. For example the microscopic degrees of freedom of lattice gauge theory, which is used in computer simulations of quantum chromodynamics, consist of a 3 x 3 unitary matrix on each link of a hypercubic lattice, together with a spinor for each type of quark on each vertex of the lattice.

As Roberto Percacci pointed out above, currently the most successful emergent model of gravity is the causal dynamical triangulations of Ambjorn, Jurkiewicz, and Loll. This is a completely combinatorial system, that consists simply of a list of a finite number of vertices, together with a list of selected quintuples of these vertices, each of which represents the four-dimensional analogue of a tetrahedron. If two selected quintuples have four vertices in common, they are the four-dimensional analogue of two tetrahedra that share a common triangular face. The list of selected quintuples is required to be such that for each quintuple in the list, and each set of four of the five vertices of that quintuple, there is exactly one other quintuple in the list that also has those four vertices. The list of selected quintuples then represents a triangulation of a four-dimensional curved space-time.

To see how the properties of a four-dimensional curved space-time can be coded into such a list of selected quintuples, consider the example of a two-dimensional curved surface. Randomly select a finite number of points sprinkled on the surface: these are your vertices. Associate to each vertex its Voronoi cell, which is the set of all the points of the surface that are closer to that vertex than to any other vertex. Then define a triple of vertices to be selected if and only if their Voronoi cells meet at a corner.

The list of the triples of vertices selected in this way gives a triangulation of the curved surface, and if you sprinkled your vertices finely enough, you can approximately study the curved surface simply by counting vertices, edges, and triangles. For example, the distance between two vertices is proportional to the number of edges in the shortest path of edges between those two vertices. And if you count the number of vertices up to some distance from a fixed vertex, and the number is smaller than you would find for a flat surface, then the surface is positively curved at that vertex, and conversely it is negatively curved if the number is larger.

Ambjorn, Jurkiewicz, and Loll found Monte-Carlo rules for randomly modifying the list of selected quintuples in their simulations such that on average, the lists of selected quintuples they generate look at large distances something like triangulations of smoothly curved four-dimensional "spacetimes". Thus these four-dimensional curved "spacetimes", governed at large distances by something like Einstein's classical action for the gravitational field, emerge from simple combinatorial rules for combining the four-dimensional analogue of tetrahedra in a semi-random manner.

In their latest article with Goerlich, they appear to hint at a connection with the "entropic gravity" ideas of Verlinde which with the subsequent suggestion by Freund are the topic of this posting, although they don't actually cite Verlinde's paper.

38. **Jack Lothian**
August 29, 2010

That response was a bit higher level than I hoped but I think I get the reference to Statistical Mechanics: you are averaging constrained micro/local topology paths in some sense to infer macro characteristics for the surface? Also, this makes me think of things like the Ising model but not sure if that is a valid comparison.

I feel somewhat uneasy about this discour though, it seems to me infering macro characteristics from the bottom up is really sensitive to initial conditions, boundary conditions, # of dimensions, grid size, etc but this is several notches above what I usually deal with so I do not feel qualified to really debate this.

I still wonder how any reporter could understand this stuff – I suspect they would only react to the word "emergent" & they would interpret the term as it is used in common language.

39. **Jack Lothian**
August 29, 2010

Oh, Chris,

I forgot to say: thanks for taking the time to respond – I do appreciate the effort even if it challenged me a little more than I anticipated. Also, I think that I sort of get the gist of the argument.

Thanks

40. **younghun park**
August 29, 2010

Peter
As jack Lothian points out above, the meaing of the word "Emergent' is seemed to be ambiguous.
What do you think this word mean in physics?

41. **martibal**
August 30, 2010

Chris:

I understand that, in some limit, the triangulated space-time looks like a smooth manifold. If I understand well, the list of selected quintuple gives you the curvature, right ?

But where does Einstein equation comes from ? Do you interpret the "randomness" as a stress energy tensor (i.e. one side of Einstein equation) that allows you to compute the curvature (i.e., roughly speaking, the other side of Einstein equations) ? If so, does this mean that various "randomness" (I am not very familiar with random objects but I believe the randomness is given by a probability law ?) correspond, in the classical GR picture, to various matter distributions ?

42. **Marcus**
August 30, 2010

Martibal: "I understand that, in some limit, the triangulated space-time looks like a smooth manifold."

No. Why should it? The CDT approach (which Chris was discussing) uses triangulation and lets the size of the triangles go to zero.
But it does not result in a smooth manifold model of spacetime.

There is no logical or mathematical reason that it should, and it does not.

The CDT authors (Loll Ambjorn et al) describe the spacetime model they get as "fractal-like" at small scale. The dimensionality, which is 4D at large, goes down continuously to around 1.9 or 2.1 at small scale. A similar spontaneous reduction of dimensionality occurs in spatial slices. Since they generate universes by computer simulation, they are able to study what happens by looking at concrete realizations. An approximately smooth deSitter spacetime emerges at large scale as a kind of path-integral "average" of many non-smooth cases.

43. **martibal**
August 30, 2010

Marcus: sorry I am not so familiar with the subject so my formulation may be not correct.

Cris Austin said: "Ambjorn, Jurkiewicz, and Loll found Monte-Carlo rules for randomly modifying the list of selected quintuples in their simulations such that on average, the lists of selected quintuples they generate look at large distances something like triangulations of smoothly curved four-dimensional "spacetimes"."
This is what I meant by saying that at in some limit (I should better say: at large) the triangulated manifold (my formulation was misleading. I should say: the fractal spacetime obtained as the limit of a triangulated spacetime with triangles of size zero) looks like a smooth manifold.

So let me try again :
I understand that at large scale, the fractal spacetimes look like a smooth manifold (e.g. de Sitter). In other terms, the smooth structure emerges from an appropriate average on fractals. And so does the curvature.

What I do not understand is: where does Einstein equation comes from ? I mean Einstein equation determines the metric, but not the topology. So if you average in a different way on the same set of fractal spaces, can you obtain – at large- various metrics on the same topological manifold ?

44. **Marcus**
August 31, 2010

Martibal,
Here is a seminal paper by Tullio Regge (1961) "General Relativity without Coordinates":
http://www.signalscience.net/files/Regge.pdf

Here are Loll's papers
http://arxiv.org/find/grp_physics/1/au:+Loll/0/1/0/all/0/1

Loll and friends don't use all identical building blocks, but they almost do. They use two types. Morally it's like all identical—in the 2D case imagine identical equilateral triangles.

You can tell the curvature at a point by counting how many triangles meet there. 6 ==>flat. 5==> pos curv. 7==>neg curv.

Einst Hilb action is essentially an integral of curvature. Regge inspires us to evaluate it by counting identical triangles and the points where they meet. If there is just the right proportion of triangles to points then on average it is flat (every point is surrounded on average by 6)

The upshot is that we can evaluate the E-H action, or the Regge version of it, just by counting. That extends to higher, like 4D.
Loll team *could* do it with all identical equilateral 4-simplices. But for technical reasons they use two classes of identical non-equilateral 4-simplices.

It only makes the counting slightly more complicated. Main thing is that the E-H or Regge action is evaluated simply by counting different types of simplex—a linear combination of census-data. Comparing how many big ones versus how many little ones where the big ones meet. (I'm oversimplifying but it's sort of like that).

Then they introduce different shuffling moves where you have this huge assemblage of simplices ("triangles") and at each point the computer looks to see if it wants to perform a re-arrangement, and *tosses a coin*. The decision to make the move or not is random.
Different probabilities for different moves. Re-arrangement of simplices can change the census data, change the average number meeting around whatever they meet around. Change the overall action.

So the probabilities of the various moves (some of which insert or remove simplices) are adjusted so it is a path integral Monte Carlo scheme.

Individual spacetimes result from millions and millions of shuffles. The individual spacetimes are not deSitter. Only the average of many individual spacetimes is deSitter.
An individual spacetime (after say a million shuffles at every location) can be studied. It will have "fractal-like" features at small scale. They are not strictly speaking fractals, people call them "fractal-like" at small scale. The dimensionality goes down at small scale.
Think of the radius to volume relation of a wad of crumpled paper.
At large scale the mass of paper within a certain radius goes up as the cube. But at small scale the mass of paper goes up as the square of the radius. The exponent of the radius-volume relation is one measure of dimension. But it is not like crumpled paper it is only remotely analogous.

Here is the paper I found most helpful
http://arxiv.org/abs/hep-th/0105267

For lots of intuitive analogies and color illustrations there is a Sci Am by Loll and friends
http://www.signallake.com/innovation/SelfOrganizingQuantumJul08.pdf

Here is a recent review or status report:

http://arxiv.org/abs/1007.2560

Reading Loll papers is better than reading what I say. They are very clear writers. But maybe this (imperfect and dashed off) will get you started.

45. **chris**
August 31, 2010

HM,

I am strongly disagreeing with your proposed meaning of emergence as applied to high energy physics. you say that the predominant picture in HEP is that of reductionism: if this is so, the what about e.g. QCD? how can reductionism be the guiding principle, when quarks are unobservable? is the effective theory of protons and pions not also "emergent"? you could argue that these degrees of freedom are not 'colective', but just look at the high temperature phases: emergent phenomena wherever you look. and this is hardcore, partially experimentally verified high energy physics.

and the specific criticism that string theory is in contradiction with emergence: the current main line of string research – as far as i know – is duality stuff. the boundary QFT of a bulk string theory – this satisfies every single criterion you set up for calling a phenomenon "emergent".

in the end, without any concrete theory behind it it is just more words.

46. **martibal**
August 31, 2010

Marcus: thanks for the detailed answer !

47. **Yasha**
September 1, 2010

I am a mathematician, with only a bit of training in general relativity, but I wanted to make a few comments/questions. I believe one of the first people to suggest gravity is an emergent phenomenon was Sakharov although he called it induced gravity http://en.wikipedia.org/wiki/Induced_gravity. How does this relate to ideas of Verlinde? Why is this not mentioned or discussed?

Of course the description of induced gravity in wikipedia is unintelligible: We are starting with a pseudo-riemannian 4 manifold or 3 manifold? I am guessing 3 manifold, since in a 4 manifold, the gravitational field is already implicit and there is nothing to induce. (I suppose that's why they say Riemannian.) I am also guessing for Sakharov the universe needs to be globally hyperbolic.

48. **Coin**
September 2, 2010

Looking at the Freund paper– the way he generalizes entropic-gravity to entropic-everything is just using the old Kaluza-Klein dimensions-as-forces thing, right? But people don't actually *use* the Kaluza-Klein dimensions in normal mainstream physics, right? Weren't there problems with the theory, like stabilization? Wouldn't an attempt to explain forces as Kaluza-Klein dimensions for entropic gravity run into the same problems that explaining forces as Kaluza-Klein dimensions for *ordinary* gravity did? Am I missing something?

49. **Shawn Halayka**
September 5, 2010

Hi Coin,

This problem is treated from a Kaluza-Klein perspective in Chapter 10.3 "Flux compactifications: Moduli stabilization" of String Theory and M-Theory: A Modern Introduction by Becker, Becker, and Schwarz (that is, THE John Schwarz).

Whether you are a fan of string theory or not, this chapter is a good read.

Researchers Discover How to Conduct First Test of "Untestable" String Theory

September 1, 2010
Categories: This Week's Hype

A couple people this morning pointed me to today's press release from Imperial College, headlined Researchers Discover How to Conduct First Test of "Untestable" String Theory and subtitled "New study suggests researchers can now test the 'theory of everything'". In case you miss the headline and subtitle, and thus the point that string theory is now testable due to the efforts of Imperial College researchers, the rather short press release repeatedly drives the point home:

> The new research, led by a team from Imperial College London, describes the unexpected discovery that string theory also seems to predict the behaviour of entangled quantum particles. As this prediction can be tested in the laboratory, researchers can now test string theory…
>
> Using the theory to predict how entangled quantum particles behave provides the first opportunity to test string theory by experiment…
>
> The discovery that string theory seems to make predictions about quantum entanglement is completely unexpected, but because quantum entanglement can be measured in the lab, it does mean that at last researchers can test predictions based on string theory…

There's a blog posting written about the preprint of this paper when it first appeared here, in which I pointed out that the result worked out in the paper is just an example of a well-known piece of mathematics that comes down to classifying nilpotent orbits. This is based on a famous 1971 theorem of Kostant-Rallis, and Nolan Wallach worked out in detail here the specific example considered by Duff et al. in lecture notes for a 2004 summer school. The initial preprint didn't refer to this mathematical literature, but a revised version was soon issued in which a reference to the Wallach notes was added to the bibliography. There's no trackback to the discussion on Not Even Wrong at the arXiv listing for the paper due to the arXiv's censorship policy, but perhaps one or more of the authors of the preprint are regular readers here…

I have no idea how this paper is supposed to contain a "test" of string theory. The simple quantum mechanics problem at issue comes down to classifying orbits of a group action on a four-fold tensor product, exactly what Wallach worked out in detail in his notes, as an example of Kostant-Rallis. If you do an experiment based on this and it doesn't work, you're not going to falsify string theory (or Kostant-Rallis for that matter). By now there's a long history of rather outrageous press releases being issued about the discovery of supposed "tests" of string theory. This one really takes the cake…

Update: The press release is having its intended effect, generating stories headlining false claims about string theory . So far today, there's String Theory:Testing the Untestable? , New study suggests researchers can now test the 'theory of everything', Scientists Say They Can Now Test String Theory and Researchers Devise the First Experimental Test of Controversial, Confusing String Theory. There's even UK Scientists discover way to test untestable string theory, which has the test already performed:

> Scientists at the Imperial College London have managed to conduct the first string theory test, destroying previous beliefs that it was untestable….
>
> The discovery will please physicists, most of whom consider string theory the best available for explaining the universe.

Unfortunately, no details on how the test turned out…

Update: The subtitle on the press release has been changed. It used to be "New study suggests researchers can now test the 'theory of everything'", now it's "New study presents unexpected discovery that string theory may predict the behaviour of entangled quantum particles."

Update: No press campaign for a "finally string theory is testable" claim is complete without a Slashdot story (actually, stories, here and here):

> Big news for theoretical physicists who are fed up with the inability to test String Theory…

Update: Lisa Grossman has a story about this at Wired Science. She went to the trouble of contacting well-known string theorists for their opinion, which is unanimous that this is not a "test of string theory":

> "Already I can imagine enemies sharpening their knives," Duff said.
>
> And they are. A chorus of supporters and critics, including Nobel laureate and string theory skeptic Sheldon Glashow and string theorists John Schwarz of Caltech, James Gates of the University of Maryland, and Juan Maldacena and Edward Witten of the Institute for Advanced Study in Princeton agree that Duff's argument is "not a way to test string theory" and has nothing to do with a theory of everything.

I'm still trying to figure out what the supposed test of string theory is, since I can't find such a thing in the published paper. The Wired article has a bit more explanation from Duff:

> Whether the result is some fundamental principle or some quirk of mathematics, we don't know, but it is useful for making statements about quantum entanglement.

As far as I can tell, we do know where their results come from, a "quirk of mathematics" known as the Kostant-Rallis theorem, applied to the invariant theory question that comes up in quantum entanglement.

The article also contains quotes from me, saying about what you'd expect.

Update: Science News has completely uncritical coverage of the "First Test of String Theory" claims.

Comments

1. **Kea**
   September 1, 2010

   Gee, that is totally outrageous! And especially disappointing, given the real scientific interest of this work. I know that at least one of the young authors on these papers is not a great fan of string theory, which is to say that he understands the quantum information theory is just that – quantum information theory.

   This is not surprising for Imperial though. They are known to care a lot more about their reputation (preventing certain people from speaking there) than about the actual science.

2. **Anonymous**
   September 2, 2010

   How can they claim this is the *first* test of string theory? The first test was quark-gluon plasma at RHIC.

3. **rrtucci**
September 2, 2010

I too think that dishonesty in academic press releases is a serious problem. Such practices erode the public's trust in science and their understanding of it. They confuse non-scientists, blurring in their minds the difference between someone advocating homeopathy and someone advocating Newton's equation. Non-scientists start thinking that scientists are lying when scientists tell them that vaccines don't cause autism, because after all, they've seen scientists lie or exaggerate in other contexts.

I hope someone starts a website like http://www.PolitiFact.com or http://www.FactCheck.com. It could have a truth-o-meter, a la poltifact, for each press release or newspaper/magazine article that any concerned scientist entered. (A good source of press releases is http://www.eurekalert.org). How to arrive at the truth-o-meter rating would require some thought (maybe by poll?). The truth-o-meter ratings for each university department could be compiled together. My impression is that some university departments are worse offenders than others. It would be nice to give each university department a grade to embarrass bad offenders into behaving better.

4. **lun**
September 2, 2010

In this, unfortunately, string theory is hardly unique.
Yale University characterized the (probably bogus in any case) discovery of topological parity-violating effects in heavy ion collisions as
"Yale scientists break the laws of physics" (!!!!!!!!!!!!!!)
(http://www.sciencedaily.com/releases/2010/03/100329214740.htm)

In our day and age, there is the perception that public relations determine funding. The people who write these announcements are neither scientifically competent nor so interested in objectivity.

THese are the results.

5. **piscator**
September 2, 2010

Anonymous's comment is either deeply depressing or wonderfully tongue-in-cheek. Unfortunately I can't decide which….

6. **rrtucci**
September 2, 2010

Correction: I meant http://www.factCheck.org, not http://www.factCheck.com

7. **nul**
September 2, 2010

This is the BNL/RHIC press release about parity-violating effects in (polarized) p-p collisions at RHIC.
http://www.bnl.gov/rhic/inside/news.asp?a=1588&t=today

Overall much more toned-down compared to "Yale scientists break the laws of physics" but also much less accessible to a general (non-physics) audience. From what I see in the BNL press release, it does not sound bogus. There can be bubbles in a QGP where parity is locally violated (but averaged over many bubbles the parity violation is zero). Why not?

As for string theory and QIT etc. — yes, publicity seems to be an essential ingredient for funding. And yes, string theory is not unique in this trend.

8. **Marcus**
September 2, 2010

It seems the new Hawking book hypes M-theory, the multiverse, etc. It goes on sale within week (7 September) and is currently #9 among all books Amazon sells. The Amazon page has a two-paragraph quote from Hawking summarizing the book's message as he sees it.
To me this suggests we are about to be engulfed in a wave of buzz, misleading half-truths, and public gullibility. But maybe it won't be that bad.

9. **Mark Decker**
September 2, 2010

Looks like people from all sides are jumping all over this story. It's too bad that string theory itself doesn't get the same critical analysis that this test claim is receiving.
rrtucci: Thank you for checking your facts on the factcheck address.

10. **lun**
September 2, 2010

nul… of course the "discovery" is reasonable. The problem is that the same _observed_ effect can be reproduced without parity-violating bubbles, via much more mundane effecs such as local momentum conservation and jet fragmentation.
See http://arxiv.org/abs/1008.4919 or http://arxiv.org/abs/1008.3846
These ideas appeared well before the public relations announcement.

It of course does not mean that parity-violating bubbles are excluded, or that this research is worthless (it is in fact extremely interesting and stimulating, and I hope it continues, eg by designing more direct experimental signatures of this effect), but it annoys me that PR announcements trumpeting great discoveries are made almost at the same time as preprints explaining the "discoveries" with more mundane mechanisms appear online.

This is the mirror image of the string theory announcements… or at least, a proof that misleading PR is far from unique to string theory.
It pervades modern science. And it will come to bite all scientists in the back, because in the long-run, it fosters (un)healthy skepticism: Maybe all scientists are full of it. Which they are not.

11. **Chris W.**
September 2, 2010

In the so-called real world this is known as marketing and healthy self-promotion.

See Feynman's example from advertising in his essay "Cargo Cult Science". Apparently many current university press releases on research at their respective institutions barely maintain that dubious standard.

12. **dexmachina**
September 3, 2010

I'm afraid the Slashdot story is my fault. I really should know better than to trust popular science stories. I've linked to this page from the Slashdot post to try to undo some of the damage.

13. **Another Mike**
September 3, 2010

dexmachina, I saw your correction link right away. Not RTFA pays off! I consider this a great way to promote this site and point out an abusive press release.

Hawking Gives Up

September 7, 2010
Categories: Book Reviews, Multiverse Mania

David Gross has in the past invoked the phrase "never, never, never give up", attributed to Churchill, to describe his view about claims that one should give up on the traditional goals of fundamental physics in favor of anthropic arguments invoking a multiverse. Steven Hawking has a new book out this week, called The Grand Design and written with Leonard Mlodinow, in which he effectively announces that he has given up:

> We seem to be at a critical point in the history of science, in which we must alter our conception of goals and of what makes a physical theory acceptable. It appears that the fundamental numbers, and even the form, of the apparent laws of nature are not demanded by logic or physical principle. The parameters are free to take on many values and the laws to take on any form that leads to a self-consistent mathematical theory, and they do take on different values and different forms in different universes.

Thirty years ago, in his inaugural lecture as Lucasian professor, Hawking took a very different point of view. He argued that we were quite close to a final unified theory, based on N=8 supergravity, with a 50% chance of complete success by the year 2000. A few years after this, N=8 supergravity fell into disfavor when it was shown that supersymmetry was not enough to cancel possible ultraviolet divergences in the theory. There has been a recent revival of interest as new calculational methods show unexpected and still not completely understood additional cancellations that may fully eliminate ultraviolet divergences. Hawking shows no interest in this, instead signing on to the notion that "M-theory" is the theory of everything. The book doesn't even really try to explain what "M-theory" is, we're just told that:

> People are still trying to decipher the nature of M-theory, but that may not be possible. It could be that the physicist's traditional expectation of a single theory of nature is untenable, and there exists no single formulation. It might be that to describe the universe, we have to employ different theories in different situations

The book ends with the argument that

- Our TOE must contain gravity.
- Supersymmetry is required to have a finite theory of gravity.
- M-theory is the most general supersymmetric theory of gravity.

ergo

> M-theory is the unified theory Einstein was hoping to find. The fact that we human beings – who are ourselves mere collections of fundamental particles of nature – have been able to come this close to an understanding of the laws governing us and our universe is a great triumph.

This isn't exactly an air-tight argument…

The book begins in a more promising manner, with a general philosophical and historical discussion of fundamental physical theory. There's this explanation of what makes a good physical model:

> A model is a good model if it:
>
> 1. Is elegant
> 2. Contains few arbitrary or adjustable elements
> 3. Agrees with and explains all existing observations
> 4. Makes detailed predictions about future observations that can disprove or falsify the model if they are not borne out.

The fact that "M-theory" satisfies none of these criteria is not remarked upon.

The book is short (about 100 pages of actual text, interspersed with lots of color graphics and cartoons), and contains rather little substantive science. There are no references of any kind to any other sources. The discussion of supersymmetry and M-theory is often highly misleading. For example, we are assured that

> various calculations that physicists have performed indicate that the partner particles corresponding to the particles we observe ought to be a thousand times as massive as a proton, if not even heavier. That is too heavy for such particles to have been seen in any experiments to date…

With no references, one has no idea what these "various calculations" might be. If they are calculations of masses based on the assumption that the supersymmetry and electroweak-symmetry breaking scales are similar, they typically predict masses visible at the Tevatron or LEP. I suspect that the logic is completely backwards here: what is being referred to are calculations based on the Tevatron and LEP limits that require masses in the TeV range.

As for the fundamental problem of testability of M-theory, here's the only thing we get:

> The theory we describe in this chapter is testable…. The amplitude is reduced for universes that are more irregular. This means that the early universe would have been almost smooth, but with small irregularities. As we've noted, we can observe these irregularities as small variations in the microwaves coming from different directions in the sky. They have been found to agree exactly with the general demands of inflation theory; however, more precise measurements are needed to fully differentiate the top-down theory from others, and to either support or refute it. These may well be carried out by satellites in the future.

This looks like one of many dubious claims of "testability" of multiverse theories, which tend to founder on the measure problem and the fact that one has no idea what the underlying theory actually is. Without any details or references though, it's hard to even know exactly what the claim is here.

One thing that is sure to generate sales for a book of this kind is to somehow drag in religion. The book's rather conventional claim that "God is unnecessary" for explaining physics and early universe cosmology has provided a lot of publicity for the book. I'm in favor of naturalism and leaving God out of physics as much as the next person, but if you're the sort who wants to go to battle in the science/religion wars, why you would choose to take up such a dubious weapon as M-theory mystifies me. A British journalist contacted me about this recently and we talked about M-theory and its problems. She wanted me to comment on whether physicists doing this sort of thing are relying upon "faith" in much the same way as religious believers. I stuck to my standard refusal to get into such discussions, but, thinking about it, have to admit that the kind of pseudo-science going on here and being promoted in this book isn't obviously any better than the faith-based explanations of how the world works favored by conventional religions.

For some reviews of the book showing a bit of skepticism, see ones by Craig Callender, Fred Bortz, and Roger Penrose. For much more credulous reviews, see for example James Trefil (who evidently has his own multiverse book coming out). The Economist has a news story about this, which assures us that Hawking is

> a likely future recipient of the Nobel prize in physics (if, as expected, his 1974 theory that black holes emit radiation despite their notorious all-engulfing gravitational pull is confirmed by experiments at the Large Hadron Collider in CERN).

Update: There's a new posting at physicsworld.com by Hamish Johnston that brings up the issue of the potential damage caused by this to the cause of science funding in

Britain:

> This morning there was lots of talk about science on BBC Radio 4's Today Programme — but I think it left many British scientists cringing under their duvets.
>
> Hawking explained that M-theory allows the existence of a "multiverse" of different universes, each with different values of the physical constants. We exist in our universe not by the grace of God, according to Hawking, but simply because the physics in this particular universe is just right for stars, planets and humans to form.
>
> There is just one tiny problem with all this — there is currently little experimental evidence to back up M-theory. In other words, a leading scientist is making a sweeping public statement on the existence of God based on his faith in an unsubstantiated theory…
>
> Physicists need the backing of the British public to ensure that the funding cuts don't hit them disproportionately. This could be very difficult if the public think that most physicists spend their time arguing about what unproven theories say about the existence of God.

Update: Today's Wall Street Journal has a quite positive review of the book by Sean Carroll.

Update: See here for John Horgan's take on the Hawking book:

> I've always thought of Stephen Hawking—whose new book The Grand Design (Bantam 2010), co-written with Leonard Mlodinow, has become an instant bestseller—less as a scientist than as a cosmic, comic performance artist, who loves goofing on his fellow physicists and the rest of us…
>
> Toward the end of the meeting , everyone piled into a bus and drove to a nearby village to hear a concert in a Lutheran church. When the scientists entered the church, it was already packed. The orchestra, a motley assortment of blond-haired youths and wizened, bald elders clutching violins, clarinets and other instruments, was seated at the front of the church. Their neighbors jammed the balconies and seats at the rear of the building.
>
> The scientists filed down the center aisle to pews reserved for them at the front of the church. Hawking, grinning ear to ear, led the way in his motorized wheelchair. The townspeople started to clap, tentatively at first, then passionately. These religious folk seemed to be encouraging the scientists, and especially Hawking, in their quest to solve the riddle of existence.
>
> Now, Hawking is telling us that unconfirmable M-theory plus the anthropic tautology represents the end of that quest. If we believe him, the joke's on us.

Comments

1. **Marcus**
   September 7, 2010

   Perceptive review in NYTimes:
   http://www.nytimes.com/2010/09/08/books/08book.html
   "…the real news about [the book] is how disappointingly tinny and inelegant it is."

2. **Greg Sivco**
   September 7, 2010

   Excellent, Peter. This is the objective review we have been waiting for. I feel so bad for Hawking, whom I otherwise admire. FOX News' review showed its usual stripes in choosing what had to be the ugliest picture ever taken of Professor Hawking in its horrible unfair and unbalanced review, presented as usual to engender its usual fear-mongering policy.

   Nothing more to add really, except for Roger Penrose's excellent opening words in his review of same which you linked to, which are:

   "In *The Grand Design*, Stephen Hawking gives his perspectives on physical reality and expectations for **future fundamental physics**, ably assisted by the fine science writer Leonard Mlodinow. These issues are made accessible to general readers via apposite analogies. Nonetheless, I doubt that adequate understandings can arise in this way. This applies particularly to "M-theory", a popular (but fundamentally incomplete) development of string theory …"
   … Roger Penrose, 4 Sept. 2010

   I get SO sick and tired of SuperStrings' M-Theory being presented as "theory", rather than the "idea of a theory" that it really is.

3. **Cale**
   September 7, 2010

   off-topic so i hope you find it interesting:
   sean carrol has made this talk here:
   http://www.youtube.com/watch?v=GFMfW1jY1xE&feature=player_embedded
   in which he partly discusses the Boltzman brains problem but also talking about how baby universes can be created out of vacuum due to quantum fluctuations given endless amounts of vacuum and endless amounts of time. Does this immediately ring untrue to you for some reason?

4. **Yatima**
   September 7, 2010

   "The fact that we human beings – who are ourselves mere collections of fundamental particles of nature – have been able to come this close to an understanding of the laws governing us and our universe is a great triumph."

   This begs the question of "how close is that" and is there a metric space involved?

   Reminds me of a short story (by Alastair Reynolds I think) wherein *actual* understanding of the physical laws was made unreachable by the fact attaining full understanding immediately caused the understanding agent to collapse into a black hole, taking his knowledge with him. [That would mean "understanding" has to do with energy density, which would open novel ways of thinking about thinking. Turing Machines won't do for that.]

5. **Marcus**
   September 7, 2010

   That review of the Hawking potboiler was so perceptive and sharply written that it put the reviewer, Dwight Garner, on the map for me. He's good. I normally don't read book reviews, but I'm going to start following his. He does non-fiction. As a sample here is his list of 10 favorite non-fiction books from 2009:
   http://www.nytimes.com/gift-guide/holiday-2009/giftguide-garner/list.html?pagewanted=print

What he picks, and the one or two-sentences he says about each, can give you an idea of what he's like.
Here again is the link to his review of "The Grand Design"
http://www.nytimes.com/2010/09/08/books/08book.html

6. **Peter Woit**
September 7, 2010

Cale,

Sean Carroll's views on the arrow of time etc. are definitely off topic, but I was going to point out that, unlike me, he is interested in the God thing, and has a recent posting about Hawking's book from that point of view, which has attracted a huge number of comments. People interested in that aspect of the book are encouraged to discuss it there.

7. **Anonymous**
September 7, 2010

Though Hawking is not a string theorists himself, through his numerous popular books starting from "A Brief History of Time", he may be the single person most responsible for spreading the hype of string theory to the general public. As an iconic figure in front of mass media, his endorsement of string theory means a lot. I'm sure string theorists feel indebted.
As for N=8 supergravity, at least according to Lubos, you can't get any realistic phenomenology out of it. So finiteness may not be the only issue that affects people's opinion of SUGRA.

8. **Christian Takacs**
September 8, 2010

I am not a physicist, I am not a mathematician, but I am a student of philosophy, history, logic, science, and the human mind. With all due respect, It seems that Mr. Hawking does not know the difference between Mathematics and Reality. They are not the same thing, and can't be the same thing by their very nature …and by definition in any respected dictionary.
For Mr. Hawking to be calling upon "infinite" unknowable, unobservable, unmeasureable multiverses to resolve any physics problem in this reality is ridiculous… unless his intended genre is actually fantasy or metaphysics.

9. **Joe Bob**
September 8, 2010

Does any serious physicist take Hawking very seriously anymore?

10. **chris**
September 8, 2010

What always irked me about Hawkings arguments is that they would rank rather highly on the crackpot index due to his frequent mentioning of Einstein.

11. **DB**
September 8, 2010

The real problem is that many very successful theoretical physicists become agents of negative influence when they pass the age at which they are capable of making fundamental breakthroughs, roughly the age of forty to forty-five. As they age, they become an embarrassment to the field.

Einstein, post 1930, was the prime example and his malign influence is felt today in the obsession with TOEs and mathematical beauty. Dirac and Heisenberg showed similar symptoms in their dotage.

Driven perhaps by a touch of megalomania, and stripped of their ability to recreate their past success they venture into the intellectually sloppy regions of speculative physics.

12. **Anon2**
September 8, 2010

Hawking is just following the fashion trend set by Susskind's "Cosmic Landscape" and Dawkin's "God Delusion" in claiming that the scientific theory of string disproves God by providing a large landscape of parallel universes, so that fine tuning can be by anthropic self-selection (with no need for a prayer-deaf old man in a beard).

More exciting news: Roger Penrose's new book "Cycles of Time" is published in the UK on 23 September. Penrose hasn't given up!

13. **Chris Oakley**
September 8, 2010

I was feeling depressed about the state of theoretical physics when I heard a voice say, "Cheer up! Things could be worse!" So I cheered up, and, sure enough, things *got* worse. Hopefully Penrose's book will be better.

14. **BigG**
September 8, 2010

First, its always to good have alternative view points and people following paths outside the mainstream. And if the people who do this are respected physicists all the better.

Second, all this critisism of Hawking and Einstein is unfounded. The same things were being said about Einstein in 1905. Further, in the early 20th century the same kind of people were saying there's only mechanics and e&m; all that's left of physics is to figure out this particular case or that. The use of the word 'crackpot' is highly over used. Yes, there are certainly people who are way out there but the same was said by the old generation of the new in the earth 20th century. Besides, how many of you who criticize Einstein or Hawking have ever written anything close to what they've done. I apologize for going off topic but its shameful to read this stuff. People who know how science works would never make the criticisms you are. Imagine youself 100 years ago defending strict determinism in the face of quantum theory.

15. **wolfgang**
September 8, 2010

>> the age at which they are capable of making fundamental breakthroughs, roughly the age of forty to forty-five.

Planck was 42 when he discovered quantum theory in 1900.
Born was 43 when he formulated matrix mechanics.
Einstein was 45 when he wrote about what we now call Bose-Einstein statistics.
Hahn was 59 when he discovered fission.
Bethe proposed neutrino oscillations when he was 80.

Just saying.

16. **Arun**
September 8, 2010

Imagine youself 100 years ago defending strict determinism in the face of quantum theory.

You mean the "God does not play dice with the world" Einstein?

The criticism of the physics here is that it has ZERO experimental or observational content, which is rather the opposite of the situation with quantum mechanics a century ago.

17. **younghun park**
September 8, 2010

Peter
From your writing, I don't think Hawking gave up the unified theory. Like many physicist, he has had the dream on the unified theory, the theory of everything.

I feel that the thing he gave up is the hope to reach one perfect
theory by using current methods, supersymmetry, string theory and so on. He seems to ask us how the unified theory can be made.He seems to long us to find the key toward that theory.

I have learned that physics aims at describing the nature by simple, very simple idea. I have fallen in love with physics due to that point.

I believe that physics can advance continuously when it aims at the unified theory even if that is impossible.

18. **stan**
September 8, 2010

It is interesting to note that the timing of David Gross' exhortations to "never give up" coincided quite closely with the cessation of his research output. Who's doing the giving up here?

19. **BigG**
September 8, 2010

Arun,

You've taken that quote out of context. Einstein was working within QM to find some kind of derterminism. My post was talking about those of the older generation who opposed it merely on belief or speculation, like those here are criticising Hawking.

20. **Giotis**
September 8, 2010

Why Hawking relates M-theory to the Multiverse? From what I read for the book in various places is like if M-theory directly implies and explains the Multiverse and the Multiverse concept could not be understood without it. This is not true of course.

The KKLT model which triggered the multiverse frenzy is in the good old IIB. The counting of the flux vacua by Douglas which resulted the notorious 10^500 number was performed in IIB also. M-theory is not needed to derive the Multiverse and to say that M-theory (and M-theory alone) implies it (and thus explains why God is not needed) is simply wrong. On the contrary I may add direct compactifications of M-theory to 4 dimensions (i.e. on G2 manifolds) and its vacua are not well understood.

21. **Chris Oakley**
September 8, 2010

Hi BigG,
Let me see if I have understood you correctly. Around 1905 Einstein explained the photoelectric effect – an experimental result – by proposing that light, as well as being a wave governed by Maxwell's equations, was also a quantum of energy $h\nu$. Notwithstanding the success of the interpretation, some of the older generation of physicists never accepted this because they refused to try to wrap their minds around the idea that something could be a wave and a particle at the same time.

105 years later Hawking is proposing that because a theory, or at least framework for speculation, called M-theory, something that he has never worked on, is incapable of predicting anything we need to adjust our definition of "prediction" so that it does, and if we cannot do that then we are just like those who could not accept wave-particle duality in the early part of the 20th century.

Have I got this right?

22. **Mark Decker**
September 8, 2010

BigG,
Your comment: "People who know how science works would never make the criticisms you are" is absolutely absurd.
It is the very people who know how science should work (and haven't lost their way) who are the ones making these critical comments. Don't confuse the actual word "Science" with modern day individuals who have the credential to refer to themselves as "Scientists" as they spew endless nonsense.
I like Chris Kennedy's quote (on the majority of Theoretical Physicists today): "They have become heroes to the stupid and laughingstocks to those who know better."

23. **MyrtleParker**
September 8, 2010

"This could be very difficult if the public think that most physicists spend their time arguing about what unproven theories say about the existence of God."

My estimation of Stephan Hawking has gone so far down because of this and his times article. Really sad.

There really is very little difference between so-called scientists engaging in vapid anthropic/Multiverse/M-Theory speculation and religion.

24. **MyrtleParker**
September 8, 2010

Sean Carroll's praise of Hawking and absurd statements that science understands the creation of the universe is equally shameful. Our knowledge of the laws of physics break down completely with the Big Bang. He should know better. Looks like he has really bought into the physicist as well known ego-hype-charlatan. Very sad.

25. **Consumer Reviews**
September 8, 2010

Interesting review! One thing is for sure, Stephan Hawking is a fascinating personality.
Kind regards.

26. **DaveC**
September 8, 2010

Steven Hawking and Sean Carroll both have something in common with an increasing, perhaps even overwhelming, majority of theorists nowadays. They have never once had the experience of either predicting or convincingly interpreting the results of a good experiment (nor have they come up with any original mathematics themselves). Perhaps Hawking is one of the oldest of whom this could be said. After spending a career playing mind games with others in the same boat, and being praised for doing so, it's not too surprising that they end up like this.

It's hard not to see a big crunch ahead for physics, as generations are trained by people who haven't had this experience, compounded with all the other overwhelming pressures on us nowadays to live and breathe hype, pretending our work will answer the mysteries of the universe, solve the energy crisis in one blow, allow us to simulate reality, or whatever, in order to get funded and attract students.

27. **neo**
September 9, 2010

Stephen's (not Steven's!) accomplishments speak for themselves. Why he has embarked on this exploitation tangent is beyond me. His approach seems to be the substitution of one form of theology for another.

28. **longchenpa**
September 9, 2010

so if an actual physicist who is hundreds of times smarter than you says things that go against your pet peeve, of course, something must be wrong with him.

29. **neo**
September 9, 2010

longchenpa:

That is appeal to authority. Stick to arguments. No one is so smart that they cannot be wrong.

30. **BigG**
September 9, 2010

Chris & Mark,

No you don't adjust anything. My point is we don't know what the future holds. We don't know for sure if Hawking's prediction will turn out to be true. Let him follow his own path. Why are so many people afraid? If his theory is proven its accept it, if not its rejected. The method will take care of the problem. The whole point I'm making is you don't know. That's what I mean by people who know science wouldn't say what's going on here. The only certainty in science is what was will most likely be overturned to some extent.

I have two qurstions:

1) can you predict the future
2) what have you contributed to physicss besides criticism.

If you want to voice a disagreement this is reasonable but the hostility is unfounded. based on the comments here I'm not sure you know how science works.

31. **Arun**
September 9, 2010

BigG:
If his theory is proven its accept it, if not its rejected. The method will take care of the problem.

What he proposes falls outside the "method". That is the problem.

32. **Coin**
September 9, 2010

Actually, the NYT review linked a couple times above strikes me as darn weird. The author seems to spend more time expressing concern that a multiverse theory would potentially render God unnecessary, or concern that Hawking&Mlodinow think it would, than anything else about the book. In short he doesn't seem concerned with whether the multiverse hypothesis is good science, he's just upset by its perceived consequences– its theological consequences even? Now of course if H&M "started it" by bringing up atheism on every page or something then that doesn't strike me as good science writing, but the NYT reviewer doesn't give much indication that was the case– he just seems offended the subject was at some point broached and doesn't seem concerned with the actual substance of the book. I feel like I didn't learn much about the book by reading that review.

A question, do we really know how much of this book was written by Hawking?

33. **Wavefunction**

September 9, 2010

On a related note, what do you think of Shing-Tung Yau's new string theory book "The Shape of Inner Space"?

34. **Peter Woit**
September 9, 2010

Wavefunction,

I did read the Yau book quite recently and plan to write about it here very soon. About all I'll say now is that I liked the book a lot more than I expected (the opposite of the case with Hawking's).

35. **Mark Decker**
September 9, 2010

BigG'
You ask: "Why are so many people afraid."
I don't think they are afraid. I'm certainly not. And I don't consider my statements to be hostile either. I think most people are responding the way they are out of frustration. I can understand why anyone who just wants to get a responsible discussion going on these matters sees the Hawking book as just another setback. However, I don't see this as a setback. I think the lines have been drawn and there are two camps. The Greene-Kaku-Hawking, etc… camp who get all of the media attention including guest spots on CNN, shows on PBS, etc.. and the other camp, who are a little more responsible when it comes to investing themselves in certain theories. The latter camp, although more scientifically minded than the former, have been reduced to an underground movement. No big lights or fancy promises of extra dimensions. Just people who want to get to the truth. That's actually fine with me. Let the masses be entertained with science fiction. As long as there is an outlet for the continuation of this underground movement (like Woit's blog) I'm happy.
Can I predict the future? No
And to answer your other question: My criticism is my contribution to physics, and I think an important one.

36. **Marcus**
September 9, 2010

Coin,
you miss the point of the first 1/3 or so of the NYT review, which took Hawking to task for "Godmongering"—getting books talked about by issuing provocative pronouncements about God. Pro or anti, doesn't matter.

To illustrate: Hawking and Mlodinow had a byline piece in the WSJ (3 September) with the heading
Why God did not create the universe
which was described as an excerpt from their book. The article contrasts modern science with primitive superstitions concerning natural phenomena, raises questions about why the universe is the way it is, and proceeds as follows:

==quote==
… Luck in the precise form and nature of fundamental physical law is a different kind of luck from the luck we find in environmental factors. It raises the natural question of why it is that way.

Many people would like us to use these coincidences as evidence of the work of God. The idea that the universe was designed to accommodate mankind appears in theologies and mythologies dating from thousands of years ago. In Western culture the Old Testament contains the idea of providential design, but the traditional Christian viewpoint was also greatly influenced by Aristotle, who believed "in an intelligent natural world that functions according to some deliberate design."

That is not the answer of modern science. As recent advances in cosmology suggest, the laws of gravity and quantum theory allow universes to appear spontaneously from nothing. Spontaneous creation is the reason there is something rather than nothing, why the universe exists, why we exist. It is not necessary to invoke God to light the blue touch paper and set the universe going.
==endquote==

If it matters to you, it is clear they STARTED IT as you said in your post, and that they are USING theological provocation to get attention (e.g. from WSJ readers) and build sales.

The reviewer, Dwight Garner, is not critical of the atheism *per se* but of the cynical potboiler aspect. He is just as critical of the seemingly "pro-God" teasing that Hawking used in his 1988 book. Godmongering can be worked either way. Ambiguous pronouncements aimed at firing up discussion.
http://online.wsj.com/article/SB10001424052748704206804575467921609024244.html

The NYT reviewer spent only about 1/3 of the article on the cheap theological provocation. He then ripped into the book's other superficial potboiler characteristics.

To make it clear that it was not simply the atheism *per se*, I will quote briefly from the NYT review.

==quote Dwight Garner review==
In "A Brief History of Time" Mr. Hawking also dabbled in what the science writer Timothy Ferris has called "Godmongering." Mr. Hawking… ended "Brief History" by declaring that the discovery of a unified theory of physics could help us to **"know the mind of God."** It was a line that — cynically, some thought — allowed glints of fuzzy sunshine to warm the cold blade of his thinking.

Mr. Hawking's new book, "The Grand Design," … has already made headlines … thanks to a **different sort** of Godmongering. This time Mr. Hawking has, we're told, declared God pretty much dead…
==endquote==

I read it as a kind of teasing which involves taking phony pro- or anti- *poses* that, partly because of their deliberate ambiguity, contribute neither to science nor to theological discussion.

37. **Marcus**
September 9, 2010

Since I quoted a few lines of the NYT review I should probably give the link:
http://www.nytimes.com/2010/09/08/books/08book.html
I gave it earlier but you'd have to scroll back quite a ways to find it.

38. **Chris W.**
September 10, 2010

For more on the discussion in the U.K. of Hawking and Mlodinow's book, see this Physics World blog post by James Dacey.

39. **Anonymous**
September 10, 2010

Leonard Susskind also debunked Intelligent Design as an "illusion" based on the idea of string multiverse. The non-uniqueness of string theory is obviously our best weapon in fighting religious dogma.

40. **Anon2**
September 10, 2010

Newton could have "gone anthropic" to predict gravity on the basis that people would have drifted off into space without it and would have been unable to move with too much. He could thus have done rough and ready calculations of the order of magnitude of the gravitational acceleration needed to keep most people's (not string theorist's) feet on the ground long enough for them to behave sensibly and thus exist.

However, Newton didn't waste his time on such pseudoscientific anthropic arguments. Lee Smolin made a comment here a few years ago (Not Even Wrong) claiming that every "anthropic" prediction is vacuous. E.g. Hoyle claimed to anthropically predict a significant cross-section for carbon synthesis in stars from the fusion of three alpha particles (necessary because of the beryllium bottleneck) in order to produce the carbon-12 for life. But all he was really doing was making a very rough and ready *ad hoc* prediction from a theory to explain the observed carbon abundance in the solar system.

41. **Nono**
September 10, 2010

> The non-uniqueness of string theory is obviously our best weapon in fighting religious dogma.

The *only* weapon to fight religious dogma is the scientific method. Take a look at the book "Facing Up" by S. Weinberg.

42. **notan**
September 10, 2010

"the apparent laws of nature are not demanded by logic or physical principle"

Most of us are aware of the fact that the apparent laws of nature are not demanded by logic since, if they were demanded by 'logic' then this 'logic' could not be logic. To put it differently, if some theory gives you some information about the (laws of) nature it can't be logic in any sense reasonable sense of the word "logic" (unless you think you could learn something about nature while staying in your bedroom).

So we are left with

"the apparent laws of nature are not demanded by physical principle"

Then you should stop searching for physical principle and find another job.

43. **zanzibar**
September 10, 2010

RE: Bethe's work on neutrino oscillations –

I saw him talk on this when he was indeed 80 years old. I remember it being inspirational – deep physical insight and mathematics. Very impressive.

I also remember watching the difficulty he had backing his rental car out of a space in the parking lot afterward. He was alone, and though I admired his independent spirit, I do remember a certain measure of concern I had for the other drivers who had to subsequently share the road with him.

For a mathematical counter-example against youth, see E.T. Bell's "The World of Mathematics", chapter 12 – "Invariant Twins, Cayley and Sylvester" –

http://books.google.com/books?id=Bnh3FKIKT9AC&pg=PA340&lpg=PA340&dq=bell%27s+men+of+mathematics+cayley+sylvester&source=bl&ots=44L8UFK08L&sig=kr4d3gjz31fgC_hv9vteJeiVCnKTLncEMKblgfLnczECw&sa=X&oi=book_result&ct=result&resnum=2&ved=0CBkQ6AEwAQ

Newton was undoubtedly a great scientist but he was not a paragon of scientific rationality. Quoting Wikipedia:

"In his Hypothesis of Light of 1675, Newton posited the existence of the ether to transmit forces between particles. The contact with the theosophist Henry More, revived his interest in alchemy. He replaced the ether with occult forces based on Hermetic ideas of attraction and repulsion between particles. John Maynard Keynes, who acquired many of Newton's writings on alchemy, stated that "Newton was not the first of the age of reason: He was the last of the magicians."[40] Newton's interest in alchemy cannot be isolated from his contributions to science; however, he did apparently abandon his alchemical researches.[5] (This was at a time when there was no clear distinction between alchemy and science.) Had he not relied on the occult idea of action at a distance, across a vacuum, he might not have developed his theory of gravity."

Hawking doesn't know what he's talking about when he criticizes philosophy. He also speaks about science as having proved something related to the origin of the universe. Like a lot of physicists he mixes up terminology. They should know better than to use meaningless terms like 'theory of everything' and 'nature of space and time'.

Arun,

there is no method. It is as real as the nature of space and time.

46. **Phil Warnell**
September 11, 2010

Dr. Woit,

You may find that Hawking is inconsistent with his theoretical preferences, yet he has now also apparently completely changed his philosophical standpoint, as coming to believe that science can dismiss the question why as being superfluous; whereas before he thought holding any opinion on such matters to be never the correct place for the discipline. It was not that long ago that he expressed this clearly in a critic he made in respect to Roger Penrose's views when it came to such matters when he wrote upon Penrose's invitation the following:

"Roger Penrose and I worked together on the large-scale structure of space and time, including singularities and black holes. We pretty much agree on the classical theory of General Relativity but disagreements began to emerge when we got on to quantum gravity. We now have very different approaches to the world, physical and mental. Basically he is a Platonist believing that there's a unique world of ideas that describes a unique physical reality. I, on the other hand, am a positivist who believes that physical theories are just mathematical models we construct, and that it is meaningless to ask if they correspond to reality; just whether they predict observation."

– The Large, The Small and the Human Mind- Roger Penrose (page 169)-Cambridge University Press (1997)

It has long been clear to me that Hawking's craving for notoriety has always been more important to him than the search for truth, scientific or otherwise. In such respect I think Sean Carroll's assessment to be the best, which he expressed in the summation of the review you pointed to in saying:

"Answers to the great "Why?" questions are going to be subtle and difficult. Our best hope for constructing sensible answers lies with scientists and philosophers working together, not scoring points off one another."

In my view, if any concern is to be had with books such this, it is to wonder how they serve the public at large able to distinguish the difference between science and religion, when we find the self appointed spokesman for the one built upon doubt places his faith in theory which claims as being reasonable although not able to be tested. It also has me to wonder if Hawking would ever be willing as Penrose was to open himself up to the criticism of one of his peers. I think if science demands anything of its practitioners, that is beyond adherence to the scientific method, it is to at least endeavour to maintain the integrity of the discipline, if not their own.

Best,

Phil

47. **Loki**
September 12, 2010

Perhaps the ALS has caught up with him, and he has lost his ability to rationally convey or understand arguments.

If this is the case, it would be a sad day indeed.

48. **Giotis**
September 12, 2010

I realize now after seeing the big publicity and the way the story is covered by large mainstream media (especially the Larry King interview) that this will have a huge impact in the long run. Hawking not only introduced String-M theory to the general public but more importantly he presented it as the celebrated undisputed theory which represents the climax of human knowledge. The uninitiated one is lead to assume that M-theory is the pinnacle of science endeavour and the only hope we have to understand the world. I'm sure String theorists are celebrating right now.

49. **Peter Woit**
September 12, 2010

Loki,

The problem with your hypothesis is that the pseudo-science Hawking is promoting is rather popular in some circles, so you would need an implausible amount of organic brain damage to explain this phenomenon that way.

50. **Benjamin Gal-Or**
September 12, 2010

Hawking love-story with the media and the masses intimidates many shy-away-from-the-media scientists, mainly by pushing the image of science far into mysticism and a misleading populism, which bluntly exploits the layperson ignorance of what is verifiable science. But the root problem is not Hawking but the many opportunistic scientists that support and even exploit such an approach to the fundamental pillars of verifiable science. Without their support the media would have failed to make an icon out of this false prophet; would at least resort to the audacity of truth: The entire Hawking festival does not even rise to the level of being wrong in the domain of verifiable science.

An unknown personal fact is added next:
Nature was among the first to publish a review on my "Cosmology, Physics and Philosophy" [1981, 1983, 1987, Springer Verlag], which, inter alia, contained criticism of Stephen Hawking's theories as lacking any possible future verification and some are not his but of J. D. Beckenstein.

The review was written by Hawking, who hinted there that instead of my not-easy-to-understand book he would write one for the masses , which he did in 1988 by omitting all mathematical equations and adding mysticism. [BTW: As far as I know some key Hawking's claims in science were first ridiculed by professor Yuval Neeman.]
["People University Online", Cf. my Facebook].

51. **mark davis tortino**
September 12, 2010

i wonder if hawking ever read feynman's cargo cult science speech?

"The first principle is that you must not fool yourself–and you are
the easiest person to fool. So you have to be very careful about

that. After you've not fooled yourself, it's easy not to fool other scientists. You just have to be honest in a conventional way after that.

I would like to add something that's not essential to the science, but something I kind of believe, which is that you should not fool the layman when you're talking as a scientist. I am not trying to tell you what to do about cheating on your wife, or fooling your girlfriend, or something like that, when you're not trying to be a scientist, but just trying to be an ordinary human being. We'll leave those problems up to you and your rabbi. I'm talking about a specific, extra type of integrity that is not lying, but bending over backwards to show how you are maybe wrong, that you ought to have when acting as a scientist. And this is our responsibility as scientists, certainly to other scientists, and I think to laymen.

So I have just one wish for you–the good luck to be somewhere where you are free to maintain the kind of integrity I have described, and where you do not feel forced by a need to maintain your position in the organization, or financial support, or so on, to lose your integrity. May you have that freedom."

September 13, 2010

Question from a non-physicist:
First of all, in the Feynman path integral theory, how in the world do you make sense mathematically of the constant branching of possibilities in all places and at all moments? (Since apparently quantum mechanics is not simply a diffusion process). Maybe the answer is that measurements take place only at discrete places and times. But then same question re the many-worlds theory (since then presumably this splitting takes place everytime and place). I mean is there a mathematical way of formulating this at all, even approximately? I am thinking that the number of possible worlds should certainly not exceed the continuum in cardinality (!) and should in fact lead to a measure space. Now naively the problem seems to be magnified enormously with the landscape idea… especially if it's infinity and not just 10^500. (???) Enlighten a bit please!

My impression is things are way too speculative for Hawking to put his considerable scientific and public weight on one side of the scale…unless of course he REALLY believes what he is saying.

56. **Chris Oakley**
September 13, 2010

Bugsy,

You are conflating things that have very little to do with each other.

1. The Feynman path integral. This is the notion that a system takes all possible paths from a state at an earlier time to a later time, but only the ones which follow the "correct" equations of motion are actually seen because of phase cancellations. It may or may not be rigorous, depending who you talk to. Either way, though, I personally have never understood (or seen the point of) it.

2. The measurement problem in quantum mechanics. Physical observables are only ever eigenvalues of some quantum operator. This does not require and has nothing to do with path integrals, or String Theory.

3. The Landscape in String Theory. The world is, as far as we know, 3+1 dimensional. String Theory is typically 10+1 dimensional. The process of losing dimensions is called compactification and current understanding is that the process can be done in about 10^500 different ways. The options are thus either (i) to give up or (ii) to say that because string must be right physics can therefore be reduced to choosing the right one of these compactifications.

Whether Hawking believes in (ii) or not is not so much the issue as whether anyone should care if he does. However I have noted generally a tendency for the elder statesman of the physics community (with the possible exception of Veltman) to support the status quo, whatever that may happen to be.

57. **Anthony McCarthy**
September 13, 2010

After reading here and other places, I went to my sister-in-law the aquatic biologist, with the happy news that now that physics has been freed from the requirement of actually being tied to physical evidence that she didn't have to go out this winter to do her sampling anymore. She wasn't as happy about it as I thought she would be, though she did take the opportunity to vent about theoretical physicists and cosmologists, their politics, their dirty politics and their hogging of funding. I think she might have felt better after that.

Being a complete outsider I have to say that the idea of an entirely artificial physics generating an entirely artificial mathematics to service it gave me a lot of entertainment while I was doing my chores this weekend. It came to me that the results might be a science that has has more in common with fan fiction than it does the natural universe. But that's only a musician's view of it.

58. **Jeffrey McGowan**
September 13, 2010

True story, I was at a math conference maybe 15 years ago, at a talk on something to do with Riemann surfaces, and the number 26 (or maybe 24) kept coming up. Someone asked "is that the 26 dimensions from string theory?" (back then, if I remember correctly, string theory somehow involved 24 maybe + 2 dimensions?). At least now they've got it down to 10 + 1. I've been told by several very good mathematicians who are much more involved than I am that there is very interesting math involved in string theory, then again, sometimes I get the impression that it's actually inconsistent, and you can prove anything you want to…

59. **Bruce Keener**
September 13, 2010

I'm just a layman, but do have an interest in what makes our world tick, and I tend to buy most of the popular physics books to try to understand current thinking.

I was very disappointed in Hawking's book. My full review of it is here.

But, in short, he makes no attempt to summarize the various ideas regarding the origin of our universe and to say why M-theory is a better candidate … he basically just says it is, like we are supposed to believe him. The problem is, many will just believe him, and will never know that there are competing theories. And to treat cosmic inflation and supersymmetry as fact is just downright deceitful, given that many of his readers will never know that there are many reputable physicists who dispute both. (For all I know, both theories are true, but they are certainly not established fact.)

60. **Peter Woit**
September 13, 2010

Jeff,

Actually there is some quite good mathematics related to string theory, problem is that it tends to be orthogonal to those parts of string theory that are supposed to give unification.

The number 26 of dimensions for the critical bosonic string does have a nice relation to the moduli space of Riemann surfaces. The 10 for superstring theory less so. This is kind of typical: as you focus on those aspects of string theory that might give unification, things become more and more complicated, less and less mathematical elegance is to be found.

61. **Jeffrey McGowan**
September 13, 2010

Peter,

It was a moduli space thing where the 26 came up, back then I had very little to do with that sort of thing, now I'm big into Teichmuller theory, go figure. I do know there is quite interesting math lurking around, interesting what you say about the loss of elegance. Maybe that's why I ended up in math, much easier not to end up jamming a square peg into a round hole.

62. **Bugsy**
September 14, 2010

Chris (Oakley),
Thanks for your patient response.
I guess I was conflating "many paths", "many worlds", and "many universes"! And wondering if anyone thinks all three belong in the same "model", and further wondering if any of that can be formulated mathematically in any sense at all. Is there an actual topological space,
or measure space, which should be phase space, acted on by the dynamics of time evolution?

To try your patience one more time:
from what you say it seems the number 10^500 is really meant to be finite, as it comes from topological or algebraic considerations, and is not a continuum. Does that mean the possible values for each of the various physical constants are also of that number? (Is there a map from the compactification space to a vector space of possible constants?)Thanks….!

65. **steve newman**
September 14, 2010

On these blogs and elsewhere i often read word to the effect that
' string theory might not cut it as a physical theory, but it has led to very interesting mathematics".
Just what is this 'interesting math' ??
Can anyone refer me to a book or article for non-specialists that communicate this?
(I am mathematically and scientifically literate (phd theoretical physics, Columbia U 1966), so it needn't be a words-only book for a popular audience.) I follow current physics developments as an

interested outsider, and i'm genuinely interested in knowing about the interesting mathematics that is coming from superstring research.

66. **Peter Woit**
September 14, 2010

Steve,

My book "Not Even Wrong" has a bit about this. There's a new book by Yau and Nadis that just came out (The Shape of Inner Space) which has a lot more.

67. **Chris Oakley**
September 14, 2010

Bugsy,

I would rather not go there – it is too depressing. If it was me I would have thrown out the theory as soon as I discovered that it did not work in 3+1 dimensions. But yes, each string vacuum (=compactification) has its own mass spectrum and coupling constants. The only things that are common are c (the speed of light), h (Planck's constant) and G (the gravitational constant).

68. **Giotis**
September 14, 2010

Chris,

The gravitational constant is not common in all compactifications. It depends on the volume of the extra dimensions.

69. **John Baez**
September 15, 2010

Bugsy writes:

> from what you say it seems the number 10^500 is really meant to be finite, as it comes from topological or algebraic considerations, and is not a continuum.

Yes, it's supposed to be finite – but as far as I can tell, it's just a wild guess, or maybe a lower bound. It's gone up a lot during my lifetime. 🙂

However, I believe that beyond this large finite number of choices, there are also theories that involve choices that come in continuous families. The buzzword is "moduli space".

> Does that mean the possible values for each of the various physical constants are also of that number?

There are lots of theories with different numbers of particles, different kinds of particles, etc. Then you get to choose certain numbers governing the behavior of these particles.

70. **Henrick**
September 15, 2010

Hello Professor Baez!

Where do Hawking & Sean Carroll rank on your crackpot index?

71. **Glenn**
September 15, 2010

"The main reason I wrote about the Bogdanov story, (besides for its entertainment value), is that I think it shows conclusively that in quantum gravity in general, many people have lost the ability or willingness to recognize non-sense for what it is."

Could this quote from you, Peta, also describe Hawking's purpose for writing the book? If so, it reminds me of Picasso's descriptions of the kind of stuff that art galleries promote. I seem to recall an interview with the painter on "60 Minutes" where he confessed to trying to find how far the art world would follow him.

72. **Peter Woit**
September 15, 2010

Glenn,

The Bogdanov story was pretty different. They were producing sophisticated sounding gibberish, which required some expertise to recognize as such. The multiverse stuff being promoted by Susskind, Hawking and many others uses no sophisticated math, and is easy to understand. It's quite easy for even a non-expert to quickly realize that this is not legitimate science. Here I think the only reason that many people take it somewhat seriously is that they can't believe that smart experts would engage in something so obviously flawed. I'm mystified by this myself…

73. **Glenn**
September 15, 2010

Peter, my apologies for the last post addressing you as Peta. Although I feel that animals should be treated kindly, I have very different feelings about this handwriting recognition program on my tablet. It makes changes to previous text when I hit the submit button.

74. **tristes_tigres**
September 15, 2010

> Without any details or references though, it's hard to even know
> exactly what the claim is here.

Something like this ?

http://arxiv.org/abs/1009.2525

75. **Peter Woit**
September 15, 2010

tristes_tigres,

Presumably that's it, although the book was likely written a year or so ago.

I'll stack my guess that any such claim would have trouble with "the fact that one has no idea what the underlying theory actually is" up against the abstract's admission that the paper's "predictions" only apply to "a certain class of landscape models". M-theory itself is the final theory replacing religion since it can never be falsified.

76. **steve newman**
September 16, 2010

Re my request yesterday-
On these blogs and elsewhere i often read word to the effect that
' string theory might not cut it as a physical theory, but it has led to very interesting mathematics".
Just what is this 'interesting math' ??
Can anyone refer me to a book or article for non-specialists that communicate this?

and your answer-
My book "Not Even Wrong" has a bit about this. There's a new book by Yau and Nadis that just came out (The Shape of Inner Space) which has a lot more.

———————-

THANKS. that's exactly what i wanted. I read your book when it first came out but i had forgotten that it covered this. I am revisiting it now with great interest and will also check out the Yau book.
I'm glad this made me look at your book again. It does a really great job of reviewing the field.

77. **Chris W.**
September 16, 2010

More on a rather more humorous note from Physics World's James Dacey, excerpting this piece in the Guardian.

"Some subjects are so serious that one can only joke about them."

— Niels Bohr (see Wikiquote)

78. **John Baez**
September 17, 2010

Henrick writes:

> Where do Hawking & Sean Carroll rank on your crackpot index?

I don't usually go around publicly rating physicists, but I'll do it just for you. Both these fellows have their sins, but neither are 'crackpots' by any stretch of the imagination. And Hawking did such incredibly profound work in his earlier years that he deserves vast amount of slack now. Don't read his new book: read the book he wrote with Penrose, and get a beautiful description of black holes and why they radiate.

79. **John Baez**
September 17, 2010

Sorry, I somehow linked to a $390 *video* version of the Hawking-Penrose book *The Nature of Space and Time*. Or something like that. I have no idea what this video is — does anyone know?

The actual book is just $14.95.

Short Items

September 17, 2010
Categories: Experimental HEP News, Langlands, Multiverse Mania, Not Even Wrong: The Book

- The Fermilab Physics Advisory Committee recently recommended that the Tevatron be kept running for an additional three years (until 2014). By the end of that time it should be able to accumulate a total of 20 fb^{-1} of data, which would give sensitivity to a standard model Higgs at the 3-sigma level over the entire interesting mass range. The cost for this would be a total of about \$150 million, which would likely have to come out of Fermilab's $810 million/year budget. While the idea of continuing to do physics at the high-energy frontier and possibly beat the LHC to the Higgs, for less than 10% of the lab budget/year seems to be a no-brainer, director Oddone still may not be completely sold on the idea. Keeping the Tevatron going would set back some of the projects the lab has planned for its future in a post-Tevatron world. There's also significant concern about the future federal budget situation, and how to make sure that the best possible case is made for a future of Fermilab, in an environment where people may be looking for large, expensive programs that could be cut. For more about this, see Adrian Cho's article Higgs or Bust? in Science.

One huge consideration in this decision is that of what will happen at the LHC. CERN is facing its own budgetary problems, and has just decided to shut down during 2012 not just the LHC (for repair of magnet interconnections), but the entire accelerator complex. Work continues this year on trying to raise the luminosity of the machine, but progress is slow. They still are an order of magnitude lower than where they want to be by the end of the year, with only a few more weeks left before the machine is shutdown as a proton-proton collider and reconfigured for a heavy-ion run. If all goes according to plan, by late 2011 the LHC would have 1 fb^{-1} of data, enough to compete with the Tevatron in the Higgs search. But, so far, plans like this have turned out to be overly optimistic, with things taking longer than expected.

In today's CERN Bulletin and Fermilab today, Oddone and CERN DG Heuer issued a joint statement downplaying the competition between their labs:

> The press makes much of the competition between CERN's LHC and Fermilab's Tevatron in the search for the Higgs boson. This competitive aspect is real, and probably adds spice to the scientific exploration, but for us such reporting often feels like spilling the entire pepper shaker over a fine meal.

- CheapUniverses.com is now selling a Universe Splitter iPhone app for $1.99, complementing its other products. At $3.95, the Basic Universe:

> Using quantum physics, we split your universe into two branches, then we send you an email to inform you which branch you're in.

As celebrity endorser, they have Garrett Lisi explaining:

> The functioning of this app is in complete agreement with the many-worlds interpretation of quantum mechanics.

- The author is always the last to know such things, but I've heard rumors that someone intends to bring out a Czech edition of Not Even Wrong.
- High quality videos of talks from the Princeton IAS summer school on supersymmetry are available here.
- In Langlands-related news, there's an excellent new preprint by David Nadler about the fundamental lemma and Ngo's proof. This is one of the most ferociously difficult topics to understand in current math research, and Nadler's article is about the best expository piece on the subject that I've seen.

This semester there's a program on Langlands Duality in Representation Theory and Gauge Theory at Hebrew University.

There's a fascinating recent preprint by Kevin Buzzard and Toby Gee on The conjectural connections between automorphic representations and Galois representations. They conjecture a reciprocity sort of relation between algebraic automorphic representations and Galois representations, not just for GL(n), but for arbitrary reductive groups. This involves invoking a twist by "half the sum of the positive roots", a phenomenon that arises in various places in representation theory, often indictating that spinors are involved ("half the sum of the positive roots" is the highest weight of the spinor representation).

Comments

1. **Sven Johnston**
   September 17, 2010

   Will Lubos Motl be translating the Czech edition of Not Even Wrong? And if he does so, can we order the iphone universe splitter so that we can live in a universe where Garrett Lisis translates it?

   Feynman, Einstein, Newton, Galileo, Planck–how awesome for them that they do not have to live through our era which consisted of cashing out and corroding the legacy they created. And how sad for us.

2. **Peter Woit**
   September 17, 2010

   Sven,

   I'm not sure how many joke multiverse iphone apps at $1.99 one can sell, even with Garrett's endorsement. My suspicion is that all he gets for this is the amusement value, but if he's getting paid, it's probably less than the amount I'm getting for the Czech rights to NEW. In another universe this might be more than enough to pay for a nice dinner out in New York, but not in this one…

   So, at least as far as the topics of this posting go, I don't think there's a lot of cashing out or corroding of legacies going on. The news from CERN and Fermilab reflects a likely exciting time ahead for experimental results and research mathematics is a quite healthy subject.

3. **Sven Johnston**
   September 17, 2010

   ^^^^
   "The news from CERN and Fermilab reflects a *likely* exciting time ahead for experimental results and research mathematics is a quite healthy subject."

   This kindof sums of the *likely* sentiments of the last 40 years of zero progress in physics, save for new tv shows and iphone apps for our amusement. lzozlzllz

4. **neo**
   September 17, 2010

   About the universe splitter. I already know about the branch I am in. I want to know about the branches I'm not in.

5. **Theorist**

September 17, 2010

I would argue that not running the Tevatron is a no-brainer. They don't have the resources to do anything BUT a Higgs search. It's a waste of money to run the machine just to do one measurement.

6. **physicsphile**
   September 18, 2010

   Theorist,

   Well its a very important measurement. I think they should do it. What if the LHC has some faults and never works?

7. **Paolo**
   September 19, 2010

   About the "Universe splitter", just wanted to report that by *any* criteria, even the most relaxed ones, it's a robery, in the sense that it does *not* connect to any remote source of randomness: modulo all the "funny" wording, I expected it to remotely connect to a source using an hardware device like http://www.idquantique.com/true-random-number-generator/products-overview.html but in fact it doesn't access the web *at all*.

8. **Noname**
   September 19, 2010

   You keep insisting on how slow progress is with the LHC. Well, the increase in luminosity over the past months has been exponential, with a factor 10 of improvement per month (on average). Obviously this will not continue forever, but it's difficult to find an adjective more inappropriate than "slow" to describe their impressive progress.

9. **Peter Woit**
   September 19, 2010

   Noname,

   I don't think "slow progress" is an inaccurate description of the situation, if you look globally (compare where things are to projections put out early this year), or locally (what has been happening the past few weeks).

   I also don't think there's anything at all wrong with this, it's about what you expect for this kind of project, even when things are going well (and has been the case ever since the machine was first proposed). The important point is that progress is being made and everything indicates that sooner or later the machine will work as designed. That's great.

   However it's also true that those deciding how long to keep the Tevatron running might be paying close attention both to history and the current situation and making their own projections about what luminosity the LHC will achieve over the next couple years.

10. **Peter Woit**
    September 19, 2010

    Noname,

    I checked a bit to see if I was remembering things correctly, and found documents like this from early this year

    http://lhc-commissioning.web.cern.ch/lhc-commissioning/luminosity/MG_2010_parameters.pdf

    which states

    "Making reasonable operational assumptions regarding
    fill length, luminosity lifetime and machine availability,
    the total integrated luminosity for the year would be about
    hundred inverse picobarns."

    The integrated luminosity is now at 3-4 inverse picobarns, with six weeks to go.

11. **Amos**
    September 20, 2010

    Paolo: How do you know Universe Splitter isn't touching the web? It seems to, by which I mean that it takes more or less time to run depending on the quality of my internet questions.

    Assuming that it does do what it says (and that the many-worlds interpretation is correct) its an excellent solution to a lot of thorny dating problems.

12. **Buba**
    September 21, 2010

    3 sigma is very weak – it is not enough to constitute a discovery..

13. **Eric Daniels**
    September 22, 2010

    @Paolo: The Universe Splitter actually *does* contact the quantum device you mentioned. How do I know this? Because I wrote the code. In fact, I even purchased a backup machine in case the one in Geneva breaks down… much to my wife's dismay.

    If you're at all curious, but don't want to see me make a dime, you can have fun with the online, public version at cheapuniverses.com (it says it'll cost you $3.95, but it won't; it's free until I decide otherwise, which will probably be never).

    Enjoy!

14. **Joe Kriek**
    September 30, 2010

As someone involved in science education, I can only conclude that Hawking is doing science a service by stating, to put it very crudely, that the universe is self-creating, self-organizing, and self-explaining. If this message can reach millions of Americans, it's no bad thing.

The alternative is that millions of Americans with no science background will continue to believe that an unknowable, untestable intelligence outside the universe is responsible for the entire show.

This has nothing to do with how seriously M-theory should be taken within the science community, but it's important that the public understand there is no need to insert the supernatural into science.

All of this is obvious to those in the field, but to the millions whose exposure to science is via tv, pop science books, etc, Hawking is doing us a favor when, for sales reasons, he adds a dash of no-God spice to his book.

Science is not only about what can be tested, or what is likely to be testable in the future, it's also the ideas that scientists have while at work at scientists. As such, I can buy M-theory as more useful and helpful than theology.

15. **Peter Woit**
    September 30, 2010

    Joe,

    I don't think that a scientist "stating" something is or should be convincing of anything to anyone. The whole point of science is that we can (or should be able to) back up our statements with evidence. The danger of what Hawking is doing, making statements that he backs up with a bogus argument he has no evidence for, is that it will encourage people to believe that the knowledge claims of science have no different status than those of religion. You see this very clearly in the debate in England, where theologians just have to point out that there is no evidence for M-theory to win the argument.

16. **CT**
    September 30, 2010

    Joe,

    Both religion (Christianity) and any self-creation theory require faith to believe. A big difference here is that the former is open and clear about the requirement (see, for example, Hebrews 11:6 in the Bible), whereas the latter pretends to be a scientific fact, with no evidence to back it up, as Peter said.

The Shape of Inner Space

September 19, 2010
Categories: Book Reviews

Besides the Hawking book, which was a disappointment in many ways, I recently also finished reading a much better and more interesting book which deals with some of the same topics, but in a dramatically more substantive and intelligent manner. [The Shape of Inner Space] is a joint effort of geometer Shing-Tung Yau and science writer Steve Nadis. Yau is one of the great figures in modern geometry, a Fields medalist and current chair of the Harvard math department. He has been responsible for training many of the best young geometers working today, as well as encouraging a wide range of joint efforts between mathematicians and physicists in various areas of string theory and geometry.

Yau begins with his remarkable personal story, starting out with a childhood of difficult circumstances in Hong Kong. He gives a wonderful description of the new world that opened up to him when he came to the US as a graduate student in Berkeley, where he joyfully immersed himself in the library and a wide range of courses. Particularly influential for his later career was a course by Charles Morrey on non-linear PDEs, which he describes as losing all of its students except for him, many off to protest the bombing of Cambodia.

He then goes on to tell some of the story of his early career, culminating for him in his proof of the Calabi conjecture. This conjecture basically says that if a compact Kahler manifold has vanishing first Chern class (a topological condition), then it carries a unique Kahler metric satisfying the condition of vanishing Ricci curvature. It's a kind of uniformisation theorem, saying that these manifolds come with a "best" metric. Such manifolds are now called "Calabi-Yau manifolds", and while the ones of interest in string theory unification have six dimensions, they exist in all even dimensions, in some sense generalizing the special case of an elliptic curve (torus) among two-dimensional surfaces.

Much of the early part of the book is concerned not directly with physics, but with explaining the significance of the mathematical subject known as "geometric analysis". Besides the Calabi conjecture, Yau also explains some of the other highlights of the subject, which include the positive-mass conjecture in general relativity, Donaldson and Seiberg-Witten theory, and the relatively recent proof of the Poincare conjecture. Some readers may find parts of this heavy-going, since Yau is ambitiously trying to explain some quite difficult mathematics (for instance, trying to explain what a Kahler manifold is). Having tried to do some of this kind of thing in my own book, I'm very sympathetic to how difficult it is, but also very much in favor of authors giving it a try. One may end up with a few sections of a book that only a small fraction of its intended audience can really appreciate, but that's not necessarily a bad thing, and arguably much better than having content-free books that don't even try to explain to a non-expert audience what a subject is really about.

A lot of the book is oriented towards explaining a speculative idea that I'm on record as describing as a failure. This is the idea that string theory in ten-dimensions can give one a viable unified theory, by compactification of six of its dimensions. When you do this and look for a compact six-dimensional manifold that will preserve N=1 supersymmetry, what you find yourself looking for is a Calabi-Yau manifold. Undoubtedly one reason for Yau's enthusiasm for this idea is his personal history and having his name attached to these. Unlike other authors though, Yau goes into the question in depth, explaining many of the subtleties of the subject, as well as outlining some of the serious problems with the idea.

I've written elsewhere that string theory has had a huge positive effect on mathematics, and one source of this is the array of questions and new ideas about Calabi-Yau manifolds that it has led to. Yau describes a lot of this in detail, including the beginnings of what has become an important new idea in mathematics, that of mirror symmetry, as well as speculation ("Reid's fantasy") relating the all-too-large number of classes of Calabi-Yaus. He also explains something that he has been working on recently, pursuing an idea that goes back to Strominger in the eighties of looking at an even larger class of possible compactifications that involve non-Kahler examples. One fundamental problem for string theorists is that of too many Calabi-Yaus already, so they're not necessarily enthusiastic about hearing about more possibilities:

> University of Pennsylvania physicist Burt Ovrut, who's trying to realize the Standard Model through Calabi-Yau compactifications, has said he's not ready to take the "radical step" of working on non-Kahler manifolds, about which our mathematical knowledge is presently quite thin: "That will entail a gigantic leap into the unknown, because we don't understand what these alternative configurations really are."

Even in the simpler case of Calabi-Yaus, a fundamental problem is that these manifolds don't have a lot of symmetry that can be exploited. As a result, while Yau's theorem says a Ricci-flat metric exists, one doesn't have an explicit description of the metric. If one wants to get beyond calculations of crude features of the physics coming out of such compactifications (such as the number of generations), one needs to be able to do things like calculate integrals over the Calabi-Yau and this requires knowing the metric. Yau explains this problem, and how it has hung up any hopes of calculating things like fermion masses in these models. He gives a general summary of the low-level of success that this program has so far achieved, and quotes various string theorists on the subject:

> But there is considerable debate regarding how close these groups have actually come to the Standard Model… Physicists I've heard from are of mixed opinion on this subject, and I'm not yet sold on this work or, frankly, on any of the attempts to realize the Standard Model to date. Michael Douglas… agrees: "All of these models are kind of first cuts; no one has yet satisfied all the consistency checks of the real world"…
>
> So far, no one has been able to work out the coupling constants or mass…. Not every physicist considers that goal achievable, and Ovrut admits that "the devil is in the details. We have to compute the Yukawa couplings and the masses, and that could turn out completely wrong."

Yau explains the whole landscape story and the heated debate about it, for instance quoting Burt Richter about landscape-ologists (he says they have "given up.. Since that is what they believe, I can't understand why they don't take up something else – macrame for example.") He describes the landscape as a "speculative subject" about which he's glad to, as a mathematician, not have to take a position:

> It's fair to say that things have gotten a little heated. I haven't really participated in this debate, which may be one of the luxuries of being a mathematician. I don't have to get torn up about the stuff that threatens to tear up the physics community. Instead, I get to sit on the sidelines and ask my usual sorts of questions – how can mathematicians shed light on this situation?

So, while I'm still of the opinion that much of this book is describing a failed project, on the whole it does so in an intellectually serious and honest way, so that anyone who reads it is likely to learn something and to get a reasonable, if perhaps overly optimistic summary of what is going on in the subject. Only at a few points do I think the book goes a bit too far, largely in two chapters near the end. One of these purports to cover the possible fate of the universe ("the fate of the false vacuum") and the book wouldn't lose anything by dropping it. The next chapter deals with string cosmology, a subject that's hard to say much positive about without going over the edge into hype.

Towards the end of the book, Yau makes a point that I very much agree with: fundamental physics may get (or have already gotten..) to the point where it can no longer rely upon frequent inspiration from unexpected experimental results, and when that happens one avenue left to try is to get inspiration from mathematics:

> So that's where we stand today, with various leads being chased down – only a handful of which have been discussed here – and no sensational results yet. Looking ahead, Shamit Kachru, for one, is hopeful that the range of experiments under way, planned, or yet to be devised will afford many opportunities to see new things. Nevertheless, he admits that a less rosy scenario is always possible, in the even that we live in a frustrating universe that affords little, if anything in the way of empirical clues…
>
> What we do next, after coming up empty-handed in every avenue we set out, will be an even bigger test than looking for gravitational waves in the CMB or infinitesimal twists in torsion-balance measurements. For that would be a test of our intellectual mettle. When that happens, when every idea goes south and every

road leads to a dead end, you either give up or try to think of another question you can ask – questions for which there might be some answers.

Edward Witten, who, if anything, tends to be conservative in his pronouncements, is optimistic in the long run, feeling that string theory is too good not to be true. Though, in the short run, he admits, it's going to be difficult to know exactly where we stand. "To test string theory, we will probably have to be lucky," he says. That might sound like a slender thread upon which to pin one's dreams for a theory of everything – almost as slender as a cosmic string itself. But fortunately, says Witten, "in physics there are many ways of being lucky."

I have no quarrel with that statement and more often than not, tend to agree with Witten, as I've generally found this to be a wise policy. But if the physicists find their luck running dry, they might want to turn to their mathematical colleagues, who have enjoyed their fair share of that commodity as well.

Update: I should have mentioned that the book has a web-site here, and there's a very good interview with Yau at Discover that covers many of the topics of the book.

Update: There's more about the book and an interview with Yau here.

Comments

1. **Anon2**
September 20, 2010

Minor typo corrections:

"…Particularly influential for his later career was a course by Charles Morrey on non-linear PDEs, which he describes losing all of **it** students except for him…" {**its**}

"…anyone who reads it is likely to learn something and to get a reasonable, if perhaps overly optimistic summary of what **it** going on in the subject. …" {**is**}

"… Looking ahead, Shamit Kachru, for one, is **hopefuls** that the range of experiments under way …" {**hopeful**}

Just a comment about the claim Yau makes (which you agree with) that mathematics can provide inspiration when experimental data runs out:

"But if the physicists find their luck running dry, they might want to turn to their mathematical colleagues, who have enjoyed their fair share of that commodity as well." – Yau

To the naive public, the problems in string theory are mathematical. Einstein added a time dimension to Euclidean space account for gravity, Kaluza and Klein added a spatial dimension for electromagnetism, and string theory adds further spatial dimensions to build in the rest of particle physics. Then the mathematics is so complex due to the need to hide the extra dimensions in a Planck scale sized Calabi-Yau manifold, it becomes an uncheckable and ugly mathematical guess. Similarly, Lisi's E8 Lie algebra or older SU(5) GUT ideas have apparently come from mathematicians, and don't really lead anywhere.

In what way should physicists turn to mathematicians?

2. **Peter Woit**
September 20, 2010

Anon2,

Thanks, typos fixed.

The problems with string theory are not mathematical, but physical. Adding an extra dimension is a physical idea. Yes, the mathematics string theorists end up using is not only sophisticated, but quite complicated and rather ugly. This is because they're pursuing a wrong physical idea.

My own ideas about where inspiration can be found in mathematics are more in representation theory than in geometry these days (although the two subjects are closely related). I've written about them here often.

Please though, comments should be about Yau's book, generic "math sucks, no it doesn't" arguments are tedious and will be deleted.

3. **PM**
September 20, 2010

Peter: "Towards the end of the book, Yau makes a point that I very much agree with: fundamental physics may get (or have already gotten..) to the point where it can no longer rely upon frequent inspiration from unexpected experimental results"

It always puzzles me when I hear that it's the lack of experimental data that is the problem in physics. There is plenty left to explain about the data we already have: masses and coupling constants – still unexplained, structure of nuclei – still unexplained, origin of symmetries – still unexplained, dark matter and dark energy – still unexplained, and so on…

As far as I see it the lack of experimental data is not the main problem, sure more data would make things easier but it's not like we have nothing left to explain.

I would say current problems are mostly:

1. Cultural
First many people manage to convince themselves that there are no explanations to be found – QM is complete and final. Take the decay of unstable nuclei for example it is thought to be acausal and random – an idea which I find absurd, but if you are OK with it you won't look for a better explanation even though there may very well be one just waiting to be found.

This is often striking in retrospect when fairly straightforward generalizations or concepts took decades simply because people weren't looking for them.

Second the existence of certain candidate theories which cannot be tested makes many simply stop looking for alternatives until these candidates can be confirmed or ruled out, but it may take decades or centuries to do so so we need to keep looking for alternatives.

2. Foundational
I think physics is currently trapped in a deep local minimum so to speak and the road in every direction will be up a steep hill for a while. To me we have simply reached the limits of the current conceptual framework and further progress will require a radical rethinking of the very foundations.

This is problematic however as such alterations to foundations threaten to ruin all the intricate modern physics which rests upon them and since it works so well many feel the foundations should not be altered. But I think it's a necessary step and I expect that once the better foundations are found all the current results will be rederived from them and many more.

Two examples of such radical thinking from the past which I particularly like even though they failed are the geometrodynamics of Wheeler and Dirac attempt to reformulate classical theory without point charges. Those are the kind of imaginative and far reaching ideas which I think are needed to move us forward.

Those were also true unification attempts since they tried to modify two distinct pieces of physics to unify them unlike certain modern approaches which just try to come up with some "glue" to stick them together.

Finally I also like that they tried to improve the classical theory as I think this is where the problems are. I see quantum theory as simply emerging from an underlying classical theory and I believe it is this classical theory has to be improved to see progress..

4. **Peter Woit**
   September 20, 2010

   PM,

   My point is not that there's no experimental data still unexplained, but that for many years now we've had very little new such data. We have hints from experiment about what a better theory should look like, but the problem is that we haven't been getting new hints, so are stuck facing the same intractable problems. Something physicists should be thinking about is how to make progress under these circumstances, but instead the tendency seems to be to just keep doing the same thing, no matter how long goes by without it working.

   But, again, I encourage people to discuss Yau's book, not other unconnected speculative ideas about physics.

5. **Wouarnud**
   September 20, 2010

   Peter,

   Thanks for that. I may actually read this book, since, as you rightly say, it is rare to find a book that tries to explain complex ideas to people who don't have all the necessary math background without using false and crude metaphors (in my case the math was somewhat there too long ago, those particular gray cells have been reallocated to fascinating tasks like management plans and shopping lists).

   I was wondering first if Yau addresses a question I often think about, regarding the part about new directions in physics. One rather glaring experimental fact is that of dark matter and dark energy. As far as I understand, it is lacking from standard models and theoretical explanations of it are, to say the least, incomplete. As far as I've seen as a member of the general public, mathematical theories about these facts are fairly basic, rather non-specific and unimaginative (modified gravity et al). I don't really understand why this isn't the hottest of the hot areas in fundamental physics and mathematics today rather than String theory or any competing alternative. Does Yau mention that in his book?

   As an aside, working in a Space Agency, I once had a scientist making the point to me that since dark energy is 90% of the actual energy in the universe, it should receive 90% of the funding (including of course the mission he was promoting, a far-UV telescope if I remember well). It's hard to argue with that…

   Wouarnud.

6. **Peter Woit**
   September 20, 2010

   Wouarnud,

   Dark matter and dark energy are perhaps the hottest topics in fundamental physics. The problem is that no one has a really good idea about their origin, using geometry or any other argument. I forget whether Yau and Niadis say much about the problem in the book, but if so there's just not much that the study of Calabi-Yaus adds to the question.

7. **Giotis**
   September 20, 2010

   I've read only half of the book and I like it so far. Yau is focusing mainly on the mathematical aspects which was expected in some extend and indeed he makes an ambitious honest attempt to explain these difficult issues. On the other hand he is rather sketchy regarding the physical concepts and String theory itself; at least so far. The autobiographic parts are embedded in a natural way and they serve the overall scope of the book.

   BTW I've noticed that on page 125 he attributes the 10 dimensions of the theory to the Green–Schwarz mechanism although it is a direct consequence of superconformal invariance which is of central importance. He mentions conformal variance on page 152 but he doesn't relate it to the critical dimension.

8. **neo**
   September 20, 2010

   I thought it interesting that Yau, in his Discover interview, says that he ended up proving the Calabi conjecture because he began by thinking it was wrong, and that he had proven it so. Perhaps this is an approach that should be actively adopted more often.

9. **Coin**
   September 20, 2010

   Thanks for this review, this sounds like the kind of string theory book I have been wanting to read. I will try to give this one a shot. (And I'd actually be curious if there are any books which treat AdS/CFT in a similar non-physics-math-person friendly manner!)

   I do have a question, something that has perplexed me for awhile and I think I should try to get a better understanding of before I read Yau's book– just so that I know how to interpret what I'm reading:

   When I look at people talking about string theory, I see two different notions of how space is treated in string theory– how we get from ten or eleven dimensions down to the perceived four. Sometimes people talking about string theory seem to be using one of these notions, sometimes they seem to be using the other, sometimes I can't tell.

   The Calabi-Yau Manifold notion is the first. When string theory is described this way, "the universe" is in fact a ten dimensional manifold, it's just that six of the dimensions are compactified. This manifold isn't embedded in anything else, it stands alone as a background space by itself. Calabi-Yau theory describes this manifold's structure.

The other notion of space I sometimes see is this "M-Theory" picture, where there's an open ten-eleven-ish dimensional "bulk" filled with arbitrary N-dimensional "brane" objects. In this picture "the universe" is described as something "stuck to" (or similar vague phrasing) the outside of one of the branes; the structure of the manifold our universe *seems* to be located in winds up being dictated by how some less-than-ten-dimensional brane restricts our universes's strings.

How do I reconcile these two pictures? Are the Calabi-Yau manifolds of the first picture actually embedded in the "bulk" of the second? Are the manifolds of the first picture somehow dual to specific configurations of branes in the second? Or are these two different incompatible versions of string theory altogether? In short, when I'm reading about how the Calabi-Yau manifolds work, how (if at all) do I connect that to things people say about M-Theory-alikes?

10. **Robert**
September 21, 2010

Hi Peter,

a small correction:

by Yau's solution of the Calabi conjecture there exists a unique Ricci-flat Kahler metric in each Kahler class.

If you don't fix the Kaehler class (and the complex structure), the uniqueness statement is obviously wrong, e.g. if you take a Ricci-flat Kahler metric and rescale it you get another one.

11. **Chris Austin**
September 21, 2010

Coin,

In brane compactifications of the 5 ten-dimensional superstring theories, the 6-dimensional Calabi-Yau space is the bulk, and the brane, called a Dirichlet brane or D-brane, is the Cartesian product of the 3 space dimensions we live in, and a closed surface embedded in a topologically non-trivial fashion in the Calabi-Yau. For example, if the closed surface is a 1-dimensional closed loop, embedded in the Calabi-Yau so that it can't be contracted to a point without breaking it, then the brane is a 4-brane, meaning it has 4 spatial dimensions. Open strings are associated with matter fields and often have both ends attached to the brane, but free to move along it, while closed strings are associated with gravitational fields and are free to move through the bulk.

M-theory usually refers either to the strong coupling limit of type IIA string theory, which is d = 11 supergravity compactified on a circle from 11 to 10 dimensions, or the strong coupling limit of the E8 x E8 heterotic string, which is d = 11 supergravity compactified to 10 dimensions on a finite 1-dimensional interval, with a d = 10 supersymmetric E8 Yang-Mills multiplet on the 10 dimensional spacetime at each end of the interval. This last version is also known as Horava-Witten theory, and the 9 space dimensions at each end of the Horava-Witten interval are sometimes regarded as 9-branes, with the Cartesian product of the interior of the Horava-Witten interval, and the 9 space dimensions perpendicular to it, constituting the bulk.

Burt Ovrut, who Yau quotes twice in the extracts above, works on Horava-Witten theory, with 6 of the 9 space dimensions perpendicular to the Horava-Witten interval compactified on a 6-dimensional Calabi-Yau space. We live on the boundary at one end of the Horava-Witten interval, and the remaining 3 space dimensions perpendicular to the Horava-Witten interval are the 3 extended space dimensions that we see.

12. **Coin**
September 21, 2010

Chris Austin: Oh dear. Thank you for your helpful post, I am still a little confused. I think this is where I am getting stuck. You say: "In brane compactifications of the 5 ten-dimensional superstring theories, the 6-dimensional Calabi-Yau space is the bulk". Should one expect the six dimensions of the Calabi-Yau space in this case to be compactified?

13. **Chris Austin**
September 22, 2010

I should more accurately have said that the the bulk is the Cartesian product of the 3 extended space dimensions and the 6-dimensional Calabi-Yau space, and the brane is the Cartesian product of the 3 extended space dimensions and a closed surface embedded in a topologically non-trivial fashion in the Calabi-Yau space.

The six dimensions of the Calabi-Yau space are always compactified, but depending on the model, they can be as small as the Planck length around 10^{-35} metres, or as large as around 10^{-14} metres. In the latter case the closed surface embedded in a topologically non-trivial fashion in the Calabi-Yau space can be no larger than around 10^{-19} metres, so the Calabi-Yau space has to be able to support topologically non-trivial structures much smaller than itself. Calabi-Yau spaces with this property are sometimes called "swiss cheese" Calabi-Yaus.

The latter case might result in superstrings and/or quantum gravitational effects eventually being observed at the LHC, but I don't know whether Yau discusses this in the book.

14. **Nono**
September 22, 2010

Oh boy, Chris! Now I know what people mean when they talk about Rube Goldberg constructions. And you didn't even mention fluxes…

15. **Chris W.**
September 22, 2010

Someday this work will be looked upon—by physicists—in more or less the same way that some of the ideas in Kelvin's Baltimore Lectures are looked upon now. (Its mathematical interest is beside the point.)

16. **Geoff**
October 4, 2010

Hi Peter –

Yau mentions a general relativity class at Berkeley that had a profound influence on him. Would that have been R.K. Sachs' class?

Tevatron Funding

September 21, 2010
Categories: Experimental HEP News

The Fermilab web-site today has a message from Director Oddone about prospects for funding an extension of the Tevatron run after FY2011, as recommended by the Physics Advisory Committee. He has asked the DOE for additional funding of $35 million/year to pay part of the cost of an extended run, with the rest to come out of slowing down other planned experiments. If the DOE turns this down, it seems the plan is to shutdown the Tevatron next year.

This leaves prospects for the Tevatron's future very much up in the air, especially given the dysfunctional nature of the US federal budget process. With FY2011 about to begin, the Congress has yet to pass a budget, shows no signs of doing so anytime soon, and is in the middle of an election campaign dominated by calls for cutting federal spending. The general assumption is that they'll deal with this by continuing funding at FY2010 levels, until finally getting around to passing appropriations bills all together as part of an "omnibus" bill sometime deep into the fiscal year. The process of dealing with the FY2012 budget starts next February with the President's budget request, but again there's no reason to believe there actually will be a budget until long after they've already started spending the money. Luckily, the Fermilab people by now have many years of experience dealing with this system.

   September 21, 2010

   There's a saying in europe:" nothing improves a woman's appearance faster than a man's " , and since the appearance of the rather masculine LHC , I have to say that the tevatron has certainly being trying her hardest to get noticed.

   However, there's only so much you can shorten your hemline , and the point comes where that's not enough to stop the person who's paying your rent from looking at a newer model.

   But there is also another saying in europe : "failure is the fuel of success", and as such the LHC has much to thank the tevatron for.

   Bon chance, tevatron. Bon chance mon ami.

7. **Theorist**
   September 22, 2010

   Peter

   Another expert opinion:

   Pythia isn't very good at QCD. There are lots of things we know it doesn't do correctly (anything having to do with heavy flavor, for starters). In this case, Pythia only includes tree level color correlations, which could be a problem (it seems like this is an issue with interjet radiation). On top of that, there could be issues with the color string model at LHC energies.

This isn't BSM physics.

On the topic of the post, unless Tevatron can demonstrate it has the manpower to do something other than look for the Higgs, it shouldn't get any more funding.

8. **Roger**
   September 22, 2010

   I agree with theorist. As an experimentalist who uses Pythia a lot to study final states, this type of result doesn't surprise me.

   Pythia is one of our most useful tools since it provides an excellent description of most final states. However, it isn't perfect and wouldn't necessarily be expected to describe the tails of distributions well.

   No Nobel prize will ever be gained by showing that Pythia doesn't work.

9. **Tommaso**
   September 23, 2010

   Hi Peter, all,

   yes, we cannot claim that what CMS sees is new physics just because there is a difference with Monte Carlo simulations. The CMS observation is interesting because it shows an effect not seen with lower multiplicities and lower energies, but this may well be the color coherence of partons radiating in the direction along which the color strings stretch. At high multiplicity the effect should in fact be more easily discernible.

   I have discussed the topic in a post here: http://www.science20.com/quantum_diaries_survivor/new_physics_cms_huhm

   Cheers,
   T.

LHC Update

September 24, 2010
Categories: Experimental HEP News

There's been great progress made recently at the LHC, with successful commissioning of "trains" of bunches, allowing significantly higher collision rates. Last night's fill produced an integrated luminosity of .684 inverse picobarns (or 684 inverse nanobarns), which can be compared to the total integrated luminosity up until this week of about 3.5 inverse picobarn. The highest instantaneous luminosity reached is now at about 1/5 the goal set for this year, with a further increase in number of bunches planned for this weekend. For more details, there's a message from the CERN DG here.

Update: The latest fill, with 104 bunches, recently started, with an initial luminosity now at 1/3 of the goal for this year.

Update: For more information about latest events at the LHC and upcoming plans, see here. Latest luminosity plots are here, now including highest instantaneous luminosity.

Comments

1. **hasti**
September 24, 2010

Thanks for this informative post. Could you please clarify how this '.684 picobarn' of integrated luminosity has been estimated? I'm asking because the luminosity decreases since a collision run started. If you could make a rough estimation to get this number, I'd be thankful. Or if you take this number from the official page, I'd be glad to see the links.
Hasti

2. **PhilG**
September 24, 2010

hasti, instantaneous and integrated luminosity during runs can be monitored on this page: http://op-webtools.web.cern.ch/op-webtools/vistar/vistars.php?usr=LHCLUMINOSITY

3. **lun**
September 25, 2010

You are forgetting the observation of long-range correlations in rapidity observed in p-p collisions
http://arxiv.org/abs/1009.4122
They are bound to challenge quite a few people's ideas, as these kind of correlations are associated with "collective" phenomena.

Of course, its also an experimental verification of string theory 🙂

4. **gast**
September 25, 2010

hi lun,

I`ve read somewhere that the fragmentation of some " Unknown Elongated Object" could have led to the correlations seen (an UEO)
🙂 …

But You should not une such s-words here :-)…

5. **Peter Woit**
September 25, 2010

Oops, there was an "inverse" missing in original posting, fixed.

lun,

For commentary on the CMS result, see comments of previous posting. The exciting thing about the latest progress at the LHC is the promise they'll be able to say something new about something other than QCD…

6. **lun**
September 26, 2010

Thanks, I missed those comments.

I have something to add: One important thing a lot of commenters are missing is that these structures were already seen at RHIC, in A-A collisions. They are generically understood as being due to two things:
a) "hotspots" in nuclei creating "strings" (see, string theory 🙂) which stretch longitudinally across the event. These create correlations in rapidity
b) Collective flow (the fluid flows "outwards") which focuses these correlations in angle.

p-p, however, throws a somewhat big wrench in this consensus:
Are hotspots have to be smaller than the proton size (ie, Lambda_{QCD})? Is there flow in proton-proton collisions? (If so, why is it missing in particle spectra?)
Or are we misunderstanding the origin of these structures in heavy ions too?

Honestly, I think this is physics at its best: Pesky experimental data throwing an established theoretical consensus in disarray.
Its a shame in areas of particle physics "other than QCD", such events are rare to non-existant.

7. **Tommaso**
September 26, 2010

The latest fill mentioned in your update has produced 1.06/pb of data, with initial luminosity of 3.5E31. I think it is worth noting that given these numbers, the LHC is the main factory of top quarks and Higgs bosons by now (as shown here: http://www.science20.com/quantum_diaries_survivor/lhc_surpasses_tevatron_top_and_higgs_factory).

Cheers,
T.

The End of Time

September 26, 2010
Categories: Multiverse Mania

I've been critical of multiverse pseudo-science because it doesn't make any testable predictions, but it seems that tonight there really is one. According to this new preprint, multiverse arguments guarantee that time will end, with the expected amount of time left before the end about 5 billion years and

> There is a 50% chance that time will end within the next 3.3 billion years.

The argument seems to be that multiverse arguments require introducing an artificial cut-off to get finite numbers, so the cut-off must be there and we're going to hit it relatively soon on cosmological time scales. The age of the universe is about 13.75 billion years, but we're getting near the end, already entering late middle-age to senior-citizen time-frame. One interpretation given of this result is that:

> we are being simulated by an advanced civilization with a large but finite amount of resources, and at some point the simulation will stop.

It turns out that you don't even need the whole apparatus of eternal inflation to see that time is going to end. All you need to do is to think about sleeping and waking up, which, according to the paper, leads to the "Guth-Vanchurin" paradox:

> Suppose that before you go to sleep someone flips a fair coin and, depending on the result, sets an alarm clock to awaken you after either a short time or a long time. Local physics dictates that there is a 50% probability to sleep for a short time since the coin is fair. Now suppose you have just woken up and have no information about how long you slept. It is natural to consider yourself a typical person waking up. But if we look at everyone who wakes up before the cutoff, we find that there are far more people who wake up after a short nap than a long one. Therefore, upon waking, it seems that there is no longer a 50% probability to have slept for a short time.
>
> How can the probabilities have changed? If you accept that the end of time is a real event that could happen to you, the change in odds is not surprising: although the coin is fair, some people who are put to sleep for a long time never wake up because they run into the end of time first. So upon waking up and discovering that the world has not ended, it is more likely that you have slept for a short time. You have obtained additional information upon waking – the information that time has not stopped – and that changes the probabilities.
>
> However, if you refuse to believe that time can end, there is a contradiction. The odds cannot change unless you obtain additional information. But if all sleepers wake, then the fact that you woke up does not supply you with new information.

Update: Lubos doesn't think much of the paper:

> But holy crap, if physicists don't lose all of their scientific credit by publishing this pure garbage and nothing else for years, can they lose their credibility at all? Does the institutionalized science have any checks and balances left? I think that all the people are being bullied into not criticizing the junk written by other people who are employees of the academic system, especially if the latter are politically correct activists. And be sure, some of the authors of this nonsense are at the top of it.
>
> This is just bad. I urge all the sane people in Berkeley and other places to make it very clear to Bousso et al. – and to students and other colleagues – that they have gone completely crazy.

Update: In other pseudo-science news, the latest Scientific American features a piece by Hawking and Mlodinow based on their recent book.

Update: Not only does New Scientist think this nonsense deserves to be covered in a lead article, they also have an editorial urging us not to "roll your eyes" about this.

Comments

1. **Arun**
   September 26, 2010

   The cutoff is a computational device – I don't see any physical reason for a discontinuity between the region within the cutoff and the region outside the cutoff (figure 1). All that appears to be happening is that no matter how I construct an ensemble of observers in the eternally inflating universe using a geometrical cutoff, a non-zero fraction of observers will hit the boundary. I don't see how that is interpreted as time coming to an end. In particular, I can have a universe in which every observer sees 1 o'clock and 2 o'clock, but there is no way for me to select a geometrical cutoff that contains only observers that see both events, i.e., a vanishingly small fraction of observers who see only one o'clock. If I believe the paper, then my cutoff actually truncates the multiverse, which is a god-like power to ascribe to physicists.

2. **Kea**
   September 26, 2010

   Um, and the arxiv bans papers on Koide formulae for neutrino masses? What universe am I in?

4. **Christian Takacs**
   September 27, 2010

   Ok, I'm going to try very hard to be polite, and take this statement seriously: "There is a 50% chance that time will end within the next 3.3 billion years."
   Why is this prediction testible? Isn't there a 100% chance that anyone who takes this bet will not live long enough to find out if the prediction is accurate thus negating the

meaningful concept of making a prediction?

5. **slw**
September 27, 2010

If we are a simulation, we have no way of knowing what kind of laws of physics rule the universe of the beings that simulate us. It might very well be that in their universe conservation of energy does not hold, so they have in fact infinite resources for running the simulation. Perhaps the whole simulation is done to figure out how an intelligent species would adapt to a universe where resources are limited.

6. **lolphysicist**
September 27, 2010

When these people teach, what do the students gain? Does anyone have first-hand information, I wonder.

7. **Mitchell Porter**
September 27, 2010

This is an easy paper to mock, and I guess deservedly so.

Section 5.1 contains a clue to the paper they should have written. It lists assumptions, one of which must be incorrect, for the conclusion that "time ends" to be false. The second one is "Probabilities in an infinite universe are defined by a geometric cutoff".

So the paper they should have written would have been "Probabilities in eternal inflation can't be defined by a geometric cutoff", and this whole business about "time ending" would have been a one-sentence reductio ad absurdum of a particular line of argument.

8. **Nex**
September 27, 2010

Amazing how far one can drift away from rationality when one is surrounded by equally deluded peers.

The sloppiness of thinking in the paper is really remarkable, here is an example from the second paragraph:

"If it does occur in Nature, eternal inflation has profound implications. Any type of event that has nonzero probability will happen in□finitely many times, usually in widely separated regions that remain forever outside of causal contact. This undermines the basis for probabilistic predictions of local experiments. If in□finitely many observers throughout the universe win the lottery, on what grounds can one still claim that winning the lottery is unlikely? To be sure, there are also in□finitely many observers who do not win, but in what sense are there more of them? In local experiments such as playing the lottery, we have clear rules for making predictions and testing theories. But if the universe is eternally inflating, we no longer know why these rules work."

Is this for real? The rules work because the lottery is designed that way! For every winner there are thousands of non-winners, the infinite number of lotteries doesn't change a damn thing.

It's like claiming that if eternal inflation is true we no longer know why the probability of rolling 6 on 6 sided dice is 1/6!

And even if we ignore the atrocious lottery example and talk about probability in general the paragraph still makes no sense – we have an empirical way of defining probabilities and it works very well and is completely immune to eternal inflation metaphysics.

As for the main conclusion the fact that eternal inflation requires an ad hoc regulator to make any predictions means that it is a useless pile of philosophizing not that the time will end.

9. **Bugsy**
September 27, 2010

The authors run a serious risk of not being taken seriously. Is the universe inflating infinitely or merely the egos of those involved?

In fact maybe I should refrain from commenting as I admit to not reading more than the first paragraphs; I got stopped early on by the quotation cited by Nex, which t is so clearly complete BS. On the other hand, in infinitely many universes I will apparently "lose the lotto" and continue reading. In infinitely many of these same universes these authors will win jobs from places like Berkeley, Lawrence Labs, and be paid actual salaries…….

I close with a question, which should be testable: if physics articles on the arxiv keep inflating, won't the average information content approach zero exponentially fast???

10. **Bee**
September 27, 2010

So I wake up, and look at the others who've just woken up and those who are still sleeping, and see that it's 50/50. Whether or not "time will end." Don't see what's paradoxical about that.

11. **Chris Oakley**
September 27, 2010

I agree with Lubos. What garbage! The gist of their argument seems to be that because something (the end of the time) CAN happen in a large enough sample it necessarily WILL. MIT and Berkeley, eh? It may not mean the end of time, but it does seem to indicate the end of any standards in theoretical physics research.

12. **Carl Zetie**
September 27, 2010

I see this kind of "reasoning" all over the place from multiverse advocates and it's not just bad science, it's bad logic. Even my five year old son understands that when you get one random pick, "you get what you get and you don't get upset".

The glaring flaw is the assertion that "it's natural to consider yourself a typical person". THIS IS COMPLETE NONSENSE, and this cannot be repeated often enough and loud enough. Basically, we are taking a sample of size one from an allegedly very large population, and I know of no principle in probability that justifies one in drawing *any* conclusion whatsoever from this. (And no, the "Copernican principle" will not do).

In particular you cannot, as multiversians are fond of doing, reason about the population you were drawn from based on one outcome. Consider this analogy: you have a large sack of balls, some black, some white. You draw out one ball and it's white. What can you conclude about the proportion of black and white balls? Answer:

Absolutely nothing. (Well, OK, you can conclude that there was at least one white ball in there…). You can't even conclude that there are many universes, let alone that ours is typical.

13. **Jeff McGowan**
September 27, 2010

OK, I'm sorry, it used to be fun for mathematicians like myself to make fun of physicists, for example I was just at a conference celebrating Scott Wolpert's 60th birthday, and Peter Sarnak made a crack "he's a physicist, so he doesn't have to prove anything" about someone applying percolation theory to questions on nodal domains of cusp forms, and it got a big laugh. But stuff like this just ruins it all, I mean how can you make fun of people who take stuff like this seriously, at this point I'm just embarrassed for you all 🙂

14. **Carl Zetie**
September 27, 2010

Oh no, they didn't repeat the old nonsense about "in an infinite multiverse, everything must happen infinitely many times", did they? I dispatched of that chestnut in the *letters column of New Scientist*, for crying out loud. Could some friendly, patient mathematician explain to these physicists that infinities come in more than one size?

Not to mention the fact that if eternal inflation is driven by bubble universes born from existing ones, it's perfectly reasonable that the bubbles have physical laws not far distant from the parent, and that however often the bubbles are created, they never explore more than a tiny fraction of possible universes. It's even possible that they cycle through a finite set of configurations. All of this is at least as likely as the "everything must happen" nonsense.

15. **S**
September 27, 2010

The logic in this paper is a disaster. This "Guth-Vanchurin" paradox excerpt given here is just begging the question, and so is the assumption that the theory must result in "finite numbers". The logic is: I want finite results, so I will assume that finite results are correct, and then write a paper concluding time is finite.

I'm a liberal arts major. Come on, physicists.

16. **Anon**
September 27, 2010

The 'Guth-Vanchurin paradox' as written up by these people seems like nonsense but there is a very similar real effect in statistical physics based on Levy statistics.

In fact, in the last year I read of an experimental paper in PRL that observes the effect in some quantum dots.

Here is the essence: Imagine a particle (or quantum dot) with two states – glowing and not-glowing. The particle makes stochastic transitions between these two states and the amount of time spent in each of these states comes from two distributions G(\tau) and NG(\tau).

Let, say, G(\tau) have a long tail (like a Levy distribution). That is, there is significant probability of spending very large times in the glowing state. Let's say NG(\tau) does NOT have such a tail.

Then, if you take a population of such dots and observe the total brightness, you'll find that the total intensity actually increases with time even though the properties of each dot are time-invariant. This is because the longer you measure, the more of the tail of G(\tau) you start sampling…

The essence is that when you have a distribution of times like G(\tau), the length of the experiment you sets a growing cutoff on the distribution. The paper in PRL measures this effect in a real system.

My philosophical resolution of the paradox is that it is not possible to verify that a particle has the distribution G(\tau) in the first place without waiting a long time.. or something of that sort — what does it really mean to have a long tailed distribution of times and how would you verify it?

17. **Roger Schlafly**
September 27, 2010

> Christian Takacs says: Why is this prediction testible? Isn't there a 100% chance that anyone who takes this bet will not live long enough to find out if the prediction is accurate thus negating the meaningful concept of making a prediction?

Do you also object to predictions that our Sun will explode into a red giant in a similar time-frame? It is possible for a testable theory to make long-term predictions, so it is not enough to just argue that people will not live that long.

18. **Coin**
September 27, 2010

"How can the probabilities have changed?"

Because you changed the sample population and in doing so biased it arrrrgh

19. **M Brane**
September 27, 2010

Having a theory that relies on the multiverse is like making love to a beautiful married woman.

You wouldn't be doing it if you thought there was a chance you were going to be found out.

20. **Jeff McGowan**
September 27, 2010

The correct phrase in relation to this is "jumped the shark." See http://www.youtube.com/watch?v=MpraJYnbVtE

21. **Nono**
September 27, 2010

Well, although it's not April 1, has anyone considered the possibility that this is just a joke?

22. **Peter Woit**
September 27, 2010

Nono,

The problem with the joke hypothesis is that these authors have written quite a few papers already that aren't that different. If it's all a joke, they're keeping it up for a remarkably long time.

23. **luke**
September 27, 2010

@ Christian Takacs: Well if time ends there's nothing stoping the person 3 billion years in the future from just walking over and telling you right now, right?

24. **Christian Takacs**
September 27, 2010

Mr. Schlafly,
Quite honestly, I do object to long term "testible" predictions being made about anything 3.3 billion years into the future with any level of statistical accuracy worth mentioning. Please consider the very brief period of time humans have been observing the cosmos, and how many times over just the last 100 years the understanding of how this cosmos functions has changed.
To make such long term predictions with so little understanding of how gravity, light, space, and time function in this universe(not to mention as yet uknown variables) on such a large scale is pure hubris.
I believe that any math is still bound by logic; If you can't observe and measure something, you certainly can not make accurate models or predictions .

25. **Kea**
September 27, 2010

The difficulty with many successful so called theoretical physicists today is their complete lack of an education in philosophy and the humanities. They were selected mainly on their ability to mimic the computational skills of their teachers, with no regard for real scientific enquiry, mind boggling egos and a complacency that would astound any previous generation of human being.

How many of them have ever worked in a real laboratory? Or in industry? Who would have thought it was possible to wander so far from genuine scientific prediction. And when the public talk of massive funding cuts, these same peole cry foul for the future of their societies. Good riddance to it.

26. **Peter Woit**
September 27, 2010

Kea,

The weird thing is that many "multiverse" papers like this don't involve any computational skills beyond high-school level math. They consist of pages and pages of natural language text with a few trivial equations interspersed. The problem isn't that the authors are showing off computational technique without addressing philosophical issues. They're often addressing nothing but philosophical issues, but doing so in a naive and pre-scientific style.

27. **Roger Schlafly**
September 27, 2010

5B years will not be enough time for black holes to evaporate from Hawking radiation, but this story claims that the radiation has already been observed in the lab!

28. **Arun**
September 27, 2010

Do you also object to predictions that our Sun will explode into a red giant in a similar time-frame? It is possible for a testable theory to make long-term predictions, so it is not enough to just argue that people will not live that long.

"All men are mortal" is tested by looking at deaths today and not finding any reason that those alive today are somehow exempt from the same processes. Likewise, the theory and observation is that "stars like our sun do whatever" and so the prediction is that our sun will also do whatever.

29. **Awake**
September 27, 2010

> But if we look at everyone who wakes up before the cutoff, we find that there are far more people who wake up after a short nap than a long one.

I am unable to agree with this statement. Can anyone who agrees with this statement please explain why it might be true?

30. **Peter Shor**
September 28, 2010

Can I join the fun and make up a new theory of physics, too? My theory is that quantum mechanics and general relativity are irreconcilably incompatible. This will only become physically relevant at around the time when the first black hole evaporates, around 1060 years from now, at which point the universe will end.

Isn't this a much better theory than the one we're discussing? Eternal inflation is still a speculative idea, while both quantum mechanics and general relativity are extremely well tested experimentally.

But I guess a paper simply pointing out that there are serious problems with the probability measure for eternal inflation wouldn't have gotten anywhere near as much press as this paper did.

31. **Peter Shor**
September 28, 2010

10^60. Sorry

32. **Peter Woit**
September 28, 2010

Peter Shor,

I think you're missing the innovative aspect of this paper (and its similar cousins). In old-style rationalist argumentation, when you show that your hypotheses lead to absurd conclusions, you have to abandon one of more of your hypotheses. The innovation here is to turn a bug into a feature: when your hypotheses lead to an absurd conclusion, you write a paper (and possibly issue a press release) proclaiming that you have made a surprising and counter-intuitive discovery.

As long as you're careful to avoid dealing with anything experimentalists can check, and stick as much as possible to vague words, avoiding precision and equations, there's no danger of running into too-obvious-to-ignore logical contradiction.

33. **neo**
September 28, 2010

Peter Shor:

10^60. Phew. Thank goodness. You had me worried there for a minute.

34. **Jeff McGowan**
September 28, 2010

Well, you know it is more fun to work in a system with inconsistent axioms, since then you can prove ANYTHING 🙂

35. **Giotis**
September 28, 2010

I just want to remind to the people who mock Bousso (not the paper but the actual person) here and elsewhere that he is the author (together with Polchinski) of the celebrated paper "Quantization of Four-form Fluxes and Dynamical Neutralization of the Cosmological Constant".

This paper contains the only explanation the human race has so far for the observed value of the CC.

In any case I think a little respect is in order here.

36. **Chris W.**
September 28, 2010

If that paper hadn't been written by Bousso and Polchinski, I doubt it would be considered much of an explanation.

Of course, as an example of how one "explains" observations of fundamental significance in cosmology and astrophysics using M-theory, I suppose it's fairly typical.

(As for "the only explanation", that is also open to dispute, but never mind that.)

37. **Sol**
September 28, 2010

About it being "testable": ignore the long time period and think about if the prediction was there was a 50% change time will end tomorrow. Assume that's correct. Then half of the time, time keeps on going and we gain no additional information. The other half of the time, time ends — and we no longer exist to gain confirmation the theory was true!

38. **Peter Woit**
September 28, 2010

Giotis,

I'm not mocking Bousso, just the paper…

One common reaction at the time to the Bousso-Polchinski (and later, KKLT and Susskind) string theory anthropic landscape explanation of the CC, was that if you took that seriously, you were giving up on conventional scientific research and this would unleash all sorts of nonsense. There's now significant evidence for how that turned out, including this latest paper.

39. **changcho**
September 28, 2010

I didn't know that they accepted science fiction at the ArXiv – this idea could be turned into a great Star Trek episode…which is about the only (potentially) good thing about it.

40. **Dave Miller**
September 29, 2010

Kea wrote:
> The difficulty with many successful so called theoretical physicists today is their complete lack of an education in philosophy and the humanities. They were selected mainly on their ability to mimic the computational skills of their teachers, with no regard for real scientific enquiry, mind boggling egos and a complacency that would astound any previous generation of human being..

Hmmm…. tried reading any philosophy recently? Just last week, a philosopher on the Web was trying to explain to me how philosophers have proved time travel to be impossible. (No, I'm not shilling for time travel – I just question whether the philosophers have proved that it is impossible).

Kea also wrote:
> And when the public talk of massive funding cuts, these same peole cry foul for the future of their societies. Good riddance to it.

I think there may be a testable prediction there: when the public really finds out about all this, their reactions will be…?

Dave Miller in Sacramento

41. **Kea**
September 29, 2010

Dave, it is agreed that no academic discipline is immune to the disease of the times, but that is no excuse to ignore the discipline entirely!

42. **Shantanu**
September 30, 2010

Peter sorry for the spam but have a look at Andy Strominger's talk on string theory (at Harvard)

see the discussion around 50-55 mt. its a string theory report card
shantanu

43. **Peter Woit**
September 30, 2010

Shantanu,

Interesting looking talk, it's at

http://media.physics.harvard.edu/video/index.php?id=COLLOQ_STROMINGER_091310.flv&width=640&height=360

If I can find time soon to watch it, may write something about it here.

44. **Pawl**
September 30, 2010

And this in from The Economist's blog, commenting on Hawking's scientific credentials:

> …if, as expected, his 1974 theory that black holes emit radiation despite their notorious all-engulfing gravitational pull is confirmed by experiments at the Large Hadron Collider in CERN…

One can't fault Hawking for this bizarre assessmnent of "what is expected," but it is something of an index of how confused the public is.

45. **Dave Miller**
October 2, 2010

Kea wrote to me:
>Dave, it is agreed that no academic discipline is immune to the disease of the times, but that is no excuse to ignore the discipline entirely!

My reply to you disappeared, so I suppose Peter does not want a lengthy discussion on this.

So, I'll simply say that philosophy has been doing for two millennia what the string theorists have been doing for just a few decades.

And, yes, that indeed is a good reason for ignoring their discipline entirely.

46. **chris**
October 5, 2010

ah yes, i have been told in school that physics has two dangerous limits: zoology and philosophy. seems these guys hit one of the limits pretty hard.

47. **mekong**
October 8, 2010

"Hmmm…. tried reading any philosophy recently? Just last week, a philosopher on the Web was trying to explain to me how philosophers have proved time travel to be impossible."

@dave miller

Yes, one philosopher is representative of the entire discipline. How very logical of you to also accept his argument at face value, and then to make further inferential claims about an entire discipline. Especially when said discipline has multiple sub-areas, and sub-sub areas. The philosophy of time itself is split up into multiple conceptual areas [1], had you gone beyond your limited sample space of one "philosopher on the web" (who I'd wager good money wasn't a philosopher at all, though it's up to you to provide proof, please link it if this was an open web conversation …) you might have encountered the different and varied argumentative positions for philosophers of time (many of whom disagree on whether time travel can or cannot exist, and some — mostly of the empirical bent — deny whether it is meaningful to talk of completely).

Sounds like you need to read some more philosophy, namely informal and formal logic.

Notes

(1) And before someone goes "LOLPHILOSOPHERSCAN'TAGREE," let it be known that philosophy is primarily useful insofar as it keeps a philosophical inventory of arguments that are known to be useful, or useless (primarily the latter, especially for metaphysical concepts) and groups them together by category. In the case of philosophy of time, and its sub-areas, there are numerous conceptual schemes and arguments for-and-against different positions. So to say "philosophers as a whole reject time travel" shows an ignorant account of philosophy in general.

NRC Rankings

September 27, 2010
Categories: Uncategorized

One thing I've learned in life is that human beings are creatures very much obsessed with social hierarchy, and academics are even more obsessed with this than most people. So, any public rankings that involve oneself and the institutions one is part of tend to have a lot of influence. In the US, US News and World Report each year ranks the "Best Colleges", see the rankings for National Universities here. My university's administration tended in the past to express skepticism about the value of this ranking, which typically put us tied for 8/9 or 8/9/10. This year however, everyone here agrees that there has been a dramatic improvement in methodology, since we're at number 4.

For most academics though, the real ranking that matters is not that of how good a job one's institution does in training undergraduates, but the ranking of the quality of research in one's academic field. Where one's department fits in this hierarchy is crucial, affecting one's ability to get grants, how good one's students are and whether they can get jobs, even one's salary. The gold standard has been the National Research Council rankings, which were supposed to be revised about every ten years. It turns out though that the task of making these ranking has somehow become far more complex and difficult, with more than fifteen years elapsing since the last rankings in 1995. Since 2005 there has been a large and well-funded project to generate new rankings, with release date that keeps getting pushed back. Finally, last year a 200 page book was released entitled A Guide to the Methodology of the National Research Council Assessment of Doctorate Programs, but still no rankings.

Recently the announcement was made that all will be revealed tomorrow at a press conference to be held in Washington at 1pm EDT. I hear rumors that university administrations have been privately given some of the numbers in advance, to allow the preparation of appropriate press releases (see here for an example of a university web-site devoted to this issue).

The data being used was gathered back in 2005-2006, and the five intervening years of processing mean that it is rather stale, since many departments have gained or lost academic stars and changed a lot during these years. So, no matter what happens, a good excuse for ignoring the results will be at hand.

Update: University administrations have now had the data for a week or so and are providing it to people at their institutions. For an example of this, see the web-site Berkeley set up here. All you need is a login and password….

Update: (Via Dave Bacon) Based on the confidential data provided to them last week, the University of Washington Computer Science and Engineering department has released a statement characterizing this data as having "significant flaws", and noting that:

> The University of Washington reported these issues to NRC when the pre-release data was made available, and asked NRC to make corrections prior to public release. NRC declined to do so. We and others have detected and reported many other anomalies and inaccuracies in the data during the pre-release week.
>
> The widespread availability of the badly flawed pre-release data within the academic community, and NRC's apparent resolve to move forward with the public release of this badly flawed data, have caused us and others to urge caution – hence this statement. Garbage In, Garbage Out – this assessment is based on clearly erroneous data. For our program – and surely for many others – the results are meaningless.

The UW Dean of the College of Engineering has a statement here where he claims that, despite 5 years of massaging, the NRC data contained obvious nonsense, such as the statistic that 0% of their graduating CS Ph.D. students had plans for academic employment during 2001-5.

Update: Boston University has broken the embargo with this press release. They give a chart showing that almost all their graduate programs have dramatically improved their ranking since the 1995 rankings, while noting that the two rankings are based on different criteria, the NRC says you can't compare them, and the 2010 rankings in the chart are not NRC numbers, but are based on their massaging of the data. I suspect that the NRC data will be used to show that, like the kids in Lake Wobegon, all programs are above average.

For more on this story, see coverage by Steinn Sigurdsson at Dynamics of Cats.

Update: The NRC data is out, and available from its web-site. But, no one really cares about that, all they care about are the rankings, and the NRC is not directly putting those out. Instead, they've subcontracted the dirty work to phds.org, where you can get rankings here, using either the "regression-based" or "survey-based" score. In mathematics and physics, the lists you get are about what one would expect, with perhaps somewhat of a tilt towards large state schools compared to the 1995 rankings (most dramatically, Penn State was number 36 in 1995, number 8 or 9 this year).

Comments

1. **X**
   September 28, 2010

   The UW dean appears to be correct. I've been perusing the data set for schools that I have been connected with. There are some flagrant errors that seem to significantly impact the results. For example, they record that the Boston University physics department has a faculty that is 75% female. This gives them a huge bump in the "diversity" rating. In addition, despite having a median time-to-graduation of 6 years, they claim only 9% of physics grad students graduate within 6 years. Basic sanity-checking does not seem to have been applied.

2. **anon**
   September 28, 2010

   I have some doubts about the Penn State ranking, at least in math, where they made a similar jump. I think it's a fine dept, but to jump from 35 to 10th seems dubious to me. Perhaps they're strong in areas outside of my interests, but I wonder what's going on with they're data.

3. **anonymous coward**
   September 28, 2010

   There are some terrible flaws here, and I don't really have enough time to comment on the utter incompetence that these rankings have displayed.

   What I will say is this. This is an extremely confusing and misleading ranking, and to have ranges instead of a simple ranking has to be one of the dumbest things any ranking system has done. My guess is that they did this so that colleges can brag about how high they are possibly perceived to be. This is a ploy to make NRC a more popular ranking, but it won't happen, since no one's going to through all the trouble and confusion of phds.org to get a half-assed confusing-as-hell ranking system. US News, unfortunately, will become the standard for graduate school rankings. In a way, it already has.

   Also, there are serious data problems. anon above me states that Penn State jumped from 35th to 10th in math. Chicago went from 5th to 12-39 with a survey ranking of 27-57. This is despite the fact that Chicago is within the mathematics world reputed as top 5 in the United States and in the last year, just recruited a Fields medalist (which are quite rare within US institutions). Something must have gone seriously wrong with data collection.

Anyway, that is all I can say. It is just very disappointing that this was what I was waiting for for the last five years…

4. **JSE**
September 29, 2010

There's some good drill-down into the math numbers going on at my blog In particular, one commenter points out that all of Chicago's many postdocs were counted as faculty, while none of (e.g.) Yale's were. As you can imagine, this plays havoc with measures like "proportion of faculty holding external grants."

5. **Peter Woit**
September 29, 2010

Thanks JSE (fixed link),

The way faculty are counted seems to be one of the main weaknesses of this survey. They had some very elaborate counting scheme, involving "core", "associated", "allocated" faculty, and each institution had to figure out separately how to reconcile their own way of counting faculty with what the NRC wanted. The definition of "core" involved things like whether you were on phd committees, etc. It seems that different institutions made different choices about how to count, which in some cases benefited them immensely, in others hurt them a lot.

6. **rrtucci**
September 29, 2010

So what is the job and yearly budget of the National Research Communism agency. The wikipedia article on it is very short on details.

7. **Peter Woit**
September 29, 2010

rrtucci,

I don't know about the NRC in general, but this particular project is described as costing "well over $4 million", and I think that's the cost of the NRC people's effort. The cost to universities to get this data together, analyze it, and put out press releases might be an order of magnitude more than that.

8. **ObsessiveMathsFreak**
September 30, 2010

Looks like if you want a higher ranking from the NRC, you're going to have to grease a few palms. I suppose that technically a bribe or two to the odd council official could be marked under "research expenditure" since promoting the university's profile/ faculty salaries is all research is about nowadays.

These rankings are all nonsense anyway. The London Times brought out one of these lists recently and it's essentially an Anglo-Saxon Academy Award ceremony—and every bit as insular. The US and especially the UK were vastly overrepresented, as were most anglophone countries.

The UK had ~26 universities, while France has only 4, despite the fact that both have similar population sizes (~60 million) and development levels. Germany (~80 million) has about 14. Ireland (pop ~4 million) had 2. There were no Russian(~150 million) universities in the top 200—or Indian ones (~1.3 billion).

These rankings are bogus to begin with. Their only purpose is to satisfy the deep need for our society to reduce entire institutions and their collective efforts down to a single number, which can be compared to other numbers to produce a league table. It's a pathological disorder of the modern world (I blame the press) to seek such numbers regardless of whether they hold any real meaning(They are generally meaningless).

The effect of all of this is debilitating to education everywhere it is applied. Who is the "best"? Whoever has the higher "number". How good is an institution? Check its "number" on the table next to all the other numbers. Forget the other factors; there's a number. This is like publication counts/citations, only applied to entire universities and schools.

This is why I'm quite serious when I say that universities should allocate money to bribe the officials making these numbers. Better that than play the corrupting game of juking the stats; rushing to meet meaningless targets to up the number(s), fudging figures and cutting corners all the way, and likely wrecking the university in the process.. If your aim is to turn your institution into an elaborate machine for producing a higher number, then you might even succeed; but your institution will likely fail in the process.

On a deeper note, what does it say about our society if we base our collective decisions on numbers which mean nothing? Price Indices, league tables, stats of all kinds. Numbers without meaning(or mathematics), which emerge from calculations which make no sense, based on data which has been manipulated. And then we feed them all back into the systems which run our lives. All rather dystopian.

9. **anon**
September 30, 2010

Dear ObsessiveMathsFreak — Academics love of rankings (as much as many of us, such as myself, try to deny it) is, in my opinion, partially built from our own early success in school. More or less, everything you said could be applied to a test score achieved in fourth grade. My own realization that I _might_ be good at math started when I got a 51/52 in some test on fractions. What does that 51/52 really mean? Some different test might have score me 15/52. It's so arbitrary and meaningless etc etc.

However, what I do remember is my teacher's happy reaction to my performance, and that ultimately made a difference to me. I went off to do well in school (meaning, more meaningless A's), as do many of our peers. It's hard to shut off caring about grades after years of benefiting from them!

10. **rrtucci**
September 30, 2010

A guy named Jules posted the following very interesting comment about this issue in Scott A-Ronzoni's blog:

Deans and department chairs want to kill off any ranking system, because they do not want prospective graduate students to get this data. I hope that they are not successful now, because you can be sure they won't put anything in its place.

For example, UW does not report any of the NRC-requested data on its website. If you email them for it, they will not respond. Now they complain that their faculty count is wrong when they themselves inflated the count. Cry me a river.

As to MIT, I don't know what "found academic employment" means precisely. What counts is how many PhDs found tenure-track positions. I doubt this is 50%.

11. **Place Holder**
October 1, 2010

@rrtucci: Scott was talking about the MIT EECS department, in terms of “found tenure track jobs”. Tenure track jobs were much easier to find in EECS as opposed to math and physics.

12. **International**
October 3, 2010

Look at the tables of honors and awards recognized for adding points! The NRC claim that “starting in fall of 2005, NRC staff compiled lists of international, national and disciplinary awards in all the taxonomic fields …” so how come in more than 3 years they failed to find the academie des sciences in Paris, the Royal Society of London, and other leading and internationally respected sources of honors – in Cambridge MA alone there are 28 Fellows and Foreign Members of the Royal Society, and those associated with graduate programs are overlooked. Yet the Maple Leaf Farms Duck Research Award is included as Prestigious – doubltess meritorious on some scale, but in all fairness not at the level of the academie des sciences of Paris or the Royal Society of London, or many other awards completely overlooked by the NRC. I thought there was something about not disciminating against people based on nationality and national origin here in the US, but perhaps the NRC thinks it’s above the law as well as courtesy and thoroughness.

13. **Andrew L.**
October 3, 2010

I really don’t think I can improve on ObsessiveMathsFreak’s commentary-except to add I’ve found in my travels the reality of the quality of the top schools is often far removed in reality due to many factors:Not the least of which is the archaic practice of placement of wealthy “legacy students” in top programs who can barely read.This takes a very limited spot from deserving students of lower pedigree. It’s nothing new at prestigious universities,of course-but it’s certainly new in the sciences. I think this is one of the great unspoken factors undermining scientific training in this country.

14. **Peter Shor**
October 3, 2010

To Andrew L.

I don’t know for sure about other graduate departments, but I do know that the MIT Math Department does not admit any legacy students (and I strongly suspect that most other graduate programs do not). Undergraduate admissions is another matter.

As for the ranking, all I can say is that there are a number of instances where School A is ranked well above School B, and where I would advise most graduate students who had this choice to attend School B.

15. **Eli Rabett**
October 3, 2010

What obviously happened is that some departments figured out how to game the data entry and others ignored them (it was a lot of work).

16. **former chair**
October 5, 2010

It wasn’t always at the department level…the data collection was administered at the university level.

17. **Andy P.**
October 8, 2010

@Andrew L : I’ve seen you make this claim in other forums (eg on mathoverflow), and I have to call BS. I’ve either been a student at or been employed by several “top” departments, and I’ve got close friends at several others. I’ve never encountered any students like you describe.

Simply put, I think you don’t know what you’re talking about.

18. **Peter Woit**
October 8, 2010

Andy P.,

Agreed. I’ve been associated with my share of “prestigious” universities and have seen few if any incompetent rich kids in math and science classes. The main effect of legacy admissions (and it is of significant size) is to give a big help to people who are part of the large group with similar qualifications around the cut-off for admission. The number of those with much inferior qualifications getting in is small; for this I believe you need to be not only a legacy, but from a family with significant financial or political power. And in those few cases, the students involved tend to major in something other than math or science.

And this only applies to undergraduates. From what I’ve seen graduate admissions pretty much completely ignores considerations of legacy status or wealth.

19. **Anonymous**
October 8, 2010

Just one more comment … I have seen (very rarely) incompetent students admitted to graduate programs, but in at least one case this was because in their home country, they had a family with significant power, and this let them obtain incredible recommendation letters, excellent grades, and very good scores on standardized tests.

Grading String Theory

September 30, 2010
Categories: Uncategorized

Commenter Shantanu points to this video of a recent colloquium by Andy Strominger at Harvard, which includes some extensive comments on the current state of string theory. Strominger is one of the most prominent string theorists in the business, and has been working in the field for more than a quarter-century since the first "Superstring Revolution" of 1984. In the talk (at about the 52 minute point), Strominger gives a "report card" for string theory, where he assigns it 3 As, 2 Bs, 3 Ds and 2 Fs, for an average grade of about C. It gets an F for making no unambiguous testable predictions, a D for prospects of saying anything about LHC, an F for the CC (Strominger isn't sold on the anthropic landscape) and a D for cosmology. Some of the high grades are debatable, with an audience member pointing out to him that there was a tension between his A for "Not being ruled out as theory of nature" and F for no testable predictions. Strominger repeatedly claimed that most string theorists would agree with him on these grades (except maybe the F for the CC).

As an overall evaluation, he said that it was debatable whether this was a passing or failing report card, then arguing:

> But this is the only student in class, so if you flunk her you have to shut the school down.

Along the same lines, a bit earlier in the talk one of his slides characterizes all that theorists can do as "go home and watch TV" if they believe in the landscape ("String theory is everything") or if they think string theory is a failure ("String theory is nothing"). The positive argument he was trying to make is that there still is something for string theorists to do even after they are forced to give up on particle physics: they can try applying AdS/CFT and black holes to other areas of physics (nuclear physics, solid state physics, fluid mechanics).

I think Strominger is right that his grades and point of view about string theory are now conventional wisdom among leading theorists. What I find striking about this is the argument that if you are forced to give up on string theory, you have to "shut the school down" or "go home and watch TV". More than 25 years of working on string theory has left Strominger and others somehow believing that there is no conceivable alternative. The failure of string theory as a theory of particle physics leads them to the conclusion that they must not abandon string theory, but instead must abandon particle physics and try and apply string theory to other fields. The obvious conclusion that string theory is just one speculative idea, and that its failure just means you have to try others, is one that they still do not seem willing to face up to.

Comments

1. **Kea**
   September 30, 2010

   Yes, it is fascinating to see people dictating to Nature the impossibility of alternatives, merely on the assumption that nobody else could possibly do better than they have. I feel that Nature would rather we were somewhat more productive than TV couch potatoes, since TV watching uses less brain power than sleeping. Well, Nature has a simple cure for this kind of behaviour, othewise known as Extinction.

2. **Anonymous**
   September 30, 2010

   So what's the alternative theory that gets better grades on these issues?
   By the way, abandoning particle physics is not really a bad idea, if you accept the premise that a field of inquiry should only receive resources proportional to the amount of new experimental evidence arising in this field.

3. **hsearles**
   September 30, 2010

   Reminds me of the Karl Popper quote: "Whenever a theory appears to you as the only possible one, take this as a sign that you have neither understood the theory nor the problem which it was intended to solve."

4. **Peter Woit**
   September 30, 2010

   Anonymous,

   You could also argue that fields should get resources inversely proportional to amount of new experimental evidence, on the grounds that if there are lots of new experimental clues, any unfunded idiot will be able to make progress. It's only when there are few experimental clues that the work is hard, so should get more resources.

   Also, by your criterion, mathematical physics should never be funded at all.

   The argument that "sure, string theory is a failed idea, but since we don't have better ones, we're going to keep doing it anyway" has been the main thing keeping string theory research afloat for a very long time now. It wasn't a good argument 15 years ago, and with the landscape, etc., it's not getting any better.

5. **Roger Schlafly**
   September 30, 2010

   The alternative theory with better grades is the Standard Model.

6. **Yatima**
   September 30, 2010

   That's quite an interesting little talk but it's hard to figure what the linkage of black hole theory or string theory to solid state physics, fluid dynamics and whatnot is all about. It's also difficult to ascertain what the author classifies as belonging to string theory and what not. A colored diagram with the mathematical bridges linking the main idea blocks and equations would be useful.

7. **flunkemall**
   September 30, 2010

   The Standard Model is the baseline. The challenge is to find a successful extension. That determines the grades.

8. **Dave Miller**
September 30, 2010

Peter,

What do you think of the view that string theory is simply a framework for theories, but that you need some additional ideas to narrow it down to get a specific theory? It's an analogy to QFT: i.e., no one criticizes QFT on the grounds that thee are an infinite number of QFTs. We just accept QFT as a framework that, fortunately, includes one specific example that works extremely well — the Standard Model.

Perhaps even string theory enthusiasts should accept the fact that the community just needs to "sleep on it" for a few years to come up with some novel ideas. After all, QFT goes back all the way to 1930 or so, but it wasn't until the '60s that the Standard Model was actually invented.

Dave Miller in Sacramento

9. **neo**
September 30, 2010

I, for one, do not think physicists and mathematicians should give up on string theory. They should stop the hype and stop blocking the consideration of alternatives, but not give up. One should wonder though, absent evidence, when you go down a path that gets ever more convoluted, whether you are on the right path. At least the QFT folks were led into a labyrinthic theory by the existence of hard facts.

10. **DB**
October 1, 2010

"The obvious conclusion that string theory is just one speculative idea, and that its failure just means you have to try others, is one that they still do not seem willing to face up to. "

Indeed it is. But Strominger is 55 years old and therefore completely passed it in terms of making fundamental new contributions to theoretical physics. So for him to abandon String Theory is to acknowledge that his whole research career has been a failure. Since String theory has been going for thirty years most of his colleagues are in the same boat. Psychologically he, and his fellow workers can't face up to this. And practically speaking, it would mean the end of their mentoring role – the only meaningful role they have left. And this, more than any other factor, explains their bizarre committment to a failed theory.

11. **Jose**
October 1, 2010

"You could also argue that fields should get resources inversely proportional to amount of new experimental evidence…"

…in which case string theory should get infinite funding.

12. **Fabien Besnard**
October 1, 2010

I know that this is not "a place for people to promote their favorite ideas about fundamental physics", but surely the names "loop quantum gravity", on the quantum gravity side, and "noncommutative geometry", on the unification side, must have come to the ears of Strominger and other promoters of the TINA argument. I would understand if they said "there is no good alternative", since this would clearly be the expression of an opinion, but choosing instead not to even mention the other theories surely qualifies as propaganda.

13. **M Brane**
October 1, 2010

In many ways, string theorists are like wives and string theory itself is like the husband that beats them.

"But I love him"
or
"I can't leave him, because where would I go?"
or
"He only does those things because he's incomplete, and I can FIX him"
or
"I'm too old to start seeing someone new"

However in some violent relationships, the surprising happens: The husband leaves. So it may end up that string theory itself may leave the theorists and not the other way round.

Indeed since 1998 , when string theory said "I'm just going to the shop to get some CC-igaretes" , the theorists have been waiting for it to come back by keeping it's dinner warm in the landscape oven.

14. **Seth Thatcher**
October 1, 2010

M brane:

I think the abandoned wife of string theory has lately been internet dating "Multiverse" in "String theory's" absence to pick up CC-igarettes. "Multiverse" sounds good and is quite interesting, but he is elusive and refuses to meet her at the local Starbucks for a face to face. She's never seen him and can't verify who he is or that she he even really exists, but she's hopeful.

Seth

15. **Peter Woit**
October 1, 2010

Dave,

If you're going claim to just be a "framework", the question becomes whether you're a useful framework, i.e, whether you're able to provide a testable scientific explanation of anything. Claiming that "God did it" is also a framework, just not a very useful one.

The QFT framework historically used by physicists is not "pick any random, arbitrarily complicated QFT and try and use it. What is really powerful is the idea: pick one of a small number of the simplest QFTs and compare these to the world. This is what physicists have been doing since the earliest days of quantum theory, with great success in terms of getting a scientific explanation this way. The simplest string theories are just dead-wrong, so you're forced to look at more and more complicated ones, evading confrontation with experiment.

16. **Roger Schlafly**
October 1, 2010

So it appears that Strominger, Woit, Motl, and everyone else are in broad agreement about what is string theory, and what it has and has not accomplished. Motl even agrees with Strominger's report card. Controversy only arises when someone argues that a failed theory is still worth pursuing if all the experts say that it is the only game in town.

17. **Smurf**
October 1, 2010

DB

…therefore completely passed it in terms of making fundamental new contributions to theoretical physics…

Hidden conformal symmetry of the Kerr black hole (2010), Kerr/CFT correspondence (2008), Chiral Gravity Conjecture & its proof (2008), OSV conjecture (2004) & its proof (2006), 4D/5D black hole connection (2005),… Enough for you?

18. **JC**
October 1, 2010

At this point, I doubt people like Witten, Strominger, etc … are going to publicly renounce string theory. Nobody wants to admit their entire research career was all in vain.

From a more pragmatic perspective, they don't want to "nuke" the careers of their younger colleagues, previous students, and postdocs, whom are still climbing up the academic system (ie. looking for an assistant professor job, on tenure track, etc …). They also don't want to give the funding agencies any more excuses to reduce or outright cancel funding for string theory.

With that being said, the earliest I can think for somebody like a Witten or Strominger to renounce string theory, would be after they are retired and no longer have their offices at the university, IAS, etc …

For a die hard fanatical string theorist, they probably will not renounce string theory at all. Though if they do renounce, for whatever reasons (ie. seeing the light, etc …), it will most likely be when they are on their deadbeds.

19. **Dave Miller**
October 1, 2010

Peter wrote to me:
> The QFT framework historically used by physicists is not "pick any random, arbitrarily complicated QFT and try and use it. What is really powerful is the idea: pick one of a small number of the simplest QFTs and compare these to the world. This is what physicists have been doing since the earliest days of quantum theory, with great success in terms of getting a scientific explanation this way. The simplest string theories are just dead-wrong, so you're forced to look at more and more complicated ones, evading confrontation with experiment.

Yeah. I think what probably will happen, and probably should happen, is that people will gradually drift away from string theory, simply because no one really knows what to do with it. However, it seems to me quite possible that, forty years from now, some bright young kid will be working on LQG or non-commutative geometry or whatever the hot thing is then, and will see that it connects with string theory in a cool way, and that this was the missing idea that kept string theory from being useful.

Stranger things have happened: it took a long time after Riemann and Gauss worked out the initial ideas in differential geometry until Einstein saw how to use those ideas in general relativity. Of course, GR has an indefinite metric, as suggested by special relativity, and this gives a structure not imagined by Riemann or Gauss. It seems to me that something like that may happen someday in string theory: some old ideas banging around from string theory may mate with some entirely new ideas from some other source and produce some viable offspring.

I don't think I'm really arguing with you here: I don't think you've ever suggested that we should simply burn all the books and journals with string theory stuff in them to prevent future generations from being polluted with string theory! Obviously, string theory has not worked, but I do not think it is crazy to suspect that some ideas from string theory may eventually make it into real elementary-particle physics. At any rate, I doubt it is possible to hide the stuff that has been worked out in string theory from future generations of theorists, even if they find it of limited interest.

The other point I'd like to raise is basic math issues about string theory: I'm still bothered by the different quantization procedures (Gupta-Bleuler-like quantization, light-cone gauge, etc.), by the question of a true string field theory, by whether or not "M theory" actually exists, and, indeed, by the question of what string theory actually looks like in spacetime (the jump from 2-D quantization in the sigma-tau plane to actual 9+1 or 25+ 1 or whatever-dimensional spacetime is slid over pretty slickly in everything I have seen).

You recall Streater and Wightman's "PCT, Spin and Statistics, and All That"? There was nothing about real-world field theories there (certainly not gauge theories), just an attempt to figure out what sort of critters field theories are.

It seems to me that there are a few decades (at least!) of similar work in string theory, and, to my tastes, that might be worthwhile. Most of us don't pooh-pooh the work put into proving that phi^4 theory is trivial in 3+1 dimensions: it did not teach us anything about the real world, but it did teach us something about field theories.

Similarly, if someone could actually present "M-theory" in a well-defined way and show that it exists mathematically, I'd find that interesting as work in mathematical physics, even if it never connects with the real world.

Alas, string theory does not seem to attract too many people with the personalities of Streater and Wightman.

Dave

20. **Tom Whicker**
October 2, 2010

Chiral Gravity has been proved? Does this mean that Uncle Al has been vindicated???

21. **Anonymous**
October 2, 2010

Similarly, if someone could actually present "M-theory" in a well-defined way and show that it exists mathematically, I'd find that interesting as work in mathematical physics, even if it never connects with the real world.

By AdS/CFT, this is probably at least as hard as showing the existence of Super Yang-Mills theory. What a hopelessly difficult challenge.

22. **Dave Miller**
October 2, 2010

Anonymous wrote, re my earlier post:
>By AdS/CFT, this [showing M-theory exists] is probably at least as hard as showing the existence of Super Yang-Mills theory. What a hopelessly difficult challenge.

I should have been clearer with my Streater/Wightman example. I don't expect anyone to work out string theory with the level of math rigor that Streater/Wightman used.

But, it would be nice to have *some* demonstration that there is such a thing as M-theory at the same level of understanding we all used to accept for field theory – some single Lagrangian or *something* that really is a single presentation of M-theory. As far as I can tell, there have been rather wild jumps to possible phenomenology, brane-worlds, the landscape, and all that, without even knowing if M-theory exists in terms of the relaxed standards of rigor physicists usually accept (or used to accept).

Similarly, "first-quantized" string theory seems actually to be a classical field theory of strings (just as Klein-Gordon theory actually is a classical field theory that needs quantization). However, if you try to work out the details based on the standard approaches – light-scale "quantization," Gupta-Bleuler-like imposition of the constraints, etc. – well, I have not seen that done, and it looks to me to be fairly difficult.

I suspect that some string theorists would claim that this is obvious, and that I am just too dumb to see it.

Maybe so. In which case, surely one of them could have mercy on us poor dumb theorists and write it out for us at the same level as any of the old classic field-theory textbooks.

I don't think they can. I have most of the standard string-theory texts – GSW, Polchinski, etc. It's just not there.

If string theory is real, even at the level of mathematical physics, it should be possible to work this stuff out and write it up. Trying to do so might clarify a lot of what is going on.

I'm an agnostic on this: I don't know if the basic ideas of string theory make sense or not.

But, it would be nice if someone were actually trying to work this out.

Dave

23. **anonymous**
October 2, 2010

What grades does he claim are A's and B's?

There's a huge difference between LHC and cosmology.
LHC physics, while very important, is at an energy scale (TeV) for which string theory
may well have little to say. In very early universe cosmology there is a greater possibility for connection with data, since the subject depends on high energy physics (Planck-suppressed operators). In this subject, there are testable signatures of some well-defined theories; moreover the theory has motivated
new, more systematic studies of field theory and CMB signatures
which are central in that field. The speaker has not worked on this much, and may not have thought carefully about it.

It is surprising that he would claim to speak for others on this; I would guess the grades would vary wildly.

24. **Peter Woit**
October 2, 2010

anonymous,

Strominger's grading of string cosmology with a D I think accurately reflects both its lack of success and the general opinion of the subject of cosmologists, string theorists and others. The only disagreement among most physicists would be whether a D or an F is the right grade. Trying to claim that he doesn't know what he's talking about is just absurd.

JC,

I think giving a public colloquium in which you award your own subject Ds and Fs for its progress in saying anything about particle physics and describe the future of this subject as its adherents having to go home and watch TV is about as close to admitting failure as you are ever going to get. What's at issue now is what you do after admitting this failure. Strominger is arguing that theorists should leave particle physics and try applying techniques they have learned from string theory to other subjects. I'd be happier if he and others argued that people should be looking for new techniques.

25. **DB**
October 2, 2010

JC

"From a more pragmatic perspective, they don't want to "nuke" the careers of their younger colleagues, previous students, and postdocs, whom are still climbing up the academic system"

I think it's more insidious that this. The reason, I believe, for the relentless incantation of the mantra "this is the only game in town" is a cynical pr-style attempt to influence young talent into taking up String Theory. I think this is the only rational explanation for their behaviour. The old burnt-out hands, who now sit in very influential positions, know that the only real chance for progress is to attract the young talent that might be capable of making the breakthrough that they have failed to make and are now too old to realistically hope of achieving. The alternative is that their long toil of thirty years of research is consigned to the dustbin of history.

Putting myself in their place, I can see why they are driven to relentlessly spin and hype their field. If by some miracle a young genius was to sort out what appear to be completely intractable problems with the field, the shameful history of hype and spin would soon be forgiven and they would be celebrated as pioneering visionaries.

@smurf

Your filter as to what constitutes “fundamental new contributions to theoretical physics” appears to be set at a considerably lower threshold to mine. Historically, really important new breakthroughs by theoretical physicists over the age of 45 are extremely rare.

26. **piscator**
October 2, 2010

Not sure that anonymous really appreciates particle physics. The inflationary scales are no more Planckian than the TeV scales.

In large classes of models (all versions of gravity mediation), *all* the soft terms – i.e. the terms in the Lagrangian that in the best of all possible worlds the LHC will measure – arise as Planck-suppressed operators.

In both susy and cosmology, understanding the physics requires understanding Planck-suppressed operators. How well defined the models are is another question, but if you want to understand the origin and physics of these Planckian operators, there is still only one game in town (sorry Peter).

27. **anonymous**
October 2, 2010

piscator: TeV physics may or may not involve SUSY, which if it exists may or may not involve gravity mediation. Inflationary cosmology necessarily involves Planck-suppressed operators, in the cases protected by symmetry, an infinite class. However I do agree with you that particle physics is very interesting and we could get lucky in terms of connections to string theory. SUSY grew out of string theory as well, as a spinoff.

Peter: actually cosmologists do take this seriously. WMAP papers and various cosmo white papers written by the experts in the field refer at an appropriate level to string theoretic mechanisms and their corresponding signatures, for standard reasons. Moreover, string theory contributed in a clear way to the development of the field theoretic classification of single-field inflation mechanisms.
This is all standard by now in the cosmo community. Unfortunately, it is not absurd to say that string theorists including perhaps Strominger are not all caught up on this, but CMB physicists by and large are.

28. **piscator**
October 2, 2010

anonymous,

OK, we aren’t that far from each other. Personally I feel cosmo people place too much emphasis on string-motivated ideas, and pheno people too little, but we can agree to differ.

Inflation is in some sense twice as hard as susy breaking though, because for inflation you need controlled susy breaking to start with, and then controlled inflationary dynamics on top of that.

29. **careful**
October 2, 2010

Wow. The one thing I would think all theorists would have learned by the age of 55, is to never claim to speak for a whole community.

I know a lot of string theorists. I have even been called a string theorist on occasion. I am not sure what “grades” I would give this huge framework (which in my opinion has contributed a lot to theoretical physics, but is not yet in anything close to a finished form). But I am pretty darned sure that if you took a poll of string theorists, you would get a nice, diverse statistical distribution of answers about where the theory has done best/is most promising, and where it has been most deficient (or what areas are most overgrazed to little continuing benefit).

I suspect Strominger, for instance, might emphasize calculations of highly idealized “black hole” entropies (counts of field theory BPS states) as a great success, where others might instead be happiest with models of cosmology (which promise eventual contact of a more physical nature), or particle physics, or geometric engineering of various known and previously unknown field theory results, or even relations to pure mathematics. I am not advocating any of these views, but it is clear from the arXiv that many people view each as a prime motivation to work in this area.

This is as it should be; since there has been no smoking gun success at the level of making contact with nature, any agreement would be purely sociological, and I’m happy to say that we haven’t reached that level of groupthink yet.

30. **vasisdas**
October 2, 2010

Amusing colloquium but very political, with lots of preferential references to present and former Harvard people. Does he really believe that black holes are the harmonic oscillators of the 21st century? They seem pretty 20th century to me, just like Strominger’s powerpointless slides. I doubt that referencing Subir repeatedly for using black holes to solve CMT will help extend the lifetime of this peculiar fad. Of course, trying to explain the Big Bang is what string theory should be good for. He might not like the progress on this so far, but this is a far more likely arena for eventual string theory contact with real world than LHC energy scales. If LHC discovers some new physics that will be great, but having it distinguish between different BSM scenarios (let alone string constructions) is unlikely. So, grading both as D looks misleading.

31. **Shantanu**
October 2, 2010

Peter, here is another interesting talk by Avi Loeb on advice to young astrophysicists. Although this is more astrophysics based(although string theory and landscape is mentioned), the same method applies
to particle physics also
http://www.cfa.harvard.edu/itc/events/Loeb.Future_Frontiers.mov
Someone should give a similar talk about particle physics

32. **Anonymous**
October 3, 2010

As well as being an accomplished scientist, Loeb has a very open mind. Among other points, he thinks dark matter/dark energy may not eventually be proven correct, and our current understanding of cosmology leading to the theory of galaxy formation may well turn out to be another theory of epicycles.

Ironically, string theorists seem to be absolutely certain that there is a cosmological constant, while astrophysicists, who actually study this issue directly, at least do not view competing theories like quintessence as crackpottery.

33. **lun**
October 3, 2010

Dave Miller's comment is very appropriate given Witten's paper of a few days ago http://arxiv.org/abs/1009.6032

Strictly speaking, it is not on string theory at all, let alone of string theory as a theory of quantum gravity. However, objects which arise naturally in string theory are shown to be somehow equivalent to objects which arise in certain quantum field theories and even quantum mechanics.

Seiberg's dictum, if we find something beyond string theory well call it string theory, is not COMPLETELY unjustified.

34. **Chris W.**
October 4, 2010

The writeup that Avi Loeb refers to in his talk is arXiv:1008.1586.

35. **Geoff**
October 4, 2010

Hi Peter –

My bias is that string theory does too much violence to GR, but there is an interesting problem that makes me wonder if string theory isn't entirely useless from a computational standpoint. If I had been a student of DeWitt and he asked me to calculate graviton-graviton scattering as described here:

http://arxiv.org/abs/0805.2935

it would have taken over 500 terms and I'm quite sure I would have never gotten it right. If someone told me there was a quick way to get the right answer with only one term, I certainly would have used it without regard as to whether the underlying theory solved the unification problem.

36. **Coin**
October 4, 2010

"Among other points, he thinks dark matter/dark energy may not eventually be proven correct"

Hm. Loeb's general philosophy on research is fascinating, but I'm surprised to find people still doubting dark matter. I'd be curious how any alternative to the dark matter hypothesis could possibly be made compatible with the bullet cluster/MACS J0025 observations…

Also:

"SUSY grew out of string theory as well, as a spinoff."

Really?

37. **Peter Woit**
October 4, 2010

Geoff,

Sure, the applications of string theory giving sums of lots of Feynman diagrams in terms of one world-sheet diagram are impressive. It's worth pointing out that this is still a non-trivial calculation (to really connect to GR, you should quantize the 10d superstring and then extract 4d info from it).
Lots of things coming out of string theory are useful, just not the ones coming out of conjectured unification via string theory.

I don't know who Yau's GR instructor was, don't think he says in the book, may be wrong.

Coin,

Dark matter has nothing to do with this posting, which is one of the problems with string theory unification…

I wrote extensively about the history of 4d SUSY in my book. It was first discovered in the Soviet Union, through motivations having nothing to do with string theory. Later it was independently discovered in the West, there string theory was part of the motivation.

38. **np**
October 5, 2010

http://edition.cnn.com/2010/LIVING/10/05/sweden.nobel.physics/

It's NP (Physics) day today. Not string theory by any stretch of the imagination, but I suggest it's time for a new post.

39. **Peter Woit**
October 5, 2010

np,

Sorry, but the Nobel news is about something I know nothing about. Earlier this year I was at a series of talks which was supposed to include Geim, but he didn't make it because of the volcano. So, I remain ignorant and I fear you'll have to find better informed blogs for insight on today's news.

40. **zanzibar**
October 5, 2010

RE: Nobel prize (graphene) and Black Holes (!?)

Interestingly, Motl's blog on the Nobel prize contains material apropos this thread's topic:

//quote
————————————————————————-
Just four days ago, graphene was also mentioned on TRF because it appeared in Andy Strominger's talk – as an example of a physical system for which the string-theoretical AdS/CFT correspondence has been useful.

That's partly because graphene is a nearly perfect fluid – much like the other systems that are well covered by the holographic dual (and reinterpreted as a black hole). This fact is just another example of the tight relationships with string theory and its brand of quantum gravity that the most important state-of-the-art discoveries even in as faraway disciplines as atomic or condensed matter physics display.
————————————————————————-
/endquote

See:

http://motls.blogspot.com/2010/10/physics-nobel-prize-geim-novoselov.html?utm_source=feedburner&utm_medium=feed&utm_campaign=Feed%3A+LuboMotlsReferenceFrame+%28Lubos+Motl%27s+reference+frame%29

(Sorry about the double posting, but how do I quote material via this blog's editing interface?)

41. **ohwilleke**
October 5, 2010

The good news is that there actually more kids in the classroom (LQG and entropic gravity most notably) than there were a decade ago.

42. **MathPhys**
October 9, 2010

I personally liked Strominger's seminar and it is clear to me that he has thought about the issues that he was talking about, deeply and for a very long time.

It is natural that he referred frequently to contributions by Harvard people. The seminar took place at Harvard, the audience were mostly Harvard students and he was being patriotic, so to speak. It is also a fact that he was mostly talking about traditional, non-stringy physics.

His opinions on string theory in the final part of the talk were, well, his opinions and he's entitled to them. What's he expected to say? Someone else's opinions? I think he was very reasonable.

Various and Sundry

October 11, 2010
Categories: Uncategorized

Yet another random collection of topics of possible interest:

- Things have been going well at the LHC recently, and there's a new dashboard page at which progress can be followed. For the latest from the LHC, see the talks at last week's LHC Days in Split. The LHC machine is discussed here, with the news that restart of proton-proton collisions (after a November 1 stop for a heavy-ion run and holiday shutdown) is tentatively scheduled for February 4. Long-term plans for the machine are covered here, including projected running at 6.5 TeV/beam in 2013, 7 TeV/beam in 2014, and a possible rebuilding of the machine with new magnets that would give 16.5 TeV/beam in 2031.

Now that the experiments have 10 inverse picobarns of data, the search for supersymmetry can begin in earnest, and various talks cover this. According to Maria Spiropulu of CMS "the time between O(10) and O(100) inverse picobarns of well-understood data will be critical for the discovery and characterization of SUSY".

The other hot topic is that of how well the LHC will be able to compete with the Tevatron for discovery of the Higgs. Tommaso Dorigo discusses this here and here, using LHC projections given here.

- In news of non-scientific projects of mathematicians and physicists, Edward Frenkel has a screenplay out called The Two-body Problem. Lisa Randall has curated an exhibition in LA entitled Measure for Measure.
- Frank Wilczek is working on a murder mystery novel to be called *The Attraction of Darkness*, which will mix "science, music, sex, and murder." There was a recent Bloggingheads conversation with him here. His response when asked about his take on string theory: "It needs work."
- For commentary from Charles Day, an editor as Physics Today, about why their coverage of string theory has been sparse, see here. For Clifford Johnson's commentary on the commentary, see here.
- Later this month the Princeton Center for Theoretical Science will have a workshop on Rare Events in Computational, Financial and Physical Sciences, co-sponsored by the hedge fund D.E. Shaw. D.E. Shaw has been a large employer of mathematicians and physicists, but recently hasn't been doing so well, announcing the firing of about 10% of their staff.

The new documentary about the financial crisis that just came out, Inside Job, is surprisingly good, I highly recommend it.

- Past proceedings of the International Congress of Mathematicians are now available on-line here.

   October 11, 2010

   Thanks for the LHC dashboard link. This is a great
   page with all the relevant information nicely viewable.
   This makes the endless switching between the various
   OP Vistars pages largely obsolete.

2. **jal**
   October 11, 2010

   I hope everyone becomes aware of "INSIDE JOB". You will find out that reality is worst that the film.
   jal

3. **Anonymous**
   October 11, 2010

   For commentary from Charles Day, an editor as Physics Today, about why their coverage of string theory has been sparse, see here.

   I hope editors of Science and Nature also review why their coverage of string theory is sparse. And some official clarification from the Nobel committee would be also very welcome:)

4. **Jim Clarage**
   October 11, 2010

   Thanks for alerting us to the Past proceedings of the International Congress of Mathematicians. Having these papers available from my armchair next to the fireplace is almost science-fiction. The 1893 address by Felix Klein on "The present state of Mathematics" could almost be written today. Klein points out certain problems in astronomy where "even the professional mathematician finds here much to be learned." The problem he's referring to involves infinite determinants ("unendlichen Determinante") discussed in the paper by Burkhardt from that same year — also available online of course. The infinities physicists continue to toss at mathematicians e.g., Feynman diagrams and renormalization, come to mind.

5. **Benni**
   October 12, 2010

   Although it is off topic:

   Roger Penrose has published a new book. It will appear at 26.th of this month:

   http://www.amazon.de/gp/product/0224080369/ref=s9_newr_gw_ir01?pf_rd_m=A3JWKAKR8XB7XF&pf_rd_s=center-4&pf_rd_r=036A8N9W4SYJTTF5MH12&pf_rd_t=101&pf_rd_p=463375133&pf_rd_i=301128

   It is called "cycles of time", with the description saying:

   One of our most distinguished scientists offers a radical new theory of the origin, and ultimate end, of the Universe.

   Professor Sir Roger Penrose's groundbreaking and bestselling The Road to Reality provided a complete guide to the laws that govern our universe. In Cycles of Time, Penrose offers a completely new perspective on the often-asked question, 'what came before the Big Bang?' The answer that Penrose proposes involves a curious but fully rational way of looking at the expected ultimate fate of our acclerating expanded universe, and showing that its end can in fact be reinterpreted as the 'Big Bang' of a new universe.

6. **Benni**
October 12, 2010

The book has already appeared in the uk, therefore, amazon.uk page has reviews:

http://www.amazon.co.uk/Cycles-Time-Extraordinary-View-Universe/dp/0224080369

The good news is, that the book may contain interesting technicalities, since an amazon.co.uk reviewer writes:

"There is some hard maths however and this has been relegated to the Appendix (30 pages). This maths is very advanced and another of Penrose's technical books (Penrose and Rindler Volume 2) would be needed to understand it fully – so that is only for the experts. "

7. **Yatima**
October 13, 2010

>The good news is, that the book may contain interesting technicalities

Hell yes. They are all in the appendix (Penrose uses the word "banished"), but keep your skills in 2-spinor formalism and operator algebra handy.

Sadly, there is no bibliography.

The book is about Penrose's blueprint of an idea on how to connect the low-entropy Big Bang state to the high-entropy "end of times" state of an exponentially expanding universe. The states apparently can be made conformally equivalent assuming rest masses and charges all vanish to 0 as the universe ages.

8. **noname**
October 14, 2010

The LHC continues to make (very slow?) good progress and starts to fullfill its goals for 2010. Hey, make an effort and try to look cheerful when you report on that!

9. **Peter Woit**
October 14, 2010

noname,

You seem to have missed the lead-off sentence here:

"Things have been going well at the LHC recently" which, if I were the sort to editorialize, I'd say was great to hear….

They've reached their peak luminosity goal for the year, with a couple weeks to spare. I hope they can run for physics long enough during the remaining time to have something interesting in the data.

10. **Tommaso**
October 14, 2010

Hi all,

noname is of course reading another book. The LHC is performing surprisingly well, and we experimenters on the receiving end are simply delighted. 10^32 with 240 bunches means we have a much better emittance than predicted, which is great news and is not an ephemeral plus.

With 15/pb already in the bag and probably over 50 before the end of the year, we are with both foots into "discovery territory", if you buy into the theorists' hype that new physics is behind the corner. Sure, it is, but the corner is nowhere to be found.

Best,
T.

11. **Jacek**
October 14, 2010

couple weeks to spare = two weeks

12. **Tommaso**
October 14, 2010

Ah, and… Forgot to write the real reason for my above comment – thanks for the links Peter!

Cheers,
T.

13. **SteveB**
October 15, 2010

Thanks for the info. While the LHC dashboard looks promising it is not working well for me. The screen flashes every second and it seems to clear all but the top 20% of the image and then fills the rest in slowly so I get to see the bottom portion of the display for about 1/3 of second. Also, none of the buttons on the bottom of the dashboard work for me. I am using a fairly common OS and browser(Windows7 and IE8) and have no issues with other web sites. I have not yet checked the dashboard at home with snow leopard and Safari.

14. **noname**
October 15, 2010

I'm not reading a different book. I simply remembered previous posts here in which Peter was very lukewarm
in reporting progress at the LHC (he almost seemed happy thinking the Tevatron would always be on top). It's very difficult to read him totally excited about the LHC, which goes a long way in showing what type of physicist he is.

15. **Peter Woit**
    October 15, 2010

    noname,

    There have been times this year when the LHC was significantly behind its goals and I've reported that. At other times, like now, when it has been reaching its goals, I've also reported that.

    The current situation is that if all goes well, they'll end this year's pp run at about 50 inverse picobarns of integrated luminosity (versus expectations early this year of 100 inverse picobarns, see

    http://indico.cern.ch/getFile.py/access?contribId=26&sessionId=7&resId=2&materialId=paper&confId=76921

    Peak luminosities are now a bit above half the projected final value in the above document, may go higher in the next couple weeks.

    So, I think a fair summary is that things are going well, in some ways better than projections (as Tommaso mentions), in other ways not quite at projected levels. I'll leave overhyping this situation to others.

    Like everyone interested in particle physics, I'm following with great interest the progress of the machine and of the experiments. If there's any difference between my point of view on the LHC and that of certain other people's, it's just that I'm dubious about widely advertised supersymmetry or extra dimensional scenarios, and think the most likely important result to come out of the LHC will be an understanding of the origin of electroweak symmetry breaking. Looking at how difficult it appears to be to see the Higgs, this may take quite a while. If, on the other hand, a dramatic violation of the Standard Model shows up this fall in the first tens of inverse picobarns, that would be fantastic.

    As for what type of physicist I am, unlike "noname", I put my name on everything I write so that people can judge for themselves.

16. **PhilG**
    October 16, 2010

    The LHC was never "significantly behind its goals" this year. The 100/pb was just an estimate, not a goal.

    What has actually happened is that they have adapted their plans to take advantage of better than expected beam stability at high intensity. In the original plan that Peter linked to you can see that they expected to have to go to much higher bunch numbers using 50ns separation and lower beta* of 2m to reach the 100/μb/s target. In fact they were able to do it with less bunches seprated by 150ns and beta* of 3.5m. The good news is that it is relatively easy now to decarease bunch spacing and increase beta* giving a potential luminosity increase factor of about 5 times. They might do that early next year so that if the LHC runs with good efficiency they can reach the 1/fb target more quickly.

    Of course they have had to deal with many problems along the way, but no more than they had allowed time for. There have been no major problems and not a single unplanned quench. This has been a great year for the LHC and we have every reason to expect the next to be even better.

The Gathering Storm: Category 5

October 14, 2010
Categories: Uncategorized

Back in 2005 an illustrious group was organized to produce a report addressing the state of science and technology in the United States, resulting in what became known as the "Gathering Storm" report since it was entitled Rising Above the Gathering Storm. This report recommended that various steps should be taken to increase the number of science Ph.D.s produced in the US and going into the US labor market (while noting that there was no evidence of a shortage of such Ph.D.s).

Last month the group was back, now claiming that the gathering storm has become a hurricane of nearly category 5 intensity, with a new report entitled Rising Above the Gathering Storm, Revisited: Rapidly Approaching Category 5. Yesterday they appeared before the House Science and Technology Committee. In an analysis of what happened to their recommendations, they noted that the call for more Ph.D.s had been effective, with the NSF spending $475 million on graduate student funding during FY 2009-2010. As for the effect of this on their goal of more well-paid jobs for Americans, here's what they had to say:

> A paradox exists in the debate over whether there is a shortage of scientists and engineers or whether there are too many scientists and engineers for the jobs that are available. Most business leaders maintain the former; however, with regard to the more "conventional" functions of these fields it may well be that *de facto* there can no longer be domestic shortages of scientists and engineers. Firms facing this proposition are simply moving work elsewhere. Similarly, the observation that many scientists and engineers elect to pursue careers in other fields is in many instances simply reflective of the value placed on education in these disciplines by business, law, and medical schools and related employers and should not necessarily be decried. However, if the sole purpose of a PhD in science is considered to be to prepare future educators in science, then a surplus of scientists (often evidenced as a surplus of Post-Doctorate researchers) seems inevitable. The Gathering Storm recommendations are based upon the premise that federal investment in research must be doubled (the report's second highest priority recommendation)—in which case there will be commensurate increases in demand for researchers . . . and not solely for the purpose of providing educators.

It seems that the idea is that while there's no Ph.D. shortage at the moment, the Congress will double funding for scientific research over the next few years, so just maybe there could be a shortage in the future and this must be addressed right now.

As for the "paradox" that business leaders see a shortage of the kind of trained scientists and engineers they would like to hire at the wages they would like to pay, it appears to be the same paradoxical shortage I regularly encounter of first-class plane tickets to Paris available at the price I would like to pay for them.

In the real world, the latest Notices of the AMS has data showing the number of mathematics graduate students increasing from 10,883 in fall 2008 to 11,268 last fall. The situation graduating students face is described as:

> The job market for doctoral mathematicians took a decided turn for the worse during the 2008-2009 hiring season. For all mathematics departments combined, the number of full-time positions under recruitment during 2008-2009 for employment beginning in fall 2009 decreased 27%, dropping to 1,464 from 2,012 reported last year. This is smallest number of such positions reported since 1997 when it was 1,246. The number of tenured/tenure-track positions under recruitment during this period was 930, down 23% from the previous year's figure of 1,213. The number of full-time positions filled was 1,274, with 710 of these tenured/tenure-track positions. These figures are down 30% and 27%, respectively, from the figures reported for the 2007-2008 hiring season.
>
> For all mathematics departments combined, the number of new doctoral recipients hired for positions beginning in fall 2009 was down 13% from the previous year's number, to 656. Likewise, there was a decrease in the number of new doctoral recipients obtaining tenure-track positions for fall 2009 with 301 such hirings reported compared to 378 reported for fall 2008.

   October 14, 2010

   "As for the "paradox" that business leaders see a shortage of the kind of trained scientists and engineers they would like to hire at the wages they would like to pay…"

   I believe this is exactly correct and the aforementioned business leaders would then proceed to break the airline unions so they can get the price they would like to pay for that Paris trip. There is a shortage of various types of engineers in the US based on demand, but business leaders would rather setup operations overseas to get reduced labor. I have seen the first hand effects of this – unfortunately, it's not easy applying the kind of mind-games that business leaders like to play on scientific personnel when their minions are half-way around the globe and can't be forced to work late in their own time-zone. So they bring the jobs back to the US and secretly pray for the equilibrium to shift in the other direction (towards a surplus of people) by dumping personnel in the market, hoping that it will create the conditions they want. Not being very good at analyzing the dynamics, they don't quite understand why it doesn't work (including why many engineers leave the field altogether, reducing the supply). Maybe we should use NSF funds to properly educate business leaders, including requiring them to take (and pass) the real calculus that the rest of us take in school.

3. **CIP**
   October 14, 2010

   The shortage, I think, is of graduate students profs would like to train for jobs that don't exist.

4. **Anonymous**
   October 14, 2010

   The problem is that since graduate student can be used as cheap labor, there are far more openings for graduate students than for faculty members. When the scientific institutions finish exploiting a graduate student, the student is dumped with little hope of landing a faculty position. He's also in effectively at a disadvantage if he seeks jobs elsewhere, because of the amount of time wasted in graduate school. I can't see how this problem can possibly be resolved in any manner.

5. **anonymous**
   October 15, 2010

   This is something I feel deeply and personally. I'm 27 and just drive as a courier currently because I can actually live well on it. I'd love to pursue a higher education in physics but the debt load and prospects seem crushing. What to do about housing and money, the intensity and deadlines all scare me, not the complexity. I love to learn naturally on my own, for fun, with the feeling of exhiliration and pursuit of deep understanding. Yes work can be a drag, but at least I can pursue art, music, reading, science and FUN in relative freedom.

In other words I'm doomed!

6. **Bugsy**
October 15, 2010

Thanks for the link and comments, Peter; the article linked to by Ralph Ballart is also fascinating. The comments there are also worth reading….
Interesting that on the AIP site and also the cited report site there seems to be no place for comments. Good for them, as a lot of us would no doubt call "BS" on the whole enterprise.

Bad news from across the seas: the Sarkozy regime is making life so unbearable for academics that I predict many (those who can) will try to "get out", though given the situation in the US now that could only affect the very top levels.

Some examples: general low pay, and now apparently those previously privileged CNRS researchers will now have to undergo "evaluations" every 6 months??? with similar hurdles on the way for all academics, the overwhelming emphasis being put on sheer numbers of publications…there are many opportunities in the new system for friends to help friends, in a desperate race for
grant money and hence survival, which will encourage all manner of abuse of power and influence….there is a general threat in the air that those who are a bit older or are "less productive" will be rewarded by a doubled teaching load….social services are being cut…and on and on.
So my prediction, other than many wishing they could leave the country, is an increased suicide rate among those who feel trapped in the present situation, for a multitude of reasons…

7. **gs**
October 15, 2010

As for the "paradox" that business leaders see a shortage of the kind of trained scientists and engineers they would like to hire at the wages they would like to pay, it appears to be the same paradoxical shortage I regularly encounter of first-class plane tickets to Paris available at the price I would like to pay for them.

Exactly. Back in the 1980s when IBMer Erich Bloch headed it, the NSF was stating that a boom in demand was a few years ahead and scientists would be writing their own tickets in the 1990s.

8. **Peter Woit**
October 15, 2010

gs,

Yes, I should have mentioned that there's a long history of these bogus claims about "shortages" of US scientists. I think the NSF one you refer to calculated that by now (2010), the US would be in truly desperate straits, with a shortage of about 700,000 scientists.

9. **Yatima**
October 16, 2010

@Anonymous: "I believe this is exactly correct and the aforementioned business leaders would then proceed to break the airline unions so they can get the price they would like to pay for that Paris trip."

Really now. Whatever happened to economic education? I know it has been in the dumps since at least WWII, but still.

What *would* happen is that aforementioned business leaders would proceed to set up an airline that could offer low, low rates to engineers wanting to get a correct price for plane ticket to Paris.

It's that simple.

What would furthermore happen is that unions would mess the plan up by demanding higher wages or cushy job conditions for employees that are also unions members, then the governement would demand special "green" taxes, income taxes or nonsensical antiterror measures so the airline would go bankrupt and we would be back at square one.

Then capitalists get blamed for "greed".

10. **Peter Woit**
October 16, 2010

Please, no more ideological rants pro or con unions. In the job market at issue here, for better or worse, the number of union members and people interested in trying to form unions is infinitesimally small.

11. **Charlie C**
October 16, 2010

"The job market for doctoral mathematicians took a decided turn for the worse during the 2008-2009 hiring season. For all mathematics departments combined, the number of full-time positions under recruitment during 2008-2009 for employment beginning in fall 2009 decreased 27%, dropping to 1,464 from 2,012 reported last year. This is smallest number of such positions reported since 1997 when it was 1,246. The number of tenured/tenure-track positions under recruitment during this period was 930, down 23% from the previous year's figure of 1,213. The number of full-time positions filled was 1,274, with 710 of these tenured/tenure-track positions. These figures are down 30% and 27%, respectively, from the figures reported for the 2007-2008 hiring season.

For all mathematics departments combined, the number of new doctoral recipients hired for positions beginning in fall 2009 was down 13% from the previous year's number, to 656. Likewise, there was a decrease in the number of new doctoral recipients obtaining tenure-track positions for fall 2009 with 301 such hirings reported compared to 378 reported for fall 2008."

It would be interesting to know what the equivalent numbers are for China. Does anyone have data on that?

12. **Iowa Beauty**
October 17, 2010

The Miller-McCune argument is pretty compelling so long as we continue to imagine that the only successful employment for a STEM doctorate is research and teaching in a world class university. The system is heavily biased toward that belief, but it's deeply unfortunate. Industry needs people both in research and product development that have the knowledge and skills of PhDs. But most new doctorates consider an industry job second class, PhD programs do little or nothing to prepare their graduates for non-faculty positions, and most industry disdains to nurture their employment outside the few genuine industry research labs still operating.

We need a track toward the end of PhD programs that actually prepares graduates for real-world positions – allowing them to specialize their skills in directions that would make them business savvy, or properly geared up for undergraduate education, or for the very most creative, research.

Of course, we also need industry that can see beyond next quarter's results, but I guess that's a topic for another place and time.

13. **David**
October 17, 2010

Doesn't the quoted text including "For all mathematics departments combined, the number of full-time positions under recruitment…."
show exactly what the problem is?

Their idea is that people with a PhD should go into industry, not get jobs in math departments. The math departments can quite obviously produce many more PhDs than the universities need, the over production is for the benefit of industry, and the graudate students should know that a majority of them will not get university jobs. This is already the situation in e.g. Germany.

14. **Anonymous**
October 17, 2010

@David: You're entirely correct that the majority of PhD students should expect to build their future career outside academia. However, unless you know you probably want to stay in academia, doing a PhD is a bad career move (in most case anyway). Is the industry really craving for PhD applicants rather than those with a Master's degree but several more years of work experience? I don't think so. Beside, doing a PhD already means losing several years of salary (Working anywhere else is better paid).

15. **bane**
October 17, 2010

There's another paradox in the process. People who've come up through the industry route know different things than PhDs — indeed the fact that doing academic research causes you to learn different useful stuff (in stuff like mathematics; dunno what it means for a theoretical physicist) is presumably why business people want PhDs. But in the interview process it's customary that you can only answer the questions you're asked, and you generally get interviewed by an industry person. They ask you the questions they know the answer to from their background, then reject you with the reason "you don't seem to know as much interesting stuff as I expect", completely missing the point that you might know different stuff they don't know.

If there's one good thing about interviews for academic posts, it's that the interviewers are very good at giving you opportunities to tell you about stuff YOU know about that THEY don't.

16. **Iowa Beauty**
October 17, 2010

"on the interview process it's customary that you can only answer the questions you're asked"

Man, not in my world. I always ask open ended questions, such as "what do you think you can do for me?" (after explaining the position), and I encourage people to demonstrate problem solving ability and creativity by telling me about their hardest and most interesting accomplishments. Anybody really wanting a job would take those openings and run with them.

That said, I do expect people to come to me prepared to relate their skills and knowledge to the position, and to understand that we hire people to accomplish business goals, not purely intellectual ones. I don't see that many PhDs, but the ones I do see seem as often as not to consider industry work a consolation prize, and not be as fully engaged as others.

And of course, everything above is anecdotal, so apply appropriate error bars.

17. **bane**
October 18, 2010

I suspect it may vary with field. I work with computers, which is perhaps unusual in that graduate level mathematics is often powering what the user sees. I've recently been to interviews with various software companies, including some of the most famous ones in the world, and ALL the questions have been "Here's this problem I like, solve it", no questions that were remotely open ended or picking up items I'd drawn attention to in the cover letter. Probably I wasn't right for any of those jobs, but what's annoying is the feeling that the interviewers didn't ask the more open-ended questions that would have given them a feel for what I could have done for the company. In contrast, every academic position interview has had a mix of "testing questions" and "show me something useful you know questions". If you're consciously asking open ended questions to get a better view of the potential employee then I think you stand above many other interviewers.

18. **Hutom**
October 18, 2010

Nobody retires. New positions are created by people dying or by expansion of departments. The real surprise is that so many new positions are still available every year.

19. **truth**
October 29, 2010

It's not even really the business leaders. They want BS in Comp Sci from India (for same reasons of cheaper). But wrt Ph.Ds in sciences or math, that is just professors and unis wanting to have research programs and needing the transiet slave labor for the faculty.

20. **Terra**
October 29, 2010

The tenured establishment welcomes anything that increases the numbers of PhD's produced because they've already got secure jobs, and they can hire more graduate students to do slave labor in both research and teaching.

Looking at from another perspective, if we're thinking ahead for the good of society, the older generation owes the younger generation a chance to be trained for careers that actually exist.

I got my Ph.D. in physics at a time when the APS estimated that 3% of Ph.D. students would get permanent jobs in the field. I went to an elite school, and out of a graduating class of 50 or so, I think two people got jobs. One was an affirmative action case (female child of a professor) and another (child of a professor) is working at a new university in the Middle East.

It gratifies the narcissism of the tenured establishment to believe “the cream floats to the top”, but they’re actually filtering for desperate people who will tolerate an intolerable environment. Something I’ve noticed is that an overwhelming majority (80%+) of the professors at this elite school have parents who were also professors.

I got into a discussion with a professor (who I hope is in English or some other un-quantitative field) who told me that, at best, he could manage to get somebody placed by a connection once in his career. Well, when tenure-track jobs are in a steady state, that one act of nepotism effectively lowers the chances of the son of construction worker to spend a life in science to zero.

21. **Bugsy**
November 1, 2010

Terra, don’t assume all kids of professors get jobs because of nepotism.
There are very simple reasons for kids to want to try a career similar to that of their parents–
it is something you grow up around so it seems natural, accessible and understandable and, if you are lucky, interesting (and that part can apply to academics’ kids just as well as to those of the owner of a small business). So the sample is bound to be (very) biased. Plus, knowing the ropes in an intuitive way can sure help out a lot in any career.

Beyond that, I agree with all else you said. And indeed, life can be tough in a dfferent way for a professor’s kid:
dreaming you can copy your daddy’s success in perhaps a very different epoch but then seeing your own chances for “a life” go down the drain is emotionally challenging to say the least (brutal and dehumanizing being much more like it!)

Bogdanov Update

October 18, 2010
Categories: Uncategorized

Earlier this year the Bogdanov brothers published Le Visage de Dieu, yet another book dealing with their ideas about the big-bang and pre-big-bang physics. This follows their earlier Avant le Big Bang, and L'équation Bogdanov : Le secret de l'origine de l'Univers? a book that they somehow got Lubos Motl to take credit for. I haven't seen the new book, but it seems that it takes off from George Smoot's comment that looking at the CMB was like "seeing the face of God." Somehow the brothers have managed to get well-known cosmologists Robert Wilson, Jim Peebles and John Mather to contribute pieces to the book.

In other Bogdanov news, I hear from a Paris correspondent that an interesting document has recently come to light, a report commissioned by the CNRS after the Bogdanov Affair made headlines back in 2002. For press coverage of this, see here, here, here. The CNRS critique, from November 2003 is detailed, harsh and devastating. For instance, about Igor Bogdanov's thesis (which ended up being published in multiple copies in several respectable journals, including the highly thought of Classical and Quantum Gravity), the conclusion is "la valeur de ce travail est nulle", this work is of no value.

Update: For another informative article about the Bogdanovs, from this summer, see here.

Comments

1. **Chris Oakley**
   October 18, 2010

   On the subject of Avant le Big Bang, we had a Horizon (popular science) programme here in the UK recently on the very topic. The title actually was "What happened before the big bang?" The obvious answer to this question is "I have no idea, and neither have you", which is more or less where they got to, but not before taking in extensive and largely contradictory contributions from Linde, Penrose, Smolin, Turok, and a few others I had not heard of. Still – it was interesting to see the world's largest vacuum chamber and the gravitational wave detector on the way.

   What? Peebles contributed to Bogadanov's book?

4. **Anonymous Number 2**
   October 19, 2010

   It would be good to check whether Robert Wilson, Jim Peebles and John Mather *knew* that their pieces were being used for this book, before assuming they did.

5. **Anonymous Number 2**
   October 19, 2010

   The CNRS report on Grichka Bogdanov's math thesis describes his results in one page. It says (translating from the French) that they are "presented with great naivety and with errors which demonstrate the author's misunderstanding of a concept that is taught at the maîtrise level."

   "It would be easy, but cruel, to list the numerous errors which spatter this text, for example "SO(2,2) has no matrix representation" (p. 17). We shall content ourselves with observing that the space Σtop that he uses is simply the Cartesian product of R2 by (R3 × R3)/SO(3) and that this removes any potential meaning from the phrase "unique singular point" which is the essential [foundation] of the statements in this chapter, and [equally removes any potential] relevance of this study to the "Initial Singularity" of space-time."

   […]

   "In conclusion: one of the eight chapters of this thesis contains a construction at the level one might find in an undergraduate essay, but very badly written: the other seven contribute nothing to mathematics."

   The report spends much longer — 15 pages — dissecting Igor Bogdanov's physics thesis. It concludes:

   "Unfortunately, even a rapid reading evokes strong suspicions about the scientific contribution and about the quality of presentation of this work; and a deeper analysis only confirms these suspicions. It seems that the text contains no coherent construction. On the contrary, this work is a constellation of incoherencies, of serious confusions and of propositions so imprecise as to be incomprehensible. The conclusion of this report, based on the detailed analysis presented below, is clear and unambiguous: according to the criteria set out above, the value of this work is nil."

6. **Chris W.**
   October 19, 2010

   Well, I guess one could give them credit for pulling off a moderately successful scam, inasmuch as some reputable people felt compelled to spend valuable time exposing it, and granted them some publicity in the process. If you're enough of a narcissist, that feels like success. ("I don't care what they say about me, as long as they spell my name right.")

7. **Coin**
   October 19, 2010

   "Bogdanov" is hard to spell

8. **Anonymous**
   October 20, 2010

Does anyone have an actual link to the CNRS report?

9. **Peter Woit**
   October 20, 2010

   There is a link in the posting:

   http://www.marianne2.fr/docs/rapport_cnrs_bogdanoff.pdf

   It's unclear to me though whether this is the full CNRS report or just an appendix to it. If there is a more complete version of the report somewhere, I haven't seen it.

10. **MathPhys**
    October 20, 2010

    Peter, What do you mean by

    "This follows their earlier Avant le Big Bang, and L'équation Bogdanov : Le secret de l'origine de l'Univers? a book that they somehow got Lubos Motl to take credit for"?

    How do you know that Motl did not write the book? I thought he wrote on his web site that he did.

11. **Peter Woit**
    October 20, 2010

    MathPhys,

    I don't know what the real story of the "Bogdanov equation" book is, just that it must be a very odd one, and that in matters involving the brothers, things are often not what they are claimed to be.

    I don't actually have a copy of the book, but from its table of contents, some chapters sound like Lubos, others, not so much. The first chapter, available on-line, just doesn't seem to me at all like something Lubos would write. But, again, who knows….

12. **YBM**
    October 20, 2010

    Here is the first part of the CNRS report :
    http://www.marianne2.fr/attachment/62240/

    The full report is supposed to be published in a few weeks.

13. **Random**
    October 20, 2010

    FYI: the Marianne link to the CNRS report is just the overview, the non-technical pages. There should be an appendix for each thesis detailing the criticism. The CNRS is in the process of clearing it for release to the general public.

    The real question is why that report was left to snooze at the bottom of a drawer in the first place!

14. **Peter Woit**
    October 20, 2010

    Random,

    Interesting question!

    The report YBM links to does a good job of demolishing the idea that the Bogdanovs did any serious science, but seems to whitewash the failure that led to them both getting Ph.Ds. The names of those responsible for allowing this are blacked out, and the claim is made that this is such an unusual case that it's not worth doing anything to keep it from happening again.

    More interesting might be the internal discussions at the journals that published the Bogdanov articles….

15. **MathPhys**
    October 20, 2010

    ".. whitewash the failure that led to them both getting Ph.Ds. The names of those responsible for allowing this are blacked out,"

    These very pages that are linked (or something equivalent to them, but I think the same) were available a number of years ago without the blackouts. Parts of the reports on the theses were also made available.

    I remember one of them. It was like ".. this is revolutionary, very deep, …".

    "… and the claim is made that this is such an unusual case that it's not worth doing anything to keep it from happening again."

    The scary thing, Peter, is that it does happen on a regular basis. I can tell you of a specific example of a thesis (also on string theory) that was approved in the late 80's (the glory days of string theory) by very well known scientists at a very well known university.

    We now know that everything in this thesis was either wrong or plagiarized. None of the examiners had a clue. Those of us who suspected foul play in advance couldn't say a word. One becomes very unpopular for rocking this type of boat.

    But it also happens on a daily basis in papers that are being refereed for publication. How many referees are actually willing or able to re-derive the technical details of a technical paper. If it sounds reasonable, you approve it and hope for the best. But reasonable can turn out to be totally wrong.

16. **Bugsy**
    October 21, 2010

John Baez has some very interesting links on all this…last updated 2006:
http://math.ucr.edu/home/baez/bogdanoff/

This is one reason why advisers should never feel steamrolled into accepting or sticking with a student they feel is not up to the level, PARTICULARLY if they suspect the student is dishonest….someone with delusions or no scruples who can then parlay their PhD into money or influence. And who but a borderline sociopath would try that anyway?

17. **e.**
October 21, 2010

Bugsy, if someone is dishonest or wrong then this doesn't have to do with adviser ethics. It's much simpler. On the other hand what you suggest is tricky, since the inverse occurs a quadzillion times more often.

To the case itself — a friend of mine is a talented artist; yet I see her how her and her peers are willing to accept any piece of art, as long as it's self-proclaimed as abstract, no matter how silly, meaningless or downright bad it is (and I don't think that all abstract art is meaningless), reaching a point where they deny themselves the right to taste and critical ability. I still don't get why they do so, especially considering how this diminishes the value of their own works, although I have some ideas: a wish for paving acceptance for themselves, a wrong notion of abstract, and the rules of the market, among them.

I could end with a grande phrase outlining certain similarities but I think it'd be redundant 😐

18. **Chris W.**
October 21, 2010

Speaking of sketchy to non-existent journal reviewing standards, see the recent exploits documented on the SCIgen blog.

If you're thinking of establishing a publication record in computer science you could try SCIGen yourself. 🙂

19. **Sascha Vongehr**
October 23, 2010

Glad to see that people do not tire of pointing out how easy it is to publish absolute crap in the most respected journals, as the Bogdanovs did. I wish to support those here that stressed that such is not seldom and involving bad apples, but that the problem is systemic and growing.
My few cents to this subject I wrote about involving the subject of nanotechnology, where such is also going rampant (not quite as easy to use as SCIgen, but I thought of doing something similar with this paper generator):
http://www.science20.com/alpha_meme/pop_physics_free_nanotech_scientific_journal_article_generator

20. **clmasse**
October 25, 2010

"La valeur de ce travail est nulle"? I wasn't aware that French were the official language of the "physical community." A franco-french revenge about a cartoon character, or a real scientifical "huge problem"? To say the truth, in many year I've seen many valueless works, the least of them not being the supersting and other supercheries, without any bearing of any kind with empirical data. For me, controversies about for instance the climatgate is a better loss of time.

21. **martibal**
October 25, 2010

clmasse: i do not think the CNRS reports intended to be the voice of the physical community, but only the voice of CNRS, dealing with a problem internal to the french university (namely is it or not a scandal that a university delivered the Bogdanoff a PhD diploma ?). And one may also wonder whether they would have been such a mess if they were not (ex)-TV stars ? I mean, is their paper really the worst ever published in Class. Quant. Grav. or any other good journal ? At least from a surrealistic-poetry point of view, claiming that "the Big Bang singularity is aligned with Foucault pendulum" is not so bad 🙂

Also it should be emphasize that thanks to their TV program (which I find a crap) many people hear about science. Is it better to hear about almost-zero-value science, or not to hear about science at all ? Of course it would be better to hear about good science on tv, but there is no hope to find a science program prime time on some national network.

A last comment: it is also not so clear that they are dishonest. They worked several years on their PhD without being paid. So to some extend they may believe in what they say, even it what they say sounds total nonsense.

22. **MathPhys**
October 26, 2010

Many of the things they did 'after' their PhDs, including the Prof Yang alias e-mails, websites for research institutes that do not exit, etc, etc, make it clear (to me) that they are less than honest.

This Week's Hype

November 3, 2010
Categories: This Week's Hype

Way back in 1997, string theorists were already getting rather touchy about people pointing out string theory's testability problems. At that time, Gordon Kane published an article in Physics Today with the title String Theory is Testable, Even Supertestable in which he wrote:

> A decade ago in PHYSICS TODAY (May 1986, page 7), Paul Ginsparg and Sheldon Glashow raised this question dramatically, and effectively began a widely repeated myth that string theories, candidates for a primary theory, are not testable. Here I want to dispel this myth, and describe some of the many ways in which string theories are testable. If nature is supersymmetric on the electroweak scale, for which there is exciting but not yet compelling evidence, then string theories are even testable in essentially the same ways as traditional ones. All the tests I describe are doable now or in the foreseeable future with existing or proposed facilities or projects.

Kane went on to give a long list of testable things that string theory was going to predict, including as an example a detailed spectrum of superpartner masses, all in the range 50-300 GeV (he assures us that supersymmetry is a prediction of string theory, quoting something Gross and Witten wrote for the Wall Street Journal).

Now that LHC data has finally started to arrive, in amounts large enough to soon start seeing all of the superpartners advertised back in 1997, Physics Today has decided to put out a rather spectacular piece of string theory hype from Kane as their cover story, under the title String Theory and the Real World. In the story, the main theme is the same as 13 years ago: it's a myth that string theory doesn't make testable predictions. Now though, the many 1997 predictions are forgotten, and much of the article is devoted to a tendentious discussion of what it means to test a scientific theory. In the 2010 version, there's no longer a detailed list of things that string theory should be able to predict, instead Kane describes two specific predictions of string theory:

- the first one is about neutrino masses and is rather bizarre, describing work on one specific string theory compactification:

> We showed that in no case could the theory generate light but not massless neutrinos. That work represents a clear example of a test of string theory.

So, one specific string theory compactification is known to not look like the real world. That's a test of string theory????

- Kane advertises a recent paper of his from this past June (updated version of a couple weeks ago) about "non-thermal cosmological history". I'll leave it to readers to decide for themselves how compelling a test of string theory the paper provides.

Whatever one thinks of these latest "tests", the difference between what string theory tests looked like back in 1997 and what they look like in 2010 is rather remarkable.

Comments

1. **Anonymous**
   November 3, 2010

   "We showed that in no case could the theory generate light but not massless neutrinos. That work represents a clear example of a test of string theory." means that string theory predicts, correctly, that neutrinos have mass. I think you were confused by the multiple negations in the statement.

2. **Nex**
   November 3, 2010

   Anonymous you are the one being confused, if it said "string theory predicts light but not massless neutrinos." it would mean string theory predicts neutrinos have small mass (not massless =with mass).

   But the actual statement is the negation of the above since it says that in *NO* case could the theory generate light but not massless neutrinos.

3. **Jupiter**
   November 4, 2010

   I have been reading this blog with increased enthusiasm.
   Unfortunately, I do not have a background in theoretical physics
   and so it is difficult for me to evaluate the testability of this hypothesis.

   My basic question was:
   What is the endpoint, if there is one, of string theory? If there are major disagreements regarding the experimental evidence of a theory that has been around for 30 years, what can one conclude about the nature of the propositions that will be posited in the next 30 years?

4. **Bee**
   November 4, 2010

   I read the article yesterday, and found it to be really disappointing. I was very sure you'd comment on it 🙂 The most interesting sentence is this one

   "interested readers can find others in talks accessible from the website of the international String Phenomenology 2010 conference held in Paris this summer (http://stringpheno.cpht.polytechnique.fr)"

   I'd have expected that his article provides a summary of these efforts, rather than just advertising two of his own papers.

5. **Peter Woit**
   November 4, 2010

   Anonymous,

   I still think my interpretation of that "prediction" is correct. After what I quoted, the paragraph goes on:

   "Although the particular compactification we studied did not yield the desired neutrino masses, different compactifications may allow for neutrino masses consistent with experiment and offer explanations of observed neutrino properties."

Maybe though Kane is claiming that string theory "predicts" light but not massless neutrinos because they occur in one particular compactification. If so, "bizarre" would still be an accurate description of the argument.

6. **T.T.**
November 4, 2010

String theory is testable in a certain range of its fundamendal mass scale. Its tests are high on the LHC priority list and possible with only 2.9 inverse picobarns of data. See
http://128.84.158.119/abs/1010.0203
for latest results.
The statement that string theory is not testable is false.

7. **Peter Woit**
November 4, 2010

OK T.T.,

Since the LHC experiments have nearly 50 inverse picobarns collected, at the Winter conferences we should see announcements of the results of testing string theory. If the result is failure, I guess that's it for string theory, right?

Or maybe string theory gets to have it's own special kind of test, the kind where it doesn't matter if the test-taker fails…

8. **T.T.**
November 4, 2010

Peter,
The main premise of your blog was that "string theory is not testable". On many occasions you stressed that it does not matter for you whether it was right or wrong, so I will not answer your question. Furthermore, in experimental physics, we do not use the word "failure" to describe results — we rule out or confirm theoretical predictions.

If you want to make true statements, you'll need to add footnotes or small print.

It looks however that the main purpose of this posting was to make fun of Gordy Kane and other people who are enthusiastic about the prospects of the theory.

9. **Tim van Beek**
November 4, 2010

Peter wrote:

> …much of the article is devoted to a tendentious discussion of what it means to test a scientific theory.

I don't have access to physics today and can't read the article, but I would like to know what this discussion is about: If someone could provide a synopsis I would be thankful.

T.T. wrote:

> String theory is testable in a certain range of its fundamendal mass scale.

From the abstract of the paper you refer to:

> The data exclude new particles predicted in the following models at the 95% CL: string resonances, with mass less than 2.50 TeV…

AFAIK string theory can be adapted to not predict anything below 2.5 TeV (or XY TeV, for that matter), at least that is the state of the art right now. Therefore this is maybe a test of certain versions of string theory, but it is still not possible to falsify the theory. (My apologies to Peter if this remark starts the kind of discussion he has grown weary about).

10. **Peter Woit**
November 4, 2010

T.T.,

I think the person who needs to add small print to their claims is you. In the conventional understanding of what it means to "test a theory", when the experimental result differs from what the theory predicts that carries negative implications for the theory. And yes, people apply the word "failure" when this happens. If the LHC data differs significantly from standard model predictions, this will rightly be described as a failure of the standard model and be taken extremely seriously.

On the other hand, not even the most enthusiastic string theorist seriously expects the LHC to see strings in the first 2.9 inverse picobarns of data. Claiming that your theory is being tested by an experiment when you don't actually expect the experiment to see anything is just a not very honest abuse of language.

11. **Peter Woit**
November 4, 2010

Jupiter,

I think the endpoint of the history of claims about string theory being a unified theory of nature is already just about here: this is an idea that doesn't work. The lack of any support for such claims in the LHC data over the next few years should put the final nail in that coffin.

On the other hand, there will always be some people and some publications that will never admit what has happened. Extrapolating from the last two examples, by around 2025 we'll see Physics Today publishing a special issue by Kane on "String theory is too testable, darn it!". Hard though to even guess what the arguments for this will be by then.

12. **Manuel Bärenz**
November 4, 2010

T.T.,
I think Peter really has manners enough not to try to make fun of Gordy Kane. There are bloggers who do make fun of other people (most of us know at least one of

those…) but it appears that Peter does something far more intelligent – he points out that some people are making fun of themselves, without intention.
Switching from the meta-topic to the topic, I just wanted to add that there are AFAIK variants of string theory making predictions that are visible with the amount of luminosity you mentioned at the LHC. This is what some people mean when the talk about sensitivity of the LHC to string theory.
It is however not given that we *must* see evidence of this. I believe it takes an average string theory phenomenologist and two hours to set up some model that does explain why we don't see the signal. This is, why a reasonable man should not say that the LHC is sensitive to string theory, but at most to a tiny tiny fraction of some huge parameter space.

13. **Peter Woit**
November 4, 2010

Manuel,

Thanks, although I fear my last comment does show a certain willingness to make fun of this kind of thing. I agree though that mostly what's going on here is Kane (and Physics Today) choosing to embarrass themselves.

14. **Sam**
November 4, 2010

Peter:
There is no problem with the predictions changeing. This is exactly what we should expect of an evolving theory. You accuse the string theorists of claiming that they expect to see nothing, while saying their theory is being tested. Surely, that would not be a wise strategy for them, would it? Rather, the point is the unification of physics is a non-trivial exercise of the humans. It is absolutely incredible to think that a finite machine might reach the energies necesssary to probe this realm, but it is not necessary.

15. **Peter Woit**
November 4, 2010

Sam,

The problem isn't that string theory makes changing predictions, it's that it makes no legitimate predictions at all. Back in 1997, Kane wasn't making predictions, he was saying that in the future it would make predictions. Now that the future has arrived, all that has happened is that his past predictions of predictions have collapsed.

16. **MathPhys**
November 4, 2010

G Kane makes a living out of proposing experimental tests for supersymmetric (not necessarily string) theories. He did a lot of work on testing supersymmetric GUTs in the early 80's before superstrings. I heard him give talks on testing super GUTs in 1983 before the work of Green and Schwartz on anomaly cancellation in type I superstrings.

That's more than 25 years ago. I wish I could hear Kane admit once that he made a clear prediction that turned out to be wrong but he never does. That's not right.

Consider on the other hand Ch Thorne who is one of the true fathers of string theory (works on string since the late 60's) and who very clearly says that string theory as a unified theory of all interactions is not working.

We can do many things with it (come up with new, beautiful mathematics, for example), but at this stage, in this form, unification is not one of them.

17. **Richard**
November 4, 2010

For any who are looking for the original article by Gordon Kane but have not any clue where to access it, I have uploaded a copy on file-hosting websites

[*Sorry, but using a Columbia University web-site to provide a link to less-than-legal copies of documents is asking for trouble I don't want. If anyone has a better, legally non-problematic, link to this content, I can post that*]

18. **pt**
November 4, 2010

Write a letter to Physics Today about Kane's article. Quote from his 1997 article, for example the detailed spectrum of superpartner masses, all in the range 50-300 GeV. Point out that many 1997 predictions are forgotten in the 2010 article. Ask Kane how many of the 1997 predictions have been verified, or point out that none have been successful.

PT may not accept the letter, or may edit it heavily. KISS ~ I think you know what that means.

19. **Bee**
November 4, 2010

On the matter of scientific prediction, I just wanted to mention something I explained in my post [What is a scientific prediction?](). It is in practice very rarely the case that a theory is falsified. More often, it is what one could call "implausified": You constrain parameters so much the theory becomes implausible (most often because the parameters are unnatural). The problem with the LHC "predictions" is that if nothing is found, you can just go and say "naturally" we wouldn't have expected to see anything, because that particular model wasn't the right one or because this compactification scale, mass spectrum, etc wasn't plausible to begin with or swhatever. That's very likely what's going to happen within the next couple of years. (But you know, we would totally expect to see something at the ILC!!) I think you're actually better off sticking to cosmology, though even there you have the problem that the model doesn't uniquely follow from the theory, so there's always an escape route. In essence, one has to be careful what one calls a prediction of the theory itself and what a prediction of a particular model that is based on the theory. For all I know, everything you'll hear at the string pheno is of the latter, not of the former type. Consequently, if you try to reverse the logic, falsifying the model doesn't falsify the theory. (Besides that, it also isn't much of a "pre"diction to claim neutrinos have small but nonzero masses.) Not that this problem is unique to string theory in particular. In any case, it's unfortunate Kane is making his points so badly because I welcome the string pheno efforts.

20. **Coin**
November 4, 2010

So, I am looking at T.T.'s link and trying to understand exactly what the "string resonances" that have been excluded at the 95% level under 2.5 TeV are.

Poking at google I am seeing explanations that the thing being tested by the search described in T.T.'s link is not string theory in general, but rather the "low-scale string" scenario, where the "fundamental string mass scale" is in the TeV range. Is this correct?

It furthermore appears that even in a universe where string theory is correct, it would be more surprising than not if the "low-scale string" scenario were true. So in contrast to, say, Supersymmetry or the Higgs Boson (which, if they are not found at the LHC scale, this will be considered alarming and potentially threatening to the acceptance of those theories, because although you can still rescue the theory you have to do contrived things to the models to do so), if the fundamental string mass scale is not found in LHC ranges then string theorists would legitimately consider this basically to be the expected result, because the low-scale scenario is relatively exotic among string theories. Is this also correct?

Also, I am seeing suggestions that low-scale string theories require "large extra dimensions". Are the low-scale string theories, then, the same ones where the LHC is predicted to eventually generate the vaunted "micro black holes"? But it looks like the search is not looking for signs of micro black holes being created, it is looking for "string Regge excitations" (http://arxiv.org/abs/hep-ph/0001166 , reference [3] in T.T.'s link) of quarks and gluons. Is there a simple explanation of why these "excitations" occur in the scenario being tested?

21. **neo**
November 4, 2010

Taking these statements at face value, it is fair to say that string theory is indeed testable, or at least one specific compactification of it. Kane claims that this theory is inconsistent with light, non-massless neutrinos, and exactly that form of neutrino has in fact been observed, so this specification of string theory has been tested and refuted. Is this not right?

22. **Peter Woit**
November 4, 2010

neo,

The criticism of string theory is that it predicts nothing since you can find a "solution" that has any feature you want. Showing that there is a solution with the wrong neutrino masses doesn't exactly refute this.

23. **T.T.**
November 4, 2010

Strings vibrate. The quantized modes are Regge excitations. This is a universal property and is valid for all models, not a "feature" of any particular "solution". If Nature chose just one parameter, the fundamental scale of order TeV, LHC will discover string resonances in dijets and many other places. This is very simple, so if you have a scientific (as opposed to social group-thinking that you despise) argument why Nature made a different choice, I'll be glad to hear it.

24. **disproof**
November 4, 2010

The phlogiston theory was never disproved, per se. The luminiferous ether theory was also never disproved. They were merely forgotten or abandoned, because better theories came along which could explain the facts without increasingly artificial contrivances. So it will be with string theory. One can complain about the state of physics TTWP etc, and commit suicide as Boltzmann did, but that is neither here nor there.

25. **Mitchell Porter**
November 5, 2010

"The criticism of string theory is that it predicts nothing since you can find a "solution" that has any feature you want."

Wouldn't it be rather big news if a solution of string theory which looked exactly like the real world was found?

26. **Bee**
November 5, 2010

T.T.: Because there's no deep reason the relevant scale should be at a TeV.

27. **John**
November 5, 2010

At Mitchell Porter,

No it would not be big news if string theorists found such solution because it wouldn't explain much: the strength of such explanation would be similar to the Greek 'explanation' of positions of planets by epicycles. I am sure that the Greek thought in that time that this was the best exlanation one could get, just like string theorists now believe that science has to 'progress' through antropic reasoning… History has shown this type of 'ideas' to be wrong again and again and one should not take it seriously.

28. **Peter Woit**
November 5, 2010

Mitchell Porter,

If a string theory solution is found in which all the parameters of the standard model can be reliably calculated and they come out right, that will definitely make the newspapers.

So would the observation of a flock of pigs circling the CERN site at an altitude of 100 meters.

29. **Thomas Larsson**
November 5, 2010

Theorem [Larsson 2007, 2009]
Supersymmetry will not be discovered at the LHC.

Proof: String theory predicts supersymmetry (Witten 1984-2002). String theory predictions are always wrong. Hence supersymmetry does not exist, and will in particular not be found at the LHC. QED.

Corollary
Lubos Motl will lose his experimental-susy-by-2006 bet.

30. **Mitchell Porter**

November 5, 2010

Peter – there is an obvious contradiction between "string theory can be made to look like anything" and "string theory can't be made to look like reality". So what are you saying – that string theory *can* resemble reality, but that the calculations would be hard?

31. **John**
November 6, 2010

???? Mitchell Porter, I don't understand what is so difficult to comprehend from the last comments… There are really a few issues here
(a) String theory hasn't managed yet to resemble reality
(b) string theory contains 10^{500} solutions of which presumably the large majority do not look like reality
(c) even if string theory would solve (a), it probably never can *explain* (a) in the context of (b).

So like I said, this is the situation the Greeks had with epicycles, they could solve (a) but never got an explanation for it … until galileio and newton came by. Peter appears to think that solving (c) is never going to happen and I tend to agree with him.

Usually, a common feature of all scientific revolutions is that calculating out the old theories was *easy*. It was a piece of cake for Newton to verify the correspondence between the 1/r^2 force of gravity and the equal area swept out in equal times by planetary motions. It was simple for Einstein to deduce a Newtonian limit for the gravitational laws and the mere fact that the classical quantum correspondence is *not* so straightforward – in my mind – indicates that we are missing something. Consistency checks have always been easy … it was calculating the new phenomena which was usually a bit more difficult (see for example the three body problem in Newtonian gravity).

Why is this difficult to understand? It is not because people have a lack of good ideas that we should desperately try to defend the only things we can come up with so far…

32. **Peter Woit**
November 6, 2010

Mitchell,

The problem with "string phenomenology" is two-fold:

1. You can't actually calculate much at all reliably. Even in the limiting cases where perturbation theory is valid, an example of this problem is that you don't have explicit metrics for the Calabi-Yaus compactification spaces you would like to use. After 25 years of work on this, the state of the art is not much advanced. This is why even Kane has given up on his 1997 claims, and why it's highly implausible that all of a sudden you will be able to start exactly matching up string theory models and the Standard Model parameters.

2. As far as anyone can tell, when you are able to calculate something, you can get almost any values you want, by choosing a complicated enough string theory model. Even if you solved 1, there's no reason to believe that this problem would go away, and that all of a sudden a relatively simple model would appear that matched the standard model. One can't logically rule such a thing out, but believing in its existence at this point is pure wishful thinking.

33. **Eric**
November 6, 2010

Mitchell,

It's not really true that you can't calculate much reliably in a given string compactification. For example, in Type II string theory with D-branes on toroidal orientifolds, all parameters such as gauge and Yukawa couplings can be calculated reliably. Additionally, there are string models which strongly resemble the Standard Model. The problem is really of uniqueness. In order to fix the values of parameters such as couplings, the problem of moduli-stabilization must be addressed. This is on top of the problem of the huge number of possible vacua. Peter is right that the so-called top-down approach by which the Standard Model may be derived uniquely from string theory has thus far failed. However, the 'bottom-up' approach is alive and well.

Recent Hot Topics in Hep-th

November 4, 2010
Categories: Uncategorized

SLAC's SPIRES database has a link you can use to search for articles heavily cited during 2009 and 2010. Just looking at the hep-th papers, three are review articles of older work on applying AdS/CFT to condensed matter physics, three are about Erik Verlinde's claims that gravity is an "entropic force", and the rest are about Petr Horava's non-relativistic theory of quantum gravity.

The story of hep-th in 2009/10 seems to be that the only new ideas getting attention are ones coming from prominent string theorists who have become apostates advocating non-string theory approaches to quantum gravity. The idea of getting gravity out of simple thermodynamics didn't get much attention back in 1995 when Ted Jacobson was discussing it, partly because it didn't seem to go anywhere, partly because the conventional wisdom was that the spin-two massless mode of a string was the reason for gravity. Now that, fifteen years later, a prominent string theorist is promoting the idea (see his recent Harvard colloquium on the topic here), it is getting a lot of attention.

Those abandoning string theory as an explanation for quantum gravity do need to be careful in how they describe what they are doing; see for example the first part of the most heavily cited hep-th paper of 2009 (Horava's), which begins as follows:

> In recent decades, string theory has become the dominant paradigm for addressing questions of quantum gravity. There are many indications suggesting that string theory is sufficiently rich to contain the answers to many puzzles, such as the information paradox or the statistical interpretation of black hole entropy. Yet, string theory is also a rather large theory, possibly with a huge landscape of vacua, each of which leads to a scenario for the history of the universe which may or may not resemble ours. Given this richness of string theory, it might even be logical to adopt the perspective in which string theory is not a candidate for a unique theory of the universe, but represents instead a natural extension and logical completion of quantum field theory. In this picture, string theory would be viewed—just as quantum field theory—as a powerful technological framework, and not as a single theory.
>
> If string theory is such an apparently vast structure, it seems natural to ask whether quantum gravitational phenomena in 3 +1 spacetime dimensions can be studied in a self-contained manner in a ''smaller'' framework. A useful example of such a phenomenon is given by Yang-Mills gauge theories in 3 + 1 dimensions. While string theory is clearly a powerful technique for studying properties of Yang-Mills theories, their embedding into string theory is not required for their completeness: In 3 + 1 dimensions, they are UV complete in the framework of quantum field theory.
>
> In analogy with Yang-Mills, we are motivated to look for a ''small'' theory of quantum gravity in 3 + 1 dimensions, decoupled from strings.

Update: A commenter points out that Verlinde has just received a 2 million euro grant to support this kind of research, more info available here.

Comments

1. **Anonymous**
   November 4, 2010

   What a great analogy of Yang-Mills! 🙂

   Entropic gravity and Lifshitz gravity indicate that the subfield known as quantum gravity may enter a "model-building" era, as opposed to "formal" approaches like superstring theory. Yet another possibility is that with continued frustration, this subfield will shrink and become non-mainstream, much like how so few people are working on the million-dollar Yang-Mills existence problem because they don't see any hope of success.

2. **anon.**
   November 4, 2010

   It's a little odd to call these "hot topics". I think it's more that they're relatively non-technical ideas that are easy to work on, so they've been latched onto by not-very-competent people mostly in countries where publishing a large number of papers is required for employment but publishing quality papers is not. Horava-Lifshitz gravity, in particular, seems to be looked askance at by most good people. This isn't because of prejudice against non-stringy ideas but because the field has already had a few iterations of clever modified gravity ideas and, through painful trial and error, learned the lesson that they almost all fail in a universal way. So few people were surprised when it turned out that H-L gravity has the usual problem. More recently people (including those who successfully found the expected problem) have claimed to modify it in ways that make it sensible, at least at a linearized level. I would bet that the problems are still lurking in the background, waiting for someone to do a more careful analysis. If not, then I think if anyone really convincingly shows they are absent, the field would pay attention.

   My assessment would be that there *are* no hot topics at the moment. The only recent big advances of high quality are being made in technical areas with a high barrier to entry, so they're not picking up huge citation counts. In the hep-ph world, driven by experimental results, light (5 to 10 GeV-ish) dark matter is trending toward being a hot topic.

3. **Anonymous**
   November 4, 2010

   The only recent big advances of high quality are being made in technical areas with a high barrier to entry, so they're not picking up huge citation counts.

   What's your list, or a few examples, of these big advances?

4. **a**
   November 4, 2010

   What about http://arxiv.org/abs/0906.3219 and http://arxiv.org/abs/0901.3753 ?

   Somehow you don't mention these two recent developments, quite convenient indeed…

5. **Peter Woit**
   November 4, 2010

   a,

   The reason is simply that they don't appear in the SLAC recent topcites list I linked to. The Horava paper, of similar vintage, has about four times as many citations.

6. **Marcus**
November 4, 2010

There could be some problem with the Spires search because you asked for 100+ topicites with date = 2009. And the Alday et al paper mentioned by "a" has 111 cites (according to Spires.)

Since Spires knows that http://arxiv.org/abs/0906.3219 got 111 cites, why would it not have included it on the list? Looks like a bug in the search engine to me. (Certainly not an intentional omission on anyone's part.)

7. **Marcus**
November 5, 2010

The other 2009 paper that "a" mentioned is this:
http://www.slac.stanford.edu/spires/find/hep/www?rawcmd=FIND+EPRINT+0901.3753
and it did not meet the search requirements, so there was no error.

You asked that 2009 papers have 100+ cites and this one has 97.
=============

What puzzles me is
http://www.slac.stanford.edu/spires/find/hep/www?rawcmd=FIND+EPRINT+0906.3219
with 111 cites.
It fits the terms you defined but did not appear on the list.

8. **Marcus**
November 5, 2010

There appears to be something wrong with the record for that paper.
When I tell Spires
FIND A GAIOTTO AND DATE 2009
then it finds the paper. (but says it is 50+ cites when it should say 100+)

On the other hand when I tell Spires
FIND A ALDAY AND DATE 2009
it does not find the paper at all.

Somebody should tell Alday about this so that he can write to Spires and get the record of his paper corrected.

Everybody benefits from the reliable operation of a database like that so we should thank "a" despite his sarcastic and suspicious tone of comment, for revealing the flaw 😀

9. **Bee**
November 5, 2010

I don't think the reason Verlinde's paper got so much attention is that he's a string theorist. It's just that he's formulated his claim by using only a handful of simple equations. Or possibly because people had nothing better to do.

10. **Peter Woit**
November 5, 2010

Marcus,

There are other examples easily found of papers with a bit more than 100 citations that are topcite 50, not topcite 100. I suspect that this is because they only periodically go through the whole database to update the topcite status. If so, this just means that for a 2009 paper to make the SLAC recent topcites list, it needs not just more than 100 citations now, but this had to be true a few weeks ago.

11. **anon.**
November 5, 2010

Anonymous asked:

What's your list, or a few examples, of these big advances?

Definitely the things "a" linked to: Alday/Gaiotto/Tachikawa (which I'm a little surprised has 100+ citations, but good for them!) and integrability. Plus other work of Gaiotto on N=2 supersymmetric field theories. Also progress in relating scattering amplitudes with Wilson loops, Grassmannian representations of N=4 amplitudes, continued advances in using twistors and momentum twistors, improved understanding of consistency conditions in supergravity… Probably there's a lot more that isn't coming to mind, since I'm not actively involved in any of these things. I would say there's been steady and significant progress in technical aspects of understanding quantum field theories, especially highly supersymmetric ones, for the last few years.

12. **BS**
November 5, 2010

Hi Peter, have you heard of the ERC grant for Erik Verlinde? This is quite a big success for him and the University of Amsterdam. Although I was very surprised to see that the research will be about emergent gravity.
http://www.science.uva.nl/english/home.cfm/7BA87E2C-CC3F-4C2A-84FA5A77B6AD6B27

13. **Peter Woit**
November 5, 2010

Thanks BS. I had seen from Verlinde's twitter feed that he got the grant, but had assumed it was one or two orders of magnitude smaller in size. $3 million or so is a huge amount for a grant of this sort. So, "entropic gravity" is now not only a hot-topic, but an extremely well-funded one….

14. **Vince**

November 5, 2010

Has anyone read this paper:
http://arxiv.org/abs/1009.5414

If there's nothing wrong with it, why is entropic gravity being funded?

15. **somebody**
November 5, 2010

Entropic gravity is really nonsense. I have tried to read the paper giving Verlinde the maximum leverage in what he *could have* meant, and I still can't come up with anything useful. Everything that was worth saying there was already said by Jacobson long ago. (In my opinion, of course!)

On the other hand, Horava's theory, you have to give him credit for trying something new… even if it is also likely to be unsalvageably wrong.

16. **Kea**
November 5, 2010

And will Verlinde give some of the money to all the starving people who have been working on related ideas for decades?

17. **Mitchell Porter**
November 6, 2010

In Erik Verlinde's recent talk at KITP, starting at 31 minutes, he switches to a non-entropic perspective involving individual pure states rather than ensembles of them. Listen especially to the start of the 37th minute, where he says that under the right conditions, ergodic motion in a phase space would be macroscopically indistinguishable from a genuine thermal state. So it looks as if he's moved to a deeper perspective that might evade the Motl-Kobakhidze argument.

18. **MathPhys**
November 6, 2010

"And will Verlinde give some of the money to all the starving people who have been working on related ideas for decades?"

When I read what Padmanabhan writes on the topic, I feel that there is probably a point to it.

Simons Center Inaugural Conference

November 5, 2010
Categories: Uncategorized

I was out in Stony Brook for the past couple days, to attend festivities surrounding the inauguration of the new building there which will house the [Simons Center for Geometry and Physics](). The Center is funded by Jim Simons, whose Renaissance Technologies is one of the world's most successful hedge funds. The plan is to ultimately have six permanent members (half in physics, half in math) and a director, as well as quite a few postdocs and visitors. The founding director of the center is John Morgan, who until recently was my colleague here in the math department at Columbia. Mike Douglas is a permanent member in physics, current and recent senior visitors include Nikita Nekrasov and Graeme Segal.

The building is quite attractive, with the two lower floors forming a public area that includes two auditoriums, an atrium and a dining area which will serve lunch and bring together the local math and physics communities. The three upper floors have offices and seminar rooms. Construction is nearly finished, but not quite, with part of the ground floor still walled off for some last-minute work. The atrium features a large mural containing a selection of historically important equations, the choice of which evidently was a major undertaking. Guests noted one typo, but luckily the current mural is a temporary printed one, with the plan to cut the equations in stone not yet implemented.

Tuesday night featured a gala opening event, with music provided by the Emerson quartet, and short speeches from various dignitaries. Simons was presented with an original edition of one of the works of Isaac Newton, with the comment that he had shown much greater success than Newton at turning things into gold. He gave a wonderful talk describing the early stages of interaction between math and physics that he was involved in as chair of the math department at Stony Brook in the early seventies. Evidently soon after his arrival he was invited to meet with Frank Yang, who had just started up an institute for theoretical physics there. Yang described his current research on gauge theory, which Simons claims to not have understood a word of. The same thing happened again a year later. However, the third time this happened, Simons all of a sudden realized that what Yang was talking about was something that geometers knew very well: a connection in a principal bundle. This led to a series of lunch-time lectures by Simons to the physicists, to visitor Is Singer getting interested and taking what he learned back to MIT and Atiyah at Oxford, and finally to the modern period of interaction between math and physics that began in the mid-seventies centered around questions related to instantons.

On Wednesday, the Simons Center hosted a day-long [inaugural conference]() (videos and slides of talks should appear on their web-site at some point). Appropriately, the first talk was an inspirational one from Michael Atiyah, going over a wide variety of different mathematical ideas. One theme was the quaternions, with Atiyah pointing out that Hamilton had written down a square-root of the Laplacian many decades before this trick was re-discovered by Dirac in writing down the Dirac equation. After recalling the relation between the division algebras (real and complex numbers, quaternions, octonions) and the Hopf invariant one problem, Atiyah suggested that the [Freudenthal magic square]() has a similar relationship to the Kervaire invariant one problem, with the recent complicated proof by Hopkins et al. an analog of the original Adams proof in the Hopf case, with the analog of Atiyah's "postcard proof" still to be discovered. He ended with some comments about ideas of Alain Connes about non-commutative geometry and the Riemann hypothesis, and suggested that the conjectured self-adjoint operator that could explain the Riemann hypothesis might be the Hamiltonian of quantum gravity. I noticed that Atiyah was supposed to be giving a talk at the IAS today with the impressive title of "Quantum Gravity and the Riemann Hypothesis", but it appears to have been canceled.

The second morning talk was a rather rambling and elementary one by Polyakov about topics related to Wick rotation, ending with the claim that in the gravitational case the usual ideas about Wick rotation fail and this has something to do with explaining the cosmological constant. The afternoon began with a talk by my colleague Andrei Okounkov using symplectic resolutions to study quantum cohomology, followed by Witten whose topic was "A New Look at Khovanov Homology". This talk covered similar material to the ones described [here](), involving a really beautiful story about various 3 and 4 dimensional topological quantum field theories. As in the earlier talks though, at the end there's a transition to 5 and 6 dimensional theories where I got just as lost as before. I had been hoping that the Simons Center talk would explain the ideas I was missing, but I fear that there's no way around digging into the details in Witten's [recent paper]() about this. The last talk was by Cumrun Vafa, who gave a very nice and elementary discussion of the "wall-crossing" phenomena in certain 2d qfts, as motivation for recent work on wall-crossing in 4d gauge theories.

The talks were uniformly of very high quality, it's wonderful to see that the Simons Center is off to a great start.

Update: I just did take another look at Witten's recent paper, and realized that the part involving 5 and 6 dimensional theories is not there, but in a paper in progress on "Five-branes and Knots". So, that story will just have to wait for now…

   Walked out my door this morning, fired a bugler, palmed a handful of sand and said in lingua franca "Gee, how almost perfectly god damn delightful it is to be right."

   Just a nod from the not so tenured and noble for your work, expressions and teachings.

   Thank you

2. **Jim**
   November 6, 2010

   Great new ctr for theoretical physics, only one sad note.
   There are no stipends or fellowships for grad students.
   Seems hard to believe such a small contingent could get
   anything significant done.

3. **Ken Yokoyama**
   November 7, 2010

   Regretably!

   > Atiyah was supposed to be giving a talk at the IAS today with the > impressive title of "Quantum Gravity and the Riemann
   > Hypothesis", but it appears to have been canceled.

4. **Peter Woit**
   November 7, 2010

   Jim,

   The center won't teach classes or have its own students, but I'm sure Stony Brook physics and math grad students will participate in its activities, and they are already funded. Given the huge imbalance already existing between the number of students in this field and the number of jobs for them, funding more students isn't really a good idea.

5. **The Vlad**
   November 7, 2010

   @Peter Woit

   That's a viewpoint framed with the welfare of potential students in mind. Yet I would have thought you would be encouraging funding for more students and post-docs. After all, if the field is as stuck as you say it is, and assuming younger researchers (students/post-docs) are the most likely source of a major breakthrough, isn't it better to have more of them?

6. **Peter Woit**
   November 7, 2010

   The Vlad,

   More is not necessarily better. I don't see much evidence that really good people can't get into Ph.D. programs because there are too few grad student positions being funded.

   The post-doc situation is much more complicated. One aspect of it is that you need post-doc jobs structured so as to recruit the kind of person able to make a big advance, and give them an environment and time to do this. The Simons Center should be a good place for this. More post-docs, of the right kind, might be a good idea, but the mismatch between numbers of these jobs and numbers of permanent jobs will continue to be a problem worth worrying about.

    Would love to hear or read the Atiyah talk, I wonder if it'll be available anywhere.

Once Before Time

November 8, 2010
Categories: Book Reviews

There's a new popular book out this week entitled Once Before Time: a whole story of the universe, by Martin Bojowald, promoting his ideas about "Loop Quantum Cosmology". It's a translation of the original German edition, Zuruck vor den Urknall, published last year.

The topic of the book is work by Bojowald on toy models using loop quantum gravity that avoid the Big Bang initial singularity of classical general relativity. For a much shorter version of all this, see his 2008 Scientific American cover story Big Bang or Big Bounce?

There's a very deep human desire to understand origins and thus to trace the history of the universe back before the earliest periods for which cosmological theory and observations have provided some degree of scientific understanding. Unfortunately this has led in recent years to a flood of over-hyped claims by physicists claiming to have a scientifically viable theory of what happened "Before the Big Bang". To qualify as legitimate science, such claims need to be backed up by some conventional sort of evidence. This might take the form of experimental predictions, testable either now or in principle in the future. It might also take the form of a highly constrained and beautiful theory whose success in other realms makes a compelling case that it could also explain experimentally inaccessible phenomena. I don't know of any example of such pre-Big Bang scenarios now being sold to the public that comes even close to having such backing.

The cover of Bojowald's book tells us about Loop Quantum Cosmology:

> Now the theory is poised to formulate hypotheses we can actually test.

I'm no sure exactly what that is supposed to mean, but it appears to be misleading hype, not corresponding to anything actually in the book. The text of the book itself wavers back and forth, sometimes explaining the overwhelming problems one faces if trying to extract some kind of prediction out of the LQC framework and emphasizing how speculative it all is, at other times expressing ungrounded optimism that somehow these problems will be overcome. It ends on an upbeat, hopeful note

> Will we ever, with a precision that meets scientific standards, see the shape of the universe before the big bang? The answer to such questions remains open. We have a multitude of indications and mathematical models for what might have happened. A diverse set of results within quantum gravity has revealed different phenomena important for revealing what happened at the big bang. But for a reliable extrapolation, parameters would be required with a precision far out of reach of current measurement accuracies. This does not, however, mean that it is impossible to answer questions about the complete prehistory of the universe. Cosmology as well as theoretical investigations are currently moving forward and will result in unforeseen insights. Among them might well be experimentally confirmed knowledge of the universe before the big bang.

but I found nothing in the book to justify this optimism. The few allusions to specific attempts to find some relation to something observable are vague and suffer from the book's nearly complete lack of any references to more technical sources of information.

About fifteen years ago, in The End of Science, John Horgan described the field of fundamental physics as degenerating into what he called "ironic science", something more like literature, art or philosophy than traditional science, pursued in a "speculative post-empirical mode". At the time I thought he was going too far, but Bojowald's book provides an unfortunate confirmation of the phenomenon Horgan was describing. It's written in a rather dense and sometimes impenetrable style, featuring quotations from Nietzsche, some science-fiction set off in italics, and a few pictures of contemporary art-works supposedly relevant to the argument. Attempts are made to claim a role for pre-Socratic philosophy, with LQC finally providing a means of going beyond the pre-Socratics:

> Otherwise, one can find among the pre-Socratics most of the elements of modern cosmology. Only with quantum gravity did truly new elements enter the game.

Aficionados of the loop quantum gravity – string wars will find various accurate comments about string theory and the sociology of science, and Bojowald also describes an interesting insider's point of view on the story of the development of loop quantum gravity and the scientific figures behind it. He's quite right that it's a fascinating possible approach to quantum gravity well worth pursuing, but the applications to cosmology seem to me not even close to being ready for prime-time and this kind of treatment in a popular book.

Update: There's a review by Brian Clegg at the Wall Street Journal here.

   Observing the Big Bounce with Tensor Modes in the Cosmic Microwave Background: Phenomenology and Fundamental LQC Parameters
   Julien Grain, A. Barrau, T. Cailleteau, J. Mielczarek
   12 pages, 5 figures
   (Submitted on 8 Nov 2010)
   "Cosmological models where the standard Big Bang is replaced by a bounce have been studied for decades. The situation has however dramatically changed in the last years for two reasons. First, because new ways to probe the early Universe have emerged, in particular thanks to the Cosmic Microwave Background (CMB). Second, because some well grounded theories — especially Loop Quantum Cosmology — unambiguously predict a bounce, at least for homogeneous models. In this article, we investigate into the details the phenomenological parameters that could be constrained or measured by next-generation B-mode CMB experiments. We point out that an important observational window could be opened. We then show that those constraints can be converted into very meaningful limits on the fundamental Loop Quantum Cosmology (LQC) parameters. This establishes the early universe as an invaluable quantum gravity laboratory."

2. **Peter Woit**
   November 8, 2010

   Marcus,

   Seriously evaluating that paper requires more time and expertise than I have available. A quick look at it though indicates that it is discussing the possibility of features in a possible B-mode power spectrum in the CMB that would differentiate between a conventional inflationary potential scenario, and an LQC-inspired one. LQC doesn't seem to give any actual prediction of the size of these features, that's a free paramater.

   At this point, there's no observation of CMB B-modes at all, and these authors don't seem to be claiming relevance to anything measurable by current experiments

(Planck). So, the bottom line is that some possible next generation experiments (how many years out?) might see not only the power spectrum predicted by inflation, but some variation of this IF unknown numbers parametrizing our ignorance about LQC are in the right ranges.

I don't think any of that is much reason for optimism that we're going to be seeing pre-Big Bang effects anytime soon (or ever). But, even if Bojowald is much more optimistic, the fact remains that no specific results like that in this paper are described in the book. A serious description of CMB B-modes and the challenges of observing them and finding interesting signals in them would have made the book a lot more interesting.

3. **Marcus**
November 8, 2010

A serious description of CMB B-modes and the challenges of observing them and finding interesting signals in them would have made the book a lot more interesting.

A good point, Peter. Would make any book on the topic (LQG cosmology) more interesting. I haven't read Bojowald's book and can say nothing about it, but I have read the paper by Aurelien Barrau and friends. It's first rate.

4. **Daniel Tung**
November 9, 2010

Hmm..How about Penrose's book ? He also talked about the time before big bang, in which he suggested to be just the end of another period of universe, and that the same thing will happen to the end of our current universe.

5. **Bee**
November 9, 2010

Hi Peter,

You might find it interesting to check section 2.4.7 and 3.3 of my recent paper

http://arxiv.org/abs/1010.3420

It summarizes the work Marcus is also referring to. If you have a bounce scenario, the bounce would leave a distinct signal in the tensor mode spectrum. That is in principle observable, though, as always, it will eventually only constrain the parameters of the model. In this regard, also have a look at this paper for constraints from presently available data

http://arxiv.org/abs/1007.2396

Now one might plausibly say that the range in which the model can be tested is so far not a particularly strong constraint, but at least it's something. Best,

B.

6. **Tim van Beek**
November 9, 2010

> …the applications to cosmology seem to me not even close to being ready for prime-time and this kind of treatment in a popular book.

Here is what I know from newspaper stories published in Germany last year: Bojowald did LQC calcuations about the big bang for his PhD, which is an acceptable topic in the sense that the PhD candidate can prove that he/she understands some physics and can do reasearch/calculations on his/her own.

Then, for reasons unkown to me, several newspapers interviewed him or published articles about this work: My impression is that people simply wanted to publish something about theoretical physics for a change, and Bojowald's work held the promise to be interesting because it is about the "origin of the universe and everything". It would seem that some publisher succeeded in convincing Bojowald to use the ensuing publicity to write just another "popular science" book about highly speculative ideas that no one needs 🙁

Well, Bojowald *did* write an interesting (to theoretical physicists!) survey of this area in living reviews:
Loop Quantum Cosmology.

7. **Physicsphile**
November 9, 2010

I haven't read the book or the paper, but its fair to say the CMB B-modes potentially offer a unique new window into the early Universe. But, Unfortunately, their amplitude will probably be too small for us to ever detect.

8. **Marcus**
November 9, 2010

Here are white papers/websites discussing the proposed B-pol and CMBpol missions

http://cmbpol.uchicago.edu/
http://www.b-pol.org/index.php

There you can see what kind of time-frame and instrumentation they are talking about.

9. **Peter Woit**
November 9, 2010

Thanks Bee,

I just took another look at the book to see if I missed something. The section discussing possible early universe experimental tests is about four pages long and very vague. No specific mention of B-mode polarization at all (earlier in the book there's a vague mention of CMB polarization).

10. **Anonymous**
November 9, 2010

Horgan's "The End of Science" is really the end of Moore's law for science, the end of "one revolution after another" exponential growth for science, which prevailed the

20th century but can’t possibly sustain forever.

11. **k97**
November 9, 2010

“Now the theory is poised to formulate hypotheses we can actually test.”

How is any of this different from Kane 1997 or Kane 2010?

12. **Marcus**
November 9, 2010

How is any of this different from Kane 1997 or Kane 2010?

Rhetorical question? I haven’t read the book and I suspect neither have you, so we can’t actually tell *how it is different* (if it is different in kind) out of context.

One obvious difference COULD arise if Bojowald should point to a small body of literature by phenomenologists/observational cosmologists. I know of about a dozen papers along similar lines as the latest by Barrau and friends. The authors are not Loop community—they write about observational testing of other stuff including string.

Obviously Barrau would like to see the B-Pol mission funded. It was a proposal for the 2015-2025 timeframe, in response to a NASA call for proposals.

In the current economic condition what is going to happen to projects which take a closer look at the CMB?

I am not advocating. You asked *what is the difference*. I am replying that there is a hard dollar bread-butter difference. Personally I don’t think Kane 2010 was talking about one specific testing project, like putting one specific CMB observatory in orbit. In the 2015-2025 timeframe. Check the B-Pol mission link out for concrete detail.

So I think in answer to your question that if there is a difference, it is probably a difference in the degree of concreteness. And I think that Bojowald and Barrau and others are going to have to build on that, and make that point, if they are going to get Lqc early universe models tested by observation, or any other early universe models, in the present economic/political situation.

13. **Bee**
November 10, 2010

Hi Peter,

Well, I think the results are fairly new, so possible he just didn’t have them when the book was written. Best,

B.

14. **Peter Woit**
November 10, 2010

Bee,

Maybe that’s it, but then it’s still somewhat of a mystery why the cover of the book claims that LQC was “poised to formulate hypotheses we can actually test”, since I haven’t heard of any others besides the B-mode ones, and couldn’t find any in the book.

15. **cormac**
November 10, 2010

It’s not a great translation of the title, is it?

16. **chris**
November 12, 2010

Peter,

I really like your scepticism against all sorts of hype – not just string related. it is good to see that among all the “publish or perish” crazieness that has gotten hold of high energy during the dire dataless decades there is still a voice of reason.

LQG people are amazing. after 20 years without being able to find the Hamiltonian constraint they still feel superior to string theorists and point at their lack of progress.

17. **Marcus**
November 12, 2010

chris,
Please try to keep your comments reality-based 😀

LQG people are amazing. after 20 years without being able to find the Hamiltonian constraint they still feel superior to string theorists and point at their lack of progress.

I don’t see Loop researchers “pointing the finger” at stringers. They have plenty to do in their own field, and some temporarily cross over now and then if they see an interesting stringy problem to tackle. Can you cite some recent instance of finger-pointing?

There may or may not be some inner feelings of good fortune, or of having a superior rate of progress, but it’s hard to tell inner feelings. Every Loops conference so far has had a plenary talk by a string theorist. Could be their respect and openness is good policy.

The progress in Loop just in the past three years 2008-2010 has been remarkable. Approaches have converged and what has emerged is looking very much like coherent theory ready for testing.
See for example 1004.1780 and 1010.1939

Something that could, in fact, be falsified by astrophysical observation. But I think it would be naive to start making bets at this stage. My attitude is to keep my eyes open, watch the scene develop, and refrain from trying to pick winners. Emotional/partisan statements tend to sound stupid to me.

18. **Marcus**
November 12, 2010

I forgot. Loops 2009 in Beijing broke that pattern. They didn't have a plenary talk by someone from the string community at that conference. Otherwise it's been a regular custom starting in 2005 with Robbert Dijkgraaf. Just a little thing–may not seem very important to you if you have a "two-camps" mentality.

19. **Bob**
November 13, 2010

Marcus, no-one in the field will take the Mielczarek et al calculations seriously – from what I understand even among the LQC cohort he's considered a joke.

20. **Moore**
November 14, 2010

Horgan published a brief update to the End of Science in Discover magazine a few years ago for those interested:

http://tinyurl.com/323dfub

No, he doesn't really give any ground; yes, he references this blog.

21. **stavrogin**
November 14, 2010

marcus cites two of rovelli's papers as a proof of how a coherent picture is emerging in LQG. These papers have absolutely nothing to do with hamiltonian constraint of LQG. These works are summerising recent progress in spin foam models whose relation to canonical LQG to put it modestly, quite overhyped.

22. **Marcus**
November 14, 2010

Bob, what you posted is absurd. Mielczarek is not the lead author of the paper I mentioned, which follows in a line of some half-dozen by Barrau and Grain. Barrau is the senior author. Grain started out working with him when he was a PhD student as I recall.

The Barrau Grain papers are taken seriously, and cited, by LQC folks last time I checked. You can probably find a citation by Ashtekar.

The third author Cailleteau of the paper I mentioned is I believe a PhD student of Barrau, or postdoc working with him.

I don't remember seeing Mielczarek's earlier work (before this collaboration) cited in Loop papers, so can't offer an opinion, but it is irrelevant since this paper is out of Barrau's group.

Barrau gave a talk on this at ICHEP 2010 in Paris this summer.

Here is a 7 page paper on the topic published by Physical Review Letters if you want a sample:
http://arXiv.org/abs/0902.0145
Cosmological footprints of loop quantum gravity

Have to say, Bob, that your post strikes me as dishonest to the point of being mildly disgusting. Thanks for the opportunity to reply.

23. **Marcus**
November 14, 2010

Stavrogin,
What I said was *Approaches have converged and what has emerged is looking very much like coherent theory ready for testing.
See for example 1004.1780 and 1010.1939*

There has been considerable convergence of spinfoam LQG with the older canonical version. This is detailed in the two papers I mention here, which constitute a brief status report. The application to cosmology is now being based on the spinfoam ("path integral") formulation as you can see from recent papers by Ashtekar, Rovelli and others.

I haven't seen any claims that the convergence is complete or that there is an exact equivalence. Why don't you see if you can find some statement about it in either of those two papers which you would call "hype"? It has been an important trend, to which Lewandowski's work has contributed a lot, but the statements reporting on it that I have seen in the research literature have been amply qualified and rather cautiously worded. See if you can find a sample of "hype" to show us.

I think the main point to make is that the picture with (esp. spinfoam) LQG and its application to cosmology has changed significantly in the past couple of years and that there is a robust implication for cosmology that looks testable. (See Bee Hossenfelder's comments earlier.)

24. **Peter Woit**
November 14, 2010

Bojowald has a new paper out this evening claiming something about falsifiable predictions about the CMB based on LQC. It's

http://arxiv.org/pdf/1011.2779

and it's hard to compare its claims to those of the recent paper Marcus referred to, since Bojowald doesn't refer to it.

I agree with Marcus's general evaluation of comments like that of "Bob", and had thought of deleting that comment. Please, do not use anonymity to engage in personal attacks.

I took a quick look at the new Bojowald paper, but it looks like it would take a lot more time to figure out whether there's a there there than I have the willingness to devote to such a project. By now there's a long history of claims about quantum gravity imprints in the CMB. Some of the first I paid attention to were those of my colleague Brian Greene and his collaborators ten years ago

http://arxiv.org/abs/hep-th/0104102

I'm afraid I'm still a skeptic about all efforts of this kind. The information so far read off of the CMB is impressive, but corresponds to relatively low-energy physics, very far from telling us about higher energies scales, much less the Planck scale.

25. **Terra**
November 17, 2010

The proliferation of QG models in which we can actually compute things (that includes strings, LQG, and a number of other approaches) has lead us to believe that quantum gravity respects unitarity — since we've got no idea how we'd do quantum calculations without unitarity, we're like a bunch of drunks searching for our keys under the streetlight, because that's where the light is.

(Although most people work with orthogonal basis sets, unitarity is the property that's actually needed for a basis set to work… It's very possible to work with phase space representations that aren't orthogonal, although you open up another can of worms when you do that.)

Anyhow, if you believe in unitarity, there's no information loss in a black hole, no singularity in a black hole, and no singularity at the beginning of the universe…. These results hold up whatever model you're using.

Paul Ginsparg wrote an editorial where he pointed out that we don't have any proof that QG (in the real world) respects unitarity — all of the QG approaches we have now are still castles in the air. On the other hand, if you believe in unitarity, you get such wonderful results that it's hard to give up.

Of course, that's the tragedy of modern physics; the interior of black holes is one of the most exciting things right now, but nobody will ever get to go inside one, see what it's like and tell us the tale. 😉

This and That

November 9, 2010
Categories: Experimental HEP News, Langlands, Uncategorized

- There's a new preprint here explaining the scientific case for running the Tevatron past 2011. A couple weeks ago the P5 subpanel came out with its report on the subject, generating news stories "Momentum builds for Tevatron extension" and "Panel Wants U.S. to Chase 'God Particle'—If There's Money". The panel recommended extending the Tevatron run, but only if another $35 million/year in additional federal funding was provided to do it. Prospects for this are very unclear, with the next stage in the process a decision about whether to include this in the President's DOE budget request for FY2012, due next February.

The US for a long time now has operated under a bizarre budgeting system, where government agencies typically spend much of the time operating without a budget. FY 2011 began October 1, with the Congress still far from having come up with a FY 2011 budget, instead operating the government on a series of "continuing resolutions", which allow spending at the FY 2010 level. The latest of these expires December 3, after which there will undoubtedly be another one. Sooner or later an "omnibus bill" setting the actual budget will presumably get passed and one might think the result would correspond to the levels set by the appropriation committees of the House and Senate (which contain an increase of FY 2010 levels). Every other year though is an election year, so the Congress that had left town for weeks to campaign comes back after a post-election rest as a lame-duck organization, with lots of its members pushing for delaying everything until next year if their side did well in the election. This year the Republicans did very well at the polls arguing that the government spends too much money on "discretionary" things. Unfortunately for HEP, it's in the relatively small "discretionary" part of the budget. There will undoubtedly be a strong push from the Republicans to not wait for FY 2012, but to start cutting this year's budget, in the middle of the fiscal year. Given the dysfunctional nature of the US political system, it's anybody's guess how this will turn out. For comments from the Fermilab director about this situation, see here.

- One organization that doesn't have to worry about federal funding is FQXI, which was initially funded by the Templeton Foundation with a grant that was supposed to take them through the end of last year. I don't know where their money is coming from these days, but they have recently announced a new essay contest carrying $40,000 or so in prize money (the Gruber Foundation is one sponsor), on the topic "Is Reality Digital or Analog?".

Among other FQXI activities, next August its members will go on a cruise during which they will discuss foundational questions related to the nature of time.

- The LHC proton-proton run has ended for 2010, with an integrated luminosity of about 45 inverse picobarns. The plan is to restart around February 4 and collide protons for 9 months in 2011. It's possible that the energy of the beams will be raised from 3.5 TeV to 4 TeV. Detailed plans will be made at workshops at Evian and Chamonix (January 24-28). For recent news and some idea of long term plans, see this talk at the US LHC users organization meeting. It has the LHC shutdown to replace splices from December 2011-March 2013, and another long shutdown for a luminosity upgrade in 2016. In the very long term, there are discussions of upgrading the machine with new, higher field magnets that would allow operation at 16.5 TeV/beam, but this is probably about 20 years off…
- The theorists at CERN have been retreating, see here.
- There's an interview with Steven Weinberg in Scientific American, see here.
- Nature Physics has a review by Eva Silverstein of the Yau/Nadis book (that I discussed here).
- See Dennis Gaitgory's website here for some notes in progress on geometric Langlands.

Update:
One more: An interesting diavlog between Lee Smolin and Robert Wright at the Big Questions Online site.

Update: Tommaso Dorigo has a critical discussion of the paper making the case for an extended Tevatron run.

Comments

1. **Seth Thatcher**
   November 9, 2010

   Peter,
   Physics is my hobby, but politics is my area of expertise. Our system of budgeting is strange indeed. I am pleased with the direction of the mid-term elections and I expect to see spending dramatically decreased going forward. But, politicians have a way of disappointing. I write this post, however, to put forth the idea that funding the Tevatron is no run of the mill congressional earmark. It is one of the truly necessary and fruitful federal expenditures. How can we leave real science unfunded or underfunded when there is so much good that can come from it. Also, there is much pseudo-science being generated these days as you point out regularly. Let's not let crackpot science get any better foothold than it already has. In my humble opinion, we should give the Tevatron the funding it seeks. Let's find the Higgs first (if it exists)! A little scientific competitiveness is a good thing.

2. **bmenrigh**
   November 10, 2010

   @Seth

   I agree and I'm sure most readers on this site agree. It seems unlikely that Congress will agree though…

   Let's hope they do!

3. **DB**
   November 10, 2010

   Killing off the Tevatron is part of a bigger picture: putting the nail in the coffin of any grandiose plans that may exist to build expensive new accelerators on US soil.

   Killing off Constellation served a similar purpose in relation to NASA.

   However, the US will remain the world leader in String Theory, of that you may be certain.

4. **Kris Krogh**
   November 10, 2010

   The interview with Lee Smolin was refreshing, particularly his comments on time. His colleague, Carlo Rovelli, argues it is only an illusion and has claimed for years that loop quantum gravity will solve the "problem of time" by making time go away completely. (Reminds me of Frank Wilczek's remark that "String theory is promising. And promising, and promising.") Smolin takes the opposite (less fashionable) position that time may be something we need to accept as truly fundamental.

5. **Shantanu**
   November 11, 2010

Peter, any comments/interesting stuff about the conference
http://www.pirsa.org/C10023
which has talks by Weinberg (among others)?
shantanu

6. **Verified Armonyous**
November 11, 2010

Wow, no exclamation marks to spare for the outstanding performance of the LHC…A cold status report that would make jump any hypothetical student of yours into willing to work on high-energy Physics!

7. **Peter Woit**
November 11, 2010

VA,

Given that the projected total luminosity for 2010 was 100 inverse picobarns and they ended up with 45 or so, I don't think that a large number of exclamation points are really justified. They did get peak luminosities above their goal, and prospects for reaching their goal of 1000 inverse picobarns next year look good, but that's next year. I hope things work out well and they manage to reach that goal and more.

As for whether students should be excited about the future of HEP and go into it, that depends not on how much data the LHC produces, but what's in it. The time for exclamation points will be when there's a real non Standard-Model signature (or at least a solid SM Higgs signal).

8. **Peter Shor**
November 12, 2010

I can give my view about the topic in the essay contest: Reality is quantum, which is both (and neither) digital nor analog, in the same way that an electron or a photon is both (and neither) a wave and a particle. I probably won't enter it, though.

9. **Shantanu**
November 13, 2010

Peter, any comments about the Miniboone result which may be confirming LSND result? Is this an exciting development for
particle physics?
http://arxiv.org/abs/1007.1150

10. **Peter Woit**
November 13, 2010

Shantanu,

No, I think you need a statistically more significant difference from the Standard Model (with neutrino masses) to get excited.

Massive

November 10, 2010
Categories: Book Reviews

There's a wonderful new book about particle physics that has just come out, [Massive:The Missing Particle that Sparked the Greatest Hunt in Science](), by Ian Sample, who is a science correspondent for the Guardian. The topic is the huge open question currently at the center of particle physics: is the Higgs mechanism the source of electroweak symmetry breaking (and, at the same time, the source of the mass terms in the Standard Model)? The Tevatron and the LHC are now in a race to either detect the Higgs particle or rule out its existence, with one alternative or the other very likely to come through within the next few years.

Truly explaining what the Higgs mechanism is can only be done with mathematics and physics background far beyond that expected in a popular book, but *Massive* makes a good try at it. Sample does a wonderful job of telling about the history behind this subject. He's the first writer I know of who has gotten Peter Higgs to tell his story in detail. The original paper on the subject by Higgs was rejected by Physics Letters, but ultimately published by Physical Review Letters. There's a complicated priority issue one can argue over and that someday soon a Nobel committee may need to resolve, involving Higgs, Englert, Brout, Guralnick, Hagen and Kibble. My personal opinion is that it was condensed matter theorist Philip Anderson who first understood and described the Higgs mechanism, quite a while before anyone else.

Sample's book is full of wonderful stories about particle physics, and alludes to some that he can't give the details of:

> On June 8,1978, Adams marked the achievement in extraordinary fashion. He jotted down a poem about Rubbia and Van der Meer's efforts and sent it out as a memo. The poem — too offensive to reprint here — suggested that Rubbia had exploited van der Meer's brilliance to further his own career.

The footnote to this says that the memo is in the CERN archive, dated June 8,1978 and entitled "Approval of ppbar facility".

One of the later parts of the story involves the discussion of Higgs rumors on particle physics blogs, and debates among the experimental collaborations about this. With a little bit of luck, we may hope to see more of this soon.

All in all, the book is a great read, by far this year's best popular book that could be recommended to lay people who want some idea of what's going on in particle physics now and why it is exciting.

Comments

1. **Nameless**
   November 10, 2010

   Here's the poem (I'm not sure what's offensive about it):

   Clever Simon met a Bagman,
   Leader of a Team.
   Said Clever Simon to the Bagman
   I can cool a beam.
   Bagman said to Clever Simon
   I can use this scheme.
   By being first and talking faster
   Bigman I will be.
   Clever Simon is Simon van der Meer and Bagman is Carlo Rubbia.

2. **More Nameless**
   November 10, 2010

   The above poem is correct. Beaten to the post by Nameless!
   Adams also said in public that Rubbia was the 'entrepreneur' of the ppbar project and that Rubbia was a 'CERN staff member and well known transatlantic commuter'. This was deemed extremely offensive and Adams was forced to apologize for the above, in August 1978.

   Sir John Adams was a master accelerator builder at CERN in its early days.
   He died in 1984, just at about the time the ppbar project came to fruition, producing the W and Z and making Rubbia a Nobel Prize winning Bigman.

   November 11, 2010

   "… the huge open question currently at the center of particle physics: is the Higgs mechanism the source of electroweak symmetry breaking (and, at the same time, the source of the mass terms in the Standard Model)?"

   It's not much of an "open question" if people are just searching for a Higgs boson in connection with electroweak symmetry breaking and particle mass! If Higgs is "the only game in town" on this subject, then it's a "closed question". Does the book give any discussion for alternative theories of mass? Does the book seriously discuss the physics implications if the *broken* (observed) electroweak "symmetry" is broken at all energies, i.e. if the speculative electroweak unification at 246 GeV (or whatever) doesn't occur? Does it clearly point out that the existing tests of the Standard Model with regard to electroweak unification merely validate the need for gauge boson mixing (not unification) of U(1) hypercharge and SU(2) isospin to produce the required vector bosons? The idea that electroweak symmetry may exist is much analogous to the "beautiful" mathematical idea of Plato that atoms must be regular geometric solids, or else God has missed a good idea. Well, God missed Plato's good idea. Until there is some evidence for electroweak unification beyond dreams, we should not limit our theories to one guesswork idea.

6. **Bugsy**
November 11, 2010

Adams died at 64; von Neumann and Feynman also died young. I have always wondered if exposure to radiation had anything to do with that….
maybe things weren't as safe back then as now?

7. **Seth Thatcher**
November 11, 2010

As a layman, I have been wondering why Higgs seems to get the honor when a simple reading of Wikipedia will show that others were first in theorizing the mediator of mass, if in fact it even exists. I was explaining this concept to my wife the other night as she drifted off to sleep. She made the mistake of saying something about CERN not realizing my deep interest in this subject. Well, lets just say it was like taking a sip of water from a firehose for her. I find these discussions utterly fascinating. Peter, thanks for the tip on the book and the blog.

8. **passb**
November 11, 2010

Phil Anderson's model was nonrelativistic (BCS and how the photon becomes effectively a massive field). Anderson never developed a relativistic model, although he may have made some statements that such a thing is possible. Also Anderson was (is?) terribly bigoted about HEP. Recall that Kobayashi and Maskawa were awarded the Nobel Prize, but Cabibbo was left out, despite Cabibbo clearly being first with a 2×2 matrix, and the 3×3 matrix is universally called the 'CKM matrix'. Cabibbo is a much clearer case of well-deserved priority. Many NP awards are controversial, even when the evidence seems clear.

9. **Nameless**
November 11, 2010

@cyd: anyone with real knowledge of this issue knows that extending Anderson's results from the condensed matter framework to the high energy one, namely, introducing the Lorentz group in the play, is a highly non-trivial task. This is, in fact, the reason why Anderson didn't do this himself.

Furthermore, Anderson's bigotry towards HEP just serves to murk the waters even more: if he ever made claims that this issue would be easily solved in HEP, he was wrong.

Aside from that, there's a very nice read on this topic, by one of its founders (Guralnik),

» "The History of the Guralnik, Hagen and Kibble development of the Theory of Spontaneous Symmetry Breaking and Gauge Particles", http://arxiv.org/abs/0907.3466

10. **Peter Woit**
November 11, 2010

Nameless,

One justification for Anderson's bigotry toward HEP might be the way HEP theorists handled references to his work. His 1963 paper clearly and explicitly laid out the physics of the Higgs mechanism (he claimed that this was independent of the issue of relativistic vs. non-relativistic, and was right). Among the 1964 papers, Higgs referred to Anderson, the rest didn't. Guralnik explains how he and collaborators dealt with this:

"At the same time, Kibble brought our attention to a paper by P.W. Anderson…. We did not change our paper to reference the Anderson work."

11. **Nameless**
November 11, 2010

@Peter,

For completeness' and context's sake, here's the full quote that you referred to (above), straight from the Guralnik paper I cited:

> At the same time, Kibble brought our attention to a paper by P.W. Anderson [26]. This paper points out that the theory of plasma oscillations is related to Schwinger's analysis of the possibility of having relativistic gauge invariant theories without massless vector particles. It suggests the possibility that the Goldstone theorem could be negated through this mechanism and goes on to discuss "degenerate vacuum types of theories" as a way to give gauge fields mass and the necessity of demonstrating that the "necessary conservation laws can be maintained." In general these comments are correct. However, as they stand, they are entirely without the analysis and verification needed to give them any credibility. These statements certainly did not show the calculational path to realize our theory and hence the unified electroweak theory. It certainly did not even suggest the existence of the boson now being searched for at Fermi lab and LHC. The actual verification that the same mechanism actually worked in non-relativistic condensed-matter theories as in relativistic QFT had to wait for the work of Lange [28], which was based on GHK. We did not change our paper to reference the Anderson work.

So, it's not that GHK simply ignored or hand-waived Anderson's work; quite the opposite, as Guralnik clearly explains above.

The bottom line is that you have to deal with PCT and Lorentz symmetries, and also Goldstone's theorem; and none of these play a role in condensed matter.

Thus, things are not as straightforward as they're made to sound…

12. **Nono**
November 11, 2010

> maybe things weren't as safe back then as now?

I don't know whether von Neumann or Feynman where significantly exposed to radiation, but Madam Curie and Fermi, to quote just two examples, were, and paid with their lives for it. Things were definitely not safe back then.

13. **Peter Woit**
November 11, 2010

Nameless,

After reading Guralnik's justification for not referring to Anderson, I went back and took a look at Anderson's paper. It's remarkably modern, with his understanding of the Higgs mechanism much as it's explained in textbooks today. I find Guralnik's excuses for not referring to it kind of ridiculous. It's rather rich that he and his co-authors have spent much of their lives complaining that other people don't refer to their work on this given the way they treated Anderson. I have no idea whether Anderson cared at all about this, but he would have been fully justified in being unhappy with their behavior.

14. **anon.**
November 11, 2010

The bottom line is that you have to deal with PCT and Lorentz symmetries, and also Goldstone's theorem; and none of these play a role in condensed matter.

Since when does Goldstone's theorem not play a role in condensed matter? Goldstone bosons are everywhere in condensed matter: phonons, magnons, ….

15. **Anonymous**
November 11, 2010

HEP is much more popular with mass media and attracts more bright young students. These are enough reasons to make condensed matter theorists feel bitter and under-acknowledged.

16. **famelessnameless**
November 12, 2010

Nameless:

Whatever Guralnik says, that's not an excuse to not even reference the paper! He could have referenced it, and could have pointed out whatever he wrote in the para of his that you quoted.

Not referencing such a paper once you're aware of it, and which is clearly doing something directly connected and useful to your own paper, is just plain dishonesty.

17. **beta**
November 12, 2010

It puzzles me slightly (i.e. I don't really lose any sleep over this since I have no aspirations to a Nobel) that everybody (i.e. you) discusses the Higgs only in the context of spontaneous symmetry breaking (and Goldstone bosons). That may be its immediate raison d'etre, but I see the Higgs is the culmination of a story that goes back to Ernest Rutherford. After the discovery of radioactivity by Becquerel, Rutherford found that there were three types of radioactivity, termed alpha, beta and gamma rays. This was circa 1899, and to this day we continue to seek the full explanation of beta decay. It is a great story of scientific advance, with many twists and turns, which have greatly altered our understanding of Nature at the most fundamental level. The Higgs boson is the culmination of a century-long quest. Does one doubt that the quest is worthy?

And yes, it is a great story, and makes for excellent press! HEP does appeal to the mass media, and schoolchildren, and for good reason. It has a central thread, which is easy to state and is obviously worthy, that of seeking to understand Nature at its most basic. And by that I mean not only particles but also the nature of space and time, and all this spills over into efforts to understand the Universe (or the Multiverse if you prefer). Condensed matter (theory or expt) has no such central thread.

18. **A.J.**
November 12, 2010

Feynman was nearly 70 when he died. That's close to the average for a male of his generation.

Presumably Bugsy meant to write "Fermi".

19. **jpd**
November 12, 2010

"Adams died at 64; von Neumann and Feynman also died young"
64 is the new young?
i feel better already

20. **46**
November 12, 2010

I'm on the way out!

21. **Mark Decker**
November 12, 2010

If the Higgs doesn't exist afterall (which is my bet) then the electroweak theory of Glashow, Salaam and Weinberg goes down the tubes. Then it's time to look at other theories. I know John Moffat has published one (sorry don't have link handy) as I am sure others have too.

22. **tubes**
November 12, 2010

GSW does NOT go 'down the tubes'. Remember that weak neutral currents have been observed, the W and Z have been found, numerous branching ratios have been measured (neutral to charged currents?), all in agreement with the GSW theory. These aspects of the theory will survive.

BUT if indeed the Higgs is not found (or rather is ruled out in a large area of parameter space), THEN one begins to search for alternative explanations for the existence of massive bosons. The alternative answer may not be a gauge theory (who knows?) but it must reproduce weak neutral currents and branching ratios etc.

Remember that the discovery of the photoelectric effect, and the failure of the wave theory of light to explain it, did not mean the wave theory went down the tubes. (Ok, you have to define a tube.) Instead the wave theory was woven together with the particle theory of light. More precisely, the discredited corpuscular theory of light was resurrected in a manner compatible with the wave theory.

23. **Nameless**
November 12, 2010

@anon. (November 11, 2010 at 7:54 pm): The constraints imposed by Lorentz symmetry and the Spin-Statistics theorem (PCT) render Goldstone's theorem quite a different beast in High Energy (compared to its Condensed Matter application) — I didn't mean to imply anything else other than this.

Indeed, it is these intricacies (Lorentz symm, PCT, Spin-Stat, etc) that render High Energy quite a different beast than Condensed Matter, even though most techniques can be applied in both. See, e.g., Goldstone Theorem in Nonrelativistic Theories (note that R. V. Lange worked closely with G. Guralnik — and is, thus, cited by Guralnik).

Case in point: this discussion about Anderson's claims in this topic of the "Higgs".

24. **Nameless**
November 12, 2010

@PWoit: i disagree: GHK was the only paper that counted the degrees-of-freedom in the problem of symmetry breaking: Higgs' first paper was classical and BE was semi-classical; GHK was the only quantum mechanical calculation.

Further, Guralnik was working with Lange and knew fairly well the issues in Condensed Matter (see above response to 'anon.').

In hindsight, however, vision is always 100% (this is the only part that's truly "ridiculous"). But, if you contextualize appropriately, things are not so straightforward. For example, there is a reason why Streater only cited Guralnik in this paper (see seciton 4: "The Guralnik Model"): Spontaneous Breakdown of Symmetry in Axiomatic Theory.

So, as you can see, what i'm saying here is a more widely known fact among 'old timers'… but, somehow, this information (and history, and details) got lost through the years.

25. **Nameless**
November 12, 2010

@Mark Decker: The result presently known as "Higgs boson" is a perturbative one. Unfortunately, only very recently some non-perturbative aspects of QFT have come to light, e.g., Complexified Path Integrals and the Phases of Quantum Field Theory.

In fact, as it turns out (check the ref above), you can have symmetry breaking without the so-called "Higgs", and without destroying any of the current structure of the Standard Model (namely, QFT and Gauge Theories).

So, not so quick to draw… 😉

26. **Grumblenik**
November 12, 2010

http://en.wikinews.org/wiki/Prospective_Nobel_Prize_for_Higgs_boson_work_disputed

Look at this!
But J J Sakurai Prize 2010 awarded to all six.

27. **Peter Woit**
November 13, 2010

For some other views of the history of the Anderson-Higgs mechanism, see this

http://www.scholarpedia.org/article/Englert-Brout-Higgs-Guralnik-Hagen-Kibble_mechanism

by Kibble, and an interview with Anderson here:

http://www.aip.org/history/ohilist/23362_3.html

He describes his paper published in 1963 as based on work he did during the summer of 1962, and says:

"So it was probably completed summer '62. Very little attention was paid to it except that in fact— well, Higgs reinvented it. In some ways the particle physicists tell me had less understanding; in some ways he had more. He certainly made a real model out of it where I had only a mechanism…

about the Anderson-Higgs phenomenon, if I may use the word. In the paper that I wrote I definitely said people have been worried about the Goldstone boson in broken symmetry phenomena. The Goldstone boson is not necessary. Here is the possibility of removing the Goldstone boson, mixing it with a gauge boson, and ending up with zero mass. [should be "non-zero" maybe a transcription error]…So I think I really understood the nature of the mechanism…

It was not published as a paper in the Condensed Matter Physics. It was published as a paper in Particle Physics. Brout paid attention to it. And he and Englert two years alter produced a model of symmetry breaking, which if you'll read carefully the summary of their work that t'Hooft and Veltman give (Nobel Prize winner this year), they say that they took off very much from the Brout-Englert paper, and there's no way Brout was not perfectly aware of my work and I would be surprised if the Brout Englert paper doesn't reference it rather than Higgs or along with Higgs. So in fact it didn't fall completely on deaf ears."

Actually, Englert-Brout (why not Brout-Englert??) doesn't refer to either Anderson or Higgs, in the case of Higgs because his paper had been rejected by Physics Letters and thus not yet published.

Higgs gives his version of the history here

http://www2.ph.ed.ac.uk/peter-higgs/history.shtml

properly recognizing Anderson's prior work, but claiming credit to be the first to discuss the mode that gives the "Higgs particle". He uses the term "Anderson mechanism" to refer to what is usually called the "Higgs mechanism".

28. **Peter**
November 13, 2010

What about Ernst Stueckelberg? Wikipedia says "In 1938 he recognized that massive electrodynamics contains a hidden scalar, and formulated an affine version of what would become known as the Abelian Higgs mechanism."

In the Discussion section somebody writes: "his despite the fact that he invented the renormalization group, despite the intermediate bosons, despite covariant perturbation theory, and despite the first Abelian Higgs mechanism, in 1957, remember this is same year as BCS, before Anderson, before Brout. His lack of recognition is a notable and sad fact."

29. **MP**
November 13, 2010

I can recommend another fantastic book for laymen (of which I am one) on this subject. Deep Down Things: The Breathtaking Beauty of Particle Physics by Bruce A. Schumm

This book does a great job of explaining the Standard Model, Gauge Theory, Lie Groups, and the basics of the Higgs Mechanism at a level that should be comprehensible to anyone who remembers a little high school algebra and trigonometry.

The Anderson-Higgs Mechanism

November 13, 2010
Categories: Favorite Old Posts, Uncategorized

One reason for this posting is that exchanges in the comment section of the previous one led me to look into some history, and I found some odd and possibly interesting facts I hadn't previously known. So, part of this will just be lifting of some links from comments in the last posting.

Another reason is that while the history may seem obscure, what's at issue is the central unsolved problem of particle physics: the nature of electroweak symmetry breaking, and no excuse for thinking more about this topic should be let to pass by. The Yang and Mills work on non-abelian gauge theory published in 1954 had one huge problem: in perturbation theory it has massless particles which don't correspond to anything we see. One way of getting rid of this problem is now fairly well-understood, the phenomenon of confinement realized in QCD, where the strong interactions get rid of the massless "gluon" states at long distances (they are relevant at short distances, visible in terms of jets seen at colliders).

By the very early sixties, people had begun to understand another source of massless particles: spontaneous symmetry breaking of a continuous symmetry. If the vacuum state is non-invariant under a continuous symmetry, you expect to find one massless state in the theory for each generator of the symmetry. These are called "Nambu-Goldstone" particles, and pions provide an example (only approximately massless, since the symmetry is approximate).

What Philip Anderson realized and worked out in the summer of 1962 was that, when you have both gauge symmetry and spontaneous symmetry breaking, the Nambu-Goldstone massless mode can combine with the massless gauge field modes to produce a physical massive vector field. This is what happens in superconductivity, a subject about which Anderson was (and is) one of the leading experts. His paper on the subject was submitted to Physical Review that November, and appeared in the April 1963 issue of the journal, in the particle physics section. It explains what is commonly called the "Higgs mechanism" in very much the same terms that the subject appears in modern particle physics textbooks and notes:

> It is likely, then, considering the superconducting analog, that the way is now open for a degenerate-vacuum theory of the Nambu type without any difficulties involving either zero-mass Yang-Mills gauge bosons or zero-mass Goldstone bosons. These two types of bosons seem capable of "canceling each other out" and leaving finite mass bosons only.

All that is missing here is an explicit relativistic example to supplement the non-relativistic superconductivity one. This was provided by several authors in 1964, with Higgs giving the first explicit relativistic model. Higgs seems also to have been the first to explicitly discuss the existence in models like his of a massive mode, of the sort that we now call a "Higgs particle", the target of active searches at the Tevatron and LHC.

Anderson tells his story here:

> So it was probably completed summer '62. Very little attention was paid to it except that in fact— well, Higgs reinvented it. In some ways the particle physicists tell me he had less understanding; in some ways he had more. He certainly made a real model out of it where I had only a mechanism…
>
> about the Anderson-Higgs phenomenon, if I may use the word. In the paper that I wrote I definitely said people have been worried about the Goldstone boson in broken symmetry phenomena. The Goldstone boson is not necessary. Here is the possibility of removing the Goldstone boson, mixing it with a gauge boson, and ending up with zero mass. …So I think I really understood the nature of the mechanism…
>
> It was not published as a paper in the Condensed Matter Physics. It was published as a paper in Particle Physics. Brout paid attention to it. And he and Englert two years later produced a model of symmetry breaking, which if you'll read carefully the summary of their work that t'Hooft and Veltman give (Nobel Prize winner this year), they say that they took off very much from the Brout-Englert paper, and there's no way Brout was not perfectly aware of my work and I would be surprised if the Brout Englert paper doesn't reference it rather than Higgs or along with Higgs. So in fact it didn't fall completely on deaf ears.

Note added 5/15/2013: I've heard from Martin Veltman that at the time they were working on the renormalizability of Yang-Mills, he and 't Hooft were not aware of the Brout/Englert work, or of the general issues about the Goldstone theorem and the Higgs mechanism that Brout/Englert and others were addressing. Veltman's Nobel lecture describes the history in detail, and has nothing like what Anderson describes (neither does 't Hooft's).

Given the background Brout had in condensed matter physics and Anderson's claim that "there's no way Brout was not perfectly aware of my work", it is quite surprising that no reference to Anderson occurs in the paper he and Englert published in Physical Review Letters. It arrived at the journal June 26, 1964 and came out in an issue dated August 31, 1964. In historical talks about this given back in 1997 (available here), Brout and Englert write:

> We knew from our study of ferromagnetism that long range forces give mass to the spin waves and we were aware, from Anderson's analysis of superconductivity , of the fact that the massless mode of neutral superconductors, which is also a Nambu-Goldstone mode, disappears in charged superconductors in favor of the usual massive plasma oscillations resulting from the long range coulomb interactions in metals. Comforted by these facts, we decided to confront, in relativistic field theory, the long range forces of Yang-Mills gauge fields with the Nambu-Goldstone bosons of a broken symmetry.
>
> The latter arose from the breaking of a global symmetry and Yang-Mills theory extends the symmetry to a local one . Although the problem in this case is more subtle because of gauge invariance, the emergence of the Nambu-Goldstone massless boson is very similar. We indeed found that there were well defined gauges in which the broken symmetry induces such modes. But, as we expected, the long range forces of the Yang-Mills fields were conflicting with those of the massless Nambu Goldstone fields. The conflict is resolved by the generation of a mass reducing long range forces to short range ones. In addition, gauge invariance requires the Nambu-Goldstone mode to combine with the Yang Mills excitations. In this way, the gauge fields acquire a gauge invariant mass!
>
> This work was finalized in 1964.

Very oddly, the only reference to Anderson's work that they give (their) is to a 1958 paper of his, not to the 1963 paper which had the same conclusions as theirs, a year earlier.

Brout and Englert don't give a full model, just assume existence of a scalar field with spontaneously broken symmetry, and specified couplings to the gauge fields. Working independently, Peter Higgs in July 1964 sent a paper to Physics Letters arguing that, even relativistically, Anderson's argument worked and there is no need for massless particles in the case of spontaneous symmetry breaking with a local symmetry. This paper was published, but a paper he sent a week later in which he wrote down an explicit model (the Abelian Higgs model) was rejected. It was later submitted to (August 31, 1964) and accepted at Physical Review Letters (published in the October 19, 1964 issue), where the referee (Nambu) made Higgs aware of the Brout-Englert paper, which Higgs refers to in a footnote. The Higgs paper does refer to Anderson's 1963 paper, writing in the introduction:

> This phenomenon is just the relativistic analog of the plasmon phenomenon to which Anderson has drawn attention.

Higgs gives his version of the history here, and refers to the "Anderson mechanism", writing:

> During October 1964, Higgs had discussions with Gerald Guralnik, Carl Hagen and Tom Kibble, who had discovered how the mass of non-interacting vector bosons can be generated by the Anderson mechanism.

Guralnik, Hagen and Kibble had been working on what Higgs calls the "Anderson mechanism" and Anderson the "Anderson-Higgs mechanism", writing a paper about it for submission to PRL. Guralnik gives his version of the history here (writing about the "Brout, Englert, Guralnik, Hagen, Kibble, Higgs phenomenon", Higgs last, no Anderson), Kibble's is here. In Guralnik's version:

> as we were literally placing the manuscript in the envelope to be sent to PRL, Kibble came into the office bearing two papers by Higgs and the one by Englert and Brout. These had just arrived in the then very slow and unreliable (because of strikes and the peculiarities of Imperial College) mail. We were very surprised and even amazed. We had no idea that there was any competing interest in the problem, particularly outside of the United States. Hagen and I quickly glanced at these papers and thought that, while they aimed at the same point, they did not form a serious challenge to our work.

His explanation for why they did not refer to Anderson is:

> At the same time, Kibble brought our attention to a paper by P.W. Anderson . This paper points out that the theory of plasma oscillations is related to Schwinger's analysis of the possibility of having relativistic gauge invariant theories without massless vector particles. It suggests the possibility that the Goldstone theorem could be negated through this mechanism and goes on to discuss "degenerate vacuum types of theories" as a way to give gauge fields mass and the necessity of demonstrating that the "necessary conservation laws can be maintained." In general these comments are correct. However, as they stand, they are entirely without the analysis and verification needed to give them any credibility. These statements certainly did not show the calculational path to realize our theory and hence the unified electroweak theory. It certainly did not even suggest the existence of the boson now being searched for at Fermi lab and LHC. The actual verification that the same mechanism actually worked in non-relativistic condensed-matter theories as in relativistic QFT had to wait for the work of Lange , which was based on GHK. We did not change our paper to reference the Anderson work.

See Guralnik's paper for a detailed discussion of those points which he feels Anderson, Brout, Englert and Higgs had missed about all this. It remains true that the full understanding of how this works non-perturbatively is rather tricky, especially in the chiral, non-perturbative context that is relevant to the Standard Model. It may very well be that there is some important piece of understanding about this that has been missing and will someday lead to a final understanding of the origin of electroweak symmetry breaking.

Update: For two other recent expository articles about this subject and its history, see here and here.

3. **Peter**
   November 13, 2010

   I have to post this again (I already did in the previous thread).

   What about Ernst Stueckelberg? Wikipedia says "In 1938 he recognized that massive electrodynamics contains a hidden scalar, and formulated an affine version of what would become known as the Abelian Higgs mechanism."

   In the Discussion section somebody writes: "his despite the fact that he invented the renormalization group, despite the intermediate bosons, despite covariant perturbation theory, and despite the first Abelian Higgs mechanism, in 1957, remember this is same year as BCS, before Anderson, before Brout. His lack of recognition is a notable and sad fact."

   Does anyone know more about this? I'm always amazed "Stueckelberg" pops up so many times in priority discussions. As far as I know, Feynman is the only Famous Physicist that acknowledges his work.

4. **es**
   November 13, 2010

   My information comes from "The Second Creation" by Crease and Mann. Ernst Stueckelberg was at the University of Zurich. Wolfgang Pauli was the big cheese at nearby ETH Zurich. From what I can tell, Stueckelberg suffered from low self-esteem. Pauli was a disaster for Stueckelberg. Pauli mercilessly put down Stueckelberg's ideas. Stueckelberg published his papers in French, and in obscure journals. It is also recognized that Stueckelberg's papers were very difficult to read. It is only with hindsight that we recognize much of Stueckelberg's contributions.

   On the subject of Yang-Mills and massive gauge vector bosons, it is a matter of record that Pauli formulated models of field theories with non-Abelian local gauge invariance before Yang and Mills. But Pauli also realized that the inclusion of a nonzero bare mass term for the gauge bosons violated gauge invariance and made the theory unrenormalizable. And on this basis Pauli rejected locally non-Abelian gauge theories as valid candidates for physics. It is a matter of record that Pauli attacked C.N. Yang on this basis. Read articles by Jeremy Bernstein on the subject.

   Pauli is perhaps admired for the phrase "Not Even Wrong" but Pauli also put down much that was Not Even Right.

5. **Peter Woit**
   November 13, 2010

   Peter,

What Stueckelberg did uses a scalar field to make a gauge field massive in a different way than the Anderson-Higgs mechanism. It's generally called the "Stueckelberg mechanism", and doesn't seem to be relevant to the electroweak symmetry breaking of the standard model. For more about it, see here

http://arxiv.org/abs/hep-th/0304245

6. **Louis**
November 13, 2010

Some other interesting notes in this plot that you may have (or not) uncovered.

The 1979 winners (AS and SW) primarily worked from the GHK paper due to the completeness and proximity to each other at Imperial College London. All six Sakurai winners are referenced in the 1979 Nobel talks by AS and SW. AS mentions that Kibble "tutored" him on these concepts.

It is odd that the Brout-Englert Historical Account posted in blog does not mention GHK – why introduce anything to the history that ruins "Nobel Math" of three. So this is in-line with how they treated PA.

t'Hooft and Veltman's story has changed over time. They referenced all three 1964 PRL papers and actually refer to it as the "Higgs-Kibble Mechanism" on page one of their Nobel Paper (see link below). Since being buttressed by their Nobel they have pushed a BEH award – particularly BE.

http://igitur-archive.library.uu.nl/phys/2005-0622-155148/13877.pdf

7. **egan**
November 14, 2010

Peter, if you were a member of the Nobel Prize comitee after the discovery of the Higgs boson at the LHC, what would be your decision ?
Who deserve the prize ? And don't forget the rule : no more than 3 names 😉

8. **bjm**
November 14, 2010

"Three papers written in 1964 explained what is now known as the 'Englert-Brout-Higgs-Guralnik-Hagen-Kibble mechanism' "
http://en.wikinews.org/wiki/Prospective_Nobel_Prize_for_Higgs_boson_work_disputed

I don't know a lot about physics but I know what's funny. Should that now be the "Anderson Englert-Brout-Higgs-Guralnik-Hagen-Kibble mechanism"?

9. **aebhghk**
November 14, 2010

In its own way the 2010 Sakurai Prize reflects the prejudices of HEP. Even though Anderson's 1963 paper was published in the Particle Physics section of the Physical Review, it is nevertheless viewed as condensed matter (and the work is of course nonrelativistic).

10. **Evgeny**
November 14, 2010

Just for the reason of completeness I would like to mention
the paper by A.A. Migdal and A.M. Polyakov in
Sov.J. -JETP 24 , 91 (1966)
"Spontaneous Breakdown of Strong Interaction Symmetry and the Absence of Massless Particles"

11. **Peter Woit**
November 14, 2010

egan,

In some sense the right Nobel for that has already been given (Weinberg-Salam), but if one wanted to go further back, I think Anderson + Higgs would be justifiable, Anderson for discovering the Higgs mechanism, Higgs for first writing down a relativistic theory implementing the Anderson mechanism and noticing that it had a physical mode that would be the Higgs particle.

But, in any case I'm hoping that what the LHC discovers involves some much more interesting mechanism for electroweak symmetry breaking than a Higgs field.

12. **Toma Susi**
November 14, 2010

Would make an awful acronym.

13. **Paul Klavan**
November 14, 2010

nice post peter–'tis why this is one of the best science blogs out there.

speaking of blogs, anderson should have blogged his work in 1962!

all kidding aside, i imagine the internet, and the numerous forums/blogs/archives will help us prevent such controversy in the future.

the knowledge that one cannot easily get away with forgetting to reference work will work wonders, as well as the permanent record via blogs/arxiv/groups/forums/facebook/blogs, all of which are dated and the vast majroity of which can be trusted, as it would be impossible to hack a facebook date!

thoughts? comments?

also, it appears journals are becoming less relevant, with their long delays vs. the immediacy of the internet.

14. **book**
November 14, 2010

FWIW there's a whole book on this stuff (reprints of papers). The papers by Anderson (1958, 1963), Nambu, Schwinger (2D electrodynamics) are all there. Migdal-Polyakov also. But the papers by Higgs, Brout-Englert and Guralnik-Hagen-Kibble are not reprinted. I suppose the book is about "dynamical" symmetry breaking ~ BCS superconductivity? ~ although in the HEP context I have no idea what would be a condensate bilinear in fermion fields.

http://books.google.com/books?id=1BSj1N3IMP8C&printsec=frontcover&dq=farhi+jackiw&source=bl&ots=kr-zPCoU8D&sig=nSqxex5tjf69WONZdvpukMl0n8g&hl=en&ei=L0fgTO37EoH6swOtgMmICw&sa=X&oi=book_result&ct=result&resnum=1&sqi=2&ved=0CBMQ6AEw

November 14, 2010

They used to be posted here but seem to be removed.

http://prl.aps.org/50years/milestones#1964

16. **N. Nakanishi**
November 14, 2010

Comment 1
I believe that the first person who pointed out that a gauge boson can acquire a nonzero physical mass in the relativistic quantum field theory is J. Schwinger. He solved 2-dimensional massless QED, called the Schwinger model; the gauge field becomes massive (PR 128(1962),2425). At that time, this was called Schwinger mechanism, but it turns out to be nothing but the dynamical Higgs mechanism.

Comment 2
Higgs did not resolve the dilemma between the Goldstone theorem and the Higgs mechanism. He merely avioded the
contradiction by adopting Coulomb gauge. The Goldston theorem holds in the manifesly covariant field theory, and the requirement of manifest covariance is very important backbone of the Standard Theory. I emphasize that the Nambu-Goldstone boson does exist in the electroweak theory.
It is merely unobservable by the subsidery condition (Gupta condition). Indeed, without NG boson, the charged pion could not decay into muon and antineutrino (or antimuon and neutrino) because the decay through W-boson violates angular-momentum conservation.

Comment 3
I know that it is a common belief that pion is regarded
as an "approximate" NG boson. But it is quite strange to regard pion as an almost massless particle. It is equivalent to regard nuclear force as an almost long-range force! The chiral invariance is broken in the electroweak theory. And as I stated above, the massless NG boson does exist.

17. **pidecay**
November 14, 2010

I would agree about Schwinger and his conclusions based on his model. GHK stated that in the Lorentz gauge a NG boson would exist but it would be "pure gauge" and not observable. (Higgs did not say this, in his 1964 paper anyway.)

The decay of a charged pion principally into (muon, mu_antineutrino) and not (electron, e_antineutrino) has long been regarded as a demonstration of the V-A structure of the weak interactions. The resulting helicity suppression is the reason that the branching ratio for the decay to (electron, e_antineutrino) is so small, despite having a much larger phase-space. "Indeed, without NG boson, the charged pion could not decay into muon and antineutrino … the decay through W-boson violates angular-momentum conservation." ??

18. **N. Nakanishi**
November 15, 2010

Explanation on Comment 2
Pion's spin is zero, while W-boson's spin is one. People usually understand that the pion decays into a muon and a neutrino through an intermediate state consisting of one W-boson. But this is forbidden by the angular-momentum conservation law in the rest frame of the pion. Note that conservation law (
possibly except for energy because it is canonically conjugate to time) must hold even in intermediate states.

19. **pidecay**
November 15, 2010

No good. But I shall let the bigshot experts deal with it, if anybody cares.

20. **Chris Oakley**
November 15, 2010

> But, in any case I'm hoping that what the LHC discovers involves some much more interesting mechanism for electroweak symmetry breaking than a Higgs field.

Amen to that. Has it occurred to anyone that all this scrabbling for credit for the Higgs mechanism might turn into scrabbling for the exit if the Higgs particle is not found?

21. **nohiggs**
November 15, 2010

"… scrabbling for the exit …" There's probably a Monty Python sketch for that. More likely there will be a generous attribution of credit to the *other* person. For example the Higgs may be renamed the Kibble, or the Brenglert, or all the HEP theorists will join forces to point the finger at Anderson. But it will he hard to conclude that the Higgs does not exist simply because it is not found. The mass limit (with 95% confidence) will be pushed up. Eventually the limit may reach outrageous levels, but that may require more than the LHC.

22. **chris**
November 15, 2010

Regarding Schwinger, there is one big problem in the argument that he discovered the dynamical symmetry breaking mechanism we usually call Higgs mechanism: in 2D there is no spontaneous symmetry breaking (Mermin-Wagner theorem). His paper is a well known landmark and recognized for its contribution towards understanding the confinement phenomenon and effective field theories (bosonization). On the other hand, it is also well known, that it misses one of the most prominent features of 2D QED (and 4D QCD), the theta-vacuum structure, entirely.

The Schwinger model is an early toy model study of QCD. I guess that therefore – by a very large leap of faith – one might even call it a grandfather in spirit to technicolor theories and therefore an early precursor study of a dynamical Higgs phenomenon. (This notwithstanding that the fact that the condensate one would like to associate with the Higgs is simply not formed in 2D because that would violate the Mermin-Wagner theorem) . But attributing to it the discovery of the Higgs mechanism is way beyond reasonable argument.

23. **erhard**
November 15, 2010

In all this discussion about the early years of the Higgs et alii "mechanism" we should not forget that another link was searched for, once in a while, by considering a scale covariant scalar field as a bridge to gravity, e.g.:
F. Englert, E. Gunzig, C. Truffin, P. Windey 1975 (Conformal invariant general relativity with dynamical symmetry breakdown,Phys. L. 57B, 73ff.) tried a link to Jordan-Brans-Dicke theory.
L. Smolin 1979 (Towards a theory of spacetime structure at very short distances, Nucl. Phys. B 160, 253ff.) started to play around with Weyl geometric gravity of the Dirac-Utiyama type.

Every ten to fifteen years similar ideas seemed to have popped up, but remained marginal annotations to the main discourse. If something came out of these attempts, would n't that be already a bit "more interesting" than the ordinary Higgs field; or do you expect even more, Peter?

24. **Peter Woit**
November 15, 2010

Erhard,

Well, if somehow the origin of electroweak symmetry breaking has to do with gravity that would be truly spectacular, one certainly couldn't expect "even more" than that.

25. **N. Nakanishi**
November 15, 2010

chris,

Your assertion that in 2D there is no spontaneous symmetry breaking is not valid in the indefinite-metric quantum field theory. The specialty of 2D is the non-existence of the 2-point funtion of a massless scalar field in the Hilbert space, but it does exist in the indefinite-metric space.

The theta vacuum business appears in the massive Schwinger model but not in the massless Schwinger model. Furthermore, the appearance of the theta vacua depends on the choice of the representation; it is possible to avoid the theta vacua.

I of course do not regard Schwinger as the discoverer of the Higgs mechanism. He is a precursor. Probably, Anderson should also be regarded as a precursor.

26. **chris**
November 16, 2010

Then please tell me the symmetry that gets broken dynamically in order to give the Schwinger particle its mass.

27. **N. Nakanishi**
November 16, 2010

chris,

The manifestly covariant formulation of the Schwinger model contains massless ghost particles. Gauge symmetry is broken so as to give a mass to the gauge particle. The ghost particle, which is unphysical because of the subsidiary condition, plays the role of the Goldstone boson.

The fact that Schwinger mechanism is nothing but a dynamical Higgs mechanism was shown by
K. R. Ito, Prog. Theor. Phys. 53 (1975), 817,
N. Nakanishi, Prog. Theor. Phys. 54 (1975), 840.
For a review, see N. Nakanishi and I. Ojima, Covariant Operator Formalism of Gauge Theories and Quantum Gravity,
(World Scientific, 1990), Sec.2.5.4.

28. **chris**
November 17, 2010

I am sorry, but there is no dynamical symmetry breaking in the Schwinger model. In your work, you explicitly broke the gauge symmetry by a gauge fixing condition. Of course ghosts will arise then – but they are unphysical.

The mass of the Schwinger boson is due to the anomaly term. This is not symmetry breaking, there was no symmetry to begin with.

29. **N. Nakanishi**
November 17, 2010

chris,

You seem not to understand the fundamental points of the quantum theory of a gauge field. Let me explain. Any classical theory which has local symmetry cannot be quantized without violating it by introducing gauge fixing. Instead, the theory should become BRS invariant; the BRS symmetry is the quantum version of local gauge symmetry. For the abelian gauge theory, FP ghosts decouple, so only the B field remains.
Although local symmetry does not exist in quantum gauge theory, global symmetry remains unbroken if spontaneous symmetry breaking does not occur. I emphasize that local gauge symmetry plays no role in the Higgs mechanism of the quantum gauge theory. Local symmetry is a classical concept!

The Schwinger mechanism is NOT an anomaly. It is not good to regard anything which you cannot understand as anomaly.
The Schwinger model has essentially the same mechanism as that of the chiral gauge theory.

30. **Shantanu**
November 20, 2010

See
http://web.mit.edu/dikaiser/www/Kaiser.WhoseMass.pdf
for an interesting historical retrospective on connection between
Higgs and Brans-Dicke theories and how people who worked on one

were completely ignorant of the other.
shantanu

31. **Greg S**
November 30, 2010

Here how I judge the three 1964 PRL papers discussed above by Peter – nice post and blog by the way.

1) Does paper have the mechanism?
2) Does paper have the boson?
3) Does paper show explicitly how Goldstone theorem is avoided?
4) Is paper accurate and error free?

Brout-Englert (PRL, August 1964)
1 – Yes, has mechanism
2 – No boson
3 – No – paper assumes Goldstone's theorem is correct throughout
4 – No. Messes up poles at top of page 322

Peter Higgs (PRL, October 1964)
1 – Yes
2 – Yes
3 – No. In his Physics Letters Paper PH stated Goldstone theorem could fail in radiation but does not show how. In PRL paper, PH does not pick a gauge nor did he not give a quantum mechanical argument to the Goldstone theorem which is purely a quantum phenomenon.
4 – Yes

Guralnik-Hagen-Kibble (PRL, November 1964)
1 – Yes
2 – Yes (bottom of p. 586)
3 – Yes. Shows explicitly how Goldstone Theorem fails in radiation gauge. This is large focus of their 1964 paper and explained in Guralnik's 2009 historical paper. Hagen also discusses on YouTube in Sakurai Prize lecture http://www.youtube.com/view_play_list?p=BDA16F52CA3C9B1D
4 – Yes (Points 1-4 are probably why Ian Sample in "Massive" (p.70) points out "some regard (GHK) as the most comprehensive version of the theory"

The papers have gone down in history together as they should. It is a shame the Nobel "rule of three" tries to segment these as TOGETHER they each brought different pieces to this and formed the basis of the standard model. Again, nice post Peter. Certainly Anderson's work was also critical to this whole phenomena and period.

A Geometric Theory of Everything

November 17, 2010
Categories: Uncategorized

The December issue of Scientific American is out, and it has an article by Garrett Lisi and Jim Weatherall about geometry and unification entitled A Geometric Theory of Everything. Much of the article is about the geometry of Lie groups, fiber-bundles and connections that underpins the Standard Model as well as general relativity, and it promotes the idea of searching for a unified theory that would involve embedding the SU(3)xSU(2)xU(1) of the Standard Model and the Spin(3,1) Lorentz group in a larger Lie group.

The similarities between (pseudo)-Riemannian geometry in the "vierbein" formalism where there is a local Spin(3,1) symmetry, and the Standard Model with its local symmetries makes the idea of trying to somehow unify these into a single mathematical structure quite appealing. There's a long history of such attempts and an extensive literature, sometimes under the name of "graviGUT"s. For a recent example, see here for some recent lectures by Roberto Percacci. The Scientific American article discusses two related unification schemes of this sort, one by Nesti and Percacci that uses SO(3,11), another by Garrett that uses E_8. Garrett's first article about this is here, the latest version here.

While I'm very sympathetic to the idea of trying to put these known local symmetry groups together, in a set-up close to our known formalism for quantizing theories with gauge symmetry, it still seems to me that major obstructions to this have always been and are still there, and I'm skeptical that the ideas about unification mentioned in the Scientific American article are close to success. I find it more likely that some major new ideas about the relationship between internal and space-time symmetry are still needed. But we'll see, maybe the LHC will find new particles, new dimensions, or explain electroweak symmetry breaking, leading to a clear path forward.

For a really skeptical and hostile take on why these "graviGUT" ideas can't work, see blog postings here and here by Jacques Distler, and an article here he wrote with Skip Garibaldi. For a recent workshop featuring Lisi, as well as many of the most active mathematicians working on representations of exceptional groups, see here. Some of the talks feature my favorite new mathematical construction, Dirac Cohomology.

One somewhat unusual aspect of Garrett's work on all this, and of the Scientific American article, is that his discussion of Lie groups puts their maximal torus front and center, as well as the fascinating diagrams you get labeling the weights of various representations under the action of these maximal tori. He has a wonderful fun toy to play with that displays these things, which he calls the Elementary Particle Explorer. I hear that t-shirts will soon be available…

Update: T-shirts are available here.

Comments

   November 17, 2010

   Oh dear lord. Again?!?

2. **chris**
   November 18, 2010

   oh, that guy. thanks for pointing this out.

   by the way, Lisi seems to have gone into comercials lately…
   http://cheapuniverses.com/universesplitter/

3. **Peter Woit**
   November 18, 2010

   I'm deleting a sequence of comments triggered by an anonymous attack on one of the authors of the SciAm piece, Jim Weatherall. If you want to attack someone from behind anonymity here, it better be me, or it better be extremely fair, otherwise it's a good candidate for deletion.

   The exchange did contain links to something Weatherall wrote for Slate based on early Higgs rumors

   http://www.slate.com/id/2167563/

   and a blogposting he wrote about it featuring an exchange with Nima Arkani-Hamed.

   http://stevens.edu/csw/?p=42

4. **D R Lunsford**
   November 18, 2010

   I applaud this work if for no other reason than the work involved in juggling all the multiplets, although I think it is pretty clear that toying with gauge groups is not going to produce a breakthrough. The particle explorer is a fantastic toy!

   -drl

5. **anon**
   November 18, 2010

   Hmm.. Motl has a post just now about Weatherall, attacking him. He happens to have the very same two links (to Slate and the blog posting) you've retained here.

   Coincidence?

6. **Chris W.**
   November 19, 2010

   This wouldn't be the first of such "coincidences".

7. **Tristan Hubsch**
November 19, 2010

How is a mathematically rigorous disproof of a concrete proposal “really skeptical and hostile”? Facts simply **are**.

Or, are you suggesting that Distler-Garibaldi’s disproof is incomplete, (perhaps not unlike the very productive examples of some well-known past “no-go theorems”)? If so, please do share: we all might learn a great deal more.

8. **Peter Woit**
November 19, 2010

Tristan,

My understanding is that Garrett is well aware that his proposal has problems. In the Scientific American article he writes:

“All new ideas must endure a trial by fire, and this one is no exception. Many physicists are skeptical—and rightly so. The theory remains incomplete.”

I have no problem with skepticism, I’m skeptical about many of Garrett’s ideas too. If Jacques wants to make a clean technical argument showing the nature of the problems with Garrett’s proposal, that’s great, and could be potentially worthwhile. But I don’t see any reason for the hostile, sneering tone of Jacques’s blog posting explaining these points. This is not the way to professionally make a credible technical argument.

He and Lubos have done an excellent job of convincing many people that there’s something seriously wrong with string theory and string theorists. Instead of writing in here to complain about my accurate characterization of Jacques’s writings as “hostile”, you might want to think seriously about whether his behavior is worth defending, given how much it has cost your field.

9. **Garrett**
November 20, 2010

Peter: Thanks for posting on the SciAm piece.

Chris: It was an (unpaid) endorsement of a fun app, not a commercial.

D R Lunsford: Glad you like the Elementary Particle Explorer — I think it’s a fun and worthwhile educational tool.

Tristan: What is it, precisely, that you think Distler and Garibaldi proved? Their claim is that they proved “the theory doesn’t work.” But does that follow from what they technically proved, or is it in fact a lie, dependent on a hidden assumption?

Peter: Agreed. Except I see several reasons for Distler and Motl’s sneering tone, all of which speak to their character rather than that of those they malign.

10. **D R Lunsford**
November 20, 2010

I wonder if anyone remembers Feza Gursey, who was always finding suggestive patterns in the objects of algebra. I was entranced at first, and then just sort of decided that even if that was the right way, I preferred to not go crazy thinking about it, and so good luck. It seemed to me that nothing could possibly be that complex 🙂

So my point is, this goes back a long way and not much has come of it, because it doesn’t have a new dynamical principle.

-drl

11. **Casey Leedom**
November 20, 2010

I’m reminded of the old quote “Academic politics are so vicious precisely because the stakes are so small.”[1] It seems that so little has happened of real import in HEP over the last 30 years that practitioners are left squabbling for the scraps. It’s very sad. I think it was Peter who said something along the lines that when he started his career, the Standard Model had just had the finishing touches applied to it after nearly a century of bold, dramatic progress in the field of physics. Who knew that a whole generation of physics PhDs were going to see very little happen on their watch?

[1] http://ask.metafilter.com/80812/Academic-politics-are-vicious-because-the-stakes-are-so-low

12. **John Baez**
November 20, 2010

Garrett wrote:

> But does that follow from what they technically proved, or is it in fact a lie, dependent on a hidden assumption?

What do you think? I’ll guess you’re hinting it’s the latter. if so, could you be really specific about what hidden assumption they’re using, and why it’s wrong?

13. **Bugsy**
November 20, 2010

As a complete outsider, when I skimmed through some of the Distler-Lisi exchanges when Lisi’s first preprint came out, I was amazed to see Lisi keep his cool again and again while Distler consistently displayed a belittling, arrogant tone. It seemed to me that all concerned were getting something out of the exchanges, and since both were some of the very few people in the world who could possibly understand the arguments involved, why in the world would one of them seem to consistently view the other as an “enemy”? Now to prick Distler’s enormous pride a bit, if he were such a damn expert why would he need to rely on a coauthor to “do the math” for him in the new preprint? Methinks there is more behind his anger than greets the eye, some “hidden variables” of jealousy, bitterness and frustration that keep rearing their ugly heads and interfere with what should be simply a fascinating, INSPIRING intellectual debate. Lisi’s best move is to keep reading zen books for the philosophy and leave the snide remarks to others. Beauty is not only in the eye but in the heart of the observer. Nastiness in academia has driven many gentle but brilliant souls away from the ivy halls, Lisi will have to be strong inside to continue to weather all this with wistful good humor.

14. **Bugsy**
November 20, 2010

Addendum: just skimmed Lubos’ twin posts on the matter, and along with some (apparently well done) general exposition, he makes some concrete criticisms which (apparently) should be seriously addressed. I say apparently because of my own ignorance, and will now shut up and watch the discussion by those who know something unfold. I will just say to Lisi that if you write an article about your own work in a popular magazine, then you are setting yourself up for a really big fall IF your work turns out to be wrong. But that fall would be no problem at all, if all that really matters to you is what is so- in all its aspects. In skiing and surfing we fall all the time, right? The wave shows us the reality, we laugh and shake our heads, look at the amazing sky and keep on going…

15. **Peter Woit**
November 20, 2010

Bugsy,

Jacques has always been quite consistent in starting out his various blog postings on the topic by explaining that it is "mind-numbingly trivial", elementary, and intellectually far beneath him, even if he is requiring the efforts of a specialist. This is pretty funny stuff if you know something about the technicalities of the subject. If you don't know the technicalities, the humor still becomes pretty obvious when you see David Vogan writing to Jacques to explain to him why he has it wrong. For amusement, read Jacques's first blog posting on the topic:

http://golem.ph.utexas.edu/~distler/blog/archives/001505.html

The comic high point there though is not Jacques, but an anonymous string theorist who writes in:

"Nice post. It would make a good final exam question for a first course on baby Lie theory, too. (A 4th year undergrad course, these days, I should point out; something worth pondering.)"

There are some other hilarious parts of this story that unfortunately I'm not at liberty to discuss here. Over the years mathematicians have learned some beautiful and important ideas from string theory, they've also had some very amusing interactions with string theorists.

16. **Garrett**
November 20, 2010

DR: Yes, Gursey was one of the first to consider E8 for unification. I think what held people up was not knowing how to include gravity (that needed a new dynamical principle).

Casey: There have been several interesting developments in HEP, but yes, nothing as dramatic as in the previous 30 years.

17. **Garrett**
November 20, 2010

John: Yes, they are relying on two hidden assumptions:

(1) Having mirror fermions makes a theory unviable.

(2) There is no way of getting rid of mirror fermions.

The first assumption is wrong because we just don't know why particles have the masses they do, and there could be mirrors with large masses. Since what Distler and Garibaldi prove is that, under a direct decomposition of E8, there are mirror fermions, they then use (1) to claim this E8 theory is unviable. But that is a lie, based on (1), which they initially obscured. I am using this strong language because I talked to Distler in person and his strategy of obscuring (1) was made clear to me. (You might recall a lengthy and repetitive exchange on Urs' ncat post, during which Distler refused to acknowledge what was going on.) And Garibaldi was following Distler's word on the physics.

Issue (2) is more subtle, and harder to argue, since I haven't written up the precise mechanism yet. But I think what's really going on is that these mirror fermions may be related to usual fermions using an E8 gauge transformation, so that they never appear as mirrors but rather as another generation.

18. **Garrett**
November 20, 2010

Bugsy: Sage advice. But I suspect I am too gritty to completely take the high road. However, the concrete criticism has been seriously addressed. Here's a summary of criticism, and how it has played out:

(1) Impossible mixing of bosons and fermions.

The superconnection was quickly agreed to be viable.

(2) Violation of the Coleman-Mandula theorem.

The novel loophole in the theorem is addressed in the Scientific American article, and was described in more detail here. If nothing else, this new understanding opens the field for gauge-gravity unification.

(3) The dynamics is not described (with an action) invariant under the full E8 symmetry.

A couple of LQG researchers and I recently found such an action.

(4) Even one generation of fermions does not fit in E8.

This misconception, introduced and propagated by Distler and Garibaldi, is directly countered here. It was one of the more enjoyable experiences of my life to see this issue discussed in Banff with Garibaldi in attendance. I think it still pains Distler to use the standard terminology "fermions and mirror fermions," instead choosing to say "no chiral fermions," which is synonymous but misleading.

(5) The theory is not quantized.

The theory is compatible with the usual methods of quantum field theory. Although extensive renormalization calculations have not been carried out, I think they can and will be. The lack of a background spacetime does make this difficult though — a known problem with quantizing gravitational theories. In any case, the QFT of nonabelian Yang-Mills theories, and the geometry of BRST, is an extremely rich area that should be further explored.

(6) The theory does not accommodate three generations of fermions.

This issue was identified (by me) as the most serious problem from the beginning, with a potential solution coming from triality. As of a year ago I was discouraged, but with some insights gained at Banff I now think triality will indeed work. It's tricky though (for the noncompact case), and I'm working on that now.

Peter: Since Distler has been very effective at persuading physicists that there is nothing to this E8 stuff, it has been less funny from my perspective. But it has certainly been interesting. And my interactions with mathematicians have been fantastically enjoyable and informative.

19. **Mark**
November 20, 2010

Garrett, it is an established fact that your theory has a non-chiral spectrum. This is what Distler and Garibaldi rigorously proved. It has been known for 40+ years that in order to describe the real world the fermion spectrum must be chiral. Hence, unless you impose some extra symmetry that would forbid the vector-like mass terms, ALL fermions will get large GUT scale masses through quantum corrections and will automatically decouple at the scale far above the electroweak scale. Thus, the electroweak scale spectrum of your theory looks nothing like the real world. This is not a lie but a basic QFT argument that cannot be refuted just by waving your hands and saying that "The first assumption is wrong because we just don't know why particles have the masses they do, and there could be mirrors with large masses."

20. **Aaron**
November 20, 2010

Oh for christ's sake, Garrett. Do we really have to go through this again? You can call your 'superconnection' whatever you want (although you still have not acknowledged that the very BRST superconnection you cite and don't seem to understand is related to a Grassman symmetry), but that doesn't mean it makes sense. For example, are the currents that relate the fermions and bosons in your model Grassman or commuting? If they're Grassman, do they fit into an ordinary Lie algebra or a superalgebra?

For the Coleman-Mandula theorem, you need to address what happens in the low-energy theorem. In particular, what breaks the symmetry mixing spacetime and internal indices and at what scale?

For your paper with Lee, I'd be a lot more interested if it had fermions in it.

The idea of net numbers of generations has been standard in high energy physics for at least thirty years and probably longer. You're welcome to present a reason why your mirror fermions don't pair up with a high mass and disappear from the low energy spectrum, but until you do no one's going to care about the fact that you don't like the standard terminology; they're just going to ignore you.

For quantization, if it's so easy, why don't you sit down and compute something? Like the low-energy spectrum, say. If you're going to go around and talk about what particles your theory predicts at the LHC, I'd think you'd at least have the responsibility to compute a scattering amplitude or two.

Or, for that matter, what are the free parameters in your theory? What sets the Yukawa couplings? What sets the Higgs self coupling? Neutrino masses? The CKM matrix? The value of the cosmological constant? Even if you're not able to give numbers, can you at least explain the mechanism by which these parameters arise? Are they all undetermined? Are there relations between them?

And, seriously Peter. The math here is the computation of a few branching relations for the adjoint of various real forms of E8. Big fucking deal. There's probably a computer program out there that will do that for you these days. Must all these discussions end up focussing on how mean Jacques and all the other people on the internet are? We could just cut and paste from the old discussion on Cosmic Variance and save us all some time.

21. **Peter Woit**
November 20, 2010

Aaron,

Sure, the kinds of mathematical questions raised by Jacques are answerable with known mathematical techniques. But, no, they're not trivial, and only an idiot would think they'd make a good final exam question for an undergraduate course on Lie theory.

I've had extensive experience trying to have technical discussions with Jacques, just about all of which are publicly available on various blogs, so anyone who cares can read them and see for themselves what they think. Based on that experience, I can easily see why Garrett, who's a very polite, mild-mannered guy, describes what he encountered with a strong word like "lying". The problem with Jacques is not that he's mean (I hear that, like Lubos, he's a perfectly nice guy in person, the problem is just when he gets a keyboard in his hands). The problem is that he's unprofessional and dishonest. There are well-understood rules for how professionals conduct intellectual arguments (e.g. avoid ad hominem attacks, try to accurately describe your opponents arguments, etc.). Jacques and Lubos don't play by those rules. In Lubos's case it's immediately obvious, with Jacques it takes a while to figure out.

22. **mark davis tortino**
November 20, 2010

"There are well-understood rules for how professionals conduct intellectual arguments (e.g. avoid ad hominem attacks, try to accurately describe your opponents arguments, etc.). Jacques and Lubos don't play by those rules. In Lubos's case it's immediately obvious, with Jacques it takes a while to figure out."

Well, it's not an ad hominem attack to state that Garrett has never published a peer-reviewed paper on his "theory."

Nor is it an ad hominem attack to note that Distler *has* published a paper refuting Lisi's theory.

What *is* an ad hominem attack is to label the physicist publishing peer-reviewed papers as somehow being unprofessional, while cheering the one who does not publish peer-reviewed papers and receives all the "fantastic" hype as behaving professionally. What you are doing, Peter, is "attacking the man"–Distler–while ignoring his superior physics and math, which was published in a peer-reviewed journal.

23. **mark davis tortino**
November 20, 2010

Bugsy writes, "Now to prick Distler's enormous pride a bit, if he were such a damn expert why would he need to rely on a coauthor to "do the math" for him in the new preprint? Methinks there is more behind his anger than greets the eye, some "hidden variables" of jealousy, bitterness and frustration that keep rearing their ugly heads and interfere with what should be simply a fascinating, INSPIRING intellectual debate. Lisi's best move is to keep reading zen books for the philosophy and leave the snide remarks to others."

"enormous pride" is a snide, ad hominem attack.
"if he were such a damn expert" is a snide, ad hominem attack.
"methinks there is more behind his anger than greets the eye, some "hidden variables" of jealousy, bitterness and frustration that keep rearing their ugly heads " is a snide, ad hominem attack.

hey peter et al.–instead of the snide, ad-hominem attacks, why not try to refute distler's paper on a scientific, mathematical level, and then publish it like distler did?

seems distler is taking the high, professional road, while you guys are taking the snide low road…

24. **Peter Woit**
November 20, 2010

Mark,

I have no dog in the argument between Garrett and Jacques over chirality problems in what Garrett is trying to do. As I said, I'm in the camp of skeptics that Garrett has a workable unified theory. I agree that you can't automatically conclude from the fact that Jacques or Lubos argues in a dishonest and unprofessional way that they're wrong.

Again, I'm just telling you what my personal experience with Jacques is, going back now quite a few years, on several different topics. The relevant exchanges are in the public domain, if anyone cares.

25. **Tristan Hubsch**
November 21, 2010

Peter,

I'm glad that your skepticism is not as one-sided ("I'm skeptical about many of Garrett's ideas too") as it seemed to me; sorry about that: my bad. In turn, however, writing "you might want to think seriously" implies that you know that I don't. But, never mind.

Finally, thanks for a nice book; I've learned a lot about human nature.

Peace, out.

26. **John Baez**
November 21, 2010

Just for my own peace of mind, I'll try to summarize my own understanding of various problems that confront Lisi's theory, or indeed *any* attempt to pack all known particles into the adoint representation of E8.

I'll try to do this in a fairly lowbrow sort of way, so more people can understand what I'm saying. This increases the risk of oversimplifications, but doubtless I'll be corrected here if I make any mistakes, and even if I don't.

So here goes:

Most importantly, particles have very distinct personalities, whereas all 248 dimensions of E8 look alike. E8 is very symmetrical, that's why people like it. But this beautiful symmetry needs to be severely broken for anything like real-world physics to fall out.

First, particles come in two kinds: bosons and fermions. If we chop E8 into a bosonic part and a fermionic part we no longer have the whole symmetry of E8. Garrett writes:

> The superconnection was quickly agreed to be viable.

but I'm not sure anyone there agreed it was 'viable': Urs merely suggested this idea as a way forward, but as Aaron notes,

> …that doesn't mean it makes sense. For example, are the currents that relate the fermions and bosons in your model Grassman or commuting? If they're Grassman, do they fit into an ordinary Lie algebra or a superalgebra?

I see no way to get E8 symmetries that mix fermions and bosons in a model where the symmetry of E8 has been broken by deliberately chopping it into bosonic and fermionic parts.

Second, even among fermions, different particles have drastically different personalities: for example their masses, and the rates at which they turn into each other, which are described by the numbers in the Cabibbo-Kobayashi-Maskawa matrix and the Maki-Nakagawa-Sakata matrix. Similarly, in the realm of the bosons there's the Higgs mass and other numbers. Garrett's work has nothing to say about these. Without these numbers we can't do real-world physics. But the big problem is this: I don't see any way to get these numbers into the game without further breaking down the symmetry of E8. Why? Because again, E8 symmetry wants all particles to be alike, but these numbers describe how they're not.

Third, there's no way to pack all known fermions into E8 without positing two copies of E8 and giving every fermion a mysterious unseen partner called a "mirror fermion". To keep these rascals from being seen we could claim they're more massive than the guys we see – but no method for this has been described yet, to my knowledge.

(This should be vaguely reminiscent of the problem with supersymmetry, where every known particle gets a "superpartner", and then we have to wave our hands frantically and try to find a way for those superpartners to be a lot heavier, to explain why we haven't seen them. But at least in the case of supersymmetry, a method for doing this has been described. It's a completely ad hoc, ugly method that involves breaking supersymmetry by hand, and throwing over a hundred extra unknown parameters into the Standard Model! But it's still a method.)

Given all this, it should not be surprising that Garrett has not yet done calculations with his theory that reproduce the physics of the world we see around us. I am very glad to be doing something easy like trying to prevent global warming.

27. **mark davis tortino**
November 21, 2010

I have an idea! Lisis should:

a) publish some papers in journals
b) answer john baez et al.'s skepticism
c) present some testable predictions
d) have them tested
e) be labeled the next-einstein and move on to selling i-phone universe-splitter apps and t-shirts

But right now he is beginning with e), and naturally, this rubs some hard-working physicists doing a) the wrong way. 🙂

Add to this the powerful behind-the-scenes financial and media forces at play here, and that this has been going on for over three years with no new developments nor solutions to the problems from Lisi which teh greater community recognizes, and some physicists are a bit frustrated that they have to take time off of their research to get the simple truth of the E8 hype heard above the well-funded media train.

28. **Peter Woit**
November 21, 2010

Tristan,

My apologies for any mistaken assumptions, I should know better. Glad you liked the book.

29. **Peter Woit**
November 21, 2010

Mark,

The idea that what motivates Jacques is willingness to bravely stand up to a well-funded, powerful lobby promoting over-hyped ideas about unification to the public is very funny.

30. **mark davis tortino**
November 21, 2010

Yes Peter–it is perhaps funny. But true! And props go to Distler here for actually publishing sound peer-reviewed papers, which is what physics has ever been about, long before this era of anonymous wikipedia editors/blogs/postmodern/ironic/behind-the-scene machination physics and t-shirt sales.

And yes–I do realize how in certain ways Lisi was used by some to satirize the String Theorists, but two not even wrongs do not make a right GUT.

Best,

Mark 🙂

31. **Brian Hsu**
November 21, 2010

At this point in time, what distinguishes Lisi's claims from those of the Bogdonavs?

At any rate, Lisi has had almost four years to publish a single peer-reviewed paper since all the hype started with… so what exactly is he waiting for?

In the history of science, has an unpublished, unaccepted, and now refuted theory ever received so much attention and hype?

Is this a product of our times, whence politics has trumped physics?

Something like this would have been impossible, even ten years ago.

32. **Giotis**
November 21, 2010

"It's a completely ad hoc, ugly method that involves breaking supersymmetry by hand"

The SUSY breaks in the hidden sector sponteneously and is mediated to the visible via a certain mechanism; so this is not what I would call an ugly/unnatural ad hoc method.

33. **Brian Hsu**
November 21, 2010

From reading through the above, it seems that Peter is motivated largely by his past interactions with Distler, and that he finds Lisi to be a "nice guy." Does Peter think that bringing personalities into a discussion of physics is "professional?" It seems the professional viewpoint would be to note that while Distler has published a paper refuting Lisi's theory in a peer-reviewed journal, Lisi has yet failed to publish a paper supporting his theory. And so, I guess the best Lisi's supporters can do is to use ad hominem attacks. But is this professional. If so, what has the physics profession become, where spurious, unpublished science is hyped, and those who question it are attacked on a personal level?

34. **Peter Woit**
November 21, 2010

Brian,

The Bogdanovs (not "Bogdanavs") are the poster-boys for the problems with peer-review. They published five peer-reviewed articles, two of them in very well-known and highly-respected journals. One of them was given his Ph.D. on the basis of having published such peer-reviewed articles. The articles are complete gibberish, and very different than Garrett's. Garrett is making clear statements and proposals, some of which may be wrong and/or incomplete. What he's saying is so clear that Jacques can write a mathematical physics paper purporting to give a rigorous refutation of some of it.

The fact of the matter is that one can't judge this kind of research on whether it is peer-reviewed or not, you have to read the things, understand them and make up their own mind. In my posting I gave links people can follow to do this, and that's what they should do if they are seriously interested in this particular question. I've also noted in the comments that my experience with Jacques is that he doesn't follow the usual rules for intellectual debate, which you can check by reading my public exchanges with him. You may or may not find that relevant if you try and follow his arguments with Garrett.

35. **Peter Woit**
November 21, 2010

Giotis,

You're conjecturing an unobserved entirely different "hidden sector" of physics that spontaneously breaks the symmetry, interacting with ours through interactions cooked up to completely escape any currently observable effects.

Tastes may vary, but ugly/unnatural/ad hoc all seem to me reasonable adjectives to apply to this scenario.

36. **Brian Hsu**
November 21, 2010

 Thanks Peter,

 You write, "Garrett is making clear statements and proposals, some of which may be wrong and/or incomplete."

 Which of Garrett's "clear statements" are "right" and "complete?"

 I have read his work and while he stated that the LHC can test his theory, in reality his theory makes no predictions. Perhaps I missed that part? If so, please do share!

 And if peer-review is so completely broken, what should replace it? Media campaigns, anonymous wikipedia editors, and the suppression of all peer-reviewed articles mathematically refuting Garrett's theory?

37. **Peter Woit**
November 21, 2010

 Brian,

 As I've noted repeatedly, I'm somewhat of a skeptic on the subject of Garrett's theory. I'm not going to spend more of my time defending his work for him. All I'll say is that I've read his papers, I've read the Bogdanov papers and the two things are completely different.

 Obviously I'm not arguing for the suppression of anyone's articles, peer-reviewed or not. Given the broken nature of the peer-reviewed system, I don't think you can conduct an argument about the value of an idea by saying that X is peer-reviewed and Y isn't. Or by seeing that Z has made it into Wikipedia, or is the subject of an article in a popular magazine.

 You need people who know what they are talking about to discuss the issue as honestly and clearly as they can. In many cases things will come down to whether there's any hope that future work will fix known problems with some idea (and I think that's what's going on here, as well as in string theory). Reasonable people will differ, with those who believe problems can be overcome going on to try and do so.

38. **Giotis**
November 21, 2010

 Peter,

 Yes it's a matter of taste if you like but my main point is that you don't put the soft SUSY breaking terms in the langranian completely arbitrary and by hand as Baez said. There is a proposed theoretical mechanism/justification for the presence of these terms and in any case the SUSY breaks spontaneously which is not unnatural at least.

39. **Brian Hsu**
November 21, 2010

 Thanks very much for your time, Peter,

 I do not wish to take up more of it, but I feel that if Garrett Lisi has made clear statements and proposals, it would take but a moment for you to express them. For instance, Einstein and Newton made clear proposals: E=mc^2 and F=ma.

 You write, "Garrett is making clear statements and proposals, some of which may be wrong and/or incomplete."

 Which of Garrett's "clear statements" are right and complete?

 Thank you for your time.

40. **Peter Woit**
November 21, 2010

 Brian,

 Sorry, Garrett's ideas are a lot more complicated than F=ma, and I believe the same will be true of whatever ideas finally get us beyond the Standard Model.

 You appear to be a complete fanatic on the Garrett issue, posting seven highly repetitive and uninformed comments here in the past few hours. That's enough, I'm deleting the rest. If you want to carry on this kind of campaign, you'll have to do it somewhere else.

41. **ned**
November 21, 2010

 Mr. Woit,

 I'm no physicist, so of course I don't have the slightest idea of the merits of the arguments in this discussion.

 But on reading through this exchange I did notice something which was not mentioned:

 Some of the postings, though on the surface pretending to be about physics, seem to me to have a closer connection with another branch of science – psychology.

 What the real problem here seems to be is addressed quite beautifully in a single sentence – the last one in a recent article about Mr. Lisi in the Telegraph:

 "… [Lisi] tells me: "I've been spending every other day surfing or kitesurfing here in Maui." No wonder his peers are jealous."

 At least some of them.

42. **Garrett**

November 21, 2010

Before I address the many points that have been raised, I'd like to say something on the personal and meta level about where I'm coming from. Many people seem to be behaving as if this E8 Theory is being forced on them, or as if I am some kind of salesman or trickster. What I am is a physicist who struck out on his own to pursue a question (specifically, what spinor fields are geometrically) that was of little interest to the broader community. I worked on this question largely in isolation for ten years, self supported, never pushing my ideas on anyone, and happened to find something incredibly cool. If I seem pushy now it is because I'm excited about this E8 Theory and I want to share it. At the same time, I openly acknowledge its current deficiencies and where there is work left to do. Regarding the media… sometimes excitement tempered by scientific skepticism is too subtle for editors and tv hosts, and hype gets extremized, which is unfortunate. I do have a tendency to say "yes" to interviews, invitations, and speaking engagements — so I am complicit to that degree, but in my defense it is because I'm excited about what I've found, and where it may lead. Also, as prospective theories of everything go, this one does look pretty awesome on a tshirt. (No, I'm not going to make money off of them, nor have I made money selling anything — the shirts are for love.) That said, I will now throw myself back into this comment thread and address the points raised. I generally enjoy and benefit from the high level of discussion on this blog.

-Garrett

43. **Garrett**
November 21, 2010

Mark: You're wrong on several counts. Distler and Garibaldi proved that *their* version of E8 Theory has a non-chiral spectrum. It is my thinking that mirror fermions (and 64 other E8 root vectors) can be gauge transformed to another chiral generation. However, since this is yet to be formally established, I'm willing to play along with the possible existence of mirror fermions. And the bottom line is that the existence of mirror fermions has not been ruled out. So although they are bad, they do not make a theory wrong, merely unattractive — and I expect this to change so that the problem is irrelevant.

44. **John Baez**
November 21, 2010

Giotis wrote:

There is a proposed theoretical mechanism/justification for the presence of these terms and in any case the SUSY breaks spontaneously which is not unnatural at least.

I don't really follow particle physics much these days, so I could easily be behind the times. Spontaneous symmetry breaking is, of course, much nicer than adding soft SUSY breaking terms by hand! I'd like to learn more about the state of the art.

Is the idea of spontaneously broken supersymmetry widely used in particle physics phenomenology, or is it just a proposal that's been studied in some toy models?

If the former:

Does someone know how to get a supersymmetric extension of the Standard Model where supersymmetry is broken spontaneously? If so, how do the superpartners get their masses? Is there some theoretical reason why all observed particles have superpartners much more massive than they are, rather than comparable masses – or is this fact somehow fed in by hand?

Etcetera, etcetera – lots of questions.

45. **mark davis tortino**
November 21, 2010

Garrett–in your Scientific American article, you claim that the LHC will test your theory.

How will it do this?

What are the specific particles and masses predicted by your theory?

Thanks!

46. **Aaron**
November 22, 2010

Sure. There are tons and tons of such models. The usual idea is that you have some hidden sector with a bunch of stuff that spontaneously breaks supersymmetry. The breaking is then communicated over to the MSSM by some sort of mediating particle. This is often a gauge field (gauge mediated susy breaking) or a graviton (gravity mediated supersymmetry breaking). It's a little old, but I think Martin's review hep-ph/9709356v5 has a pretty decent overview. As is often the case with these things, as soon as you solve one problem, another one will often pop up.

47. **Garrett**
November 22, 2010

Aaron:

> You can call your 'superconnection' whatever you want (although you still have not acknowledged that the very BRST superconnection you cite and don't seem to understand is related to a Grassman symmetry), but that doesn't mean it makes sense.

The superconnection I am using — the formal sum of a 1-form and a Grassmann field — is a well established mathematical construction. There are references cited in my papers, as well as from the link I provided. Such a superconnection is conventionally used in the BRST approach to YM gauge quantization. I am simply using the same well established mathematical formalism, with a different physical interpretation. I am sorry if it's unfamiliar to you — it's unfamiliar to most physicists, but it's an interesting geometric structure worth understanding.

> For the Coleman-Mandula theorem, you need to address what happens in the low-energy theorem. In particular, what breaks the symmetry mixing spacetime and internal indices and at what scale?

An excellent question, which is answered in detail in this paper with Lee and Simone. To summarize: the E8 connection obtains a nonzero VEV, separating the gravitational and gauge sectors of the connection, thus satisfying C-M at low energies.

> For your paper with Lee, I'd be a lot more interested if it had fermions in it.

It does. See Section 3.

For the rest of your questions, they're being addressed elsewhere in this thread — or they're pure snark. If I'm failing to address a question you have, try posing it more politely. In general, if you think E8 Theory is hopeless, then yes, do what you like and ignore it. Might I recommend you choose one of the other ToE's that have made fruitful progress over the last 30 years — oh wait, there are none. Maybe you can find one yourself that you like better.

48. **Garrett**
November 22, 2010

Mark:

> Well, it's not an ad hominem attack to state that Garrett has never published a peer-reviewed paper on his "theory."

No, but it's wrong. The paper with Lee and Simone lays out 90% of the theory, and was published in J. Phys. A: Math. Theor. 43 (2010). Lee and I tend to just put papers on the arxiv, but Simone thought it would be good to put it in a journal. There was no problem getting it published.

> why not try to refute distler's paper on a scientific, mathematical level

I did. The resulting paper is here, which I believe makes things crystal clear, as well as forming a more complete introduction to E8 Theory.

49. **onymous**
November 22, 2010

Aaron wrote:

This is often a gauge field (gauge mediated susy breaking) or a graviton (gravity mediated supersymmetry breaking).

This is not what "gravity mediated supersymmetry breaking" means. "Gravity mediated supersymmetry breaking" means "supersymmetry breaking mediated by any set of Planck-suppressed operators." In some sense, the minimal version of it is what's known as "anomaly mediation," but it encompasses a huge range of models (and some not-quite-models, like "mSUGRA" or "minimal supergravity" which is more of an ansatz than a model, and which unfortunately is most of what experimentalists have been setting limits on for decades).

The trouble with generic Planck-suppressed operators is the flavor problem. As John said, there are about a hundred parameters in the MSSM with soft SUSY breaking, but phenomenology imposes strong restrictions so that really only about 20 are completely independent. If you tried to wander very far outside of this low-dimensional subspace in the 100-dimensional parameter space, you would be in gross conflict with observations. To give an example, if selectrons and smuons are both light, they have to be almost the same mass. So gravity mediation requires extra structure to explain these phenomenological facts, and this structure must be present at or near the Planck scale and survive running down to low energies.

As for John's question:

Does someone know how to get a supersymmetric extension of the Standard Model where supersymmetry is broken spontaneously?

It's important to note that particles beyond those of the MSSM are needed for supersymmetry to be broken spontaneously, which is why models always involve a hidden sector. This was realized quite early on; the paper by Dimopoulos & Georgi that introduced the MSSM with soft SUSY breaking explained that without a hidden sector (i.e. if SUSY is broken spontaneously in the MSSM alone), the theory would always have a scalar lighter than the up or down quark.

November 22, 2010

John: Thanks for this — I hope we can clarify a lot, and maybe even make some new progress.

> Most importantly, particles have very distinct personalities, whereas all 248 dimensions of E8 look alike. E8 is very symmetrical, that's why people like it. But this beautiful symmetry needs to be severely broken for anything like real-world physics to fall out.

Excellent point. Here's what happens. We start with an E8 principal bundle with connection (not a superconnection). The symmetry breaks when this connection gets a vacuum expectation value (VEV), [tex]A \simeq E_0[/tex] (I'm not sure if TeX is working here in the comments, as it once was), which leaves the curvature 0. (One way this could happen spontaneously, starting with an E8 invariant action, is described in the paper with Lee and Simone, but the particular mechanism isn't so important.) This spontaneous symmetry breaking picks out some directions in E8 as *special*, allowing all other generators in E8 to be identified (and named) with respect to these, based on their Lie brackets. Since it's key, let me describe this in more detail. If we describe the E8(-24) Lie algebra as

e8 = spin(12,4) + 128^+_S

then the VEV of the connection is [tex]E_0 = 1/4 e_0 \phi_0[/tex], in which [tex]\phi_0[/tex] is the VEV of a Higgs multiplet that transforms as a 12 vector under a spin(11,1) subalgebra of the spin(12,4), and [tex]e_0[/tex] is the 1-form frame field of deSitter spacetime, transforming as a 4 vector under a spin(1,3) subalgebra of spin(12,4), such that the nonzero VEV is in the complement of spin(1,3) and spin(11,1) in the spin(12,4) of e8. It had to be deSitter spacetime if the curvature of the connection is to be 0, with cosmological constant related to the Higgs VEV. Personally, I think this symmetry breaking mechanism — combining cosmogenisis with a Higgs model — is… awesome. I'd enjoy getting your feedback on it.

> I see no way to get E8 symmetries that mix fermions and bosons in a model where the symmetry of E8 has been broken by deliberately chopping it into bosonic and fermionic parts.

The "bosonic and fermionic" parts of the connection can only mix before spontaneous symmetry breaking — which is to say, before our universe technically exists. However, if an appropriate action has been chosen that is independent of the "fermion" parts of the E8 connection, then there is a prescription for replacing the "fermion" parts of the connection (1-forms valued in the parts e8 that we're calling the fermion part, based on [tex]E_0[/tex]) with Grassmann fields, which are identified as fermions (or pre-fermions, if you like). Now, based on our action, and on [tex]E_0[/tex], we could separate out the [tex]128^+_S[/tex] as the fermion part, or, as I consider preferable, we could break e8 up as

e8 = spin(4,4) + spin(8) + 8×8^+_S + 8×8^-_S + 8x8_V

and consider those last three blocks of 64 as pre-fermion Grassmann fields. This works because spin(4,4) + spin(8) is reductive in e8.

Ah, as I'm reading this, I see I have an email from you…

John Baez,

A recent, up to date, small (20 pages) concise review with a comparison of the various mechanisms (pros and cons) and potential string theory realizations is the following

arXiv:1006.0949 by Alwis

52. **Aaron**
November 22, 2010

This is not what "gravity mediated supersymmetry breaking" means.

Geez. I go away for a few years and I already start forgetting things. Enh. Phenomenology was never my thing anyways.

For Garrett, you still haven't explained whether the infinitesimal generators of your symmetry are all commuting or if some or Grassman.

And do you still claim to be able to reproduce any part of the standard model action?

I do apologize for confusing your paper with an earlier one of Lee's which was fermion free, however. However, your paper seems more along the lines of Percacci's earlier paper where fermions are considered separately and not in the same multiplets as bosons.

I will probably have to bow out of this discussion now, however.

53. **Wolfgang**
November 22, 2010

"This works because spin(4,4) + spin(8) is reductive in e8"

How the Standard Model gauge group sits inside of spin(4,4) + spin(8) ?

"Personally, I think this symmetry breaking mechanism — combining cosmogenisis with a Higgs model — is… awesome."

Does that mean that you predict the cosmological constant is electro-weak scale in size?

54. **Rhys**
November 22, 2010

> The resulting paper is here, which I believe makes things crystal clear, as well as forming a more complete introduction to E8 Theory.

Except that you have still completely failed to answer Distler's criticism. Allow me to quote the relevant excerpt from your paper:

> Distler and Garibaldi prove that … when one embeds gravity and the Standard Model in E8, there are also mirror fermions. They then claim this prediction of mirror fermions (the existence of "non-chiral matter") makes E8 Theory unviable. However, since there is currently no good explanation for why any fermions have the masses they do, it is overly presumptuous to proclaim the failure of E8 unification – since the detailed mechanism behind particle masses is unknown, and mirror fermions with large masses could exist in nature.

This is completely misleading. For one thing, the phrase "mirror fermions" is ambiguous. There are models of particle physics which impose exact parity symmetry, which requires introducing so-called "mirror matter". However, in this case, the extra particles are charged under a different gauge group to the visible particles, and are easy to 'hide'. What you have is nothing like this.

In the standard model, no fermion mass terms are allowed, because they violate the gauge symmetry. The reason is that the left-handed fermions are in a complex representation of the gauge group. After electroweak symmetry breaking, all fermions are vector-like with respect to the remaining gauge symmetry, and mass terms can be written down. In practice, these come from Yukawa couplings to the Higgs field. However, in your model, the fermion content is doubled, such that the left-handed fermions now fall into a real representation of the standard model gauge group (in fact, R + R-bar, where R is the standard model rep). Therefore there is nothing to forbid mass terms for all the fermions, and in fact these should be generated radiatively in the absence of supersymmetry. So generically, all fermions in your theory should have masses roughly of the cut-off scale (probably the Planck scale here).

This is a serious problem, and why Distler rightly calls your model a 'zero-generation' model. You can't just wave your hands about it — you have to at least provide a solution in principle, or there is no reason to think your model is anything more than a pretty exercise in group theory.

Let me finish by explaining why this is so different to supersymmetry. Before SUSY breaking, there are no mass terms in the MSSM. For the fermions, the reason is the same as for the standard model, and the bosons are related to the fermions by SUSY. After SUSY breaking, nothing stops us writing down mass terms for the bosons, but those for the fermions are still forbidden by chirality. That's why it is natural for the (unseen) scalar partners to be significantly more massive than the standard model fermions. The Higgs is different, because there is an up-type Higgs and a down-type Higgs, and together they form a real representation, so one can write down a supersymmetric mass term.

55. **Urs Schreiber**
November 22, 2010

Garrett suggested to sombody:

> Might I recommend you choose one of the other ToE's that have made fruitful progress over the last 30 years okay, I will — oh wait, there are none.

I suppose you have followed Alain Connes' construction (here is a survey and links) of the standard model by a Kaluza-Klein compactification in spectral geometry. It unifies all standard model gauge fields, gravity as well as the Higgs as components of a single spin connection. Connes finds a remarkably simple characterizaiton of the vector bundle over the compactification space such that its sections poduce precisely the standard model particle spectrum, three chiral generations and all.

Alain Connes had computed the Higgs mass in this model under the big-desert hypothesis to a value that was in a rather remarkable chain of events experimentall ruled out shortly afterwards by the Tevatron. But the big desert is a big assumption and people got over the shock and are making better assumptions now. We'll see.

Apart from being a nice geometrical unification of gravity and the other forces (credits ought to go all the way back to Kaluza and Klein, but in spectral geometry their orginal idea works out better) Connes' model has some other striking features:

the total dimension of the compactified spacetime in the model as seen by K-theory is and has to be, as they showed, to produce exactly the standard model spectrum plus gravity: D= 4+6.

Now "as seen by K-theory" was shown by Stolz and Teichner and students to mean in a precise sense: as seen by quantum superparticles (here is some link — you can ask me for a better link). In fact what they consider is almost exactly the spectral triples that Connes considers, with some slight variation and from a slightly different angle. For the relation see the nLab entry on spectral triple (ask me to expand that entry…).

As also indicated at that entry: there is a decent theory of how to obtain a spectral triple as the point particle limit of a superconformal 2-dimensional CFT. Yan Soibelmal will have an article on that in our book Precisely because Connes' model turns out to have real K-theory dimension 4+6 does it have a chance to be the point particle limit of a critical 2D SCFT. That would even give it the UV-completion — as they say — that would make its quantization consistent (which, remember, contains gravity).

I think there is some impressive progress here. It is not coming out of the physics departments, though, but out of the math departmens. For some reason.

56. **Garrett**
November 22, 2010

(I'm continuing through the comments chronologically, picking up where I left off, trying not to miss anything directed to me that's important. Peter, thanks for allowing the discussion.)

John:

> Second, even among fermions, different particles have drastically different personalities: for example their masses, and the rates at which they turn into each other, which are described by the numbers in the Cabibbo-Kobayashi-Maskawa matrix and the Maki-Nakagawa-Sakata matrix. Similarly, in the realm of the bosons there's the Higgs mass and other numbers. Garrett's work has nothing to say about these. Without these numbers we can't do real-world physics. But the big problem is this: I don't see any way to get these numbers into the game without further breaking down the symmetry of E8. Why? Because again, E8 symmetry wants all particles to be alike, but these numbers describe how they're not.

Getting the CKM and MNS matrices is the goal, and it is true, E8 Theory is not there yet — and I have been completely candid about this at every opportunity. But I do think there is hope, and my work may soon have something to say about these. How can this possibly work? Well, it all has to start with symmetry breaking, as described in my previous comment. After that, the masses of all other particles are determined by how they interact with the Higgs.

> Third, there's no way to pack all known fermions into E8 without positing two copies of E8 and giving every fermion a mysterious unseen partner called a "mirror fermion". To keep these rascals from being seen we could claim they're more massive than the guys we see – but no method for this has been described yet, to my knowledge.

There is potentially a way to fit three generations of fermions into E8 and avoid the mirror fermion problem. The basic idea is that, using an inner-automorphism of E8 related to triality, we can independently gauge transform the 64 mirror fermions, and 64 pre-fermions in the 8_Vx8_V of a so(4,4)+so(8) subalgebra of e8, into generations of usual fermions that will all interact differently with the Higgs. I don't yet know if CKM and MNS will come out of this, but I'm working on it. In the meantime, yes, it's fair to say the model is incomplete, and the burden is on me (or some other researcher) to figure out how this can work, but it's premature to say it can't work.

57. **Garrett**
November 22, 2010

Mark:

> Lisi should: a) publish some papers in journals

Did that.

> b) answer john baez et al.'s skepticism

Working on it. But, I also encourage skepticism.

> c) present some testable predictions

The testable predictions are that if any new particles are found that don't fit E8, such as superparticles (which many expect to see), then this theory is wrong.

> d) have them tested

In progress.

> e) be labeled the next-einstein and move on to selling i-phone universe-splitter apps and t-shirts.

What people label me, whether it's crackpot, next-einstein, or surfer-physics dude, isn't really up to me. And I'm not selling anything. I am, however, helping friends sell things I think are cool, and see no problem with that. Also, I did get paid to write the SciAm article, and will use the money to buy a new surfboard.

> Add to this the powerful behind-the-scenes financial and media forces at play here

What powerful financial and media forces?

> and that this has been going on for over three years with no new developments nor solutions to the problems from Lisi

If you look at my list of (1)-(6) issues in my comment above, you'll see that there has been good progress on several of them.

58. **Garrett**
November 22, 2010

Brian: Peter has addressed your points. My only addition is that I have published work on the theory, without difficulty, with coauthors. But as the Bogdanovs showed, this means little.

59. **Garrett**
November 22, 2010

Peter:

> You need people who know what they are talking about to discuss the issue as honestly and clearly as they can. In many cases things will come down to whether there's any hope that future work will fix known problems with some idea (and I think that's what's going on here, as well as in string theory). Reasonable people will differ, with those who believe problems can be overcome going on to try and do so.

Precisely. Thank you.

60. **Garrett**
November 22, 2010

ned:

> "I've been spending every other day surfing or kitesurfing here in Maui." No wonder his peers are jealous."

My life hasn't been all roses. But I am working on making it easier for other scientists to come spend some time in Maui — that's what the Pacific Science Institute is about.

61. **Garrett**
November 22, 2010

Aaron:

> For Garrett, you still haven't explained whether the infinitesimal generators of your symmetry are all commuting or if some or Grassman.

The superconnection is the formal sum of a 1-form and an anti-commuting Grassmann field, both valued in different parts of some algebra. That algebra can be a Lie algebra, such as E8, or it can be a Lie superalgebra — the necessary restriction is that the 1-form be valued in a reductive subalgebra.

> And do you still claim to be able to reproduce any part of the standard model action

Yes, see the paper with Lee and Simone.

> I do apologize for confusing your paper with an earlier one of Lee's which was fermion free, however. However, your paper seems more along the lines of Percacci's earlier paper where fermions are considered separately and not in the same multiplets as bosons.

True. We wanted to make this less unfamiliar and upsetting to people by keeping the bosons and fermions separate.

> I will probably have to bow out of this discussion now, however.

Sorry to lose your input.

62. **Garrett**
November 22, 2010

Wolfgang:

> How the Standard Model gauge group sits inside of spin(4,4) + spin(8) ?

Excellent observation. It doesn't. The Standard Model and gravity fits in spin(12,4), and spin(4,4)+spin(8) fits in that. There are two SM generators, W^+ and W^-, that occupy the complement. When considering triality, one needs to use spin(4,4) and/or spin(8). I'm not yet sure whether those W's will remain in the complement as bosons, displacing two fermion degrees of freedom, or whether things will work some other way. A key idea that came from Banff is that the spin(4,4)+spin(8) subalgebra of e8 which relates to triality might be a different subalgebra than the one containing the Standard Model, including having different Cartan subalgebras. This will, of course, give a mixing mess, but the question will be whether that mess is the CKM and MNS mess.

> Does that mean that you predict the cosmological constant is electro-weak scale in size?

Yes! That seems terrible, but the hope is that the cosmological constant runs from this value at the unification scale down to the tiny value we see at low energies.

63. **Wolfgang**
November 22, 2010

"There are two SM generators, W^+ and W^-, that occupy the complement. When considering triality, one needs to use spin(4,4) and/or spin(8). I'm not yet sure whether those W's will remain in the complement as bosons, displacing two fermion degrees of freedom, or whether things will work some other way."

Didn't you explain that all the generators of e8 are either in spin(4,4)+ spin(8) or in one of the 8×8 blocks exchanged by your triality?

So, if some of 8×8 block is bosons, where are rest of fermions? And, if Ws live in 8×8 block, does that mean they form triplet under triality? Do different generations have different gauge bosons coupling to them?

Sorry for so many questions, but this is very confusing!

64. **Garrett**
November 22, 2010

Rhys:

> Except that you have still completely failed to answer Distler's criticism.

No, Distler and Garibaldi's claim is that one cannot even get one generation of fermions in E8. This paper answers that directly by showing explicitly how a generation of fermions does fit in E8. (And it explains it via a direct identification of generators, which is quite nifty.)

> This is completely misleading.

No, it is direct. It is Distler's language that is misleading. When he says "there are no chiral generations," what he actually means is that there is a generation and what he calls an anti-generation and I call mirror fermions. For him and you to use this twist of mathematical language to say "there are no generations" is a lie.

> For one thing, the phrase mirror fermions is ambiguous.

The top Google hits and I disagree.

> There are models of particle physics which impose exact parity symmetry, which requires introducing so-called mirror matter.

If I had said "mirror matter," then yes, it would have been ambiguous. But I did not.

> fermions in your theory should have masses roughly of the cut-off scale

That's such a fun word, "should." With that one word, you are presuming what nature does — when the truth is that we just don't know. It is fine if you want to say "it should not be," it is a lie to say "it can not be," at least until we know what nature actually does. And in that same phrase, you are incorrectly presuming, as do Distler and Garibaldi, that *my* theory must have mirror fermions in it, when I have said several times that I expect these to be gauge transformed to usual fermions.

> You can't just wave your hands about it — you have to at least provide a solution in principle, or there is no reason to think your model is anything more than a pretty exercise in group theory.

This is a valid point. I cannot say I have a complete theory of everything, and I do not, until these problems are solved. But I can and do wave my hands about how they might be solved in principle. And even if it ends up having been a pretty exercise in group theory, I won't have considered it a waste of time, because I think there is a lot here — especially the dodge of the Coleman-Mandula theorem via symmetry breaking — that is true about nature, even if we don't yet have the full picture.

65. **Steve**
November 22, 2010

This may not be the proper place to bring this up. But does anyone have a view on Penrose's 'conformal cyclic cosmology'? I am reading his book now and but have only seen a couple of arxiv articles mentioning it…..

66. **Garrett**
November 22, 2010

Urs: I agree that Alain Connes' model is fascinating and deserves more attention from physicists. But it has not been fruitful in making successfully tested new HEP predictions — nor has any model in the past 30 years. It was not my intent to be discouraging, or particularly disparaging of other ideas — I was mostly counter-snarking Aaron.

67. **Peter Woit**
November 22, 2010

Steve,

I've heard Penrose talk about this, but didn't really understand the point. I look forward to reading his book (it isn't out in the US yet), and might write about it then. But, I'm no cosmologist, best to find a blog run by someone who is to discuss the subject.

68. **Urs Schreiber**
November 22, 2010

> But it has not been fruitful in making successfully tested new HEP predictions — nor has any model in the past 30 years.

It has. Within weeks even. It was experimentally verified that the big desert assumption is inconsistent in this model with experiment.

It's an impressive model. And I didn't quite say that "it deserves more attention from physicists". Let them spend their time with what pleases them. Instead I mentioned this in reply to your insinuation that there is nothing promising in fundamentall model building out there besides your idea. It occurred to me that you might actually think that's true. And maybe because the most impressive progress in fundamental physics these days does not quite percolate through the physics community.

69. **Garrett**
November 22, 2010

Wolfgang (and John):

> So, if some of 8×8 block is bosons, where are rest of fermions? And, if Ws live in 8×8 block, does that mean they form triplet under triality? Do different generations have different gauge bosons coupling to them?

Here we are on the edge of what I'm working on. So I don't yet know what the complete picture is, and my remarks here will be speculative. We do know that under the decomposition

e8(-24) = spin(12,4) + 128^+_S

that one generation of fermions can be the 64^+_S rep (part of the above 128) of a spin(11,3) subalgebra of the above spin(12,4). And in fact, the known gravitational and Standard Model bosons can fit in a spin(5,3)+spin(6) subalgebra of spin(11,3). But, spin(5,3) and spin(7,1) don't have triality automorphisms. However, spin(4,4) and spin(8) do, so we can decompose e8 as

e8(-24) = spin(4,4) + spin(8) + 8x8_V + 8x8_+ + 8x8_-

and consider innner automorphisms of e8, corresponding to so(4,4) and so(8) triality, that interchange those three blocks of 64. If we put gravitational spin(1,3) in the spin(4,4), and strong su(3) in the spin(8), and the photon and the Z in both, then we're stuck with at least the W^+ and the W^- in that 8x8_V. And you're right that if we're identifying those three blocks of 64 by triality that we're probably going to be missing at least three sets of two fermion degrees of freedom to accommodate those W's. Maybe nature has chosen to exclude the right-handed components of neutrinos in this way? Or, an even weirder speculation, maybe that particular spin(4,4)+spin(8) is not completely in the spin(12,4)? There would have to be a lot of mixing angles to describe the geometry of how these spin groups are mutually related, but we want something like that to come out anyway that corresponds to CKM and MNS. The bottom line is that I don't know how this works yet, but it's really fun and interesting! (And please do correct me if I've made any mistakes here.)

70. **Garrett**
November 22, 2010

Urs: I didn't mean to insinuate that there aren't other promising models. But I don't consider a prediction proven false to be a "fruitful" prediction in the usual sense, though these impressive events and the positive aspects of Connes' model are not lost on me. I do consider this E8 Theory to be even more fascinating and promising, but I'm biased. Although, it indisputably looks really good on the new T-shirts. 🙂

71. **Tony Smith**
November 22, 2010

Garrett, about
e8(-24) = spin(4,4) + spin(8) + 8x8_V + 8x8_+ + 8x8_-
where you put
gravity spin(1,3) in the spin(4,4)
and
color su(3) in the spin(8)
but
are "stuck with at least the W+ and W- in that 8x8_V"

could you find within "that 8x8_V" a spacetime base
manifold that is an 8-dim Kaluza-Klein M4 x CP2
where
M4 is 4-dim Minkowski spacetime
and
CP2 is internal symmetry space.

Then since CP2 = SU(3)/U(2)
you would have the electroweak U(2) (weak bosons and photon)
naturally included in your structure,
and
the added benefit of getting not only fermions and bosons,
but spacetime itself as part of your E8.

The 8-dim Kaluza-Klein idea is not mine,
but is due to N. A. Batakis
who wrote Class. Quantum Grav. 3 (1986) L99-L105 in which he showed
that "… In a standard Kaluza-Klein framework,
M4 x CP2 allows the classical unified description of an SU(3) gauge field with gravity
… an additional SU(2) x U(l) gauge field structure is uncovered …
As a result,
M4 x CP2 could conceivably accommodate the classical limit of a fully unified theory
for the fundamental interactions and matter fields …".
Roughly, he uses the structure CP2 = SU(3)/U(2) with the local U(2) giving electroweak and the global SU(3) working for color since its global action is on CP2 which is, due to Kaluza-Klein structure,
local with respect to M4 Minkowski spacetime.
As to why Batakis is not well known and his model fell into obscurity,
Batakis never handled fermions properly in his model.
Since he had nothing to work with but M4xCP2 Kaluza-Klein,
he was reduced to introducing fermions sort of ad hoc by hand,
and he could not show that they worked nicely with his gauge bosons.
However,
since all your structures (spacetime, gauge bosons, fermions) would come from E8 they can be shown to work together nicely.

Tony

72. **Wolfgang**
November 22, 2010

"If we put gravitational spin(1,3) in the spin(4,4), and strong su(3) in the spin(8), and the photon and the Z in both, then we're stuck with at least the W^+ and the W^- in that 8x8_V."

If I understand what you are saying, there are three W^+s and three W^-s (the ones in the 8x8_V and their triality partners in the other 8×8 blocks). How to reconcile that with there being only one SU(2), whose gauge field corresponding to the diagonal generator occurs only once?

How does the SU(2) Yang Mills action look?

I understood that you wanted the physics of having three generations of fermions, but I don't think you want three generations of W's.

73. **Garrett**
November 23, 2010

Tony:
Your idea sounds pretty close to constructing a Cartan geometry starting from E8. However, if we mod E8 by spin(4,4)+spin(8), we get not only the 8x8_V but also the 128 spinor as the base, which is waaaay too big. It seems much cleaner to consider an E8 principal bundle over a 4D base. If it turns out that structure isn't rich enough, then I'm open to re-considering an 8D base and KK with CP2. I agree it looks pretty good, but I want to see what I can do with just a 4D base, E8, and triality first.

74. **Garrett**
November 23, 2010

Wolfgang:
You are understanding things perfectly.

But when looking for a mixing mechanism, I think it's probably good to have these issues in mind but not focus on them too hard. The W's are important, but they're not the only problem. We also have to either get rid of or give large masses to all the X bosons somehow — the various gauge fields other than those of the SM. And, of course, we want to mix the fermions (including mirrors) and get the CKM and MNS for them — all of this in one go, with limited options.

I think a good thing to try is going to be using the so(4,4)+so(8) decomposition to calculate a set of E8 inner automorphisms related to triality, then try applying those inner automorphisms back in the so(12,4) + 128 decomposition to see how it can mix elements. I want to see what is learned from trying that before focusing on specifics.

75. **chris**

November 23, 2010

> Also, I did get paid to write the SciAm article, and will use the money
> to buy a new surfboard.

this is the coolest statement on this blog yet 🙂

and kudos that you resisted invoking the anthropic principle … yet

76. **Steve**
November 23, 2010

Peter,
Penrose's book has been available on Amazon since late October.

77. **Wolfgang**
November 23, 2010

"The W's are important, but they're not the only problem. We also have to either get rid of or give large masses to all the X bosons somehow"

OK. But other gauge symmetries could be broken at Planck scale. Standard Model gauge symmetries are supposed to be unbroken down to low energies. That seems much more restrictive.

One more question:

In previous comments, you seemed to say that even if triality idea doesn't work out, E8 theory is still OK.

My understanding from trying to read distler-garibaldi paper is that they show two things,

1) 128 (out of 248) fields are fermions
2) fermion spectrum is non-chiral

so (assuming no triality), fermions are at best 1 generation and 1 mirror-generation of Standard Model. From this they conclude E8 theory is not viable.

Do you say E8 theory with 1 generation and 1 mirror-generation (even if no triality) is still viable theory of Nature?

If so, could you explain how?

78. **thomas schaefer**
November 23, 2010

The lack of response to Connes' theory is indeed interesting. I think the problem is that nonbody has been able to explain in a language that particle theorists can understand whether this is indeed a new idea (and if so, what the new idea is) or whether this is just a complicated way to formulate an old idea (GUT's or maybe Gravi-GUT's). Where is Witten when you need him?

79. **Wolfgang**
November 23, 2010

Sorry. I have one more question. About cosmological constant being electro-weak scale in size, you said:

"Yes! That seems terrible, but the hope is that the cosmological constant runs from this value at the unification scale down to the tiny value we see at low energies."

Does that mean the relation between electro-weak scale and cosmological constant is accidental feature of your classical lagrangian? Is there a more general lagrangian where they are independent parameters?

I ask because in renormalizable theory all counterterms should appear as possible terms in classical lagrangian.

80. **Thomas Larsson**
November 23, 2010

Didn't Connes predict a 170 GeV Higgs? Which was the first region to be ruled out by the Tevatron?

81. **Tony Smith**
November 23, 2010

Just to be clear,
my intent was not to suggest
"… mod E8 by spin(4,4)+spin(8) …"
in which case "… we get not only the 8x8_V but also the 128 spinor as the base …"
but to suggest
mod E8 by both spin(4,4)+spin(8) and also the 128 spinor
(that may be a 2-stage process)
so that
we get only the 8x8_V as the base
and then
to let the 8x8_V represent an 8-dim M4 x CP2 Kaluza-Klein.

Tony

November 23, 2010

> The lack of response to Connes' theory is indeed interesting. I think the problem is that nonbody has been able to explain in a language that particle theorists can understand whether this is indeed a new idea (and if so, what the new idea is) or whether this is just a complicated way to formulate an old idea (GUT's or

> maybe Gravi-GUT's).

Yes. Generally my impression is that the number of theoretical physicists actively aware of or at least interested in the issues of what it means to find a conceptual or even axiomatic framework for fundamental physics is currently much lower than it used to be. It seems to me that in the early 90s or so the situation has been very different. In fact from that time date a few articles by string theorists who had read Connes, had understood what he is after and had tried to connect it to string theory.

Because the curious thing is: what Connes suggests is precisely the 1-dimensional version of the very idea of perturbative string theory (which is the 2d version of an even more general idea):

regard the algebraic data characterizing a d-dimensional super QFT as a stand-in for the geometric data characterizing the target space of which this QFT would be the sigma-model, if it were one. What in Connes's setup is a spectral triple is a vertex operator algebra for the string.

(References that discuss how to make this statement precise are at [spectral triple] and [2-spectral triple]).

> Where is Witten when you need him?

And why do you necessarily need him?

Lately Witten seems to be busy providing more evidence for the [holographic principle of higher category theory] (scroll down to see what i mean).

83. **Garrett**
November 24, 2010

Wolfgang:

> In previous comments, you seemed to say that even if triality idea doesn't work out, E8 theory is still OK.

What I was saying was slightly different. I do think the triality idea is going to have to work out for E8 Theory to be a *good* theory. However, since I only have some rough ideas on how triality might work out, I have been forced by critics to defend the theory without it. Without triality, the best I can say is that the theory is incomplete and unattractive, but not necessarily wrong. The best way to look at it, in my opinion, is that we currently know exactly how gravity and the Standard Model gauge fields along with one generation of fermions can embed in E8, which is incredibly cool. And there are some indications of how to get the other two generations, with a much tighter fit, but that is not yet clear.

> My understanding from trying to read distler-garibaldi paper is that they show two things, (1) 128 (out of 248) fields are fermions. (2) fermion spectrum is non-chiral. So (assuming no triality), fermions are at best 1 generation and 1 mirror-generation of Standard Model. From this they conclude E8 theory is not viable. Do you say E8 theory with 1 generation and 1 mirror-generation (even if no triality) is still viable theory of Nature?

This is a straw man setup. I disagree with Distler and Garibaldi at step (1) — they insisted on using this [tex]Z_2[/tex] grading of E8 even though I said the theory would rely on other options. However, even this silly straw man is not easy to knock down, because mirror fermions have not been completely ruled out, even if they make it ugly.

Essentially, I think E8 Theory is about half way done. We've got gravity, the Standard Model, a generation of fermions, and a nice symmetry breaking mechanism. And the triality-related gauge transformations I'm working with are very encouraging. It is kind of stupid to assess a half-done theory as if was supposed to be a complete theory of nature. It's like looking at a half-built house and saying "oh, that's no good — it's leaky." Rather, one needs to assess E8 Theory as a research program moving towards a complete ToE. And, from that point of view, it's doing pretty well.

84. **Garrett**
November 24, 2010

Wolfgang:

> Does that mean the relation between electro-weak scale and cosmological constant is accidental feature of your classical lagrangian? Is there a more general lagrangian where they are independent parameters?

The relation between Higgs VEV and cosmological constant is even more fundamental than the Lagrangian. If the bosonic connection is

[tex]H = \frac{1}{2} \omega + \frac{1}{4} e \phi + A[/tex]

then its curvature is

[tex]F = \frac{1}{2}(R – \frac{1}{8}\phi^2 e e) + \frac{1}{4} (T \phi – e D \phi) + F_A[/tex]

and the relationship between Higgs VEV and cosmological constant, [tex]\Lambda = \frac{3}{4} \phi_0^2[/tex], comes from [tex]F_0 = 0[/tex], which I consider more fundamental than the Lagrangian. One might be able to cook up a way to change that relationship, but I wouldn't recommend it.

85. **Garrett**
November 24, 2010

(Hmm, that "8211;" above is a "-". I don't know why it did that.)

86. **Garrett**
November 24, 2010

Tony: I think one is only allowed to mod out by subgroups.

87. **Wolfgang**
November 24, 2010

"This is a straw man setup. I disagree with Distler and Garibaldi at step (1) — they insisted on using this Z_2 grading of E8 even though I said the theory would rely on other options."

Maybe I expressed myself badly.

Fermions transform as Lorentz spinors. Your triality idea is to change how fields in the 248 transform under Lorentz group. Without triality (which remains to be worked out), fields transform according to the “naive” transformation rule. Do you agree that naive transformation rule gives 128 fermions or is even that part wrong?

Put differently: if the triality idea doesn’t work out, do you have another way to avoid distler-garibaldi conclusion?

“The relation between Higgs VEV and cosmological constant is even more fundamental than the Lagrangian. … One might be able to cook up a way to change that relationship, but I wouldn’t recommend it.”

If you don’t change it, how do you avoid cosmological constant of order the electro-weak symmetry breaking scale?

In earlier comment, you said “the hope is that the cosmological constant runs from this value at the unification scale down to the tiny value we see at low energies.” But if Higgs VEV and cosmological constant are tied together as you say how can one be big (250 GeV) and the other tiny?

88. **Tony Smith**
November 24, 2010

Garrett, you say “one is only allowed to mod out by subgroups”.

Maybe you and I are not using “mod out” in the same sense,
and maybe (since it is a term with which I am not very familiar)
I have been misusing it, so here is what I am trying to say in
terms of graded Lie algebras:

Consider Thomas Larsson’s 7-grading of E8 which is of the form
E8 = g_-3 + g_-2 + g_-1 + g_0 + g_1 + g_2 + g_3
with graded dimensions
E8 = 8 + 28 + 56 + (sl(8) + 1) + 56 + 28 + 8

The odd graded part of E8 has 8+56 + 56+8 = 64+64 = 128 dimensions
and corresponds to your 128 spinor.

The even graded part of E8 has 28 + 64 + 28 = 120 dimensions
and corresponds to your D8 Lie algebra so(4,12)

My first stage is to “mod out” the odd graded 128 spinor,

which leads to the next stage about the D8.

The D8 Lie algebra has a 3-grading which is of the form
D8 = g_-3 + g_-2 + g_-1 + g_0 + g_1 + g_2 + g_3
with graded dimensions
D8 = 28 + (sl(8) + 1) + 28

The odd graded part of D8 has 28 + 28 = 56 dimensions
and corresponds to your D4 + D4 Lie algebras so(4,4) and so(8)

The even graded part of D8 has 64 dimensions
and corresponds to your 8x8_V.

My second stage is to “mod out” the odd graded D4 + D4,

which leaves your 64-dimensional 8x8_V to represent
an 8-dim spacetime that can (by breaking octonionic symmetry
down to quaternionic) give you a M4 x CP2 Kaluza-Klein
with the Batakis structure giving you the U(2) from CP2= SU(3)/U(2).

Then you can construct a nice Lagrangian as follows:

Base Manifold from the 8-dim Kaluza-Klein in the 8x8_V

Gauge Boson terms from D4 + D4 “modded out” in stage 2

Fermion terms from 128 half-spinor “modded out” in stage 1.

Then,
if you look at the geometry of the octonionic/quaternionic
symmetry breaking down to 4+4 dim Kaluza-Klein you see
that Meinhard Mayer’s mechanism (Hadronic Journal 4 (1981) 108-152)
(he is physics professor emeritus at U. C. Irvine)
gives the Higgs scalar.

Tony

89. **Daniel de França MTd2**
November 24, 2010

Garrett,

What about this: whenever you talk about using triality on a part of E(8), it seems you are not talking about E(8) anymore, but a semiderect product of SO(8)XE(8), SO(8) being the group that “insert” the triality. Now, what do you think of this?

90. **Gregor Samorasky**
November 25, 2010

Hello Peter & Garrett,

Well, it seems that Peter is quite skeptical of Garrett's theory, and that Garrett is too, if less so. The question, then, is why does it keep getting so much attention and funding?

Peter writes, "
Tristan,

My understanding is that Garrett is well aware that his proposal has problems. In the Scientific American article he writes:

"All new ideas must endure a trial by fire, and this one is no exception. Many physicists are skeptical—and rightly so. The theory remains incomplete."

I have no problem with skepticism, I'm skeptical about many of Garrett's ideas too. If Jacques wants to make a clean technical argument showing the nature of the problems with Garrett's proposal, that's great, and could be potentially worthwhile. But I don't see any reason for the hostile, sneering tone of Jacques's blog posting explaining these points. This is not the way to professionally make a credible technical argument. "

Are there not a lot of other theories out there which we can be skeptical about? So why is Garrett's "theory" getting all the attention from television, magazines, and the press? Who is pushing/promoting this and why?

Insights? Ideas? Thanks!

91. **Garrett**
November 25, 2010

Wolfgang:

> Fermions transform as Lorentz spinors. Your triality idea is to change how fields in the 248 transform under Lorentz group. Without triality (which remains to be worked out), fields transform according to the "naive" transformation rule. Do you agree that naive transformation rule gives 128 fermions or is even that part wrong?

That is correct.

> Put differently: if the triality idea doesn't work out, do you have another way to avoid distler-garibaldi conclusion?

No, without triality, we're stuck with mirror fermions. But the Distler-Garibaldi conclusion that "the theory can't work" would still be untrue, because mirror fermions could exist. But I don't think they do — I think triality will work.

> But if Higgs VEV and cosmological constant are tied together as you say how can one be big (250 GeV) and the other tiny?

I haven't done the calculation, but perhaps they run independently, with the effective cosmological constant getting contributions from gravity, and the Higgs mass from Standard Model and other interactions.

92. **Garrett**
November 25, 2010

Tony:
If one were to try and build a universe by deforming the E8 Lie group, the nicest way to do it would probably be to use [Cartan geometry](), by which the base spacetime is modeled on the (too large) symmetric space obtained by moding E8 out by a subgroup.

Of course, you're also welcome to just start with an 8D base and a principal bundle, which is less restrictive, and play with different gradings and KK schemes as you are here.

93. **Garrett**
November 25, 2010

Daniel:
When I am talking about E8 triality I am talking about the triality outer automorphisms of the so(4,4) and so(8) subalgebras, and the corresponding inner automorphisms of E8.

94. **Garrett**
November 25, 2010

Gregor:
Since you cannot accept that the media has been attracted to a story about an unusual physicist who has come up with an interesting new theory, the attention must be because I am so incredibly handsome.

Happy Thanksgiving!

95. **Wolfgang**
November 25, 2010

"No, without triality, we're stuck with mirror fermions. But the Distler-Garibaldi conclusion that "the theory can't work" would still be untrue, because mirror fermions could exist."

Sorry. That I don't understand.

Without triality, you are stuck with one generation and one mirror-generation. I don't see how you can say that "works" as a theory of nature. Could you explain?

" But I don't think they do — I think triality will work."

Maybe it will. But it faces serious obstacles (see above discussion about W bosons).

"I haven't done the calculation, but perhaps they run independently,"

Every independently-running coupling constant corresponds to an independent term you can add to classical lagrangian. You just explained that in your theory electro-weak scale and cosmological constant are not independently adjustable coupling constants. So how can they run independently?

96. **chris**
November 26, 2010

>"No, without triality, we're stuck with mirror fermions.
> But the Distler-Garibaldi conclusion that
> "the theory can't work" would still be
> untrue, because mirror fermions could exist."

> Sorry. That I don't understand.

i guess he just means that you can build a model that looks like the SM at low energies without chiral fermions. and he is right – you can. you just need fine tuning, which is "ugly" but not forbidden.

and of course you can add 2 carbon copy generations and by hand add CKM mixing. it's not pretty – but who says that top-color assisted extending walking technicolor is? 🙂

97. **Peter Woit**
November 26, 2010

I've had to delete repeated anonymous comments by someone who couldn't be bothered to either look things up for himself or read Garrett's previous response to the same question:

http://www.math.columbia.edu/~woit/wordpress/?p=3292&cpage=1#comment-69686

98. **Tony Smith**
November 26, 2010

Garrett, please correct me if I misunderstand. It seems to me that what you are now doing is (using "mod" in your Cartan geometry sense):

Mod E8 / so(4,4) x so(8) to get 8x8_v + 128_s+

which by reducing the 128_s+ half-spinor of D8 into 64_s+ + 64s_s-
(is this done by looking at things in terms of D6 instead of D8?)
to get

E8 / so(4,4) + so(8) = 8x8_v + 8x8_s+ + 8x8_s-

Then you use the fact that both so(4,4) and so(8) have triality among their three 8-dimensional representations
8-vector
8-halfspinor+
8-halfspinor-

to construct a triality automorphism inside E8 among the three 64-dimensional things
8x8_v
8x8_s+
8x8_s-

so 8x8_s+ + 8x8_s- must inherit mirror-image halfspinor structure from both the so(4,4) and the so(8)
You do not identify them with fermion particles and antiparticles as would be natural from so(10) models,
but
you identify them with one fermion generation plus one antigeneration,
and you say that the antigeneration somehow is suppressed.
Does that not destroy the triality symmetry and so render it useless for further things, such as higher generations ?

Also, the 8x8_v must inherit vector structure from both the so(4,4) and the so(8)
and that vector structure includes signature,
so it seems to me to be an inconsistency because
the so(4,4) split signature (4,4)
Is not
the so(8) Euclidean signature.

Can you address these concerns?

Tony

99. **Daniel de França MTd2**
November 27, 2010

Garrett,

"Daniel:
When I am talking about E8 triality I am talking about the triality outer automorphisms of the so(4,4) and so(8) subalgebras, and the corresponding inner automorphisms of E8."

But what about the operators that do the outer automorphisms inside 8? Where will they find space inside E8 if everything is already busy with other fields?

Would you give me an example of that in a simpler theory?

Best,

Daniel.

100. **Garrett**
November 28, 2010

Wolfgang: (Thanks Chris.) Without triality it "works" in the same sense that the SO(10) GUT works — there are many predicted particles, and the three generations are left unexplained. For the cosmological constant and renormalization, the [tex]\frac{4}{3} \Lambda e e[/tex] term might be independent but related to the [tex]\phi^2 e e[/tex] term.

Tony: Your analysis is correct. However, keep in mind that an 8D vector is triality-equivalent to an 8D chiral spinor wrt so(8) or so(4,4).

Daniel: The triality operator is an element of the E8 Lie group, and can be used to gauge-transform between the vector and positive and negative chiral spinor parts of E8. I'm afraid I don't know of an example.

101. **Wolfgang**
November 28, 2010

Chris said:

"i guess he just means that … you can add 2 carbon copy generations and by hand…"

If that's what he means, then there is even easier solution:

1) Give large vector-like mass to the fermions that Garrett found "in E8" (distler-garibaldi theorem guarantees these fermions are in vector-like representation, so can be given a gauge-invariant mass).
2) Add 3 chiral generations "by hand".

Problem solved! No need for triality or other fancy mechanism.

Garrett said:

"Without triality it "works" in the same sense that the SO(10) GUT works — there are many predicted particles, and the three generations are left unexplained."

Unexplained, or unexistent? If you don't allow to add fermions "by hand", then I would say "unexistent." If you allow to add fermions by hand (as in SO(10) GUT), then "unexplained" is more accurate, but then why big fight with distler-garibaldi, who explain how to get rid of unwanted (and now unnecessary) fermions originally from E8?

"For the cosmological constant and renormalization, the $\frac{4}{3} \Lambda e e$ term might be independent but related to the $\phi^2 e e$ term."

What does "independent but related mean"? Are these independent terms in the action, or do they come from expanding a single term in fluctuations about VEV?

102. **Tony Smith**
November 29, 2010

Garrett and Daniel, the simplest example of inherited triality within a larger group containing so(8) is 52-dim F4 which is made up of:
28-dim so(8) D4
8-dim vector 8_v
8-dim +halfspinor 8_s+
8-dim -half-spinor 8_s-

Pierre Ramond describes F4 (mostly from the point of view of superstring theory, but the basic math structures are the same regardless of physics point of view) in hep-th/0112261 and hep-th/0301050. Please read the papers for a lot of very interesting details that may be relevant to E8 physics models. Here, in this comment, I will only mention a general F4 quote and a quote about fermions, bosons, and spacetime dimension.

In the earlier paper 0112261 Ramond says:
"… the triality of the … little group so(8) … links its tensor and spinor representations via a Z3 symmetry …
The exceptional group F4 is the smallest which realizes this triality explicitly …".

In the later paper 0301050 Ramond says:
"… In four dimensions, fermions and bosons are naturally differentiated, as fermions have half-integer helicities while the boson helicities are integers. …
In d+1 spacetime dimensions, fermions transform as spin representations of the transverse little group so(d-1), while bosons are transverse tensors.
As a result … In 9+1 dimensions, the little group is so(8), with its unique triality property according to which bosons and fermions are group-theoretically equivalent …
This triality is explicit in the F4 [containing] so(8) decomposition …".

In short, by Ramond's 0301050, the nice fermion-boson correspondence in E8 physics does NOT work with a 4-dimensional spacetime, but requires a 10-dim spacetime as in superstring theory (or at least an 8-dim spacetime if you reduce it to the so(8) vector structure),
so
Garrett's E8 over 4-dim spacetime structure will NOT inherit the nice fermion-boson correspondence and WILL violate spin-statistics
(unless its spacetime structure is enlarged to the 10-dim of string theory or at least to the 8-dim Klauza-Klein of Batakis).

Tony

PS – Note that an 8-dim Kaluza-Klein can be extended to 10-dim
by extending its 4-dim Minkowski part to a 6-dim Conformal spacetime.

103. **MarkusMaute**
December 1, 2010

"I find it more likely that some major new ideas about the relationship between internal and space-time symmetry are still needed."
Don't we have them already in noncommutative geometry ? (According to Alain Connes, NCG allows for breaking the chains of the Coleman-Mandula theorem). I wonder if non-commutative geometry plays any role in Lisi's E8 model, given its success ? (E. g. the derivation of the full-fledged Lagrangian of the standard model).

104. **Wolfgang**
December 2, 2010

It seems Garrett has lost interest in answering questions about his theory. But I'll ask this one anyway.

Nesti-Percacci study SO(3,11) theory. Their SO(3,11) gauge fields form a subset of E8 gauge fields. And their frame field (1-form with values in the 14 of SO(3,11)) also sits in E8.

So one might expect that their theory forms a subsector of yours. Is that correct? If so, do you agree with their analysis of that subsector? If not, where would you say their analysis is incorrect?

105. **Garrett**
December 2, 2010

Wolfgang:

> Unexplained, or unexistent? If you don't allow to add fermions "by hand", then I would say "unexistent." If you allow to add fermions by hand (as in SO(10) GUT), then "unexplained" is more accurate, but then why big fight with distler-garibaldi, who explain how to get rid of unwanted (and now unnecessary) fermions originally from E8?

Yes, if one is less ambitious, then there are many ways to make things work by hand. But I am not so interested in that. I want to figure out how the three generations derive naturally from geometry, and I think triality in E8 may do that.

> Are these independent terms in the action…

I suspect they might be independent terms that could arise in the perturbative expansion when doing the renormalization. But I'm just guessing. It would be really nice to also have a geometric understanding of why the action is what it is, which might shed some light on this question.

106. **Garrett**
December 2, 2010

Tony:

Funny you should mention F4… that's what I'm working on right now, as a warm up. The triality automorphisms of so(4,4), and corresponding automorphisms of the F4 Lie algebra, are tricky, but fascinating! You make an interesting point about 8D vs 4D spin-statistics; I'll ponder that.

107. **Wolfgang**
December 3, 2010

"But I am not so interested in that. I want to figure out how the three generations derive naturally from geometry, and I think triality in E8 may do that."

If one is going to add fermions "by hand", is hard to see any advantage of your "E8" theory over Nesti-Percacci SO(3,11). So, yes, your triality idea seems to be "last best hope" for E8 theory.

"I suspect they might be independent terms that could arise in the perturbative expansion when doing the renormalization."

In your paper, they come from expanding a single term in the action about VEV, so it is hard to see how that could be true.

On the other hand, Nesti-Percacci (this is why I have been looking at their paper) have a very different analysis of this subsector of your theory.

Could it be that their analysis is the correct one?

Assorted News

November 18, 2010
Categories: Experimental HEP News, Uncategorized

- HEPAP is meeting in Washington today, presentations available here. The idea of this regular meeting is for the US HEP community and the funding agencies to meet and plan for the future, something that's not easily done in an environment where these agencies have no budget at all for the current year, just an authorization to spend money at last year's rate that expires in a couple weeks from now. No one seems to be sure what funding prospects are for the next few months, much less the next few years. Fermilab is dealing with this situation by offering 600 of its staff incentives to quit or retire next month (see here). There's a new DOE Committee of Visitors report out here, it contains the bizarrely familiar recommendation of all such reports: the US needs to fund more HEP theory students (they don't explain why, or where the money should come from).
- In dark matter news, Princeton this week hosted a workshop on the subject, talks available here. Still no results from the latest Xenon100 run. This week's Nature has a nice review of the various searches for WIMP dark matter, with conclusion:

> With the advent of the Large Hadron Collider at CERN, and a new generation of astroparticle experiments, the moment of truth has come for WIMPs: either we will discover them in the next five to ten years, or we will witness their inevitable decline.

(Update: a commenter points out that this article is also available on the arXiv here.)

One new astroparticle experiment that is supposed to look for evidence of dark matter is Sam Ting's Alpha Magnetic Spectrometer, set to be launched in February, and described in a front-page New York Times article yesterday.

- Ten days after first collisions, Alice already has two papers out (here and here) with experimental results on lead-lead collisions at an energy more than an order of magnitude higher than ever before. String theorists are very enthusiastic about this (see here and here), claiming that what is being observed is "properties of a type that can be nicely captured using string theory models". I'd be quite curious to see any AdS/CFT based predictions that could be compared to these new results (or to forthcoming ones).
- For the latest from the LHC, see here. Current plan is to have a proton-proton beam back around February 21, followed by at least 2 weeks of beam recommissioning. The proton run would end in November, followed by another ion run. First estimates for 2011 are that the run will be at 4 TeV/beam, and a "reasonable" estimate of total luminosity would be 2.2 inverse femtobarns, double the initial goal. Even more optimistically, the possible "ultimate reach" for next year would be a luminosity that would give a total of 7.2 inverse femtobarns if sustained over the hoped for 200 days of running. This kind of higher luminosity would allow the LHC to see evidence of a Higgs over the entire expected range, as well as allowing it to finally overtake the Tevatron in the Higgs race. The experiments so far are reporting results that match exactly the Standard Model, more announcements to come at the Winter Conferences early next year.
- There's an interesting trend of our LA-based theorist-blogger-media-stars starting to resist making dubious media appearances. A few months ago Sean Carroll described storming off the set of a TV pilot here. Now Clifford Johnson (whose media mishaps include appearing as a scientific expert on the question of how big women's breasts need to be to crush beer cans, see here) tells us that Sometimes I Say No.

Comments

1. **luny**
   November 18, 2010

   Regarding the heavy ion predictions: While the "low viscosity" discussion has generated a lot of publicity, it is somewhat unsuitable for quantitative comparisons: The number of free parameters and uncertainities is such that determining the viscosity to much better than an 100% error will be very difficult. Equally, determining stringy corrections to the "infinitely strongly coupled" value is somewhat controversial, especially in view that we do not,trivially live in a CFT world.

   Thus, "AdS/CFT viscosity over entropy density=1/4pi" is a great publicity gimmick, but not really an experimentally verifiable prediction.

   The best hope we have for the latter is the interactions heavy quark physics. Here, there will be very high quality data at the LHC, AND the strongly coupled theory might allow something of a systematic expansion whose results are _qualitatively_ different from the perturbation theory.

   As a matter of fact, some of the "pioneers" on this live a few hundred meters from you:
   http://arxiv.org/abs/0706.2336
   http://arxiv.org/abs/0907.3062

2. **Anonymous**
   November 18, 2010

   Thus, "AdS/CFT viscosity over entropy density=1/4pi" is a great publicity gimmick, but not really an experimentally verifiable prediction.

   Hasn't it been verified already at RHIC, with an error of around 1/N^2=10%?

3. **luny**
   November 18, 2010

   Not really,although there have been excellent tries (the latest effort is
   http://arxiv.org/abs/1011.2783).

   Baiscally, initial conditions in the transverse plane (currently controversial and well studied) give you an 100% or so error
   (viscosity is really ~1/4pi for "Glauber" initial conditions but more like 2-3/4pi for "Color Glass condensate" ones).

   That leaves controversial initial conditions which have NOT been studied:
   How much flow forms BEFORE hydrodynamic expansion? How good is the longitudinal ansatz examined by the hydrodynamic calculations? What about corrections to Navier-Stokes?
   These, together, could easily add another 100%.

   Also, some observables do not fit the hydrodynamic theory at all (google "HBT puzzle"), which leaves some doubt that theorists have radically misunderstood the data. Its not impossible.

4. **Nige Cook**
   November 19, 2010

   "… Clifford Johnson (whose media mishaps include appearing as a scientific expert on the question of how big women's breasts need to be to crush beer cans, see here) …"

I believe this is a bona fide piece of research. Crushing cans flat makes recycling more efficient, because you can then fit more empty cans into recycle bins, which don't then need to be emptied so often, thus reducing the carbon-footprint of the can recycling enterprize. It's also good entertainment, after a few beers.

   For those of us without a subscription to Nature, the article on dark matter is available at http://arxiv.org/abs/1011.3532

6. **J. E. Connett**
   November 21, 2010

   Peter,

   On Dec 9, 2009, I sent a message to your blog regarding the
   Hydrino Study Group, a forum which has since been discontinued. My
   comments included the following:

   "One of the regular posters to the HSG Forum, an
   electrical engineer named John Barchak, frequently cites your blog as
   evidence that quantum mechanics is hopelessly wrong."

   I would like to post a retraction of that statement. Mr. Barchak has
   often quoted your blog on the HSG, and I think it is fair to say he is not
   a fan of quantum theory, but in fact his quotations from your blog are
   generally in support of his views regarding the Standard Model and String
   Theory and the Higgs boson, and not directly in support of his views
   regarding QM itself.

   Thanks,

   J.E. Connett

7. **Peter Woit**
   November 21, 2010

   Thanks John. I've added that link to the posting.

8. **Estrella**
   November 22, 2010

   Hi,

   I would like to know your take on this article purposing a real life application of string theory:
   http://www.scientificamerican.com/article.cfm?id=string-theory-tackles-strange-

9. **Peter Woit**
   November 22, 2010

   Estrella,

   I'm not a condensed matter theorist, so I really have no idea how significant this is. It doesn't have anything to do with using string theory to get quantum gravity and unification. It's plausible that AdS/CFT might lead to new approximate models that would have condensed matter applications. But, given the history of hype surrounding string theory, I'd like to hear about this from an expert.

10. **Estrella**
    November 23, 2010

    Thanks for your opinion, Peter. 🙂
    I am not an expert on the subjet either. I am just a Physics PhD student (on the Complex Systems area), so I am not an expert on String theory or Gravity either.
    I just was curious about the subject.
    BTW, I live in Montevideo, and I know people who works in an alternative to string theory unification, quantum loop gravity.
    Do you have an opinion in this theory?

11. **Chris W.**
    November 23, 2010

    Estrella,

    Search the blog for "loop quantum gravity" and "LQG". Some of the posts (and comments) you find will include links to critical papers on the subject, as well as discussion of LQG and occasional cautious comments by Peter. For background you should look up some review articles, such as those at LivingReviews.org.

12. **Marcus**
    November 23, 2010

    Estrella, since you live in Montevideo and know some LQG people, you have undoubtably heard of Rodolfo Gambini: a major figure in the field. His research group has come out with a number of interesting and creative papers over the past 10 years. Montevideo is the top LQG place in South America, and one of a handful of top places worldwide.

    Another person at Montevideo who has contributed notably to the development of LQG is Michael P. Reisenberger. He collaborated with Carlo Rovelli around 1996-1998 on the first *spin foam* papers, an approach to LQG which has become increasingly important in recent years.

13. **Estrella**
    November 23, 2010

Thanks for the links Chris.
Yes, Marcus, I know Rodolfo Gambini and Michael Reisemberger. And I heard of their ideas on some talks they gave. Just curious what other people not related to them thought on their theories.
Moreover, as I said before, I am not an expert on that area, so I am just curious to hear all the bells.

14. **Estrella**
November 23, 2010

By "Hear all the bells" I meant hear all the opinions, pro and con.

15. **Estrella**
November 23, 2010

BTW, I am not an expert on Gambini or Reisemberger ideas either. I just asisted to some talks, but I don't work with them or in their area.

16. **Marcus**
November 23, 2010

Estrella,

By "Hear all the bells" I meant hear all the opinions, pro and con.

I understand and I think you are asking a good question, but Peter's usual policy is to discourage us from discussing non-string quantum gravity here, because he doesn't feel that he knows enough about Loop-and-allied approaches to be a good moderator.

Personally I would say that Loop (and related spinfoam) quantum gravity and cosmology have changed radically since 2006 and have made remarkable advances. To where phenomenologists begin to study how test (and even possibly to falsify). Relative to the size of the field a few years ago, there are a lot of young researchers, new energy, and even more job openings than before. So it is an exciting time.

One way to hear various opinions is to go to Physicsforums, this part of it: http://physicsforums.com/forumdisplay.php?f=66
and ask questions. Then people will sometimes point you to discussions that have already occurred—and sometimes, instead of that, when you ask a question they will begin immediately to argue among themselves.

17. **Peter Woit**
November 23, 2010

Yes, please, enough about LQG right now. I have to keep reminding people this is not a general discussion board, I don't want to manage such a thing.

I think there's a lot interesting about LQG, but lack motivation to spend much time on quantum gravity theories that don't unify with the rest of physics and tell us where the standard model comes from. I'm willing to believe that everyone who has a quantum gravity for sale may be right, which means that there are at least 10^500 of them….

18. **Estrella**
November 23, 2010

Thanks for all the answers. 🙂

19. **Marcus**
November 23, 2010

Estrella, here are 281 LQG papers from the two years 2009 and 2010 assembled by a Spires database search.
http://www.slac.stanford.edu/spires/find/hep/www?
rawcmd=FIND+K+SPIN%2CFOAM+OR+DK+FIELD+THEORY%2C+GROUP+OR+DK+QUANTUM+GRAVITY%2C+LOOP+SPACE+OR+QUANTUM+COSMOLC

You can change the parameters as you wish–get the papers sorted by citations or in other ways, change the keywords, the timeframe. I have included spinfoam, group field theory, and loop quantum cosmology, which is the sector closest to being testable (by CMB observation).

20. **Anonymous**
November 24, 2010

@Peter Woit: You've called for hep-th community to diversify, and they did, but it seems that you're not impressed by any of the following: susy, string theory, LQG, Horava's theory, Verlinde's theory, Lisi's theory… So what exactly is the "diversity" that you long for? You're only impressed with stuff along the line of "elucidating the mathematical structure of non-supersymmetric QFT". If everyone is doing this, I'm sure the community will be truly diverse!

21. **Peter Woit**
November 24, 2010

Anonymous,

Susy and string theory are still by far the dominant research areas in the subject. LQG and Horava's theory also get attention, which is great. Verlinde's theory doesn't seem to me to be a theory at all, but maybe I'm missing something. Lisi's theory is being worked on by, well, Lisi. That's still not a whole lot of diversity.

You're right that if everyone was working on better understanding non-perturbative QFT using new mathematical methods, that would not be diverse. I think we're a long way however from having to worry about that particular danger right now….

22. **Loco**
November 25, 2010

@Peter Woit

If you ever comment on Penrose Conformal cyclic cosmology, could you put the links again? There's a 6σ claim going on:

http://fr.arxiv.org/ftp/arxiv/papers/1011/1011.3706.pdf

23. **Peter Woit**
November 25, 2010

Loco,

My only comment about that claim is that I'm not a cosmologist and have no way to evaluate it. If someone else can point to somewhere an expert in the subject has commented on this, that would be interesting.

24. **Derek Teaney**
November 25, 2010

Responding to

"Thus, "AdS/CFT viscosity over entropy density=1/4pi" is a great publicity gimmick, but not really an experimentally verifiable prediction."

Perhaps I can offer some perspective (I work in this field). I would not say that
1/4pi is a publicity gimmick. The importance of the AdS/CFT
result is that there exsist field theories (in any theory!)
where is \eta/s is as low as 1/4\pi. Before this calculation
in the AdS/CFT it seemed extreme to imagine that QCD
would have \eta/s less than 1.

The other important point is that the gradient expansion
which underlies the hydrodynamic results at RHIC would
not converge (for typical initial) conditions for \eta/s > 0.4.
For say η/s less than 0.3 the gradient expansion
does clearly converge, i.e. ideal hydrodynamics provides
the baseline result, the navier stokes theory provides a correction,
and the second order corrections are small.

Thinking about hydrodynamics in AdS/CFT led to a precise
formulation of second order corrections in hydrodynamics.

25. **Loco**
November 25, 2010

To date I found only one comment which seems interesting.

http://www.physicsforums.com/showthread.php?p=3003554

26. **Casey Leedom**
November 26, 2010

And back to your original blog posting, re "an interesting trend of our LA-based theorist-blogger-media-stars starting to resist making dubious media appearances," check out the latest Abstruse Goose:

http://abstrusegoose.com/321

Casey

27. **luny**
November 27, 2010

Derek… I do not disagree that 1/4pi is a very important result from a theoretical point of view which spurred quite a lot of interesting work.
It is however wrong to claim that "Before this calculation
in the AdS/CFT it seemed extreme to imagine that QCD
would have \eta/s less than 1". A "lower limit" on viscosity in a quantum field theory was argued for in the '80s, in the context of heavy ion collisions, from back-of-the-envelope arguments stemming from the uncertainty principle, see
Phys.Rev.D31:53-62,1985
(the limit is surprisingly similar to 1/4pi!).
So its not quite correct that the AdS/CFT result is the first result suggesting that a quantum field theory can exhibit hydrodynamical behavior at microscopic scales.

In any case, by "publicity gimmick" I mean that, while there have been a lot of popular science implying that string theory calculations can be quantitatively tested in heavy ion collisions, this has simply not been the case: The phenomenological uncertainity in hydrodynamic simulations, and the lack of knowledge of how to relate infinitely strongly coupled N=4 Nc=infinity SYM to not-quite-infinite-coupled N=0 Nc=3 QCD prevents any kind of real comparison at present.
I am not saying this comparison is impossible in the future, but at the moment it can not be done.

It of course does not mean this work is a waste of time! The Sine-Gordon model was also very important for field theory which led to important theoretical developments of QCD, but it would be a "publicity gimmick" to say it can be used as a quantitative test for anything.

28. **Derek Teaney**
November 27, 2010

Luny,

The calculation you refer to was a extrapolation of weak
coupling results where $eta/s >> 1$ deap to a regime where it is not valid.
So it was terribly unclear wether such field theories actually
exsist. The only thing which was clear from such extrapolations
was that when $eta/s \sim 1$ something must happen.

The 1/4\pi showed that there exist field theories (where you
can calculate at strong coupling) . This result gave a kind of
reason to suggest that hydrodyamics (as opposed to alternatives which don't seem to hang together anyway)

was actually responsible for the observed elliptic flow

You write,

” In any case, by “publicity gimmick” I mean that, while there have been a lot of popular science implying that string theory calculations can be quantitatively tested in heavy ion collisions, this has simply not been the case ”

This is true. Last comment, the heavy quark results you quote above
are really no better in this regard

The BMO Financial Group Isaac Newton Chair in Theoretical Physics

November 29, 2010
Categories: Uncategorized

I learned this morning from Matin Durrani's blog that the Perimeter Institute has announced today the first of what they expect to be five very well-funded Perimeter Research Chairs in theoretical physics. The next four will be named after Maxwell, Bohr, Einstein and Dirac (as well as whatever other wealthy individual or organization comes up with funding).

The BMO Financial Group is putting up $4 million and $4 million is coming out of the Perimeter endowment (which is mostly from Blackberry's Mike Lazaridis). An endowment of $8 million for a chair is quite high. It seems that typical numbers for endowment payouts these days are around 5%, so this would make available $400,000 or so a year to pay some prominent theorist. For comparison, the Simons Foundation has recently announced that it will fund endowed Math+X chairs aimed at mathematicians working at the interface with some other subject. Simons may be the wealthiest hedge-fund manager in the world, but he's a piker compared to the Canadian financiers, with only $1.5 million going to each chair (to be matched by $1.5 million from the institution that gets the chair, for a total of $3 million). Then again, it just may be that prominent mathematicians are dirt-cheap compared to prominent theoretical physicists.

The Perimeter Institute in recent years has moved away from supporting non-mainstream topics in theoretical physics, while expanding dramatically. The only two conferences announced there for the next year or so are on the topics of LHC physics and AdS/CFT, about as mainstream as one can possibly imagine. If they manage to fund what might be the five highest-paid theoretical physics positions in the world and hire the people they want into them, they will be well on their way to a dominant position in the subject. While, like most industries these days, the tactic here is to shower the top few people in the field with cash, they are also expanding their hiring at more junior levels. According to the rumor mill, last year out of a total of fourteen people hired to tenure-track positions in theoretical particle physics in North America, three of the fourteen went to Perimeter.

For more on this, see here, and an interview with Lazarides and the BMO CEO here.

Comments

1. **Gregor Samorasky**
   November 29, 2010

   Wow! Only "fourteen people hired to tenure-track positions in theoretical particle physics in North America"–in America and Canada combined!! Wow!!

   Who/where is still saying there will be a shortage of physicists?

   🙂

2. **Kalyan**
   November 29, 2010

   It would be nice if the 400K/yr funding would include 2-3 post doc salaries to both spread the wealth and support the chair holder.

3. **Peter Woit**
   November 29, 2010

   Kalyan,

   PI already has about 45 postdocs, and surely their new 400K/yr researcher will have some say in choosing these.

   Actually, if they're taking $4 million out of the endowment, that may mean a bit less money for postdocs.

4. **$$$$**
   November 30, 2010

   half would go in Canadian taxes?

5. **Mark Decker**
   November 30, 2010

   It is sad that Perimeter has become more mainstream. Kind of defeats their original purpose? Look on the bright side though. If string theory is eventually verified then movie theaters will be able to start showing movies in 11-D. I wonder what the glasses will look like?

6. **Robert Guttenberg**
   December 1, 2010

   Are these chair endownments higher than those at the IAS? I read Simonyi donated $25 million in 2005…

7. **Peter Woit**
   December 2, 2010

   Robert,

   The Simonyi $25 million was a general gift, not for an endowed chair. Looking at the IAS site, the last gift of an endowed chair that I see announced was at $5 million. It's unclear exactly how Perimeter plans to spend the $8 million, and at other institutions one doesn't know for sure if an announced gift for an endowed chair will cover the entire expenses involved.

   For another point of comparison, endowed chairs at Harvard Law School supposedly go for $4 million, and law professors tend to be among the best paid of academics.

   All in all, theoretical physics may not be doing so well intellectually, but it appears that the financial prospects of its stars are bright.

8. **rrtucci**

December 2, 2010

I think this is so wrong. A good theoretical physicist does does not crave for large amounts of money. Large amounts of money just distract and pervert him.

Anyway, how long can BMO continue their charitable contributions at high levels. Not very long, I dare say. Their products have become quite obsolete in the past year, due to Android and iPhone.

9. **rrtucci**
December 2, 2010

Also, good theorists usually thrive in places where there is good experimental physics going on too. (Think Bell Labs) My impression is that Canada has very little good experimental physics and technology going on. In my field of quantum computing, they are a giant flop. Perimeter institute specializes in turkey technology like quantum cryptography (which is snakeoil) and NMR quantum computers (which are non-scalable and an obvious dead end)

10. **Peter Woit**
December 2, 2010

rrtucci,

BMO is the Bank of Montreal, and as far as I know Canadian banks are doing fine. It's RIM, the company of Lazaridis that makes the Blackberry.

11. **rrtucci**
December 2, 2010

Yes. I should have said RIM.

Why is BMO doing this.? I thought Canadian banks are much less leveraged, and therefore poorer than American ones. Is Lazarides behind this BMO move, somehow?

12. **Peter Woit**
December 2, 2010

rrtucci,

On the scale that large financial organizations operate the highest paid theorist in the world is working for peanuts, and funding even the most highly endowed chair in the world doesn't involve coming up with what they consider a lot of money. I believe BMO's profits are a couple billion dollars a year or so.

13. **anon.**
December 2, 2010

I've been trying to think of anyone who is prestigious enough to live up to PI's expectations for these chairs, but also plausibly willing to leave their current job and move to Waterloo. I'm coming up short.

14. **Peter Woit**
December 2, 2010

anon.,

It's not just "leave their current job and move to Waterloo", but maybe "leave their current job, where things are kind of depressing, move to Waterloo, double their salary and be able to hire lots of people in your field". One advantage Perimeter has is that lots of other places are in financial trouble (think University of California, Great Britain and lots of the rest of Europe). Many US physics departments aren't so keen on speculative things like quantum gravity research these days (be it string theory, loop quantum gravity or anything else). So there are not a lot of places out there offering well-paid positions to theorists at a large and expanding theory group. The Simons Center at Stony Brook is in a somewhat similar position, but they're going after mathematicians and the mathematical end of theoretical physics, which is something Perimeter doesn't seem to have much interest in.

So, it's not an easily solved problem, but neither is it an insoluble one…

15. **Jack Lothian**
December 2, 2010

rrtucci,

I am not sure that being less levered makes one poorer? Some might argue the opposite. Canadian banks operate under tighter regulation than American banks. The few Canadian banks rival the larger American banks in size & have earned incredible returns year-in-year-out for over a century. Unlike in the US, in Canada, small banks do not exist. So despite the fact Canada is a tenth of the size of the US, our banks are very big by North Americam standards. I suspect our big 5 banks rank in the top 25 banks in North America.

Waterloo is not out in the Canadian wilderness. It is effectively a suburb of Toronto which is very big city even by American standards & it consistenly ranks well in various surveys of city quality. I agree it is not currently a hotbed of experimental physics research but there are a lot of very good universities situtated within a hundred miles of the PI. Waterloo is dead center in our largest concentration of universities. During the previous tech boom many of these universities did stand out.

Math Research Institute, Art, Politics, Transgressive Sex and Geometric Langlands

December 4, 2010
Categories: Uncategorized

I learned from a colleague last night about recent events bringing together the topics of the title of this posting, something that one wouldn't have thought was possible. Last Wednesday there was a showing in Berkeley of Edward Frenkel's short film *Rites of Love and Math*, together with the Yukio Mishima film *Rites of Love and Death* that inspired it. Frenkel is a math professor at Berkeley, and one of the leading figures in geometric Langlands research (which he describes as a "grand unified theory of mathematics"). He's also a wonderful expositor, almost single-handedly making the beauty of a subject initially renowned for its obscurity accessible to a much wider audience. Recently he has worked with Witten on relations of geometric Langlands to quantum field theory, and with Langlands and Ngo on relations to number theory. At the same time, while a visiting professor in Paris, he co-directed (with Reine Graves) and acted in this new film.

MSRI was one of the two sponsors of the showing of the film, but pulled out of this role recently, for reasons explained here by MSRI director Robert Bryant. He had found that some people in the math community were upset by the film and MSRI's involvement with it, feeling that it glamorized an objectionable view of the relationship of women to mathematics. There's a plan to organize some sort of event at MSRI to discuss the issues brought up by the film and the decision to withdraw sponsorship.

I still haven't seen the film, although I gather that a DVD will soon be available. Congratulations to all involved in this for finding a unique way to make mathematics and mathematicians look interesting and worthy of media coverage. I had no idea it was still possible to stir up controversy in the Bay area with art involving transgressive sex, and would never have thought that using research mathematics was the way to do it.

Update: Andrew Ranicki has written a review of the film for the London Math Society newsletter, available here. He identifies the notorious equation in question (5.7 of http://arxiv.org/abs/hep-th/0610149), and makes the comment that, sartorially, this film is a breakthrough, since, in other films:

> By and large, male mathematicians are portrayed as crazies who are smart and lovable, but badly dressed. Likewise for female mathematicians, although they tend to be better dressed. This said, in the □film under review, the actors are either very well dressed, or not dressed at all.

Comments

1. **feministisch**
   December 4, 2010

   I didn't see the movie. But what I read about it was more than enough to make me disgusted. There's enough (barely) hidden misoginy in mathematics as is. I'm glad the MSRI has withdrawn support.

2. **ObsessiveMathsFreak**
   December 4, 2010

   From the trailer, the film looks like a standard "high art" pornography flick to me. I'm not surprised that people objected to the MSRI being associated with it.

   Does this mean that mathematics isn't an art after all?

3. **Bugsy**
   December 6, 2010

   Between the right and left-wing thought police it seems there is no place left for art, expression or intellect in the US of A. For MSRI to cow under to uninformed anti-art politics is disgraceful. Not one of the critics seems to have seen more than the trailer, and no one accusing the film of "sexism" seems to have noticed that the director is, apparently, a woman.

4. **Chris W.**
   December 6, 2010

   I notice that NEW mentioned this film (and quoted from IMDB) in a post from last April — the day after April Fools Day.

   I guess that's why I didn't remember it. (*Cough*…)

5. **MathPhys**
   December 7, 2010

   He writes on her belly, pucturing her soft flesh with a sharp pen. She screams in pain. He continues to write.

   Since when is doing mathematics meant be physically painful to another person? I thought the whole point and main attraction of pure mathematics as well as all of pure science is that it's harmless. You don't abuse, exploit or hurt another person.

   And I didn't enjoy the sight of his backside. I only want to read his papers. I don't want to see his backside. But it was in the very first frame of the trailer, so it was forced on me. Maybe that's another reason why so many people were disgusted by the trailer. He made us see his backside.

6. **tulpoeid**
   December 8, 2010

   Impressive how people think that every single image in a movie is about conveying the maker's intention, without any reference to the overall plot or the symbolism or the hidden ideas. Also, impressive how people think that a woman can't direct sexist movies (ahem, just have a look at the number of women editors in glossy sexist magazines). Ok, has anyone watched the whole of it?

7. **Aki**
   December 8, 2010

   "Bodily violence is a displeasure done with the intention of giving pleasure"

   –John von Neumann

   http://www.reference.com/browse/john+von+neumann

8. **andreask**
December 8, 2010

I think, at least judging by the trailer, one has to contextualize the film, without contextualizing it, it is mainly an aesthetically appealing example of what germans would call erotic/exotic 'edel kitsch', by contextualizing, as it was already mentioned it does indeed tell the audience something about how women are represented my male mathematicians, also about how women of color are represented by white male americans. I suppose the rest of the film, granted its title, supports these views. Certainly one has to consider Yukio Mishima's original in the context of his biography, saying this, there is certainly a non-vanishing amount of narcissism and homo-eroticism also involved and that is of course also reflecting 'something' in (mathematical) reality..so this seems interesting in many ways.

9. **ahmed**
December 8, 2010

"You don't abuse, exploit or hurt another person."

Some poor grad students would disagree

10. **Richard Mlynarik**
December 8, 2010

Non-review of the movie makes the local free paper: http://www.eastbayexpress.com/ebx/erotica-intrigue-and-arithmetic-in-rites-of-love-and-math/Content?oid=2258787

11. **Chris Oakley**
December 9, 2010

From UC Berkeley News:

> In Frenkel's film, the mathematician faces a quandary familiar to theoretical scientists. He has found, at long last, the mathematical formula of love. But then he realizes that others could use his formula to cause harm — and that he must die to safeguard the world. He saves the formula by etching it into his lover's body.

Familiar to theoretical scientists? In my research years I do not remember having to confront this particular issue (although I thought that Lie groups were kind-of neat). But if another reader of this blog has discovered the mathematical formula of love and then realised that since it could be used to cause harm the only decent thing to do is to die having etched the formula into their lover's body, then I would be interested to hear. Oh – wait – you may be already dead!

George, so that would be something like the 1/4pi universal value. And no theory but string theory is capable of deriving a number like 4pi?

George,

I guess I do need to keep up on these things, so done. Glad you enjoy the blog!

Peter

Thomas,

I see that you too are getting into this whole etch-your-equations-into-your-lover's-body-and-then-kill-yourself thing. All I can say is, don't do it! After all (i) if your equations turn out not to be harmful to mankind anyway, you will have died for nothing; (ii) thinking that one's equations are that important is in any case pretty arrogant; (iii) your wife/lover is entitled to an opinion on all of this <aside>interesting moral point: would a wife have cause to be angry if her husband killed himself after etching his equations into *another* woman's body?</aside>

Ok, so this is another movie about a non-white woman being subjugated and perhaps arguably tortured by a white man? *Yawn*. Oh please. I do not see this being a big hit outside of Berkeley and some mathematics circles, if only for the controversy. Now what really would have been interesting: the submissive woman gets her moxie, the tides turn, she subjugates the man, steals the formula, and…. could be a variety of more interesting endings.

Mishima's film is generally seen as an extreme expression of his narcissism and ultra-romanticism; in other words, Mishima at his worst. It is a little odd that someone would want to emulate this.

elsie, indeed from an exterior-mathematical perspective this event bears nothing new at all, what I meant above saying the discourse around the film would be interesting in 'many ways' is mainly that it possibly sheds light on a certain degree of (again, in traits narcissistic) ignorance that the mathematical community would treat such subjects as 'gender' or 'critical whiteness studies', in fact Frenkel's remark, that he couldn't deal 'with any problem of the world at the same time' is quite a typical example of the manifestation of the 'white privilege', the unspoken racist discourse creates the pictures the audience has in mind when watching and the 'other' need to manifest an explicit counter-discourse to oppose the image. I actually wonder if the bare fact that the subjugated women in the film is non-white made any appearance in the mathematical discourse on the film yet and certainly the possible argument that Frenkel is just 'replacing' the male character in Mishima's original by himself without further consequences is quite misleading.

20. **Oh well...**
December 21, 2010

Most of those who have posted comments above have not seen "Rites of love and math". But apparently this is not considered as a serious impediment to expressing "expert opinion" and passing judgement.
