October 16, 2022

Since we are interested in application to maths, shouldn't machine learning methods be run in parallel with automated theorem provers? History is full of almost solved problems with only trivial results omitted like ABC conjecture or Fermat's last theorem. What we need the least is another instance of artificial intelligence announcing that the new result is 90% correct. What would be really useful is the ability to quickly convert between natural language or LaTex and rigorous maths, possibly going all the way to set theory and logic.

As for taste, I think the problem is that there is only one physical Universe but an infinity of mathematically abstract universes. In physics, everyone wants to find the god-like equation, and if you think you have a good candidate, you will defend yours no matter the cost. Mathematicians could do similarly with their abstract universes, but then they would isolate themselves from others. So instead, they are trying to find common ground by constructing bridges, dualities etc. and by sharpening the language so no ambiguity is left.

Perhaps, as a mathematician who has been involved in computer-aided mathematics for more than four decades, I might be allowed to comment? In my experience, humans are good at conceptualisation, and methodology, and computers are good at calculations, but no-one is very good at the bit in between – that is, organising the calculations, and deciding which calculations to do.

The first famous example of a computer-aided proof was the four-colour theorem. The proof is in fact very simple and elegant, based on a small number of clever ideas devised over more than two centuries. I was sufficiently fascinated by it that I wrote a book about it. But the clever bit of Appel and Haken's proof was that they got the computer to organise the calculations, not just do them. Using heuristics based on knowledge of several decades of attack on the problem, they assembled a toolkit of methods to prove special cases, and gained experience of which methods tended to work in which kinds of cases. They then programmed a computer to look for a division into cases consisting only of cases they thought should be amenable to one or other of the toolkit of methods. Then by running this toolkit on the cases, and finding out which cases did not in fact work, they were able to refine the heuristics, until eventually a covering set of solvable cases was obtained.

In my opinion, that is the part of the problem where AI could be most useful. The calculations themselves are already in the domain of the computer, and there is little sign that the conceptual end of things is moving away from the human domain, so it is the middle ground where exciting developments might happen.

October 17, 2022

Perhaps people here are interested in a workshop we are organising to discuss exactly these kinds of questions:

Creativity in Mathematics & Artificial Intelligence
(Maastricht, Netherlands, 18-21 January 2023)
https://www.aanmelder.nl/cmai/home

The workshop will bring together a unique interdisciplinary community of researchers from mathematics, computer science, psychology, and philosophy of mathematics, that will discuss the future of mathematics and the role that AI plays in it. One of the aims is to work together through interactive engagement and publish collaborative projects in a post-proceedings with groups formed at the workshop.

Keynote speakers:

Anna Abraham | University of Georgia
Gemma Anderson | University of Exeter
Kevin Buzzard | Imperial College London
Simon Colton | University of London
Jessica Hamrick | DeepMind
Yang-Hui He | University of London
Maithilee Kunda | Vanderbilt University
Catherine Menon | University of Hertfordshire
Catholijn Jonker | Leiden University
Paige Randall North | University of Pennsylvania

Early registration deadline: 15 November

October 18, 2022

One thing that strikes me about the practice of mathematics is that it often involves starting with an untrustworthy intuitive idea and converting it into successively more trustworthy forms, or going back and fixing things if a mistake is found. One begins with just a thought based on a vague picture, which is put into words, then explained to a collaborator, then checked with calculations on paper, then written down in a first draft, then edited, shown to experts, made public, refereed, and, occasionally nowadays, computer formalized. Each step has a chance to catch mistakes that are not found in the previous steps.

So the fact that gpt3 is untrustworthy doesn't mean it can't be part of useful computer mathematics systems if it is used as a "babbler" that spits out a mix of true and false ideas that are then checked by another part of the system. This seems to necessitate working in a formal system but conceivably a written language checker can be found, although I would worry about convincing written language proofs of novel results produced by a machine even if they were checked by human experts.

Given limitations of the amount of data, machine learning systems for constructing formal proofs will probably eventually be trained primarily on synthetic data, and the question of their mathematical taste might depend a lot on how that data is constructed.

Another thing I notice about the practice of mathematics is that it is self-similar, with analogies between large-scale and small-scale tasks. Just trying to interpret a single sentence in a published paper occasionally requires the same loop of formulating a conjecture, trying to prove it or disprove it, and coming up with a new formulation that can make up a decades-long research program. So I think that even for the tasks of converting LaTeX to formal proofs, machines will require significant mathematical creativity, and thus good taste.

19. **Ys Wei**
October 21, 2022

Stephen Wolfram has been discussing his experience in letting machines doing math 'freely' for many years. He finds the way machines do math will not be enlightening for humans.

In many talks that can be found on Youtube, he gives quite interesting remarks on how implementation of proof search and ‘step by step integration’ in Mathematica/WolframAlpha sheds light on the thinking processes of humans and machines.

His latest writing on this subject is https://arxiv.org/abs/2204.05123 although as usual his writing is unnecessarily verbose.

20. **Trigonotops horridus**
October 27, 2022

Dear all,

I hesitate to say anything, since I don’t think anybody actually cares what I think, but perhaps I will be cut some slack as a first time commenter after all these years of following this otherwise excellent blog:

As an actual mathematician I must insist here that real mathematicians are absolutely horrible at getting any details of any argument right. I regularly make the mistake of agreeing to peer review my illustrious collegues’ work, and I am always disappointed by the countless elementary (read: very freshmanlike) mistakes they confidently make. And this even in the case of otherwise truly excellent and deeply creative mathematicians that I personally know and otherwise trust! (Certainly more creative than I will ever be!) (And my research has not been spared such embarrassing mistakes either!)

And I am very distressed to observe that having incredible internationally aclaimed prizes such as a Field’s medal is not an antidote to this; I have had some very bad time trying to interpret the mad ramblings of otherwise absolutely brilliant Field’s medalists, never mind the writings of the recipients of lesser prizes.

My conclusion from all these sad experiences is that we humans are barely able to do mathematics at all. The talk about good taste is, well, in bad taste, since we human mathematicians are so bad at all this.

That being said, I am personally not so optimistic about the prospects of the so-called AIs (which to me personally exhibit no intelligence worth the name) to perform major mathematical feats, but perhaps I am wrong. In some vague sense, pure mathematics does perhaps form a hermetically sealed system like the transcendentally beautiful game of go, so perhaps it might be possible for a computer to massively outperform a human mathematician after all. But I am not holding my breath!

With the bestest of regards and deepest apologies to all,
Trigonotops horridus

21. **David Roberts**
October 27, 2022

@Trigonotops horridus

wow, that’s incredible. What area do you work in? In my line of work, when I’ve refereed papers I very rarely see errors. I know I have made one (completely fixable) error in a paper that got picked up by a referee (maybe others that no one has picked up?), so I cannot hold myself up as a paragon of virtue. I’ve found errors (again, fixable) in older papers in my area that were non-obvious and, but seeing “freshmanlike” errors in papers sent to journals? :-/ Am I just so perfectionist that I couldn’t stand sending something that sloppy even to the arXiv?

22. **Trigonotops horridus**
October 28, 2022

Dear David Roberts,

The work in question involves analysis, where, say, a concrete inequality must be occasionally proven. This sort of thing can be very technical and involve complicated expressions with many parameters. And so there can be many opportunities to make mistakes such as basic arithmetical mistakes, more complicated computational errors, copying and pasting an expression wrong and then continuing the analysis with the wrong expression, or considering only one of two similar cases and then mistakenly thinking that the other case must work in the same way.

Best regards,
Trigonotops horridus

23. **David Roberts**
October 28, 2022

@Trigonotops horridus

thanks for the clarification! Still boggles my mind, but I can fully appreciate how large calculations with many moving parts are hard to proof read esp. after months of editing and rearranging.

David E. Kaplan interview

October 23, 2022
Categories: Uncategorized

There's a long interview with David E. Kaplan (not the same person as David B. Kaplan…) by David Zierler at the AIP Oral Histories site. The whole thing is quite interesting and I recommend reading it, but I do want to point out that it shows that I'm a voice of moderation on the string theory issue. Some extracts follow:

About Ann Nelson and string theory in the 1990s:

> She was extremely dismissive of string theory, and thought it was—you know, there was—my impression from her and from other people of that generation that weren't doing string theory was that the string theorists were colluding in a sense, or were dismissing anything but string theory, and deciding that if you did string theory then you're much smarter than the people who are not doing string theory. There was some unhappiness in the theoretical field. And the cancellation of the SSC probably added to that tension between the two.
>
> But I don't think she came of it from taking a side. I think she looked at the situation and said, "String theory is total bullshit." In the mid-'80s, there were some realizations—there were some consistency checks that kind of worked in string theory, and people got super excited. Oh, my god, string—yeah, it could be the, you know, underlying thing to particle physics. But that was it.
>
> The successes after that were few and far between. But there was an obsessive—like we're studying the theory of quantum gravity. And it was deridingly called the theory of everything. And then they took that on, you know. We're studying the theory of everything. And then the young people who want to do the greatest stuff would go to string theory. And there was a concern and some upset by the people not doing string theory that they're absorbing a lot of people to do this crap, which is not very physics like. "It's I believe the theory, and so I'm going to study all aspects of it, and maybe one day we'll connect it with the physical world." As opposed to I believe in the phenomenon, and I'm trying to explain that and more, and so I'm going to try out different theories and see what they're consequences are.
>
> And now I look back, and it's obvious that string theory was bullshit in the sense of there were so many people working on it, and they were not manifesting any real progress externally. It was all internal consistency checks and things like that. And so at the time, you know, whenever it came up—and it didn't come up much because there were no string theorists in Seattle—she was just very dismissive, like, you know, "What are those people doing? I don't know what they're doing."

About being a postdoc at SLAC:

> There were a lot of string theorists at Stanford. I didn't understand any of those talks. Or sometimes when the talks were not in strings, Lenny Susskind would yell at the speaker that this is bullshit or whatever, da, da, da, da—you know, abusive at some level. So Stanford was weird in that way.

About realizing what was going on in string theory, his evaluation of past (Strominger-Vafa) and current claims about string theory and black holes:

> But—so I don't—and it's part of probably why I didn't understand—I didn't think of myself as a physicist because there's a lot of physicists working very hard on what? I don't know what they're working on. It's not—you know, I used to just think I'm too stupid to understand what they're working on. And finally reading some of those papers, they're not what—it's stupid. There's a lot of stupid stuff in there. String theory really is just stupid. It's unbelievably stupid. There's so many people who are working on it that don't actually know physics that they can't even describe a physical characteristic of the thing they're calculating. They're missing the whole thing.
>
> …
>
> So that's when I realized string theory is like a video game. There are people just addicted to it. That's all that's happening. And it's couched in the theory of everything and da, da, da, da.
>
> So that's all. I just kind of—I learned quite a bit about these things. And then I saw the people like Lenny Susskind, who was terrorizing people who work on regular physics, as just a plain asshole. That there are actual people who are deciding string theory's important, wanting to do string theory, and they're even protecting the field. And some of those people are talking about how entropy now of a black hole can be described as a geometric thing, an entanglement, and that Hawking's paradox about evaporating black holes is really wormholes, virtual wormholes coming from the inside to the outside, and all kinds of language. And you could test information theory of black holes using atomic physics experiments. And it's literally bullshit.
>
> There are people—prominent people—in physics who say, "I'm applying for this money from the DOE, but I know it's bullshit." And then there are experimental atomic physicists who don't know and are shocked to learn that "What? String theorists don't have a Hamiltonian? They don't actually have a description? What am I testing?"
>
> So I have converted a little bit to the opinions of my predecessors, only because I've actually done the work. I've actually tried to understand black holes of late, and I've gone back to those papers which are the breakthrough, celebrated, amazing papers about black holes, and there's nothing in them. It's really—it's just a very simplistic picture where, look, if you take this hyper-simplistic picture, these numbers match these numbers, which means thinking about a black hole having entropy is correct, da, da, da, da, da.
>
> No matter that the black hole they're talking about is extremal. It doesn't actually Hawking radiate. It's a totally hyper-supersymmetric, multiple charges, free parameters. So now that I've finally dug into it, I realize that—not that all humanities fields are bad. But it's much more like a humanities field where there are the prominent people in the field, and they decide what's interesting. And that if you impress those people, you can get ahead. But that dictates then what research is done. And they're not going to discover anything in that context. They're not going to get anywhere. There's not a lot of people doing—you know—thinking outside the box or just thinking diff…you know, doing different things, you know.

About the argument that string theory must be worthwhile because lots of people are doing it:

> **Zierler:**
>
> What is your response to a string theorist who would say, and I know this because one has said this to me, "Look, four people were doing this in 1968, 20 people were doing it in 1984, 1,000 people were doing it in 2000, and now there's 6,000 people who are doing string theory all over the world. And that's proof that there's something here that's worthwhile"? What is your response to that line of reasoning?
>
> **Kaplan:**
>
> Take those numbers, continue the exponential, and apply it to Christianity—
>
> **Zierler:**

Kaplan:

—and Islam and Judaism and Buddhism. Give me a fucking break. They're describing a religion that can attract and addict people. That is exactly the kind of statement that shows it's bullshit and non-scientific. They've proven it for me that they are not about discovering something. They're about dominating the field for the purpose of what? That's proof? Give me a break. Give me a fucking break. Slavery was very popular, and became widely used. Nazism. Come on. You can take extreme examples and show that that is so non-scientific and sick that the progress they have made is to get more people to work on something that isn't producing anything. Oh, man, I wish you didn't tell me that.

About the current state of the field:

There are so many things to think about. I don't know what narrowed our field. I don't see it as we're dying because we're coming to the limits of what we can do, the limits of what we can calculate in string theory, and the limits of how big of a ring we can build. I think most people are just doing useless stuff.

…

And so that's why I—the whole depression or whatever, that's a product of the non-willingness to feel stupid by the majority of our field. Expertise is more important to them than discovery. And that's what I think is happening. And so what we're seeing is not the death of the field, but the death of a direction that is being committed to by 98% of them.

Comments

1. **Anonyrat**
   October 23, 2022

   Via the Kaplan interview, an antidote to string theory that you might enjoy:
   https://arxiv.org/pdf/2204.03085.pdf

2. **Marco**
   October 24, 2022

   String Theory is the field in which it is possible to publish several papers every year and thus believe that you are a theoretical physicist like Einstein or Dirac. I did my PhD in string theory and then dropped out of physics out of disappointment. In addition, the community of physicists, at least here in Spain, is very self-centered and hierarchical. If you are a student, you cannot criticize, you have to obey. Your professors, who have been working on string theory for years, give you as the only argument to pay attention to them that they have been working on string theory for years and their experience is beyond the doubts of a 25-year-old about string theory. So you have to shut up, and if you want to have a PhD you have to eat String Theory. I finally dropped out of physics, disappointed not only by the so-called theory of everything, but above all by the aggressive attitude of my professors. Too much ego is a sign that deep down they know they're wrong, but… "I've been working on this for many years, so it has to be true."

3. **Alessandro Strumia**
   October 24, 2022

   You would enjoy the video of the 2001 CERN Christmas recital. Despite being done at the peak of string popularity, it featured physicists reading the sacred Schwarz-Witten Green book dressed as barbosi Talibans chanting "why are we doing this? why are we doing this?". When I joined the recital, CERN offered me one of the two available positions: either string theorist or dog. That's why I bark in the video. Hopefully it has now been cancelled because it contains the politically-incorrect word Christmas.

4. **Mitchell Porter**
   October 24, 2022

   Ann Nelson had a more positive view by 2005:

   https://www.preposterousuniverse.com/blog/2005/07/21/two-cheers-for-string-theory/#comment-228

5. **Peter Woit**
   October 24, 2022

   Mitchell Porter,
   Kaplan explains that his attitude towards string theory used to be less hostile, that at some recent point he came to the conclusion that the late 90s analysis that it is "bullshit" was correct. Perhaps Nelson later did or would have come to the same conclusion.

   A strange aspect of the interview is that it does not cover at all Kaplan's film "Particle Fever" (made 10 years ago, see https://www.math.columbia.edu/~woit/wordpress/?p=6308) in which he and Arkani-Hamed are filmed going on uncritically about LHC implications for multiverse scenarios made popular by string theorists.

   An important aspect of this story (and for understanding at any time what is going on in theory) is that of battles over funding. By the mid-90s string theorists were winning the battle with phenomenologists for funding and positions (for some data, see https://particle.physics.ucdavis.edu/rumor/doku.php?id=statistics), which had a lot to do with Nelson and others feelings about string theory. By 2005 things were starting to change, partly due to the "large extra dimensions" models of people like Arkani-Hamed and Randall which brought together the string and phenomenology people. If you were a phenomenologist you could add something about this and string theory to your grant proposal and benefit from the string theory hype yourself. The upcoming LHC and the the increasing problems of string theory also helped a lot starting around this period.

   I haven't really been paying attention to current trends in how funding affects what people are working on, but for string theorists being able to claim that they are working on "quantum information" surely is helpful on the grant front.

6. **Brathmore**
   October 24, 2022

   Peter – I would be interested in your assessment of the following claims made by one of the physicists that your post references:

   https://www.preposterousuniverse.com/blog/2005/07/21/two-cheers-for-string-theory/#comment-228

   1. "That said, the field and its practitioners have redeemed themselves by discovering deeper and more interesting insights into Quantum Field Theory then ever would have been found by phenomenologists or by traditional formal quantum field theorists."

2. “Spin-offs of string theory including D-branes, AdS/CFT, orbifolds, dualities, supersymmetry, and new dimensions have all found their way into testable particle physics phenomenological model building, and particle theory would be would be completely moribund without them.”

3. “Also some interesting experiments have been done in response to some of the string-inspired models, such as tests of the gravitational inverse square law at the sub-centimeter level, that would not otherwise have been conceived, and which very well might find something revolutionary. Other approaches to quantum gravity dont offer many such spin-offs, as far as I can tell, and neither do other formal approaches to quantum field theory.”

4. “Finally, as to whether string theory and its predictive power should be thought of in an analogous way as quantum field theory—ADS/CFT has taught us that string theory IS quantum field theory and vice versa. For instance QCD, which is certainly a quantum field theory, can very likely also be formulated as a string theory and the ADS/QCD approach shows that the latter formulation can give interesting insights into phenomenona such as vector meson dominance and confinement.”

7. **Peter Woit**
October 25, 2022

Brathmore,
See my above comment in response to Mitchell Porter. I don’t think any of those 2005 arguments for string theory have held up very well (as opposed to the counterarguments I spent a lot of time making back then, and don’t want to repeat now).

In 2005 “string theory spinoffs” were a popular topic among phenomenologists, but none of that worked out and that sort of thing is now quite unpopular. I suspect that, like Kaplan, if Nelson were still with us she would now have have a more skeptical take on string theory than in 2005.

8. **James**
October 25, 2022

Susskind may be a jerk, but I always understood that yelling at the speaker at a physics talk is fairly common.

9. **Peter Woit**
October 25, 2022

James,
In my experience, yelling at the speaker in physics talks isn’t common at all. But, in any case, Kaplan’s accusation seems to be that Susskind was doing this just to non-string theory speakers (terrorizing them by yelling at them that their work was bullshit).

10. **suomynona**
October 25, 2022

@Brathmore:

Point 3 is demonstrably false. See for example doi.org/10.1103/PhysRevD.9.850 and its references and citations. Absolutely no mention of anything stringy as motivation here. Sure, the more recent work mentions string theory’s extra dimensions, but investigations into possible violations of gravitation’s inverse square law have a long history irrespective of any string-based inspiration.

11. **Peter Woit**
October 25, 2022

Brathmore, suomynona,

To get an idea of the nature of the widespread hype from that era, take a look at this 2000 NYT article about how “Physicists Finally Find a Way to Test Superstring theory”
https://www.nytimes.com/2000/04/04/science/physicists-finally-find-a-way-to-test-superstring-theory.html
and subsequent Physics Today pieces “Large Extra Dimensions: A New Arena for Particle Physics” in 2002
https://physicstoday.scitation.org/doi/10.1063/1.1461326
and “The case for extra dimensions” in 2007
https://physicstoday.scitation.org/doi/10.1063/1.2761818

Most people at the time thought these models were bullshit, but sociologically they did manage to bring together the phenomenology and string theory communities, giving them both something exciting-sounding to point to and use to justify their funding. The whole subject disappeared without a trace once the LHC turned on and immediately, as expected, saw no evidence for such models. I don’t know if Kaplan at the time would have acknowledged this was bullshit, but he at least seems very aware of that now.

12. **Jim Eadon**
October 25, 2022

This is the funniest interview about physics I’ve read. And incredibly insightful at the same time, for example, pointing out intimidation. I wonder if the String Theory bubble is more threatened by people laughing at it, than by seriously-stated refutations. Which funding body wants to fund a joke? (I don’t meant to be provocative, it’s a genuine supposition). I wonder, is this level of derision of ST commonplace in physics?

13. **Peter Woit**
October 25, 2022

Jim Eadon,
I think this level of derision about claims to get any information about a unified theory out of string theory is now very much commonplace in the physics community. You’ll hear it often privately and sometimes even publicly, not only about the fringe claims of Michio Kaku and Gordon Kane, but also about the claims being made for the “Swampland Program” for instance.

String theorists are well-aware of this, and most now are careful to argue that they are no longer pursuing a unified theory, knowing that would not be taken seriously.

It was somewhat remarkable that Kaplan referred to the currently popular “it from qubit” stuff as “literally bullshit”, since that is well-funded and taken very seriously by the powers that be.

14. **Attendee**
October 25, 2022

I attended one of these It from Qubit meetings. I dont work in that area and I was simply curious. I concur with Kaplan’s opinion. It is absurd to believe that quantum gravity can be obtained by appealing to quantum information. Why dont these guys first derive the standard model from quantum information before trying to figure out physics that is 17 orders of magnitude higher in energy?

15. **Scott Aaronson**
October 26, 2022

As someone who considers Particle Fever one of the finest science documentaries ever made, and without commenting on the much harder questions that Kaplan raises — I'll just remark that the portrait of Lenny Susskind here is unrecognizable to me from 16 years of knowing him. Yes, Lenny is passionate beyond belief about whatever he's currently working on, and blunt in his opinions. Yes, he often lets hunches run light-years ahead of either theorems or data. Yes, he may have been different in the past, or have some Jekyll-and-Hyde thing going on. But I never once saw him yell at or abuse anyone. On the contrary, I've been struck by his willingness to listen intently to any new idea, however seemingly farfetched and however junior the proposer, and to abandon his own ideas once he's convinced they're wrong.

16. **Bartek**
October 27, 2022

I just want to second what Scott said. I was a postdoc at Stanford for 3 years. I did not write papers with Susskind. I disagreed with Susskind a lot. I had exactly 1 (that is: one) situation when he was impatient with my questions and kind of brusquely told me off. Then, an hour later, he came to my office and apologized. That apology doubled my already deep respect for him. I'm very skeptical of what's being said in this interview.

17. **A Stunned Reader**
October 27, 2022

A verbatim copy from the full interview transcript that's linked at the beginning of the post:
.
"I am still of the attitude that I would do physics if I lived in a van. I really—I cannot help but do this. And those are the people who are going to come up with something. The people that cannot do anything else but this will do it in their sleep. We're just addictively trying to figure things out. Those are the people."
.
So basically only Kaplan and people that are just like him are the ones bound to make great breakthroughs and discoveries. Right. The level of self-involvement displayed throughout this interview is stunning.
.
Maybe next time he is interviewed he can tell us all about his grand breakthroughs, instead of spending the whole time bashing other people's field of research by continuously repeating the very sophisticated argument that it is "all bullshit". (The word "bullshit" appearing an impressive 8 times.)

18. **Peter Woit**
October 27, 2022

It may be that the Susskind behavior Kaplan reports was specific to the period of the late-90s at Stanford. It was a time string theory was not doing well, and phenomenologists were often very scornful of the subject, before the reconciliation between string theorists and phenomenologists caused by brane-world models. Stanford I think was a bit of an unusual case, with positions divided between SLAC and the university. At the university, the ideology of the string theorists was becoming more extreme, at the SLAC lab there would have been tension about funding work that had nothing to do with experiment. From what I've seen over the years in physics, the worst behavior comes about when people are fighting over grants/positions.

In all the years I've seen talks by Susskind or ones where he was in attendance, I've never seen any bad behavior of the sort Kaplan reports. On the other hand, I have heard a vast amount of complete bullshit from him at such talks…

19. **Leo**
October 27, 2022

A long time ago I got really pissed at Susskind's demeanor towards anything that was not his research, I'm glad I finally have an opportunity to show it:

Please watch the first minute of this video

where I believe he shows his true colors. Also, before anyone says he is being sarcastic, consider who he is talking to (mostly string theorists at Santa Barbara) so he is preaching (Bill Unruh calls him a preacher) to his quire, where he feels safe and comfortable to make such claims.

20. **Peter Woit**
October 27, 2022

Leo,

About Susskind's claim that
"If you're not working on eternal inflation you're a blooming idiot and I can't help you."
it has always required a great deal of self-control on my part to not say things like
"If you are working on eternal inflation you are a blooming idiot and I can't help you."

21. **Interested amateur**
October 27, 2022

What paper is Kaplan referring to when he says:

Kaplan:
[laugh] There's a semi-famous paper in model-building in my field, particle physics. The semi-famous paper was written by Lisa Randall and Raman Sundrum, and so it's just called Randall-Sundrum. And there was some geometric, extra dimension that could solve the problem with the Higgs without supersymmetry. And it was kind of—you know, it had problems but the picture was kind of cool.

—the reason it had that mini crash the last year was because of Randall-Sundrum [laugh]—

—because of this stupid paper. And Jeff Harvey was like, "What? What was so bad about"—Kutasov said, "It was not even the most interesting paper to come out that day."

22. **Peter Woit**

Thanks Peter; that's the paper I had in mind, but Kaplan's claim that it was "semi-famous" and "stupid" made me think he was referring to another joint paper of Lisa and Raman, or that I was misinterpreting as serious his possible tongue in cheek humor at this point.

24. **Peter Shor**
October 28, 2022

Attendee:

You say

> It is absurd to believe that quantum gravity can be obtained by appealing to quantum information. … Why don't these guys first derive the standard model from quantum information before trying to figure out physics that is 17 orders of magnitude higher in energy?

You can't possibly figure out the Standard Model from quantum information. There are an immense number of different possible quantum field theories, and quantum information gives you no clue whatsoever as to which one is correct.

But you might be able to figure out *some* properties of quantum gravity from quantum information (just like you're able to figure out a few properties of classical physics from thermodynamics) even though I think it's very improbable that you'll be able to derive a unique, complete theory of quantum gravity from it. Still, figuring out exactly what quantum information tells you about quantum gravity seems like a worthwhile research endeavor to me.

I have no idea whether the It from Qubit people know this and are indulging in exaggerated hype about deriving quantum gravity from quantum information merely to get more publicity and more funding, or if they have simply deluded themselves. If anybody has any clues as to the answer to this, I'd love to hear them.

[In fact, quantum information has already shed some light on quantum gravity. The paper of Almheiri, Marolf, Polchinski, and Sully (AMPS) showed that Susskind's "complementarity" hypothesis for how information escapes from a black hole was wrong, at least in its original form.]

25. **Peter Woit**
October 28, 2022

Interested amateur,
The comments by Kaplan about what string theorists at Chicago thought of this paper are pretty unclear, I'm wondering if there's a transcription error, or maybe he just didn't clearly express what he was trying to say.

26. **Anonyrat**
October 28, 2022

Months after David Kutasov called Randall-Sundrum "not even the most interesting paper that came out today" , Kutasov, Shifman and Randall were co-organizers of the Conference on Extra Dimensions in Field Theory and String Theory, ITP, Santa Barbara, November 1999.

In trying to find out more about that conference, I came across this parody, titled "Lobotomy".

http://insti.physics.sunysb.edu/~siegel/parodies/lobotomy.html

—

The actual conference used "New" instead of "Extra", and here is it is:

Peter Shor – Quantum Information relies on general properties of quantum mechanics I.e. statements that are true for any Hermitean Hamiltonian. And indeed, as you correctly say, one cannot use these general properties to learn about theories (such as the Standard Model) where there are detailed dynamics. An actual theory of quantum gravity would need to describe dynamics such as the evolution of the universe from a gravitational singularity or the nature of black hole singularities and the theory in the low energy limit needs to reduce to spin 2 GR. These are detailed and essential questions that any quantum gravity theory needs to answer and I think it is highly improbable that appeals to generic properties of every Hamiltonian system will yield insights into these specific questions (from your response, I expect you agree with this – I just wanted to clarify my comment).

But, I agree that one can rule out silly fantasies such as Susskind's black hole complementarity as being incompatible with the basic properties of quantum mechanics using arguments such as the AMPS paper. While this is useful, its utility as a tool to actually learn something non trivial about quantum gravity is highly limited.

In the specific case of complementarity, it had always been clear it was a fantasy – Mathur articulated these arguments in the late 2000s. Moreover, if you actually tried to implement a physical mechanism for information transfer from a 3D object falling into a black hole info a 2D surface, you immediately ran into trouble (I.e. not enough time to couple degrees of freedom falling in to stuff going out).

28. **disillusioned humanities PhD student, saddened/amused by string theory**
October 29, 2022

From the interview: "So now that I've finally dug into it, I realize that—not that all humanities fields are bad. But it's much more like a humanities field where there are the prominent people in the field, and they decide what's interesting. And that if you impress those people, you can get ahead. But that dictates then what research is done. And they're not going to discover anything in that context. They're not going to get anywhere."
————————
This is spot on. I am a humanities PhD student who, after much tribulation, realized it would be psychologically impossible for me to pursue a career in my field, because it is so full of exactly the type of bullshit described in this interview (and on this blog). It is uncanny how closely the pathologies of string theory, as far as I understand them, resemble the pathologies of most contemporary humanities disciplines. As far as I can see, they are basically identical, except that string theory is much more consequential, and so much more money/funding/fame is at stake, than in any humanities field.

As a PhD student, gradually gaining enough expertise to evaluate the claims of professors in their field, and then realizing that at least 60% of them, and ~80% of the most successful, are intellectual frauds who routinely doctor evidence/repress inconvenient evidence/promote their “theory” without any sense that evidence is even necessary, sometimes subconsciously from long practice, but often in full awareness of what they’re doing–well, this is depressing, disorienting, and psychologically disturbing. I have been surprised to learn that some bright physicists have this same experience, with string theory, and I sympathize with them.

For both physics and the humanities: the subject matter is important and worth studying, and can be studied in ways that produce knowledge rather than bullshit. The world, and PhD students everywhere who love their subject matter, deserve better than this bullshit!

29. **Peter Shor**
October 30, 2022

@Attendee:

Maybe it was clear to you that complementarity was a fantasy, but there seem to be a whole lot of smart people to whom it wasn’t clear.

And as for listening to Mathur … I believe people considered his theory of fuzzballs to be much more improbable than Susskind’s theory of complementarity, so of course nobody listened to him.

30. **Attendee**
October 30, 2022

@ Peter Shor: The situation with complementarity is actually quite amusing. Publicly, many people would tout that as the party line, though privately, quite a few people would admit that they didn’t know how it could work. This is not exactly a surprise since complementarity never had an actual mechanism (otherwise, AMPS would not have been able to rule it out). AdS/CFT was supposed to be evidence for complementarity – but this is not true. AdS/CFT is a duality – it describes (say) a 3D AdS space in terms of a dual theory on the boundary – i.e. – just a variable redefinition. It does not actually provide a mechanism to move information around.

The community around Susskind is highly entertaining – for most of the 2000s they were engaged in solving the “measure problem” of eternal inflation that Peter mentioned above. In fact, there is no actual measure problem : given a Cauchy surface, quantum mechanics and General Relativity provide a sensible time evolution. Now the problem with eternal inflation is that the answer depended on the choice of initial conditions and thus one did not have universal answers like one did with classical inflation. These guys didn’t like that answer since it didnt fit with their anthropic philosophy and thus they spent over a decade trying to come up with a “solution”. This was of course silly since you can’t get around the fact that the solution to this particular Cauchy problem did not have an attractor. All of these people were considered “smart” 🙂

I agree that fuzzballs dont seem like a plausible end result of gravitational collapse.

31. **Peter Woit**
October 30, 2022

disillusioned,
While there are commonalities between the problems of string theory and those of other academic fields, I don’t think a broad brush analysis of the problems is helpful. I also disagree with Kaplan’s analysis that the problem is the power of leaders of the field to determine who gets jobs and what research gets done. That’s the way human society works, it’s the way all fields work at all times. And yet, some fields at some times are healthy and make progress (HEP theory up til the 1970s/80s, many subfields of pure math these days), while others are unhealthy and stagnant (HEP theory post mid 80s).

The problem is to understand why the leadership of a field is failing at their job. In the case of HEP theory, there’s a complicated set of reasons for why this has come about (I wrote a whole book about it…). It always seemed to me that a solution to the problem needed to start with this leadership admitting failure and trying to change its ways in order to do better. Unfortunately, this shows no signs of happening in HEP theory (try finding somewhere in the mass of Snowmass reports anything of this kind), and the field seems likely to just continue its recent trajectory (giving up on the subject without admitting it).

32. **disillusioned humanities PhD student, saddened/amused by string theory**
October 30, 2022

Peter Woit,
You say: “I also disagree with Kaplan’s analysis that the problem is the power of leaders of the field to determine who gets jobs and what research gets done. That’s the way human society works, it’s the way all fields work at all times. And yet, some fields at some times are healthy and make progress …
The problem is to understand why the leadership of a field is failing at their job. In the case of HEP theory, there’s a complicated set of reasons for why this has come about (I wrote a whole book about it…). It always seemed to me that a solution to the problem needed to start with this leadership admitting failure and trying to change its ways in order to do better.”

I agree with all of the above, and should have clarified this in my comment. It applies equally well to those academic humanities disciplines I am familiar with that are both floundering epistemically and have as their subject-matters phenomena/questions that one can in principle pursue knowledge about (which is not all humanities disciplines, and that’s fine).

Of course, there are epistemic challenges distinctive to various humanities disciplines/subject-matters that aren’t present in physics (or any natural science). But, at least in my judgment, the central problem in these potentially-knowledge-producing humanities disciplines is exactly the failure of leadership that you describe in the case of HEP, if I understand your comment correctly (I have not had a chance to read your book). Because they too have made progress in the past, and aside from that, one can see in principle how they could make progress. The problem is that a critical segment of the most powerful/successful people continue holding on to “results”/methodologies that turned out to be demonstrably false/not productive of knowledge, and this in spite of by now reasonably well-established alternatives. If that is the (or a) problem in HEP, then it is shared with these humanities disciplines.

Personally, I would say (again assuming I don’t fundamentally misunderstand the issues in HEP) that in both cases there is a failure to “care enough” about the truth/truthfulness, though I understand that others would not want to put it this way. Whether it is helpful to focus on these commonalities depends what one’s concerns are. I agree that when it comes to trying to improve a particular discipline, like HEP or history or anthropology, the broad-brush analysis is not the most productive (analytically or rhetorically) thing to focus on.

33. **Scott Aaronson**
October 31, 2022

@Peter Shor: It’s very hard for me to imagine any of the It from Qubit people I know disagreeing with the following paragraph of yours:

But you might be able to figure out some properties of quantum gravity from quantum information (just like you’re able to figure out a few properties of classical physics from thermodynamics) even though I think it’s very improbable that you’ll be able to derive a unique, complete theory of quantum gravity from it. Still, figuring out exactly what quantum information tells you about quantum gravity seems like a worthwhile research endeavor to me.

That’s why your next sentence…

I have no idea whether the It from Qubit people know this and are indulging in exaggerated hype about deriving quantum gravity from quantum information merely to get more publicity and more funding, or if they have simply deluded themselves.

strikes me as a both uncharitable AND unexhaustive list of possibilities!

34. **Peter Woit**
October 31, 2022

Scott,
What’s disturbing to me is that the exaggerated hype problem here looks much the same (involving even much the same group of people) as the decades-old string theory hype problem which has done a huge amount of damage. In the string theory case most string theorists I know had reasonable arguments for the work they were doing, with the hype coming from a vocal and influential minority. The same thing seems to be going on now, with likely the same ultimate effect on serious quantum gravity research (sooner or later the hype collapses, those responsible claim victory and move on, leaving a toxic mess of confusion behind that convinces most everyone to give up completely on the subject).

The next blog entry is good example of this. Joe Lykken (until recently deputy director of Fermilab, now head of the Fermilab Quantum Institute) is giving a CERN colloquium on Wednesday claiming that prospective quantum computer calculations of SYK models with around 100 degrees of freedom will be “experimental quantum gravity”. He did something very similar back in the early aughts, making bogus claims that the LHC would be testing string theory based on large extra dimension/SUSY models. This kind of thing leads one to uncharitable thoughts about his motivations and behavior, but more importantly, shouldn’t something be done about it? Shouldn’t the leaders of this field be held to some basic standard of responsibility?

35. **Scott Aaronson**
November 1, 2022

Peter: To say we have an analogous hype problem in quantum computing would be a titanic understatement (and as you’ve alluded to, QC hype and QG hype are even starting to intersect). Of course, I *have* spent years trying to fight QC hype on my blog—but I don’t manage to address even 10% of what’s out there, certainly not today. Does that mean I’m giving my tacit approval to the other 90%? Or that my colleagues who are careful in their own statements, but ignore the hype, are giving tacit approval to 100%? That seems like too high a bar, even while I vociferously agree with you that more needs to be done.

36. **Peter Woit**
November 1, 2022

Scott,
I understand that you have your hands full with the QC hype and are doing what you can to deal with that intractable problem. In some sense the quantum gravity hype is not your problem, but is the responsibility of the part of the theoretical physics community working on quantum gravity.

I’m trying to raise awareness of two issues:

1. Claims that “we’ve finally found a way to do experimental quantum gravity” by doing calculations or experiments with some QM system that has a conjectural gravitational dual (one that has nothing to do with physical gravity) are bullshit, but are now being promoted by very prominent members of the theory community.
2. We’ve seen this kind of hype before, often from the same people, and there never has been an effective way of dealing with it. Can we do better this time? Who is responsible for doing something?

37. **Peter Shor**
November 2, 2022

Hi Scott:

My previous comment was undoubtedly phrased too strongly.

But many of the It from Qubit people seem to be fairly confident that they can figure out *how* the quantum information escapes from the black hole just by looking at quantum information. Given that quantum information isn’t adequate to come up with the correct theory of quantum gravity, I don’t really see why they can be sure that quantum information considerations are enough to tell them that.

This Week's Hype

October 31, 2022
Categories: This Week's Hype, Wormhole Publicity Stunts

CERN on Wednesday is hosting a colloquium talk by Joseph Lykken, who supposedly will discuss [Prospects for experimental quantum gravity](). There's by now a long tradition of string theorists dealing with criticism that their research program is inherently immune from experimental test by making bogus claims about experimental testability. Lykken has been at it for at least twenty years (see [here]()), and this sort of misleading claim about testability is the latest in a long campaign.

If you read the abstract, it looks like what Lykken is actually talking about is numerical simulations of an SYK model with of order 100 Majorana fermions on a quantum computer. Ignoring the quantum computer hype (unclear how long it will really be before such simulations are feasible), keep in mind that the SYK model is a quantum mechanical toy model, not a model of quantum gravity in a physical dimension. The only thing a quantum computer could test would be the validity of certain approximations schemes in such a toy model. For comments by David E. Kaplan about similar testability claims, see the interview discussed in the previous posting, which includes:

> That there are actual people who are deciding string theory's important, wanting to do string theory, and they're even protecting the field. And some of those people are talking about how entropy now of a black hole can be described as a geometric thing, an entanglement, and that Hawking's paradox about evaporating black holes is really wormholes, virtual wormholes coming from the inside to the outside, and all kinds of language. And you could test information theory of black holes using atomic physics experiments. And it's literally bullshit.
>
> There are people—prominent people—in physics who say, "I'm applying for this money from the DOE, but I know it's bullshit." And then there are experimental atomic physicists who don't know and are shocked to learn that "What? String theorists don't have a Hamiltonian? They don't actually have a description? What am I testing?"

Update: Lykken was giving Colloquium talks on [Experimental String Theory]() nearly a quarter century ago. He was also one of the main sources for the embarrassing NYT 2000 article [Physicists Finally Find a Way to Test String Theory]().

> "For the first 25 years, the thinking has been that superstring theory is so difficult to see experimentally that you have to figure it out by its own mathematical consistency and beauty," Dr. Lykken said. "Now that's completely changed. If this new picture is true, it makes everything we've been talking about testable."

Hopefully science journalists have learned something and we won't see a forthcoming NYT article on how "Physicists Finally Find a Way to Test Quantum Gravity".

Update: Lykken's slides are [here](). His proposal for an experimental test of quantum gravity is explicitly acknowledged as the same as one made by Lenny Susskind [here]() in 2017. At the time that made no sense to me and I wrote about it [here](). It still makes no sense.

Comments

1. **Andrew**
   October 31, 2022

   Peter, Lykken is deputy director of Fermilab and heads the Quantum Institute there. Just from the abstract it's unclear if this is Lykken the physicist or Lykken the politician presenting.

   A few years ago, I saw a talk he gave at Aspen definitely as Lykken the politician. His unabashed enthusiasm for quantum computing as the vanguard of HEP was, frankly, difficult to watch and he received significant backlash from the audience that this quantum push depleted resources from other important directions of the field. Since then, it seems that quantum computing, machine learning, etc., have only grown in funding support from the DOE and NSF HEP divisions.

2. **Attendee**
   October 31, 2022

   SYK, with its 100 Majorana fermions, is as relevant to quantum gravity as homeopathy is to medicine. Indeed, the 100 Majorana fermions can't feel their mutual Newtonian gravity but by a profound miracle they are going to describe quantum gravity.

3. **Nick M.**
   October 31, 2022

   Trick or Treat: Yet another claim that the CMB contains evidence for the multiverse:

   https://www.newscientist.com/article/0-the-cosmologist-who-claims-to-have-evidence-for-the-multiverse/

   If my 'trick-or-treat' bag had a candy for each and every one of these claims,…

   -Nick

4. **Sabine Hossenfelder**
   November 1, 2022

   I'm just here to support the "It's bullshit" statement. And I too have encountered physicists who full well know that what they are saying is bullshit, but do it because they can get money for it. At the moment this is everything quantum simulation. Most of them delude themselves into thinking that somehow something will come out of it. (And those who don't manage to delude themselves leave — strong selection bias.)

   Quantum computers are the new particle accelerators, basically. All the nonsense that we saw 20 years about about bullshit to test at the LHC is now bullshit to test on a quantum computer. Except no quantum computer is anywhere in sight, so they can keep on doing this for much longer.

   It's extremely worrisome that this is still possible and no attempts at fixing the problem have been made.

   @Andrew: I believe he is no longer director.

5. **d_b**
   November 2, 2022

   "the SYK model is a quantum mechanical toy model, not a model of quantum gravity in a physical dimension"

I am curious why the "physical dimension" part matters so much. One common technique we use to solve complicated problems in physical dimensions is to start with a simpler but analogous problem in lower dimensions and try to work our way up. I am not claiming that this always works (certainly there are phenomena we see in low dimensions that don't show up when we go to higher dimensions, or vice versa) nor am I claiming that it will definitely work in the case of quantum gravity, but it does seem like a reasonable thing to try in the face of an (apparently) intractable problem.

6. **Peter Woit**
   November 2, 2022

   d_b,
   Remember that the whole reason quantum gravity is a problem is the lack of renormalizability, and this problem comes about because of the behavior at short distances of physical degrees of freedom describing space-time. In 1+1 and 2+1 dimensions there are no physical degrees of freedom, just gauge (and topological). So, in these dimensions the problem you are trying to solve is not there. In more than 3+1 dimensions the non-renormalizability problem is there, even worse. The original claim of the string theorists was that string theory solved this problem (in 9+1 dimensions), but that's another story…

   The SYK model isn't even a QFT. It's a 0+1 dimensional model. I've nothing against people doing calculations in toy models, but you can't then claim to have solved problems of actual quantum gravity based on toy models of a very different nature. And claiming that when you do such calculations you are doing "experimental quantum gravity", creating wormholes in a lab, etc., etc. is just complete bullshit.

7. **Emil Martinec**
   November 2, 2022

   Lack of renormalizability is not the only problem for quantum gravity. The whole point of the black hole information problem is that it involves arbitrarily large distances (the horizon scale of a black hole that can be as big as you like, with arbitrarily low curvature), and nearly 50 years of attempts to solve the problem using quantum field theory has not led to a definitive resolution.

   The construction of toy models in low dimensions makes the problem particularly acute – there is NO dynamics in gravity itself and no short-distance problem in constructing the quantum theory; at the same time, there is no underlying statistical physics explanation of black hole thermodynamics (because of the paucity of dynamical degrees of freedom in gravity itself), so quantizing gravity as a field theory cannot be the whole story.

   The interest in the SYK model stems in part from the fact that it exhibits a collective mode whose action is equivalent to that of 2d topological (JT) gravity. So you have an underlying quantum statistical mechanics, and can derive from it an effective thermodynamics which happens to be the same as that of AdS2 black holes. It is less clear, however, that there is any sense in which one has local bulk physics in two dimensions (there are reasons to think not).

   Quantum systems that accurately model black hole thermodynamics are relatively rare; solvable ones are rarer still. So it seems worthwhile to learn what one can from this one, while indeed being careful not to get carried away with what aspects of gravitational physics can be captured by such a model. Thus far, picturesque evocations of quantum wormholes remain largely just that – picturesque evocations.

   Coming from the other direction, if one wanted to try to strip away as much as possible from quantum gravity in trying to address the black hole information problem, one has to retain at least the qubits responsible for the black hole entropy, and the gravitational collective modes that capture the thermodynamics. I'm not saying that what is left is the SYK model, I'm simply saying that what is left after such a winnowing of content shares many of its features. If one wants to answer questions about what is going on locally at a black hole horizon, and how specifically information is stored and re-radiated from a black hole, I suspect the baby has been thrown out with the bath water here.

8. **Peter Woit**
   November 2, 2022

   Emil Martinec,

   Thanks for the clear explanation of the significance of the SYK model as a toy model for black hole thermodynamics. It's a good point that in principle this might indicate the nature of the resolution of the black hole information paradox (although it would be a resolution that says nothing about the fundamental problem of finding a consistent dynamics of the short-distance degrees of freedom).

   It would be really helpful if all people working on this stuck to providing accurate explanations of what this research is about, and avoided misleading claims about how the study of these models on a computer or in corresponding actual quantum systems was somehow experimentally accessing wormholes and physical quantum gravity effects.

9. **Shantanu**
   November 3, 2022

   Peter: I always considered Joe Lykken has a phenomenologist as he was always keynote speaker in DPF and another major conferences. Did not know he works on string theory or quantum gravity. (He has only 3 papers in gr-qc). However I see that has papers on string theory and D-branes (mainly in 90s).

10. **Peter Woit**
    November 3, 2022

    Shantanu,
    Lykken became a string theorist when everyone else did (late 1984), then spent many years promoting the idea of testing string theory at the LHC. The full Wikipedia entry for his research is currently
    "In 1996 Lykken proposed "weak scale superstrings," which posited extra dimensions of space within the reach of particle colliders, such as the Fermilab Tevatron, and the CERN Large Hadron Collider. This, and related ideas will be subject to direct and indirect experimental tests in the coming years."
    Like many others, he seems to now be rebranding himself as a quantum information theorist, see https://arxiv.org/abs/2010.02931

Physical Mathematics c. 2022

November 9, 2022
Categories: Uncategorized

The arXiv today has a very comprehensive survey of a conventional point of view on where "Physical Mathematics" is in 2022 and where it is going, written by a group of six authors. "Physical Mathematics" is a term popularized by one of them, Greg Moore (see here and here, with some commentary here), and it's an expansion of a Snowmass white paper. A separate paper by Nikita Nekrasov covering the material listed in Section 10 is advertised as forthcoming with the title "The Ghosts of Past and Future Ideas and Inspirations on Interface of Physics and Mathematics".

The term "Physical Mathematics" is a play on the more conventional name of "Mathematical Physics" to describe work being done at the intersection of math and physics. In its usage by Moore et al. it refers to a point of view on the relation of math and physics which heavily emphasizes certain specific topics that have been worked on intensively during the last four decades. These topics mostly have roots in seminal ideas of Witten and his collaborators, and involve calculational methods developed in quantum field theory and string theory research. The huge volume of this research is reflected in the fact that the survey reference section contains 62 pages giving 1276 separate references. A major problem for anyone taking up an interest in this field has been the sheer scale and complexity of all this work, and this survey should be helpful in providing an overview.

While some of these 1276 papers could equally well be simply characterized as "Mathematics", it's hard to describe exactly what makes a lot of the rest "Physical Mathematics" rather than "Physics". Part of the answer is that these are not physics papers because they don't answer a question about physics. A striking aspect of the survey is that while a lot of it is about QFT, the only mention at all of the QFT that governs fundamental physics (the standard model) is in a mention of one paper relevant to some supersymmetric extensions of the SM. The only other possible connection to fundamental physics I noticed was about the landscape/swampland, something only a vanishingly small number of people take seriously.

Also striking is the description of the relation of this field to string theory: while much of it was motivated by attempts to understand what string/M-theory really is, section 3.1 asks "What Is The Definition Of String Theory And M-Theory?" and answers with a doubly-boxed

We don't know.

with commentary:

> This is a fundamental question on which relatively little work is currently being done, presumably because nobody has any good new ideas.

In the background of this entire subject is the 1995 conjecture that there is a unique M-theory which explains various dualities as well as providing a unified fundamental theory. After nearly 30 years of fruitless looking for this, the evidence is now that there is no such thing, and maybe the way forward is to abandon the M-theory conjecture and focus on other ways of understanding the patterns that have been found.

I share a faith in the existence of deep connections between math and physics with those doing this kind of research. But the sorts of directions I find promising are very different than the ones being advertised in this survey. More specifically, I'm referring to:

- the very special chiral twistor geometry of four-dimensions (no twistors in the survey)
- the subtle relation of Euclidean and Minkowski signature (only a mention of the recent Kontsevich-Segal paper in the survey)
- the central nature of representation theory in quantum physics and number theory (very little representation theory in the survey)

Looking back at Greg Moore's similar 2014 survey, I find that significantly more congenial, with a more promising take on future directions (in particular he emphasizes the role of geometric representation theory).

Comments

1. **Brathmore**
   November 9, 2022

   Disclaimer: I am neither a professional physicist nor a professional mathematician. But writing as an outsider with some technical background, it strikes me that people in this new field of "physical mathematics" have stumbled on something wonderful: physical mathematics doesn't sound like it is constrained either by the exacting rigor of logic (as in "mathematics") or the crucible of experiment (as in "physics").

   But such constraints in mathematics and in physics are precisely the things that make both fields so hard, as well as so useful. I imagine that centuries of effort in both fields led people to conclude that such constraints *were* essential. Does "physical mathematics" indeed lack the constraints above? Does it have new ("emergent"?) constraints not shared by physics or math? Or is it essentially without constraint? Is it essential for an intellectual area with scientific aspirations to be bound by rigorous logic or experiment?

2. **Peter Woit**
   November 9, 2022

   Brathmore,
   The problem is that among the 1276 papers there's everything from the fully rigorous to the highly incoherent. Typically though, calculations are being done based upon some list of assumptions about how the objects involve behave (e.g. you don't have a rigorously defined QFT, but do have a conjectural part of a theory with conjectural properties). One thing that makes the subject difficult is that these assumptions are rarely explicitly stated. There are constraints: your assumptions have to be internally consistent, otherwise you'll get nonsense.

   The best of this work does capture non-trivial new deep ideas about mathematics, even if not completely understood. A good example would be Witten's work on Chern-Simons which won him the Fields medal. One thing that was clear was that he had his hands on a powerful new set of topological invariants, which he could compute in many cases. His QFT methods for getting these were somewhat ad hoc and not clearly consistent, but the result was compelling.

3. **Will Sawin**
   November 10, 2022

   @Brathmore,

   Jaffe and Quin wrote an article ("Theoretical mathematics": Toward a cultural synthesis of mathematics and theoretical physics) motivated by exactly the question of how theoretical-physics-style speculation in mathematics can be sufficiently constrained to avoid bad consequences. They advocated basically for a balance between speculation and rigorous proof, lumping not just physicsy stuff but any kind of conjecturing together under speculation.

This article is perhaps most famous for a brief comment they made criticizing Thurston's proof of the geometrization theorem for Haken manifolds as an example of insufficiently rigorous work that damages the field, inspiring Thurston to write a rebuttal in the form of his beautiful "On Proof and Progress in Mathematics".

   November 11, 2022

   A shout0ut and second re Kontsevich – Segal …

5. **David Roberts**
   November 11, 2022

   Because no one has linked to it, here's the Kontsevich and Segal paper: *Wick rotation and the positivity of energy in quantum field theory*, arXiv:2105.10161.

6. **Cedric BARDOT**
   November 13, 2022

   Graeme Seagal presents his "rival" version to the standard Wightman axiomatisation of QFT in the following video (answering questions by Alain Connes & Nigel Higson among others).
   At 10'30" he starts to explain how does Wick rotation fits to this new axiomatisation and exposes the most important idea of his recent paper with Maxim Kontsevitch at 37'06".

   Waiting for Nikita Nekrasov future paper on his panorama of physical mathematics, we can relax and learn about his personal trajectory at the interface of theoretical physics & mathematics with a short video interview (from 2018?) at IHES I don't think Peter has ever mentioned.
   One can hear and interpret his slight hesitation & correction while defining string theory at 16'39".
   Less anecdotal, more objective and relevant piece of info I think for Peter's blog post: Nekrasov answer to the question "how do you make peace with the difficulty in your field to make predictions that are experimentally testable…?" at 23'40". It reveals IMHO the human rather than epistemic necessity of "physical mathematics" as a kind of "Compagnons du Devoir" craft's guild name for these bold & brilliant (& sometimes almost stateless) people who have engaged in the conflation of gauge theory, general relativity, supergravity, bosonic strings, supergraviton & Mp branes, IKKT model, BFSS Matrix model, 2D quantum gravity, gauge/gravity duality, AdS/CFT correspondance… hoping to build a cathedral (have a seat at the wedding feast at Planck scale?)

7. **Jonathan**
   November 13, 2022

   In the 2014 post Peter linked one of the questions he asked was, "What is QFT?" At the bottom of page 4 in the survey there is reference to another Snowmass paper that may be of interest to readers of this blog, titled "The Quest to Define QFT". It gives a go at answering this question and reviews various axiomatic approaches to defining what is QFT in 11 pages with 531 references.

   https://arxiv.org/abs/2203.08053

8. **eitan bachmat**
   November 14, 2022

   Glimpsing at the survey paper it seems to describe some of the efforts at mixing math with explorations which are inspired and motivated by physics. The Simons foundation seems very fond of such efforts and many of its collaborations (and the physics and geometry center at Stony brook) mix mathematicians, physicists and some computer scientists. The current survey seems strongly related to the rather recent global categorical symmetries collaboration and the survey also mentions the Special holonomy collaboration, both of which mix mathematicians and physicists in the general sense of the word (people who learned physics, think using the methods and jargon that they have learned, sit in physics departments and whose papers are not in the form of lemma, lemma, theorem…, trying to avoid the question of whether these people are actually doing physics which is very popular here). Math has profited immensely from such mixing of people and ideas and sometimes actual physical studies of the real world also profited.
   Waiting for the sometimes related surveys of the Homological mirror symmetry, localization of waves, Hidden symmetries and fusion energy, New structures in low dimensional topology (essentially mathematicians but strongly inspired by physicists), extreme wave phenomenon based on symmetries collaborations to provide a broader view of physical mathematics.

No Landau-Siegel zeros?

November 10, 2022
Categories: Uncategorized

A couple weeks ago rumors were circulating that Yitang Zhang was claiming a proof of a longstanding open conjecture in number theory, the "no Landau-Siegel zeros" conjecture. Such a proof would be a very major new result. Zhang was a little-known mathematician back in 2013 when he announced a proof of another very major result, on the twin prime conjecture. Before that, he had a 2007 arXiv preprint claiming a proof of the Landau-Siegel zeros conjecture, but this was never published and known to experts to have problems such that at best the argument was incomplete.

Zhang now has a new paper on the arXiv, claiming a complete proof. The strategy of the proof is the same as in the earlier paper, but he now believes that he has a complete argument. At 110 pages the argument in the paper is quite long and intricate. It may take experts a while to go through it carefully and check it. Note that this is a very different story than the Mochizuki/abc conjecture story: Zhang's argument use conventional methods and is written out carefully in a manner that should allow experts to readily follow it and check it.

For an explanation of what the conjecture says and what its significance is, I'm not competent to do much more than refer you to the relevant Wikipedia article. For a MathOverflow discussion of the problems with the earlier proof, see here, for consequences of the new proof, see here.

Update: I'm hearing that the above is not quite right, that what Zhang proves is weaker than the conjecture, although strong enough for many of its interesting implications. Perhaps someone better informed can explain the difference…

Update: Davide Castelvecchi at Nature has a news story here.

Update: Via David Roberts on Twitter, Zhang answers some questions about the paper here.

Comments

1. **Anon**
   November 10, 2022

   I believe what he proves is strictly weaker than the non-existence of zeros.

2. **Peter Woit**
   November 10, 2022

   Anon,
   Thanks! I had asked an expert about this, but there must be some detail I misunderstood. Maybe someone who understands the difference can explain…

3. **Will Sawin**
   November 10, 2022

   The difference is pretty simple.

   The "no Siegel zeros" conjecture is that the distance of any real zero of L(s,chi_D) from 1 is bounded below by a constant times 1/log D.

   The result Yitang Zhang claims is that this distance is bounded below by a constant times 1/(log D)^2024.

   So both involve the claim that there are no zeroes too close to the point 1, but one is stronger than the other by a large power.

   However, Yitang Zhang's stated result is a big improvement on what was known before – the only effective estimates had a lower bound for the distance of something close to 1/sqrt(D).

   The situation is very analogous to the twin primes paper where he improved the bound from the previously known infinity to 70,000,000, and it was expected that optimization of the method would rapidly get it down further, though falling short of the conjectural value of 2.

4. **anon**
   November 11, 2022

   And even in this case he says that the exponent could be optimized further, but the method falls short of reducing it to 1.

5. **Georges E. Melki**
   November 11, 2022

   Will Sawin,

   Thanks for the explanation! It helps greatly…
   However, I checked the ArXiv paper, and the power of log D is (-2022) and not (-2024).

   Regards

6. **Will Sawin**
   November 11, 2022

   @Georges E. Melki

   I am referring to Theorem 2 of the paper, on the zeroes, not Theorem 1, on the special value.

7. **David Roberts**
   November 11, 2022

   That's unfortunate about Davide C's article getting the facts wrong. Random on Twitter like me jumping the gun a little pales in comparison with reporter with access to experts.

8. **Peter Woit**
November 11, 2022

David Roberts,
Not sure what you mean about Davide C's article getting facts wrong. As far as I know, the only one who had facts wrong here was me, and the problem was the combination of my access to experts and my own ignorance (which led me it seems to misinterpret what one of them was telling me).

And I should have been following your discussions of this on Twitter, for instance the latest:
https://twitter.com/HigherGeometer/status/1590871536457879552

9. **Peter Woit**
November 11, 2022

Rereading the Nature article I see it doesn't make clear that what Zhang claims to have proved is somewhat weaker than the usual Siegel zeros conjecture. Perhaps Castelvecchi made the mistake of reading my blog post and trusting me to get it right…

10. **David Roberts**
November 11, 2022

Yeah, it's not explicitly said, but the implication is that Zhang proved the LS zeroes conjecture, since his earlier, incomplete preprint on that was mentioned, and there's a bunch of talk about it and quotes and so on.

I was a bit enthusiastic and misunderstood the intro, so at some point *I* claimed he'd solved the LS zeroes conjecture. But people set me right pretty quickly.

But I'm sure a correction will be made before too long, with a little note pointing out the change to the article 🙂

11. **Anonymous**
November 12, 2022

Will Sawin,

What is the best known ineffective bound previously ? Is it Siegel $1/D^\epsilon$?
So Zhang's effective bound is even better than the best known ineffective bound ?
So this is a hugh improvement, if correct.

12. **Davide Castelvecchi**
November 12, 2022

My understanding was that indeed the statement was weaker than the one normally referred to as Landau-Siegel conjecture but that this was strong enough for many of its interesting implications, as Peter put it — and it was those implications that were the focus of my article anyway

13. **David Roberts**
November 12, 2022

@Davide

and Steven Strogatz just tweeted your article, and based on it he claimed Zhang has proved the L–S zeroes conjecture. A very small edit would make it clear what has and hasn't been proved, but you know the process and the magazine better than I do.

14. **Jim Eadon**
November 13, 2022

Hi, may an expert please comment about the implication, for the educated layman (MSc Physics), of this new proof for the generalised Riemann hypothesis?

15. **Davide Castelvecchi**
November 13, 2022

@David: I know, it's just difficult to do on a weekend 🙂

16. **David Roberts**
November 13, 2022

@Jim none, unfortunately, as the implications go the other way. But it might be seen as adding to our confidence that GRH is true.

@Davide that's definitely true!

17. **Conrad**
November 14, 2022

As of now, there are some significant issues with the paper that need to be addressed by the author (some seem to be just editing issues, but some seem to be substantive), so there will be some time until one can see if the author is able to address them and the paper to be accepted as valid; see the following
https://terrytao.wordpress.com/2021/09/15/the-hardy-littlewood-chowla-conjecture-in-the-presence-of-a-siegel-zero/comment-page-1/#comment-660236 and
https://mathoverflow.net/questions/434583/philosophy-behind-zhangs-2022-preprint-on-the-landau-siegel-zero?noredirect=1#comment1119426_434583

18. **Nicola Maiorino**
November 23, 2022

Peter (and others),

I just came across this fairly readable article in 'Science, The Wire' titled, "Riemann Hypothesis: What Yitang Zhang's Paper Means and Why You Should Care":

https://science.thewire.in/the-sciences/yitang-zhang-landau-siegel-zeroes-riemann-hypothesis/

The article presents a non-expert introduction to the Riemann Hypothesis, and trys to clear up precisely what it is that Zhang has proved (at least, tentatively so), and not proved.

Career Prospects for HEP-TH Students

November 14, 2022
Categories: Uncategorized

Guangyu Xu, a student just finishing his Ph.D. at the Centre for Particle Physics at Durham University, recently sent me a public letter he wrote, explaining the story of his job search, in hopes that it might be useful to others in a similar situation. As he acknowledges, his research record has been rather weak, so not surprising that his postdoc applications were not successful.

Back when I was writing Not Even Wrong, I did some detailed research into whatever information I could find about the HEP-TH job market, but I haven't tried to do this more recently. Erich Poppitz did some analysis of data from the Theoretical Particle Physics Jobs Rumor Mill (available here), but only up to 2017. Given the large investment of various government agencies in the support of Ph.D. students, I would think that there would be data on career outcomes gathered by such agencies, but haven't tried to look. Any pointers to this kind of data from anyone who has been looking into it would be appreciated.

Also of interest would be any up-to-date job search advice from those like Guangyu Xu who have been going through this recently.

Comments

1. **Alessandro Strumia**
   November 14, 2022

   Bibliometrics allow to infer most hires in hep worldwide. Fig. 6b of https://direct.mit.edu/qss/article/2/1/225/99129/Gender-issues-in-fundamental-physics-A shows the fraction of InSpire authors hired in hep up to ≈now as function of the date of their first paper. There are systematic issues, one needs to avoid misinterpreting, but the fraction is clearly declining.

2. **mimi**
   November 14, 2022

   I joined the tech industry after completing a physics PhD. My job search and later career experience differ quite a bit from Guangyu's.
   1. It is very easy for a hep-th PhD to become a strong software engineer or data scientist with a few months' preparation. These subjects are much easier than hep-th, so with some practice hep-th PhDs should be very attractive candidates. Even at high-paying FANG companies many engineers and machine learning researchers have physics PhDs.
   2. Directly applying to the companies leads to nowhere. In this industry one gets hired through recruiters or referrals by current employees. As a new grad one should try to get referrals from one's network. Since many physics PhDs already work at these companies, it should not be too hard.
   3. I find it unfortunate that Guangyu thought head hunters / recruiters useless. They come in different qualities and good recruiters can be very useful in navigating the application process.
   4. Most of these jobs are located in the US so American candidates will probably have an easier time. It's possible that being in the UK made Guangyu's job search difficult.

3. **anon**
   November 15, 2022

   I think getting hired in the tech industry as a physics PhD has become harder compared to a few years ago and especially at this moment with all the layoffs happening that route is difficult.

   I don't quite agree that software engineering is significantly easier in itself; with the larger number of jobs available (in normal times) one doesn't need to be all that great in it to get hired, but being a top software engineer is very hard and those people are very rare.

4. **BB**
   November 15, 2022

   The competition for professor level positions in research universities in technical areas is roughly as difficult as the competition to play professionally in first division in the Premier League or in the NBA (this could be off by an order of magnitude – in either direction – but I'd be surprised if it were more off than that). The main difference is that once obtained a professorship lasts for decades while a professional sports career lasts less than a decade (this makes the comparison difficult in certain ways), but the total net economic rewards are probably comparable (ignoring extreme cases).

   In healthy development of potential professional athletes there is a serious effort to prepare them for alternative careers that is lacking in most development of potential future professors.

   Those who make it suffer from various biases of perception. One is attributing success to hard work and innate talent and not to luck. Another is underestimating how much innate talent is needed to make it, and how many others simply lack that talent.

   The notion that any high energy physics PhD can just succeed in programming or finance seems to me a fallacy of a similar sort. I'm among those who made it as a professor (something I attribute to stubborness), and despite some trying I've never gotten good at programming nor managed to understand finance. I suspect that most of those for whom these alternatives seem easy are simply better suited for those alternatives rather than that these alternatives are inherently "easier" (this reeks of arrogance).

   The systemic failure is the lack of feedback until the end of the PhD program. Too few students are told that although they might finish the PhD program their prospects to continue are not good (one must be careful – I know several persons who *were* told their prospects were dim who persisted and had successful careers – but perhaps this apparently irrational persistence is precisely one of the qualities necessary to succeed as a professor).

   I don't think any of this is particular to high energy physics. There are always temporal variations in the employability of different fields, for diverse reasons, but the perspectives are difficult in any technical area because the competition is serious because the rewards are high.

   I doubt that the prestige of the doctoral institution is as important as the letter write believes. In the US this probably matters more than in Europe, but mostly what is observed is akin to observing that Real Madrid's youth development places more players in European leagues than does the Rayo Vallecano's – one signs all the future Messis at age 12, the other signs from among the rest. More bluntly – one expects more future professors to come out of Imperial than out of Durham because of who entered these institutions.

5. **cgh**

November 15, 2022

I left physics almost 22 years ago for a quant role. Today I am responsible for a team of 95 people, about 1/3 being PhD level quant, and another 1/3 being MSc level quant. We deploy trading strategies, maintain massively parallel code bases used for extensive simulation, have risk managers, and a decent amount of reporting and analytics to support the business side. In retrospect I am glad I left physics, but I did turn one set of challenges in for another.

1. There's more to the crossover opportunity than simply going and finding "alphas" at a fund. Educate on the space of opportunities.
2. Educate oneself on business in general. Often junior quants are hammers looking for nails. Further, they don't always progress much beyond quant factotums. This is because everything gets rendered as a quant problem as opposed to a business problem (that may have a quant solution). Understanding the business is the key to mobility. Note that when I started out I basically build pricing engines – writing down equations, solving them, and coding them. These were state secrets at the time. Eventually they became shared software, then commodified for sale, then free, and essentially useless today; so the ability to adapt becomes crucial.
3. Starting out try to find ways to contextualize ones' research so that it can be differentiated. Example: many CV today indicate "[…] using machine learning". When asked why the answer is usually along the lines of "If the grant proposal doesn't involve some type of …." Being able to show some conviction and use cases can help in a tight job market or simply just getting the job one wants.
4. Try to find more than one reason (money) to want to become a quant. Many junior quants wash out for one reason or another after a few years (how many CVs have "1 year 3 months" at investment firm) while others seem to simply not progress beyond a certain point. Make sure the grass is really greener; or, as I tell people, that you're pulled at least as much as you feel pushed into the profession.
5. Understand that it is an evolving space. There aren't really any textbooks or guides. There's dated materials out there and there's a bias for people that write to either not really know or not have spent enough time to really be in a position to tell people. It's amazing how many guides and books exist written by people with little or no actual experience. Some of the better physicists I know moved away from HFT when the first books were being published and into crypto before there were any books on crypto. Make diverse friends and be curious about trends to be able to see around corners.
6. Use all resources. Headhunters included. Show some grit in looking. About 10 or so years ago I started getting cold-called (eg on bloomberg) from job seekers writing a note, attaching a white-paper, and a link to some code, indicating that they worked on some problem they thought would helpful. When I started there were no email addresses (shops indicated they didn't solicit, rather they recruited; iow, they had direct contact with certain select universities and didn't need other avenues.) Things have changed and potential candidates have evolved. Don't be closed to any type of advocacy.

Best of luck to all.

6. **Peter Shor**
November 15, 2022

mimi:

I think you underestimate how hard learning to program is for some people. If you're a good programmer (which I expect the majority of physics graduate students are) finding a job in machine learning, finance, or similar areas shouldn't be that hard.

However, in my experience, people's programming abilities vary widely, and if you are on the lower end of the scale, a few month's preparation will not get you very far. I have met at least one top-notch mathematician who absolutely could not think algorithmically, and thus would have made an utterly hopeless programmer. These people will have a much harder time finding a job.

Luckily for Guangyu Xu, he was a competent programmer, although at the start of his job search he didn't have any evidence for this. Eventually, he was able to amass enough evidence to convince at least one potential employer of this, and he was able to find a job.

7. **Peter Woit**
November 15, 2022

BB,
I don't want to turn this into a discussion of the problems with getting permanent positions at research universities. That competition via postdocs/tenure-track jobs/tenure is pretty well understood by all involved. It's much less obvious what advice to give to the huge majority of people entering the field who won't succeed at this competition.

A couple comments though about the specific situation of hep-th:
1. The other field I have a lot of first-hand information about is pure mathematics. The job situation there is nowhere near as bad as hep-th.
2. The comparison to successful professional athletes is flawed in one crucial respect: they win games and provide joy to spectators. For several decades now basically all of those successful in the hep-th competition have failed miserably at the game of understanding nature, depressing everyone who watches closely.

8. **Ben**
November 15, 2022

I read Guangyu Xu's open letter. The first time I read it, it struck a chord with me and reminded me of my own job-hunting struggles after I got my Ph.D. I felt a kinship to him. But after reading his letter a few more times, I find it curious that he does not even mention his native China and its need for well-trained physicists like him.

9. **corvid**
November 15, 2022

I bailed out of doing high energy theory postdoc ~ 15 years ago because I had stopped believing the field was going anywhere and I didn't think I was willing to do what it takes to become a professor. I found the transition to being a hedge fund quant relatively easy, but I was a good candidate because I cared about and decently understood programming, happened to know a reasonable amount of probability theory, and at heart was someone who was good at and just wanted to be able to spend time solving problems in applied math. With a bit of preparation I was able to brush up on options math and passably fake knowing a few facts about finance, statistics and data analysis. Some observations:
1. as a physicist who could program, I could go to a website, download a useful library, and write some files of code that would compile and do some calculation for me that I could use in a paper. This skillset is far from knowing basic software engineering, where you write code that interacts with hundreds of thousands of lines of code that may change and any time and that was written by hundreds of different people, use source control tools, unit testing, have a build and release process, etc. This was a shock.
2. Even fifteen years ago, the time when physicists could just show up and get a job was over. Banks were starting to hire from quant finance masters programs (incidentally, I suspect one of the main functions of these programs is not so much to teach anything especially useful to employers, but to produce OPT visas for bright students from abroad). The big funds never focused exclusively on physicists, but have always hired people from CS, math, EE, stats, operations research etc. You still sometimes meet candidates who think because they have a string theory PhD from a fancy school they will have the red carpet rolled out for them. Not the case.
3. Another ex-physicist told me before I left academia that the hardest math I would ever need again was to take the moving average of some numbers. That has turned out to be far from the truth. On the other hand, I'm pretty sure Rentec isn't so astoundingly successful because they have the deepest bench of algebraic geometers.
4. By far the biggest change over the past fifteen years has been the rise of "data science" and machine learning. A lot of nonsensical marketing fluff goes along with this, but obviously there are real skills there. By and large physicists are cut off from this, at least at the cutting edge, though you do sometimes meet people who have used machine learning in a legitimate way for a real project. This seems to be true for theorists as well as people doing, say, high energy experiment or working on big data

projects in astronomy or whatever.
5. No doubt being from a well known, fancy school helps you get an interview.

10. **Andrew Bolt**
November 16, 2022

Having made the transition from academia to industry myself several years ago, I'd say the most useful skill was knowing how to learn. In interviews I'd tell them that I didn't know much about computer networks or satellites, but I was willing and able to learn. That ended up getting me into a pretty good career.

Now that I sit on the other side of the table, I find that recruiting people is often less about the specifics of what someone knows, but more about the attitude they bring to the team. I'd much rather hire someone smart who is willing to stick with tough problems than take someone who looks good on paper but won't actually deliver all that much.

11. **Grad student**
November 16, 2022

Ben:

I would be very reluctant to infer anything from the lack of references to China. There are many, many reasons why someone may not consider returning to their original country a desirable option.

12. **Brathmore**
November 16, 2022

I sympathize with grad students facing dim prospects for making a career out of their passion, but join the very, very large club. Most people don't get to pursue their passion as their career. If you got in a PhD in your passion, you had years more passion than most of us, and you are not haunted by the question of "what if I had…"

There are plenty of options besides software or finance for PhD physicists who aren't tenure track. Among them:

1. TEACHING high school, community college, adjunct professor, teaching at smaller liberal arts colleges. At a high school like Andover, you'd get to mentor some of the top students in the country.

2.LAW SCHOOL (in the US), potentially going into IP law. (Please first spend time with attorneys and see if you can imagine spending your days doing law. Average career satisfaction is low, but some are happy with their choice. I know a former Physics PhD making millions as a partner at a big firm, but the stars really aligned for him).

3. MEDICINE (in the US). You may need 1-2 years to take the bio and chem prerequisites (this can be done at an "extension school"). Then 4 years of med school, then 3 to 7 years of residency (where you're getting paid $50K – $70K per year). Then income ranging from $200-600K depending on the specialty. But make sure you like medicine first.

4. CONSULTING. If you have good people skills, you might be able to land a position at consulting firms like McKinsey or BCG, which can serve as a platform for other business jobs.

5. If you have trouble breaking into finance/software, get a master's in Statistics, Data Science, Financial Engineering, CS, etc. (or possibly do a post-doc in these subjects). For software, there are "coding camps" that take less than 1 year, and that have good placement rates. The intellectual content of these programs should be less demanding than a physics PhD, and the MS degree (or post-doc, or coding camp) should help get you into the field.

13. **CERN Particle Theorist**
November 17, 2022

Peter,

Sorry for the off-topic comment, but you, and your readers, would surely be interested to hear this.

I'm at CERN—I'd like to remain anonymous. CMS+Atlas picked up a 1350 GeV four-lepton excess, currently at three sigma. That's the rumor. There will likely be a press release this coming week.

14. **mimi**
November 17, 2022

Various commenters have said that software engineering is not necessarily easy to learn. My point was not that it was easy on an absolute scale but only relatively for hep-th PhD students. I've worked at some top tech companies and have met quite a few other physics/math PhDs there. All of them agree that software engineering / data science are much easier than what they had to study in grad school. I'm sure there are some physicists/mathematicians for whom programming is hard (as Peter Shor pointed out) but most can become quite good with a few months of intensive work.

15. **Peter Woit**
November 17, 2022

CPT,

Hadn't heard anything like that, and that rumor sounds implausible (a joint CMS-ATLAS press release????). Informed sources encouraged to confirm or deny….

16. **cgh**
November 17, 2022

I'll make one last comment in response to mimi and Peter S re programming that may be useful to physics/math people thinking about a transition:

It's been my experience that there's roughly two types of programmer that do what I do – the scrappy programmer and the programmer's programmer. The former tends to be a quant with good problem solving skills that can accurately generate prototype models that solve a problem. c++, cuda, python, matlab, apl applied to pdes, optimizatin, simulation, valuation, etc. What they tend not to be good with is how the latter excels. Coding standards, documentation, scalability, extensibility, compute costs. I've run into real problems early on in my career mediating this interaction. It's not uncommon to inherit tens, if not hundreds of thousands of lines of "spaghetti code", perhaps calling other code across a zoo of languages. Long ago I figured out how to solve this. I have a dedicated tech team that has front, middle, and back end programmers; and they own the code base. The back end are real low-level programers with PhD comp sci, hard physics, backgrounds. The front tends to be app dev. The middleware folks deal with the transmission of data. The pure quant teams prototype while the tech teams productionalize according to standards we've developed, inclusive of testing and documentation.

So one bit of advice that I have is an incoming quant that is a scrappy programmer, who I assume is good at problem solving in their IDE/language of choice, is to be amenable to learning about the broader ecosystems to allow for smoother handoff and assimilation of prototypes. I've seen places literally shut down or taken over because people ignored design, architecture, costs, and standards as growth overpowered considerations around continuity and sustainability. Some math/physics types can't be bothered with this stuff, or think it's beneath them, but the ones that do think about it tend to do better and certainly have an easier time having their ideas accepted amongst a team and, most gratifyingly, their solutions put into production.

17. **Engineer**
November 17, 2022

I recently retired from leading an organization with thousands of engineers, mathematicians, and scientists. I'd hired a lot of them. Over 35 years I learned to look to hire physicists (and mathematicians) for engineering roles. When we had to invent a solution to a novel problem, the physicists always started from first principles. To make a long story short, they helped the team find solutions our competitors never dreamed of. If you are a leader looking to amplify innovation in your team, bring some physicists in.

November 18, 2022

@CERN: by four-lepton excess, do you mean the possible discovery of a new lepton, in addition to the electron, tau and muon ?

19. **William Orrick**
November 18, 2022

@martibal Presumably the poster meant collision events with four leptons coming out and a reconstructed mass of 1350 GeV. Four leptons were one of the main signatures looked at in the original announcement of the Higgs boson discovery

20. **Peter Woit**
November 18, 2022

All,
At least one of the comments here about a supposed new LHC result was an impersonation by a troll. Most likely the whole thing is trolling. So, deleting any more comments about this that come in (unless you send me the draft of the paper, with the plots…).

21. **Matt Grayson**
November 18, 2022

FWIW, my experience (heading a global financial modeling group) agrees with @cgh in every particular. The different approaches to programming is a point that cannot get too much emphasis.

Math Job Rumors

November 17, 2022
Categories: Uncategorized

I noticed yesterday a website named Math Job Rumors that has been operating for a couple months. No idea what the story behind it is other than that it's clearly a descendant of Economics Job Market Rumors, which had some small participation by mathematicians, but is somewhat of a dumpster fire of misinformation, trolling, misogyny and various sorts of juvenile behavior. It looks like someone is trying to provide something similar aimed specifically at mathematicians, with some improvement over the EJMR environment.

One aspect of the site are threads devoted to rumors about tenure track and postdoc hiring in pure math, I don't know if there has been something like this before. In theoretical physics there's the venerable Theoretical Particle Physics Jobs Rumor Mill and the HEP Theory Postdoc Rumor Mill, but these are run in a very different way, with all information posted coming from one or more people who run the site, based on information sent to him/her/them.

The problem with the EJMR or Math Job Rumors model is that anonymity is needed for the whole thing to work, but once you start allowing people to post things anonymously, if you don't moderate what is posted, you'll quickly get overrun by idiots, trolls and other sorts of bad actors. Some kind of moderation is going on at the new site, but it's unclear who is doing it or on what basis.

After starting with the Official Peter Woit blog hate thread, I moved on to reading a few other threads. Lots of dumb stuff, lots of inside jokes, lots and lots of trolling. I confess though that in one case the trolling was clever enough to make me laugh out loud, but it's aimed at a really small audience. I did learn one piece of information that appears to be true, that prominent string theorist Shamit Kachru has gone on leave from his position at Stanford to work as a consultant in the finance industry.

In summary, for those mathematicians who read this blog and feel that they are not wasting enough time on mostly dumb internet stuff, you might want to take a look…

Comments

1. **David Appell**
   November 17, 2022

   Congratulations on having a hate thread. You have arrived.

2. **Jackson Jules**
   November 17, 2022

   I checked out your hate thread out of morbid curiosity, and overall it seeemed…weirdly supportive?

   Like don't get me wrong: there are a couple people throwing unwarranted potshots at you. But overall, the vibe was that people are quietly thankful for your willingness to talk about thorny topics like the ABC conjecture and string theory. Which surprised me somehow.

3. **lowly graduate student**
   November 18, 2022

   As grad student on the job market, as much as I find certain posts there to have kind of a toxic vibe, the discussion there does serve a purpose. How do mathematicians evaluate/rank one another? What/who is considered good/not good and why? These are the kind of conversations that people don't make face to face (at least when you're a graduate student) due to politeness, but somehow you really need to get a sense of this going forward in your career. And when there is a demand and a vacuum /lack of discussions in our everyday life, its gets filled by anonymous threads like mathjobrumors. I hope after much effort in sifting through the trolling, what I find will at least be somewhat resemblant of the truth – which is what people are too polite to say to my face.

4. **Peter Woit**
   November 18, 2022

   First a general comment: looking more at the math job rumors site and especially at recent threads, the extreme level of unfunny trolling and low quality of most of the supposedly serious comments doesn't bode well. Whoever is responsible for this needs to figure out a better solution to their moderation problem than whatever they're doing.

   lowly graduate student,
   You need to be very careful about taking seriously anything you read there, unless it's something factual you can check elsewhere. Besides the large amount of intentionally incorrect material (trolling trying to be funny and fool people), there's also a lot of just dumb stuff coming from people who don't know much about what they're talking about.

   This is the big problem with anonymity: if people don't put their name and reputation behind their words, this encourages all sorts of bad behavior. On the other hand, on certain topics (from hot button political issues to negative evaluations of certain fields or people), no one who sensibly wants to avoid making enemies is going to publicly say exactly what they think.

   Probably the best advice at the moment about an anonymous site like math job rumors is to (putting aside the trolling if you can recognize that) take whatever you read there about as seriously as you would take something another graduate student tells you when they're drunk late night at a bar. Actually, a lot of the comments on that site probably are posted by your fellow graduate students, drunk late at night, even if not actually at a bar…

5. **anon**
   November 18, 2022

   It almost looks like many people posting there want it to fail. The ratio of obvious troll posts to even semi-serious ones is probably five to one if not more. Looking at the earlier threads, it doesn't look like it was that bad in the beginning.

6. **Probabilist_omni**
   November 19, 2022

   This really got a laugh out of me for some reason:

   *"Starting fall of 2021, I will be taking an extended sabbatical/leave. Much of my effort during this period will be spent developing my skills in rapidly developing areas

like machine learning, with a view towards the science emerging from analysis of large datasets" . Nothing wrong with that of course and you never stop learning new stuff that you might find interesting etc etc, but still hilarious for "some" reason. I think every student that might still consider at this point going into string theory should be directed to that page; just food for thought.

*Section of Kachru's profile in the Research and Scholarship section

7. **Peter Woit**
November 19, 2022

Probabilist_omni,

Somehow his fall 2021 goal of working on "the science emerging from analysis of large datasets" turned into a 2022-23 job "as a consultant in quantitative research for a company which is active in a number of global financial markets."

8. **I**
November 24, 2022

"In summary, for those mathematicians who read this blog and feel that they are not wasting enough time on mostly dumb internet stuff, you might want to take a look…"

Oh no, Peter! Why did you push your readership into the quicksand? Some of them will be stuck in that pit for life.

Jokes aside, there's clearly some demand for something like this. Even if it degenerates into a cesspool of trolls and string theorists, well, the people on there are adults. If they're using it and having fun, isn't that a good thing? Plus, maybe they'll be more inclined to troll people there than on a blog's comments.

If you view the site as providing rumours worth checking out, then it does seem like you could still get valuable information from it. Though the signal to noise ratio would be quite low, maybe with good enough search tools that wouldn't be a problem.

9. **Peter Woit**
November 24, 2022

I,
They seem to be struggling with trying to find a workable moderation system that can deal with not just the kind of grotesque stuff that afflicts EJMR, but also a flood of garden-variety stupidity. I'm skeptical that there's any way to run a completely anonymous site that people with something well-informed and intelligent to say will want to use unless one can figure out how to keep the idiots under control. We'll see…

10. **Daniel Litt**
November 30, 2022

Ugh, really horrible stuff. Ruined my day, honestly.

The Mystery of Spin

November 22, 2022
Categories: Quantum Mechanics

Scientific American has a new article today about the supposedly mysterious fact that electrons have "spin" even though they aren't classical spinning material objects. The article doesn't link to it, but it appears that it is discussing this paper by Charles Sebens. There are some big mysteries here (why is Scientific American publishing nonsense like this? why does Sean Carroll say "Sebens is very much on the right track"?, why did a journal publish this?????).

These mysteries are deep, hard to understand, and not worth the effort, but the actual story is worth understanding. Despite what Sebens and Carroll claim, it has nothing to do with quantum field theory. The spin phenomenon is already there in the single particle theory, with the free QFT just providing a consistent multi-particle theory. In addition, while relativity and four-dimensional space-time geometry introduce new aspects to the spin phenomenon, it's already there in the non-relativistic theory with its three-dimensional spatial geometry.

When one talks about "spin" in physics, it's a special case of the general story of angular momentum. Angular momentum is by definition the "infinitesimal generator" of the action of spatial rotations on the theory, both classically and quantum mechanically. Classically, the function $q_1p_2-q_2p_1$ is the component L_3 of the angular momentum in the 3-direction because it generates the action of rotations about the 3-axis on the theory in the sense that
$$\{q_1p_2-q_2p_1, F(\mathbf q,\mathbf p)\}=\frac{d}{d\theta}_{|\theta=0}(g(\theta)\cdot F(\mathbf q,\mathbf p))$$
for any function F of the phase space coordinates. Here $\{\cdot,\cdot\}$ is the Poisson bracket and $g(\theta)\cdot$ is the induced action on functions from the action of a rotation $g(\theta)$ by an angle θ about the 3-axis. In a bit more detail
$$g(\theta)\cdot F(\mathbf q,\mathbf p)=F(g^{-1}(\theta)\mathbf q, g^{-1}(\theta)\mathbf p)$$
(the inverses are there to make the action work correctly under composition of not necessarily commutative transformations) and
$$g(\theta)=\begin{pmatrix}\cos\theta&-\sin\theta&0\\ \sin\theta &\cos\theta &0\\ 0&0&1\end{pmatrix}$$

In quantum mechanics you get much same story, changing functions of position and momentum coordinates to operators, and Poisson bracket to commutator. There are confusing factors of i to keep track of since you get unitary transformations by exponentiating skew-adjoint operators, but the convention for observables is to use self-adjoint operators (which have real eigenvalues). The function L_3 becomes the self-adjoint operator (using units where $\hbar=1$)
$$\widehat L_3=Q_1P_2-Q_2P_1$$
which infinitesimally generates not only the rotation action on other operators, but also on states. In the Schrödinger representation this means that the action on wave-functions is that induced from an infinitesimal rotation of the space coordinates:
$$-i\widehat L_3\psi(\mathbf q)=\frac{d}{d\theta}_{|\theta=0}\psi(g^{-1}(\theta)\mathbf q)$$

The above is about the classical or quantum theory of a scalar particle, but one might also want to describe objects with a 3d-vector or tensor degree of freedom. For a vector degree of freedom, in quantum mechanics one could take 3-component wave functions $\vec{\psi}$ which would transform under rotations as
$$\vec{\psi}(\mathbf q)\rightarrow g(\theta)\vec{\psi}(g^{-1}(\theta)\mathbf q)$$
Since $g(\theta)=e^{\theta X_3}$ where
$$X_3=\begin{pmatrix}0&-1&0\\ 1&0&0\\0&0&0\end{pmatrix}$$
when one computes the infinitesimal action of rotations on wave-functions one gets $\widehat L_3 + iX_3$ instead of $\widehat L_3$. $S_3=iX_3$ is called the "spin angular momentum" and the sum is the total angular momentum $J_3=L_3 + S_3$. S_3 has eigenvalues $-1,0,1$ so one says that that one has "spin 1".

There's no mystery here about what the spin angular momentum S_3 is: all one has done is used the proper definition of the angular momentum as infinitesimal generator of rotations and taken into account the fact that in this case rotations also act on the vector values, not just on space. One can easily generalize this to tensor-valued wave-functions by using the matrices for rotations on them, getting higher integral values of the spin.

Where there's a bit more of a mystery is for half-integral values of the spin, in particular spin $\frac{1}{2}$, where the wave-function takes values in $\mathbf C^2$, transforming under rotations as a spinor. Things work exactly the same as above, except now one finds that one has to think of 3d-geometry in a new way, involving not just vectors and tensors, but also spinors. The group of rotations in this new spinor geometry is $Spin(3)=SU(2)$, a non-trivial double cover of the usual $SO(3)$ rotation group.

For details of this, see my book, and for some ideas about the four-dimensional significance of spinor geometry for fundamental physics, see here.

Update: I realized that I blogged about much this same topic a couple years ago, with more detail, see here. One thing I didn't write down explicitly either there or here, is the definition of spin in terms of the action of rotations on the theory. It's very simple: angular momentum is the infinitesimal generator of the action of rotations on the wave-function, spin angular momentum is the part coming from the point-wise action on the values of the wave-function (orbital angular momentum is the part coming from rotating the argument). Using a formula from my older posting, for a rotation about the z-axis, the total angular momentum operator $\widehat J_z$ is by definition
$$\frac{d}{d\theta}\ket{\psi(\theta)}=-i\widehat J_z \ket{\psi(\theta)}$$
The spin operator $\widehat S_z$ is what you get for $\widehat J_z$ when you act just on the wave-function values. For a spin n/2 state particle, the wave-function will take values in $\mathbf C^{n+1}$. For the spin 1/2 case the action of rotations is by 2 x 2 unitary matrices of determinant one (the spinor representation). For a rotation by an angle θ about the z-axis, this is
$$e^{-i\theta\frac{\sigma_3}{2}}$$
so the spin operator is
$$\widehat S_3=\frac{1}{2}\sigma_3$$

   One more big mystery that you forgot to mention is why Scientific American writes about this three years after its publication (and four and a half years after it first appeared on the arXiv)?

2. **Shantanu**
November 23, 2022

   One more mystery is that this is published in physics section of arxiv and not hep-th etc.

3. **Peter Woit**
November 23, 2022

   Shantanu,

That’s not really a mystery at all…

4. **Pascal**
November 23, 2022

Peter, can you elaborate on your objections to Seben’s paper? The bulk of the paper seems to be a history of the understanding of spin, from classical ideas to modern ideas based on QFT, and on the obstacles that had to be overcome to get there. Seben also uses this opportunity to advertise his own interpretation. He carefully states that this is just an *interpretation* (perhaps in the sense of “interpretation of quantum mechanics”), not a new theory leading to any new prediction.
Do you think his history is wrong? Or correct, but this material is so well known that writing a historical paper about this is pointless? Did he get the physics wrong? Are you against the discussion of interpretations in general? In summary, to use your own punctuation style: what is wrong with this paper?????

5. **Doug McDonald**
November 23, 2022

Something that came to mind. Mayybe this is a nonsequitor, but still …

Peter: you’re a mathematician. You are giving a mathematician’s argument. Its based on the Poincare group, which includes spinors. It works. It agrees with the world. But still, it just suggests from the existance of spinors that there might be spin 1/2 particles, or more generally, particles of half-integer spin.

But ….

by the same argument there could be … and is … a “Super-Poincare” group that promotes spinors to generators of a sort of “Supersymmetry” which we should have a look at for particle physics. We HAVE had a look or two or ten thousand … and it doesn’t work.

I see that as a generic problem of going from math to physics. Or to be a bit kinder, of going from math to lots of funding for theoretical physics that does not work.

6. **Peter Woit**
November 23, 2022

Pascal,

I’m not commenting on the history or “interpretation” in the Sebens paper. The “paradox” Sebens and Becker (and others before them) go on about is based on the idea that “angular momentum” is the usual $\mathbf q \times \mathbf p$ formula from high school physics, a measure of how an extended object is rotating about a point. You can’t understand spin this way, no matter how hard you try to give strained interpretations to terms in the Dirac free field.

The point I was trying to explain in the posting is that you need to start not from high school physics, but from the fundamental fact that angular momentum is the generator of the action of rotations on your theory. Becker and Sebens seem either unaware of or uninterested in this basic fact. From this more fundamental definition, you can not just assume the formula $\mathbf q \times \mathbf p$ you learned in high school, but derive it (by looking at how the theory behaves under infinitesimal rotations of space).

From this point of view, whenever you have fields, wavefunctions or whatever that are not scalars under rotations (a 3d-vector field the simplest example), when you compute the formula for angular momentum, you will get not just a $\mathbf q \times \mathbf p$ orbital angular momentum term, but another term. This is the “spin” angular momentum. It has nothing to do with stuff moving in space.

Another point I was trying to make is that this has nothing to do with the complexities of 4-d space-time, spinors, the Dirac equation, etc. This is a purely 3d story, just look at a vector-valued field in 3d (any dynamics you want, the definition of angular momentum doesn’t depend on dynamics).

7. **Peter Woit**
November 23, 2022

Doug McDonald,
First of all, my Ph.D. is in physics, not math…
Secondly, as I tried to explain in my previous comment, this has nothing to with 4d symmetries (Poincare), nothing to do with spinors, certainly nothing to do with SUSY. The mathematics is very basic: rotations of physical 3d space (applied to whatever kind of physics you are doing, Hamiltonian, Lagrangian, classical, quantum, field theory or not).

I am only bringing mathematics into this with the claim that to understand what angular momentum is, to derive the formula for it, you have to look at what 3d rotations do to your theory. Not everyone needs to be willing to use this level of math, but if they’re not willing to do so, they shouldn’t be making complicated arguments about supposed paradoxes with angular momentum.

8. **anon**
November 23, 2022

The field (2nd quantization) gives mass and affects electric charge (vacuum polarization). So why can’t it have an effect on spin, too?

9. **Peter Woit**
November 23, 2022

anon,
The fundamental definition of angular momentum and spin is the same in QFT as in any other part of physics (generator of infinitesimal rotations) and has nothing to do with the dynamics.

I realized that I actually worked this out very explicitly for the simple cases of spin zero and spin 1/2 in non-relativistic QFT in my book. See sections 38.3.2 and 38.3.3 of https://www.math.columbia.edu/~woit/QMbook/qmbook-latest.pdf

10. **Peter Woit**
November 23, 2022

Another comment: here and in the book I’ve emphasized phase space (Hamiltonian) methods. Same thing works in the Lagrangian formalism, where Noether’s theorem first tells you how to define the angular momentum (including the spin term) from the infinitesimal action of rotations on the fields, then tells you that if the Lagrangian is rotation invariant, the angular momentum will be conserved.

11. **George**
November 23, 2022

The single particle theory is not really a good theory, as it does not give energies that are bounded from below for free particles. Of course, you can have a wavefunction in the spinor representation of rotations and you will get spin quantum numbers indeed. But you do not get the energy spectrum correctly without Dirac sea voodoo. The first time that spin is explained within a logically acceptable framework is in QFT, I would argue.

12. **akhmeteli**
November 23, 2022

Peter Woit,

Thank you for mentioning the article in the Scientific American.

You wrote: "I'm not commenting on the history or "interpretation" in the Sebens paper." However, Sebens' work is specifically about interpretation. He wrote: "What follows is a project of interpretation, not modification."

Sebens' work may be good or bad, but I would appreciate your arguments. What you wrote so far sounds to me like "Sebens cannot discuss interpretation of spin unless he uses the same mathematical formalism as I do." My understanding is your formalism has the same predictions as the traditional one(s), so I am not sure one must exclusively use your formalism to triage interpretations.

If I misunderstood your arguments, I apologize.

13. **Peter Woit**
November 23, 2022

George,
The problem of negative energies in relativistic quantum mechanics has nothing to do with spin (you have the same problem in the spin-less theory).

Non-relativistically (or in the non-relativistic limit of a relativistic theory), there's a perfectly well-defined quantum theory of a single spin 1/2 degree of freedom. Sometimes called the Pauli-Schrodinger theory, see chapter 34 of the book I linked to. In this theory you can easily compute the angular momentum and see that it has separate orbital and spin angular momentum terms, and see the simple origin of the spin angular momentum term.

14. **Peter Woit**
November 23, 2022

akmeteli,
My formalism is exactly the standard one in the textbooks: the angular momentum observable of a theory is the infinitesimal generator of the action of rotations. The most common version of this is the Lagrangian version, and if you compute this by the textbook Noether method in a theory where the values of the fields transform under rotations that gives you the "spin" part of the angular momentum.

Sebens is doing some rather obscure calculations in a relativistic theory and seems to be claiming that these justify "interpreting" spin in terms of some kind of motion in space. This doesn't explain anything. It's the exact opposite of an explanation, an attempt to mystify and confuse. In a rough analogy it's like saying I don't like potential energy, all energy should be kinetic energy, so I need to come up with a complicated way to "interpret" potential energy as kinetic energy.

15. **Blake Stacey**
November 24, 2022

The paper's conclusion, as the last line of the abstract says, is that "The electron's gyromagnetic ratio is twice the expected value because its charge rotates twice as fast as its mass." Personally, I'd take that as *another objection to the idea that you can think of the electron as "spinning."* If you work very hard to dodge all the objections that physicists raised decades ago, the best case is that you still run into the problem that the charge rotates twice as fast as the mass, which is not how a classical charged body can behave. Your picture of the electron as a classically spinning object is unphysical in a new way.

I feel like *Scientific American* should have mentioned that Sebens and Carroll were coauthors. It's not a major thing (that was several years ago), but still. I'd expect that to be included if someone quoted me about work an erstwhile colleague did.

16. **Alex**
November 25, 2022

I think the reason some people see quantum spin as mysterious is that, even when you correctly define angular momentum in both classical and quantum as the infinitesimal generator of rotations, in the quantum case you get a sum of the usual quantized so-called orbital angular momentum (which has a clear classical counterpart) with the so-called spin angular momentum, which lives in an "internal" finite-dimensional Hilbert space, tensored with the usual L^2(R^3), and which, naively at first sight, doesn't seem to have a classical analogue.

But you can actually give a more general Poisson structure on the classical phase space so that you indeed get a new internal space and generators that correspond to a sort of classical spin. The reason for calling this an analogue of the quantum spin is that it's related to it by a deformation quantization, so it's indeed its true classical analogue in the sense of quantization theory. For some details see page 31 here: https://arxiv.org/abs/quant-ph/0506082

17. **4gravitons**
November 25, 2022

"but one might also want to describe objects with a 3d-vector or tensor degree of freedom"

I would have guessed that this is the crux of the discussion, though. Why would one want to do this (independent of our having observed objects that do indeed have this property)? I would think that when people think of spin as mysterious, they're asking a question of this form (and as Doug McDonald points out, the principle can't be something like "if you can describe such objects they exist", if you don't expect SUSY to exist).

(Can one say that of the original classical setup too? Kind of? Angular momentum of extended objects is at least derivable from (to speak loosely) linear momentum of point particles. I think it's a bit silly for a philosopher to decide arbitrarily that motion of point particles is the most fundamental thing in the universe, but eh, I'm skeptical of metaphysics in general, most people aren't.)

I'd also guess that, to whatever extent Carroll and/or Sebens think the problem is solved in QFT, it's not because of the mathematics of QFT, but rather because QFT motivates us to think of point particles as not ontologically basic, and thus makes it more acceptable to think of objects as just carrying whatever degrees of freedom we find convenient. Obviously you can do this in QM as well, but you're less motivated to, in the same way that you're less motivated to develop classical field theory before Maxwell develops E&M.

From what you describe of Sebens' "explanation", it indeed sounds like it's addressing this in a stupid way, regardless, especially if it's invoking charge (does he think sterile neutrinos can't exist?).

18. **Low Math, Meekly Interacting**
November 25, 2022

99% of this is completely over my head, but I do wonder: Could there be any pedagogical value in abolishing "spin" from the quantum lexicon? I got enough of a physics education to know where the average person gets led astray, and it's not entirely our fault. "Classically non-describable two-valuedness" is rather a mouthful, but is there any alternative to "spin"? Could the world be rid of the notion that "spin angular momentum is like spin, only it's not, and nothing's spinning"? Seems a good place to start would be to swear off entirely the high-school/first-year physics picture asking us to "imagine a little bar magnet spinning".

Seems the only proper way to popularize QM is to stop putting paradoxical ideas in our heads to begin with, such that we need to spend so much time and energy later disabusing ourselves of misunderstandings rooted in bad classical analogies. Obviously, even professional physicists and philosophers continue to fall into the very same traps the pioneers of QM did, so it seems the first priority is to drill into everyone's brains that there are no classical analogs worth using. Perhaps then SciAm, etc. would have nothing of general interest to write about.

19. **Low Math, Meekly Interacting**
November 25, 2022

I think it's not too hard for a high-school student to absorb the following (assuming I'm not screwing something up myself):

Lorentz invariance and Noether's Theorem represent two of the deepest and, to the best of our knowledge, inviolate truths of the natural world. It follows directly from the fact we occupy four space-time dimensions that particles like the electron must have four intrinsic degrees of freedom to allow for conservation of energy and momentum. These are fundamentally quantum degrees of freedom with no classical analogs, but bear some resemblance to classical, extended objects in the fact that these degrees of freedom have quantum units of charge and angular momentum.

I.e, if you can handle thinking about charge as an "intrinsic" property of an electron, there's no justifiable reason to think of "spin" any differently, except that our brains are evolved to conceive of such properties in classical terms. Nevertheless, they allow for no better explanation, and indeed none are necessary.

Start teaching it that way early and ditch "spin"! Many a wayward and frustrated brain would be grateful.

20. **Peter Woit**
November 25, 2022

Alex,
It's true that there's a good way to think of the classical limit of "spin", as adding a new factor to phase space of a sphere in $\mathbf R^3$. This idea is actually very general: if the values of your field transform under a group G as an irreducible representation of G, take as new factor in phase space the corresponding co-adjoint orbit in the dual of the Lie algebra of G. If you want, you can then use a phase-space path integral, and think of your classical spinning particle as moving along a trajectory in the usual phase space times the sphere (or co-adjoint orbit in general).

The problem with this is that a curved, finite volume phase space like the sphere behaves rather differently than the conventional phase space. Additionally, it's only in the limit of infinite spin that you recover a classical limit. Things like spin 1/2 and spin 1 are at the opposite, truly quantum limit.

21. **Peter Woit**
November 25, 2022

LMMI,
The word "spin" is part of the problem, but just part of the more general problem of trying to explain what a quantum particle is, starting from a classical particle. This just can't work, it inherently makes quantum theory seem like incoherent, incomprehensible voodoo.

To understand angular momentum you just need to think about 3d space and 3d rotations of this space, invoking four dimensions and special relativity only makes this harder to understand. There is a difference between spin and purely internal degrees of freedom like charge. In both cases in quantum theory you are using the fact that the values of your wave-function (or field) transform under a group acting point-wise on the values. In the internal symmetry case (charge), your group doesn't act on space. But in the spin case, the group is the rotation group, acting at the same time moving around points in space. You can separately see the action on values and the action on spatial points, and this separation is the separation between spin angular momentum and orbital angular momentum.

22. **Andrew Thomas**
November 25, 2022

Could the world be rid of the notion that "spin angular momentum is like spin, only it's not, and nothing's spinning"? Seems a good place to start would be to swear off entirely the high-school/first-year physics picture asking us to "imagine a little bar magnet spinning".
Well, I would suggest exactly the opposite. I think we need to get away from this idea that a particle's spin is "nothing like actual spin and nothing's spinning". The particle has angular momentum: if you shine a beam of electrons with each having the same spin value onto a object (like a brick) then that object will start to spin – for real. I don't think this is generally appreciated. That sounds a lot like real spin to me.

Here's Frank Wilczek (Nobel prize particle physics) on the subject from his book Fundamentals: "If you've ever played with a gyroscope, you'll have a head start on understanding the spin of elementary particles. The basic idea of spin is that elementary particles are ideal, frictionless gyroscopes which never run down. Spin changed my life. I always liked math and puzzles, and as a child I loved to play with tops". Argue with Frank at your peril.

Nobody is suggesting that quantum spin is the same as classical spin, but it is much closer in nature than is generally realised, certainly closer than is usually suggested in popular science books.

23. **Peter Woit**
November 25, 2022

Andrew Thomas,
Yes, spin is angular momentum, and if you want to play with metaphorical descriptions of it as Wilczek does that's fine. But you should keep reading in the text (page 75-6) that you quote. In the rest of the paragraph he goes on to explain that the way "spin changed my life" for Wilczek is that he took Peter Freund's advanced course on "the application of mathematical symmetry" (e.g. Lie groups and representations) to physics. In this course
"Professor Freund showed us how some extremely beautiful mathematics, building on the idea of symmetry, leads directly to concrete predictions about observable physical behavior… To me, the most impressive example of this connection was – and still is – the quantum theory of angular momentum, which he showed us… To experience the deep harmony between two different universes – the universe of beautiful ideas and the universe of physical behavior – was for me a kind of spiritual awakening. It became my vocation. I haven't been disappointed."

To me what Wilczek is saying is that if you want to talk about physics at the level of vague metaphor, fine to think of spin as something spinning. If you want to understand what spin actually is, you need to understand it as a contribution to angular momentum, where angular momentum is defined mathematically in terms of rotational symmetry.

24. **Lars**
November 27, 2022

The spin of elementary particles like electrons is one thing.

But the spin of composite particles would seem to be a different beast.

For example, the experimental evidence indicates that the spin of the proton IS at least partly the result of "motion in space", depending on the "orbital" angular momentum of the component quarks.

See
"What we know and what we don't know about the proton spin after 30 years" (Y. Zhao, 2020, Brookhaven National Laboratory)

"Results from Jlab 6 GeV experiments and HERMES data suggest a substantial quark orbital contribution"

25. **Peter Woit**
November 27, 2022

Lars,
When you have a composite bound state like the proton which does not correspond to an elementary field, you can assign it a spin, by looking at the lowest energy state and seeing how it behaves under rotations. For a proton, you find it transforms as the spinor representation, so has spin 1/2. The relation between the spin of the proton and the spin of its constituents is complicated and as far as I know not completely understood. The problem is that the proton is a strongly coupled system of both quarks and gluons, and we lack good calculational methods for such systems. For a composite system of free particles you can understand the total angular momentum in terms of the spins of the components and orbital angular momentum, but a strongly coupled system is something different.

I think what is going on with some people is that they don't like intrinsic spin of an elementary particle because it doesn't correspond to something they can visualize in a model of reality which consists of scalar elementary particles moving in space. They want to explain the spin 1/2 of an electron in terms of this model of reality. But when you do this, you run into an intractable problem: if you have spinless particles and only orbital angular momentum, all states will have integral total angular momentum, no possible way to get 1/2 integral values.

If you ignore the half-integrality problem and try and build a model of electrons as bound spinless particles anyway, you run into the problem that electrons exhibit pointlike behave on scales much smaller than their Compton radius. Then when you try to explain spin 1/2 in terms of orbital angular momentum you get into problems with your hoped-for model, since it would imply faster than the speed of light motion of the component particles.

26. **Peter Orland**
November 27, 2022

Hi Peter,

Feel free to delete this, if it seems off-topic, but spin (the physical phenomenon) can be visualized as mechanical revolution. Wess-Zumino actions for spin are well-known (even for Dirac particles, which I wrote a paper about ages ago. There is a close relation with twistors).

Now these Wess-Zumino actions are equivalent to (Fock-Tamm) charge-monopole systems, even if one does not accept the charge and monopole as existing in physical space. This picture is actually useful for understanding Skyrmion spin.

Of course, this way of understanding spin has nothing to do with the topic of the Scientific American article.

27. **Peter Woit**
November 27, 2022

Peter,
That's related to what Alex above brought up. If you enlarge phase space by adding a factor of a co-adjoint orbit (for 3d rotations, the orbit is a sphere in 3d space) and quantize this, you get wave-functions with values in a non-trvial representation of the rotation group. The phase-space path integral for the sphere factor will be given by integrating over paths on the sphere with action a Wess-Zumino term, one you could think of as the phase factor picked up from the vector potential of a monopole at the center of the sphere. But, the monopole is unphysical, as is the sphere you're moving on.

This whole story leads to really beautiful mathematics, it's the simplest case of the Borel-Weil-Bott geometric constructions of representations of compact Lie groups. I'm a huge fan of this way of thinking, but I don't think those who want to get more sophisticated mathematics out of physics really want to go down this path…

28. **Davide Castelvecchi**
November 28, 2022

Peter,

This is a very interesting discussion! You point out that there is a well-understood machinery for understanding spin, based on group representations. But the very fact that there is Dirac's correspondence between Poisson brackets and commutators and that all of this works is at least a bit mysterious, no? (Also, I thought the quantization procedure wasn't even uniquely defined?)

Two: the thing that's measurable, spin along a certain axis, is often described as telling us that the spin is "up" or "down" — even though it doesn't tell us that the angular momentum points in a certain direction, only that it has a certain angle with the axis; it ostensibly measures a component of a vector, but that vector is not even well-defined (because you can't measure all of its components).

Three: the ontology of a particle's spin. If are to believe that the wavefunction has physical meaning, then each electron in a (unpolarized) beam has a well-defined spin state — in the sense that at any given time and place there exists a direction along which it will have 100% probability of giving a spin "up". But there doesn't seem to be a way to do anything with this because we can only ever deal with mixed states and the properties of the ensemble. (Ok I guess this is a mystery about the quantum measurement problem, not specifically spin.)

Four: The Hilbert space where the spin state lives is some abstract three-dimensional sphere outside of the physical world. And if I understand correctly, when you associate an operator L_z to measuring spin in a certain direction, the correspondence between the operators L_x and L_y and the other directions of space is partly arbitrary.

All of this sounds pretty mysterious to me!

29. **Peter Woit**
November 28, 2022

Davide,
I'm not claiming there are no mysteries here, just that trying to understand what spin is in terms of stuff moving in space is a huge mistake. Also, that trying to do this in the 4d relativistic (Dirac equation) context is another sort of mistake, since the situation there is quite tricky, and the phenomenon you are trying to understand is already there in a much simpler context in the 3d non-relativistic theory. Maybe you can shed some light on the mystery of why this article was published by SciAm…

I just took a look at various sources to see how they explain "spin". Found everything from the completely dreadful (Wikipedia) to some places that get things right. As you might expect, one of the latter is Weinberg, who in his QM book (chapter 4) starts off with "we should think of the existence of both spin and orbital momentum as consequences of a symmetry principle" and an explanation of how to get from rotations to angular momentum. He also correctly states "there is nothing about spin that requires relativity to be taken into account".

About your four mysteries, the first three involve the basic mystery of the relation of classical and quantum mechanics, including the mysteries of measurement theory. The spin 1/2 system doesn't explain any of these mysteries, but it does provide the simplest examples of non-classical behavior so a good place to start in thinking about this basic mystery.

For the fourth, it is an observed fact of nature that fundamental particles are best described by a $\mathbf C^2$ valued wave-function, transforming as a spinor under rotations. This is mysterious in the sense that it is highly non-classical and not in accord with our classical intuitions at all. It's also telling you that fundamental physics is described not in terms of usual geometry, but in terms of spinor geometry. To me that's a big hint about what to look for in a more fundamental theory. It should most naturally be formulated in terms of spinors, with a compelling argument for twistors that in twistor theory a point in space time is tautologically a spinor $\mathbf C^2$. Yes, this is an argument from mathematical beauty.

What's not mysterious here is how you get from "particles are described by spinor-valued wavefunctions" to the description of what spin is. This is nothing other than the simple fact about 2 by 2 matrices that you rotate spinors by exponentiating Pauli matrices.

Was thinking of writing a part II of this posting that explains this more, maybe later today…

30. **Arnold Neumaier**
November 28, 2022

Peter,

"transforming as a spinor under rotations. This is mysterious in the sense that it is highly non-classical and not in accord with our classical intuitions at all."

In fact, everything about spin 1/2 was already discussed by Stokes in 1852, long before quantum mechanics was born. He had no problems with intuition, though it was different from the usual one!
See my article "A Classical View of the Qubit" at
https://www.physicsforums.com/insights/a-classical-view-of-the-qubit/

31. **Levy-Leblond**
November 28, 2022

Levy-Leblond explained how spin can arise without relativity more than 50 years ago:

https://link.springer.com/article/10.1007/BF01646020

32. **Peter Woit**
November 28, 2022

Levy-Leblond,
This goes back much further than that, to more than 95 years ago, and Pauli's 1927 paper
https://link.springer.com/article/10.1007/BF01397326 (which Levy-Leblond refers to).

What Levy-Leblond is working out is going from the usual story about elementary particles being irreducible representations of the Poincare group given by solutions of relativistic wave-equations to instead the non-relativistic case of the Galilean group and its representations. But this is still more complicated than you need, the Galilean boosts have nothing to do with spin. All you need is spatial translations and rotations (the Euclidean group in 3d). Quantized these give momentum and angular momentum operators. If you look at one component wave functions you just get orbital angular momentum, if you take multiple component wave-functions, with rotations acting non-trivially on the values at a point, the angular momentum acquires the additional spin angular momentum term.

Again, I worked out the details of all of this explicitly in chapter 34 of my book, but there's nothing there that Pauli (with some help from Weyl) wouldn't have already understood in the late 1920s.

33. **martibal**
November 29, 2022

Is there any conceptual explanation of why the multicomponent wave function transforms under the double cover of the rotation group, and not the rotation group itself ?
(I know this is a fact of nature, is there any understanding of why it should be so ?)

34. **Arnold Neumaier**
November 29, 2022

martibal,

not every multicomponent wave function transforms nontrivially under the double cover of the rotation group, , and not the rotation group itself; only (and precisely) those for fermions do. This is explained by the spin-statistics theorem from relativistic quntum field theory.

35. **Peter Woit**
November 29, 2022

Martibal,
To me the conceptual explanation is just that the geometry of physics is inherently spinorial, not surprising since spinor geometry is more fundamental than the usual

geometry in terms of vectors. In arbitrary dimensions you have a non-trivial double-cover of the rotation group and spinor representations. The spinor representations are more fundamental than the usual vectors (and tensors built out of them) since you can build vectors out of spinors but not spinors out of vectors.

In three dimensions there is a very simple way of seeing this using the quaternions. If you identify space with imaginary quaternions, rotations are given by conjugation by unit quaternions q. Unit quaternions form a 3-sphere, isomorphic to group SU(2). The double cover comes from the action of q and -q being the same rotation. The spinor representation and its fundamental nature comes from the fact that SU(2) acts on $\mathbf C^2$, and all representations of SU(2) can be build out of this one.

36. **vmarko**
November 29, 2022

I can see that the discussion has covered a wide range of points of view and properties of spin, but apparently not all, so maybe I can chip in a bit. 🙂

Maybe it should be emphasized that the notion of spin does not really have much to do with quantum mechanics. Rather, it can be regarded as a field theory phenomenon, completely classically.

For example, in Maxwell's electrodynamics, the electromagnetic wave has nonzero (integer) spin. Likewise for a massive Proca theory, and for general relativity. And likewise for the half-integer spin of the Dirac, Weyl, Majorana, Rarita-Schwinger fields. All of these can be understood as classical field theories. And as Peter noted, even the nonrelativistic Schrodinger-Pauli equation (regarded as a classical field theory) describes nonzero spin.

In general, in field theory one can talk about the action of a rotation operator on the spacetime point (the "argument") and on the field components (the "function"). The former gives rise to orbital angular momentum, while the latter gives rise to spin. And there is nothing quantum-mechanical in any of that.

Also, regarding the distinction between non-relativistic and relativistic theories — while both can describe spin, there are a few subtle differences. First, the Dirac equation predicts the electron magnetic moment, whereas the Schrodinger-Pauli equation makes no such prediction (magnetic moment is a free parameter). Second, in relativistic theory the action of a rotation group element has to have the same parameter for both the orbital and spin parts (since relativistically there is just one notion, the "total" angular momentum operator, as a generator of the Lorentz group), while in non-relativistic theory the actions of the orbital and spin parts are independent, with a priori different parameters. This has been known to lead to incorrect predictions in nonrelativistic theory, since one is falsely allowed to "rotate" the orbital and spin angular momenta independently of each other. And finally, in QFT there is the spin-statistics theorem, which is inherently a relativistic (and also quantum) statement, with no non-relativistic counterpart.

Best, 🙂
Marko

37. **Jeffery**
November 29, 2022

Hi Peter,

I came across an old paper with similar claim published in 1985. Does this make any sense at all?

https://physics.mcmaster.ca/phys3mm3/notes/whatisspin.pdf

38. **Peter Woit**
November 29, 2022

Jeffery,
Sebens references that one, likely used some of it in whatever he is doing. Very explicitly same motivation: the only "physical explanation" of spin angular momentum is to try and interpret it as some kind of orbital angular momentum. Zero mention of or any interest in what angular momentum really is (generator of action of rotations on the theory). The 1985 author quotes 1928 and 1939 papers with similar claims. Another mystery is why SciAm is selling this as something new.

39. **martibal**
November 30, 2022

If you think classically (i.e. non quantum) then why the need of going to the double cover of SO(3) ? Why is nature not happy just with rotations and needs to go to the double cover ? And why does it stop to double cover and do not consider other covering group ?

40. **Peter Woit**
November 30, 2022

Martibal,
The only interesting covering group of SO(n) is the spin double cover, other covers are trivial. Why should nature be happy with vectors and SO(3) and not exploit the more fundamental spinor representation and the double cover?

The classical situation is a little complicated to state, but here are some comments:

You can make a classical theory of a particle with spin in two ways:

1. Extend phase space by a sphere. You'll then get an extra "spin" contribution to angular momentum, which can take any non-negative value (determined by the radius of the sphere). No integrality or half-integrality of spin until you quantize.

2. Extend phase space by an anti-commuting coordinate. This is "pseudo-classical" mechanics and gives you a spin-1/2 term in the theory.

If you work with classical fields, you can write down classical field theories where the field transforms under any representation (including spinor) of the rotation group that you want. These can only be half-integral.

Spinors are not inherently quantum. If you go from 3 to 4 dimensions, the story of 4d spinors is very much a basic part of the theory of twistors. Twistor theory is not a quantum theory, almost all the work in twistor theory has been based on applying the twistor geometrical setup to classical field theories.

41. **tulpoeid**
December 2, 2022

I might be naive in my knowledge of QM (honestly), but having to "take into account the fact that in this case rotations also act on the vector values, not just on space" is or at least results in a very deep mystery. And definitely not the case that "When one talks about "spin" in physics, it's a special case of the general story of angular

momentum". Spin is fundamentally about more than rotation and angular momentum, while at the same time surprisingly connected to them.
If I'm misunderstanding something obvious, I'd be grateful for a useful nudge.

42. **Peter Woit**
December 2, 2022

tulpoeid,
There is no mystery. All I'm saying is that if you write down a theory of fields (classical, quantum, whatever) and decide to use fields that take 3d vector values, then when rotations act on your theory, you have to take into account that the values of the fields rotate (giving spin angular momentum, "spin 1" in this case) not just the arguments (giving orbital angular momentum).

43. **Giorgio Pastore**
December 3, 2022

Peter,

I think that your judgment of Seben's work is too drastic. Your considerations about angular momentum as the generator of the rotations are correct, of course, but I think they do not exhaust the subject. Indeed, they do not directly address the content of Seben's paper.

I understand that the central issue is not to reduce the angular momentum to some cross-product of position and momentum. I think that Seben's work is on the same track as previous work by Belinfante and other people, one of the last being Ohanian.
Work that was not, and it is not an alternative to the view of angular momentum as the generator of rotations, and it is not a nonsense either. It is a work that helps to address a different issue: why, in the case of charged particles, such orbital and angular momenta carry a magnetic moment?

Electromagnetism requires the presence of charged currents to get magnetic moments. Seben's point of view has the advantage of clarifying the relation between such currents and the properties of the wave field. How would you get the presence of magnetic moment from the generators of the rotations?

44. **Arnold Neumaier**
December 3, 2022

Giorgio Pastore,

"How would you get the presence of magnetic moment from the generators of the rotations?"

It simply comes from the current $j(x)=:\psi(x)^*\sigma\psi(x):$

45. **Peter Woit**
December 3, 2022

Giorgio Pastore,

From my reading of Sebens (and Ohanian), their main arguments are not about the magnetic moment issue. The way spin couples to EM is very interesting and non-trivial, but I don't see how anything they do elucidates that question at all.

Comments on AdS/CFT

November 30, 2022
Categories: Uncategorized

This is something I wrote back in June, for context see the next posting.

First of all, there's the following, which is not strictly scientific, but very relevant to how one decides to evaluate progress in a subject.

- The Maldacena AdS/CFT paper is almost 25 years old and has nearly 18,000 citations. Trying to exploit ideas based on AdS/CFT has been the main goal of thousands of the best theorists in the world for decades. Questions like "what about getting this to work in the more physical case of dS?" are not new but very old and have been the subject of tens of thousands of person-years of unsuccessful effort. This doesn't mean it can't be done, I think it does mean that what's needed are some quite different ideas, there's little point in further banging away at ones that haven't worked for this long, after this much effort.
- Some of the hype surrounding AdS/CFT has been outrageous. One example is the claim that AdS/CFT gives a good way to calculate things about heavy-ion physics. This is just not true, and the people saying things like this should know better. Seeing people do things like this make me question their arguments about whether other ideas work or not (or have good prospects for working).
- As time goes on, people start using "AdS/CFT" to mean a wider and wider array of things. It often now denotes very general and vague conjectures about duality relations between gauge theory and gravity systems, or holography, or entanglement. It becomes impossible at some point to have a coherent discussion about the subject since there is no well-defined thing to talk about.

Sticking to the specific meaning of a duality between a specific superstring theory on AdS_5 x S^5 and N=4 super Yang-Mills on the conformal boundary, back in 1997 there were two reasons to get excited about this:

- Reading the duality as telling you about gauge theory in terms of string theory, you could hope that the duality could be extended to non-supersymmetric Yang-Mills, providing the long-sought string dual to QCD, allowing reliable strong-coupling QCD calculations. After a few years post 1997, it started to become clear this wasn't working, and why. N=4 SYM has zero beta-function and is conformally invariant, so the effective coupling and physics are the same at all scales. QCD has a running coupling constant, with weak-coupling and strong-coupling physics very different. AdS/CFT allows strong-coupling calculations on the gauge theory side using weakly-coupled strings, but this has the same problems that we've always had with QCD: there are ways to write down strong-coupling expansions, but no way to match those to weak coupling physics, no way to capture the way physics changes from strong to weak coupling.

  By the way, I noticed the Simons Foundation has just announced a collaboration to study QCD and strings

  > Foundation Announces the Simons Collaboration on Confinement and QCD Strings

  and this doesn't even mention AdS/CFT. People have tried really, really hard over decades to use AdS/CFT to say something about QCD, with very limited results.

- Reading the duality as telling you about strings and quantum gravity in terms of gauge theory, the hope is to understand quantum gravity this way. There are a bunch of problems with this:

  There's the gravity in AdS rather than dS problem that you mention. As noted above, back in 1997 it was reasonable to expect a useful extension to dS. After 25 years of failed efforts, if there is such a thing it has to be something very different.

  You want gravity in 4d, not 5d. This may not be a serious issue since you can take 5d with one small dimension, or brane or whatever to get rid of a dimension.

  There's a fundamental problem with doing gravity this way: string theory-based quantum gravity uses weakly coupled strings with the graviton a weakly-coupled mode. But this theory is dual to strongly-coupled gauge theory where you can't calculate anything. So, AdS/CFT is telling you nothing about the usual picture of how gravity arises from string theory. What it supposedly tells you about are strongly coupled strings (using weakly coupled gauge theory), but then the connection to gravity is something very different than what was originally advertised for string theory.

  Put together, the problem is that, to the extent AdS/CFT is telling you something about strings and quantum gravity, it's telling you about the wrong kind of space-time (AdS) in the wrong dimension (5) with the wrong kind of strings (strongly-coupled). The general philosophy seems to be that at least it's telling us about some kind of quantum gravity, which is a reasonable motivation, but leaves one far from real physics, in the land of general issues like resolving the black hole information paradox. But 20 years ago we were being told that it was resolved by AdS/CFT, then ten years later we were being told it wasn't (the "Firewall"). Again, given the level of hype people operate with, it's hard to evaluate any of this kind of thing with no relation to anything measurable.

I'm all in favor of good toy models, and from what I can see the main activity in AdS/CFT these days is trying to understand lower dimensional toy models. This leads to lots of interesting things to study, but you seem to end up with very complicated things happening even in much lower dimensions (0+1 SYK models, 1+1 JT gravity models), far from the 3+1 dimensions one wants. There are no physical gravity degrees of freedom below 3+1 dimensions, so it's all too possible that what one is studying in these lower dimensional models is exactly the things of no physical relevance to the real problem.

Finally, my feeling has always been that the difficulty of measuring purely quantum gravitational effects means that the only convincing quantum gravity will be one unified with the rest of physics, fitting together well with what we can observe. The danger with studying pure quantum gravity is that you'll end up with not one theory, but an infinite number of them, empty of any predictive value. The landscape is a realization of that danger.

Update: By the way, this is roughly the 25th anniversary of AdS/CFT, Scientific American has a piece by Anil Ananthaswamy.

Comments

1. **Thomas**
   November 30, 2022

   The very first prediction of a property of the QGP based on AdS/CFT correspondence, $\eta/s=1/(4\pi)\simeq 0.08$, remains very close to the most accurate determinations from RHIC data. For example, Bass et al. (https://inspirehep.net/literature/1763462) find $\eta/s=(0.085\pm 0.025)$ at the critical temperature. Obviously, this prediction ignores all the differences between the two theories, such as finite N_c, finite coupling, different matter content. I'm happy to admit that it must be somewhat of a coincidence — but a remarkable coincidence it is.

2. **Joseph**
   December 1, 2022

It seems to me that quite a few of your arguments boil down to "There hasn't been progress on X in 25+ years"

Using algebraic geometry as an analogy the motivic picture has developed tremendously since the 1960's but the fundamental pieces of the program rest on existence theorems for algebraic cycles which no one knows how to prove. These are so out of reach that I wouldn't be surprised if we saw no progress on even the weakest existence theorems this century.

Yet, this is a crucial issue and vast swathes of mathematics from the Langlands program to transcendental number theory are waiting to be revolutionized.

Going back to physics, imagine if in 2080 physicists finally manage to quantize string theories with Ramond-Ramond fields thus enabling computations beyond the supergravity limit in AdS/CFT.

Maybe in 2200 the QCD string is found and in 2500 M-theory is finally understood. The point being I don't think the amount of time there hasn't been progress means anything. So what if it takes a 1000 years?

3. **Peter Woit**
   December 1, 2022

   Joseph,
   The problem with AdS/CFT, as a way to do calculations in QCD, or as a theory of quantum gravity, is not that there has been no positive progress, but that all the work on it over 25 years has just clarified the underlying reasons why it doesn't work. In the comments posted here I was trying to explain those underlying reasons. The problem is not positive progress being so slow that we have to wait til 2080, but that the derivative is the wrong sign: progress is towards proving that there is no way anything like this can work, that you need to find something quite different.

   In the math analogy, it's as if almost every implication of the motivic picture didn't work correctly, giving completely incorrect relations between cohomology groups, and that those working on this keep saying "we still believe in the picture, we just need to keep calculating and maybe someday someone will come up with the right idea that fixes everything not working". This situation would be a strong argument for abandoning the motivic picture. Some people might want to continue to work on it, but such work should be in the context of admitting the original ideas didn't work, not continuing to hype them uncritically.

4. **Anonymous**
   December 6, 2022

   " What it supposedly tells you about are strongly coupled strings (using weakly coupled gauge theory)"

   Incorrect.

   Gauge theories at large N are dual to weakly coupled strings.
   Weakly coupled gauge theories are dual to tensionless weakly coupled strings.
   Indeed, strongly coupled gauge theories at large N are dual to 'standard' gravity, but such gauge theories are under much better control analytically/numerically when compared to gravity. Also, we 'know' their completion to finite N and any coupling using the same techniques.

5. **Peter Woit**
   December 6, 2022

   Anonymous,
   You're taking the quote out of context, also out of the context of what this email was about. The point I was making is that AdS/CFT is completely irrelevant in the usual picture of how string theory is sold as the answer to quantum gravity: gravity as the effective space-time low energy theory due to the graviton mode of a weakly coupled string. In this picture you can compute how the strings behave using perturbation theory, AdS/CFT is irrelevant.

This Week's Hype

November 30, 2022
Categories: This Week's Hype, Wormhole Publicity Stunts

This morning Quanta Magazine informs us that Physicists Create a Wormhole Using a Quantum Computer, promoting the article on Twitter with BREAKING: Physicists have built a wormhole and successfully sent information from one end to the other and Physicists have used Google's quantum computer to send a signal through a wormhole, a shortcut in space-time first theorized by Einstein and Rosen in 1935.

This work is getting the full-press promotional package: no preprint on the arXiv (unless I'm missing something?), embargoed info to journalists, with reveal at a press conference, a cover story in Nature, accompanied by a barrage of press releases (see here, here, here, with Harvard, MIT and Google to come). This is the kind of PR effort for a physics result I've only seen before for things like the Higgs and LIGO gravitational wave discoveries (OK, and the primordial gravitational wave non-discovery). It would be appropriate I suppose if someone actually had built a wormhole in a lab and teleported information through it, as advertised.

An additional part of the package is the Quanta coverage, with a very long article by Natalie Wolchover and an over-the-top seventeen minute film How Physicists Created a Wormhole in a Quantum Computer, with abstract

> Almost a century ago, Albert Einstein realized that the equations of general relativity could produce wormholes. But it would take a number of theoretical leaps and a "crazy" team of experimentalists to build one on Google's quantum computer.

The two senior physicists behind this, Joe Lykken and Maria Spiropulu, have histories that go way back of successfully promoting to the press nonsense about exotic space-time structures appearing in experiments that have nothing to do with them. Back in 1999, the New York Times published Physicists Finally Find a Way to Test Superstring theory, which featured Joe Lykken. In 2003, they featured Maria Spiropulu explaining how she was going to find extra dimensions (or "something just as 'crazy'") at the Tevatron, or failing that, the LHC.

I just saw that the New York Times also has a big story about this: Physicists Create 'the Smallest, Crummiest Wormhole You Can Imagine'. At least this article has some sensible skeptical quotes, including:

> "The most important thing I'd want New York Times readers to understand is this," Scott Aaronson, a quantum computing expert at the University of Texas in Austin, wrote in an email. "If this experiment has brought a wormhole into actual physical existence, then a strong case could be made that you, too, bring a wormhole into actual physical existence every time you sketch one with pen and paper."

An odd thing about the Quanta article is that it contains a couple quotes from me, that aren't at all about the wormhole business. They're about the attempt to use AdS/CFT to either solve QCD or get a viable theory of quantum gravity. Back in June Wolchover contacted me with some questions about AdS/CFT. It seems that she was planning a long piece on AdS/CFT, one which somehow many months later got amalgamated with the wormhole nonsense. I had forgotten that I was thinking of turning what I sent her back then into a blog posting but never got around to it, so just earlier today posted it here.

On the substance of what is really going on here, it's exactly the same as what was discussed extensively a month ago in this posting and in its comment section. The claim that "Physicists Create a Wormhole" is just complete bullshit, with the huge campaign to mislead the public about this a disgrace, highly unhelpful for the credibility of physics research in particular and science in general.

Update: Here's the promotional piece from Google, and Will Kinney's reaction.

Update: Physics World has Quantum teleportation opens a 'wormhole in spacetime' with a quote from Witten saying positive things about this experiment ("a 'milestone' in developing control over microscopic quantum systems"), nothing about the wormholes.

Update: I tried reading the paper in some more detail. Almost all the calculations in the paper were done on paper or on a classical computer. As far as I can tell, all they did was perform elaborate SYK calculations on a classical computer, together with simulations of noise on the Google quantum computer, trying to find a possible calculation on the quantum computer that would have signal, not just noise. Once such an N=7 SYK calculation was identified, they used a 9 qubit quantum computer and the noisy result matched the simulation result from the classical computer, exactly as expected. Seeing the completely expected match between results from a 9 bit noisy quantum computer and the results of the simulation of this on a classical computer caused Maria Spiropulu to say that "I was shaken" and "It was nuts. It was nuts", while Joe Lykken felt that the moment was on a par with discovery of the Higgs particle.

I hadn't noticed that the Nature issue comes with an article by Brown and Susskind, A holographic wormhole traversed in a quantum computer. Amidst the hype, they do at least point out:

> because nine qubits can be easily simulated on a classical computer, the results of this experiment cannot teach us anything that could not be learnt from a classical computation, and will not teach us anything new about quantum gravity.

New Scientist is the sober one here, with their headline the relatively reasonable A quantum computer has simulated a wormhole for the first time

Update: MSN is going for the larger context: physicists didn't just create a wormhole in a lab, also This tiny 2D wormhole could finally solve the biggest problem in physics

Update: Andreas Karch on Twitter I think has an accurate characterization of this "mostly a publicity stunt":

> Experimentally it's of course cool they can do SYK – as a demonstration they have control over their device. They can couple 9 qbits in a pre-specified way. But I guess we knew they could do this before. Going after SYK in particular, in my mind, is mostly a publicity stunt.

Update: Quanta has changed the title of their article from "Physicists Create a Wormhole" to "Physicists Create a Holographic Wormhole".

The MIT press release is out, and it's comical in the other direction, explaining the huge breakthrough as MIT researchers use quantum computing to observe entanglement.

Chad Orzel is getting flashbacks to 2006, which I can well understand. Many of the worst offenders in this hype campaign were hard at work doing the same thing back then (and earlier), and I was, as now, ineffectually trying to do something about it (the first edition of "This Week's Hype" dates back to that year).

Update: Quanta has also deleted the original "BREAKING: Physicists have built a wormhole and successfully sent information from one end to the other" tweet. Davide Castelvecchi at Nature as a more sober story, ending with

> The theory tested at the Google lab "only has a very tangential relationship to any possible theories of quantum gravity in our Universe", says Peter Shor, a mathematician at the Massachusetts Institute of Technology in Cambridge.

Update: More coverage of this here, here, here and here. Quanta and Wolchover are, quite appropriately, blaming the "some of the best-respected physicists in the world" who sold them this nonsense, see here, here and here.

Comments

1. **Blake Stacey**
   November 30, 2022

   The original arguments in the "ER = EPR" paper would imply that a wormhole exists between two correlated toy bits in the Spekkens toy model, which would be farcical.

   The very thing that makes AdS spacetime a "good box to put gravity in" — a boundary that a geodesic can reach in finite proper time — is what makes it unlike the universe we live in. You can have toroidal black holes in AdS! "De Sitter space looks like anti-de Sitter locally" also ignores stability. Like, the answer to the question "if I do this, will my lab implode into a black hole" is different between the two.

   I could buy that the research sold under the "it from qubit" slogan may yield an interesting and useful geometric description of entanglement in some multipartite quantum states. That's a far cry from a physical theory of quantum gravity, however. And I say this as a quantum information specialist who'd love to see my own specialization unlock the mysteries of the cosmos!

2. **Adam Treat**
   November 30, 2022

   Good on Scott Aaronson actually pushing back on this incredible hype. Let's see how many other responsible QC researchers and quantum gravity researchers do the same. Peter, do you think the actual researchers are the drivers of this hype or is it more likely the institutions (Google, CalTech, etc) + Natalie Wolchover are the drivers and the actual researchers are complicit by not pushing back on the over-the-top hype?

3. **Somdatta**
   November 30, 2022

   Can't say much until I have read the paper which I hope appears tomorrow. But the wormhole they are talking about is of course a fictitious one, the question is whether the experiment that they do has any tell-tale signs of the wormhole, which apparently they do, and that is all that matters. AdS/CFT tells you that a gravity description is sometimes more useful in discerning what is going on than the underlying strongly coupled quantum system, hobbled too much by strength of the coupling, to be amenable to analysis. The SYK system is of course one where the two descriptions are demonstrably in agreement, and yet there could be features that are easily explained by the gravity description than the quantum one, and that is what's in contention, I guess. However through this, no wormhole will ever open up in ordinary spacetime, if that's what people are pondering over.

4. **Peter Woit**
   November 30, 2022

   Adam Treat,
   I don't think the journalists are blameless, this is not Quanta's finest hour. Overbye at the New York Times did a much better job (although I'd argue it would have been better to not cover this at all, or as a story not about physics, but about an out-of-control hype problem).
   The main people responsible though are the researchers involved. In the case of several of them, if physicists could be brought up on malpractice charges, they'd be in trouble.

   Somdatta,
   The paper is up on the Nature site, released same time as the hype campaign. Funny thing is I suspect you're talking about when it will be on the arXiv. New rule, don't take anything in Nature seriously, until it's on the arXiv…

5. **Somdatta Bhattacharya**
   November 30, 2022

   Peter,
   I was aware of the Nature paper, but I don't have access. The New Scientist article is good. Thanks.

6. **Peter Woit**
   November 30, 2022

   Somdatta,
   Thanks for the explanation. It does seem that publishing in a commercial venue like Nature and not putting on the arXiv makes your paper inaccessible to a lot of its scientific audience.

7. **Somdatta Bhattacharya**
   November 30, 2022

   Peter,
   You're welcome.

8. **Regan E howard**
   November 30, 2022

   I was hoping for something "real" but it's just a sim. And doing the sim on a quantum computer made it a publicity stunt. The video was a bit flashy in the sales sense. Note that tech companies included Google are under some financial strain now and the accountants are looking at chopping non-revenue producing entities. I'm not sure who is playing whom.

9. **Low Math, Meekly Interacting**
   November 30, 2022

   Depressing.

   Blogs are great, but where else do I go for science journalism now?

10. **Bobak H**
    November 30, 2022

Peter, what do you think about this surrogate model they found. As someone with a very limited background in this kind of physics, it's hard for me to understand whether their checks are sufficient: to wit "winding size", various properties of mutual information between qubits, and some properties between the correlation functions of the state (which I guess in this context are amplitudes for the state to return to itself at time t?).

Thanks for your post!

11. **Alessandro Strumia**
December 1, 2022

Peter writes: «if physicists could be brought up on malpractice charges». This is excessive. Just pay their analogous wormhole work with analogous Monopoly money.

12. **John Baez**
December 1, 2022

Unfortunately Natalie Wolchover didn't seem to realize that this hype was merely hype: on Twitter she wrote: "Curious to see so many people approve of the article but bristle at the headline. Can someone (who has actually read our article or the Nature paper) articulate *why* they don't think it's valid to say the experiment created a wormhole?"

Various people who know what's going on tried to explain it carefully and gently. But I think one has to be brutally clear in situations like this, so I replied:

They did an simulation that crudely, roughly mimicked a system dual to a 2d wormhole. So it's like a kid scrawls a picture of an inside-out building and the headline blares

BREAKING NEWS: CHILD BUILDS TAJ MAHAL!

13. **Mike**
December 1, 2022

I came to this blog (after not visiting for a while) expecting I would find the story surrounding this article featured in a "This Week's Hype" post and Peter did not disappoint me.

As a condensed matter/ultracold atom theorist who works on non-equilibrium dynamics of strongly correlated systems, who has been following the activity on SYK from a bit of a distance, and saw the emergence of the first theory papers talking about wormholes in SYK appear and being reported in workshops and seminars a couple of years ago, I have only one thing to say about this whole business:

Yuck! And the way the media has been dealing with work is appalling and makes me really ashamed of being in the "same" community as the authors…

14. **Mateus Araújo**
December 1, 2022

Clearly Wolchover was fed some garbage by the scientists involved and believed it uncritically. She writes that simulating stuff with quantum computers is fundamentally different than simulating stuff with classical computers, because on quantum computers "the system evolves according to the actual laws of nature".

I guess then that the classical computer I'm writing this comment with doesn't run on the actual laws of nature. Maybe it's a cellular automaton? Or an abstract Turing machine, coming straight from Platonic heaven? Whereas the rest of the world runs on regular physics?

Now, if you believe this nonsense, it makes sense to get excited by the simulation on a quantum computer and not by the much easier and better simulations one can do on classical computers.

15. **Mateus Araújo**
December 1, 2022

Or, to be a bit more charitable, she believes that a simulation with an analogical computer is "more real" than a simulation with a digital, programmable computer. She just missed the fact that Sycamore is not an analogical computer, but in fact a digital, programmable computer.

Which, incidentally, is why people are interested in Sycamore in the first place!

16. **Theorist at UC Irvine**
December 1, 2022

Peter:

Even if the headline isn't strictly accurate (a topic for another time, although I think you're splitting hairs here), what's the harm? It's a cool-sounding result which gets people interested in theoretical physics, science more generally. As long as science journalists are driving interest and engagement, I think they're doing a good job. If you want to discuss bad science journalism, surely a better use of your time would be all the anti-science fake news coming from the populist right in the U.S.

17. **Marshall Eubanks**
December 1, 2022

Today, Quanta did a 10 tweet thread explaining and (to some degree) walking back yesterday's hype:

To avoid further confusion with wormhole in the sci-fi sense of a passageway that a person can fly through, we have changed our headline to read "Physicists Create a Holographic Wormhole Using a Quantum Computer."

https://twitter.com/QuantaMagazine/status/1598353637515853827

18. **A reader**
December 1, 2022

"She writes that simulating stuff with quantum computers is fundamentally different than simulating stuff with classical computers, because on quantum computers "the system evolves according to the actual laws of nature"

I think what she meant is simulating stuff with classical computers you are solving the Schrodinger equations whereas with quantum computers you are actually performing a quantum experiment.

19. **Nicola Maiorino**
December 2, 2022

@John Baez

I also like Sabine Hossenfelder's blunt response to Natalie Wolchover's Twitter query "Curious to see so many people approve of the article but bristle at the headline. Can someone (who has actually read our article or the Nature paper) articulate *why* they don't think it's valid to say the experiment created a wormhole?".

Sabine wrote the following on Twitter in an attempt to clarify the difference in understanding (in the lay-person's mind) between the hype in the article's headline, and the nature of the experiment that was actually performed:

"To say the hopefully obvious, when the average person reads "wormhole" they don't think "the [holographic] dual of an AdS2 wormhole", because they know neither what "dual" means, nor what "AdS2" is."

20. **Peter**
December 2, 2022

Am I the only one to notice that publicized "breakthroughs" etc. in physics are becoming more and more esoteric?

On one side, there's a quantum mechanical system doing its expected quantum mechanical things. One the other side, there's a description, based on toy models and all kinds of speculative assumptions. It suggests there may be a relation between the quantum mechanical system and gravity, if gravity would be something that can be described by these toy models and assumptions – which remains to be seen, but actually is very hard to see at the moment.

Is that a breakthrough? It smacks of desperation, to be honest.

Very striking is the Witten quote you mention. I think it's called "damning with faint praise" in English. It's a level above "hmmm, nice, thanks" but not by much.

21. **sdf**
December 2, 2022

If there were a "Hall of fame" for this sort of thing, then surely this would be at the top? I can't think of a more egregious example of over-egging a paper.

22. **Mateus Araújo**
December 2, 2022

A reader: Ah indeed, that's probably what she had in mind. Still it's a weird mysticism about quantum computers. It doesn't really mesh with how much the computation is abstracted from the physical subtract. The correspondence is on the logical level, not physical.

23. **Alessandro Strumia**
December 2, 2022

I found a 2017 newspaper announcing that the first wormhole for time travel was built in Napoli using graphene. This raises an issue of scientific priority. Please add an "update" to recognise that wormholes, like pizza, have been invented in Napoli, and we will return your integrity by offering a 50% discount on Trevi Fountain.

https://www.ansa.it/canale_scienza_tecnica/notizie/fisica_matematica/2017/03/18/costruito-il-prototipo-di-uno-wormhole-per-i-viaggi-nel-tempo_9e619d68-b6c8-4333-9dac-9dc270ebe847.html

24. **martibal**
December 2, 2022

Trevi Fountain is free 😉 Nice try. The great breakthrough would be wormhole with ananas.

25. **Peter Woit**
December 2, 2022

Theorist at UC Irvine,
I think your attitude explains one source of the whole problem and the behavior of people like Lykken, Spiropulu and Jafferis. They likely are thinking "as long as this gets people excited about our field and our research, that's good for them (and good for us). So, doesn't matter if what we're saying is false or misleading."

Besides the minor matter of scientists being supposed to be concerned about what is true and what is false, engaging in outrageous behavior like this discredits the whole field. In this case they may have gone so far as to destroy their own credibility with their colleagues. Joe Lykken may have thought that appearing on a video claiming this result was as important as the Higgs discovery was a good way to get attention, but it also means a lot of people are no longer going to take seriously anything he says.

26. **Attendee**
December 2, 2022

Let me second Peter's response to "Theorist at UC Irvine". The purpose of science and science journalism is to either communicate what is true or suitably describe controversy. Neither of these attributes are true about these articles – the "science" here is total bullshit .

The average person who reads this sort of garbage and then learns it is garbage does not get "excited about science". Rather they (correctly) develop skepticism about scientists as a group and this becomes deeply problematic for both society and science.

I used to respect a lot of people who are involved in this hype. Shame on them.

27. **Low Math, Meekly Interacting**
December 2, 2022

A very diplomatic reality check on Ars…

https://arstechnica.com/science/2022/12/no-physicists-didnt-make-a-real-wormhole-what-they-did-was-still-pretty-cool/

Diplomatic to a fault, I'd say, but helpful nonetheless.

28. **Peter Woit**

December 2, 2022

LMMI,
Not claiming to have created a wormhole is good, the problems with the claims about this work go far beyond that, and articles like this one are still heavily hype-laden. The fact of the matter is that all that was done here was running a simple quantum-mechanical calculation on a nine qubit machine, with results that exactly matched what was expected. Beyond being a check that the google machine works as expected, this has no actual relation to quantum gravity, wormholes or any such. The endless verbiage about the relation of a bunch of coupled qubits to quantum gravity is still nothing but hype.

29. **Matt**
December 2, 2022

I thought hard about an analogy to tell your non-physicist friends what a „dual wormhole" is, so here it is: an angel is dual to a fishing rod, because in German the meaning of the word „angel" is fishing rod. So the analogous newsflash might have read as follows:

„Breaking: Scientists finally managed to study an angel in the lab.

Physicists from Caltech partnered with their friends from Guugle's fishing store to finally study the mysterious creature widely known as angel in their lab for the very first time. Indeed, linguists recently found out that an angel is dual to a fishing rod and thus they are basically the same thing, because the German word „angel" means „fishing rod".

Guugle provided their newest fishing gear, but some essential parts were missing, unfortunately. So instead of a fishing rod they could only provide a fishing line. However, Caltech's physicists immediately realized that the essential part of a fishing rod, and thus of an angel, is the fishing line. By studying the tension of the fishing line, they found unambiguous signals indicative of an angel. It was nuts."

Maybe that helps to contextualize the achievement of these very special scientists.

Best, Matt

30. **James A. Given**
December 2, 2022

A pity! When I saw you were quoted I said, "Great! Even Peter Woit is on board!"
Finally, they'll have to give Susskind his Nobel Prize!

31. **Low Math, Meekly Interacting**
December 2, 2022

I took Ouellette's article to be pretty clear about the tenuousness of the connection to quantum gravity, and it states explicitly "the atoms behaved exactly how one would predict they would using traditional 1920s-era quantum mechanics". A commensurately diplomatic way to characterize some of her judgements about how "exciting" or "interesting" this "new dual way to speak about certain specific systems" might be to note these are subjective terms.

But you're probably right, and I'm grasping at straws. I'm a big fan of good science journalism, and Ouellette and Wolchover have produced some of the finest, in my opinion. I'd like to think Quanta and those involved got played here, but that doesn't seem to be the case. So, again, depressing.

32. **Martin S.**
December 2, 2022

Your currently last update has twice link to [Matt Strassler's comment]().
I guess that the second case is for the [Twitter thread](), or its [6/10 part]().

PS This comment is only meant as a "typo" notice, not as a real comment.

33. **William Orrick**
December 3, 2022

In your latest update the first link in the second set of links doesn't seem to point where you intended. (It's identical to the last link in the first set of links, and doesn't contain any remarks by Natalie Wolchover.)

34. **Peter Woit**
December 3, 2022

Link in update fixed.

35. **Anonyrat**
December 4, 2022

Wolchover has pinned her tweet about her story. I.e., she is not backing down from her part in the hype.

Igor Krichever 1950-2022

December 1, 2022
Categories: Obituaries

I just heard the sad news that Igor Krichever passed away this morning at the age of 72. Igor was a great scholar, a wise man, and a wonderful human being. He will be sorely missed by his colleagues at Columbia and elsewhere. My condolences to his family, which includes another first-rate mathematician, his son-in-law Sasha Braverman. During the past year Igor had been suffering from a progressive neuro-degenerative disease. Fortunately he was still in good enough health to fully participate in and enjoy his 70th birthday conference, which took place at Columbia in early October.

In recent years Igor had been spending only one semester each year at Columbia, much of the rest of the time was in Moscow, where he was director of Skoltech's Center for Advanced Studies. He came to Columbia in the mid-90s, with his hiring the beginning of a period of successful expansion and improvement in the math department. He was a gentle and friendly person, and it was always a pleasure to have a chance to talk to him about one topic or another. When he became chair of the department I remember thinking that it seemed unlikely that someone as scholarly and laid-back as him, with a somewhat typical Russian mathematician's other-worldliness, could deal well with the challenges of the university bureaucracy. I was very, very wrong, as it became clear that he was extremely wise in the ways of the world and a great department chair. I guess that after growing up with Soviet bureaucracy, dealing with the Columbia version was child's play.

Igor was a very distinguished mathematician, one of the leading figures working at the intersection of integrable systems and algebraic geometry. For more about his scientific work, there's a biographical notice written by some of his colleagues at the time of his 60th birthday (which was also celebrated at Columbia with a conference, see here).

The Wormhole Publicity Stunt

December 3, 2022
Categories: This Week's Hype, Wormhole Publicity Stunts

The best way to understand the "physicists create wormholes in the lab" nonsense of the past few days is as a publicity stunt (I should credit Andreas Karch for the idea to describe things this way), one that went too far. If the organizers of the stunt had stuck to "physicists study quantum gravity in the lab" they likely would have gotten away with it, i.e. not gotten any significant pushback.

There have already been a lot of claims about "quantum gravity in the lab" made in recent years, and surely many more will be made in the future. It's important to understand that these all have been and always will be nothing but publicity stunts. In all cases, what is happening in these labs is some manipulation and observation of electron and electromagnetic fields at low energies. None of this has anything to do with gravitational degrees of freedom. One cannot possibly learn anything about the gravitational field or quantum gravity this way. If there is a dual theoretical description of QED in terms of a "gravitational" theory, this dual description is about other variables that have nothing to do with space-time and gravity in this world.

I'm hoping that journalists and scientists will learn something from this fiasco and not get taken in again anytime soon. It would be very helpful if both Nature and Quanta did an internal investigation of how this happened and reported the results to the public. Who were the organizers of the stunt and how did they pull it off? Already we're hearing from Quanta that the problem was that they trusted "leading quantum gravity researchers", and presumably Nature would make the same argument. Who were these "leading quantum gravity researchers"? Why weren't any of the many other physicists who could have told them this was a stunt consulted?

It's pretty clear that one of the organizers was Joe Lykken. After I wrote about his talk at CERN a month ago, someone told me that Dennis Overbye at the NYT was looking into writing about Lykken's claims. I found it odd that the NYT would be interested in this, now it's clear that the behind-the-scenes publicity campaign was starting already a month ago. If you look at Lykken's slides, there's no mention at all of the work he had done and knew was about to appear in Nature, but the whole talk is structured around arguing that such a quantum computer calculation would be a huge achievement. I still don't know what to make of his claims in the Quanta video that the result of the Google quantum computer calculation was on a par with the Higgs discovery. Does he really believe this (he's completely delusional) or not (he's intentionally dishonest)?

It's extremely unusual to not distribute a result like this on the arXiv before publication, to instead keep it confidential and go to the press with embargoed information. By doing this though you control the first wave of publicity, since you pick the press people you deal with and the terms of the embargo. One thing that first mystified me about this story is why Natalie Wolchover at Quanta was quoting comments from me on a different issue in her story, but hadn't asked me about the article and its "physicists create wormholes in a lab" claims. One possible explanation for this is that the terms of the embargo meant she could not discuss the Nature article with me. I have to admit that if I had heard from her or any other journalist that a group was about to hold a press conference and announce publication in a major journal of claims about quantum gravity in a lab, and would I respect embargo terms so they could share info with me and get a quote, I would have said no. Likely I (and others in a similar situation) would immediately have gone and written a blog entry about how a publicity stunt was about to happen.

Update: I just noticed that the "It from Qubit" community will be gathering Monday thru Wednesday in Princeton and Thursday thru Friday in New York. One of the Princeton talks will be from one of the Nature authors (Jafferis), talking about "Emergent Gravitational Dynamics in Quantum Experiments" (no abstract, may or may not be explaining how he created the wormholes). This would be an excellent occasion I think for this community to discuss what can be done to stop publicity stunts like this one from discrediting their subject. The New York component will be invitation only, at the Simons Foundation. Presumably the Quanta people will be there to discuss with them the huge damage to their reputation they just suffered because of the publicity stunt. I'd be curious to hear how this goes from anyone participating.

Update: Something I should have linked to before is Scott Aaronson's blog posting about this, and the comments there. One that I think is of interest explains that SYK at large N is not precisely dual to a 2d gravity theory as one often sees claimed, and has other useful explanations of issues with duality claims.

Update: According to Spiropulu on Twitter, at 2:15 Eastern Time today you can watch Jafferis talk about this stuff to a workshop at Princeton here.

Update: Just watched the livestream of the Jafferis talk. He went over in detail the paper. At the end, a few technical questions. At this point I'm seeing no evidence that anyone (other than Scott Aaronson) in this community has any problem with the outrageous hype and publicity stunts like this one being used to promote their field to the public and attract more funding.

Update: Something from Ethan Siegel, who as usual, gets it right:

> There are no lessons to be learned about quantum gravity here. There are no lessons to be learned about traversable wormholes or whether they exist within our Universe. There are not even any lessons to be learned about the uniqueness or capabilities of quantum computers, as everything that was done on the quantum computer can be done and had previously (without errors!) been done on a classical computer. The best that one can take away is that the researchers, after performing elaborate calculations of the Sachdev-Ye-Kitaev model through classical means, were able to perform an analogous calculation on a quantum computer that actually returned signal, not simply quantum noise…
>
> Wormholes and quantum computers will likely both remain topics that are incredibly interesting to physicists, and further research into the Sachdev-Ye-Kitaev model will likely continue. But the connection between wormholes and quantum computers is virtually non-existent, and this research — despite the hype — changes absolutely nothing about that fact.

Update: To get a taste of the utter nonsense people are now getting as "News" because of this publicity stunt, try watching this ABC News segment.

Comments

1. **Jay Smith**
   December 3, 2022

   This whole thing amounts to a heck of a lot of egg in the face of the world's physics community, in general, the HEP one, in particular. And at a time when sectors of western societies are already dismissive of science and scientists openly. This is bad – very bad.

2. **Ted Rogers**
   December 3, 2022

   It is somewhat encouraging that there has been so much pushback. Maybe there is finally starting to be a shift away from the "what's the harm?" attitude toward excessive hype?

3. **Peter Shor**
   December 3, 2022

It seems to me that the string theorists and "it from qubit" community seem to have this unwritten rule that they don't criticize other members of this community in public. For example, when you criticized "ER=EPR" on this blog, Urs Schreiber responded on Twitter that it was not to be taken seriously, but it was just a Zen koan. And Geoff Penington said on Twitter that "no one has ever believed that". This despite the fact that Susskind continued to give lectures where he presented ER=EPR, as described in the original paper, as an actual physical phenomenon.

This unwritten rule goes a long way towards explaining how the journalists got misled.

4. **Peter Woit**
December 3, 2022

Ted Rogers,

We'll see. Given past experience with decades of string theory hype, I'm not so optimistic that the physicists doing this kind of thing will stop doing it, or that the journalists covering the field will stop getting taken in.

5. **Peter Woit**
December 3, 2022

Peter Shor,
This kind of tribal behavior has been a big feature of the string theory community, sorry to see evidence that it is a feature of this newer community.

One aspect of this story I don't understand is why no one waved Natalie Wolchover away from writing about this in the way she did. I would have thought just about any of the "It from Qubit" people (putting aside Susskind…) would have recognized that her article and the video were highly problematic and advised her to tone them down. The only explanation I can think of is that the embargo terms kept her from getting the kind of advice she needed.

Just noticed that the Simons-funded It from Qubit group will be meeting all next week in Princeton and at the Simons Foundation headquarters. Maybe some of this will be sufficiently private that people will be willing to criticize what happened, maybe even consider doing something about it. I'm also curious to know if participants will hear from people like David Spergel and Thomas Lin, who should be concerned about the reputational hit this kind of publicity stunt may cause the Simons Foundation and Quanta.

6. **Peter**
December 3, 2022

I've got a degree in physics in the early 1980s but I've had an uncommon career and worked 10 yrs. in "the media". With that background, I guess I should feel some sympathy for Nathalie Wolchover, but I don't.
As a reporter, you know people try to use (and abuse) you. You know you're a pawn in a bigger game. If you're a halfway decent reporter, you know what you're used for. And if you don't know, you find out.
Guarding your integrity in those circumstances isn't always easy. But writing "It's debatable whether the experiment furthers the hypothesis that the space-time we inhabit is also holographic, patterned by quantum bits" simply isn't good enough; and the way she used your quotes without you knowing the context in which they would be published, is below par, to put it mildly.

7. **Dimitris Papadimitriou**
December 3, 2022

They just "trusted leading QG researchers"?! That's really hard to believe..
One thing that baffles me is that the whole attempt seems so naive, almost childish. The fanfare and the pomposity of the video, especially, was laughable (or cringe worthy , perhaps- it depends on one's point of view…).
This kind of hype could not last for more than a few days (at best!), so what was the intention of the people who prepared/ organized this?
It seems almost logically inexplicable. As if they wanted any kind of publicity, even negative…
The situation with science communication is getting worse. I don't believe that this will change for the better anytime soon.

8. **Peter Woit**
December 3, 2022

Peter,
The problem for journalists covering this sort of theoretical physics has always been that it is ferociously technical and obscure. Experts have enough trouble trying to figure out themselves what is going on, it's hopeless for journalists. The standard method journalists have for dealing with this is to recognize who is a credentialed expert, call up a bunch of them, then try to evaluate what they say. If you've got one expert who tells you wormholes are being produced in a Google quantum computer, and a bunch who say that's not right, you will stay out of trouble. If the majority of the experts you call up tell you that wormholes are being produced in a Google quantum computer, the natural thing to do is to get very excited about how amazing that is and work hard to bring it to the public.

9. **Peter Woit**
December 3, 2022

Dimitris Papadimitriou,
Looking at that video, I suspect that all involved did believe what they were saying, which means that they're in the grip of a delusion. Human beings are prone to delusion, especially if those around them are enthusiasts of the delusion. The idea that you're going to "study quantum gravity in a lab" is a delusion shared by an unfortunate number of people. How to shake the deluded out of their delusion, especially when all the incentives are on the side of sticking to the delusion, is a difficult problem.

10. **Pierre**
December 3, 2022

Peter,

I thought you'd be interested to know that the "wormhole created in a quantum computer" story is now being covered in some far-right-wing media. I won't name them here (they're very far-right sites, not sure if you'd allow a link here), but they're essentially saying "isn't this manifestly stupid? See? Why should we believe scientists when they publish bullshit like this?" and essentially use the story to argue that scientists and science journalists are all a bunch of idiots, hence why should we trust them on vaccines/climate change etc.

This is another consequence of bad publicity stunts like this: it erodes trust in scientists.

11. **Peter Woit**

December 3, 2022

Pierre,
Thanks, interesting to hear about that, although I'd just as well not drive traffic their way. The problem though is very general. Unless they're unusually gullible, most people, left, right and center, are going to react to the "physicists create wormholes" headline by wondering if there's something wrong with physicists and this may also extend to other scientists. I keep wondering when other scientific fields are going to start demanding defunding of theoretical physics because of the reputational damage they're seeing from headlines like this.

12. **Alex**
December 3, 2022

"I'm hoping that journalists and scientists will learn something from this fiasco and not get taken in again anytime soon."

Considering how systematic this has become, and how the same people seems to be always somehow involved, I really believe that they actually *want and look forward* to be "taken in" again. Which is just a diplomatic way of saying they are either delusional or intellectually dishonest. In the case of N.Wolchover, this is not the first article I have seen by her which is enthusiastic about highly controversial claims coming from the same group of ex-string theorists behind these ideas. She usually mentions the obvious caveats, but only at the end of her articles and after the strongly enthusiastic first half. Let's not forget she has an actual bachelor degree in physics and went to graduate school in physics for some time. So, she's not that naive and I don't buy that "we just asked the experts" lame excuse. I recall reading somewhere that one of her favorite topics in physics was string theory and that the people she most respected worked in that topic. So, my take is that she quite understands a lot of what she writes about and likes it, she's on the wagon, as simple as that. She believes in these ideas, I don't think she's intellectually dishonest, in the sense that I think she probably thinks the caveats are solvable problems (which is a common view in that research community). Regarding the other people involved, I would say there's a bit of both of the mentioned things. About Susskind in particular, I really don't know at this point. But it baffles me how well respected he is.

My take is that nobody of the involved will learn anything about this because they knew exactly what they were doing. And they will keep doing it again and again. If anything, the fiasco will make them to get better at it.

This simply *has* to go on, for a simple reason: the absence of any actual new results and ideas in fundamental physics. People simply have nothing else to talk about, so the discussions quickly derail to the surreal. The same happens in politics.

13. **Ex YouTuber**
December 3, 2022

So from what I understand, no wormhole has been created in the experiment. But does the experiment really prove the ER=EPR conjecture as stated in the video? Also, scrolling down the comments below the video (which has up to now 339k views), I didn't see a single warning comment from the viewers that no wormhole was created. Why didn't any real expert post a comment in the comments section of that video to inform people about the "fiasco"? Another video on YouTube where the same people held a Zoom meeting is available!

14. **Peter Woit**
December 3, 2022

Ex YouTuber,
As far as I know, all Quanta has done is change "wormhole" to "holographic wormhole" in the title of the Wolchover article and in a tweet. They've left the bizarre and delusional video as is.

15. **Douglas Natelson**
December 3, 2022

The discourse on Twitter about the press coverage has been morbidly fascinating. If anything, this whole affair feels like the BICEP2 business, complete with massive media coverage and pre-made breathless promotional video. I don't think there's anything wrong with putting out a press release when publishing work that you think is important, but waging a well-choreographed media campaign feels wrong to me, even if you've done something amazing.

Have the "it from qubit" people actually written a clear technical claim, and if so, could someone point me to it? I've asked this before. It just seems absurd on it's face to think that, e.g., creating two entangled photons through parametric down conversion by a nonlinear optical element is truly creating a Planck-scale wormhole in actual spacetime.

16. **Matt**
December 4, 2022

Regarding your question who the organizers were, my guess is that Hartmut Neven could have been one of them as well. Neven is heading Google‘s quantum AI division and has been managing their quantum computing endeavour since John Martinis brought his superconducting qbit expertise to Google in 2014. Neven also appears in the video, so at least he wasn‘t opposed to this publicity stunt.

Google undoubtedly has deep pockets, but I always suspected that they look at quantum computing as a means to an end, rather than a means without end. Don‘t get me wrong, huge kudos to them for pushing superconducting qbits as far as they did, but in the big picture they basically have nothing to show for. After almost 10 years, they still seem to be lightyears away from any commercially viable application.

Looking at the situation, I‘d suspect that the QC guys at Google slowly but desperatly need something to show for. So any publicity that convinces Google to keep paying the bills appears to be good for them.

17. **Klaus**
December 4, 2022

Peter,

one of the cited "It from Qubit" abstracts contains the sentence: "We show that a very old black hole can tunnel to a white hole/firewall by emitting a large baby universe."

Clearly, the Quanta/Nature wormhole claims are negligible compared to this one. Imagine what a quantum computer can do if you simulate very old black holes…

I do not know how much alcohol is needed to submit such a statement to a physics conference. No wonder that scientists are seen as untrustworthy. It seems that the authors confuse doing physics research with writing scripts for the next Hollywood movie.

18. **martibal**
December 4, 2022

@Peter: about defunding theoretical physics, isn't it that this kind of "wormhole by google" actually is a good way to get some funding by non national-entities like breakthrough prize , or whatever foundation of some "visionary" billionaires that are looking for breakthrough every day? What would happen if someone, say Musk, decides that this sounds a pretty cool stuff and invest a few hundred millions dollars on this subject ? For him this would be a joke, but in theoretical physics world, this would be a great deal of money and allow this kind of bs to go on ever and ever..
.

19. **Dimitris Papadimitriou**
December 4, 2022

Ex YouTuber
There were some "warning" comments about that video (I tried myself) but they were few and sparse.
And, of course, they were buried under tons of "wow" comments (many of them demanded even the …Nobel prize for the "breakthrough").
That's what is usually happening in such cases, as we all know very well.
Trying to do a sensible or carefully critical comment that is relevant to the content of such videos is almost a pointless exercise.
Only a few people will notice…

20. **Sabine Hossenfelder**
December 4, 2022

"Why weren't any of the many other physicists who could have told them this was a stunt consulted?"

I do not buy for a second that the people who wrote these articles didn't know other physicists think this is bullshit. They knew it, they just thought they'd — as usually — get away with it.

As you undoubtedly know, I have been very outspoken about this, it's one of the examples of quantum hype in my last year's video, and I also commented on Overbye's wormhole piece from two months ago here.

Granted, maybe those journalists don't watch my videos but the vast majority of them are on twitter. After all, it's their JOB to have an eye on these things. And a few years ago I wrote an article for (oh the irony) Quanta Magazine that one shouldn't confuse mathematical black holes with real ones. It was also the last piece I wrote for them.

The bottomline is that they had all the information to properly judge the new paper, they just thought that most physicists, as usual, would keep their mouth shut when confronted with bullshit headlines because they have this idea that any kind of attention is somehow good attention.

I am extremely grateful for the outcry over this headline because I hope it'll send a message that science news readers wand to read about real science, and that that, in return, will have an impact on research in the field.

21. **Sabine Hossenfelder**
December 4, 2022

Another comment on your somewhat broad-sweeping statement:

"There have already been a lot of claims about "quantum gravity in the lab" made in recent years, and surely many more will be made in the future. It's important to understand that these all have been and always will be nothing but publicity stunts."

I am afraid I have to disagree because there are some experiments that quite plausibly have a chance to see weak field effects of quantum gravity in the laboratory. I understand that that's not what you had in mind — you were referring to analogies and simulations for which your statement is entirely correct — but let's not throw out the baby with the bathwater.

I wrote about this possibility a few years ago here, and for all I can tell the experimental groups have since slow but steadily made progress.

22. **Frank**
December 4, 2022

One more curious thing. In HEP author names are usually alphabetical. When they are not, the order should indicate who contributed the most (first author) to who contributed the least (last author). Spiropulu is the last listed author, but the piece by Wolchover describes the group as being led by Spiropulu. So which is it?

23. **Peter Woit**
December 4, 2022

Sabine,
Thanks, your caveat is right, there could be lab results actually relevant to quantum gravity. I should have specified that what I'm referring to are all such claims involving a supposed duality, with the gravity stuff taking place on the other side of the duality from the physics being studied.

24. **Peter Woit**
December 4, 2022

Frank,
Thanks, I hadn't noticed that, and the ordering is interesting The first two authors are Jafferis and Zlokapa, which I guess means they are the ones who did most of the work, presumably Jafferis the general theory, Zlokapa (an MIT student) actual calculational work. Putting Spiropulu at the end, while Wolchover calls her the leader of the group suggests that what she led was the PR effort.

25. **Peter Woit**
December 4, 2022

martibal,
You're right, any potential NSF/DOE defunding could be more than made up by billionaires who want to go through the traversable wormholes.

The money from Jim Simons though flows through the Simons Foundation, and I'm curious what its director (David Spergel) thinks of all this.

26. **Peter Woit**
December 4, 2022

Klaus,

The people doing this refer to supposedly analogous structures in toy models using the same name as used in a physical theory. Part of the problem here is that after spending too many years in a toy model, you can forget that it's not the real thing. Journalists then often seem to think that there's no reason to make clear to the public the difference (i.e.use a misleading headline, bury the fact that it's a toy model deep in the article).

27. **tulpoeid**
December 4, 2022

Frank and Peter,

No; it's among the common practices to put the PI at the end of the authors list. I've worked for years at a lab where this was the practice, and I know it's elsewhere as well.

28. **Peter Woit**
December 4, 2022

tulpoeid,
Thanks. Looks like grant involved is this one
https://pamspublic.science.energy.gov/WebPAMSExternal/Interface/Common/ViewPublicAbstract.aspx?rv=b31f0e55-de01-4635-91d1-2bf112daea20&rtc=24&PRoleId=10
Spiropulu PI, Jafferis co-PI

29. **Peter Shor**
December 4, 2022

@Sabine:

You may be in the position of the boy who cried wolf. You have criticized so many things in physics, some of which many physicists perceive as actually valid (like dark matter), that the Quanta Magazine people may not be paying attention to you anymore.

And while I realize that your criticisms of dark matter have a lot more caveats in them than your criticism of calling simulations "wormholes," this may not be apparent to journalists.

30. **Peter**
December 4, 2022

Peter W.,

"The problem for journalists covering this sort of theoretical physics has always been that it is ferociously technical and obscure."

You're very mild for Nathalie Wolchover. As I understand it, she was given news under embargo. That alone should have made alarm bells ring. It's a trick providers of information often use to give undue weight to something. Every halfway decent reporter knows that. So the first question you ask yourself when given the embargoed news is: "Why is it embargoed? Interesting, relevant news doesn't need embargos."

The second question a halfway decent reporter asks is: "Why me?" An embargo puts you in a difficult position. You can't talk to a credentialed expert and try to evaluate what they say, because you can't tell them what your questions actually are about – it's embargoed. So you ask them a few general questions. The experts give equally general and usually polite answers, which invariably sound quite meek when confronted with the forcefully made and detailed statements by the provider of the embargoed information.

I could go on forever, but I won't. Quanta made a fool of itself here.

31. **martibal**
December 4, 2022

Simon's foundation has an excellent reputation among mathematicians, right ?
Are they related to the hype, or are they just hosting a conference on a related topic ?

32. **math**
December 4, 2022

Hi
I am not sure I understand everybody's criticism here.
The publication's authors have attempted to address a small aspect of a vast question in fundamental physics and published their result in a well reputed journal (vetted through a peer review process, AFAIK).
Are you criticizing their scientific result or the aggressive PR operation they have orchestrated?
About the latter, everyone is doing PR's these days. People need to «sell» their stuff (to attract funding, apparently…). The science is still valid (or else please explain why the published result is wrong and should not have been published).

33. **Peter Woit**
December 4, 2022

martibal,
The Simons Foundation is funding this sort of research with a large grant, see
https://www.simonsfoundation.org/mathematics-physical-sciences/it-from-qubit/
the conferences this week are part of what is funded by that grant.

It looks though like the PIs of the Simons grant and the authors of the publicity stunt are a disjoint set.

34. **Peter Woit**
December 4, 2022

math,
The scientific result I assume is correct, but it is not of any substantial significance and should not have been published in Nature. The authors ran a computation on a nine-qubit quantum computer and got the expected result, showing nothing more than that the Google machine works as expected. The publicity stunt aspect of what they did goes way beyond anything I've seen theorists do before.

35. **martibal**
December 5, 2022

math: since when does the refereeing process means embargo ? Basically all maths results are freely available on arXiv much before they get published in a journal. The paradigmatic case is Perelman's proof of Poincaré conjecture. The same is true, maybe less systematically, for high energy physics.
One may understand that the publication of the Higgs discovery is under embargo (given that there are two collaborations that work on the subject and this is really a huge result). But none of these is true in the quanta case.

"People need to «sell» their stuff (to attract funding, apparently…). "
That would be hearable (also discutable) if there were actually "stuff" to sell. Selling science as the last season of whatever Sci Fi series ruins the credibility of the field. One really does not need that at the moment.

36. **George**
December 5, 2022

Just by looking at the comments under the Youtube video, I can tell for certain that the public has been completely misled about the actual content of this work. And that will, in the long term, damage the trust between public and scientists, I am afraid.

37. **clayton**
December 5, 2022

in experimental groups (and also in astro), it's very common to put the PI at the end — eg the final author of https://www.nature.com/articles/s41586-019-1666-5 is Martinis, who was the head of the group and did all the press for it. The breakdown is very roughly "actual major contributors to the entire paper first; people who worked on a section or two, or who did direct mentoring of people in the first group, come second; people with private data, instrumental knowledge, etc., that we couldn't have done without, but who didn't do lots on the paper itself, third; people who got the grant money and oversaw stuff last"

38. **anon**
December 5, 2022

PI as the last author is common in experimental physics (as well as chemistry and life sciences, as far as I know), but I've never seen it happen in astrophysics. Maybe it happens in instrumentation groups, which are closely related to experimental physics.

39. **Steven Bratman**
December 5, 2022

I engaged in some twitter back and forth with Thomas Linn on the subject. His stonewalling and defensiveness was depressing. I offered as constructive criticism that if an expert is mentioned in an article, and that expert feels the article is utter nonsense, it would be appropriate to mention this. He insisted that the article already did so by including the words,"said Woit, a critic of AdS/CFT research." As you've explained, you gave those quotes in an unrelated context, which might excuse Quanta if they were unaware of your opinions. But he also told me that he knows all about your thoughts on the subject, and told me I was "partisan" because I found your opinion on the subject credible. Sigh.

40. **clayton**
December 5, 2022

in astro it differs very much between theory and then what you might call interdepartmental experiment (which is most of them) and single-department experiment (where it can be idiosyncratic). In the first case there wouldn't really be a PI as such, and in the second case you'd be in the "thermodynamic limit" of PIs (where there's so many that they all become alphabetical again). I had in mind the final one, which indeed would often be either a small experiment or the instrumentation paper for a larger experiment but centered in one particular group.

Regardless, it seems that this particular piece is following the PI-last standard inherited from experimental groups.

41. **Peter Woit**
December 5, 2022

Steven Bratman,
I saw that Twitter exchange. In general it's really depressing that both Lin and Wolchover seem to not understand the problems with what they have done. I did go back and reread more carefully the Wolchover article. The main quote from me is completely out of context and misleading (it quotes a 6 month old email from me about AdS/dS, which has nothing at all to do with this story, in a context set out as being about the experiment.)

42. **Laurence Lurio**
December 5, 2022

The hype in the press about this was so outrageous that I went and looked at the actual article in nature. There is no hint of this crazy hype in either the blurb about the article in Nature, or in the abstract to the article itself. All quite sober and no hint of "creating" a wormhole. The blame for this sits squarely on the press and not on the journal.

43. **Somdatta Bhattacharya**
December 5, 2022

You guys are indulging in ad hominem. What exactly is wrong with what Jafferis had to say today?

44. **Peter Woit**
December 5, 2022

Laurence Lurio/Somdatta Bhattacharya,

Nature isn't completely blameless, they devoted their front cover to a picture of a "Holographic" wormhole and a claim that this work was "a step towards investigating quantum gravity using quantum computers", although the Brown-Susskind summary of the research inside the issue says "the results of this experiment cannot teach us anything that could not be learnt from a classical computation, and will not teach us anything new about quantum gravity."

As for the Jafferis talk, nothing wrong with it, but it would have been an excellent opportunity for at least one person in the audience to confront him about why he had participated in the publicity stunt based upon this work.

45. **Adam Treat**

December 5, 2022

One reason you might not see pushback on Jafferis talk is that the blame for the hype is being placed on the experimentalists. At least that is what Matt Strassler has to say on his blog. He says that he's known Jafferis for over a decade and considers him a young genius and that he's not responsible for the hype, but rather the experimentalists are… I take his comments to mean that he blames Spiropulu and Google for launching the media campaign for which young Jafferis was unknowingly being used. See [here.]()

46. **Peter Woit**
December 5, 2022

Adam Treat,

I've learned a lot more about how this was done today. One thing I learned is that Spiropulu has been planning this for about four years (i.e. trying to find some kind of calculation that can be done on a quantum computer that could be sold to the public as "first quantum gravity in a lab" or "physicists create a black hole/wormhole in the lab"). Doubtless the Google people were happy to sign on and make their machine available for the stunt. From what I can tell, Joe Lykken (a theorist, not an experimentalist), was also part of the planning.

If you take a look at the video, Jafferis doesn't play a really big part, but he's filmed together with the whole group of them, played along, and cannot have been unaware of what the stunt was that Spiropulu was trying to pull off, and his own role in it.

47. **David Roberts**
December 6, 2022

Young researcher getting a chance at a Nature paper isn't going to complain too hard if the senior collaborators are drumming up some publicity.

48. **Somdatta Bhattacharya**
December 6, 2022

@peter,
Why focus obsessively on the publicity stunt and not on what they are actually doing. Also no one confronted him because it wasn't the appropriate forum. BTW, the bigger story is unfolding in Matt's blog today ICYMI.

49. **Ex YouTuber**
December 6, 2022

This YouTube video shows that all of them are accomplices; that the blame should not be put on Spiropulu alone:
https://youtu.be/PlZroYSYq8k

50. **tulpoeid**
December 6, 2022

Peter,

If your comments are used out of context, you should demand that they get deleted from the article and that the edit is mentioned explicitly. At the very least, the editor has the obligation of mentioning your ask for retraction next to your comments if they are kept in the article.

In other hype, not anything as spectacular, but Maryland theorist uses the landscape as solid base to tell the public that there are no laws of physics.
https://link.newscientist.com/view/62f685a7fc1bdc567268bdc8hrq9c.exx/0177a14a

51. **Peter Woit**
December 6, 2022

David Roberts,
Jafferis is a tenured full professor at Harvard, I think he's at a point in his career where he doesn't need to go along with this kind of thing if he doesn't want to.

52. **Peter Woit**
December 6, 2022

tulpoeid,
I've had a discussion with the editor at Quanta. My point of view on their article is that it is not fixable, with far more serious problems than my quote. I'd like to convince them that there's a problem and they need to do better in the future: there will be a lot more people coming to them with "quantum gravity in a lab" stunts. My arguments about this are having limited effect since I'm not a researcher in this field. I urge researchers in this field to contact Quanta with any complaints about the article. Jafferis would be an example of someone who has responsibility to do something about the situation, but he's not the only one…

53. **Peter Woit**
December 6, 2022

Somdatta Bhattacharya,
I watched the entire Jafferis talk, the reason for not concentrating on discussing their calculation in a sparsified N=7 SYK model is that it's not interesting. The only significance of the calculation is as a publicity stunt which Jafferis has significant responsibility for. Given this, I'd argue it was inappropriate for people to spend the question time on technical questions, they should have been asking him about the larger significance of what he had done, which was the stunt.

Matt Strassler I think agrees this is a publicity stunt, he's trying to use it as an opportunity to discuss a completely different topic close to his interests.

54. **David Roberts**
December 6, 2022

@Peter W

Oh, I was taking the phrase "young Jafferis" at face value. I guess "young" is relative. I really should have checked, though… :-S

On a different note, I'm sure every single illustration attached to this story is using a cartoon of a wormhole with too many dimensions. Instead of the problem of not being able to accurately picture 3+1d spacetime and an ER bridge in it, here the problem is that accurately picturing the appropriate and accurate 1+1d would uncover the hype for what it is.

55. **Santo D'Agostino**
December 12, 2022

Martin Bauer explains the physics of the experiment here for lay people. As usual for him, the explanation is clear and insightful. Tl;dr: No wormholes were created.

https://twitter.com/martinmbauer/status/1602240035478183936

56. **Peter Woit**
December 12, 2022

Santo D'Agostino,
From what I've seen, post the publicity stunt, the coverage of this story by physicists has been uniformly on the negative, no wormholes side. Matt Strassler for instance has "an international spectacle about a quasi-simulation of a cartoon of a wormhole" as his description. Since the stunt, I've yet to see anything, anywhere from one of the authors or anyone else defending what they've done. It just doesn't seem to matter that the physics community overwhelmingly is critical of this: journalists at Quanta and others taken in won't admit now that they were taken in, likely never will.

57. **Evgeni Ku**
December 25, 2022

What would the point of a publicity stunt be here? Opportunity for future grants for the scientists involved?

It seemed fishy to me even as a lay person with minimal understanding of the matter beyond pop-sci books, which is how I got to this blog post. I can't understand the reason for making such an elaborate hoax though.

One thing I could imagine is this being heavily pushed by Google as a form of marketing for their quantum computer work, though it feels like that should also be doable with far more reasonable and non-contraversial experiments.

58. **Peter Woit**
December 25, 2022

Evgeni,
For the Google people involved, this was pretty explicitly a publicity stunt designed to promote their Sycamore quantum computer. If you look at what was actually being done, it was a calculation for which their machine was dramatically worse than any conventional computer.
For the physicists involved, this was a stunt designed to justify current funding and attract future funding. Some of the people involved have been at this for 25 years, back then concentrating on misleading people about "experimental tests of string theory". This is just more of the same, with "string theory" evolving into "holographic quantum gravity".
What's remarkable is how successful this was, with the con taking in not just the press but the directors of the IAS and Fermilab. There will clearly be an ongoing effort to pursue this, we're going to see a lot more bogus "quantum gravity in the lab" claims, unclear if those at the IAS and Fermilab who have been conned will wise up.

59. **Frank**
December 25, 2022

Why in the world do you think the directors of Fermilab and the IAS were not in on the con? They benefit from increased funding for "quantum gravity in the lab" and had access to experts who could explain the significance of what was done. Fermilab in particular has severe cost overrun problems and needs to fight for continued funding.

Publicity Stunt Fallout

December 6, 2022
Categories: This Week's Hype, Wormhole Publicity Stunts

Latest news this evening from Scott Aaronson at the IAS in Princeton:

> Tonight, David Nirenberg, Director of the IAS and a medieval historian, gave an after-dinner speech to our workshop, centered around how auspicious it was that the workshop was being held a mere week after the momentous announcement that a wormhole had been created on a microchip (!!)—in a feat that experts were calling the first-ever laboratory investigation of quantum gravity, and a new frontier for experimental physics itself. Nirenberg speculated that, a century from today, people might look back on the wormhole achievement as today we look back on Eddington's 1919 eclipse observations providing the evidence for general relativity.
>
> I confess: this was the first time I felt visceral anger, rather than mere bemusement, over this wormhole affair. Before, I had implicitly assumed: no one was actually hoodwinked by this. No one really, literally believed that this little 9-qubit simulation opened up a wormhole, or helped prove the holographic nature of the real universe, or anything like that. I was wrong.

Scott has been the one person in this field I'm aware of who has tried to do something about the out-of-control hype problem that has been going from bad to worse. I do disagree with him about one thing. He goes on to write:

> I don't blame the It from Qubit community—most of which, I can report, was grinding its teeth and turning red in the face right alongside me. I don't even blame most of the authors of the wormhole paper, such as Daniel Jafferis, who gave a perfectly sober, reasonable, technical talk at the workshop…

I do blame all those people. Unlike Scott, they've been either participating in hype for years, or staying quiet and enjoying the benefits of it. Grinding their teeth and turning red in the face is not enough. They need to finally say something and take action.

Update: Still unclear to me what the ultimate fallout of the publicity stunt will be. One thing that is becoming clear is that the publicity stunt is part of a vigorous and very effective campaign to mislead funding agencies and those making funding decisions. The goal is to convince them that "quantum gravity in a lab" is a real thing and the way forward for fundamental theoretical physics. The bogus Quanta story, video, headlines are not a bug, but a feature. Among the funding agencies, DOE is on board, their grant funding the publicity stunt, and they are advertising it prominently in their presentation to HEPAP today (see page 7 here). At the IAS, it seems director Nirenberg's claims that the "first quantum gravity experiment on a chip" was possibly the biggest breakthrough in a century were not off-the-cuff comments based on what he had read in the paper or at Quanta, but prepared remarks based on conversations with IAS senior faculty. I gather that what he has been hearing from at least some of them is that the wormhole "experiment" vindicates their past research and justifies supporting them in the direction they are choosing for the future. He has though now been hearing other viewpoints.

If researchers in this field want to know what they can do about the problem, contacting places like Quanta to get them to fix their coverage is one thing, another is contacting people with funding responsibilities (ie. program officers at funding agencies, directors of institutes) who seem to have been misled by the hype campaign.

Update: Quanta hasn't done anything more to fix the wormhole article, but they have now updated their original "Physicists have built a wormhole and successfully sent information from one end to the other." tweet. New one reads "Experimental physicists built the mathematical analog of a wormhole inside a quantum computer by simulating a system of entangled particles."

Update: Today at HEPAP the Fermilab director was prominently advertising the wormhole publicity stunt as a Fermilab initiative (see slide 67 here). She describes future plans for more of the same, with these calculations being performed not on one quantum computer, but on two spatially separated quantum computers connected by a quantum network. This would somehow allow for a big increase in the "quantum gravity in the lab" hype with a new Nature cover story: "FNAL scientists connect two quantum computers by a wormhole between two labs". A question for those in the "It from Qubit" field. Are you willing to contact those responsible for funding this, who are now prominently advertising this work as a major success and new direction of research they intend to fund (e.g. Glen Crawford at DOE, and Lia Merminga at FNAL)?

Update: 4gravitons has a blogpost about the Quanta article, concentrating on the issue of "tone" of the coverage. That's relevant for the usual problematic sort of physics coverage, but in this case something much more unusual is going on. This was a well-organized publicity stunt designed to justify funding "quantum gravity in a lab" research. Quanta was taken in more so than many other journalism venues. But the really disturbing part of this story is who else was taken in: the IAS director, the Fermilab director, the DOE division director and others, who are sophisticated consumers of science journalism, and independently getting their information from senior scientists in the field.

Comments

1. **Sabine Hossenfelder**
   December 7, 2022

   The worst are the people who've been brainwashed by the "experts" but don't themselves understand enough of the topic to actually have an own opinion. Like Lockyer going on about naturalness and why that means bigger colliders will find something (see here). I actually wrote to him asking what he was going on about in this interview just to make sure. In explanation he sent me a link to a blogpost by Matt Strassler, not kidding.

   Scott is asking what went wrong and what can be done about it. I know I sound like a broken record, but here we go again. Large communities of likeminded people are affected by social reinforcement, aka, group think. This, I cannot stress often enough, is a well documented phenomenon and, no, intelligence does not protect from it. The more you hear other people talk about X, the more you think X is important, and the more you yourself will talk about it. In the end, everyone thinks X is great and important because everyone else thinks that, not because it's actually important.

   (I actually suspect the problem is worse among intelligent people because they believe they're too intelligent to be affected, but that's just a conjecture on my part.)

   It's easy enough to address the problem: Give every scientist a basic education on the sociology and philosophy of science, and social and cognitive biases. I believe that if they think about it, they should realize they don't actually want to waste their time on research that will turn out to be entirely irrelevant. Though there is a case to be made that it makes money and popularity in the short run, I don't think it's what most of them are driven by.

   I have a longer list with recommendations for what can be done by scientists, higher-ed admin, policy makers, and members of the public in the appendix of my 2018 book which is available here.

2. **Pascal**
   December 7, 2022

   What went wrong: it is probably not a coincidence that this is happening in fundamental physics, where actual progress has been rather slow for several decades (according to some of the blogs I read).

What can be done about it: change the system so that people do not have to overhype their results in order to find a job / keep it / get funding. A tall order, perhaps.

3. **David Roberts**
December 7, 2022

Wow. Just wow. I really, really want to ask the journalists involved if they can hear this, and then think they communicated the result properly. This is not Jo Bloggs who gets science news fourth-hand on Facebook. This is someone who should be able to go and ask the experts down the hall to explain at length over coffee.

4. **vmarko**
December 7, 2022

Next time I read a Quanta article, whatever the topic, the first thing I'll put in my comment is "And did they also create a wormhole in the lab?"

I'll stop when I see a meme on the net along the lines "Chuck Norris creates a wormhole…". 🙂

5. **martibal**
December 7, 2022

After dinner speech… maybe D. Nirenberg were just a little drunk 😉
or is there something rotten in the kingdom of Princeton ?

6. **Mark Hillery**
December 7, 2022

Yesterday in my intermediate mechanics class a student pulled out a copy of the latest Nature issue and asked about the wormhole article. He had some very good questions, which indicated that he was pretty suspicious of what he was reading. I was able to confirm his suspicions and explain that most of the claims in the article were nonsense, and that Nature had been hoodwinked.

Toward the end of my time as an editor at Physical Review A (15 years was quite enough, thank you), we started getting papers where all the authors had done was run something on a quantum computer. Sometimes this was even phrased as, "We did an experiment." Real experiments are hard work, and running something on a cloud quantum computer does not count. Claiming you created a wormhole is worse. Most of these papers were rejected out of hand. If the paper contained something new that was run on a quantum computer as an illustration, that was different. On that basis, and, for the moment, ignoring the hype, the "wormhole" paper would probably be publishable in Physical Review D (this is a guess, I know nothing about quantum gravity, and I don't want to speak for the PRD editors). The hype, however, is appalling, and it is clearly causing a lot of damage, which will only get worse when people realize how vacuous the claims are.

7. **NoGo**
December 7, 2022

Oh yeah, a lot of people were taken in by this publicity stunt.

In the comment section under the Ars article I pointed out the reaction of specialists, including Peter Woit and Scott Aaronson, to the stunt — with quotations and links. (I definitely did not try to pose as an expert myself)

I've got angry responses, attacking me and the experts, some saying that these reactions were "dumb" etc.

Out of curiosity I've checked the comment history of the people responding in this way. They seem to be intelligent techies, who made thoughtful and informed contributions to discussions of computer and technology topics, not some trolls.

I don't think that these people are going to be convinced by blogs like this one; at this point only serious pushback by media and (ideally) the scientists involved in that research can help…

8. **Laurence Lurio**
December 7, 2022

I agree, this has gotten out of control. Perhaps it might be appropriate to contact the American Physical Society. Is there any way someone with some clout in the field could draft a letter and then invite cosignatures?

9. **Anonymous Referee**
December 7, 2022

Mark Hillery,

Some of the papers that you did not reject out of hand came to me to referee. I then rejected them. The most ludicrous was one claiming they had done an experiment with indefinite causal orders by implementing a causally ordered quantum circuit in a causally ordered quantum computer.

10. **Peter Woit**
December 7, 2022

Sabine,
I think you're right about the group-think problem, but in this particular case there's something else even more disturbing going on. Most of the people in this field are well-aware the wormhole thing was a publicity stunt, but saying so publicly, or doing anything about it more privately, would carry personal costs they are not willing to bear. The main author of the stunt, Spiropulu, has spent four years working on it, funded by a DOE grant. Getting a "physicists create wormholes" headline in this case (unless it blows up in her face…) carries major professional and financial rewards, which may have a lot more to do with this than group-think.

Scott describes the quantum gravity research community as "grinding its teeth and turning red in the face", but not as doing anything. I gather no one spoke up at the time to publicly tell Nirenberg he had just embarrassed himself and the IAS by being the victim of a publicity stunt. Did anyone explain this to him in private later? If not, could it be not groupthink, but not wanting to take the professional cost of being the one to explain to someone in a powerful position that you and your community have a serious hype problem, highly damaging to his institution, which it is unwilling to do anything about?

11. **Alex**
December 7, 2022

Allow me to seriously doubt about the sincerity of these "teeth grinding" and "red faces" that Scott reports. I mean, this has been happening in the field for years, many of them probably contributed with both nonsensical research and hype themselves, but now suddenly they feel ashamed? I think they are actually feeling shame because of how grotesque and caricaturesque it all resulted at the end. I bet that, in their minds, they were hoping for something much more serious, credible and professionally looking. But, alas, it's just the mirror: sometimes it gives you back an image which ain't pretty… if you have nothing to offer to it, the mirror cannot do magic and put substance where there's none.

12. **Adam Treat**
December 7, 2022

    The entire reason this happened is because the general public – which is illiterate on the subject matter at hand – passionately wants to believe that their science fiction dreams are becoming real. The editors/writers at Quanta, the NYTimes, Reuters, and ABC perfectly understand this is the hook for their audience: report that their science fiction dreams are slowly becoming real and make money by feeding this audience.

    The purveyors of this hype – whether it was the experimentalists or the theorists or both – who actively drove Quanta and these other media outlets to write about it – knew perfectly well the incentives at play. Had they soberly explained the research and not hyped it, then it would not have gotten the worldwide media fame that it has gotten them. Whether there is self-deception here on the part of the scientists I can't say. But the whole field does take a hit when that eager audience for their science dreams come true realizes they were bamboozled.

13. **Peter Woit**
December 7, 2022

    Adam Treat,
I think you're partially blaming the victim here. If physicists actually created wormholes in a lab in Santa Barbara, most people would sensibly be interested in hearing more about this. The problem isn't an illiterate and unsophisticated general public, since the people believing this include the IAS director, a Pulitzer prize-winning science journalist and editors at Nature. Best to put the blame where it belongs: those directly responsible for the stunt, and the larger community of researchers which enabled them.

14. **Geoff Penington**
December 7, 2022

    Scott is someone who enjoys science communication, is good at it, and is willing to devote significant time to it. As a result, he has a blog where he publicly posts his opinions on things like this. Most physicists do not have a blog, do not regularly engage in science communication and so did not publicly comment on the article or hype. If everyone working in the field other than Scott should be blamed for this whole mess, is your claim that any practising physicist has a moral obligation to make a blog? That takes a lot of time, effort and skill as I assume you know.

    As someone in the field, I have been on multiple emails threads in the last week about how embarrassing a failure of science communication this was, and how we need to get better at communicating to journalists to avoid such events in the future. I was also at the dinner with Scott last night and there was loud heckling throughout the talk (think: "I don't know whether this will be as impactful as the eclipse observations in 1919" "I really think we do") to an extent that I have never seen or even imagined was possible in such a setting.

    I certainly don't blame David at all, and clearly as a field we have some collective responsibility to not let stuff like this happen. But all the actual It from Qubit researchers quoted as independent experts (Scott, Dan Harlow etc.) made skeptical comments, and even the authors of the paper who actually work in the field were not the ones saying completely ridiculous stuff. Daniel Jafferis gave a nice and entirely reasonable talk on the paper this Monday. In particular, I'm not really sure what the vast majority of people in the field, who all first learned about the paper when they saw the quanta/NYT articles, were supposed to do to prevent this whole thing.

15. **JT gravity**
December 7, 2022

    "If everyone working in the field other than Scott should be blamed for this whole mess, is your claim that any practising physicist has a moral obligation to make a blog?"

    I believe there exists a serious (very serious) fallacy in this "argument."

16. **Peter Woit**
December 7, 2022

    Geoff Penington,
I've also been having multiple email threads the past few days about this, with people's position either "nothing wrong here" (IAS and Quanta point of view) or "yes, this was bad, I don't see anything though I can do about it". Scott's taking a "this is bad and I'm trying to do something about it" position is an exception.

    My comments blaming all involved in this except Scott should be taken in that context, and in the context of unsuccessfully complaining about disturbing levels of hype in this field (string theory – > AdS/CFT -> "It from Qubit") for decades, watching it getting worse and worse in recent years. This past week it has gone off the charts on the crazy meter.

    I agree that not everyone should be out there making public statements about this. But if people don't want to get blamed for craziness in their field, they should do something. Here's one example: personally I believe Quanta should pull the article and video from their site and re-report this story properly. Thomas Lin (Quanta chief editor) made the argument to me that he would not change anything about their coverage because he was not hearing from quantum gravity experts that there was a problem with it. Why not? Whenever a publication covers your field of expertise and gets it very wrong, why not write to the editor and argue that they should fix it? My impression is that everyone (except Scott…) is saying "someone else should do that, not me, not my responsibility, I don't want the cost in time/energy/making enemies that I'd incur".

    Another comment: I think your problem is not so much being bad at communicating with journalists, but rather not being willing to take on those in your midst who are very good at communicating with journalists, but do so to self-promote and push bad science.

17. **Amitabh Lath**
December 7, 2022

    Peter, no. I do not believe Jafferis and members of his group are to blame, and I do not think you do either. While they had some control over the contents of the Nature article they cannot prevent their co-authors from beclowning themselves on the popular media forums.

    I brought this up with some eminent Rutgers theorists and their consensus is that the questions Jafferis et al are asking about a small group of interacting fermions that mimic "…(some sort of) (TWO DIMENSIONAL) quantum gravity with a wormhole…" is not crackpot stuff. (All caps theirs!)

    Unsaid but implied: calling the implementation of this on a computing device (of any sort) a "crummy wormhole" is crackpot.

    I agree with Scott Aaronson: let's not tar everyone on the author list with the same brush.

18. **Ken**
December 8, 2022

For those who say that the authors are not to blame: Has anyone watched the video clip released by Quanta (https://www.youtube.com/watch?v=uOJCS1W1uzg) in which the authors kept crying "wormhole", "wormhole", "This is a wormhole. I think I just saw one", "I think we have a wormhole, guys", "I never really believed that we'd get all the way to something that was real"…? Should we blame the popular media people for what the authors said in the video clip? Am I missing something?

19. **Attendee**
December 8, 2022

Amitabh, you should ask your theory friends if they can derive Newtonian gravity by studying these small group of interacting fermions.

The fact that theorists feel duty bound to defend this garbage even in private discussions is disturbing.

That is the actual sad part of this story. Maria is a publicity seeker and thus easy to condemn. But, she was encouraged by all of these theory people to do this experiment since they claimed they were going to learn something deep about quantum gravity from it. Sadly, she is not the only experimentalist who has been misguided. There are quite a few groups around the world doing this sort of work (using cold atoms etc.) and there is nothing to be learned from these experiments – the experiments will work as predicted by well understood quantum mechanics and it is then "reinterpreted" in fancy holographic language.

20. **Peter Shor**
December 8, 2022

First, let me say that I hardly understand this stuff at all, so I may easily be missing things.

But I am puzzled by something here. Looking at the *Nature* paper, Eq. 1 is essentially the original SYK model, where you construct a Hamiltonian on Majorana fermions that contains all four-element terms, and you give each one a random Gaussian coefficient. When I first heard about the SYK model, if my memory is correct, this was described as either a zero-dimensional or an ∞-dimensional theory.

With the AdS-CFT correspondence, the dimensionality of the dual should differ from this number (0 or ∞) by 1. But the article clearly says that the dual is a 2-dimensional theory (as do some of the commenters here). What am I missing? Could somebody who knows something about the SYK model enlighten me?

And another question: It takes quite a bit of work to make things behave like Majorana fermions on a quantum computer. How did the authors manage to do this? Or did they just use ordinary distinguishable qubits instead? Would doing this change the dynamics of the system so that it's not actually equivalent to teleporting through a wormhole? (The teleportation protocol itself should work fine whether you're using Majorana fermions or plain distinguishable qubits.)

21. **Peter Woit**
December 8, 2022

Amitabh Lath,
Sorry, but I do think Jafferis in particular has a lot to answer for here. Yes, his part of the paper may be the part that contains some non-trivial science, but he has played a significant role in the publicity stunt aspect of this. He appears in the ludicrous Quanta video, the promotional podcast, and is quoted in the Quanta article as claiming that the stunt shows "a filament of real space-time". If he has any problem with the way he has been used in the publicity stunt, I haven't seen any evidence of it or heard privately anyone mention this.

Perhaps more significantly, the stunt was organized by Spiropulu, who recruited him as co-PI on a DOE grant that has funded them and the stunt. The stunt is now being advertised by DOE as a great accomplishment (this is happening today, at a HEPAP meeting, audience other funding agencies and top people in HEP, see page 7 of this presentation: https://science.osti.gov/-/media/hep/hepap/pdf/202212/Crawford_DOE_HEP_Research_Program_Status_HEPAP_202212.pdf)

So, from what I can tell, Jafferis has been deeply involved in the misleading publicity stunt, has been getting paid to do so, and has shown no signs of having any problem with it. I think it's perfectly fair to blame him.

22. **Leo**
December 8, 2022

Peter Shor, the SYK model has time in it (space is a point) so it is a 0+1 dimensional theory being the boundary theory of a 1+1 dimensional gravitational theory in principle.…

Geoff Penington, I appreciate you commenting on this blog which is much more than what most of your colleagues do. Consider a "hypness index" = [Influence x Exposure]/ [Achievements] , then the hypness index of the "it from quibit" community is 2 orders of magnitud above any other field in physics, specially after this stunt. Also think of the following: If any government agency gives a lot more money after this stunt to your community, will anybody within it come out and ask for moderation? Your colleagues may grind their teeth as Scott says but they will gladly take the extra money that comes from this and forget why they got it. You may say that every community has this hypocrisy problem but by my made up hypness index the most insulting and in urgent need to correct case is the "it from qubit" one.

23. **Peter Shor**
December 8, 2022

I figured out the answer to my first question: the wormhole is 2D because it has one dimension of time and one dimension of space, since the SYK model has zero dimensions of space.

I still don't know the consequences of replacing Majorana fermions with ordinary distinguishable qubits in the SYK model.

24. **JT gravity**
December 8, 2022

Well… it should be well-known that there is no m=0,s=2 particle in the representation theory of Lorentz group SO(1,d) for d=1,2, hence no propagating DoF's in d=2,3, thus it's questionable if it makes sense to speak of gravity theory in low-dimensions; unless one is considering near-extreme solutions of the d=3 theory. But, then, all work on JT gravity relies on heavy Wick rotation, and reading Witten+Stanford paper, https://arxiv.org/abs/1907.03363, you see computations of Z in the JT theory with genus g!=0 in Euclidean signature, so, there's not well-defined Lorentzian structure on their computations. Hence, no graviton DoF's propagating in their calculations, and it's not even clear if one can recover the Lorentzian manifold structure in the end.

But if this seems already bearing on the absurd, the JT/SKY pseudo correspondence is based on a NEARLY AdS2/CFT1 "duality." So, these It from Qubit people are studying an approximation of a toy model of an approximation of a theory which is not even clear whether it corresponds to any gravitational theory at all.

25. **Amitabh Lath**
December 8, 2022

Attendee: I believe you may be misconstruing what my Rutgers theory colleagues said about this work. They remain skeptical about the main claim, but do not claim any expertise on SYK connections to QI, so from what I gather they are driving past this car wreck after giving it a short glance, without slowing down to consider it in too much detail (this is a skill you develop driving in New Jersey).

Peter: I do not know Jafferis and cannot speak to his inner thoughts and opinions. I did not watch the Quanta video but surely we can make a distinction between appearing in a video and saying something (maybe) impolitic and imprecise about "filaments of spacetime", and what Lykken is doing going on about having created actual wormholes. A lot of my colleagues think very highly of Jafferis (he was a PD at the Rutgers NHETC) and as a community we would be better off not excommunicating him and members of his group.

26. **Peter Woit**
December 8, 2022

Amitabh Lath,
I'm not suggesting "excommunicating" Jafferis. He's a tenured full professor at Harvard and will do fine. He has though clearly signed up as co-organizer of the publicity stunt. If it succeeds he'll be rewarded, if it blows up in his face he may suffer some reputational damage, and I'll have trouble feeling too sorry for him about this.

As for the junior people in this collaboration, they're not responsible for the hype/publicity stunt aspects. Some of them will though have tough decisions to make about how to pursue a career and try and find a permanent position. If the "quantum gravity in the lab" hype works and that's where positions are, their best bet would be to go along with that. If it blows up and gets discredited (I'm doing what I can…) they should be looking for different sorts of projects to work on and stay away from this kind of over-hyped activity.

27. **David Roberts**
December 8, 2022

Since there seem to be relevant experts here, what is the (local) topology of the 1+1d spacetime with the SYK wormhole? It's a Lorentzian surface, with boundary I guess, so it should be possible to get a concrete handle on it, no? Pun not intended…

28. **George H.**
December 8, 2022

Just a lurker, x-experimentalist; I would have heard nothing of this if I didn't follow SA's blog. So the general public(GP) knows nothing (IMHO), however the general trust I see in the GP is at an all time low, and this just increases the mistrust. Citation rankings reward fame, so to succeed in science you need fame, which rewards hype, and you all forgive that… because they are just trying to succeed in the fame game. I often think that so many problems are related to having the wrong feedback variable.

29. **James Smith**
December 9, 2022

I have to say that the spectacle of tenured academics calling the general public illiterate and unsophisticated in this instance I find a little ironic.

Various and Sundry

December 8, 2022
Categories: Uncategorized

If you're sick of hearing about bogus wormholes, here are some other random topics:

- There's a SCOAP^3 for books initiative, lots of textbooks in the field of particle physics now made open access and available here.
- It's completely mysterious to me why this is so, but Mochizuki's failed proof of abc is now getting promoted at various places outside Kyoto, including Stony Brook, France (note what comes first in the suggested survey articles) and maybe even Oberwolfach.
- One thing I've never understood about the dark matter story is whether just having right-handed neutrino fields (which fit very well into the pattern of fields of the Standard Model) is enough to get fundamental physics to be consistent with astrophysical observations usually interpreted as evidence of dark matter. Stacy McGaugh despises this kind of idea, where you predict particles with only gravitational interactions, making fun of it here as The Angel Particle. He has a specific agenda (modified gravity), which I think explains the vehemence.

  Ethan Siegel has an extensive discussion of gravity-only dark matter models, under the title Is dark matter's "nightmare scenario" true?

  John Baez has a blog post on Neutrino Dark Matter, based on talking to Neil Turok about this recent paper by Boyle, Finn and Turok.

- The National Academy has appointed an EPP-2024 committee, which has been holding various meetings. Taking a look at some of the videos, I was struck by what Lisa Randall (about 34:00-38:00 and 46:00-48:00) and Nima Arkani-Hamed (about 48:00-53:00) had to say in this one. They both emphasized the problem that it is hard for young theorists to make a career for themselves by trying to come up with a new idea, as opposed to a series of small improvements on ideas currently being pursued by many other people (often things that have been around for a long time). This I think has been a huge problem in the field for a very long time, possibly has gotten worse for some reason in recent years, and is part of the explanation for the moribund state of the subject. While they eloquently state the problem, unfortunately I don't see much from them or anyone else about how to do something concrete to address it.

Comments

1. **Mark Weitzman**
   December 8, 2022

   Thanks for the SCOAP link – what a fantastic resource – you have now expanded my list of unread theoretical physics books by 33%.

2. **Frank**
   December 8, 2022

   Did you notice that none other than Maria Spiropulu is co-chair of the EPP-2024 committee?

3. **Peter Woit**
   December 8, 2022

   Frank,
   Yes. Other fun fact: that video I watched and linked to was recorded on Nov. 30, the day of the wormhole announcement. From what I saw, I thought Spiropulu did an excellent job of chairing the meeting, especially considering that she likely had other things on her mind that day.

   But, I was trying to make this posting wormhole-free…

4. **Dimitris Papadimitriou**
   December 8, 2022

   E. Siegel's " nightmare scenario" article considers only one possibility (the "wimpzillas"). But there are other candidates for gravitation – only interacting dark matter like primordial black holes, or proposals about quasi-stable black hole remnants (assuming that Hawking evaporation stops near the end stage), or Penrose's proposal.
   It goes without saying that most (if not all) of these scenarios are more or less speculative, but the same holds for many other proposals that have to do with this subject (including modified gravity and the like).

5. **Norbert**
   December 8, 2022

   Well, at least at Stony Brook the promotion comes with some caution « Dr. Fumiharu Kato (…) spent some time explaining the approach of professor Shinichi Morizuki to prove it. We want to caution those watching the video that at the time of the lecture there is no universal consensus in the mathematical community that the ABC conjecture is proven. Some details and references can be found in https://en.wikipedia.org/wiki/Abc_conjecture. »
   Best

6. **Marty Tysanner**
   December 9, 2022

   Stacy McGaugh despises this kind of idea, where you predict particles with only gravitational interactions, making fun of it here as The Angel Particle. He has a specific agenda (modified gravity), which I think explains the vehemence.

   In reading various blog posts and a few papers of his, I have found Stacy to be knowledgeable, fair minded and intellectually honest. My understanding is his disagreements with the theoretical cosmology community center around the willingness of many theorists to overlook data that disagree with the standard cosmological model (LCDM), who propose *ad hoc* "solutions" when observations/data disagree with simulations, who introduce unmotivated particles and fields for dark matter when the best motivated candidates (e.g., WIMPs) are ruled out or are no longer plausible, and yet who willingly ignore or denigrate modified gravity proposals that actually predict a wide range of phenomena that LCDM cannot naturally explain or that conflict with dark matter simulations.

   From his writings, Stacy sees dark matter theory as a moving target that can always be fixed by introducing new hypotheses or fine tuning existing parameters whenever conflicts with observations arise, essentially avoiding falsification of dark matter as an explanation of observations. This theoretical "approach" probably looks familiar to you from your own observations of many HEP/BSM theorists.

   What Stacy calls "angel particles" — particles that interact gravitationally but in no other way, effectively rendering them unobservable and non-falsifiable — would be another example of avoiding conflict between observations and dark matter theory without abandoning currently held views.

Stacy seems well aware that the key reason modified gravity is so disagreeable to cosmologists (beyond its conflicts with the approach they have devoted much of their careers to) is that it does not fit nicely with GR. And since GR is a very well tested theory that forms a backbone of fundamental physics, it is really problematic to propose without very strong evidence that GR is wrong in a domain where it is expected to be valid. He freely acknowledges in his blog posts that if one starts with GR as a governing fundamental theory for galactic scale structure and beyond, the need for dark matter is unavoidable. He says he, too, was strongly in the dark matter camp during the first part of his career, but repeated conflicts between observational data and dark matter phenomenology caused him to gradually change his thinking.

So I'm not sure it's really fair to say "He has a specific agenda (modified gravity)."

One thing I've never understood about the dark matter story is whether just having right-handed neutrino fields (which fit very well into the pattern of fields of the Standard Model) is enough to get fundamental physics to be consistent with astrophysical observations usually interpreted as evidence of dark matter.

I'd be surprised if this is an unexplored idea. Why not ask Stacy if he is aware of observations that strongly disfavor or rule out the idea, assuming you have an idea/proposal for the neutrino mass? How would you test the idea observationally so that it is more than metaphysics, especially since we don't currently know if right-handed neutrinos actually exist?

7. **Dimitris Papadimitriou**
December 9, 2022

Marty Tysanner

The same objections you mentioned about DM are also equally valid for modified gravity proposals:
Those alternative theories that incorporate additional fields/ forces are obviously associated with unknown particles that need to be detected for any of these proposals to be tested and confirmed. So we can't avoid the need for detection of unknown particles even in that case…
Another alternative (for those who try to avoid this) is theories with massive graviton(s) that are already on the verge of falsification.
Moreover, the so far proposed MOND -oriented models need also DM as an addition, to explain observations, (I think that most MOND proponents admit that) so they're just complicating things further.

Also, I'm not sure I'm following the reasoning about the "falsifiability" of only gravitationally-interacting DM:
Only detection via any of the three interactions of the standard model of particle physics is " legitimate " for the confirmation of existence of DM?
Gravity does not count as an interaction? What about alternative hypothetical "purely gravitational" theories without additional fields? Are they unfalsifiable too?
Gravitational effects (lensing etc) do not count?

Ok, exactly because gravity is so "weak" there's a need for additional observations, nobody disagrees with that.
But these criticisms seem to me a bit over the top.

8. **clayton**
December 9, 2022

As a dark matter phenomenologist, let me just remind everyone that the _primary reason_ to believe in the phenomenon of cold dark matter is the _very high precision_ with which we measure the CMB power spectrum, especially modes beyond the second acoustic peak. There is a stone-cold, qualitative, crystal clear prediction of CDM about the relative sizes of the second and third peaks that modified gravity _profoundly and irremediably_ gets wrong: it thinks the third peak should be relatively larger than the second (due to the difference between compression and rarefaction — see Wayne Hu's tutorials for pictures), whereas CDM thinks they should be about the same or the third peak should be lower. They are, in fact, at _very high precision_ about the same. All the thousands of other modes confirm this picture (now up to ell of 2000 which hardly any deviations), but this _simple, qualitative fact_ is to me the most convincing way to see that we need a new matter-like field. Any talk I've ever seen by McGaugh (or more exotic modified gravity people like Verlinde) elides this fact, and they evade the questions when I put my hand up to ask. I have invited McGaugh to a conference before specifically to discuss this point, and he just doesn't want to.

In fairness to McGaugh, he pointed out some very interesting features of galactic DM distributions that do deserve answers. But it turns out that there are a plurality of possibilities, from complex DM physics (self interactions) to unmodelable SM physics (stellar feedback, galaxy-galaxy interactions). There are no such alternatives to CDM to explain the CMB power spectrum.

As to Peter's question of whether right-handed neutrinos could be the DM particle — sure, but you still have to explain why they're generated in the quantity we measure from the CMB (this isn't trivial). But yes, this is a credible possibility, the details of which are elaborated every day on the hep-ph arXiv. And interestingly, such models can have similar features to the self-interacting CDM mentioned above.

9. **Peter Woit**
December 9, 2022

Marty Tysanner,
I have followed Stacy McGaugh's blog for a while, much of his critique of dark matter models seems well-argued. This particular argument though seemed to me very unconvincing, partly because the ratio of sneering polemic to serious content was high, partly because right-handed neutrinos seem to be an extremely well-motivated theoretical idea, and particles with only gravitational interactions are not at all unobservable (they may very well be exactly what explains galaxy rotation curves, CMB peaks, etc).

If you want to argue against a massive right-handed neutrino model of dark matter, to me you need a much more serious argument.

clayton,
Thanks for your comments. I've always assumed this was a well-studied topic in the field, just never have had the time or energy to look into this. Two problems I wonder about are, given just the SM with right-handed neutrinos, and what we currently know about mass terms (from Higgs couplings)
1. can you get the right amount of dark matter production in very early universe models?
2. in the later universe, is the way this dark matter evolves consistent with everything you observe?

10. **Stacy McGaugh**
December 9, 2022

Hi. This is an interesting discussion. I think it goes a long way to illustrate how much we take for granted in our own experience that is not shared with others.
My distaste for the angel particle has nothing to do with right-handed neutrinos or any position on modified gravity. It has everything to do with my lived experience with the search for WIMP dark matter, in which the goalposts have been moved time and time again – chiefly to lower interaction cross-section. So, I reasoned (long ago – see this 2008 page: http://astroweb.case.edu/ssm/darkmatter/WIMPexperiments.html), that the obvious culmination of the failure to detect dark matter would be to come up with a particle that was utterly undetectable. This might be true – who could tell? – but it is also the logical (and predicted) extrapolation of a failed hypothesis. I do indeed sneer at the latter.

Right-handed neutrinos are a specific kind of particle that does make a certain kind of sense, as described here. I've nothing against that. There is, however, no guarantee that, should they exist, they have anything to do with the dark matter problem.
I take considerable umbrage at the presumption that everything I say can be attributed to an agenda in favor of modified gravity. That is simply not correct. It isn't my theory.
It may surprise readers to learn that I was an advocate of dark matter before I ever heard of MOND. What changed, for me, was that MOND made predictions that came true in my data. So, I changed my mind: perhaps I had been wrong to be so sure that the answer had to be dark matter and couldn't possibly be modified gravity. This was an excruciatingly painful admission, but isn't that what we're supposed to do as scientists?

11. **Stacy McGaugh**
December 9, 2022

OK, now to answer Clayton. I don't recall ever refusing to discuss the CMB at a conference. I have done so many times. Nor have I done as he says, and "elided" the phenomenology he describes in the CMB. Quite the contrary; I agree with most of what he says above and have said so on many occasions. I have lots else to say, so I can't fit into every talk something I don't have much to say about.
One thing Clayton elides is that I did make a prediction for the CMB peaks, both with and without dark matter, and it was the prediction without dark matter that came true. This has remained true in every data set as the CMB data have improved (see https://tritonstation.com/2020/07/31/second-peak-bang-on/). But it is also true that the ansatz I used to make the correct prediction for the second peak also predicts a smaller third peak. This is not observed, as he says, so maybe it was just a huge coincidence – or maybe that's just how far the ansatz could take us.
The presumption for a long time has been that no modified theory of gravity could get the CMB right. I have a lot of sympathy for that attitude. I have had just as much difficulty trying to get dark matter to explain observed rotation curves. It only does so at the level of "we need more mass." It does not do what MOND does in predicting what we get from what we see.
It is no longer true that it is impossible to explain the CMB and galaxy power spectra with modified gravity. Skordis and Zlosnik have done just that (arXiv:2007.00082). I don't know if that is the right theory, but it is at least a demonstration that what was thought to be impossible can be done. It is simply not correct to say that there are no alternatives to CDM to explain the CMB power spectrum.

12. **Peter Woit**
December 9, 2022

Stacy McGaugh,
Thanks for your comment and apologies for misrepresentation of your position. I had been following some of the same goalpost movement in the context of SUSY models. Over the years one can find endless plots of "SUSY predictions" on plots of dark matter limits, always extending below the current limits, but within reach of the next generation experiment. This kept going over many generations of experiments, and many orders of magnitude improved limits. In recent years I've stopped looking at these things, since I think most people have now given up on this.

On dark matter research in general, it's a huge and confusing topic. I'm aware of the time and effort it would take to master the subject and have well-informed views, and it's time I don't have. I've followed your blog with curiosity, the idea that there's a problem with the conventional wisdom is one I'm not unwilling to believe, given my experience in the rest of HEP theory. At this point not much I can do except to hope that better work and better data lead to a consensus. The reason for bringing this up here was mainly to ask for more information about what to me looks like the most theoretically attractive explanation.

13. **Marty Tysanner**
December 9, 2022

Hi Dimitris Papadimitriou,

Those alternative theories that incorporate additional fields/ forces are obviously associated with unknown particles that need to be detected for any of these proposals to be tested and confirmed.

Logically speaking, is this an example of "proof by assertion"? Modified gravity proposals (like MOND) modify the form of the gravitational interaction without adding new particles/fields to the already-known set. That doesn't mean that modified gravity proposals account for every observational fact, or even "make sense" from the standpoint of our current theoretical understanding, but those are different issues.

Only detection via any of the three interactions of the standard model of particle physics is " legitimate " for the confirmation of existence of DM? Gravity does not count as an interaction?

Since I'm not aware of suggestions that gravity can't be treated as an interaction, or that we can't infer physical facts from gravitational effects, I don't know how to respond other than "of course gravitation counts as an interaction." But that's beside the point.

If all you see are gravitational effects with no signature from any of the other three known interactions, what can you infer from it? If you put a thermally and electromagnetically shielded box on a sensitive torsion balance and measure the mass of its contents gravitationally, can you say, in a *practical* sense, whether the box contains a ham sandwich, a glass of water or a lump of an exotic new metallic alloy? Can you falsify the experimentalist's claim that the box holds an exotic alloy without opening up the box and examining its contents via a non-gravitational interaction?

Likewise, how can you meaningfully claim observation of any dark matter particle if said particle interacts only gravitationally? How can you *empirically* distinguish two hypothetical dark matter candidates, both of which only interact gravitationally?

14. **Marty Tysanner**
December 9, 2022

Hi Peter,

[…] right-handed neutrinos seem to be an extremely well-motivated theoretical idea, and particles with only gravitational interactions are not at all unobservable (they may very well be exactly what explains galaxy rotation curves, CMB peaks, etc).

Even with good theoretical motivation, how would one test the idea that right-handed neutrinos meaningfully contribute to dark matter phenomena if they only interact gravitationally? How can we empirically distinguish them from other possibilities, so that the idea can become more than a story we tell ourselves?

On a different note… Since I haven't studied the right-handed neutrino idea at all, please forgive me if the following question is naive. Presumably right-handed neutrinos would be included as a term in an expanded Lagrangian that includes the SM plus gravity (gravitons), and thus would be governed by a QFT. Hence there should be at least one interaction vertex for them, one that describes the necessary coupling to gravity. The question I have about the idea is the following: Is there an additional coupling whereby right-handed neutrinos are created in the early universe but not today, and if so, what might that coupling look like? Or does the neutrino/graviton coupling alone mediate the right-handed neutrino creation, with the required energy to create them only being available in the early universe?

15. **Peter Woit**

December 9, 2022

Marty Tysanner,
I'm not a cosmology or dark matter expert, maybe one can answer your questions. I have plenty myself, just know that the SM with neutrino masses to me most naturally has right-handed neutrino fields. About contact with observation, I'm assuming your cosmological model produces gravitation-only particles, they evolve and you get structure formation. Does this match what you are seeing now? I have no idea what the problems here are.

16. **Stacy McGaugh**
December 9, 2022

Hi Peter,
Thanks. I have bent over backwards to remain objective and address the data that people say I don't address (e.g., arXiv:1404.7525). There is just too much to know, and ultimately, which way we lean depends on how we weigh rather disparate lines of evidence.
Much of the discussion in the context of particle physics seems not to do this, and skip directly to "what could the dark matter be?" This is indeed an interesting question, but its phrasing also presupposes the answer. We've invented dark matter for good reason, but now that we have it wedged into our consciousness, how could we tell if we were wrong?
I see Marty is posing a similar question about distinguishing different types of non-interacting particles. That's a good question. My concern is that, and also more general: is the dark matter paradigm falsifiable?

17. **Felix**
December 10, 2022

The statement by clayton that stellar feedback and galaxy-galaxy interactions are 'unmodelable SM physics' might come as a surprise to all the people who've spent their careers modelling those things

18. **clayton**
December 11, 2022

to respond to Stacy (to whom I do want to reiterate my genuine admiration for pointing out many interesting features of galactic rotation curves) and Felix and anyone else — the CMB is a linear system that we are able to model at _extremely high precision_, and the predictions without CDM are _qualitatively wrong_. The CMB allows a precise measurement of the CDM and baryon densities independently because it is such a simple linear system.

Galaxies are not! Star-formation physics is incredibly complex and nonlinear. So perhaps it's a bit imprecise to say that galaxies are "unmodelable" — they are unsolvable in the same sense that the Navier-Stokes equations are unsolvable. Obviously, all such systems are modelable. But we simply do not have sufficiently good models at this time to make high-precision measurements of fundamental physics from them.

As for the Skordis and Zlotnik papers — they require a new field that carries a substantial energy density that redshifts like a^-3. It walks and quacks like CDM (even though it doesn't have perturbations like CDM, but they also don't solve for the matter power spectrum — another linear quantity that CDM gets right).

Some resources:
https://chrisnorth.github.io/planckapps/Simulator/# (click on the "Toggle power spectrum plot" button on the top right, the one that looks like a squiggle, and see how different the power spectra and the CMB maps look with and without CDM!)
http://background.uchicago.edu
https://arxiv.org/abs/1112.1320

19. **Maurice**
January 15, 2023

Dear Clayton,

Maybe you could try to enter the discussion with Dr McGaugh here https://tritonstation.com/2023/01/13/what-we-have-here-is-a-failure-to-communicate/

If not, well, silence is better than an answer, a confession.

Best,
Maurice

Wormhole Publicity Stunts: Past, Present and Future

December 9, 2022
Categories: Wormhole Publicity Stunts

Most of the news I'm hearing today about the current wormhole publicity stunt is that physicists who could do something about it are instead blaming any problem on journalists and defending the stunt as some sort of progress forward.

I've been wondering what the future for this kind of thing looks like, got a partial answer by looking at this presentation today by the director of Fermilab. On page 67 she explains

> Future experiments with better QC and with QCs connected through quantum networks, such as those under development at Fermilab, could provide better insight through better resolution and adding non-trivial spatial separation of the two systems.

So, next generation wormhole publicity stunts will involve, beyond going from 9 qubits to more, putting two quantum computers in two places and connecting them by a quantum network. The press reports will explain that physicists not only created a wormhole on a chip, but created a wormhole connecting two different labs.

I started looking for more information about these next-generation wormhole publicity stunts, and found instead something I hadn't been aware of, an older such stunt, described in Towards Quantum Gravity in the Lab on Quantum Processors, which got attention last spring not at Quanta, but in the much lower profile Discover Magazine, where one reads:

> The team developed quantum software that could reproduce wormhole inspired teleportation on both quantum computers and then characterized the results. "We have designed and carried out "wormhole-inspired" many-body teleportation experiments on IBM and Quantinuum quantum processors and we observe a signal consistent with the predictions," say Shapoval and co.

One reason for the lack of significant attention to this publicity stunt as opposed to the current one surely is the decision of the authors to claim not "wormhole teleportation" but "wormhole-inspired teleportation".

The past is the past, but it looks like the field of quantum gravity research is from now on going to be dominated by these wormhole publicity stunts, using more qubits and more quantum computers. This kind of research project is nearly ideal: you can get lots of funding from conventional sources like DOE, or even better, funding from and access to equipment at large tech companies like Google and IBM. You can convince the director of your lab or institute that you're doing research of significance comparable to the discovery and testing of general relativity 100 years ago and your work will be vindicated by cover stories in Nature and all over the rest of the media.

Back in 1996, in *The End of Science*, John Horgan worried that this kind of science would end up in a "speculative post-empirical mode", and quantum gravity theorists have for years now worried about accusations of not being connected to experiment. The solution to this problem is now clear: no one will take your wormholes seriously if they're just on paper, so the thing to do is to get them realized in an algorithm that you run on the most twenty-first century experimental hardware available, a quantum computer in a tech company lab.

Update: There was a hoax comment posted here last night, supposedly from Natalie Wolchover, which had me fooled for a while. Whoever was doing this seems to have been making excellent use of ChatGPT, together with manipulating other aspects of how the comment was posted that helped fool me.

Comments

1. **Alessandro Strumia**
   December 10, 2022

   In my opinion, worse than the overhyped wormhole was the overhyped 2021 Fermilab presentation of muon g-2 results as a 4.6σ anomaly, done ignoring one lattice computation that was in agreement with the measured value. Now ≈three lattice computations agree, so the g-2 anomaly is likely over, but the Fermilab director (in the recent presentation you link) still writes: "Muon g-2: Complete data production, analysis, theory to achieve 5σ".

   Furthermore, I don't understand the claim, in the same presentation: "U.S. is universally acknowledged as the world leader in neutrino science for decades to come". Main results come from Japan, and their future HyperKamiokande can be faster/better than DUNE.

2. **John Horgan**
   December 10, 2022

   Thanks for the shout-out Peter. The phrase with which I describe physics involving strings, multiverses and other untestable stuff is "ironic science," which should be considered more akin to philosophy or science fiction than science. This wormhole story seems like a fascinating example of it. The details of the "experiment" described in Nature are obscure to me, but here is how I understand it: The authors postulate that entanglement is carried out via wormholes. Then they perform quantum computations, which supposedly exploit entanglement. To emphasize the wormhole angle, they simulate a wormhole with their computations, and on that basis they claim to have actually created a wormhole, because entanglement entails wormholes. Is that right? If so, it's a spectacular case of question begging, in the sense of assuming what you set out to prove. And by the way, I am not an AI bot, this is the real, fully sentient John Horgan.

3. **Peter Woit**
   December 10, 2022

   John Horgan,
   I still think the best way to explain the problem is that the physics of a quantum computer has nothing to do with gravity. You can't do an experiment that has nothing at all to do with certain physical degrees of freedom, and claim that you are studying those other degrees of freedom experimentally.

   What's going on here is people muddying the waters because it sounds good, bringing in highly speculative and ill-defined theories (ER=EPR) about relations between the quantum computer physics and geometry of some space (which has nothing to do with our space-time), together with mixing up a simulation of a model and the physics being simulated itself.

   Relevant to your writings, what I wanted to point out is that many of the people involved in this have been getting beaten over the head for years about embodying the "post-empirical" part of the danger you were pointing to. What's going on here is basically a fraudulent attempt to claim that they have solved this problem, have found a way to experimentally investigate quantum gravity on a quantum computer, despite the fact that there is no relevant interaction of the experiment with gravitational degrees of freedom.

4. **Scott Aaronson**

December 10, 2022

Complicating the discussion is the fact that there really are toy models of quantum gravity for which it's currently intractable to calculate what they predict, and there really is some hope that a 100- or 200-qubit quantum computer could help with that. Indeed, because of the extreme simplicity of the toy models (typically just an array of qubits subject to some time-independent Hamiltonian), this might even be one of the *first* applications of quantum computers to become technically feasible (for some definition of "application").

Of course, as shouldn't need to be said but often does, even if this program succeeds, the question will remain of what if anything those toy models say about the real universe. *Calculating the predictions* of the toy models can only ever be one part of an answer to that question.

5. **Feliz Kemal**
December 11, 2022

Dear Peter,
As you rightfully pointed out the authors, at least the last author, love public attention. For instance, this experiment got so much media attention and it was covered everywhere as if they invented teleportation for the first time ever (look at the altmetric score)
https://journals.aps.org/prxquantum/abstract/10.1103/PRXQuantum.1.020317

However, teleportation experiments at telecom wavelengths have been around for decades, for instance: https://www.nature.com/articles/nature01376

What they did last year has improved the state fidelities etc. but the result is far from what is made out to be. For instance, they also speculate that their work would open the path towards integrating these teleportation systems with quantum memories, but even then that was done some 8 years ago:
https://www.nature.com/articles/nphoton.2014.215

6. **George Ellis**
December 11, 2022

John Horgan here repeats their mantra "entanglement entails wormholes." This is simply false. The EPR paper in 1935 had nothing whatever to do with a wormhole, it was a Minkowski spacetime calculation. Entanglement happens quite happily in flat spacetime, as has been experimentally proved. It could perhaps occur in traversable wormholes IF any were to exist in the real universe, which is highly doubtful. In any case the claimed equivalence represented in an "equation" of the form ER = EPR is not true. Don't fall for the propaganda!

7. **John Horgan**
December 11, 2022

Thanks guys, really helpful. Just one question: Are the particles in the 9-qubit Google computer, when they carry out a computation, entangled with each other? Is that why the Nature authors can claim that they have created an actual wormhole, and not just a simulation, because according to the ER-EPR conjecture entanglement entails a wormhole?

8. **Peter Woit**
December 11, 2022

George Ellis,
My problem with ER=EPR is not that it is untrue, but that it's meaningless, as about "not even wrong" as "not even wrong" gets. It's basically a conjecture that "maybe there is a duality between conventional QM and some unknown theory", but doesn't tell you what the unknown theory is (it's not conventional GR). What's going on here is a study of some toy model infinitely far from anything physical, but with some ER=EPR hoped for properties. The authors do completely standard calculations in the toy model on a classical computer. Then, they do again the simplest such one possible on a quantum computer, purely as a (very successful) publicity stunt.

9. **Peter Woit**
December 11, 2022

John Horgan,

The qubits in any quantum computer are entangled, that's the basis on which it works. It's also true that entanglement is everywhere in any quantum system. What's hard to do is not to create entanglement but to isolate the qubits so they don't entangle with the environment. See my comment to Ellis about ER=EPR: if you believe it, a quantum computer is a collections of wormholes (where the word "wormhole" is meaningless, since you have no idea what the dual theory is in which they supposedly exist).

The "wormhole" they are claiming is a name for something in the 2d gravity toy model dual to an SYK toy model. I have to advise you to not even try and understand exactly what this means and what this "wormhole" is, if you think you understand it I'll bet you're mistaken…. Such things have no relationship at all to physical reality, they're objects in toy models. Also nothing to do with quantum computers, which come into play here purely as a way to fool the rubes (such as the IAS and FNAL directors).

10. **John Horgan**
December 11, 2022

George Ellis, don't worry, I haven't fallen for the ER-EPR "propaganda." I'm just trying to understand how the Nature authors could possibly claim that their crude little simulation contains an actual wormhole. The only justification–and again, I don't believe it, I'm just trying to figure out what the authors believe–is that they assume the ER-EPR conjecture is correct, which implies that a real wormhole might underpin their quantum-computer simulation of a wormhole. Peter Woit, thanks for your clarifications, and cautions. I don't know if I'm going to write about this strange episode, but I enjoy trying to make sense of it, for my own sake if no one else's. Physics just gets weirder and weirder.

11. **vmarko**
December 11, 2022

By the way, even if one is a "true believer" in ER=EPR (as the authors of the paper supposedly are), this particular result is nowhere near the landmark for wormholes, nor a first one created. A quick google search says this about a world record for controlled entanglement:

"A team led by physicists Prof. Harald Weinfurter from LMU and Prof. Christoph Becher from Saarland University have now coupled two atomic quantum memories over a 33-kilometer-long fiber optic connection. This is the longest distance so far that anyone has ever managed entanglement via a telecom fiber. (Jul 7, 2022)"

That must be one hell of a wormhole, and moreover, inside a fiber optic cable! The media should have covered *that* wormhole, not this tiny one inside Google's processor… 🙂

However you frame it, the media outlets have been had. 🙂

Best, 🙂
Marko

12. **André**
December 12, 2022

Funnily, assuming one would take ER = EPR seriously, one would believe that the ‘real’ entanglement in the quantum computer is dual to some wormhole in some spacetime, whereas the hypothesized 2D wormhole is dual to entanglement in the simulated model.

So I guess an equally valid headline would have been: “Physicists simulate entanglement using Google’s wormholes”

Quanta might have been better off putting the qualifier in front of the ‘Physicists’ rather than the ‘wormhole’ when amending the title.

13. **Peter Shor**
December 13, 2022

@vmarko:

You say

> That must be one hell of a wormhole, and moreover, inside a fiber optic cable!

I don’t think that’s how wormholes work. A wormhole takes matter directly from the input to the output without going through the physical space in between.

Similarly, quantum teleportation takes the input quantum state directly to the output quantum state without this state being present anywhere in the physical space in between.

So clearly, by Occam’s razor, teleportation must work by transporting the quantum state through a wormhole. 😉

The New Yorker and the Publicity Stunt

December 12, 2022
Categories: Wormhole Publicity Stunts

The wormhole publicity stunt story just keeps going. Today an article about the Google Santa Barbara lab and quantum computer used in the publicity stunt appeared in the New Yorker. One of the main people profiled is Hartmut Neven, the lab founder and a publicity stunt co-author. He is described as follows:

> Neven, originally from Germany, is a bald fifty-seven-year-old who belongs to the modern cast of hybridized executive-mystics. He talked of our quantum future with a blend of scientific precision and psychedelic glee. He wore a leather jacket, a loose-fitting linen shirt festooned with buttons, a pair of jeans with zippered pockets on the legs, and Velcro sneakers that looked like moon boots. "As my team knows, I never miss a single Burning Man," he told me.

The article explains what has been going on at the Google lab under Neven's direction:

> in the past few years, in research papers published in the world's leading scientific journals, he and his team have also unveiled a series of small, peculiar wonders: photons that bunch together in clumps; identical particles whose properties change depending on the order in which they are arranged; an exotic state of perpetually mutating matter known as a "time crystal." "There's literally a list of a dozen things like this, and each one is about as science fictiony as the next," Neven said. He told me that a team led by the physicist Maria Spiropulu had used Google's quantum computer to simulate a "holographic wormhole," a conceptual shortcut through space-time—an achievement that recently made the cover of *Nature*.

There are some indications given that the wormholes aren't everything you'd like a wormhole to be:

> Google's published scientific results in quantum computing have at times drawn scrutiny from other researchers. (One of the Nature paper's authors called their wormhole the "smallest, crummiest wormhole you can imagine." Spiropulu, who owns a dog named Qubit, concurred. "It's really very crummy, for real," she told me.) "With all these experiments, there's still a huge debate as to what extent are we actually doing what we claim," Scott Aaronson, a professor at the University of Texas at Austin who specializes in quantum computing, said. "You kind of have to squint."

I took another look at the *Nature* article and realized that at the end it has a section explaining the contributions of each author (I'll reproduce the whole thing as an appendix here). For Neven it has

> Google's VP Engineering, Quantum AI, H.N. coordinated project resources on behalf of the Google Quantum AI team.

Two physicists profiled are John Preskill and Alexei Kitaev. Academia in this field is seeing a big impact of quantum computing jobs and funding. According to the article:

> Preskill and Kitaev teach Caltech's introductory quantum-computing course together, and their classroom is overflowing with students. But, in 2021, Amazon announced that it was opening a large quantum-computing laboratory on Caltech's campus. Preskill is now an Amazon Scholar; Kitaev remained with Google. The two physicists, who used to have adjacent offices, today work in separate buildings. They remain collegial, but I sensed that there were certain research topics on which they could no longer confer.

Someone told me that the Amazon lab where Preskill works has postdoc-type positions for theoretical physicists, salary about 250K.

Theoretical physics hype and quantum computing hype come together prominently in the article. Besides Shor's algorithm and its implications for cryptography, here's the rest of what quantum computers promise:

> A quantum computer could open new frontiers in mathematics, revolutionizing our idea of what it means to "compute." Its processing power could spur the development of new industrial chemicals, addressing the problems of climate change and food scarcity. And it could reconcile the elegant theories of Albert Einstein with the unruly microverse of particle physics, enabling discoveries about space and time.

How long until quantum computers unify GR and the Standard Model? We just need better, fault-tolerant, qubits, and then:

> A thousand fault-tolerant qubits should be enough to run accurate simulations of molecular chemistry. Ten thousand fault-tolerant qubits could begin to unlock new findings in particle physics.

The hype here is far hypier than any of the string theory hype I've been covering over the years, and it looks like it's got a lot more money and influence behind it, so will be a major force driving the field in coming years and decades.

Appendix:

The Nature contributions section is:

> J.D.L. and D.J. are senior co-principal investigators of the QCCFP Consortium. J.D.L. worked on the conception of the research program, theoretical calculations, computation aspects, simulations and validations. D.J. is one of the inventors of the SYK traversable wormhole protocol. He worked on all theoretical aspects of the research and the validation of the wormhole dynamics. Graduate student D.K.K.47 worked on theoretical aspects and calculations of the chord diagrams. Graduate student S.I.D. worked on computation and simulation aspects. Graduate student A.Z.48 worked on all theory and computation aspects, the learning methods that solved the sparsification challenge, the coding of the protocol on the Sycamore and the coordination with the Google Quantum AI team. Postdoctoral scholar N.L. worked on the working group coordination aspects, meetings and workshops, and follow-up on all outstanding challenges. Google's VP Engineering, Quantum AI, H.N. coordinated project resources on behalf of the Google Quantum AI team. M.S. is the lead principal investigator of the QCCFP Consortium Project. She conceived and proposed the on-chip traversable wormhole research program in 2018, assembled the group with the appropriate areas of expertise and worked on all aspects of the research and the manuscript together with all authors.

Update: John Horgan's take on the stunt is Physicists Teleport Bullshit Through a Wormhole.

Update: Quanta is still actively promoting their story that

> Physicists have purportedly created the first-ever wormhole, a kind of tunnel theorized in 1935 by Albert Einstein and Nathan Rosen that leads from one place to another by passing into an extra dimension of space.

with nothing on their site that indicates that this story has gotten an almost universally negative reaction from knowledgeable scientists. The one exception I've seen is Lubos Motl, who comments on the Quanta story. Lubos also engaged in a long exchange here with Matt Strassler. I had been worried about how Lubos was doing, it's reassuring to see that he's still out there, still himself, and still reliably defending the most indefensible products of string theory hype in his characteristic style.

Update: A surprising number of theorists seem willing to help hype the publicity stunt. See for instance this from Penn. It seems to me full of misinformation, for instance

> Heckman: In fact, the entire experiment could have been done on a classical machine; it just would have taken a lot more time.

In fact, the "experiment" was actually done on a classical computer, in a very short amount of time. For studying this kind of model, classical computers are hugely faster and more capable than any current quantum computer. Here they were used to search for a simplified version of the real problem that was easy enough that it could be done by the quantum computer.

Update: Dan Garisto on his blog has an article about the wormhole fiasco, originally intended for publication in SciAm. Garisto explains that SciAm was originally not taken in by the publicity stunt:

> I should tell you, when my editor at Scientific American sent me the embargoed press release on Thanksgiving with the subject line "Hmmm," I responded dubiously. "They used 9 qubits! What the hell could that possibly tell you?" We chose not to cover it—initially.

He also gives a correct description of what this really was:

> …the supposed bombshell dropped by the Nature paper is a calculation of an approximation of a model conjectured to be equivalent to a lower-dimensional gravity for a universe that isn't ours.

and challenges the misleading messaging from the scientists and from Quanta:

> Quantum message discipline is sorely needed. Clarifying their headline change, Quanta noted that "The researchers behind the new work — some of the best-respected physicists in the world — frequently and consistently described their work to us as 'creating a wormhole.'"
>
> When reached for comment, the study's co-leader Maria Spiropulu pointed to a Caltech FAQ in her team's defense. "Did we claim to have produced or observed a wormhole deformation of 3+1-dimensional spacetime?" the FAQ asks. The answer it then offers is a firm "No." The FAQ further elaborates that what the researchers saw was only "consistent with the dynamics of a traversable wormhole." The Nature paper is less absolute. There, Spiropulu and her co-authors describe their research as "the experimental realization of traversable wormhole dynamics on nine qubits" and discuss how they used a quantum teleportation protocol to "insert another qubit across the wormhole from right to left."
>
> And in a video produced ahead of publication by Quanta, several researchers spoke gushingly, saying, "This is a wormhole" and "I think we have a wormhole, guys." This is at best, deeply misleading.

He also has a quote from Natalie Wolchover which tries to explain the point of view which she (and others like Susskind) take that a quantum computer calculation of a toy mathematical model of a physical system is somehow really creating and doing a laboratory experiment on the physical system being modeled:

> Natalie Wolchover, a Pulitzer Prize-winning science writer at Quanta, argues that when a quantum computer simulates a toy model of quantum matter, such as the SYK model, it is really "creating" the quantum system it asks about. "It's profound but somehow I can't put my finger on what it means about the difference between 'real' and 'simulated,'" she wrote in an email.

This is complete nonsense, as Scott Aaronson tried to explain in the quote he gave for the NYT article about this:

> If this experiment has brought a wormhole into actual physical existence, then a strong case could be made that you, too, bring a wormhole into actual physical existence every time you sketch one with pen and paper.

   December 12, 2022

   I have finally watched the quanta video. On top of all the other problems, they have their history of wormhole physics completely wrong. They claim that Einstein was frustrated that the ER bridge was not traversable. But the idea to use wormhole to connect distant points in space time is not due to Einstein-Rosen'35 at all. It came much later, in the sixties, with the work of Wheeler and collaborators. The notion of a "non-traversable wormhole" is also due to these guys. In ER'35, a wormhole was a model of an elementary particle. Unfortunately, a neutron is much too small for Einstein or Nathalie Wolchover to jump through.

2. **Scott Aaronson**
   December 12, 2022

   By the usual standards for quantum computing popular articles that have prevailed for 20+ years, this one's not so bad. At least it talks clearly about the difficulty of beating classical computers in a fair comparison, and it focuses much more on quantum physics and chemistry simulation (which is indeed the best bet for near-term applications) than on doubtful uses in optimization, finance, and machine learning.

   For the record, in the quote from me, I wasn't talking about the wormhole claim, which hadn't even come out yet when Stephen Witt interviewed me, and about which I probably would've had stronger words! I was talking specifically about the quantum supremacy experiments based on BosonSampling and Random Circuit Sampling.

3. **John Pohl**
   December 12, 2022

   "Someone told me that the Amazon lab where Preskill works has postdoc-type positions for theoretical physicists, salary about 250K." Is this true? That is amazing money for a postdoc position.

4. **Peter Woit**
   December 12, 2022

   Scott (or anyone else),

   Any guess for the source for the claim about "ten thousand fault-tolerant qubits" as the threshold for getting something new in particle physics? Presumably this wasn't a randomly chosen number, but corresponds to some particular calculation on a quantum computer. Which one?

5. **Peter Woit**
   December 12, 2022

   John Pohl,
   Someone told me the 250K number. I just checked on Glassdoor, which shows

https://www.glassdoor.com/Salary/Amazon-Postdoctoral-Research-Scientist-Salaries-E6036_D_KO7,38.htm
231K (141K base, 27K bonus, 63K stock).

Yes, that's amazing money for a postdoc position. Also according to Glassdoor
https://www.glassdoor.com/Salary/Caltech-California-Postdoctoral-Scholar-Salaries-E22139_D_KO19,39.htm
the salary for a more conventional postdoc is 55K.

In the string theory hype story I never thought that money was what was motivating people to engage in hype. In this case I think it's clear money is a factor.

6. **Scott Aaronson**
December 12, 2022

@Peter Woit: I was wondering that too! I think it's plausible that, supposing you had 10,000 fault-tolerant qubits, you could do all sorts of simulations of interest for HEP. But I have no idea why the article gave that specific number.

7. **Peter Woit**
December 12, 2022

Scott,
I just realized this could refer to either simulating QCD better than usual Monte-Carlos, which could be a significant thing. But it might also be something like the SYK calculation, which supposedly was "quantum gravity in a lab", but wouldn't really tell you anything about the real world.

8. **David Roberts**
December 12, 2022

At my university, "coordinating project resources" isn't enough to officially be allowed to be an author. It has guidelines around how much people need to contribute to be an author on a paper, and merely bringing funding isn't enough, but I suspect these guidelines are sometimes treated as such, or else grant holders have a high-level project meeting once or twice, and give comments, and count themselves as having 'contributed' to the research.

9. **Peter Woit**
December 12, 2022

David Roberts,
Maybe rules are different when you're creating wormholes.

10. **Meticulous Reader**
December 13, 2022

I read John Horgan's piece. It's a nice one, but even that one contains some of the roots behind the issue. Journalists should meticulously choose their words and not fall into the trap of repeating what people in a certain group keep telling each other. As long as journalists keep referring to those people as "quantum gravity experts", hype around what those people are doing can only grow and receive wide acceptance. Calling people quantum gravity experts when those people spend their careers playing with toy models that have nothing to do with real gravity is in itself a big contribution to feeding the hype.

11. **Davide Castelvecchi**
December 13, 2022

"Soon, in what many consider the most bizarre scientific result of all time, the physicists realized that whether an electron behaved more like a particle or more like a wave depended on whether or not someone was observing it. The field of quantum mechanics was born."
— I'm not sure that's how the history of quantum mechanics went? 🙂

12. **Peter Woit**
December 13, 2022

Meticulous Reader,
I do agree there are some problems with the Horgan piece. For instance, he does not make clear that while the scientists involved produced unprecedented amounts of bullshit, none it actually got teleported anywhere.
Since this whole subfield is based on Susskind's 2017 GR=QM paper, a more accurate description of those involved than "quantum gravity experts" would be "people pursuing an increasingly outlandish failed 40 year old research program".

13. **Peter Woit**
December 13, 2022

Davide Castelvecchi,
Does make one wonder about the New Yorker fact-checking. If they got that so wrong, how could you trust them about the really hard to believe stuff, like what Hartmut Neven was wearing?

14. **Sabine Hossenfelder**
December 13, 2022

"There's literally a list of a dozen things like this, and each one is about as science fictiony as the next,"

Except in science fiction novels they can actually do something with the technology, rather than just publish papers about its interpretations in scientific magazines.

15. **David Thurman**
December 20, 2022

Peter, the identical behavior is playing out in the crypto world right now. Which BTW is a nice place for mathmaticians, computer science majors, and physics majors from MIT such as the ftx founder to make a quick billion.

Ethics is that actually science? I don't think it comes under that domain directly it manifests in it indirectly. So the article isn't all that shocking, and now it's internet hard science fact which you have to battle.for years.

Sometimes the one fooling others is the biggest fool or an idiot. Other times they lack ethics and then it becomes evil. Hard to tell here on this topic in regards to are they evil or idiots. Ethics, interesting topic, it's not science, but is profoundly and deeply relevant to good healthy science, which appears to becoming sicker by the day.

16. **Peter**
    December 20, 2022

    I did some superficial checking here in NW-Europe where I live. The Guardian in England mentioned it, but wrote "Experts who were not involved in the experiment cautioned that it was important to note that a physical wormhole had not actually been created, but noted the future possibilities" and quoted Daniel Harlow in the NYT.

    A search on "trou de ver" (wormhole in French) didn't show results in the leading French newspapers (Le Monde, Le Figaro, Libération). Same for "Wurmloch" in German.

    Nothing, as far as I can see, in the leading newspapers in the Dutch-speaking part of Belgium, although in the French-speaking part there's an article on the website of the public broadcaster RTBf. It's uncritical and ends with the message that the wormhole is not one we'll perhaps find in space, "but it allows progress in the unification of the theories of quantum entanglement, spacetime and quantum gravity" (my translation).

    A leading newspaper in the Netherlands, de Volkskrant, had an article about the experiment but it focused on the controversy and gave a lot of space to the critics. It mentioned a critic who says "if they had given their paper a realistic title (…) nobody would have batted an eyelid" (my translation).

    My search wasn't very thorough, but I have the impression the recent experiments on nuclear fusion got more attention.

17. **jonW**
    December 23, 2022

    Peter, Quanta has just put out a review of the most significant (in their view) stories of the year in Physics. It's written by Natalie Wolchover, who is much less gushing (almost backpedalling) about wormholes in this new article:

    "The holographic wormhole spawned endless opinions among physicists and lay readers alike. Some physicists thought the quantum simulation was too pared down compared to the theoretical model it was based on to have a holographic dual description as a wormhole. Many felt that the physicists behind the work, and we, the journalists who covered it, should have better emphasized that this was not an actual wormhole that could transport people to Andromeda. Indeed, to open up a wormhole in real space-time, you'd need negative-energy material, and that doesn't seem to exist. "

    It's at https://www.quantamagazine.org/the-biggest-discoveries-in-physics-in-2022-20221222/

18. **Peter Woit**
    December 23, 2022

    jonW,
    Thanks, that's a lot less over the top than the original article video. Still, listing this as one of the five great discoveries in physics this year has no relation to reality.

19. **French Dip**
    December 23, 2022

    Hi Peter,

    I'm not sure you're referencing the Penn article accurately as there's a fair amount of criticism in there. See e.g.

    Heckman: *Insinuating that there is an actual wormhole traversal happening in our world is quite misleading. The authors of the article and the press covering it are engaging in very irresponsible representations of the work.*

    Balasubramanian: *Once again, they have not built a wormhole in our world. To say that they done so requires some mental gymnastics.*

20. **Marvin**
    December 24, 2022

    Peter W and French Dip,

    About the Penn article, instead of dissipating the controversy, there is overall more hype in the article, making the experiment look a piece of reality that can be constructed from it after all:

    "The black holes in question don't exist in our world. Rather, they are present in an alternative, 'dual,' description of their quantum computing system in terms of a theory of gravity in a different number of dimensions. So, in a sense, they used this 'dual' notion of gravity to imagine a traversable bridge, or wormhole, connecting two different quantum mechanical systems, and translated this back into equivalent phenomena in the actual system they built on their quantum computer."

    So, these black holes that don't exist (wormlike connected) are represented with a gravity theory in multi-dimension (not 4 as in GR) that don't exist. What is this? A ridiculous toy model that pretend to have quantum computer properties. This trivial experiment and hype really don't help physic make progress.

21. **Peter Woit**
    December 24, 2022

    French Dip/Marvin,
    The problems with the way the publicity stunt was covered go way beyond the problem of no actual wormhole creation. The quantum computer calculation was of zero scientific value, it added nothing to our understanding of anything. The publicity stunt was in the end a huge success: its goal was to convince people (from the public to lab and institute directors) not that a wormhole had been produced, but that the organizers had accomplished something of scientific importance, that they were doing "quantum gravity in a lab". Besides the outright wrong things in the Penn article (no, this is not a quantum computer doing something better than a classical computer), it just completely mystifies what this calculation really was.

22. **Davide Castelvecchi**
    December 27, 2022

    @Peter Woit:
    Sorry I only saw your reply now. Perhaps one way to interpret "quantum mechanics was born" is that they were thinking of Einstein's 1905 paper on the photon? We knew already that light can have wavelike behavior, and this paper showed it can act like a particle, too…

23. **Alan Roxdale**

December 27, 2022

It seems pretty clear that the fuel driving all this stuff is funding pressure, and the pressure to game funding agencies by hook or by crook. A tale as old as post 1980 economic reforms.

I recall a long number of years ago this blog described a particular incident in Physics as a "reverse Sokal hoax". This one feels at at least about that magnitude …

> A surprising number of theorists seem willing to help hype the publicity stunt

…and probably more. Maybe we'll get a full-blown "N-ray redux" before it all fizzles out (it is going to fizzle out right?)

24. **tulpoeid**
December 28, 2022

I think you are wrong in attacking the Penn article. Yes, it got the quantum computing efficiency part right, but in everything else it was the complete opposite of "help hype the publicity stunt". Actually I'm a bit surprised to read that you think it contributes to the hype, while it is attacking it without mincing words.

25. **Peter Woit**
December 28, 2022

tulpoeid,
I read the article again, and I'll stick to the position that the Penn article misinforms and contributes to the hype. The answers to the questions about the role of quantum computers in this are just completely backwards and designed to further the hype. Saying
"No, they haven't created a wormhole, or a shortcut connection between two distant points in space. But what they've been able to achieve here is still very impressive and a good step forward for quantum computing."
shows the problem. Yes, Balasumbranian is correcting the nonsense about actually creating wormholes, but he's furthering the hype about this calculation ("still very impressive"). Claiming this as a "good step forward for quantum computing" is just hype and nonsense.

The point of the publicity stunt was not to convince people of the crazy idea that they had created real wormholes in the lab, but to convince the public, their colleagues, and those responsible for their funding that they had made impressive progress on quantum gravity by doing "quantum gravity in a lab". Balasumbrananian and Heckman (and many others) have decided to support this. For a more appropriate response, see Garisto's article. It's remarkable that here many science journalists are doing a much better job of getting the science right than the physicists commenting on this.

Alan Roxdale,
The danger here is that, like with string theory, this is not going to fizzle out, but instead become a dominant part of the field in the future. If funders can be convinced that where money should go is to bogus "quantum gravity in the lab experiments", that's going to be the future of the field.

26. **clayton**
December 28, 2022

I tend to agree that a lot of the coverage of this has been dreadful, but this Penn article seems to be one of the best — Heckman goes as far as to say "Insinuating that there is an actual wormhole traversal happening in our world is quite misleading", and Balasubramanian says "Once again, they have not built a wormhole in our world. To say that they done so requires some mental gymnastics." They use a lot of technical language which, honestly, I'm a bit surprised made it to this popular webpage. (Er, "popular.") Not sure what more they could have done, honestly.

27. **Peter Shor**
January 3, 2023

One final comment, although it's probably too late for anybody to read it.

> Natalie Wolchover, a Pulitzer Prize-winning science writer at Quanta, argues that when a quantum computer simulates a toy model of quantum matter, such as the SYK model, it is really "creating" the quantum system it asks about.

My response to this is that the quantum computer isn't even simulating a qubit going through a wormhole. If I understand the experiment correctly, the wormhole is in a static state; for a qubit to actually go through a wormhole, the wormhole has to have dynamics. It seems to me that is going on is that they are grabbing a qubit on one side of the wormhole, using standard teleportation to send it to the other side, and claiming that it went *through* the wormhole. This is a very bizarre interpretation of *through*.

28. **Geoff Penington**
January 9, 2023

@Peter Shor:

They're not doing standard teleportation. Instead what they do is evolve one side backwards in time, throw in a qubit, and evolve it forwards in time again. Then they turn on a simple coupling between the two sides (the "teleportation" part is that this could in theory be implemented by measuring one side and then evolving the other based on the measurement outcome), evolve the other side forwards in time, and magically the qubit pops out on the other side.

From a QI perspective the mechanism for why this works is not at all obvious, and actually relies on the dynamics of the theory creating something called "size winding". (Actually you don't need size winding to send one qubit through – any scrambling dynamics will do – but more than one qubit requires size winding.) In fact, the effect was only discovered at all by looking at holographic theories, where it literally describes a particle falling causally through a traversable wormhole.

The nontrivial "interesting" content of the nature paper involved finding sparse dynamics on only nine qubits that still exhibited signatures of size winding. This let them run the dynamics on Sycamore which is fun I guess.

Obviously this didn't push the limits of what's achievable on a quantum computer in any way. It's trivial and has been for years. I think the source of Vijay and Jonathan's confusion on this front (and I think it is confusion or at most academic politeness – not them trying to contribute to the hype) is that simulating a traversable wormhole in a meaningful way was supposed to be really quite hard – and so it's natural to think that its achievement would involve the real cutting edge of Sycamore's power. Instead the nature article just found a way to declare the bar for victory to be so low that they could step over it without really trying.

29. **Peter Woit**
January 9, 2023

Geoff Penington,

I didn't mean to accuse the Penn string theorists of intentionally trying to contribute to hype. The problem with outrageous claims like "physicists create wormholes" appearing in well-respected places like Quanta and the cover of Nature is that even quite sophisticated readers tend to assume that there must be some significant result behind the dubious headline. It looks to me like Heckman just made this assumption, without looking into what the actual result was.

Back in the days when string theory was getting this kind of hype treatment, the underlying theoretical results were very hard to understand without a lot of complicated background. But here it was very easy to see that the quantum computer business was an irrelevant stunt, it’s remarkable that any theorists were taken in by it.

Pierre Schapira on Récoltes et Semailles

December 30, 2022
Categories: Uncategorized

Earlier this year I bought a copy of the recently published version of Grothendieck's *Récoltes et Semailles*, and spent quite a lot of time reading it. I wrote a bit about it here, intended to write something much longer when I finished reading, but I've given up on that idea. At some point this past fall I stopped reading, having made it through all but 100 pages or so of the roughly 1900 total. I planned to pick it up again and finish, but haven't managed to bring myself to do that, largely because getting to the end would mean I should write something, and the task of doing justice to this text looks far too difficult.

Récoltes et Semailles is a unique and amazing document, some of the things in it are fantastic and wonderful. Quoting myself from earlier this year

> there are many beautifully written sections, capturing Grothendieck's feeling for the beauty of the deepest ideas in mathematics. One gets to see what it looked like from the inside to a genius as he worked, often together with others, on a project that revolutionized how we think about mathematics.

A huge problem with the book is the way it was written, providing a convincing advertisement for word processors. Grothendieck seems to have not significantly edited the manuscript. When he thought of something relevant to what he had written previously, instead of editing that, he would just type away and add more material. Unclear how this could ever happen, but it would be a great service to humanity to have a competent editor put to work doing a huge rewrite of the text.

The other problem though is even more serious. The text provides deep personal insight into Grothendieck's thinking, which is simultaneously fascinating and discouraging. His isolation and decision to concentrate on "meditation" about himself left him semi-paranoid and without anyone to engage with and help channel his remarkable intellect. It's frustrating to read hundreds of pages about motives which consist of some tantalizing explanations of these deep mathematical ideas, embedded in endless complaints that Deligne and others didn't properly understand and develop these ideas (or properly credit him). One keeps thinking: instead of going on like this, why didn't he just do what he said he had planned earlier, write out an explanation of these ideas?

As an excuse for giving up on writing more myself about this, I can instead recommend Pierre Schapira's new article at Inference, entitled A Truncated Manuscript. Schapira provides an excellent review of the book, and also explains a major problem with it. Grothendieck devotes endless pages to complaints that Zoghman Mebkhout did not get sufficient recognition for his work on the so-called Riemann-Hilbert correspondence for perverse sheaves. Mebkhout was Schapira's student, and he explains that a correct version of the story has the ideas involved originating with Kashiwara, who was the one who should have gotten more recognition, not Mebhkout. According to Schapira, he explained what had really happened to Grothendieck, who wrote an extra twenty pages or so correcting mistaken claims in *Récoltes et Semailles*, but these didn't make it into the recently published version. If someone ever gets to the project of editing *Récoltes et Semailles*, a good starting point would be to simply delete all of the material that Grothendieck included on this topic.

The extra pages described are available now here, as part of an extensive website called the Grothendieck Circle, now being updated by Leila Schneps. For a wealth of material concerning Grothendieck's writings, see this site run by Mateo Carmona. It includes a transcription of *Récoltes et Semailles* that provides an alternative to the recently published version.

The Schapira article is a good example of some of the excellent pieces that the people at Inference have published since they started nearly ten years ago (another example relevant to Grothendieck would be Pierre Cartier's A Country Known Only by Name from their first issue). I've heard news that they have lost a major part of their funding, which was reportedly from Peter Thiel and was one source of controversy about the magazine. I wrote about this here in early 2019 (also note discussion in the comments). My position then and now is that the concerns people had about the editors and funding of Inference needed to be evaluated in the context of the result, which was an unusual publication putting out some high quality articles about math and physics that would likely not have otherwise gotten written and published. I hope they manage to find alternate sources of funding that allow them to keep putting out the publication.

   Rereading the Cartier article I am struck by his language; C. is quite the stylist, even in translation.

   Schapira's article does not offer the same linguistic pleasure, but does at least correct the record – though little is needed. Kashiwara's genius, so evident in his extraordinary papers (not only those on D-modules, microlocal analysis, RH) speaks for itself, as does Mebkhout's subsequent output. But the historical notes in some Kashiwara-Schapira books are cringe inducingly hagiographical about K, I've often wondered what K. thinks about them.

   January 1, 2023

   Hi Peter, happy New Year! Glad to begin the year myself reading some of your excellent musing about Grothendieck. As you know, I'm greatly interested in his personality and his mathematics and I've written about him on my blog (which you kindly linked some time ago in another post you've dedicated to him).

   I've read Récoltes et Semailles (in French) in its entirety, and boy, it's a rough ride indeed. I agree with the fact it clearly wasn't edited. But I deeply feel the "unedited" version is the one we should read. Not that this version is the one Grothendieck himself would have liked us to read because I think in the end he didn't intend Récoltes to be published. But it's important we read it because in my opinion it has been assumed for too long that R&S is just the monumental rant of a terminally paranoid recluse. It's not. As you say, it has moments of absolute brilliance, mathematical or not.

   I've been in touch for some time with people who are/were familiar with Grothendieck's past, and I've somehow changed my attitude toward some of his most controversial decisions, including him leaving the IHES. I've long thought he had been overcome at a certain point by his personal problems which he somehow had rationalized in the refusal to work for the "institutions". It turns out he had a point of being wary of IHES connections to the military, and other people shared his views. But while Grothendieck was principled AND not well off, others were either principled and with enough means to get away with IHES money, or had not enough financial security to break ties with that institution. Long story, and not exactly a new one…

   January 24, 2023

   Hi, Peter. You might be interested in this mildly unpleasant experience I had with Inference magazine a couple years ago. The short story is they contacted me, asked me for an article, it went through a couple rounds of revision where at each step I had to bug them for comments, then suddenly they dropped it for no reason.

   My guess is that they were never so excited about the article in the first place. But the main thing I remember was the obsequious tone of the email from the assistant who solicited the article, followed later by a complete lack of explanation for why they dropped it.

   As I wrote in the above-linked post, I can't really be angry at them–they have every right to ask for an article and then change their mind. The whole experience was kinda weird, not like any other interaction I'd had with any other publication. A bizarre mix of hot and cold.

   This may be the place to note some sad news: Mikio Sato, the creator of algebraic analysis, who is mentioned in Schapira's article, passed away this Jan. 9th:

   https://twitter.com/SpringerMath/status/1613150057095921665

   Here's an old (1990) AMS interview of Sato:

   https://www.ams.org/notices/200702/fea-sato-2.pdf

   Like Grothendieck, he was one of the really visionary mathematicians of the 20th century.

Spring Course

January 10, 2023
Categories: Uncategorized

This semester I'm teaching the second half of our graduate course on Lie groups and representations, and have started making plans for the course, which will begin next week. There's a web-page here which I'll be adding to as time goes on. The plan is to try and write up lecture notes for most of the course, some of which may be rewrites of older notes written when I taught earlier versions of this course. I'll post these typically after the corresponding lectures. Any corrections or comments will be welcome.

This year I'm hoping to integrate ideas about "quantization" into the course more than in the past, starting off with the mathematics behind what physicists often call "canonical quantization". This topic is worked out very explicitly and in great detail in this book, but in this course I'll be giving a more stream-lined presentation from a more advanced point of view. This subject has a somewhat different flavor than usual for math graduate courses, in that instead of proving things about classes of representations, it's one very specific representation that is the topic.

This topic is also the simplest example of the general philosophy of trying to understand Lie group representations in terms of the geometry of a "co-adjoint orbit", and I'll try and say a bit about this "orbit philosophy" and "geometric quantization".

The next topic of the course will likely be more standard: the classification of finite dimensional representations of semi-simple complex Lie algebras (or, equivalently, compact Lie groups), and their construction using Verma modules. For this topic it's hard to justify spending a lot of time writing notes, since there already are several places this has been done very well (e.g Kirillov's book). After doing this algebraically, I'll go back to the geometric and orbit point of view and explain the Borel-Weil-Bott theorem giving a geometric construction of these representations.

For the last part of the course, I hope to discuss the representations of SL(2,**R**) and the general classification of real semi-simple Lie algebras and groups. If I ever manage to understand what's going on with the real Weil group and the Langlands classification of representations of real Lie groups, maybe I'll say something about that, but that is probably too much to hope for.

Throughout the course, as well as the relation to quantization, I also hope to explain some things about relations to number theory. These would include the theory of theta functions early on, modular forms at the end.

   January 10, 2023

   I am finding the study of quantization of co-adjoint orbits very timely since there's a lot of interest these days on covariant phase methods in order to compute asymptotic charges associated to asymptotic symmetry groups on GR, such as the flat-space/celestial/Carrollian holography, e.g., the Noether charges associated to BMS group. The paper by Witten on Virasoro and coajoint orbits is still very readable, by the way. Since you like BRST cohomology, this paper by Barnich could be of some interest to some of yours students wishing to see a modern application of the methods presented in the class: https://inspirehep.net/literature/567304

   January 19, 2023

   David Brown,
   That article has a lot of material I'll be covering from a somewhat different point of view. By the way, a better link might be
   https://arxiv.org/abs/math/0602056

   I've just started posting notes for the course, in a couple weeks will write something about the orbit method, will also include references, some of which I think are much more helpful than that article.

   Soon I'll be lecturing on the Weil or oscillator representation. In some sense it's just one example of the general theory of the Jacobi group that the author of that paper writes about, but I think it's better understood on its own terms as a very special structure.

   Anyway, a detailed treatment of the subject should appear in the notes over the next couple weeks.

4. **Art**
   February 13, 2023

   Class notes?

   By the way, the Berkeley Lectures link doesn't work for me, although I think I was able to find them elsewhere.

5. **Peter Woit**
   February 15, 2023

   Art,
   I fixed the link to the Berkeley Lectures. Class notes I'm writing are linked to from the syllabus. Starting to get way behind though on those.

   I've just finished the first part of the course, now will turn to more conventional material for a while, probably won't write up notes on this material since there are many very good places to read about it (the Berkeley notes one example).

What is the AdS/CFT Conjecture?

January 22, 2023
Categories: Uncategorized

In recent years I've found there's no point to trying to have an intelligible argument about "string theory", simply because the term no longer has any well-defined meaning. At the KITP next spring, there will be a program devoted to [What is String Theory?](), with a website that tells us that "the precise nature of its organizational principle remains obscure." As far as I can tell though, the problem is not one of insufficient precision, but not knowing even the general nature of such an organizational principle.

What one hears when one asks about this these days is that the field has moved on to focusing on the one part of this that is understood: the "AdS/CFT conjecture." I've gotten the same answer when asking about the meaning of the "ER=EPR conjecture", and recently the claim seems to be that the black hole information paradox is resolved, again, somehow using the "AdS/CFT conjecture." Today I noticed this twitter thread from Jonathan Oppenheim raising questions about the "AdS/CFT conjecture" and the discussion there reminded me that I don't understand what the people involved mean by those words. What exactly (physicist meaning of "exactly", not mathematician meaning) is the "AdS/CFT conjecture"?

To be clear, I have tried to follow this subject since its beginnings, and at one point was pretty well aware of the exact known statements relating type IIB superstring theory on five-dim AdS space times a five-sphere with M units of flux to N=4 U(M) SYM. While this provided an impressive realization of the old dream of relating a large M QFT to a weakly coupled string theory, it bothered me that there was no meaning to the duality in the sense that no one knew how to define the strongly coupled string theory. This problem seemed to get dealt with by turning the conjecture into a definition of string theory in this background, but it was always unclear how that was supposed to work.

So, my question isn't about that, but about the much more general use of the term to refer to all sorts of gravity/CFT relationships in various dimensions. There are hundreds if not thousands of theorists actively working on this these days, and my question is aimed at them: what exactly do you mean when you say "the AdS/CFT conjecture"?

Update: The ongoing discussion between Jonathan Oppenheim, Geoff Pennington and Andreas Karch about this on Twitter is very interesting, indicates that it isn't so clear exactly what "the AdS/CFT conjecture" is. For me and presumably many others, would be great to have a source for an authoritative discussion of what is known about this topic. The Twitter format is very much not optimal for discussions like this.

1. **Bob P**
   January 23, 2023

   I actually think of AdS/CFT as being a bit like the orbit method in representation theory. Each is really a collection of results rather than a top-down theory. In both cases, the results are statements that you can do some calculations in two quite different looking setups and somewhat mysteriously arrive at the same answer. In AdS/CFT, one of the important results is the Ryu-Takayanagi formula. This formula says an entanglement entropy in certain CFTs is equal to the area of an extremal surface in an AdS spacetime. This reminds me of the orbit method result that relates dimensions of irreducible representations to volumes of coadjoint orbits. In both examples, something from quantum mechanics is related to something geometrical. Of course, AdS/CFT is much more limited than the orbit method in the sense that it only applies to certain "large N" CFTs, while the orbit method is supposed to be about all of representation theory. At any rate, I would call "AdS/CFT" the AdS/CFT correspondence and use it to refer to this collection of correspondences.

2. **Peter Woit**
   January 24, 2023

   Bob P,

   In the case of the orbit method (or of the Langlands program that Geoff Pennington made an analogy to on Twitter), a top-down explanation of why they work may be missing, but a minute of googling will get you fairly precise technical definitions of what "orbit method" or "Langlands program" means. You'll easily find the details of how specific co-adjoint orbits are supposed to match with specific Lie group representations or how specific modular forms are supposed to match with specific Galois representations. My question "what is the AdS/CFT conjecture" was not intended to be tendentious or get people arguing, but, seriously, to try and just understand exactly what people working on this mean when they use the term.

3. **Jonathan Oppenheim**
   January 24, 2023

   The proper experts will hopefully correct me if I'm wrong, but my amateur answer is that the old school version of AdS/CFT was that (i) the partition function of the bulk AdS theory (e.g. type IIB string theory in AdS5xS5) is the same as the partition function of the boundary CFT (e.g. N = 4 supersymmetric Yang–Mills theory). And (ii) the Hilbert spaces of both theories are the same. This would give us a correspondence between bulk and boundary observables and correlation functions. I think there is a lot of evidence for (i).

   The status of (ii) is very unclear to me. It would say that there is a 1-1 map between bulk states and boundary states. But https://arxiv.org/abs/1411.7041 gives an example where it can't be true in its original form because it would lead to a violation of the no-cloning theorem. So in order to preserve some sense of (ii), they postulate that the bulk is encoded in the boundary as an error correcting code. In other words, each physical state in the bulk, needs many states of the boundary in order for it to be encoded in such a way that a violation of the no-cloning theorem is avoided. So (ii) might be true in the sense that there is a correspondence between physical states of the bulk, and "code states" of the boundary. I don't know that there is much independent evidence that the CFT is an error correcting code, but it certainly has to be if some notion of (ii) is to be preserved.

   But even this is not enough, because old black holes can have "too many states". And so a more recent claim is that various bulk states which we think of as being orthogonal, are not really orthogonal. See for example https://arxiv.org/abs/2207.06536. So, I would say that (ii) is not regarded as true anymore, but it may be true in some sense (although I feel this is speculative).

   There are other additional parts of the correspondence which are more speculative but are generally acknowledged as such (e.g. complexity = something). And there are elements which are claimed to be "established beyond reasonable doubt", and yet I see no evidence for (and if anything, evidence against). Chief among them is the claim that because the CFT undergoes unitary evolution, the bulk quantum gravity theory must also be unitary, and therefore, black hole's preserve information. I see no reason for (i) and (ii) to imply this, and I see no evidence for this part of the AdS/CFT conjecture. On the contrary, it forces researchers to embrace all manner of perversions, from violations of the equivalence principle, to post-selection, to the absence of free will and local degrees of freedom. I suppose this was the cause of my Sunday morning rage-tweeting. If only I'd just gone for a walk….

4. **Andreas Karch**
   January 24, 2023

Hey Jonathan,

so we moved on to the long-text format. I think in your rant, I mean argument, you are getting yourself/us into a lot of trouble because you have a very old-fashioned notion of what states are in a theory of gravity. Diffeomorphisms are a gauge redundancy in a theory of gravity. Every statement that makes reference to local fields, local states, maybe "counts" how many states there are inside a black hole, is not really about physical states. Gauge invariant states in AdS are associated only with the boundary. It's almost true by tautology that the states of a theory of gravity in AdS are those of a CFT. The only questions is really "which CFT". I don't think anyone has come up with a better definition of what we would even mean by the states of quantum gravity in AdS other than boundary observables. This is the AdS analog of the statement that the only observables in a theory in asymptotically flat quantum gravity are S-matrix elements. Any local question in Minkowski space is gauge redundant.

You (and the papers you cite) are asking interesting questions about how local physics in AdS can arise as an approximate notion from the dual CFT perspective. There are lots of puzzles there. But I really don't see how this calls AdS/CFT into question. None of the things you call physical states in the bulk are physical.

And now I go hide in a hole …..

5. **Andreas Karch**
January 24, 2023

This is, by the way, also one of the main shortcomings of these tensor network models of AdS/CFT that are so popular these days. They capture many interesting aspects of fields on AdS space, except for the most important one: if we do gravity on AdS, none of the local states in the bulk is physical. They are all gauge redundant. Surely there is a lot one can learn from these toy models, but one shouldn't take them too seriously. It's a tall order having a toy model of quantum gravity that assumes gravity is not important.

(and now I should REALLY go hide in a hole ….)

6. **AR**
January 24, 2023

I would have said that the AdS/CFT correspondence is that any quantum gravitational theory in an anti-de-Sitter space of dimension D+1 is described by a non-gravitational quantum theory in dimension D. Fundamentally, this is because a gravitational theory is believed to not have gauge invariant local observables; the true gauge -invariant observables must therefore live on the boundary, The isometries of AdS ensure that this boundary theory is conformal.

I do think that this idea has not changed; the original correspondence between type IIB in AdS5 times S5, and N=4 SYM was only the best worked out case.

The more general correspondence leaves the nature of the boundary theory somewhat vague, and is therefore quite plausibly true. The more specific one becomes about the boundary theory, the more tests are possible. There are a few very specific duality conjectures, including the original one; I don't think the evidence for them is overwhelming.

Pace Jonathan Oppenheim, I think that if the boundary theory is unitary and the bulk theory is not, then this means that the AdS/CFT correspondence is manifestly false. But YMMV.

7. **Emil Martinec**
January 25, 2023

@Andreas, I think it is a bit too strong to say that gauge invariant states are associated only with the boundary. There are plenty of examples in AdS/CFT (e.g. the Lunin-Mathur and Lin-Lunin-Maldacena constructions) where a BPS spectrum is matched on both sides of the duality with exquisite precision. Specific BPS states in the CFT are mapped to specific BPS bulk geometries. Just because there is gauge symmetry (on both sides) doesn't mean that one is unable to describe physical states in both bulk and boundary descriptions, and say what they look like deep in the middle of AdS. Of course, when one gets away from situations where calculations on both sides of the duality are under control, one is unable to construct the map. That doesn't mean there isn't a bulk theory of quantum gravity, or that one must somehow refer all its physical properties to the conformal boundary of spacetime.

@Jonathan, it seems to me that much of your complaint stems from the fact that we don't understand much about the duality map as a detailed isomorphism in complicated dynamical situations, and that certainly includes those where black holes are involved. Even then, there are examples where one has confidence that the map is still valid. I am thinking specifically of AdS3/CFT2, where there is an infinite dimensional conformal symmetry whose representation theory highly constrains both sides. There is a moduli space of theories on both sides that includes a weak-coupling domain for the CFT where the Hilbert space is well-understood. The conformal symmetry continues to govern the asymptotic density of states through the Cardy formula over the entire moduli space, and it agrees with gravitational thermodynamics in the regime where gravity is weakly coupled. So either there is some non-unitary quantum theory of gravity which lives nowhere on this moduli space and whose thermodynamics has nothing to do with an underlying quantum statistical mechanics and its associated state-counting, or quantum gravity is indeed unitary and the thermodynamics does have such an underlying interpretation. In the latter case, it would be unreasonable to suppose there is no duality map, since the CFT is explicitly such a quantum system with exactly the same thermodynamics, with a precise match of BPS protected quantities, etc.

Many of your other quibbles with the correspondence have to do with more recent work much of which is on rather less sound a footing. I am not surprised if you are confused by it, since in some cases the authors themselves appear to be confused about how AdS/CFT works. If some of these ideas turn out to be wrong, it will not invalidate AdS/CFT but will rather tell us that certain ideas about the properties of the duality map are incorrect. I have not seen ANY evidence to date that suggests that the duality itself is in question.

@Peter, the most established part of the conjecture has to do with maps of protected quantities where (super)symmetry allows calculations on both sides of the duality that can be compared. In addition to those mentioned above, there are now quite sophisticated evaluations of the gravitational path integral that match the asymptotic series of BPS partition sums computed in the CFT. The semiclassical expansion of the gravitational path integral (with the sum over saddles generating subleading terms in the asymptotic expansion) takes one beyond the leading order gravitational thermodynamics to a fuller understanding of the correspondence. Here one is not asking gravity to describe microstates in the Hilbert space directly, that is likely the wrong thing to do (just as the terms in the asymptotic expansion of an elliptic function obtained by modular transform are not associated with individual terms in its original q-expansion); rather, gravity seems to know how to count states in aggregate (including subleading terms in the expansion) without resolving the microscopic details.

These calculations are not grand statements of principle, but rather detailed computations in specific examples where one can work out a match between the same quantity in AdS and CFT. Many checks of this sort have been done, amassing a great deal of evidence for the conjecture, but what the full scope of the duality is remains unclear. The most solid part of the correspondence is a list of explicit examples for which there is a wealth of supporting evidence. This success has led to a reasonable belief that any other example one can motivate as a limit of string theory will hold as well.

Where people seem to be running into trouble is in the arena of trying to abstract some grand principle that underlies and unifies (and perhaps extends) all the particular examples, in the process abandoning much of the string theory which makes the details work in the examples we know. One such is ER=EPR, but there are others (to paraphrase Groucho Marx). Many focus on toy models which may or may not contain the essential physics. Many have given up on understanding the bulk dynamics in favor of making inferences/conjectures about what the bulk physics must be like by analyzing the CFT, which ends up processing bulk physics through some poorly understood nonlocal map in a strongly coupled field theory; there seems to be rather less effort in the opposite direction (doing string theory in AdS), likely because the calculations are rather more difficult.

8. **Jonathan Oppenheim**
   January 25, 2023

   You can't hide in a hole Andreas, the boundary sees everything! 😉

   I think even you have to admit that this proposal that you're advocating along with Suvrat Raju and others, is very controversial within the string theory community. My impression is that it is a small minority of people who believe it, while the majority believe what you call the "old fashioned notion". But that could just be that I tend to hang out with a different crowd of string theorists…. Namely, those who believe that GR makes sense in our universe without a boundary, and "the value of the field where my finger is pointing at" is a diffeomorphism invariant statement.

   At any rate, that's besides the point, because the one thing that is obvious here, is that string theorists have extremely different opinions about what counts as a state of the bulk, and yet they all seem to agree that the AdS/CFT conjecture is obviously true. In the same way as all string theorists believe the black hole information paradox has been solved, but completely disagree on the solution.

   I find this tendency frustrating because I learn a lot from my string theory colleagues, but it is often made difficult by overly bold claims. And it is this sort of tendency which led to the wormhole-on-a-chip fiasco, and which distorts our view of which research directions are likely to be fruitful.

9. **Andreas Karch**
   January 25, 2023

   What I describe in my comments is much more basic than my work with Suvrat. The fact that there are no local gauge invariant observables in a theory of quantum gravity other than those defined at the boundary has been hammered away by people like Witten from the earliest days of AdS/CFT. Please don't mix this up with somewhat more conjectural statements about black holes. Local states in the bulk aren't physical. I don't think you'll find many people who disagree with this assertion. An interesting question is how to reproduce approximately local quantum field theory observables from the CFT.

10. **Andreas Karch**
    January 25, 2023

    PS: for the record, I am referring here to Witten's talk at the Strings 98 conference in Santa Barbara where he pointed out that the fact that there are no local observables in a theory of quantum gravity basically tells you that just by asking what you mean by gravity in AdS, the only observables we know how to define are correlation functions at the boundary. At this level, AdS/CFT is really a tautology. The fact that you find this even controversial is somewhat puzzling to me.

11. **Jonathan Oppenheim**
    January 25, 2023

    Thanks Andreas. Some genuine questions:
    1) Is there agreement that it's a tautology? What then do you make of https://arxiv.org/abs/2207.06536 which claims that there is not an isomorphism between local bulk and boundary states.

    2) When you say that the only observables we know how to define are correlation functions at the boundary, would you agree that there might be others that you don't know how to define (e.g. relating to observables inside a black hole)?

    3) There is a community of researchers who study relational observables in GR. E.g. "the value of the field where Alice's finger is pointing," is a diff invariant statement. I've always regarded this program as moreally equivalent to string theorists relating their observables to the boundary (just replace Alice with the boundary). Would you agree?

    4) I of course agree that there are diff invariant observables that you can relate to the boundary, e.g. the value of the field along a geodesic some proper time from the boundary. And via some extrapolate dictionary, reconstruct regions in the bulk from the boundary, But don't you think that https://arxiv.org/abs/1411.7041 successfully argues that you can get a potential violation of the no-cloning theorem, because naively, it appears you can reconstruct the same bulk observable from different parts of the boundary?

12. **Peter Woit**
    January 25, 2023

    Just a note that due to the way moderation of comments works, Emil Martinec's very helpful comment just now was posted, even though it is earlier in the time sequence.

13. **Andreas Karch**
    January 25, 2023

    Thanks Jonathan. I think your points 1, 2, and 4 are all about the question how apparently semi-classic physics in the bulk can arise within a large N CFT. There are open questions there. But this is a higher order question: if there are no local observables in a theory of quantum gravity, how come local QFT works so well to describe the experiences of a low energy bulk creature? We happily do experiments in labs and don't worry about this not being strictly defined an observable. But I don't think many would argue that this program contradicts the assertion that there are no local gauge invariant observables.

    Sometime it feels like rephrasing AdS/CFT in quantum information language, despite all its new insights, has made people forget some very basic lessons learned long ago.

    As to your 3, the relational observables, they are defined as integrals over all of space and as such only depend on boundary data. They are boundary observables that have the power to give you an approximate sense of local physics in the bulk. That's exactly the sort of thing I am talking about. This program accepts that there are no gauge invariant local observables and tries to do interesting physics with it.

14. **Jonathan Oppenheim**
    January 25, 2023

    Thanks Andreas. When I hear people invoke AdS/CFT, it is often to claim that the CFT is a quantum theory of gravity. And so for me, the question of how (or whether) semi-classical physics arises in the bulk, is the central question. In order for the statement that the CFT is quantum gravity to be a testable and meaningful statement, it must reproduce semi-classical gravity (or something which could reasonably be said to be the correct low-energy or classical limit). Otherwise, it is not a quantum theory of gravity, but a quantum theory of something else. That doesn't mean it can't teach us a lot about quantum gravity, but it wouldn't be quantum gravity.

    Since you call them second order questions, maybe they are impossibly to answer right now, and that's fine. But I feel like people act like it's settled, which is what I take issue with.

Regarding relational observables – I think we mostly agree here. I suppose I would say they can be defined in a space-time without a boundary and so I don't need a boundary to have gauge invariant observables which are the moral equivalent of local ones.

15. **Jonathan Oppenheim**
January 25, 2023

@Emil, thanks so much for such a detailed answer, much appreciated. Indeed, it is in these more complicated situations where I feel people's apparent certainty is less supported by evidence. Although these are complicated situations, they are important ones — the black hole information paradox & black hole thermodynamics seem to be the key questions for quantum gravity.

16. **AR**
January 25, 2023

In classical gravity, observables need to be diff invariant, but in quantum gravity, an observable is (expected to be) defined through an integral over all bulk metrics with some fixed boundary value. This is much more restrictive than the classical case. For example, "the value of the field along a geodesic some proper time from the boundary" cannot be an observable in QG; when the metric changes, the geodesics themselves change. It is for this reason that only boundary-to-boundary correlations are believed to be gauge invariant. I didn't think this was controversial, but things may have changed.

And as everybody has said, this doesn't mean that it is not interesting to talk about local bulk physics; we just have to be cognizant that this must be in some sense approximate.

17. **Emil Martinec**
January 25, 2023

@Jonathan, just to be clear: Among the complicated situations that ARE well-understood are BPS black holes with macroscopic horizon area, where there is a robust CFT state counting that agrees with the AdS gravitational path integral.

It is useful to divide the black hole information problem into two aspects: the information storage problem, and the information recovery problem. The fact that the BPS spectrum has been precisely matched tells us that AdS/CFT knows how to solve the information storage problem for this class of extremal black holes, in that on the CFT side of the duality one is explicitly counting the microstates, and the AdS gravity computation reproduces this counting at the level of an asymptotic expansion for large charge/mass.

The more complicated information retrieval problem where we throw something into such an extremal black hole and ask what comes back, and how it comes back, and which of our assumptions that lead to the information paradox is breaking down in AdS quantum gravity, is currently out of reach. Not because AdS/CFT is wrong, but because we currently lack the tools to ascertain what is going on on the AdS gravity side of the duality, let alone calculate correlators in a strongly-coupled CFT, or produce an explicit map between the two. But again, this is a statement about our poor understanding of the duality map, not about its existence.

I think most people assume that because we have all these precise tests of the things we can calculate, that the duality holds not only for symmetry-protected quantities but in general. Again, that it is unreasonable that it holds only for some class of states (which includes extremal black holes) but not others. And then the duality tells you that the information retrieval problem is solved in principle by the unitarity of the CFT under the assumption that the duality is an exact (if inexplicit) map.

I think this is where most people in the subject are at the moment — at some point you have done enough checks of the duality, assume it is true and ask what are the consequences. Much as people no longer question the truth of the Riemann hypothesis, and instead work out its implications. Which is not to say that it is unimportant to prove either conjecture; rather that until that day arrives there are useful consequences to explore assuming their respective validity.

18. **Emil Martinec**
January 25, 2023

@AR, good luck describing what is going on today say at the LHC using only the asymptotic data from the inflaton fluctuations in the far past which eventually assembled into it and its beams, and wherever those beams (and the atoms in the LHC) end up in the asymptotic future.

If (as some people were briefly fantasizing before the LHC turned on) the fundamental Planck scale had been sufficiently low for the LHC to have made small black holes, I suspect we would be trying to use a bulk quantum theory of gravity to calculate the scattering amplitudes for this process in a small spacetime region around the collision rather than worrying about where the LHC is hiding in the primordial inflaton wavefunction.

19. **Suvrat Raju**
January 26, 2023

Hi Jonathan,
I'm just entering the discussion so maybe I've missed a lot of the background. But just reading your first few comments. 1411.7041 doesn't say anything to the effect that the Hilbert space cannot be the same. The point is simply that approximately local operators in the bulk can be written in different ways on the boundary. More precisely, we have multiple operators \phi_{i} which have the property that within a low-energy set of states, the different \phi_{i} act in approximately the same way. This is quite well understood and this phenomenon occurs even about empty AdS. Where is the violation of no-cloning here?
The issue about the growing volume in the black-hole interior that leads to a seeming puzzle with the entropy is a more interesting problem. Mathur pointed it out several years back. But one popular proposed resolution is simply that states that *appear* to be independent in the bulk are not really independent. One kinematic observation is that this can happen quite easily in high-dimensional Hilbert spaces. See https://arxiv.org/pdf/2010.03575.pdf
In a Hilbert space of dimension e^{S}, with S >> 1, it is possible to find e^{S'} vectors (|\Psi_{i}>) where S' >> S which have the property that their mutual inner product || << 1 for all i,j.
There are many things we don't understand about the duality and about black holes. But I agree with Andreas. I don't think it is accurate to suggest that there are somehow well-known problems with the original formulation of AdS/CFT in terms of the equivalence of Hilbert spaces.

20. **Jonathan Oppenheim**
January 26, 2023

Thanks @Emil. Here I have to disagree. The fact that string theory gets the entropy right for a class of symmetry protected extremal black holes, does not imply that AdS/CFT implies that black hole evaporation has to be unitary. I can predict the entropy of a box of gas from it's microscopic or macroscopic properties, and that holds just as well in a unitary theory as well as an open system. I think it's perfectly reasonable to believe that black-hole evaporation is unitary for various other reasons. But that's very different from claiming that AdS/CFT tells us that black-hole evaporation is unitary (which is what is often claimed). In fact, I would say that AdS/CFT is either silent on this, or appears to lead to the opposite conclusion.

I agree that it is reasonable to assume the conjecture is correct and explore the consequences. I think that's a solid research direction to take. We do this all the time in quantum information theory and computer science, but we're always careful to append some line such as "assuming the polynomial hierarchy doesn't collapse." Even though in that example, we are virtually certain that it doesn't. This level of care is what I often find missing, and I do think it leads to genuine confusion, even amongst experts, as to what is solid and what is less solid.

In many cases, I feel that the conclusions that are drawn assuming the AdS/CFT conjecture would cause me to question the assumptions, at least in the particular setting under consideration. But I never see that happening, and so am struck by people's confidence.

21. **Emil Martinec**
January 26, 2023

Jonathan, I'm not sure what you have in mind. Among the BPS protected quantities are the operators that introduce and absorb (super)gravitons from the AdS conformal boundary, that can again be matched on both sides of the duality. For instance, such operators acting on the CFT vacuum/global AdS yield protected single-particle states. So we can begin with the AdS vacuum and send in some gravitons with enough energy (order n^2) that in the bulk description would make a black hole (this could even be two very high energy gravitons that in semiclassical gravity look like colliding shockwaves). On the CFT side, one has a strongly coupled field theory in which such excitations rapidly thermalize. On the gravity side, one has black hole formation. Now, I suppose one could try to claim that the same operator that makes a graviton excitation on the AdS vacuum does not do the same thing when acting on the single-particle excited state generated by the first graviton operator, but that seems rather unreasonable — the interpretation of the asymptotics of the operators (eg single-trace operators in N=4 U(n) SYM being dual to supergraviton creation/annihilation operators) is independent of the state they are acting on. The intermediate state is a microstate in the thermal ensemble of the CFT, and a black hole in the gravity theory, with energy of order n^2. The density of intermediate states is the same on both sides.* One can then de-excite this state long after thermalization by removing low-energy supergravitons near the boundary in the AdS description, dual to the same local single-trace operators in the gauge theory. The gauge theory description of this process is explicitly unitary. It has a dual AdS description in terms of incoming and outgoing supergravitons.

So as long as we stay outside the black hole and compare the two descriptions of the evolution, there seems to be a complete parallel. Of course, I'm not giving you the exact bulk description everywhere in the bulk because we don't have one at the moment. But the description of what's going on as seen from far away is built from parts of the duality that ARE well-understood.

Could you be a bit more explicit about what you find lacking in this line of reasoning? Do you think there are "hidden variables" that don't participate in the gauge theory description, but are there on the gravity side, that somehow invalidate the duality? The matching of the non-extremal entropy makes this unlikely. I'm puzzled as to why you say that AdS/CFT is silent or even negative on the issue of unitarity in black hole evaporation.

* There is a well-known factor of 3/4 between weak and strong coupling entropies in the gauge theory that is understood to be due to interaction corrections in the strongly coupled gauge theory. If this bothers you, we can work in the AdS3/CFT2 examples where the thermodynamics doesn't change between weak and strong coupling in the CFT2, due to the additional power of conformal symmetry in 2d.

22. **Jonathan Oppenheim**
January 27, 2023

@Emil, since we are talking about extremal or near-extremal black holes, and they don't really evaporate, to what extent can we even pose the question here, much less answer it? And even if we could pose the question, we can't check the other side of the duality, so is this not a question of faith?

In terms of what I find lacking, I would say that any attempt to reconstruct the bulk when we have a late-time evaporating black hole results in conclusions that would prompt me to reconsider the premise. The conclusions being either a break-down of the equivalence principle at low energies for large black holes, or the requirement for post-selection (which already signals a breakdown of unitarity) etc. There is no need to introduce hidden variables to consider a break-down of unitarity.

The need to consider island corrections to the entropy (because AdS/CFT seems to over-count the entropy of radiation), or the need to consider non-isometric bulk to boundary maps as in https://arxiv.org/abs/2207.06536 (and I see now Suvrat mentions https://arxiv.org/abs/2010.03575) seem to me to be symptoms of that. Which is not to say that it can't all be made to hold together, but only to say that at the moment, it doesn't. In my view we don't have a clue what is going on, and shouldn't claim otherwise.

@Suvrat, apologies, your comment was moderated so only appears now. Regarding no-cloning and error correction, this is the content of 1411.7041, and I mean no more than what is contained in that paper. My naive quantum information theorist's view of an error-correcting code is that one needs to encode the logical states in a larger physical Hilbert space. Is this still compatable with the Hilbert space's being equal?

Regarding the more important question of proposals to deal with the over-counting of states (as in 2207.06536 or 2010.03575): It is certainly possible that bulk states which we think of as being orthogonal are not actually orthogonal. But this seems unlikely to me, and one is introducing yet another radical concept to fix a problem with the original proposal. We also appear to require that states with high complexity do not have semi-classical bulk duals. These concepts may be required to save AdS/CFT in this regime, and I applaud them being explored. But if one keeps on having to introduce new mechanisms, then the project starts to look less elegant and less likely to be true. Which is not to say that it can't be made to work, only that if we need to keep introducing new mechanisms along our path, we might want to at least question whether we're heading in the right direction.

23. **Emil Martinec**
January 28, 2023

@Jonathan, a black hole in AdS can be made to evaporate by extracting energy at the conformal boundary by hand — there is a finite probability to find Hawking radiation at any radius, and we can collect it near the boundary and spirit it away. We are free to decide when and where we want to introduce the operators that accomplish this. On both sides of the duality, this corresponds to acting with field operators at the conformal boundary by a well-understood limiting procedure, which on the CFT side amounts to using local operators to extract energy from it. So as I said, one can make a black hole form by sending in quanta from the conformal boundary, let the system thermalize, wait as long as you want, and then extract energy at the conformal boundary. So yes, we can pose the question.

I have been trying to argue that all of this is much more than a matter of faith, rather it is a reasonable hypothesis supported by mountains of evidence. And that evidence points to the existence of a unitary bulk theory of quantum gravity. Of course there is more to be understood about black hole interiors, where/how does the Hawking calculation go wrong, etc. The information problem isn't solved (claims to the contrary in the popular press notwithstanding).

The utility of any duality is that it provides an alternate route for calculation; one accepts the hypothesis and then uses whichever side of the duality is simpler to analyze for the question at hand. Otherwise, what is the point? To do every calculation twice because we might find the N+1st check of the duality invalidates it? So perhaps the more germaine issue might be why, if one is interested in answering questions about physics inside the horizon, one wants to attack that problem by using the CFT side of the duality, where it is filtered though all sorts of ill-understood, nonlocal properties of the duality, and moreover in a strongly-coupled field theory. I would have thought using the side of the duality where quasi-locality in the bulk doesn't need to be "reconstructed" would be more appropriate.

You mentioned recent proposals about islands, non-isometric codes, etc. They are a work in progress, the sort of toy model that I was referring to as perhaps having discarded essential ingredients. There is no "need" to consider any of them; and they may very well be wrong-headed. They are examples of what I was calling attempts to formulate grand principles — models and interpretations layered over the basic facts of AdS/CFT. And they are not guaranteed to be correct. In some cases, they represent a radical departure from what had seemed to be settled about how AdS/CFT works. And if indeed they turn out to be red herrings, the basic facts of AdS/CFT will still stand.

I will add one more option to the menu, which obviates all the discussion about islands, old black holes, bags of gold, overcounting/non-orthogonality of states etc. We have several examples of non-geometric phases of string theory, where gravity is not the most important actor and its effects are overwhelmed by the plethora of other degrees of freedom in string theory. Examples include the high-temperature Hagedorn phase, Landau-Ginsburg phases of string compactifications, and the formation of "giant gravitons". In AdS/CFT, gravity is a set of collective modes, order N^0 among N^2 degrees of freedom. In geometric phases, most of the N^2 degrees of freedom are confined/not activated/in their ground state. In AdS/CFT, the formation of a black hole involves on the CFT side a deconfinement transition. It might then be that on the AdS side, the horizon is a phase boundary, and there is no geometric interior (the analytic continuation of the vacuum geometry past the horizon presumes that the N^2 degrees of freedom are still confined there).

Much of the confusion at the moment stems from trying to hold onto a geometrical picture of the black hole interior, and presuming that the only place we need strings and branes is well inside the horizon near the singularity where tidal forces are large. We then get painted into a corner where all of a sudden we are invoking effects over much larger distances than the horizon scale in order to rescue the theory (like saying that the black hole interior at late times is non-locally encoded in the early radiation arbitrarily far away). So the lack of a geometrical interior is a possibility which bypasses many of the things you find objectionable, though there is plenty to object to about this alternative as well. Anyway, best to shut up and figure out a way to calculate, if we can.

24. **Peter Shor**
January 28, 2023

@Emil Martinez: If there is no "need" to consider any of these unconventional proposals about islands, non-isometric codes, etc., why are physicists considering them, and claiming in their papers that they solve certain problems that arise in AdS-CFT? I have too much respect for the authors of these papers to believe that they are introducing these seeming contrived ideas solely to lengthen their publication lists.

So I can only conclude that AdS-CFT is a conjecture with many unanswered questions about how it can be applicable to our universe.

25. **anonymice**
January 29, 2023

Daniel Harlow and Daniel Jafferis claim that Jackiw-Teitelboim gravity is a quantum gravity in 1+1D AdS space which has no CFT dual:

https://arxiv.org/abs/1804.01081

26. **Peter Woit**
January 29, 2023

Thanks to all who have provided some useful explanations about AdS/CFT. I feel I'm still though lacking what I'm looking for, a specific general conjecture about which two theories are in duality. More specifically:

I see the claim for N=4 SYM in d=4 and its supposed relation to a string theory/supergravity low energy limit, compactified on S^5. I also can see how different compactifications of this in different dimensions will give different pairs of conjecturally dual theories. But:

1. In dimensions above 3/2 does the conjecture go beyond this and how do I know what the paired dual theories are?
2. In dimension 2/1 and 3/2, are the dual pairs supposed to be related by compactification to the higher dimensional story?
3. In 3/2 d, writing gravity in CS form, there's a clear analog of the usual Chern-Simons story relating 3d gauge theory to 2d CFT on the boundary. What is the relation of this to AdS3/CFT2?
4. What exactly is the current best statement of how AdS/CFT relates 2d JT gravity to 1d SYK (presumably addressing the issue in the Harlow/Jafferis paper linked above)?

27. **JT gravity**
January 29, 2023

I believe the "best" (in the sense of being as close to the rigor of mathematical physics as it is possible in the present state of our understanding of QFT and string theory) work along the lines of proving the AdS3/CFT2 correspondence is currently due to Rastelli's and Gaberdiel's school. More precisely, this school is trying to show that type IIB string theory on AdS3 × S3 × M4 with p units of NS flux contains an integrable subsector, isomorphic to the minimal (p, 1) bosonic string. Some relevant papers:

https://arxiv.org/abs/1903.08264

28. **Emil Martinec**
January 30, 2023

@Peter:

1. Dual pairs can be constructed by taking low-energy limits of brane configurations in string theory. The basic idea is that the low energy limit of the open string theory on the branes is a gauge theory coupled to matter. On the gravity side, the low-energy limit is the near-source geometry of the branes. The brane construction determines the field content and then one analyzes the field theory RG to determine whether it is (i) scale invariant or (ii) has an interesting IR fixed point. At large N this is dual to (i) a self-similar geometry, or (ii) to a non-scale invariant geometry with an AdS limit as one scales it toward the brane source. If the field theory happens to be scale-invariant from the start, then the geometry will have the AdS form.

1a. For instance, the IR limit of N D2-branes is maximally supersymmetric gauge theory in d=3. This theory is not conformal, but has a nontrivial IR fixed point that is dual to M-theory on AdS4xS7. It was subsequently realized that this theory and many other AdS4/CFT3 dual pairs can be realized as Chern-Simons gauge theories coupled to matter, going by the name of the ABJM construction and various elaborations of it.

1b. The IR limit of fivebranes yields a nontrivial 6d SCFT with (2,0) superconformal symmetry, dual to AdS7xS4. Webs of intersecting fivebranes yield 5d SCFT's dual to a variety of examples of AdS6/CFT5. So there are examples in all dimensions where there is field-theoretic superconformal symmetry.

2. Compactification of the CFT does not usually give lower-dimensional correspondences, rather one typically intersects more branes. For instance, maximally susy AdS3/CFT2 comes from intersecting two stacks of three-branes, rather than by compactifying a single stack of three-branes. The 2d SCFT lives at the intersection. There is now a rich zoology of such constructions with less supersymmetry.

3. First let's review how things work in 2d JT gravity, which can be written as a BF topological gauge theory for SL(2,R). Because it has no bulk dynamics, the dynamics

can be pushed onto a set of edge modes, whose action is the Schwarzian (the natural action of coadjoint orbits of Diff(S^1)/SL(2,R). This story lifts to 3d Chern-Simons gravity, whose only dynamics is again that of boundary diffeomorphisms, governed by a 2d version of the Schwarzian theory originally studied by Alekseev-Shatashvili in 1988 and derived in this context by Cotler-Jensen 1808.03263. Note that this is not the CFT of the duality, rather it is simply a generating function for stress tensor Ward identities and does not realize the BTZ black hole density of states.

@anonymice, the version of this statement for the JT gravity/Schwarzian theory is the content of the paper you referenced. JT gravity and the Schwarzian theory have almost no states and so do not realize (n)AdS2 BH microstates; but because gravity knows about BH thermodynamics, it can be used to compute the BH density of states (as usual, the thermal free energy is the gravitational action).

4. The Schwarzian theory can be derived as the dynamics of a set of collective modes of the SYK model via a standard set of standard manipulations, but SYK has more content than just these collective modes — for instance it actually has 2^N states while the Schwarzian has just a few. The Schwarzian theory is equivalent to JT gravity — the latter, being topological, can be reduced to a set of edge modes. Then one could ask whether there is some sort of 2d theory that is exactly dual to the 1d SYK. It is unlikely that there is a quasi-local bulk theory exactly dual to the entire SYK model, in contrast to the examples derived from string theory where it is believed that string theory in the bulk and the large N CFT are exactly dual. At the very least, such a theory would be non-local at the AdS scale.

One might say (and has) that gravity a thermodynamic collective field theory, while string theory realizes the underlying statistical mechanics. AdS/CFT makes this more than a slogan, by relating string theory in AdS to a standard quantum system with a standard quantum statistical mechanics. The astonishing fact about gravity is that it knows about the BH equation of state without knowing much about the microstates; whereas in conventional systems, one has to have the microphysics in hand first, and use it to derive the equation of state in order to then start doing thermodynamics.

29. **David Roberts**
January 30, 2023

> The utility of any duality is that it provides an alternate route for calculation; one accepts the hypothesis and then uses whichever side of the duality is simpler to analyze for the question at hand. Otherwise, what is the point? To do every calculation twice because we might find the N+1st check of the duality invalidates it?

Well, either there is a proof, or it might be that the duality doesn't actually hold in all conceivable cases. It is thus a conditional calculation. Or else you are making a definition that the result of what is happening on one side is literally the thing that happens on the other, and no one has checked that this is consistent with the definition not using the duality.

It's not about doing calculations twice, but actually proving conjectures. Is there some solid statement of some conjecture here that is proven, with the hypotheses of some proof of at least a wide class of special cases spelled out explicitly? Otherwise I fail to see how a conjectured mechanism that has only been calculated in a bunch of cases, but not proven for all the cases people care about, can be considered anything other than an open problem. Experimental mathematics is full of examples of patterns that fail to continue, and famously some of them continue for ranges that make the volume of the universe in Planck volumes look approximately zero.

30. **Jonathan Oppenheim**
January 30, 2023

@Emil, as far as I understand the process you're describing, you are inserting operators into the action, and thus changing the physical content of the theory during evolution? This doesn't seem to have much to do with black-hole evaporation, and I'd be loath to draw any conclusions about that. But I'd be happy to come away from this discussion with some reading homework if you have suggestions. It sounds like a check of the partition function, which I am not challenging.

I think evaporating black holes is more than just another N+1 check. And this is made apparent by the fact that when one tries to reconstruct the bulk using the standard rules one gets nonsense, unless one adopts the various proposals (island formula, non-isometric codes) that have recently been put forward. Maybe I'm biased, being part of It from Qubit, but I am with @Peter here — these proposals are being considered because we are being forced to — otherwise there are paradoxes. And whether these new proposals can be made consistent is very much a great challenge and an open question.

31. **Emil Martinec**
January 30, 2023

@Jonathan, no, I am not changing the action or the Hamiltonian of the CFT. The suggestion is to compute correlators in the same theory, with the insertion of a few operators at early times that make black holes as intermediate states, and then at late time insert many operators that gradually collect the Hawking radiation. The procedure for introducing/extracting such quanta goes back to the classic papers of Gubser-Klebanov-Polyakov hep-th/9802109 and Witten hep-th/9802150. That a small number of such insertions can make a black hole is exemplified by calculations in AdS3 of two energetic particles making a BTZ black hole, see for instance gr-qc/9809087. The same operators, looking at much lower energy modes, can be used at late times to collect the radiation.

A closely related procedure is to couple the CFT to a bath (which indeed involves a modification of the CFT Hamiltonian by a term that couples the same local CFT operators discussed above to creation operators for bath excitations) and thereby transfer energy from the CFT to the bath. If we turn on such a coupling adiabatically at very late times, it does the same thing as I was describing above — remove Hawking radiation from the CFT.

As to your last comment, I think we're largely in agreement that there is a problem somewhere; we just disagree on whether the takeaway is that AdS/CFT duality is wrong or whether people are making incorrect inferences about the duality map.

This Week’s Hype

January 24, 2023
Categories: This Week's Hype

The New York Times today has Where is Physics Headed (and How Soon Do We Get There?). It’s an interview by Dennis Overbye of Maria Spiropulu and Michael Turner, the chairs of the NAS Committee on Elementary Particle Physics – Progress and Promise. This committee is tasked with advising the DOE and NSF so they can “make informed decisions about funding, workforce, and research directions.”

The transcript of the interview is rather bizarre, for several reasons. Spiropulu, probably the main person responsible for the recent wormhole publicity stunt, is here the voice of sober reason:

> **Overbye**: String theory — the vaunted “theory of everything” — describes the basic particles and forces in nature as vibrating strings of energy. Is there hope on our horizon for better understanding it? This alleged stringiness only shows up at energies millions of times higher than what could be achieved by any particle accelerator ever imagined. Some scientists criticize string theory as being outside science.
>
> **Spiropulu**: It’s not testable.

whereas Turner (an ~~astronomer~~ astrophysicist with no particular background in mathematics) is a big fan of string theory as mathematics:

> **Turner:** But it is a powerful mathematical tool. And if you look at the progress of science over the past 2,500 years, from the Milesians, who began without mathematics, to the present, mathematics has been the pacing item. Geometry, algebra, Newton and calculus, and Einstein and non-Riemannian geometry.
> …
> We will have to wait and see what comes from string theory, but I think it will be big.

On the topic of particle physics and unification, there’s

> **Overbye**: You’re referring to Grand Unified Theories, or GUTs, which were considered a way to achieve Einstein’s dream of a single equation that encompassed all the forces of nature. Where are we on unification?
>
> **Spiropulu**: The curveball is that we don’t understand the mass of the Higgs, which is about 125 times the mass of a hydrogen atom.
>
> When we discovered the Higgs, the first thing we expected was to find these other new supersymmetric particles, because the mass we measured was unstable without their presence, but we haven’t found them yet. (If the Higgs field collapsed, we could bubble out into a different universe — and of course that hasn’t happened yet.)
>
> That has been a little bit crushing; for 20 years I’ve been chasing the supersymmetrical particles. So we’re like deer in the headlights: We didn’t find supersymmetry, we didn’t find dark matter as a particle.

Turner makes the case one often hears these days from string theorists: the field may have given up on unification, but it has moved on to something much less boring:

> **Turner**: I feel like things have never been more exciting in particle physics, in terms of the opportunities to understand space and time, matter and energy, and the fundamental particles — if they are even particles. If you asked a particle physicist where the field is going, you’d get a lot of different answers.
>
> But what’s the grand vision? What is so exciting about this field? I was so excited in 1980 about the idea of grand unification, and that now looks small compared to the possibilities ahead.
> …
> **Turner**: The unification of the forces is just part of what’s going on. But it is boring in comparison to the larger questions about space and time. Discussing what space and time are and where they came from is now within the realm of particle physics.
>
> From the perspective of cosmology, the Big Bang is the origin of space and time, at least from the point of view of Einstein’s general relativity. So the origin of the universe, space and time are all connected. And does the universe have an end? Is there a multiverse? How many spaces and times are there? Does that question even make sense?
>
> **Spiropulu**: To me, by the way, unification is not boring. Just saying.

The problem with the idea that we’ve moved on to a new, far more exciting time in physics, devoted to replacing conventional space-time and exploring the multiverse, is that there’s no actual way to do experiments about any of this (other than the wormholes…). If this is the vision of the coming NAS report, a possible response from the DOE and NSF may be “That’s nice, we can now shut down all those expensive labs and experiments doing the boring stuff and focus on investigating the wormholes that Google’s quantum computer is producing for us.”

Update: Ars Technica has some refreshing anti-hype: Requiem for a string: Charting the rise and fall of a theory of everything, with subtitle “String theory was supposed to explain all of physics. What went wrong?”

It’s a good explanation of what went wrong with string theory, although one might point out that pretty much the same story was first explained by others in detail 20 years ago.

There definitely seems to be a recent trend in popular science articles to finally admit that string theory unification may simply be a failed and now dead idea. This article gets brutal at times:

> The dearth of evidence has slaughtered so many members of the supersymmetric family that the whole idea is on very shaky ground, with physicists beginning to have conferences with titles like “Beyond Supersymmetry” and “Oh My God, I Think I Wasted My Career.”

   I don’t think Michael Turner is an astronomer. As far as I can tell, he’s worked on things like axions and theoretical cosmology which are much more string theory adjacent. Unless he routinely works in magnitudes, he’d be an astrophysicist at best.

2. **Peter Woit**
January 24, 2023

Felix,
Agreed that astrophysicist is more accurate than astronomer, I changed the posting to reflect this. I noticed that in 2010 a UC press release described him as the APS's "first astrophysicist president"
https://news.uchicago.edu/story/michael-s-turner-become-american-physical-societys-first-astrophysicist-president

In any case, I see nothing in his research work or educational background to indicate any expertise in the mathematics of string theory.

3. **Georges E. Melki**
January 24, 2023

What I liked best: Turner's "Einstein and non-Riemannian geometry"!!LOL

4. **Sabine Hossenfelder**
January 25, 2023

Just on the off chance that someone reading this still doesn't know. The claim that "we don't understand the mass of the Higgs boson" is an argument from naturalness. I explained in my book "Lost in Math" why that's not a scientific argument. That it's not scientific is why the "predictions" that supersymmetry should show up at the LHC turned out to be wrong.

The statement that the Higgs mass is "unstable" is bluntly wrong. Like a lot of people in the community, she is confusing as physically possible change of parameters (that can be used to identify an instability) with a physically impossible change, which is the type of change that is used in naturalness arguments. This alleged "instability" is just a property of the theory. There is nothing problematic about it. There's also nothing in need of explaining because we know where it comes from, it comes from the Higgs being a scalar. I believe particle physicists for the most part don't know what they mean by "explaining" in the first place.

Doesn't help that the words "naturalness" and "finetuning" are used with different meaning in different parts of the foundations of physics, which I would have written a review paper about if the DFG hadn't refused to finance me, which they did, so now I'm just leaving comments on blogs to complain about what other people are doing.

It's extremely worrisome that despite the fact that naturalness turned out to be wrong, particle physicists still insist on using it.

5. **Robert A. Wilson**
January 25, 2023

Perhaps non-Riemannian geometry will explain Einstein's theories better than the Riemannian sort?! Perhaps that's what's missing from quantum gravity…

6. **Peter Woit**
January 25, 2023

George E. Melki, Robert A. Wilson,

While "Einstein and non-Riemannian geometry" is considered by most to have been a failed unification research program, maybe Turner is right that non-Riemannian geometry is the way to go. Perhaps he's referring to attempts to interpret one of the factors in the euclidean 4d rotation group in terms of internal symmetry, giving a non-Riemannian sort of geometry.

7. **Marvin**
January 25, 2023

Peter W

We can look at the simpler possibility that Turner make a lapsus in his enumeration: "Geometry, algebra, Newton and calculus, and Einstein and non-Riemannian geometry", have to be corrected as : "Geometry, algebra, Newton and calculus, and Einstein and non-Euclidian geometry."

8. **Martin**
January 26, 2023

I think Einstein Non-Riemannian was meant as General Relativity and Non-Riemannnian singniture.

9. **Peter Woit**
January 26, 2023

Marvin/Martin,
My comment about this was meant as a joke. Surely Turner meant non-Euclidean or maybe pseudo-Riemannian. The striking thing about all his comments was that he appeared to have no idea what he was talking about (a main direction for HEP physics is to decide about the multiverse?????). I suspect people in HEP are pretty appalled that this is the way their field is being promoted to the public and that a chair of a committee determining their future is saying these kinds of things.

10. **Robert A. Wilson**
January 26, 2023

My comment was also meant as a joke, of course. I hope no-one took it seriously.

11. **Jim Holt**
January 27, 2023

A propos, I found this comment (from a youtube video on cosmology) to be perceptive:

"Sideshow Bob
3 days ago
Everyone has known for decades – if you want to truly explore multi verses, you need to repair your toaster with parts from the nuclear power plant."

12. **Ted Rogers**
January 28, 2023

From the Ars Technica article:

“Recently, theorists have proposed another duality, the AdS/CFT correspondence.”

Recently!?

Various and Sundry

Categories: Uncategorized, Wormhole Publicity Stunts

A few things that may be of interest:

- Fermilab is continuing to push the wormhole publicity stunt, with Joe Lykken, the lab's Deputy director for research on the 17th giving a public lecture on Wormholes in the Laboratory. The promotional text goes way out of its way to mislead about the science:

  > A wormhole, also known as an Einstein-Rosen bridge, is a hypothetical tunnel connecting remote points in spacetime. While wormholes are allowed by Albert Einstein's theory of relativity, wormholes have never been found in the universe. In late 2022, the journal Nature featured a paper co-written by Joe Lykken, leader of the Fermilab Quantum Institute, that describes observable phenomenon produced by a quantum processor that "are consistent with the dynamics of a transversable wormhole." Working with a Sycamore quantum computer at Google, a team of physicists was able to transfer information from one area of the computer to another through a quantum system utilizing artificial intelligence hardware.

  The "utilizing artificial intelligence hardware" seems to be an incoherent attempt to add more buzzwords to the bullshit. If you know anyone with any influence at the lab, you might want to consider contacting them and asking them to try and get this embarrassment canceled.

- On another embarrassment to science front, Fumiharu Kato on Twitter is announcing the publication of the paperback edition of his book promoting the IUT proof of the abc conjecture. In his talk about this at the Simons Center he dealt with the issue of the problems with the proof by pretending they don't exist, but (from what I can make out using Google Translate), he says he'll deal with this in the paperback edition. His point of view seems to be that once PRIMS (chief editor S. Mochizuki) decided to accept the IUT papers, no one should be writing things like this. Perhaps he's just trying to point out that this is potentially a huge embarrassment for PRIMS and RIMS in general, which is undeniable. But he appears to be going down the truly unfortunate path of making this not about mathematics but about Japanese national honor, with one tweet getting translated as:

  > Some non-Japanese mathematicians questioned, "This is an insult to the Japanese mathematics world! Why don't Japanese mathematicians say anything after being so insulted?" I also think the question is valid.

- Continuing with the difficult and depressing, there's the ongoing Russian war of aggression in Ukraine. The New York Times reports on the efforts of the Simons Foundation help sustain Ukrainian science. The Guardian has an excellent article on the problems the LHC experiments are having due to the fact that Russian physicists make up a significant part of the collaborations. I had heard this story back in September from John Ellis, who I met for the first time in London (at an event which now has a video of a discussion I was involved in). Tommaso Dorigo has an article about this on his blog, where he takes a point of view that is appealing (no borders or nationalism in science), but I don't think it's so simple.

  I've been wondering if there is a historical parallel to look to, with one possibility the situation in 1938-39 when Hitler invaded Czechoslovakia. By this point (as now) a lot of scientists had fled to the West, and the issue must have arisen of how scientists in the West should deal with their German colleagues who were staying in Germany.

- Turning to something much more pleasant, Michael Harris points me to a video of a talk by Manjul Bhargava that has finally appeared, one of a series of talks at a 2018 conference in honor of Barry Mazur.
- This week in my graduate class I'm talking a bit about Howe duality, and just discovered that his original unpublished articles on the subject are now available online, see here and here.
- Finally, I only recently learned about the volume of Sidney Coleman's correspondence that recently appeared, under the title Theoretical Physics in Your Face. Especially fun to read for those like me who remember the era at Harvard when Coleman was at the center of activity. One quote, his opinion in 1985 evaluating the grant to the Princeton theory group:

  > If I have any serious criticism of this group at all, it is that their recent concentration on superstrings seems to me a tactical error, too much devotion of effort to a line of development that (at least to an outsider's eye) is not that promising. However, I could well be wrong in this, and, even if I am right, they'll soon discover they've drilled a dry hole and be off exploring other fields next year.

  Unfortunately the last part of this was very wrong…

Update: Nature has an article on the resolution of the LHC Russian authorship issue.

Comments

1. **Douglas Natelson**
   February 7, 2023

   One of the best math talks I ever heard was by Manjul Bhargava, on the 15 theorem (https://en.m.wikipedia.org/wiki/15_and_290_theorems). Just outstanding for a non-expert.

2. **David Roberts**
   February 7, 2023

   > A wormhole, also known as an Einstein-Rosen bridge, is a hypothetical tunnel connecting remote points in spacetime. While wormholes are allowed by Albert Einstein's theory of relativity, wormholes have never been found in the universe.

   Doubling down on linking the "wormhole" in at best a 1+1D Lorentzian manifold to General Relativity and our universe and spacetime, even though one might argue that reading the text literally, they aren't saying this outright.

3. **Michael Weiss**
   February 8, 2023

   It is remarkable to realize that as far back as the mid-1970s Prof. Sidney Coleman included Bell's Theorem as part of his introductory undergraduate course on QM ("Physics 143" at Harvard). It was a serious yet "for fun" lecture at the end of the syllabus, not to be included on the final exam. Even as Sidney always instilled a sense of wonder and elegance, his presentation of Bell's ideas communicated its fundamental importance–the opposite of "shut up and calculate." It might be that Sidney was the first physicist nationally to include Bell in an otherwise standard sophomore course. How he would have appreciated this year's Nobel Prize in Physics (his late Harvard colleague Prof. Francis Pipkin was an early advocate of Bell-inspired experiments).

4. **Anon**
   February 13, 2023

   The Coleman book has the worst copy editing I've ever seen. The first chapter (available on World Scientific's website) has numerous occurrences of "Seldom Glasgow".

5. **Peter Woit**
   February 13, 2023

   Anon,

   I do think Sidney would have appreciated the humor of that renaming of Glashow.

6. **Anon**
   February 17, 2023

   Thanks a lot for pointing out the two Howe papers – never knew these existed, and have only ever seen his two 1989 papers on the topic. Really interesting.

   February 27, 2023

   "… the issue must have arisen of how scientists in the West should deal with their German colleagues who were staying in Germany …"

   This is a well known and deeply unpleasant story. It was a question of whether the German government permitted them to continue their research, or drove them out for political views or race, or even for having the temerity to try to help those less fortunate. By that time, the Germany government was forcing every profession to prepare for war so pure science without military uses had little respect or funding, although in October 1938 Gerhard Schrader came up with nerve agents tabun and sarin, and in December 1938 Otto Hahn and Fritz Strassmann discovered uranium fission. The Nazis put Heisenberg on charge of nuclear research, and he visited Bohr in Copenhagen in September 1941, but Bohr declined to help the Nazis and fled to the UK and then USA.

   I think and hope that unless further escalation occurs, a FAR better analogy to the present situation is given by Andrei Sakharov's Memoirs (Knopf 1990), which details the gulag and psychiatric treatment provided by the CCCP for dissidents.

   Sakharov was exiled with his wife to Gorky by Brezhnev for criticising the latter's decision to invade Afghanistan at the end of 1979. He was there relentlessly persecuted by the KGB and went on repeated hunger strikes for 7 years until Gorbachev released him. His statement of 27 January 1980 (Appendix B of his Memoirs, pp673-5):

   "On January 22, I was detained on the street and taken by force to the USSR Procurator's office … I was asked to return the medals and orders and certificates … Rekunkov also informed me of the decision to banish me to the city of Gorky, which is closed to foreigners … I was instructed to report three times a month to the police … The authorities are completely isolating me from the outside world. The house is surrounded 24 hours a day by police and the KGB, who keep away all visitors, including my friends. Telephone connections with Moscow and Leningrad are cut off. We have not even been able to call my wife's mother … Even in prison, there is more possibility of communication with the outside world …

   "The worsening of the international situation was caused by the following actions of the USSR … Supporting terrorist regimes … Supporting the actions of quasi-governmental terrorists in Iran who have violated diplomatic immunity … the invasion of Afghanistan … against the Afghan people."

8. **Justcurious**
   March 14, 2023

   Next week there's the opening workshop of a new big research network between universities in France and Japan and seems to be watchable by zoom, but only by members https://ahgt.math.cnrs.fr/activities/workshops/AHGT-2023/

   As an outsider, most talks seem to be uncontroversial mathematics including well-known people like Yves André etc. But on Tuesday 22 one of the speakers will be Shinichi Mochizuki about IUT (he is a member of that network), just before the session free discussion. It might be interesting, a pity it isn't public.

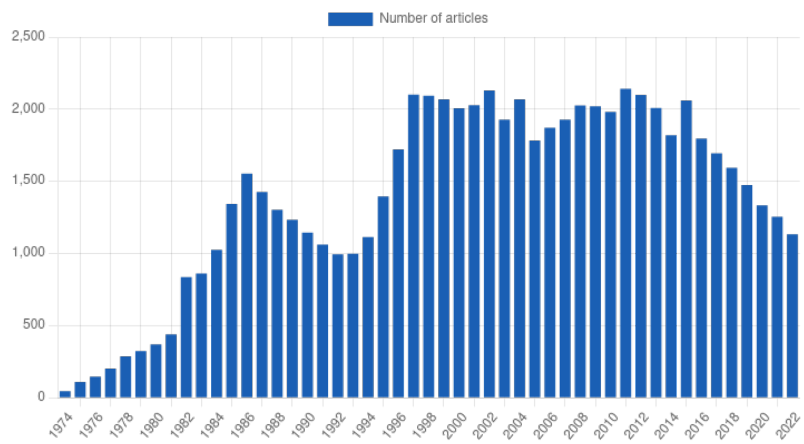
What’s Going Right in Particle Physics

February 14, 2023
Categories: Uncategorized

Since I had a little free time today, I was thinking of writing something motivated by two things I saw today, Sabine Hossenfelder’s What’s Going Wrong in Particle Physics, and this summer’s upcoming SUSY 2023 conference and pre-SUSY 2023 school. While there are a lot of ways in which I disagree with Hossenfelder’s critique, there are some ways in which it is perfectly accurate. For what possible reason is part of the physics community organizing summer schools to train students in topics like “Supersymmetry Phenomenology” or “Supersymmetry and Higgs Physics”? “Machine Learning for SUSY Model Building” encapsulates nicely what’s going wrong in one part of theoretical particle physics.

To begin my anti-SUSY rant, I looked back at the many pages I wrote 20 years ago about what was wrong with SUSY extensions of the SM in chapter 12 of *Not Even Wrong*. There I started out by noting that there were 37,000 or so SUSY papers at the time (SPIRES database). Wondering what the current number is, I did the same search on the current INSPIRE database, which showed 68,469 results. The necessary rant was clear: things have not gotten better, the zombie subject lives on, fed by summer schools like pre-SUSY 2023, and we’re all doomed.

But then I decided to do one last search, to check number of articles by year (e.g. search “supersymmetry and de=2020”). The results were surprising, and I spent some time compiling numbers for the following table:



These numbers show a distinct and continuing fall-off starting after 2015, the reason for which is clear. The LHC results were in, and a bad idea (SUSY extensions of the SM) had been torpedoed by experiment, taking on water and sinking after 20 years of dominance of the subject. To get an idea of the effect of the LHC results, you can read this 2014 piece by Joe Lykken and Maria Spiropulu (discussed here), by authors always ahead of the curve. No number of summer schools on SUSY phenomenology are going to bring this field back to health.

Going back to INSPIRE, I realized that I hadn’t needed to do the work of creating the above bar graph, the system does it for you in the upper left corner. I then started trying out other search terms. “string theory” shows no signs of ill-health, and “quantum gravity”, “holography”, “wormhole”, etc. are picking up steam, drawing in those fleeing the sinking SUSY ship. With no experimentalists to help us by killing off bad ideas in these areas, some zombies are going to be with us for a very long time…

Update: There are a couple things from Michael Peskin that are relevant to this that might be of interest: an extensive 2021 interview, and a very recent “vision statement” about particle physics. Peskin’s point of view I think is exactly what Hossenfelder is arguing against. He continues to push strongly for a very expensive near-term collider project, and doesn’t seem to have learned much of anything from a long career of working on failed ideas. I remember attending a 2007 colloquium talk here at Columbia where he put up a slide showing all the SUSY particles of masses a few hundred GeV that the LHC was about to find, and assured us that over the next 5-10 years we’d be seeing evidence of a WIMP from several different sources. According to the interview, in 2021 he was working on Randall-Sundrum models (see here) and wondering about the “little hierarchy problem” of why all the new physics was just above the LHC-accessible scale rather than at the electro-weak breaking scale. I very much agree with some of his vision statement (the Higgs sector is the part of the SM we don’t fully understand, and the argument for colliders is that they are the only way to study this), but his devotion to failed ideas (not just Randall-Sundrum, but string theory also) as the way forward is discouraging. In the interview he admits that it’s looking like post-LHC abandonment of particle physics is the most likely future:

> I think if you were a betting man, you would bet that LHC will be the last great particle accelerator, and the whole field will dissipate after the LHC is over.

Most of his prominent colleagues have the same attitude that the subject is over, and have already moved on, unfortunately to things like creating wormholes in the lab.

Comments

1. **Interested amateur**
   February 14, 2023

   It looks to me that your graph clearly shows the fall started in 2012, a huge year for the LHC, with a hopeful blip in 2016, one year after the LHC restarted in 2015.

2. **S**
   February 15, 2023

   Perhaps the experimental result of thousands of theorists coming to the ends of their career and realizing they have nothing to show for it will eventually start to tell….

3. **Sabine Hossenfelder**
   February 15, 2023

   Hi Peter,

   Thanks for digging up these numbers, which is very interesting. A lot of people in hep-ph have been shifting weight to axion-like particles and general hidden sector things, branching out into astroparticle physics and sprinkling machine learning over it for good measure.

Unfortunately, that doesn't solve the problem in the community, it just moves it elsewhere. Since they never acknowledged that their LHC predictions went badly wrong, they're doomed to repeat their mistakes.

The situation in particle physics is very comparable to the reproducibility crisis which they had in psychology. Both were driven by bad scientific methodology that had become normalized. Psychologists managed to mobilize the community and introduce better methodology. And, amazingly enough, this was a bottom-up effort, purely community driven.

I sincerely hope that particle physicists can get their act together and do the same thing. A lot could be gained in this community if everyone had a basic education in the philosophy and sociology of science. And yeah, it would to hurt for a few years, but I believe that particle physics stands much to gain from it.

4. **Tom WEIDIG**
February 15, 2023

Whatever mistake or bad strategy particle physicists (especially theorists) might have committed or followed, particle physics will naturally correct itself as physics has the most powerful feedback control mechanism in science: experiments.

Nature as expressed through experiments will tell us whether it has implemented SUSY or not!

In this respect, physics is fundamentally different to psychology, and I disagree with Sabine. Psychology experiments are very different to physics experiments, because in psychology you have to control for the informational content in people's brains. Every electron and quark is identical to any other electron and quark, whereas every human being in an experiment is different in so many ways, especially in its informational content of the brain which shapes behaviour. Moreover, the crisis in psychology was not a crisis in theory building but in using sloppy statistics (p-values) to overinterpret experimental results, whereas particle physicists are extremely carefull and accurate in its statisical interepretation of experimental data.

The wild model building bonanza is only due to a lack of experimental constraints.

5. **More Anonymous**
February 15, 2023

"So what will happen to particle physicists? Well, if you extrapolate from their past
behavior to the future, then the best prediction for what will happen is:
Nothing. They will continue doing the same thing they've been doing for the past 50 years. It will continue to not work. Governments will realize that particle physics is eating up a lot of money for nothing in return, funding will collapse, people will leave, the end."

Sabine I think your extrapolation is wrong?

I suspect particle physicists have changed their minds but not conceded it as Peter shares: "These numbers show a distinct and continuing fall-off starting after 2015, the reason for which is clear …" Now the burden of proof to show that every spin-off idea is equally unpromising (as they are "they're doomed to repeat their mistakes") is still an argument to be made? I wouldn't be surprised if this was indeed the case (at least for string theory) but I think data helps and prevents us when we make blanket statements

More Anonymous

6. **Robert Matthews**
February 15, 2023

@Tom Weidig: to be fair to Sabine, I think she may have meant questionable statistical practices like p-hacking, mis-interpretation of p-values etc when she said "bad scientific methodology that had become normalized" (perhaps Sabine would like to comment ?).

She's right that psychologists "managed to mobilize the community and introduce better methodology". These include the emergence of Registered Reports (RRs), which guarantee publication of research on the basis that the methodology is refereed and approved _before_ the study takes place, rather than afterwards.

By decoupling publication from the level of p-value achieved, RRs to date suggest that research in psychology _does_ have a problem with theory building, in the sense of failing to propose hypotheses leading to effect sizes convincingly above noise level. So they're not so far from HEP theorists really.

As someone once said, science is _hard_, but that's no excuse for persisting with stuff that's long since keeled over and died.

7. **Laurence Lurio**
February 15, 2023

I agree that the current experimental results are not encouraging. However, I was always impressed when I went to SUSY talks by the graph showing the three standard model coupling constants varying with energy and almost meeting at around 10^15 GeV. When SUSY was included they all meet at exactly the same place. Do you feel that this was never a convincing argument?

8. **Peter Woit**
February 15, 2023

All,
Please stick to the problems of particle physics, which are a big and complicated issue. A sensible discussion of the larger problems of other sciences and social science would be something way beyond my ability to moderate.

9. **Peter Woit**
February 15, 2023

Laurence Lurio,
I wrote extensively about this in my book and on the blog, agreeing that it's probably the best argument for SUSY extensions of the SM, but is still extremely weak and unconvincing. It's an argument that is often made in a misleading way.

Technically, one problem is that the graph often presented is a one-loop calculation, ignoring the fact that two-loop calculations make the "three lines join at a point" significantly less true. To really do this calculation, you need to use updated LHC limits (the SUSY-change in evolution can't start until the scale at which you see SUSY), you need to include higher-loop contributions, and you need to discuss "threshold effects" of the unknown physics of new Higgs bosons you have to introduce at the GUT scales. With all this taken into account, I don't think there ever was a very impressive "three lines join at a point", just "they join better than with no SUSY", which is something different. I haven't looked into this recently, curious if someone knows of an up to date accurate calculation.

The big problem with any such calculation though is that its assumptions are implausible and discredited by experiment. For the highly implausible, it assumes the "desert hypothesis": no new physics in between the EW breaking scale and the GUT scale. For discredited, GUTs (SUSY or otherwise) generically predict proton decay rates in conflict with observation.

In addition, beyond being implausible and in conflict with experiment, GUTs have fundamental generic problems of just adding a lot of complex structure to the SM, while not explaining anything. What you are doing is postulating a larger symmetry, but then not getting anything out of it since you have to add a complicated symmetry breaking structure to explain why we don't see evidence of this new symmetry. SUSY by itself has the same generic problem in spades (you postulate a new symmetry making your theory more predictive, the predictions are wrong, so you have to add a complicated mess purely to get rid of the new predictions of the symmetry). These problems have been around since long before the LHC put the final nails in the coffin of this subject.

10. **Anonyrat**
February 15, 2023

I think the downward trend in Supersymmetry papers would be more meaningful if compared to a baseline (e.g., compared to number of papers on Higgs, QCD, neutrinos, dark matter, or some such). I don't know what the appropriate comparison would be – perhaps QCD? – or else I would try myself.

11. **Low Math, Meekly Interacting**
February 15, 2023

What happened c. 1985? There's a similar downward trend that only reverses around 1994, perhaps sparked by developments around the Second Superstring Revolution. Then again, the earlier downswing would seem to coincide with Green-Schwarz and the First Superstring Revolution, so maybe Strings can't explain these trends in particle physics so neatly.

12. **Aristotle Pagaltzis**
February 15, 2023

To pick a nit, the graph looks to me as if 2015 was a singular outlier in a trend that actually started in 2011. But this is still compatible, in fact possibly even more compatible, with the explanation that the LHC permanently altered the trajectory of the field.

(In fact 2011 is either the highest point, or tied for highest with 2002. One might not unreasonably read this graph as a steady underlying increase leading up to 2011, with two superimposed waves of excess enthusiasm in the run-up to 1986 and 1997 – sound familiar? –, and then a steady underlying decrease since.)

Thank you for noticing this and pointing it out. It was a rare piece of genuinely heartening news, even ill as it bodes for the dispatch of less experimentally tractable zombies.

13. **Peter Woit**
February 15, 2023

Anonyrat,
I think taking a ratio with some other keyword with its own history is just going to confound different phenomena.

What's remarkable to me about the SUSY numbers are how little they changed from 1997 to 2015, which indicates a very large and stable industry of people consistently pumping out "SUSY" papers. Something happened to wreck the health and stability of this industry and it's pretty clear what it was.

14. **Peter Woit**
February 15, 2023

LMMI,
The first peak is definitely the "First Superstring Revolution", where for several years everyone was writing papers about how SUSY models derived from the superstring were going to unify physics. Not sure of what the dynamics was during the mid 90s driving up the numbers to the stable situation the subject then entered for a very long time.

15. **Alessandro Strumia**
February 16, 2023

A more accurate plot done with bibliometric codes takes into account these factors:
– The overall number of papers/year increased significantly.
– Papers on "MSSM" or "gluino" or "sugra" are on supersymmetry even if it's not mentioned, etc.
This shows a decline of "SUSY&co" and of "string&co". "Higgs" peaked and it's now declining. "DarkMatter&co" grows.

16. **Mark**
February 16, 2023

I wish people would stop saying "particle physicists". This discussion is more about particle theorists. Experimentalists might not have their backs up so much by some of the comments in popular media if this distinction was made…

On SUSY the LHC was very successful – we were told we would produce an abundance of gluinos and squarks when we turned it on. We made some rather difficult measurements that showed almost straight away that prediction was wrong.

17. **A Humble Grad Student**
February 16, 2023

Hello Peter,

If I had to guess, I would say that Witten's 1995 announcement of the equivalence of the various string theories through S and T dualities and M-Theory is the reason for the late 90s spike. Also you had Maldacena's AdS/CFT paper in 1997/98. These two milestones alone probably contributed significantly to the number of papers mentioning "supersymmetry".

Regards,
A Humble Grad Student.

Comment on traversable wormholes
https://arxiv.org/abs/2302.07897

19. **Dan Riley**
February 19, 2023

@Robert Matthews, I don't believe experimental particle physics has a statistical reproducibility problem per se. We publish null results, and have for decades–null results are informative, so publication hasn't been tied to p-values. More recently, most experiments have adopted strong measures against p-hacking–analyses have to be fully defined using simulated data, and results (especially major results) are routinely blinded.

What Sabine generally complains about is mostly the generation of theoretical models, and experimentalists using those theories to justify new and bigger machines. I'm unconvinced that the problem there is substantively analogous to the reproducibility crisis in psychology, nor as easily solved as pointing out bad statistical practices.

The Trouble With Path Integrals, Part I

February 16, 2023
Categories: Uncategorized

Two things recently made me think I should write something about path integrals: Quanta magazine has a new article out entitled How Our Reality May Be a Sum of All Possible Realities and Tony Zee has a new book out, Quantum Field Theory, as Simply as Possible (you may be affiliated with an institution that can get access here). Zee's book is a worthy attempt to explain QFT intuitively without equations, but here I want to write about what it shares with the Quanta article (see chapter II.3): the idea that QM or QFT can best be defined and understood in term of the integral
$$\int_{\text{paths}}e^{iS}$$
where S is the action functional. This is simple and intuitively appealing. It also seems to fit well with the idea that QM is a "many-worlds" theory involving considering all possible histories. Both the Quanta article and the Zee book do clarify that this fit is illusory, since the sum is over complex amplitudes, not a probability density for paths.

This posting will be split into two parts. The first will be an explanation of the context of what I've learned about path integrals over the years. If you're not interested in that, you can skip to part II, which will list and give a technical explanation of some of the problems with path integrals.

I started out my career deeply in thrall to the idea that the path integral was the correct way to formulate quantum mechanics and quantum field theory. The first quantum field theory course I took was taught by Roy Glauber, and involved baffling calculations using annihilation and creation operators. At the same time I was trying to learn about gauge theory and finding that sources like the 1975 Les Houches Summer School volume or Coleman's 1973 Erice lectures gave a conceptually much simpler formulation of QFT using path integrals. The next year I sat in on Coleman's version of the QFT course, which did bring in the path integral formalism, although only part-way through the course. This left me with the conclusion that path integrals were the modern, powerful way of thinking, Glauber was just hopelessly out of touch, and Coleman didn't start with them from the beginning because he was still partially attached to the out-of-date ways of thinking of his youth.

Over the next few years, my favorite QFT book was Pierre Ramond's Field Theory: A Modern Primer. It was (and remains) a wonderfully concise and clear treatment of modern quantum field theory, starting with the path integral from the beginning. In graduate school, my thesis research was based on computer calculations of path integrals for Yang-Mills theory, with the integrals done by Monte-Carlo methods. Spending a lot of time with such numerical computations further entrenched my conviction that the path integral formulation of QM or QFT was completely essential. This stayed with me through my days as a postdoc in physics, as well as when I started spending more time in the math community.

My first indication there could be some trouble with path integrals I believe started in around 1988, when I learned of Witten's revolutionary work on Chern-Simons theory. This theory was defined as a very simple path integral, a path integral over connections with action the Chern-Simons functional. What Witten was saying was that you could get revolutionary results in three-dimensional topology, simply by calculating the path integral
$$\int_{\mathcal A} e^{iCS}$$
where the integration is over the space of connections A on a principal bundle over some 3-manifold. During my graduate student days and as a postdoc I had spent a lot of time thinking about the Chern-Simons functional (see unpublished paper here). If I could find a usable lattice gauge theory version of CS (I never did…), that would give a way defining the local topological charge density in the four-dimensional Yang-Mills theory I was working with. Witten's new quantum field theory immediately brought back to mind this problem. If you could solve it, you would have a well-defined discretized version of the theory, expressed as a finite-dimensional version of the path integral, and then all you had to do was evaluate the integral and take the continuum limit.

Of course this would actually be impractical. Even if you solved the problem of discretizing the CS functional, you'd have a high dimensional integral over phases to do, with the dimension going to infinity in the limit. Monte-Carlo methods depend on the integrand being positive, so won't work for complex phases. It is easy though to come up with some much simpler toy-model analogs of the problem. Consider for example the following quantum mechanical path integral
$$\int_{\text {closed paths on}\ S^2} e^{i\frac{1}{2}\oint A}$$
Here S^2 is a sphere of radius 1, and A is locally a 1-form such that dA is the area 2-form on the sphere. You could think of A as the vector potential for a monopole field, where the monopole was inside the sphere.

If you think about this toy model, which looks like a nice simple version of a path integral, you realize that it's very unclear how to make any sense of it. If you discretize, there's nothing at all damping out contributions from paths for which position at time t is nowhere near position at time $t+\delta t$. It turns out that since the "action" only has one time derivative, the paths are moving in phase space not configuration space. The sphere is a sort of phase space, and "phase space path integrals" have well-known pathologies. The Chern-Simons path integral is of a similar nature and should have similar problems.

I spent a lot of time thinking about this, one thing I wrote early on (1989) is available here. You get an interesting analog of the sphere toy model for any co-adjoint orbit of a Lie group G, with a path integral that should correspond to a quantum theory with state space the representation of G that the orbit philosophy associates to that orbit. Such a path integral that looks like it should make sense is the path integral for a supersymmetric quantum mechanics system that gives the index of a Dirac operator. Lots of people were studying such things during the 1980s-early 90s, not so much more recently. I'd guess that a sensible Chern-Simons path integral will need some fermionic variables and something like the Dirac operator story (in the closest analog of the toy model, you're looking at paths moving in a moduli space of flat connections).

Over the years my attention has moved on to other things, with the point of view that representation theory is central to quantum mechanics. To truly play a role as a fundamental formulation of quantum mechanics, the path integral needs to find its place in this context. There's a lot more going on than just picking an action functional and writing down
$$\int_{paths}e^{iS}$$

   Interesting. I mentioned in an earlier thread that I was currently working through Blundell and Lancaster's *QFT For The Gifted Amateur*. Before taking up that book I looked at Zee's *Nutshell*. It's notable that Zee starts right off introducing path integrals in chapter 1 while in Blundell/Lancaster they don't show up until halfway through the book. I was wondering whether that was purely a personal choice or whether it represented a broader difference in schools of thought about how the subject should be taught.

2. **Andrzej Daszkiewicz**
   February 17, 2023

   Academic Lurker,
   and Michel Talagrand in *What is a Quantum Field Theory? A First Introduction for Mathematicians* (Peter, thanks for mentioning this book!) completely ignores path integrals: "I have also decided to stay entitely away from path integrals […]. There is no doubt that from the point of view of physics, path integrals are a correct approach, but they are not well defined mathematically, and I do not see what yet another heuristic discussion of them would bring."

In fact, I am working through all three (Talagrand, Zee's *Nutshell* and Blundell/Lancaster) and I have just finished Zee's *QFTaSaP* which I have to return to aSaP ;).

3. **Peter Woit**
   February 17, 2023

   AcademicLurker,
   Different people have different points of view, depends a lot on what your experience with qft is and what sorts of calculations you've worked on. For a long time I would have argued that the path integral is the place to start (and I think I did this when I taught a QFT course in the math department back in 2003). More recently, in the QM course I've been teaching and the book I wrote, I avoided path integrals completely. One reason for this though was that the course doesn't cover interacting QFTs.

   At this point it seems to me that it's a good idea to start off with free field theories as an infinite collection of harmonic oscillators and emphasize the propagator, without getting into path integrals at the beginning. By the way, the path integral is a horrible way to calculate things in the QM simple harmonic oscillator). The path integral formalism is a very nice way of organizing the perturbation expansion, and it comes into its own in Yang-Mills theory. But it should be taught with caveats about the necessity of analytically continuing in time, difference between configuration space path integral and (much more problematic) phase space path integral. I think the whole field is suffering from a lack of awareness of the problems with the path integral formalism (which likely point to ways in which the fundamentals of the subject are unsatisfactory).

   Andrzej Daszkiewicz mentions correctly that the Talagrand book (also Folland's) are good examples of where the authors saw no way to give the kind of careful discussion they wanted in terms of path integrals. There are other books by mathematicians (see Glimm/Jaffe) that are based on path integrals, but then they stick to a certain class of theories where the path integral works well (and stay in Euclidean space-time).

4. **Pascal**
   February 21, 2023

   A belated remark on many worlds and complex amplitudes (as opposed to probability densities): this situation is not specific to QFT at all. Think of the more elementary setting where unitary transformations are applied in discrete time steps, as is often the case in quantum information and computation. Then we get a finite sum instead of a path integral, and it is a sum of complex amplitudes (not probabilities). And that doesn't prevent many worlds from being a viable interpretation.

5. **Peter Woit**
   February 21, 2023

   Pascal,
   No intent to start a discussion of many-worlds. My point was just that readers of the Quanta article hearing that a sum over all possible paths is "how the world really is", might think this sounds like the many worlds multiverse, but it's really something quite different. This is especially clear in the Euclidean time picture, where QM is precisely a probabilistic measure on possible histories of worlds, but this is a very different thing than the Born rule probability.

6. **Matthew Foster**
   February 25, 2023

   Hi Peter

   The sphere integral is the "spin coherent state path integral" for a single spin, i.e. the first-order term is a Wess-Zumino-Novikov-Witten term. At least for 2D WZNW CFTs (Witten's nonabelian bosonization), there is no problem reproducing results from the formal affine Lie algebra rep theory (e.g. scaling dims for local operators) via perturbation theory in the corresponding matrix sigma model. The perturbation theory works at large levels. Maybe the restriction to finite KM primary fields is a nonperturbative effect that would require a more serious formulation of the path integral?

7. **Peter Woit**
   February 25, 2023

   Matthew Foster,
   Yes, my toy example is the "spin coherent state path integral" and I'm claiming it's problematic to think of it as an actual integral. You can certainly use it for a semi-classical approximation, but that's different.

   I wrote up all this way back in in 1989, published in an obscure location. A copy of the paper is here https://www.math.columbia.edu/~woit/tqtandrepthy.pdf

   This is about 0+1 theories, for 1+1 QFTs, there's a more complicated story. The WZW path integral is a configuration space path integral (analogous to taking the group manifold as configuration space in 0+1d)

   There's lots and lots more to say about these 1+1 d QFTs related to representations of loop groups or affine Lie algebras. From what I remember it was always my intention to write a follow up to the above paper that would discuss this, but I don't think I ever finished that project, should go back to it.

8. **Matthew Foster**
   February 27, 2023

   Hi Peter,

   In condensed matter, the main use of WZNW terms of this form is in the context of topological boundary modes, and the connection to associated topological theta terms in one higher dimension. For example, a 1+0-D path integral that encodes chiral edge-state wave functions of a quantum Hall droplet, in the presence of disorder, realizes a WZNW action that is a generalization of the spin coherent-state path integral. This allows one to connect directly to the topological character of the quantum Hall state in one higher spatial dimension, since WZNW is the boundary term accrued from the integration of the topological theta term in a finite system. More sophisticated "anomaly matching" arguments (e.g. with a Chern-Simons "response" action for the edge or bulk) give the same conclusions.

   Usually we have an alternative nonperturbative framework for the boundary WZNW theory, so one doesn't have to evaluate directly the likely-ill-defined path integral. Where we run into problems is with the higher-dimensional bulk, with a topological theta term that is hard to deal with and even hard to sensibly derive. This is because the coefficient of the theta term accrues contributions from the ultraviolet, and a satisfactory UV completion (in terms of a concrete lattice model in our case) is often too unwiedly to do much with.

The Trouble With Path Integrals, Part II

February 16, 2023
Categories: Uncategorized

This posting is about the problems with the idea that you can simply formulate quantum mechanical systems by picking a configuration space, an action functional S on paths in this space, and evaluating path integrals of the form
$$\int_{\text{paths}}e^{iS}$$

Necessity of imaginary time

This section has been changed to fix the original mistaken version.
If one tries to do this path integral for even the simplest possible quantum field theory case (a non-relativistic free particle in one space dimension), the answer for the propagator in energy-momentum space is
$$G(E,p)=\frac {1}{E-\frac{p^2}{2m}}$$
Fourier transforming to real-time is ill-defined (the integration goes through the location of the pole at $E=\frac{p^2}{2m}$). Taking t complex and in the upper half plane, for imaginary t the Fourier transform is a well-defined integral. One gets the real-time propagator then by analytic continuation as a boundary value. For a relativistic theory one has
$$G(E,p)=\frac{1}{E^2-(p^2+m^2)}$$
and two poles (at $E=\pm \sqrt{p^2+m^2}$) to deal with. Again Fourier-transforming to real-time is ill-defined, but one can Fourier transform to imaginary time, then use this to get a sensible real-time propagator by analytic continuation.

Trying to do the same thing for Yang-Mills theory, again one gets something ill-defined for real time, with the added disadvantage of no way to actually calculate it. Going to imaginary time and discretizing gives a version of lattice gauge theory, with well-defined integrals for fixed lattice spacing. This is conjectured to have a well-defined limit at the lattice spacing is taken to zero.

Not an integral and not needed for fermions

Actual fundamental matter particles are fermions, with an action functional that is quadratic in the fermion fields. For these there's a "path integral", but it's in no sense an actual integral, rather an interesting algebraic gadget. Since the action functional is quadratic, you can explicitly evaluate it and just work with the answer the algebraic gadget gives you. You can formulate this story as an analog of an actual path integral, but it's unclear what this analogy gets you.

Phase space path integrals don't make sense in general

Another aspect of the fermion action is that it has only one time derivative. For actions of this kind, bosonic or fermionic, the variables are not configuration space variable but phase space variables. For a linear phase space and quadratic action you can figure out what to do, but for non-linear phase spaces or non-quadratic actions, in general it is not clear how to make any sense of the path integral, even in imaginary time.

In general this is a rather complicated story (see some background in the part I post). For an interesting recent take on the phase-space path integral, see Witten's A New Look At The Path Integral Of Quantum Mechanics.

Update: A commenter pointed me to this very interesting talk by Neil Turok. The main motivation that Turok explains at the beginning of the talk (and also in the Q and A afterwards) is exactly one that I share. He argues that the lesson of the the last 40 years is that one should not try and solve problems by making the Standard Model more complicated. All one needs to do is look more closely at the Standard Model itself and its foundations. If you do that, one thing you find is that there's a "trouble with path integrals". In Turok's words, the problems with the path integral indicate that "the field is without foundations" and "nobody knows what they are doing".

I do though very much part company with him over the direction he takes to try and get better foundations. He argues that you shouldn't Wick rotate (analytically continue in time), but should complexify paths, analytically continuing in path space. For some problems doing the latter may be a better idea than doing the former, and in his talk he works out a toy QM calculation of this kind. But the model he studies (anharmonic oscillator) doesn't at all prove that going to the imaginary time theory is a bad idea, for some calculations that works very well. He's motivated by defining the path integral for gravity, where Euclidean quantum gravity is a problematic subject, but the gravitational version of the toy model I think will also be problematic. The ideas I've been pursuing involving the way the symmetries of spinors behave in Euclidean signature I think give a promising new way to think about this, and you won't get that from just trying to complexify the conventional variables used to describe geometries.

Comments

   February 17, 2023

   It's completely off-topic, sorry, but I just want to bring to your attention this comment uploaded today on the ArXiv (ref: 2302.07897) that severely criticizes the paper by D. Jafferis et al. on traversable wormholes that generated so much hype recently. According to this new analysis, that looks very solid, several essential claims made in the paper are not justified.

2. **More Anonymous**
   February 17, 2023

   @Peter

   Have you read Padmanabhan's Quantum field theory the why, what and how? His section 5.6.3 Propagator from a Fermionic Path Integral is fabulous. As someone who never really got how to extend my intuition of QM to QFT this book was a lifesaver 🙂

3. **Robert A. Wilson**
   February 17, 2023

   I am a little confused as to why you consider the discretization to be problematic. Is it because discretization is necessary for doing calculations, and if the theory doesn't discretize properly, the calculations could give the wrong answer? Or is it because discretization is necessary for the fundamentals of physics, and if the theory doesn't discretize properly, the theory is wrong?

4. **Peter Woit**
   February 17, 2023

More Anonymous,
That is a nice beginning book, one starting from the path integral. The "Fermionic Path Integral" though I think is a bit misleading, since it's not an integral…

5. **Peter Woit**
February 17, 2023

Robert A. Wilson,
Nothing to do with physics at short distances. Physicists are claiming to do certain integrals over infinite dimensional spaces. Mathematicians trying to make sense of this tend to get caught up in issues of the right formalism to define such integrals, which leads to a very complicated story.

I'm pointing out you can think about this more concretely: discretize the problem to make the integral finite-dimensional, then see if you can get a well-defined limit. For some theories like Yang-Mills, this procedure works, and is even necessary (there is no definition in infinite-dim, and the correct nature of the limit is very non-trivial). If you try to do this for other theories though (like the Chern-Simons or toy examples), trying to put the thing on a computer and calculate shows you clearly the serious problems that face attempts to get a well-defined path integral in those cases.

6. **vmarko**
February 17, 2023

Peter,

"As written, this integral doesn't exist."

What do you mean by this? Isn't that just the Fresnel integral?

Complete the square, use Euler's formula to express exp in terms of sin and cos, and thus reduce the rhs to integrals of sin(k^2) and cos(k^2), i.e. Fresnel integrals. What doesn't exist there?

Best, 🙂
Marko

7. **Peter Woit**
February 17, 2023

Marko,
Yes, what I wrote isn't right, was trying to refer to a problem with computing the propagator you see before you get to the formula I wrote. Will edit to fix.

8. **Blendletan**
February 17, 2023

My understanding is that the Osterwalder-Schrader theorem shows how this gets right to the heart of why it's so hard to construct a QFT that really exists and satisfies the Wightman axioms. You can actually build a QFT iff you can actually define this measure (for imaginary time), and show reflection positivity (which allows you to Wick rotate back to real time). So isn't the trickiness you describe exactly the right thing for mathematicians to get caught up in?

9. **Peter Woit**
February 17, 2023

Blendletan,

I just fixed the first part of this post. The point I'm trying to make in that first section is that even for the simplest scalar free field theories the path integral as written is ill-defined. What is well-defined is the imaginary time path integral.

But even in imaginary time, making sense of the path integral for an interacting field theory is very hard. If you can do this, Osterwalder-Schrader give the conditions under which you can reconstruct a real-time theory.

I've been spending a lot of time looking at this story for spinor fields, where it is very non-trivial. If you're a mathematician and want to write a QFT book using well-defined objects, you can do what Jaffe/Quinn did, sticking to scalar fields. Or, if you want to do spinor fields and QED like Folland/Talagrand, you need to avoid the path integral and define the theory in other ways.

10. **JT gravity**
February 17, 2023

What do you think about the "map" or "dictionary" from QFT to statistical mechanics using Wick rotation? The latter is such that the path integrals are well-defined Wiener integrals, so if you could justify the Wick rotation in the first place, perhaps the path-integrals of QFT would be trustworthy, no?

11. **Peter Woit**
February 17, 2023

JT gravity,
This is what Osterwalder-Schrader do for you: they tell you the condition (reflection positivity) you need to justify Wick rotation to a real time theory.

What makes the subject difficult is not this, but that, especially in more than 1+1 dimension, the statistical mechanics systems corresponding to interesting QFTs are very challenging to say anything about. Euclidean lattice gauge theory is a 3+1d stat mech system, but if you can really understand what happens in the limit as lattice spacing goes to zero, there's a million dollars waiting for you.

12. **Marvin**
February 17, 2023

Peter,

Thanks for bringing forward and clearly these core mathematical problems in physic. BTW, it is amazing how physicists can usually make things look confused, so that any mathematician trying to help for the next step can be lost in the fog.

13. **Peter Orland**
February 18, 2023

Hi Peter,

Maybe I should not interject here, but there is much heat and little light on many discussions of path integrals. Although there are problems with the real-time Dirac - Feynman path integral for Chern-Simons and first-time derivative actions, there is a way that such things make sense.

If 1. the Lie-Trotter formula is valid and 2. there is a sensible completeness or overcompleteness relation (resolution of the identity), then the real-time path integral can be sensibly interpreted rigorously! This sort of thing is discussed in an old books by Barry Simon and by Larry Schulman. This is not to say there are not problems with certain physical systems, like those you mention, but for, say standard Hamiltonian mechanics, everything is fine. Other mathematicians (like T. Kato) and physicists also worked on this. Some of the subtleties, like the mid-point prescription are automatically explained by this method.

This method goes over to real-time bosonic field theories, provided they are put on lattices. There is still the technical issue of taking the continuum limit, but that is not unique to the path-integral formulation.

I always just think of the (non-Wick rotated) path integral as an application of 1. and 2. above. You usually can't go wrong this way, although Chern-Simons models still have the problems you mention.

14. **Peter Woit**
February 18, 2023

Hi Peter,
The problem is that, yes, you can start with a quantum theory, break up the exponential of the Hamiltonian using Lie-Trotter, and if you do this in a certain way, you can claim the infinite sum is a phase space path integral. The problem is that it doesn't have lots of the properties you would expect of a path integral, since your paths are discontinuous and you crucially had to do very specific things in getting the infinite sum (eg. alternating specifying q and p).

The "path integral" you get doesn't in particular have the invariances you expect. Since it is written in terms of dpdp in the measure and pdq in the exponent, you expect it to be invariant under symplectic transformations, but it isn't (if it were, you could choose coordinates in which it was a harmonic oscillator, semiclassical approximation exact, see Schulman chapter 31). You also get into very confusing questions when you try to decide what the state space of the theory is starting with the path integral.

There's a fundamental issue behind this: there is no way to start with a classical phase space (e.g. symplectic manifold) and quantize, getting a corresponding quantum system, unless you introduce extra structure (e.g. a polarization). Without smuggling in somewhere this extra structure, your phase space path integral is doing something impossible.

15. **Peter Orland**
February 18, 2023

… but you don't need phase space, only q space in Lie-Trotter. This is very close to the Schr{\"o}dinger representation. We don't write wave functions or wave functionals as functions of phase space.

If you want to introduce p as well as q, one way is to write every other factor (exponential of the kinetic term) as a Gaussian integral, with p as the integration variable.

Dirac and Feynman did emphasize phase space (see Dirac's 1933 paper, Feynman and Hibbs or Feynman's papers from the 40's), but I never saw the point of this.

Anyway, plenty of applications don't use phase space. The book of Simons I mentioned, from the 70's, actually proves nontrivial results from this (and some yes, with real, not imaginary time).

16. **Peter Woit**
February 18, 2023

Hi Peter,
Sorry I thought your comment was referring to the third point in the posting, about path integrals over phase space. These do get used, and it's not often recognized that path integrals for Chern-Simons theory and usual fermion theories are phase space path integrals, not configuration space path integras (since the action is first order in the time derivative).

To the extent we're discussing instead the first point, and path integrals in configuration space, what I first wrote was too strong (since fixed), but there still are problems with real-time path integrals. I was just looking at the late 70s Simons book "Functional Integration and Quantum Physics". The way he puts things in the introduction is:

"By extending the notion of measure, various attempts at defining [the real time path integral} have been made; see e.g [gives references]. These methods, while useful computationally and for formal heuristics, have not thus far turned out to be analytically powerful; we will not discuss them further."

In the preface he explains "I decided to limit myself to the well-defined Wiener integral rather than the often ill-defined Feynman integral."

17. **Peter Orland**
February 18, 2023

My copy of this book is out of reach, in my office, but I will take your word for it that Simon confines the bulk of the discussion to the Wiener integral. But I do know that he ALSO discusses the proof of Lie-Trotter formula for REAL time at the beginning of the book (which is useful, even he does not use it further). I should check, but I remember the "non-analytically powerful" methods Simon refers to are some formal definitions of C. DeWitt, among others. There is also discussion of the real-time case in the second volume of Reed and Simon.

Anyway, the real Lie-Trotter formula is completely adequate for most of the applications you can find in, e.g., Feynman and Hibbs.

18. **Peter Orland**
February 18, 2023

But phase-space PI are another matter, and I apologize if took things away on a tangent.

19. **Peter Woit**
February 18, 2023

Thanks Peter,
Just took a look at Reed-Simon, vol. 2. In section X.11, they do use the free particle propagator and the Trotter product formula to write down an expression for the time evolution operator as the limit of an expression that one can interpret as a path integral using polygonal paths for a fairly general potential V.

But then they do very quickly say that while this is beautiful and heuristically an integral over path space, an actual measure on path space like Wiener measure is something quite different, and they go to imaginary time and use Wiener measure to get Feynman-Kac.

Besides my experience with lattice gauge theory and Yang-Mills, of course my current fascination with the way the symmetries of spinors work in Euclidean signature is another motiviation for thinking of imaginary time as not just a trick, but something fundamental. While it's true that for QM path integrals you can make sense of the free particle propagator without going to imaginary time (thanks Marko…) and then use this to define a limit as a path integral, for QFT, I don't think this is true. The argument now in the first section shows that then to even define the free particle propagator you have to do something, which has a natural interpretation as thinking of the propagator as something holomorphic in the upper half complex time plane.

20. **vmarko**
February 19, 2023

Just a short note – regarding the propagator and Wick rotation, I believe the problem is a bit deeper, and the issues with path integrals are just a symptom.

Namely, there is a fundamental difference between elliptic and hyperbolic PDE's, where the former have a well-defined Green function, while the latter really don't. Since the Klein-Gordon equation is a hyperbolic PDE, the only way to introduce its Green function is to Wick-rotate to imaginary time, find the Green function in Euclidean theory, and then perform analytic continuation back into real-time. It's essentially due to the difference in signature between the d'Alembertian and a 4D Laplacian.

This is a problem for all relativistic wave equations (and a consequence of Lorentz-invariance), so whenever you discuss free field theory (or perturbative one), you are bound to run into this issue. It has nothing specifically to do with path integrals, any approach to quantizing field theory will suffer from this (though it might be hidden away or appear in some other form).

Best, 🙂
Marko

21. **JT gravity**
February 19, 2023

Marko,

Where can I read in more technical details what you are saying? Is this related to the problem of choosing a vacuum for a QFT defined on a curved spacetime background? I guess this is so because, on the one hand, the choice of vacuum defines unambiguously the notion of positive/negative frequencies for the one-particle states (e.g., a positive-frequency particle state w.t.r. to Rindler is not so w.t.r. to a Minkowski observer), while on the other hand, the notion of positive/negative frequencies depends on the time-orientability of Lorentzian structure, which is avoided in Euclidean signature.

22. **Peter Woit**
February 19, 2023

JT gravity,
An important thing to notice is that, just looking at the formula for the time/energy Fourier transform, positive energy means holomorphic in one complex time half plane, not the other.
Another version of the problem with the real time path integral that I was trying to point out is that it obscures a fundamental piece of structure of a qft: what is positive vs. negative energy or, by Fourier transform, what is positive vs. negative imaginary time? In the imaginary time path integral, the asymmetry is fundamentally built in and explicit

23. **Darran**
February 20, 2023

Peter,

I went through a similar period of liking and then understanding the limits of the Path Integral.
It can actually be difficult however to find a proper canonical treatment of issues normally discussed with the Path Integral, e.g. Yang-Mills theory and the Higgs Mechanism. For this reason I recommend the books of Strocchi "An Introduction to Non-Perturbative Foundations of Quantum Field Theory" and Nakanishi and Ojima "Covariant Operator Formalism Of Gauge Theories And Quantum Gravity".

24. **Peter Woit**
February 20, 2023

Darran,
I very much agree. There are very tricky issues with how gauge invariance works in these cases, highly unclear that the path integral solution (in lattice gauge theory, just integrate over all degrees of freedom, gauge or otherwise) really works as advertised. One example of this is the no-go theorem for BRST in lattice gauge theory. I agree with the recommendation of the Strocchi and Nakanishi/Ojima books.

I should also point out that a very specific problem with the culture of "string theory" is that it promotes the ideology that there's nothing to see here and the only people who think about or work on these issues are losers, too incompetent to realize that these subjects are a closed book and serious theorists are those who move on to schemes for getting emergent space-time out of string-theory grounded ideas.

25. **JT gravity**
February 20, 2023

I regard the BV-BVF complex cohomology to be the most powerful and deep quantisation scheme for QFT, and I also consider that the true meaning of "supermathematics" is not the supersymmetry of the target-space manifold relating fermions to bosons but in the mathematical structure of graded manifolds in the sense of Kostant modelling the phase-space of a quantum dynamical systems.

You raised an important sociological question regarding the general dogmatic attitude of string theories on their faith in the path integral technique. You should remember of Bert Schroer's views on functional integrals and string theories.

Finally, returning to the question of postive/negative frequencies, it's intersting that the Fourier decomposition is not conformally invariant while the decomposition into positive/negative frequencies itself is conformally invariant. Thus, it looks like there is a deep geometric structure hidden here which becomes transparent if you holomorphically continue the green function into the Riemann sphere, so that the choice of a positive frequency is equivalent to the choice of a hemisphere. And this is one of the key motivations for twistor theory!

26. **Russell Thompson**
February 20, 2023

I’m intrigued when Peter writes that his research is, “…another motivation for thinking of imaginary time as not just a trick, but something fundamental.” In 1953, Feynman used the path integral method with Weiner functionals and the Wick rotation between imaginary time and inverse thermal energy to write the partition function for the helium superfluid system. His imaginary time trajectories are now often referred to as “ring polymers” in modern quantum simulations (see Ceperley’s 1995 review of Path Integral Monte Carlo methods). Although the use of the imaginary time/inverse thermal energy dimension is always stressed as being a trick, Feynman’s partition function is mathematically the same as that of classical, coarse-grained representations of polymer systems under the Gaussian thread model, which in turn are equivalent to quantum density functional theory. The theorems of DFT therefore allow a one-to-one mapping between a classical polymer systems with the fictitious imaginary time dimension and regular, non-relativistic quantum mechanics, without it. It is very tempting therefore to look on the imaginary time as playing some fundamental role. Even Feynman and Hibbs mused about related matters in their 1965 quantum book (see section 10.5, Remarks on Methods of Derivation).

27. **Peter Woit**
February 20, 2023

Russell Thompson,
It is truly remarkable that if you take your system defined in imaginary time to be periodic in imaginary time, you get statistical mechanics with temperature inverse to the period. In the limit as you get rid of periodicity (periodicity length infinite), you get the zero temperature limit, which is where you do conventional particle physics. “Just a trick?” I suspect not.

28. **Andras Laszlo**
February 23, 2023

Hi,
Indeed there are several mathematical issues for defining the functional integrals in Lorentz signature, and it seems also a correct statement that for fermionic fields, actually this has little to do with integrals at all in terms of measure theory. But one can translate the formal Feynman functional integrals to a differential reformulation (the master Dyson-Schwinger equation), which is an equation for the partition function, and is formally equivalent to the functional integral formulation. Then, one can further translate this equation for the partition function to the language of (Feynman type) field correlators, and there the corresponding operators and function spaces are well defined.

That is, one could say that Feynman functional integrals are just shorthands for the master Dyson-Schwinger equation, expressed on the (Feynman type) field correlators. This kind of treatment also removes this puzzling issue concerning the fermion fields mentioned by Peter.
Best regards,
Andras

February 24, 2023

Some of you may be interested in a recent (2022) work by Feldbrugge and Turok that approaches path integrals without using Wick rotation.

The paper: https://arxiv.org/abs/2207.12798
Related paper: https://arxiv.org/abs/1909.04632
A talk by Turok: https://www.youtube.com/watch?v=L17Cx-iD8uU

30. **Peter Woit**
February 24, 2023

Amateur Mathematician,

Thanks a lot: I just watched the Turok talk, found it very interesting. His motivation is very close to mine, although he takes a very different view of imaginary time, which I strongly disagree with. I’ll add something about this to the posting, with more comments.

Latest on the Wormholes

February 17, 2023
Categories: Wormhole Publicity Stunts

I had thought that the wormhole story had reached peak absurdity back in December, but last night some commenters pointed to a new development: the technical calculation used in the publicity stunt was nonsense, not giving what was claimed. The paper explaining this is Comment on "Traversable wormhole dynamics on a quantum processor", from a group led by Norman Yao. Yao is a leading expert on this kind of thing, recently hired by Harvard as a full professor. There's no mention in the paper about any conversations he might have had with the main theorist responsible for the publicity stunt, his Harvard colleague Daniel Jafferis.

Tonight Fermilab is still planning a big public event to promote the wormhole, no news yet on whether it's going to get cancelled. Also, no news from Quanta magazine, which up until now has shown no sign of understanding the extent they were taken in by this. Finally, no news from Nature about whether the paper will be retracted, and whether the retraction will be a cover story with a cool computer graphic of a non-wormhole.

Update: Dan Garisto goes through the Jafferis et al. paper, noting "Turns out it looked good only because they used an average (a fact not specified in the article)." and ending with

> The unreported averages for the thermalization and teleportation signal make a stronger case for misconduct on the part of the authors.

I don't understand why Fermilab was planning a public lecture promoting this, and with what has now come out, it should clearly be cancelled.

Update: I like the suggestion from Andreas Karch

> Quanta magazine could make a video where the wormhole authors share in vivid detail the excitement they felt when they realized that their paper isn't just overhyped but actually wrong.

Update: Garisto has a correction, explaining that the averaging is not the problem with Jafferis et al., rather that the teleportation signal is only there for the pair of operators involved in the machine language training, not there for other pairs of operators that should demonstrate the effect. In any case, best to consult the paper itself. If Jafferis et al. disagree with its conclusions, surely we'll see an explanation from them soon.

Update: The Harvard Gazette promotes the wormhole publicity stunt, with "Daniel Jafferis' team has for the first time conducted an experiment based in current quantum computing to understand wormhole dynamics." As far as I can tell, that's utter nonsense, with the result of the quantum computer calculation adding zero to our understanding of "wormhole dynamics".

Update: Video of the Lykken talk now available, advertised by FNAL as Wormholes in the Laboratory.

Comments

1. **Andrew**
   February 17, 2023

   Just attended Lykken's webinar. He did not address this refutation at all or any other voices of reason. I attempted to ask a question about this paper but it was not selected (the talk was in Zoom webinar format).

2. **Peter Woit**
   February 18, 2023

   Andrew,
   I also watched a bit of the webinar. It was completely misleading propaganda, no mention of anything skeptical or critical, he was selling this as a huge advance and success. Probably you weren't the only one with serious questions at the end, but they just chose the "when do we get to travel through a wormhole" ones. It's outrageous that Fermilab is doing this kind of thing.

   Hard to know what it will take to stop more of it. Lykken will pursue the standard successful string theory tactic of just ignoring serious criticism, pretending it doesn't exist.

   I see that the grant funding this stuff:
   https://pamspublic.science.energy.gov/WebPAMSExternal/Interface/Common/ViewPublicAbstract.aspx?rv=b31f0e55-de01-4635-91d1-2bf112daea20&rtc=24&PRoleId=10
   is up end of August. Will anyone with some sense stop this from getting renewed or funded elsewhere?

3. **Jim Eadon**
   February 19, 2023

   "their paper isn't just overhyped but actually wrong"
   Phew! I was worried for a moment, there, that the paper was, not even wrong.

4. **suomynona**
   February 20, 2023

   I suspect that unless there is public backlash at a level on par with the initial announcement, Jafferis et al. will subscribe to the policy of "we will not validate the criticism with a response". They're clearly playing the political PR game. No need to engage if the whole thing never picks up traction in the public arena.

5. **Peter Woit**
   February 20, 2023

   Jim Eadon,
   This is starting to become a serious problem with the title of this blog. If things keep going this way and I keep feeling I have to write about them, I may need to change title to something like "Utter Bullshit" to accurately reflect the nature of what I'm writing about.

6. **Peter Woit**

February 20, 2023

suomynona,

So far the authors of the stunt are following the string theory playbook for dealing with criticism: pretend it doesn't exist and keep playing the hype video.

7. **More_Nonymous**
February 24, 2023

The problem with calling this wormhole bullshit "bullshit" is that, in the unlikely event that mainstream media wants to report it, they can't. Because the FCC, y'know? So it's kinda self-defeating.

How's that appointment of a medieval historian to head the Institute For Advanced Studies working out, in your opinion? The rub here is that there are structural reasons why these positions are occupied by the kinds of people occupying them; a scientist would have, if not knowingly lied about the wormhole, then played along, while, charitably, the medievalist simply did not know better and was duped. So which of the two given choices (the hypester-hoaxster-fraudster or the innocent) is, in your opinion, uh, preferable as director of IAS?

Lastly: at what point do we start to describe these people as what they are: swindlers, hoaxers, charlatans, liars, or, if you want to, simply "dishonest, money-seeking, self-serving careerists". While some of these labels might be actionable, proper terminology is also important!

8. **Peter Woit**
February 24, 2023

More_Nonymous,
It's an interesting question about alternative universes to speculate how things would have been different if Dijkgraaf had still been IAS director. I doubt he would have have brought history into it, wouldn't have made public comparisons to the experimental vindication of GR in 1919. I also doubt he would have said anything skeptical, preferring to join his colleagues in trying to figure out how to best exploit the hype to help with funding of their field.

9. **Gali Weinstein**
February 25, 2023

The paper written by Norman Yao et al sounds compelling.
I am waiting for Jafferis et al.'s response to this paper.
I wrote two comments on the wormhole experiment. But I uploaded these comments in December and January. Anyway, I put them here:
https://arxiv.org/abs/2212.03568
https://arxiv.org/abs/2301.03522
The second comment discusses philosophical problems. I thought back then that the great achievement was to generate the sparse Hamiltonian, i.e., the greatest achievement was done by conventional computers rather than by the Sycamore. But if as Yao et al show that this sparse Hamiltonian is problematic, then I may have to update my second comment. I will wait and see…
Yao et al. claim that the systems considered in the Nature paper are unable to simultaneously satisfy scrambling + thermalization dynamics and perfect-size winding. Nevertheless, both properties are central to the holographic correspondence (AdS/CFT) and are known to occur in the SYK model at large system sizes.
Perfect-size winding is a necessary criterion of a traversable (ER = EPR) holographic wormhole. So did Jafferis et al. simulate perfect-size winding with 9 qubits?
Yao et al. argue that perfect-size winding observed by Jafferis et al. seems reliant on the small size, but not on thermalization and scrambling (quantum chaos). I wonder whether this contradiction is correctable or rather, maybe this signifies that we cannot simulate quantum teleportation through a holographic wormhole with 9 qubits (with 164 two-qubit gates circuit).
Gil Kalai wrote that we have difficulties even with 5 qubits: https://cstheory.stackexchange.com/questions/35934/states-and-probability-distributions-that-the-5-qubits-ibm-computer-can-produce?fbclid=IwAR1ntzNZ9df1wZtaIYxBl7uhXoTfRhtPkBo_1e1w4uUgEbIyLHuwUIXfiVM

10. **André**
February 27, 2023

@Gali Weinstein:
"Gil Kalai wrote that we have difficulties even with 5 qubits: […]"

I don't know too much about quantum computing, but that question you link has last been updated 5 years ago, which, I believe, in the field of quantum computing on real devices is ancient history.

Some Interviews

February 23, 2023
Categories: Uncategorized

Some interviews that readers of this blog may find of interest:

- David Zierler at the AIP interviews Lee Smolin (April 1, 2021).
- David Zierler at the AIP interviews Stephon Alexander (June 7, 2021).
- Alexis Papazoglou at IAI News interviews me (hot off the press).

Comments

1. **More Anonymous**
   February 24, 2023

   I think you missed this interview of Andrew Strominger?

   https://youtu.be/y3cw_9ELpQw

2. **Dilawar Singh**
   February 24, 2023

   In other news: https://www.quantamagazine.org/physicists-use-quantum-mechanics-to-pull-energy-out-of-nothing-20230222/

3. **Peter Woit**
   February 24, 2023

   Dilawar Singh,
   Hard to get excited about teleportation in quantum devices unless it's through a wormhole…

4. **John Baez**
   February 25, 2023

   In his interview Smolin says:

   "These very rough models [of quantum gravity] predict noise at the square root of the Planck frequency. Interestingly enough, that's where LIGO has some sensitivity to noise."

   "So, there's a story about this. The GEO down in Hannover, I don't know if it was ever actually published, but there were talks where they showed graphs of this noise, and Giovanni got very excited about it, and I got very interested in it. Again, since they didn't publish, we didn't publish. Now, the LIGO people seem to be saying that there's some inexplicable noise in the detector. Again, I'm told this second hand. I don't think they've published."

   Does anyone here know anything about "inexplicable noise" in the gravitational wave detectors LIGO or GEO600?

5. **Martin S.**
   February 25, 2023

   @JB WP has some info on it: GEO600: Claims on holographic properties of spacetime.

6. **Young physicist**
   February 26, 2023

   I learned a lot of things from Lee's wonderful interview, things he never included in his previous books, which are very important for the younger generation. I wish he would one day publish personal memoires in which he would elaborate more on his academic journey and those personal matters. One thing in particular is the contrast between the two portraits of Witten, the one found in his interview and the one found in your book Peter.

7. **John Baez**
   February 26, 2023

   Thanks, Martin S! With an apparatus so exquisitely delicate as LIGO or GEO600, the battle against noise is an endless one, and I imagine at any particular stage of this battle there will be "inexplicable noise" – or more accurately, *not yet explained* noise. So I would be very reluctant to jump to the conclusion that this not yet explained noise is due to innate properties of spacetime. But I was very curious to hear what rumors Smolin was alluding to.

8. **André**
   February 27, 2023

   Even assuming that the noise was in fact there, and would in fact be due to some aspect of Planck scale physics, I am skeptical how much you can learn from it about any specific model.
   All models I know of that attempt to make some predictions for effects like noise or decoherence are at some point putting the Planck scale in by hand – e.g. setting some arbitrary length scale in the model to be equal to the Planck length. Hence, I don't find it very astonishing if one gets results of order 1 in Planck units as phenomenological predictions. It's what I would expect from most models of quantum theory + gravity.

9. **Jim Eadon**
   February 27, 2023

   Prof Woit, I was impressed by your interview. I'm not a professional scientist (just an MSc opto-quantum physics), but I was always intrigued by the Twistor theory of Penrose. Ironically, I first heard about it, if I remember, in a String Theory book. That same book made me a big string theory enthusiast, until I eventually realised it was a dead end. I only realised that after I bought "Not Even Wrong". (Later I read "the trouble with physics", a great book. But your book was more to the point, to me.)
   I agree that String Theory has been a boon to mathematics. But for physics, ST has set physics back 20 or 30 years, I think. Perhaps I forgive string theory, a little, due to

the incredible group-theory Moonshine mathematics. >smile< I'm a fan of group theory, of John Conway RIP, Richard Borsherds, and co.

Physics With Witten

February 26, 2023
Categories: Uncategorized

I just noticed that last semester Edward Witten was teaching Physics 539 at Princeton, a graduate topics course. Since he's now past the age of 70, at the IAS he is officially retired and an emeritus professor (the IAS is the only place I know of in the US with retirement at 70, presumably since it is a non-teaching institution). I don't know if there are other times Witten has been teaching courses at the university since his move to the IAS in 1987.

Videos of the first few lectures are on Youtube here, problem sets on this web-page. It seems like the course started out covering issues with causality in general relativity, following these lecture notes, then later moved on to topics in quantum information theory.

Comments

1. **Noah**
   February 26, 2023

   Are you sure they still have mandatory retirement and it's not just a tradition? I can't see why IAS would have any kind of special exception. I guess it's also possible that just no one has bothered to sue?

2. **Peter Woit**
   February 26, 2023

   Noah,
   Legally, there is an exception for high-level executives, who can be required to retire at age 65. I had heard that the IAS argues that the positions of its faculty are more akin to high-level executives than to university faculty, since they don't teach. I'd also heard that people are well aware this might not stand up in court if challenged, but that so far no one has been interested in challenging it.

   In any case, given the nature of the IAS positions, and that there's not much practical ifference between an emeritus and non-emeritus position there, it would be hard to make an argument on fairness grounds that the IAS should keep paying people very high salaries indefinitely.

3. **Alex**
   February 27, 2023

   Ha, a bit surprised (in a good way) that he's teaching those particular topics, and to particle physicists, I presume.

   In my years reading papers, I think it has become the custom for some people with a background in (Minkowski, perturbative, path integral) QFT to simply launch into a research career in topics like QFT in curved spacetimes, the information paradox, and quantum gravity, without even knowing basic elements from causality theory in GR, like global hyperbolicity and Cauchy hypersuperfaces. These two things are key to give the correct physical interpretation in QFT in curved spacetimes to things like transitions from pure to mixed states. In normal, inertial frame Minkowski QFT, where all relevant time slices are Cauchy, that would certainly be a red flag, but in QFT in curved spacetimes, you can be evaluating the second state in a non-Cauchy time slice, and its nonpure character is a consequence of that. In fact, that's exactly what happens in the typical Schwarzschild evaporation scenario. As Wald has been stressing for decades, the problem is not the pure to nonpure transition, since that's explained by the second hypersurface not being Cauchy, but by the resulting "evaporating spacetime" not being/not appearing to be globally hyperbolic, in violation to Penrose's second cosmic censorship hypothesis.

4. **Dimitris Papadimitriou**
   February 27, 2023

   Alex
   There's an (important) implicit assumption, though, that black holes have to evaporate completely, so that after the 'final moment' of the evaporation, for external asymptotic observers the trapping horizon disappears and nothing remains but empty flat spacetime.
   In that case, there's a Cauchy horizon and spacetime is indeed non globally hyperbolic, as you said.
   That seems problematic , not only due to the violation of the weak cosmic censorship; there's also the issue with the huge (of order M^5 during the final stages of the evaporation, where M is the initial mass of the hole) internal " maximal volume" of the black hole, that (in the case of full evaporation) is disconnected (and disappears? who knows?) in a way that seems unphysical when the throat shrinks as the horizon area goes to zero.
   Another possibility is that some kind of a slowly decaying remnant is left behind, that disappears gradually (with soft gravitons/ photons, perhaps…).
   In such cases spacetime may be globally hyperbolic after all:
   No violation of CC, no information loss. This is an open possibility.

5. **clayton**
   March 1, 2023

   so is Piet Hut emeritus now?

6. **Peter Woit**
   March 1, 2023

   clayton,
   He turned 70 last fall, I'm guessing under their usual policy he'd retire after this academic year. But, given his history there, if anyone were to challenge their policy, it might be him.

Yet More on the Wormholes

February 27, 2023
Categories: Wormhole Publicity Stunts

The paper explaining that this Nature cover story, besides being a publicity stunt, was also completely wrong, has so far attracted very little media attention. The first thing I've seen came out today at *New Scientist*, a publication often accused of promoting hype, but in this case so far the only one reporting problems with the hyped result. The title of the article is Google's quantum computer simulation of a wormhole may not have worked. It contains an explanation of the technical problems:

> The first problem has to do with how the simulated wormhole reacted to the signals being sent through it….Yao and his colleagues found that for each individual test, the system continued to oscillate indefinitely, which doesn't match the expected behaviour of a wormhole.
>
> The second issue was related to the signals themselves. One of the signatures of a real wormhole – and therefore of a good holographic representation of a wormhole – is that the signal comes out looking the same as it went in. Yao and his team found that while this worked for some signals – those similar to the ones the researchers used to train a machine learning algorithm used to simplify the system – it didn't work for others.
>
> …it seems that for this particular quantum system, the size winding would disappear if the model was made larger or more detailed. Therefore, the perfect size winding observed by the original authors may just be a relic of the model's small size and simplicity.

There is a response from Maria Spiropulu:

> "The authors of the comment argue about the many-body properties of the individual decoupled quantum systems of our model," she says. "We observed features of the coupled systems consistent with traversable wormhole teleportation."

Remarkably, Lenny Susskind throws the authors of the stunt under the bus:

> "What is not so clear is whether the experiment is any better than garden-variety quantum teleportation and does it really capture the features of macroscopic general relativity that the authors might like to claim… only in the most fuzzy of ways (at best)," he says.

Comments

1. **T.J.**
   February 28, 2023

   I remember being at a student journal club discussing this work in which a curious computer science undergrad with little to no knowledge of wormholes etc. pointed out that the result would have to be reproduced with "untrained operators" to properly establish the claim. I'm surprised that nobody pointed out this basic and blatant flaw earlier.

2. **Sabine Hossenfelder**
   February 28, 2023

   I wouldn't have thought it possible, but I agree with Susskind.

3. **E.S.**
   February 28, 2023

   Can anyone explain Spiropulu's response? The only way I can think of making sense of it is if she mixed up "decoupled" and "commuting."

4. **Geoff Penington**
   March 1, 2023

   I'm not sure why it's shocking to see Lenny express scepticism about a result that has met with almost universal scepticism from experts in the field who were not co-authors of the paper.

   @E.S. I believe the authors argument is that even though the terms in each "boundary Hamiltonian" all commute, the coupling between the two sides doesn't commute with them, and so the coupled system is interesting, or even "wormhole-like", even if the individual decoupled systems are not. I find this argument uncompelling. An actual holographic simulation of a wormhole should absolutely have to thermalise without any coupling between the two sides.

5. **Jonathan**
   March 1, 2023

   This is off topic but Springer is expecting to release a Handbook of Quantum Gravity this year or next. The ncatlab has a page with published chapters on arXiv so far which may be of interest to readers:
   https://ncatlab.org/nlab/show/Handbook+of+Quantum+Gravity
   Much more CDT and LQG than I would have guessed.

6. **Peter Woit**
   March 1, 2023

   Geoff Penington,
   Susskind was in some sense part of the original publicity stunt, co-authoring the explanatory article that appeared in Nature with the technical article, see
   https://www.nature.com/articles/d41586-022-03832-z
   "A holographic wormhole traversed in a quantum computer"

   I'm assuming he recently read the Yao et al article and realized that the original article he had helped promote was likely technically wrong. Not shocking that he should now express skepticism, for shocking, see what Harvard is sending out, just got this yesterday in the newsletter they send out to their alumni

   https://news.harvard.edu/gazette/story/2023/02/one-small-step-toward-understanding-gravity/

   Last I heard from the editor at Quanta and the director of the IAS, they were standing behind this work as a huge breakthrough, since that was what they were hearing from experts in the field. Maybe things have changed, will be interesting to see if Quanta now takes seriously my suggestion that they should re-report this story.

7. **S**
   March 2, 2023

   Perhaps the interesting question is why the journalists at Quanta would take it upon themselves to decide that something *was* a huge breakthrough when such a large number of experts in the field held that it was not only not a breakthrough, but was nonsense. It's a vision of science journalism that I hope they do not decide to adopt uniformly.

8. **JdM**
   March 3, 2023

   More from Lenny ("Lost in the landscape"):

   https://cerncourier.com/a/lost-in-the-landscape/

9. **Peter Woit**
   March 3, 2023

   S,
   The Quanta article (and associated video) was produced under embargo conditions, where the claims of a "breakthrough" were being kept secret and could only be discussed with a very limited range of people other than the authors. Even after the "breakthrough" was made public, the initial reaction from a lot of experts was to try and find a way to be supportive, since it was excellent PR for their field. It took a while for many experts to look into the actual result and realize there was nothing there. More recently, the article by Yao et al has made clear that what was there was not just vacuous but wrong.

   I'm curious to see what Quanta does about this. Last time I was in contact with them, I was advising them they should re-report the story. Their response was that they were going to listen to what experts had to say (not me…).

10. **Dan Winslow**
    March 13, 2023

    It seems to be spreading. Not sure what to make of this exactly, but it sure seems like wormhole-style hype to me.
    https://phys.org/news/2023-03-counterportation-quantum-breakthrough-paves-world-first.html

11. **Peter Woit**
    March 13, 2023

    Dan Winslow,
    Yes, outrageous hype, courtesy of the University of Bristol press office. Anyone at Bristol willing to contact people there to tell them to not do this kind of thing?

12. **Mitchell Porter**
    March 14, 2023

    Anyone who wants to skeptically study the claim from Bristol about "counterfactual teleportation" might want to start with this critique by Lev Vaidman of the original concept:

    https://arxiv.org/abs/1304.6689

13. **Mitchell Porter**
    March 24, 2023

    Vaidman has coauthored another critique of "counterportation":

    https://arxiv.org/abs/2303.08962

    Meanwhile, at a popular physics Q&A site, the author of the concept may be seen defending it, alongside a skeptical answer:

    https://physics.stackexchange.com/q/755561/1486

Lost in the Landscape

March 3, 2023
Categories: Multiverse Mania, Swampland

A commenter in the previous posting pointed to an interview with Lenny Susskind that just appeared at the CERN Courier, under the title [Lost in the Landscape](). Some things I found noteworthy:

- He deals with the lack of any current definition of what string theory means by distinguishing between "String theory" and "string theory". "String theory" is the superstring in 10 dimensions somehow compactified to have some large dimensions that are either flat or AdS. This can't be the real world

  > I can tell you with 100% confidence that we don't live in that world.

  since the real world is non-supersymmetric and dS, not supersymmetric and AdS. He describes this theory as being "a very precise mathematical structure", which one might argue with.

  Something very different is "string theory":

  > you might call it string-inspired theory, or think of it as expanding the boundaries of this very precise theory in ways that we don't know how to at present. We don't know with any precision how to expand the boundaries into non-supersymmetric string theory or de Sitter space, for example, so we make guesses. The string landscape is one such guess…
  >
  > The first primary fact is that the world is not exactly supersymmetric and string theory with a capital S is. So where are we? Who knows! But it's exciting to be in a situation where there is confusion.

- About anthropics and the landscape, he still thinks this is the best idea out there, but acknowledges it has gone nowhere in twenty years:

  > Witten, who had negative thoughts about the anthropic idea, eventually gave up and accepted that it seems to be the best possibility. And I think that's probably true for a lot of other people. But it can't have the ultimate influence that a real theory with quantitative predictions can have. At present it's a set of ideas that fit together and are somewhat compelling, but unfortunately nobody really knows how to use this in a technical way to be able to precisely confirm it. That hasn't changed in 20 years. In the meantime, theoretical physicists have gone off in the important direction of quantum gravity and holography.

- About the swampland, like everyone else I know, he can't figure out what the argument is that is going to relate it to the real world:

  > The argument seems to be: let's put a constraint on parameters in cosmology so that we can put de Sitter space in the swampland. But the world looks very much like de Sitter space, so I don't understand the argument and I suspect people are wrong here.

- His comments on Technicolor strike me as odd:

  > I had one big negative surprise, as did much of the community. This was a while ago when the idea of "technicolour" – a dynamical way to break electroweak symmetry via new gauge interactions – turned out to be wrong. Everybody I knew was absolutely convinced that technicolour was right, and it wasn't. I was surprised and shocked.

  I remember first hearing about the Technicolor idea around 1979 when Susskind and Weinberg wrote about it. It was a very attractive idea by itself, but the problem was that to match known flavor physics you needed to go to "Extended Technicolor", which was really ugly (lots of new degrees of freedom, no predictivity). No idea when people supposedly were "absolutely convinced that technicolour was right", maybe it was for the few months it took them to realize you needed Extended Technicolor.

- About the wormholes, he says:

  > One extremely interesting idea is "quantum gravity in the lab" – the idea that it is possible to construct systems, for example a large sphere of material engineered to support surface excitations that look like conformal field theory, and then to see if that system describes a bulk world with gravity. There are already signs that this is true. For example, the recent claim, involving Google, that two entangled quantum computers have been used to send information through the analogue of a wormhole shows how the methods of gravity can influence the way quantum communication is viewed. It's a sign that quantum mechanics and gravity are not so different.

  Unclear to me how this enthusiastic reference to the wormholes relates to his [much less enthusiastic recent quote in *New Scientist*]():

  > What is not so clear is whether the experiment is any better than garden-variety quantum teleportation and does it really capture the features of macroscopic general relativity that the authors might like to claim… only in the most fuzzy of ways (at best).

Comments

1. **Jonas**
   March 3, 2023

   Susskind published today a paper on the Arxiv about de Sitter and holography. Take a look: 2303.00792

2. **Peter Woit**
   March 3, 2023

   Jonas,
   Thanks. This seems to be more along the lines of ideas that go back to
   https://arxiv.org/abs/2205.00315
   and further. The controversial Quanta article about the wormhole stunt ended with a section about this, I guess to show that the AdS problem was being overcome.

   An interesting thing about these recent papers is that Susskind now lists his affiliations as not just Stanford, but also Google Research in Mountain View.

3. **Jeff Berkowitz**
   March 3, 2023

   Peter, I'm curious about your "…like everyone else I know…" comment regarding the swampland conjectures. A couple of years ago when I was really trying to follow this stuff, it seemed to me that the swampland "program" was clearly targeted at KKLT – saying in effect, "you have a conjecture that DS may emerge from String Theory [note caps] but I have an equally reasonable conjecture that it cannot." Is this not the right way to think about it?

4. **Peter Woit**
March 3, 2023

Jeffrey Berkowitz,
Yes, that's the right way to understand what they are doing (although, as Susskind notes, the landscape idea of dS is string theory, not String theory). But then, where I think I join Susskind and many others in being confused, is in trying to figure out what the implications of this are supposed to be if it is successful. If you can show string theory can't give you dS, and you know we live in dS, the obvious implication is that string theory can't describe the real world. But, the people doing this claim to be string theorists devoted to making string theory work. Their plan instead seems to be to argue that since string theory has to be true, the world cannot actually be dS, it's just an illusion, with the real story quintessence or whatever. But there seems to be no good argument for this.

5. **Bob Y.**
March 3, 2023

Susskind's makes the following comment regarding the recent "wormhole" simulation:
"…two entangled quantum computers have been used to send information through the analogue of a wormhole…". What are the "two entangled quantum computers" in reality?

6. **Jerome**
March 4, 2023

Peter, your last comment is extremely illuminating. I've always been confused by the same thing: all evidence points to us existing in a dS universe, so if one could show that (S/s)tring theory is a sort of theoretical closure of the set of all Theories of Everything for AdS (and only AdS) universes, then that would constitute the closest thing you could get to an unassailable disproof of string theory. As magically energetic colliders will forever be out of our reach, this kind of no-go theorem is the only way I can imagine string theory being falsifiable in practice. I never could understand why they'd be so eager to detonate their own field of study by proving such a damning conjecture—a conjecture which all evidence points to being true, so far.

If their goal is talk themselves out of the universe being dS, then I truly don't know what hope there is for the future. We've gone from "Oh, these useless 1+1 AdS toy models of QG are just stepping stones to more realistic models" to demanding that the universe actually be such a model. I'll continue disregarding the entire subfield until the day they can describe the universe we actually live in.

7. **Adam Treat**
March 4, 2023

Something that strikes me as a theme in all of this is the repeated use of towers of conjectures. The arxiv links of Susskind in the comments are replete with conjectures based on other conjectures. It is difficult to find the motivations for such conjectures as they are often not spelled out and seem to resort to general agreement among a group of mathematically talented superstring physicists like Witten, Maldecena et al.

This makes me wonder about the claim (which I'm entirely unqualified to understand) that there is this dichotomy between S vs s superstring theory. I would *assume* that the distinction is based on some mathematically proven line of definitions/theorems in the capital S, but Susskind's fondness for Nth degree reliance on conjectures gives me pause.

Maybe time will be kind to these towers of conjectures with future generations of mathematicians/physicists following up with rigorous and formal methods, but it seems a shame that this generation is not as interested in going back and putting in the work of justifying the conjectures at the root of the tower.

8. **Low Math, Meekly Interacting**
March 4, 2023

I was also puzzled by the technicolor comment. It seemed like practically no one was talking about that when the LHC turned on. It was all sparticles lighting detectors up like Christmas trees. And now the world isn't supersymmetric at all? Why? I thought the whole "lesson" of SUSY heaving nothing to do with EW symmetry breaking is that there's a Landscape and SUSY could be broken at any scale you could imagine. Because there is no string (capitalized or not) without SUSY. I can't keep it all straight anymore. What goalpost is even left to move at this point?

9. **Peter Woit**
March 4, 2023

Jerome,
I'd be wary of any belief in illumination re the goals of the Swampland program. The only things clear to me about the motivations for this program are
1. they would like to challenge the idea that KKLT-type vacua are consistent, implying no predictivity.
2. they would like to claim that having a consistent theory of quantum gravity implies constraints on unified theories, string theory qualifies, so they have "string theory predictions".
Beyond this though, I don't understand what their vision is for a predictive theory, and Susskind seems to share my confusion about this.

10. **Peter Woit**
March 4, 2023

Adam Treat,
The distinction between string and String theory is exactly Susskind's attempt to address this. I think he's acknowledging that "string theory" now just means some very speculative "string-inspired" scenario, yes, with conjecture built on conjecture. As he says, the way to characterize this is
"Who knows! But it's exciting to be in a situation where there is confusion. "

The problem for me is that I don't see any way to have a sensible discussion about this sort of "Who knows!" string theory. Nothing wrong with people working this way if it leads somewhere, but all the evidence is that for decades this has gone nowhere.

He doesn't say exactly what "String theory" is, but it is the sort of thing I used to spend a lot of time trying to understand and argue with people about exactly what is going on. His claims that this is completely well-defined mathematics that mathematicians build on and get Fields medals for I don't think is true. But, in any case, he agrees this cannot give you a theory of the real world.

11. **Peter Woit**
March 4, 2023

LMMI,
By the time the LHC had turned on, the problems with the technicolor idea were well-known and most people were skeptical that this could work. It remained possible that something was being missed, that the LHC would turn up not the standard Higgs, but something that was a variant of the technicolor idea, perhaps an unexpected variant (I would have loved that to have happened…).

Susskind clearly isn't claiming that everyone thought technicolor was right until the LHC. He seems to say there was some point at which it "turned out to be wrong". Not sure what that would be, except it happened long ago.

12. **Topological twist**
March 7, 2023

My understanding of capital S "String theory" as a mathematician is that there are rigorous definitions of objects that could be called "topological strings" of "type IIA and type IIB". Relevant work here is due to Kontsevich-Soibelman, Costello, and Lurie. These are 2d oriented topological field theories valued in chain complexes, meaning that there are operations on some chain complex parametrised by chains on the moduli space of Riemann surfaces with disjoint homomorphically embedded discs, and some compatibilities with sewing these Riemann surfaces along embedded discs. But this seems to be a far cry from making rigorous sense of the finer structure of N=2 d=2 SCFT associated to Calabi-Yau threefolds, which seems to be the minimum of what a string theorist would mean about "String theory" of type II.

13. **Peter Woit**
March 7, 2023

Topological twist,
Yes, the things mathematicians can make sense of and that have had significant impact in pure mathematics are things like topological strings, not anything like the String theories Susskind is referring to which try to model the real world but require exact SUSY.

Not much point though in arguing about this with Susskind though, since he is conceding that the theories he is making these dubiously optimistic claims about can't be a theory of the real world.

14. **Interested amateur**
March 8, 2023

Peter, since you've mentioned SUSY in the comments, you might be interested to know that Ben Allanach of Cambridge University UK gave an interview two years ago, which can be found on Youtube: Supersymmetry and Particle Physics | Ben Allanach.

"up to last year I spent all my career working on the supersymmetry theory… it was a bridge to everything…so yeah I had to rethink last year and now I'm working in a different mode, I'm looking at the data, and looking for glitches, and so we predict with the Standard Model of particle physics"

The LHC has done a very successful hatchet job, and not just on Susskind's Technicolor.

15. **Amitabh Lath**
March 10, 2023

The "killing" of Technicolor was carried out by precision ElectroWeak measurements at SLD and the detectors at LEP1 . Peskin and Takeuchi created a set of variables (S, T) which parametrized the isospin conserving and isospin breaking part of BSM physics. If you put the SM at 0,0 in an S,T plot then Technicolor is off in the upper left somewhere. The various EW asymmetries (and also atomic parity violation measurements) shut the door on any large deviations in S,T space. By the time the LHC turned on Technicolor was long dead.
(Full disclosure: my PhD thesis was the measurement of the Left-Right Asymmetry of Z bosons made with polarized electrons).

16. **Leonid**
March 12, 2023

Composite Higgs models and Walking Technicolor models are some natural evolution of the original technicolor. These were seriously probed at the LHC, where the mass value of the Higgs boson, the production rate of Higgs signals and the exclusion of top partners were the main tests. Perhaps Susskind meant these generalized technicolor models.

17. **Topologist Guy**
March 12, 2023

Peter,

Trying to grasp the precise difference between "big s" and "small s" string theory. Is this distinction along the lines of what Susskind is referring to:

1. String theory: Perturbative superstring theory on a flat Minkowski background. This is a well-defined theory, at least up to physical rigor.

2. string theory: Some conjectured nonperturbative background-independent thing which reduces to String theory in the appropriate limit.

18. **Peter Woit**
March 13, 2023

Leonid,
I think the much earlier SLD/LEP1 results Amitabh Lath mentions are more likely what Susskind is referring to. I don't remember him (or anyone else) having much enthusiasm for Technicolor by the time the LHC turned on.

Topologist Guy,
Susskind seems to be specifically pointing to the AdS/CFT picture of non-perturbative String theory as defined as the dual of N=4 SYM on the boundary, something that goes much beyond perturbative String theory. It's debatable whether that's as well-defined as Susskind claims, but since he agrees it can't give you the real world, not worth debating.

The distinction he is making centers more on supersymmetry, where he's making the (correct…) argument that the world is not supersymmetric, but there exists no well-defined non-supersymmetric string theory.

19. **JdM**
March 14, 2023

An older (2008) article from Lenny on Technicolor (and Supersymmetry):

Thoughts on a Long Voyage
https://www.worldscientific.com/doi/epdf/10.1142/9789812779762_0005
(also: https://www.worldscientific.com/doi/abs/10.1142/S0217751X08042316)

Savas Dimopoulos wrote on TC back in 1994 (https://arxiv.org/abs/hep-ph/9412297) and again in 2000 (https://arxiv.org/abs/hep-th/0105034) – these two articles are *almost* identical.

20. **Peter Woit**
March 14, 2023

JdM,
Thanks. The Dimopoulos comment
"By the summer of 1980 it became clear that these theories suffered from generic problems of flavor violations [12] that could perhaps be cured only by complicating the theory immensely and losing any hope of calculability."
agrees with my memory that very soon after Technicolor came on the scene, people lost interest once they started looking at the kind of Extended Technicolor models needed to agree with experiment.

Not Quite What Happened

March 23, 2023
Categories: Wormhole Publicity Stunts

Quanta has an article out today about the wormhole publicity stunt, which sticks to the story that by doing a simple SYK model calculation on a quantum computer instead of a classical computer, one is doing quantum gravity in the lab, producing a traversable wormhole and sending information through it. From what I've heard, the consensus among theorists is that the earlier Quanta article and video were nonsense, outrageously overhyping a simulation and then bizarrely identifying a simulation with reality if it's done on a quantum computer.

The new article is just about as hype-laden, starting off with:

> A holographic wormhole would scramble information in one place and reassemble it in another. The process is not unlike watching a butterfly being torn apart by a hurricane in Houston, only to see an identical butterfly pop out of a typhoon in Tokyo.

and

> In January 2022, a small team of physicists watched breathlessly as data streamed out of Google's quantum computer, Sycamore. A sharp peak indicated that their experiment had succeeded. They had mixed one unit of quantum information into what amounted to a wispy cloud of particles and watched it emerge from a linked cloud. It was like seeing an egg scramble itself in one bowl and unscramble itself in another.
>
> In several key ways, the event closely resembled a familiar movie scenario: a spacecraft enters one black hole — apparently going to its doom — only to pop out of another black hole somewhere else entirely. Wormholes, as these theoretical pathways are called, are a quintessentially gravitational phenomenon. There were theoretical reasons to believe that the qubit had traveled through a quantum system behaving exactly like a wormhole — a so-called holographic wormhole — and that's what the researchers concluded.

An embarrassing development provides the ostensible reason for the new article, the news that "another group suggests that's not quite what happened". This refers to this preprint, which argues that the way the Jafferis-Lykken-Spiropulu group dramatically simplified the calculation to make it doable on a quantum computer threw out the baby with the bathwater, so was not meaningful. The new Quanta piece has no quotes from experts about the details of what's at issue. All one finds is the news that the preprint has been submitted to Nature and that

> the Jafferis, Lykken and Spiropulu group will likely have a chance to respond.

There's also an odd piece of identity-free and detail-free reporting that

> five independent experts familiar with holography consulted for this article agreed that the new analysis seriously challenges the experiment's gravitational interpretation.

I take all this to mean that the author couldn't find anyone willing to say anything in defense of the Nature article. An interesting question this raises is that if all experts agree the Nature article was wrong, will it be retracted? Will the retraction also be a cover story?

The update of the original story is framed by enthusiastic and detailed coverage of the work of Hrant Gharibyan on similar wormhole calculations. The theme is that while Jafferis-Lykken-Spiropulu may have hit a bump in the road, claiming to be doing "quantum gravity in the lab" by SYK model calculations on quantum computers is the way forward for fundamental theoretical physics:

> The holographic future may not be here yet. But physicists in the field still believe it's coming, and they say that they're learning important lessons from the Sycamore experiment and the ensuing discussion.
>
> First, they expect that showing successful gravitational teleportation won't be as cut and dry as checking the box of perfect size winding. At the very least, future experiments will also need to prove that their models preserve the chaotic scrambling of gravity and pass other tests, as physicists will want to make sure they're working with a real Category 5 qubit hurricane and not just a leaf blower. And getting closer to the ideal benchmark of triple-digit numbers of particles on each side will make a more convincing case that the experiment is working with billowing clouds and not questionably thin vapors.
>
> No one expects today's rudimentary quantum computers to be up to the challenge of the punishingly long Hamiltonians required to simulate the real deal. But now is the time to start chiseling away at them bit by bit, Gharibyan believes, in preparation for the arrival of more capable machines. He expects that some might try machine learning again, this time perhaps rewarding the algorithm when it returns chaotically scrambling, non-commuting Hamiltonians and penalizing it when it doesn't. Of the resulting models, any that still have perfect size winding and pass other checks will become the benchmark models to drive the development of new quantum hardware.
>
> If quantum computers grow while holographic Hamiltonians shrink, perhaps they will someday meet in the middle. Then physicists will be able to run experiments in the lab that reveal the incalculable behavior of their favorite models of quantum gravity.
>
> "I'm optimistic about where this is going," Gharibyan said.

I had thought that perhaps this fiasco would cause the Quanta editors to think twice, talk to skeptical experts, and re-report the original credulous story/video. Instead, it looks like their plan is to double down on the "quantum gravity in the lab" hype.

Update: Two more related pieces of wormhole news.

- On Friday Harvard will be hosting a talk on the non-wormhole.
- In this preprint Maldacena argues for another example of how to do quantum gravity in the lab, by doing a QM calculation on a quantum computer that will "have created something that behaves as a black hole in the laboratory" (no wormholes, just black holes). The calculation he suggests involves not the newer SYK model, but the ancient BFSS matrix model from 27 years ago, which at the time got a lot of attention as a possible definition of M-theory.

Update: The Harvard CMSA talk about the wormholes is available here. I didn't see anything in the slides about the Yao et al. criticism of this work. In the last minute of the video there was a question about this, and some reference to the criticism having been addressed during the talk. Supposedly there was some quick verbal summary of this response to the criticism in this last minute, but the sound was so garbled I couldn't understand it. Here's the automatically generated transcript:

> 1:16:50
> so I guess I guess um we're talking about like at the time of interpretation you do see this
> 1:16:56
> operating ghost in kind of declare the two-point function if you're looking for at later times you can ask about

1:17:01
different kind of scenarios one is accepting the single-sided systems what it's doing it's like internal reversible
1:17:07
verbal hamiltonian and you see thermalizing Dynamics in the library
1:17:12
um perhaps also the size winding uh although it's not necessarily required
1:17:18
for all of your fermions to show size winding because you have done gravitational attractions in your model we do see impact that all the pronouns
1:17:26
have quite good size winding they're good enough to allow them to teleport to size binding but the time and size
1:17:31
binding is clearly related to like the the rate of Decay the two-point function and so it seems to actually lend itself
1:17:38
to an even tighter kind of interpretation where would you associate different masses through different
1:17:44
permeons and this is quite consistent that is

Someone with more patience and interest in this perhaps can carefully follow the talk and report what the response to the Yao et al. criticism actually was.

Update: A response by the original authors to Yao et al. has been posted as "Comment on "Comment on "Traversable wormhole dynamics on a quantum processor" " ". From the abstract, the claim seems to be that the results of the toy model calculation are "consistent with a gravitational interpretation of the teleportation dynamics, as opposed to the late-time dynamics", and that this is not in conflict with the objections by Yao et al. These objections are described as "counterfactual scenarios outside of the experimentally implemented protocol." The odd thing here is the description of the quantum computer calculation as a "factual" experimental result, part of an "experimentally implemented protocol". The quantum computer calculation was not an experiment but a calculation, with a known-in-advance result (the calculation done previously on a classical computer). The criticisms of Yao et al. aren't "counterfactual" to an experimental protocol, but challenging the interpretation of a calculation. As far as I can tell, this whole discussion is about how to interpret simple calculations you can do on any conventional computer, nothing to do with an "experiment".

Comments

1. **Anonymous**
   March 23, 2023

   I would like to point out the parallel to the room-temperature superconductivity debacle, which to me appears to be a similar instance of the postmodern approach to doing physics research.

2. **Peter Woit**
   March 23, 2023

   Anonymous,

   If you're referring to the recent room-temperature superconductivity controversy, it's interesting to notice that the same Quanta writer (Charlie Wood), who wrote this hype about "quantum gravity in the lab", wrote what seems to me a much more even-handed article about that, see here
   https://www.quantamagazine.org/room-temperature-superconductor-discovery-meets-with-resistance-20230308/
   A story about an experimental development is somewhat different than one about theoretical developments. Another group can try and reproduce an experiment, and people promoting non-reproducible work will run into skepticism. For theorists there's no such thing: you can keep repeating the same nonsense about quantum gravity for ever with impunity.

   The odd thing about the "quantum gravity in a lab" hype is that all the top Quanta physics writers and editors have gone all in (Natalie Wolchover, Thomas Lin, Charlie Wood). I've heard from several experts that they tried to explain to them the problems with their coverage, but they're not listening to skeptical voices, preferring to (like the director of the IAS), take the word of a small number of people like Maldacena that quantum gravity in the lab is a real thing and the future of the subject.

   Built into the DNA of the Simons Foundation and Quanta I think is a faith in the traditional elite institutions of the US theoretical physics world. That people at the IAS/Harvard/Caltech/Stanford could just be wrong about string theory/quantum gravity/it from qubit, etc. to this world-view is nearly inconceivable.

3. **Peter Shor**
   March 23, 2023

   Don't a lot of the latest quantum gravity theories say that quantum gravity goes beyond the standard rules of quantum mechanics? For example, the AMPS paper (Black Holes: Complementarity or Firewalls?) seems to imply that something really unusual must happen. But if you can do quantum gravity in the lab, then doesn't quantum gravity have to satisfy the standard rules of quantum mechanics?

   Do any of the people writing these papers see any contradictions here?

4. **Rusty**
   March 23, 2023

   Is there anything going on in this experiment/calculation
   that can't be explained by ordinary, non-relativistic QM?

5. **Peter Woit**
   March 23, 2023

   Peter Shor/Rusty,
   That's the obvious problem with all "quantum gravity in the lab" claims. The "lab" setup is described by conventional well-tested QM/QED, and you're not planning on testing that. So, as a matter of physics, you know exactly what is going to happen, there's no need to do the "experiment" and it can't tell you anything new about physics.

   The only sense in which you don't know what's going to happen is the same sense in which any numerical calculation may tell you something new about solutions to an equation. But if I solve an equation describing a cow on my laptop, that doesn't mean I created a cow, or that I'm doing lab experiments on cows.

6. **Sabine Hossenfelder**
   March 24, 2023

I think the underlying problem here isn't Quanta, it's Nature. Nature has a bias for publishing anything that can be experimentally done, regardless of how meaningless the theoretical interpretation. This is isn't the first time this has happened. Nature has published several previous papers on this wormhole stuff (without the teleportation part). They also keep publishing anything about ultracold gases so long as someone claims it's got something to do with black holes or the early universe. (Don't get me started.)

Otoh, you'd never see them publish a theory paper in that area, and probably for the better because most of it is nonsense. So you get those theorists teaming up with experimentalists to get their stuff published in Nature and chances are the theory-part is never really scrutinized.

This doesn't really excuse that the Quanta editors can't seem to admit to themselves that they're promoting bullshit, but with Nature in their back they know they'll get through with it.

The issue with the superconductor claim I think is somewhat different. It doesn't originate in the journal, but it originates in the lab itself, and there's only so much peer review can do even in the best case.

7. **John**
   March 24, 2023

   Sabine,
   I don't think Nature is completely innocent in the superconductivity story, given the history of retractions from the same authors.

8. **André**
   March 24, 2023

   To be fair, the whole issue of claiming that doing a simulation is somehow equal to studying the real thing isn't really new. There has been similar hype coming from the analog gravity community for years (obviously, I know a lot of really decent researchers in analog gravity who are very careful about stating precisely the relevance of what they are doing, but there are also those who are very loudly claiming that they are doing "gravity in the lab" when looking at water waves or BECs).
   I always ask those people what their experiments tell us that you couldn't learn from numerical simulations, and most of the time the answer is nothing – with the additional caveat that numerical simulations have smaller statistical errors.

   I also do not understand what it is that science communicators (journalists/nature editors/…) find so unattractive about the story: We have these complicated equations that are thought to tell us something about gravity and now, thanks to quantum computers, we can learn much more about their solutions which we didn't previously understand. [Notwithstanding that the second part of this statement is probably not true yet, and the first may be not true, period.]

   My PhD supervisor used to say (not sure if his words or an unattributed quotation): Don't trust an experiment until verified by theory.

9. **jack morava**
   March 25, 2023

   It occurs to me that the best way to understand the quantum computer emulation of a wormhole is as an example of the law of similarity in

   https://en.wikisource.org/wiki/The_Golden_Bough/Sympathetic_Magic

10. **Dimitris Papadimitriou**
    March 26, 2023

    André

    I don't think that there is really an analogy between the Analog gravity papers/ experiments and the recent "wormhole" case.
    In the former, there is an actual similarity in the math description.
    In the latter, there is a conjectured duality between two different descriptions.
    The case for Analog gravity, although it has its limitations, is much more solid, not that controversial as the other.

11. **Peter Woit**
    March 26, 2023

    Dimitris ,
    The problem with analog "gravity in the lab" claims is a different one, but it's just as much nonsense, since your experiment again is not looking at gravitational degrees of freedom. You're testing whether an equation does a good job of modeling the analog system, that the same equation appears in a theory of gravity is irrelevant.

    If I'm studying cows and one of my equations modeling the cows is the same as one describing something happening near a black hole, I'm still studying cows, not black holes.

12. **Sabine Hossenfelder**
    March 26, 2023

    John,

    "I don't think Nature is completely innocent in the superconductivity story, given the history of retractions from the same authors."

    Of course they knew this too. What do you expect them to do? Reject a paper just because of prior history? That wouldn't be proper treatment either.

13. **Jesko Sirker**
    March 26, 2023

    Sabine,
    the analysis of Hirsch and Marsiglio has raised some very serious doubts about the first retracted Nature paper on room-temperature superconductivity. Their analysis seems to suggest that raw, measured data might never have existed but rather were later constructed based on the published curves. I think in such a case the onus is on the authors to provide more information about the experiment and the data analysis to the physics community before other papers by the same group can be considered for publication. Besides, the new publication is marred by the same issues as the previous one: most prominently, a zero resistance is not measured but rather defined by again subtracting some 'background'. This is not standard in the field. Several studies have already been published where none of the results in the new Nature paper could be reproduced. This whole story is very unfortunate and could have been easily avoided if Nature would have acted more responsibly.

March 28, 2023

I can simulate the Navier-Stokes equation on a computer by discretizing the equation and putting it on a grid. There is a good theory of how the errors introduced in the discretization process scale with the size of the grid. There are proofs that the errors go to zero as the grid size goes to zero.

I don't think the wormhole people have any similar kind of theory for how to estimate the errors in their approximations. So it feels to me like this conversation is going to degenerate into "feelings" about whether some output from the computer feels like this or that.

If they were calculating finite N SYK, then they could estimate their errors (the differences between finite N and infinite N). But they switch to a fully commuting Hamiltonian that "looks like" finite N SYK. I don't think they have any control over the errors that that step introduces.

March 28, 2023

Peter,

"If I'm studying cows and one of my equations modeling the cows is the same as one describing something happening near a black hole, I'm still studying cows, not black holes."

This is true of course, but misses a potential advantage of such "analog" simulations. If the same equations govern both cows and black holes, and you do the experiment with cows, you may discover new emergent or nonlinear phenomena of the cows that you didn't anticipate or understand how to extract from the equations. Most of us humans remain pretty feckless in the face of strong nonlinearity. Assuming that the same equations approximately apply in a corresponding regime of validity for black holes, one might anticipate or propose new physical phenomena in the latter.

Replacing actual experiments with numerics, some of the insights with respect to SYK and its holographic dual(s) have emerged this way, e.g. the effects of the sum over diffeomorphism fluctuations.

19. **André**
March 29, 2023

Matthew,

"If the same equations govern both cows and black holes, and you do the experiment with cows, you may discover new emergent or nonlinear phenomena of the cows that you didn't anticipate or understand how to extract from the equations."

That is correct, of course, but I think the relevant question is not whether there might be such new phenomena that you don't find from analytically studying the equations, but if studying real cows gives you any advantages (precision, practicality, …) compared to a numerical simulation of said equations. If the answer is no, then I see no point in studying the cows.

March 29, 2023

Dear Peter
you say
"Built into the DNA of the Simons Foundation and Quanta I think is a faith in the traditional elite institutions of the US theoretical physics world. That people at the IAS/Harvard/Caltech/Stanford could just be wrong about string theory/quantum gravity/it from qubit, etc. to this world-view is nearly inconceivable."

I am not sure its reading correctly the DNA of the Simons Foundation if there is one. If you look at all their MPS collaborations across all domains, there seem to be a few general themes. One main theme seems to be the teaming of people and ideas from math, physics (both theory and applied), computer science and engineering (both theory and applied), in short, trying to build interdisciplinary bridges. Another less dominant, but still important theme seems to be symmetries and dualities as powerful tools in math, physics and engineering. A faint theme, but which still seems to have some effect is classifying objects, which is a very typical mathematical activity. I think this accounts for much of their activity for better or worse and within your field of interest, this leads to a thematic bias towards the more mathematically powerful among practitioners, even if the physics is completely off, dualities and other ideas that arise commonly in string theory, or quantum field theory more generally, are extremely powerful in relating different pieces of math or even computer science, and this bias leads indirectly to your perception of the choices.

21. **Peter Woit**
March 29, 2023

eitan bachmat,
The context of that comment is one of trying to understand why a highly competent journalistic operation like Quanta would be taken in by this hype. Contrast the Quanta wormhole coverage to that at the NY Times or other prominent places.

Also, the comment was not about the topics the Simons Foundation favors (on the question of topics, I think there's a prejudice towards computational projects, but the Foundation is now funding a wide range of different sorts of things). From what I have seen over the years, Simons likes to fund elite institutions (places like Berkeley, the IAS, IHES, etc). Other donors often take a different approach, sometimes explicitly trying to build up non-elite institutions. On the whole, I'm somewhat of an elitist myself, believing that historically elite institutions have been the source of great work, and that their health is important to maintain for the health of the whole field. But, when elite institutions are captured by failed or over-hyped research programs, that’s a big problem, and one that I think Quanta is ill-equipped to recognize.

A Muon Collider?

March 30, 2023
Categories: Uncategorized

The US particle physics community has been going through a multi-year process designed to lead up this fall to a 10 year strategic plan to be presented to the DOE and the NSF. In particular, this will generate a prioritized list of what projects to fund over this period. The process began with the Snowmass self-study, concluded last year, and available here. Since last fall there have been two independent efforts going on:

- A National Academies study has been holding meetings, materials available here.
- A P5 (Particle Physics Project Prioritization Panel) is holding meetings, see here, and planning for a report to NSF and DOE by October.

Looking through all the materials relevant to particle theory, there seems to me little acknowledgement of the serious problems faced by the subject, or any new ideas for how to address these problems. Most of the effort though is devoted to where most of the money will be spent, on the experimental side. To a large degree, for the short-term it's clear where funding has to go (to continue supporting the LHC into the HL-LHC era, and finish building the DUNE/LBNF US neutrino project). The longer-term is however very uncertain, as it is unclear whether there's a viable energy-frontier project that could study higher energies than those accessible at the LHC.

Last week EPP2024 and P5 held Town Hall events at Fermilab, see here and here. There's video of the EPP2024 event here. On the question of the long-term future, one issue that is getting a lot of attention is that of whether to prioritize development of a possible muon collider. In this presentation a young physicist gives a future timeline including their likely retirement and death dates, showing that a muon collider is their only hope for new energy frontier physics during their lifetime. For those of my age the situation is a bit different, since even a muon collider is not going to do the job. At the EPP2024 event (3:28 in the video) Nima Arkani-Hamed makes the case that:

> I think the subject has not been so exciting for many, many decades, and at the same time our ability to experimentally address and solidly settle some of these very big questions has never been more uncertain. I don't think it's a normal time, it's an inflection point in the history of the development of our subject, and it requires urgency… The confluence of the technical expertise for doing so and the enthusiasm amongst the young people who are willing to do it exists now and I very much doubt it will exist in 10 or 15 years from now. If we are going to do it, we have to start thinking about doing it now.

While his point is more general, he's clearly making the case for starting a new energy frontier machine project soon, with the muon collider the one possibility for getting to higher energies than the LHC.

A few weeks ago there was a workshop at the KITP devoted to the muon collider question, with a news story here (anyone know why the video of the panel discussion is password-protected?). Arkani-Hamed gave a talk aimed at other physicists here. On the European front, a couple days ago there was this meeting.

Already twenty years ago when I was writing *Not Even Wrong*, it was clear that a muon collider was in principle a very attractive idea for how to get to higher energies and I wrote about this in the first chapter of the book. The much higher mass of the muon than the electron means that you don't have the same synchrotron energy loss problem, so can build a much smaller storage ring at the same energy, or get to much higher energies with the same size. The problem though is that muons have a life-time of only 2.2 microseconds. This implies two serious difficulties:

- You need to produce, store, accelerate and collide the muons in a very short period of time.
- As the muons decay they'll produce large numbers of high energy electrons and neutrinos, creating a difficult environment for detectors to operate in and significant radiation hazards.

Normally one thinks of neutrinos as virtually never interacting with anything, but the numbers and high energies of the neutrinos produced at a muon collider create a potential significant radiation hazard, one that cannot be dealt with by shielding.

While I might not be around to see the results from a muon collider, if such a thing is viable, I'd strongly support such a project, and would even buy a t-shirt. The US DOE HEP budget is about a billion dollars/year. One would think this should be enough to accommodate building demonstrator projects or a small collider ring on a 10 year timescale, and possibly even an energy-frontier ring on a 20 or more year timescale. What's worrying me a bit is the fact that more visible progress on this hasn't happened since I looked into it 20 years ago. Why no current demonstrator project? Have the potential radiation hazard issues found solutions? I'd be very curious to hear from anyone with expertise on these questions.

   March 30, 2023

   Mu cooling needs to be demonstrated for collider to be feasible. MICE is not doing very good

3. **Mark**
   March 31, 2023

   The MICE collaboration demonstrated muon cooling with an experiment at the Rutherford Appleton Laboratory. I understand this is needed for a future muon collider, so there is not zero progress on topics needed to be demonstrated . Would a collider demonstrator have been useful (or even feasible at all) without first demonstrating we can cool the muons enough for a real system?

4. **Nathaniel Craig**
   March 31, 2023

   Thanks for taking a look at the KITP program! Regarding the panel — we wanted to encourage the panelists to engage in critical and constructive dialogue (half the panelists were asked to highlight challenges). We felt they would be able to speak most freely if the recording was not public. I think the panel was very successful, and we are working on a transcript for public release.

   April 4, 2023

   Can someone give me some figures about the neutrino emissions from a muon collider, and how they could be high enough to be dangerous? That's surprising!

7. **Peter Woit**
   April 4, 2023

   John,
   For an early study, see
   https://arxiv.org/abs/physics/9908017
   something more recent
   https://indico.fnal.gov/event/48995/contributions/214442/attachments/143292/181217/MC_Neutrino_Radiation_Mokhov_May19_2021.pptx

   This is surprising, one normally thinks about neutrinos going through the earth without interacting with anything. But neutrino cross-sections increase with energy, it's high energy neutrinos that are the problem, and a TeV scale muon collider would produce a lot of them.

8. **Alon Faraggi**
   April 4, 2023

   There is a ready made solution to the US experimental particle physics program on the energy frontier on a time scale of 10 years. Resurrect the SSC. Possibly an upgraded version with a 100km circumference and 30TeV beam energy. The muon collider is bread & butter accelerator physics. The MICE experiment took a long while to deliver (~25 years). But eventually it did prove the feasibility of the muon beam phase space cooling (https://www.nature.com/articles/s41586-020-1958-9). As a physics machine the muon collider is a prospect of 50-100 years. Pure fantasy.

9. **Severin Pappadeux**
   April 6, 2023

   John,

   earliest is probably by N. V. Mokhov and A. Van Ginneken, "Muon Collider
   Neutrino Radiation", Muon Collider Collaboration Meeting
   Book, Orcas Island, WA, May 1997.

   or

   https://accelconf.web.cern.ch/p99/PAPERS/THP52.PDF

10. **Severin Pappadeux**
    April 6, 2023

    MICE demonstrated that muons (being counted one-by-one) going through some LH2 follow well our multiple scattering, struggling, elastic etc models. That's about it. What has to be done is (close to) full scale cooling cell, with intensive muon beam, material which could handle above mentioned beam, solenoid field, RF cavities etc.

    And it means there is ought to be reasonable target setup producing muons.

    We're talking about serious accelerator test facility, and 10 years program on the scale of $50mln/year.

    Until such program is up, approved and running, all muon collider talks will be confined to conferences.

11. **John Baez**
    April 8, 2023

    Thanks, Peter, that's fascinating. It's interesting how being underground would increase the danger of these neutrino beams.

Who was “Not Even Wrong” first?

April 10, 2023
Categories: Uncategorized

I recently heard from John Minkowski, whose father Jan Minkowksi was a student of Pauli’s in the late 1940s. He asked if I knew what the specific context of Pauli’s “Not Even Wrong” comment was, and I told him I didn’t. I referred to this early blog post, which explains that Karl von Meyenn (editor of Pauli’s correspondence) had pointed me to a biographical memoir about Pauli by Rudolf Peierls which includes:

> Quite recently, a friend showed him the paper of a young physicist which he suspected was not of great value but on which he wanted Pauli’s views. Pauli remarked sadly ‘It is not even wrong.’

Looking around for any more information about this, Wikipedia links to a 1992 letter to the editor at Physics Today from Peierls, which states

> Wolfgang Pauli’s remark “Das is nicht einmal falsch” (“That is not even wrong”) was made not as a comment on a seminar talk but as a reaction to a paper by a young theoretician, on which a colleague (I believe it was Sam Goudsmit) had invited Pauli’s opinion.

Google also turned up a translation of a talk by Peierls in this article by Mikhail Shifman, which includes:

> Somebody showed to Pauli a work of a young theorist being well aware that the work was not too good but still willing to hear Pauli’s opinion. Pauli read the paper and said, with sadness: “It is not even wrong.”

Trying to guess what the article in question might have been, I’m tempted by the hypothesis that the discussion with Goudsmit was about Everett’s “Relative State” Formulation of Quantum Mechanics paper. The timing (“Quite recently”) would have been right, with the paper published in July 1957, Pauli’s death later in December 1958. Goudsmit at the time was editor-in-chief at Physical Review, so would have been interested in Pauli’s opinion of the paper.

Complicating this story, John Minkowki sent me some pages from his father’s 1991 book Through three wars: The memoirs of Jan Michael Minkowski, which included this (in a context describing his 1946-48 student days at ETH):

> I remember a seminar in theoretical physics given by a visitor from another Swiss university. These seminars were presided over by Dr. Pauli, and after the speaker finished all eyes would turn to Pauli to pronounce the verdict in his commentary. This particular lecture was treated by Pauli with progressively faster twirling of his thumbs around and around one another and a growing benevolent smile. Bad sign, we thought. The more he smiled the more vicious he will be, we thought. And sure enough, he smiled some more and said “It isn’t even wrong.”

One possibility here is that Minkowski was mis-remembering something from forty years earlier, another is that the occasion that Peierls was referring to was not the first time Pauli had used the phrase. As evidence for the second hypothesis, see this interview with Konrad Bleuler, which points to the possibility of Stueckelberg as the “visitor from another Swiss university”:

> So these seminars took place in a common seminar having also Professor Ernst Stueckelberg, then a Professor in Geneva, also Stueckelberg being a well-known theoretician, his work was very much, if I might remind you of that fact, acknowledged by Richard Feynman. For example, his idea of the particle going back in time being interpreted as an antiparticle came as far as I know originally from Stueckelberg and many other great ideas. I remember one special seminar in which, of course this seminar could be rather called. High Court, with scientific papers in the docket, sometimes really sentenced to death. From that one might record Pauli’s classification of scientific papers. There were two classes or else there were old and right. Or the other class, new and wrong. But hardly anything intermediate. If it was even worse, Pauli would have said “it’s not even wrong.” That was the kind of atmosphere. But all what is written in physics is either understood or else it’s thrown away, and not this half-and-half, what we see at present. But then in this connection it was a search for truth. And for Pauli, a lecture hall was a kind of a holy place where only truth was allowed. And a wrong statement was a sacrilege, and in that sense one should understand his rather extremely sharp remarks he might make to some lecturer who seemed not to present things in a quite logical way. But coming to that special, to another special seminar is the following: Stueckelberg always knew really special — I might say prophetic — ideas. He gave a lecture and of course Pauli — it happened very often — didn’t agree. And said “you are not allowed to say such things.” But you see, Stueckelberg being a prophet, he’s not so easily stopped uttering his prophecies. So Pauli in despair menaced Stueckelberg with a stick and it seemed — I was not present myself but I was told — that the seminar ended like the war of Troy, Pauli, rather corpulent, with his stick after Stueckelberg around the table in the lecture hall. That was the kind of attitude at this period.

I’m not sure what to make of all of this. Perhaps Pauli used the phrase both in the late 40s to criticize Stueckelberg (probably unfairly since many of Stueckelberg’s ideas were ahead of his time) and then Everett in the late 50s (in my opinion accurately, but I don’t want to start up the usual empty arguments about MWI here).

Comments

1. **paddy**
   April 10, 2023

   Concerning your usage relative to string theory: did S. Glashow use it first in that context?

2. **Peter Woit**
   April 10, 2023

   paddy,
   Well before string theory took off in late 1984, Pauli’s phrase was well known among physicists. I don’t remember the first time I heard it, but it was surely pre-1984 and not uncommon in those days to hear it used in reference to poorly understood speculative ideas unlikely to go anywhere. While post-1984 string theory quickly attracted a lot of enthusiastic followers, there always were a large number of skeptics, many of whom might have privately been using the phrase to describe their view of the theory. I don’t know if Glashow was the first published example of this.

3. **Sheldon from The Big Bang Theory**
   April 10, 2023

   See the 1986 May issue of Physics Today where Glashow uses it.

   There are dozens of references to the fuller quote online.

   “The trouble is that most of superstring physics lies up at the Planck mass — about
   10 GeV – and it is a long and treacherous road down to where we can see the light of

day. A naive comparison of length scales suggests that to calculate the electron mass from superstrings would be a trillion times more difficult than to explain human behavior in terms of atomic physics. Superstring theory, unless it allows an approximation scheme for yielding useful and testable physical information, might be the sort of thing that Wolfgang Pauli would have said is "not even wrong." It would continue to attract newcomers to the field simply because it is the only obvious alternative to explaining why certain detectors light up like video games near the end of every funding cycle." –Sheldon Glashow, Nobel Laureate & Paul Ginsparg, Ph.D., Desperately Seeking Superstrings

4. **Low Math, Meekly Interacting**
April 10, 2023

I've only seen the account you originally cited, and find it the most plausible. Aside from his exclusion principle and his matrices, Pauli seems to be most famous for his insults. The Dorothy Parker of physics, as it were. That one, being especially pithy and cutting, makes such an impression I imagine it would have been dutifully attested and widely circulated almost as soon as any public lecture concluded. It would have already been a cliche by 1957.

5. **Peter Woit**
April 10, 2023

LMMI,
The problem with the Peierls story is that an origin in a private conversation between Pauli and Goudsmit in 1957 doesn't explain how this became so widely known. He doesn't explain how he knows about it, not explicitly saying he was there to hear it, giving the impression that his information is not first hand. During the 47-57 decade it looks like Peierls was in Birmingham, possibly stories like this from a Zurich seminar would not have reached him (there were no blogs…), but he did get a 1957 report from someone in on a Pauli-Goudsmit discussion.

So, a 1947 Stueckelberg Zurich seminar origin story, with Peierls first hearing the phrase second-hand in 1957 from a different context seems not at all impossible. The 1992 Physics Today letter explicitly rules out an origin in a seminar, but (just like Minkowski's 1991 book), the recollections very late in life of what happened forty years earlier are often not very reliable.

6. **Amitabh Lath**
April 10, 2023

What does the phrase mean? Does it mean really really wrong? Like an explanation of the Stern-Gerlach effect that did not use electron spin or SU(2)? Or maybe it means the topic belongs in philosophy or metaphysics and cannot be judged by criteria used to judge physics concepts (some might place MWI there).

7. **Peter Woit**
April 10, 2023

Amit,
I suppose the phrase sometimes gets used to mean "so obviously wrong as to be not worth discussing why it's wrong", but that doesn't seem to me to capture the appeal of the phrase or, whether it was Stueckelberg or Everett, how Pauli was using it. What the phrase captures nicely is the frustrating problem of scientific claims that come with no way of deciding if they are right or wrong. There can be multiple reasons for this, one of which is claims that are just too speculative and vague to pin down precisely enough to see if they are right or not. From what I know of Stueckelberg's work, there were times he had a very good idea, but either didn't explain it well enough or didn't understand it well enough himself. I can imagine Pauli getting exercised about a seminar with this characteristic. Everett is another case where where it's unclear exactly what is being claimed and whether any real explanation of anything is being provided. That this remains true 65 years later is my problem with MWI.

So, at least to me "Not Even Wrong" points to unclear speculative claims, but such things can have value. Most successful advances in math and theoretical physics start out as an unclear idea. Only later do things get fully understood and the value (or lack thereof) of the idea becomes manifest.

8. **D. Alder**
April 10, 2023

My understanding of the phrase is that it denotes an idea, theory, etc, that isn't even incorrect in some illuminating or interesting way which would allow one to identify some mistake or misconception and correct it. It may even be correct insofar as it can be; or correct in some trivial, misleading, or contextually irrelevant manner.

Anthropic fine-tuning is a perfect example. It's obviously true, since it's based on a tautological observation. But so what? It doesn't explain anything.

9. **Peter Woit**
April 10, 2023

D. Alder,
I don't think Pauli had in mind empty tautologies when he was using the phrase since in his day no one was making the kind of absurd claims about such things that they do now. Would be interesting to hear his reaction to some of the modern "beyond not even wrong" developments such as the landscape and the wormholes.

10. **Scott Aaronson**
April 11, 2023

It's actually pretty extraordinary, and ironic, if the phrase "not even wrong" originated to ridicule the ideas of two physicists, Stueckelberg and Everett — BOTH of whom, several generations later, many people remember less for anything they were wrong or not-even-wrong about than for being far ahead of their time!

11. **anon**
April 11, 2023

The French Wikipedia "Même pas faux" quotes K. Mendelssohn (1973), *The World of Walther Nernst*:
« Shortly before his death Pauli was handed the paper of a young American physicist whom his colleagues suspected of being a budding genius. After studying it carefully, Pauli, rocking sadly, gave it back with the acid comment: 'It is not even wrong', meaning that there was not a spark of imagination in it »

12. **Chris Oakley**
April 11, 2023

Scott,

Yes – Pauli did rather overdo it. I had not known about the stick, but I cannot say I am surprised. Sabine seems to have taken on Pauli's role of telling everyone where they are going wrong. A necessary function, and the lack of anyone doing this between Pauli's death in 1958 and Sabine's blog starting in 2006 is probably what allowed a lot of unpromising ideas to develop, such as supersymmetry and string theory. Hopefully the subject will get back on track now. The role has to be taken on by a native German speaker, and I am hoping that she will be able to produce her own catchphrase on the lines of Pauli's. Maybe she has already.

13. **Peter**
    April 11, 2023

    When I read “On Bullshit” by the philosopher Harry Frankfurt, it was striking to see how he defines “bullshit”. It’s more or less “not even wrong”, with some intention added. The only thing that counts is whether the bullshit is suitable for the purpose of the communication. It’s not a lie, rather something that doesn’t *care* about being right or wrong.

14. **Low Math, Meekly Interacting**
    April 12, 2023

    I like the application of “not even wrong” to untestable hypotheses, but I personally doubt that’s what Pauli meant. I rather think it’s for ideas so ill-conceived as to be not worth falsifying, like homeopathy. Pauli himself posited correctly that the neutrino exists. He hated doing it, because he sincerely believed that idea was empirically intractable, but did it anyway. Oddly, Pauli reportedly seriously considered the notion that his eponymous “effect”, i.e. his ability to ruin experiments with his mere physical proximity, had some other basis in reality than the terror he struck in others with his noxious persona.

15. **DrDave**
    April 16, 2023

    Mathematician Max Simon:
    “Die schlechtesten Antworten sind freilich die welche so schlecht sind daß sie nicht einmal falsch sind also nach dem Schema Die große Armut stammt von der großen pauvreté besonders beim Ansatz von Gleichungen hat man damit zu kämpfen.”
    (Didaktik und Methodik des Rechnens und der Mathematik)

16. **DrDave**
    April 16, 2023

    I think what Max Simon published in 1908 shows unambiguously the meaning of “not even wrong.” He clearly states that the idea or equation (Max is talking math) is so bad that it does make it as far as wrong, that it is below wrong in the order of things. Pauli would have known Max and/or his work, and it is more than likely that this is the earlier, published origin of the phrase as applied to science, and it is also quite possible that someone just misattributed it to Pauli like these internet misquote cards that appear on social media.
    A couple more things, Max’s syntax is typical, with the verb at the end, either in singular or plural (“ist” or “sind”) and the form in which Pauli’s “original” appears is not typical.
    All contemporaneous forms use “einmal”, more familiar as “noch einmal” which means “one time”, reinforcing the threshold meaning of the phrase, literally not even good enough to be wrong even once.
    Max’s 1908 quote translated:
    “Of course, the worst answers are those that are so bad that they are not even wrong, so according to this scheme great deprivation comes from great poverty [pauvreté], you have to struggle with it, especially with equations.” Max then gives some math examples.

17. **jbc**
    April 18, 2023

    This is rather tangential to the question of when Pauli first used this phrase but it might be helpful to put it in context. It’s usage is quite common even today in Austria, where Pauli grew up and spent his schooldays—he didn’t invent it but adjusted it to the context discussed. The original phrase is “net amoi foisch”, austrian dialect for the german “nicht einmal falsch” . As is often the case, it sounds natural and scathing in the dialect form, in contrast to the stilted high german version usually quoted. It is generally occurs as part of a trilogy, used typically by school teachers when returning written homework examples, placing the jotters on the pupils’ desks with the corresponding attributes “richtig”, “foisch” or “net amoi foisch” depending on their opinion of the solution.

    As said above, this doesn’t answer the query but it does give background information which might explain why the phrase would occur naturally to Pauli.

Reality is a Paradox

April 12, 2023
Categories: Uncategorized

Lex Fridman's latest podcast features a nearly four hour long conversation with Edward Frenkel, under the title [Reality is a Paradox – Mathematics, Physics, Truth & Love]. Normally I'm fairly allergic to hearing mathematicians or physicists publicly sharing their wisdom about the larger human experience (since they tend to have less of it than the average person), and I'm pretty sure I've never before listened to a podcast/interview longer than an hour or so. But in this case I listened to and enjoyed the entire thing. Besides sharing Frenkel's deep interests in the relation of representation theory and quantum mechanics, and views on the unity of mathematics (and physics…), I envy his positive and thoughtful outlook on life and his openness to a range of human experience. The interview left me with a lot to think about and I recommend it highly.

   April 12, 2023

   I mostly enjoy the podcasts by Lex Fridman, also the one with you. So i will listen to the one with Frenkel. I'm not a physicist but i am very interested in the subject. I just recently read the book by Sean Carroll The biggest idea in the universe in which he explains also the mathematics (calculus and linear algebra) behind physics for the layman. The second volume will go deeper into quantum mechanics. How do you feel about this translation work to a greater audience? I think he is doing very important work to make this subject (physics including the mathematics) available to the public.

2. **Peter Woit**
   April 12, 2023

   erik jan bosch,
   I don't want to change the topic here to Sean Carroll and his recent book (which I haven't read). Almost universally I've found physicist's attempts to write not about physics but about things like the meaning of life to be not worth paying attention to (with Carroll's "The Big Picture" a good example). That he's now sticking to the worthwhile (and too difficult for me) task of trying to explain real ideas about physics to a wide audience is a big improvement.

   Frenkel is a very unusual example of a scientist who has something to say about the human condition worth listening to, and it's noteworthy that he doesn't ground it in "I'm a scientist, know things you don't about math/physics, so you should pay attention to my views on life in general".

   April 13, 2023

   There was also an interesting interview with Frenkel on the Numberphile podcast, this one only an hour and twenty minutes for those with less time to spare 🙂

   https://www.youtube.com/watch?v=lMwLCSgvxtw&t=2s&ab_channel=Numberphile2

4. **Giovanni Ronchi**
   April 13, 2023

   For those with even less time to spare there is this 56 minutes interview of Edward Frenkel by Brian Keating: https://youtu.be/b67o24J3bAs

5. **Art**
   April 14, 2023

   Frenkel certainly seems like a jolly fellow. The interview sounds almost calculated to attract your specific interest, with his first mathematics epiphany being exposure to representation theory.

   It seems Oulipo is having a moment. Not only does Frenkel mention the group, but it also pops up in Sarah Hart's "Once Upon a Prime", as reviewed in the Economist. Long ago I read Perec's "Life, A User's Manual" (in translation) based solely on the title.

6. **Cleon Teunissen**
   April 15, 2023

   On the subject of complex numbers.

   The version of the story of complex numbers that Edward Frenkel gives is historically incorrect, and significantly so. (It's not necessarily the case that Frenkel is at fault there; it may be that that is how the story had come to Frenkel.)

   Generally, what tends to happen in physics/mathematics is this: there is a concept that has many contributors, and as succesive authors retell the story, relying on old memory only, the attribution gets shifted more and more to one persion.

   My information source for the story of complex numbers:
   'A Short History of Complex Numbers' Author: Orlando Merino
   https://www.math.uri.edu/~merino/spring06/mth562/ShortHistoryComplexNumbers2006.pdf

   According to the above account:
   Cardano's contribution to the overall history consisted of developing a systematic method for finding the roots of cubic equations. According to Merion Cardano avoided the class of cases that would involve considering the square root of a negative number. While Cardano's contribution is vital, it is historically wrong to attribute complex numbers to Cardano.

   Rafael Bombelli went a step further:
   There are cubic equations that obviously do have a root, but the Cardano formula involves the root of a negative number. Bombelli noticed that if you allow that root of negative number then there in the cases with obvious root that factor subsequently drops out of the calculation, and then it all works out. I infer that at that stage the root of a negative number was admitted, but only in cases where it is seen to drop out of the calculuation.

   My impression:
   Over several generations of mathematicians there was a gradual lessening of suspicion. Over time mathematicians came to see the root of a negative number something on

par with other mathematical concepts.

My point is:
Frenkel comes to the story of complex numbers from musings of how important it is to retain a child-like willingness to consider things that appear to make no sense. Then he enthousiastically gives the Cardano-centered version of the story of complex numbers to illustrate his belief.

Now, I share the concept of child-like openness that Frenkel professes. It's just: the true history of complex numbers is totally *not* the story to illustrate that.

There is a quip by Mark Twain that goes as follows:
"In the real world, nothing happens at the right place at the right time. It is the job of journalists and historians to correct that."

It's funny because it's true.
Human memory is fallible; human memory is prone to restructuring memories to suit the belief system.

When physics authors write a "historical introduction" they always end up doing the very thing that Mark Twain described. When I read a "historical introduction" in a physics textbook there are almost always significant deviations from the actual history. (Often the deviation will have accumulated from author to author.)

April 20, 2023

Frenkel's home page is worth studying.
https://www.edwardfrenkel.com
It seems that Frenkel has a newsletter that people can subscribe to via email.

8. **David Derbes**
April 21, 2023

Cleon Teunissen: Full agreement that complex numbers came about as a result of the need to explain how the Cardano formula, expressed in terms of square roots of a negative number, could possibly produce a positive real number. Tignol (*Galois' Theory of Algebraic Equations*, World Scientific) makes the case very powerfully. However, I think you are not being entirely fair to Cardano. He does not introduce a symbol for the square root of -1. But, in the article you cite, Merino cites a famous example of Cardano's from *Ars Magna* as follows, involving a *quadratic*, not a cubic, namely $x^2 – 10 x + 40$: "to divide 10 into two parts, the product of which is 40″, and completing the square. (Cardano does not actually write down the quadratic.) This leads to $x = 5 \pm \sqrt{-15}$, and, remarking that we must "put aside the mental tortures involved", finding that the product of the roots equals 40. After some discussion, he concludes, "So progresses arithmetic subtlety, the end of which, as is said, is as refined as it is useless." (See T. R. Witmer's translation of *The Great Art, or the Rules of Algebra*, G. Cardano, pp. 219-220.) The best account of the long trial to nail down the Cardano formulas, at least in English, is perhaps in M. Livio, *The Equation That Couldn't Be Solved*.

April 24, 2023

Off topic: the MJR site was put to rest until the end of summer, seems to be an strange and very unpopular decision. The site was gaining tremendous action and while it hosted some asinine posts, some of the mathematics related posts were very thoughtful and valuable

10. **Peter Woit**
April 24, 2023

Z Y,
I'll be surprised if it gets revived. Whenever I would go take a look, my impression was that the level of dumb was pretty overwhelming. Who would want to spend the time it would take to try to find the few interesting comments? What sensible person who wanted to have an intelligent discussion would comment there?

The fundamental problem with an anonymous site like that is it needs a good moderation system to stop the idiots and trolls from overwhelming the place. I never understood the moderation system in place there, but whatever it was, it was nowhere near good enough. Like everything else in our brave new world, maybe there's an AI solution in the future…

And yes, off-topic so I'll moderate out any but the most amazingly insightful discussion of what happened at that site.

April 25, 2023

Getting back to your summary and link to the Fridman interview… I'm exchanging dueling Youtube links with a friend in the social sciences/humanities. His was Martin Rees on multiverses. Mine was the shortest one here, the interview of Edward Frenkel by Brian Keating.

How would you rate this for a heuristic? "Rees says different universes may be a millimeter apart. In Langlands, our representations may be a prime number apart."

Obviously I'm using representation and prime quite loosely, as Rees, I assume, was with millimeter. I think still 120 odd years since quanta, it's difficult to convey the challenge of discreteness when things appear continuous. (Einstein's middle period frequent quoting of Ernst Mach is one way in.)

My other comments relevant to your summary would be about Frenkel's use of the term Platonic, and getting beyond it in math foundations. Scanning his book, I don't think he's going a direction I would from that (ethics in Greek drama for one), but he is wonderfully open and engaging.

Frenkel's discussion of math & physics ideas not easy to popularize is close to crystalline in the shortest video. As I haven't read the book fully, I'll suppose his philosophical direction is good too. Thanks for posting about it.

12. **Peter Woit**
April 26, 2023

kitchin,
The problem with the multiverse of Martin Rees, e.g. at
https://theconversation.com/the-multiverse-our-universe-is-suspiciously-unlikely-to-exist-unless-it-is-one-of-many-200585
is that he has no evidence and no viable theory to point to. He and others going on about this do not seem to be referring to anything well-defined (closest might be the string theory landscape, which is highly problematic).

About deep structures unifying math and physics, when Frenkel points to the Langlands program, he is pointing to something very specific, which we don't fully understand, but do know a great deal about. If you want to propose thinking of universe as at the real place, other universes at different primes p, at least there is something specific, well-defined, with a lot of interesting structure that you are pointing to. Maybe this it is useless to think about this as a "multiverse", but at least there is something well-defined to talk about.

April 27, 2023

Your own experience that you haven’t found mathematicans’ insights on non mathematical valuable is of course inarguable, but the statement
“their wisdom about the larger human experience (since they tend to have less of it than the average person)” makes me sad. I read that as separating the experience of doing (in whatever form) mathematics from “human experience “, and I disagree strongly. Math has an existence beyond us (IMO), but our experience of it is by definition human. I find it rich and rewarding (which is why I am a mathematician) and in my experience it’s deeply connected to the rest of my experience – i see mathematics in the world, and the practice of mathematics informs my worldview. I value a wide range of experience, but mathematicans are among those whose experiences I’m most interested in personally. I’d like to see more of musings on the wider world of the character of, to name a few exemplary cases, the writings of Poincare, Penrose, Ulam, Gromov, and Thurston. I’d also enjoy seeing more mathematicians engaged with the wider world; Frenkel’s doing his part, as are you (PW). I think we have a lot to contribute.

Kontsevich on the Hodge and Tate conjectures

April 26, 2023
Categories: Uncategorized

Yesterday afternoon there was an event at CUNY featuring a panel discussion on Chern-Simons terms. Nothing new there, although it was interesting to hear first-hand from Witten the story of how he came up with the Chern-Simons-Witten theory. One piece of news I heard from Nikita Nekrasov was that he was missing a talk that day at the Simons Center in Stony Brook by Maxim Kontsevich, who would be arguing that the Hodge and Tate conjectures were not true. The video of that talk has now appeared, see here.

I'm way behind in preparing for my class for tomorrow, so haven't had time to watch the full video and ask experts about it. Will try and learn more tomorrow after my class, but it does seem that if Kontsevich is right that would be a dramatic development. If you are able to evaluate Kontsevich's arguments, any comments welcome. Tomorrow I'll also try and at least find some good references to suggest for anyone who wants to learn the background of what these conjectures say.

Update: I see there's an older version of this idea described here.

Update: Having watched the video and talked to a few people about it, I fear that there's not much new here, and nothing likely to convince experts that a falsification of the Hodge or Tate conjectures is on the horizon. Kontsevich himself introduces the talk as "not really a talk, but a kind of after-dinner rant." He for a long time has been trying to find examples that could falsify the Hodge conjecture, with no success so far, and from what I can tell, he doesn't have a new compelling proposal for where to look and how to do this.

   April 26, 2023

   In his earlier talk, Kontsevich suggested looking for a counterexample to the Hodge conjecture on abelian fourfolds of Weil type. However, Markman has proved the Hodge conjecture for abelian fourfolds of Weil type with determinant 1, so this may not be such a great idea.

   Markman, Eyal The monodromy of generalized Kummer varieties and algebraic cycles on their intermediate Jacobians. J. Eur. Math. Soc. (JEMS) 25 (2023), no. 1, 231–321.

4. **Peter Woit**
   April 28, 2023

   Mike,
   I believe so, and I think the whole thing was on Zoom. I don't know if there are any plans to make the video public. If so, one place it might appear is at the Einstein Chair Mathematics Seminar Youtube site here
   https://www.youtube.com/channel/UC_jFgn51x3iXh8ljGzWRToA

5. **jsm**
   April 29, 2023

   A little history. What's interesting about abelian varieties of Weil type is that they have cohomology classes, predicted to be algebraic by the Hodge conjecture, but not obviously algebraic (not in the Q-algebra generated by the divisor classes). When Weil constructed the varieties, he wrote to Tate: "As you and Mumford seem to believe Hodge's conjecture, it is now up to you to exhibit algebraic cycles corresponding to these abnormal classes. As I incline to disbelieve it, I shall rather attempt to show that there is no such cycle; but I have no idea how this could be done."

6. **Simon Pepin Lehalleur**
   May 1, 2023

   I think Kontsevich's points are important and good to think about carefully even if one doesn't share his strong opinion about the Hodge conjecture. The philosophy of motives has a few components which can be considered independently:

   0) There are many cohomology theories for algebraic varieties (singular over C, de Rham, l-adic, crystalline…) with very different constructions and nevertheless striking similarities. Moreover, these similarities underlie interesting phenomena in algebraic geometry, arithmetic geometry, number theory, mathematical physics…

   1) There should exist a universal cohomology theory, valued in some abelian category of motives, which explains these similarities. This abelian category should be a rigid Tannakian category (with the tensor product related to products of varieties and the Künneth formula, and rigidity coming from Poincaré duality), and the corresponding "motivic Galois groups" should reduce some questions about these similarities to tractable questions in the representation theory of pro-algebraic groups. There should be a subcategory of pure motives (for motives of smooth projective varieties) embedded in the larger category of (all, mixed) motives, together with a functorial weight filtration with pure graded objects, so that every motive is canonically an iterated extension of pure motives. This subcategory of pure motives should be the category of representations of the maximal pro-reductive quotient of the motivic Galois group.

2) The category of motives should be constructed solely from algebraic geometry, and morphisms groups in that category should be ultimately describable in terms of algebraic cycles: directly via Grothendieck's original proposal for pure motives, and more indirectly (in terms of "higher Chow groups"/higher algebraic K-theory) for mixed motives.

One way to summarize Kontsevich's talk is that he believes in 0) and in some form of 1) but not in 2).

Point 0) is essentially an "empirical" observation which has been apparent and pretty uncontroversial ever since Grothendieck, and has only become clearer since then.

Point 1) still seems like the most parsimonious explanation for 0). In his talk, Kontsevich indicates that he does believes in some version of 1). In characteristic 0, mathematicians have actually constructed abelian/Tannakian categories which realise some of these desiderata (Deligne's pure motives based on absolute Hodge cycles, André's pure motives based on motivated cycles, Nori's mixed motives with an important alternative construction by Ayoub and Choudhury-Gallauer). However, we we understand very little about morphism groups in these categories, because they are built from the choice of an embedding of your base field into C and transcendental constructions involving singular cohomology, and not a priori related to algebraic geometry. We also essentially don't know what to do in positive characteristic. Consequently, these constructions only have had a few applications so far.

Point 2) is what that Kontsevich rejects. As far as I can tell, the standard heuristic argument for believing in 2) is that algebraic cycles are a clean mechanism for forming bridges between different cohomology theories: namely, two cohomology classes in different cohomology theories can be the cycle class of the same algebraic cycle! So if algebraic cycles with prescribed cohomological properties were as abundant as the Hodge and Tate conjecture (as well as a few other key conjectures about cycles like the Beilinson-Soulé and Bloch-Beilinson-Murre conjectures) predict, we could indeed construct the categories predicted by 1) purely geometrically. This was explained by Grothendieck in the pure case (where one only needs the standard conjectures), and would follow from Voevodsky's theory in the mixed case, as I discuss a little below.

Sidenote: the full force of the Hodge/Tate conjecture is not needed, one "only" needs Grothendieck's standard conjectures; personally, I would not be too sad if the Hodge conjecture was false as long as the standard conjectures are ok! But Kontsevich also rejects that possibility; as shown by André, the standard conjectures for all smooth projective complex varieties imply the Hodge conjecture for abelian varieties, and Kontsevich is looking for counterexamples to the Hodge conjecture on abelian varieties.

As Kontsevich stresses, the evidence for all these cycle conjectures is quite thin on the ground. There are simple situations like Weil-type abelian varieties where we don't know where cycles lifting certain natural Hodge classes could come from (even with recent great progress by Markman), and almost all known cases rely on cleverly bootstrapping existing cycles and not on finding new general principles of construction of cycles. I think Kontsevich is right that some of us "motivists" have become too trusting in the general web of motivic conjectures, and that more effort should go into stress-testing them by looking for counterexamples as well as new invariants which could lead to counterexamples (like his tropical proposal).

However, if 2) is false and 1) is true, then to make 1) usable we would still need an explanation of where the morphism groups of the abelian categories in 1) come from, if not from algebraic geometry! Especially in positive characteristic where we do not have the crutch of singular cohomology and we do not understand why something like independence of l-adic Betti numbers for general varieties, which would follow from any reasonable version of 1), should be true.

An interesting part of Kontsevich's discussion is about the relative setting. As he notes, in the context say of topological Q-local systems over a smooth algebraic curve over a number field with some given complex embedding, we have some tentative criteria for what "local systems of pure motives" should be: integrality of monodromy, G-function /growth of power series coefficients of solution of the associated differential equation , vanishing p-curvatures of the differential equations in characteristic p, existence of Dwork-Frobenius structures. However, (outside of recent progress in some directions for rigid local systems on higher-dimensional varieties by Esnault-Groechenig) we don't really know how to prove the equivalence of these very disparate conditions, other than to try to prove that they are all equivalent to "coming from smooth projective families of algebraic varieties"! A useful theory of 1) should include abelian categories of "motivic local systems" and needs to explain why these conditions all seem to be equivalent; again, if not by geometry, how?

To conclude, let me clarify the position of the work of Voevodsky in this picture. Voevodsky has, among many other things, constructed triangulated categories which look like the *derived categories* of the categories predicted in 1), have a purely algebro-geometric construction, and whose morphism groups can be described (by some very non-trivial theorems) in terms of algebraic cycles. This has had some nice applications and also revealed a wider picture of "motivic homotopy theory" which is interesting independently of the validity of points 1)-2). However, finding an abelian category of motives inside of these triangulated categories ("constructing the motivic t-structure") is known, at least in characteristic 0, to be essentially equivalent to the same hard conjectures about algebraic cycles.

I should also point out Ayoub has proposed a very interesting approach to the motivic t-structure on Voevodsky motives which tries to bypass the conjectures on cycles, and which so far has lead to the new construction of Nori motives mentioned above and to a functional/geometric version of the Grothendieck-Kontsevich-Zagier conjecture on periods of varieties over number fields- ironically, one of the many conjectures that Kontsevich now believes to be false…

7. **Peter Woit**
May 1, 2023

jsm and Simon Pepin Lehalleur,
Many thanks for the informative comments.

8. **Topological twist**
May 3, 2023

Bear in mind that it is commonly said that Deligne was skeptical of the Hodge conjecture and tried to find counterexamples on abelian varieties, but failing that, developed the theory of absolute Hodge cycles. This tropical speculation has been around for at least ten years. I once tried to get Katzarkov to explain to me why tropical geometry should succeed where Deligne failed, but couldn't get a reasonable answer. Someone should push Kontsevich hard on this until he says something that other people can understand.

This Week’s Hype

April 26, 2023
Categories: This Week's Hype

According to this article, string theory is going to be tested using quantum computers, by doing a lattice QCD calculation:

> The way string theory is tested involves ‘lattice quantum chromodynamics’: a calculation problem far beyond what digital computers can achieve. ‘Quantum computers,’ he writes, ‘may be the final step in finding the Theory of Everything.’
>
> ‘I’m not a computer person. I’m a theoretical physicist,’ he says. ‘But I got into quantum computers because I realised this may be the only way to quantitatively prove that string theory is correct. String theory exists in the multiverse. That is, we exist perhaps in parallel states which are bizarre, with new laws of physics, but we coexist with them. The way to prove it is with a quantum computer.’

I suppose you need to buy the book to find out more.

Comments

string theory lied to us and now science communication is hard

April 27, 2023
Categories: Uncategorized

I want to make up for linking to something featuring Michio Kaku yesterday by today linking to the exact opposite, an insightful explanation of the history of string theory, discussing the implications of how it was sold to the public. It's by a wonderful young physicist I had never heard of before, [Angela Collier](). She has [a Youtube channel](), and her latest video is [string theory lied to us and now science communication is hard]().

Instead of going on in detail about the video and what's great about it, I'll just give you my strongest recommendation that you should go watch it, now. It's as hilarious as it is brilliant, and you have to see for yourself.

Comments

1. **Sage of PHY6 Paths**
   April 27, 2023

   Life hack: If someone is not even putting enough effort to focus while talking and instead is gaming while speaking then that video is not worth watching.
   –
   She told there are 10 string theories (at 16:00) and were unified even though there are only 5. This person doesn't look like she EVEN knows string theory at the popular science level. She wrongly included String theory in a nutshell (by Elias Kiritsis) as a popular science book among Kaku's and Brian Greene's books.
   –
   So are we supposed to learn the history of string theory from someone who doesn't know what Pauli got the Nobel for?
   –
   "if they are not testable now they are not predictions": Thanks for teaching me that when Einstein "predicted" gravitational waves it was not a prediction until 100 years later.
   –
   She is wishing string theorists should never be hired (at 31:20). Looks like she is much less nuanced than people like you. Correct me if I am wrong but you don't advocate for completely stopping hiring string theorists right? She is an ASTRO person. They are well-funded. Why do some of them wish that fields like string theory and quantum gravity which are already SEVERELY underfunded to go extinct? What do they achieve if humanity stops progressing in fundamental physics?
   –
   She incorrectly said that the cost of SSC was 200 billion instead of 8.25 billion.
   –
   She is randomly saying things (making stuff up) like the public was thinking like this in 2000s and like that in 2010s etc without any SOURCES. The pop science audience is in millions and you can't assume they all have similar opinions. Even to know what the majority thinks you need a LARGE SAMPLE SIZE to get an idea.

   She is saying due to string theory people lost faith in all sciences. This is definitely a baseless CONSPIRACY theory.
   –
   So, she even left Astro (galactic evolution and dark matter), because the industry has even more cash (she exactly mentioned this as the reason) than Astro.
   –
   The reason why string theory is more appealing to the general public is that humans are fascinated by fundamental things. Post a video about how John Bardeen invented the transistor. Next post a video about how Einstein discovered GR, obviously this will get much more views even though the transistor is more useful in everyday life. The origin of the universe is a mystery that humans found fascinating even thousands of years ago (religions were created in part due to this, in another part due to fear of death)

   Most people are not fascinated by condensed matter or AMO. Most people who join undergrad join by wanting to contribute to fundamental physics. In my undergrad class, 10/50 people wanted to work on string theory or QFT/particle phenomenology, or loop quantum gravity when they joined. Only 2/50 were left in HEP by the end only because everyone understood that going into HEP is EXTREMELY bad for their job opportunities and they [reluctantly] sold their souls to condensed matter or AMO or Astro or finance.
   –
   I hate myself for wasting time by watching this.

2. **John Hessler**
   April 27, 2023

   That was the best video I have seen in months!! I loved that she brought out the M-Theory text and pointed out the Greene quote in the Einstein anniversary edition!! Thanks for pointing this out—my class will watch this next week!!

3. **Peter Woit**
   April 27, 2023

   Sage of PHY6 Paths,
   I think you're unfair on some of the specifics you're accusing her of getting wrong, but I don't think that's what's relevant. She could have made a scrupulously accurate and fair video, which would have been boring and no one would listen to. Many people quite accurately point out to me that when I write (accurately and fairly…) about the problem of string theory hype, no one is interested any more: it's beating a dead horse, a complete waste of time.

   So, how does one deal with the ongoing phenomenon of string theory hype (from the Kaku extreme, through the long list of prominent physicists still at it after all these years)? I thought this gonzo, bizarre, over-the-top, completely hilarious video was a unique answer to the question. Not something she or anyone else should try again, but I haven't seen a better answer to the question of how to deal with the likes of Kaku (ignoring him doesn't seem to work).

4. **Klaus**
   April 28, 2023

   Sage of PHY6 Paths,

   To give such a complex talk without "ahms" and without cuts while playing a video game at the same time shows that her intelligence and wit are extraordinary. Please stop hating yourself. Instead, hire her in your department!

5. **Guangyu Xu**

April 28, 2023

I think this is a valuable video. I can imagine many other physicists would have a similar perspective. The public opinions on string theories definitely did some damage to the physics community as a whole.

But I don't necessarily think Witten etal. lied intentionally, at least not in the beginning. I'm sure they were excited about their theories and did what they thought was the best for their careers. At least string theory did produce something useful for maths, even if there is no good testable predictions in the near future.

This is in stark contrast with the "wormhole in a lab" hype, which is so obviously fabricated lies to get the public funds. In one hand I feel angry, on the other hand it feels pathetic that even the most well funded areas in physics are so desperate for funding.

6. **James Smith**
April 28, 2023

I'd just like to say how shocked and dismayed I was to learn that Michio Kaku is a phony and an idiot.

7. **Bertie**
April 28, 2023

I was an avid consumer of popular science during the 90s & noughties and I think this girl totally nailed it.

As to gaming while she was talking, well that was next level multi-tasking, I was truly impressed and I don't see why anyone should whinge, I assume she was nervous and that is how she manages, good on her!

8. **Mark Olson**
April 28, 2023

It seems to me that the takeaway here is not the details of her argument or the foibles of her presentation, but that she probably represents many other newcomers to physics who are prepared to move on from this apparent dead end. "And that may be an encouraging thought." (I, too, found the gaming while talking incredibly annoying, but I dealt with it by just listening.)

Max Planck: "science advances one funeral at a time"

9. **John Horgan**
April 28, 2023

Thanks for the heads up, Peter. I love Collier's history of string theory, except for when she bashes Margaret Wertheim's book Physics on the Fringe, which I really like. Wertheim does not bash all of physics, only strings, multiverses and other ideas that cannot be tested.

10. **Peter Woit**
April 28, 2023

For my take (back in 2011) on the Wertheim book, see here

11. **lettuce field theorist**
April 28, 2023

For many young people, watching someone play a video game on camera while they're talking about an unrelated topic is completely normal. Granted, it's usually not about string theory, but it doesn't matter. As a millennial and twitch enjoyer, watching the gameplay actually keeps my attention on the video much better than if she were just talking, and this might be one of the best ways to reach a gen Z audience. It didn't even strike me as odd. If you can't deal with this format because you're a boomer or if it's simply not for you, then don't watch it. I can't believe the first commenter decided to watch the whole thing and then be a hater. You've wasted your own time, why're you complaining to us about it? The nerve…

Regarding the actual content, I find myself agreeing with the majority of her points. Her perspectives on string theory from an astrophysicist's point of view resonate with me, being a lattice QCD guy myself. Both of these fields have made incredible progress over the past 30-40 years, maybe they should've paid some string theorists to write hyped-up pop science books about it. Many of the things she said also reminded me of the angry conversations I've had with the blank wall in my office when the wormhole paper came out. It's not just that they're obviously fabricating false "breakthroughs" to reel in funding and are getting away with it by misleading the public, what really upsets me is knowing that I can't do anything about it, especially as an early-career scientist. At least string theory was sort of well-motivated back when it started, this new wave of pseudoscientific "quantum gravity in the lab" claims seems quite different from my point of view. I totally would've believed a younger Brian Greene or Ed Witten telling me that they're indeed fully convinced that string theory is the answer, even if I had disagreed myself. But they just kept going even when it didn't pan out, and as a result, the new generation of non-physicists they inspired seems to have no problem with engaging in deliberate misrepresentation in order to achieve their own career goals. I often wonder how they manage to sleep at night. No one can be this delusional, right? RIGHT???

12. **Peter Woit**
April 28, 2023

lettuce field theorist,
Thanks for providing some perspective to boomers like myself. To me seeing someone play a video game while talking on screen seriously about something else comes off as a hard-to-believe attention-getting piece of radical performance art. Interesting to hear that it's just what millenials do. Maybe I'll start making videos of myself doing things shocking and incomprehensible to millenials, like reading a physical newspaper or something and put those on my Youtube channel.

Or, maybe the lesson is that if I want to get millenial's attention for material about twistors and quantization of euclidean chiral spinor fields, I first need to take up gaming and work on that…

13. **Geoffrey Dixon**
April 28, 2023

lettuce field theorist
As a boomer who stopped maturing many decades ago (a Z-boomer, as it were), your comment was pure gold. It would give me hope for the future were it not that the likes of Sage of PHY6 Paths – dismissive, arrogant, not fun at parties – exist in your gen too, and they have a way of rising to the top. Consult Machiavelli for further references.

14. **Gabe Khan**
April 28, 2023

Even as a mathematician with some tangential connections to string theory, I completely understand the skepticism for it and very much liked the video. Personally, I would be much more comfortable with strings if they were sold as a theory which was developed by physicists and have generated deep and non-trivial mathematical insights. In that respect, it has been highly successful (and much less controversial). And although physicists might not prioritize it as highly as a mathematician does, there is real value in solving difficult mathematical problems.

But there is a real problem in researchers aggressively overselling their work before it has produced the results to match. I understand it is necessary to promote your work, since no one will read technical research unless you convince them it is worthwhile to do so. However, I still don't have a good answer to the question of how researchers can sell their work in responsible ways and not create the academic equivalent of a speculative bubble.

String theory is one the most prominent instances of this due to the success of its public outreach. However, there are many other examples which come to mind. And in the long run, this hype often proves to short-sighted and ends up detracting from serious work in the area.

15. **SPARx**
April 28, 2023

Curiously, I found your blog from the video (mentioned by user "Perfidy" in the comments section), and not the other way around. A useful feature of good science communication is that creates a cyclical effect, increasing the interest and awareness of the consumer. This increased awareness drives the consumer to seek similar but often less sensational content, which can lead to more good science communication.

An equal or greater challenge for "good science communication" is the fact that it is in no way equivalent to "good science." From my perspective walking a different path saddled with its own plethora of "pop science," it feels far rarer that the two are ever paired, in fact. It should be no surprise that people who rely on their communication skills to market their ideas rather than any facts or evidence contained therein also happen to be the smoothest communicators.
By contrast, the utility of a video such as this one, despite bearing such as egregious flaws as including videogame footage or misidentifying a cash figure, is that it serves to draw the public's opinion away from hapless acceptance OR excessive skepticism.

The relaxed tone and focus on certain specific instances of potential wrongdoing welcomes viewers who have the (frankly commonly held) belief that "string theory is cutting-edge and well validated science" to reconsider this belief without reflexively disavowing physics – or indeed even string theory itself – outright. Perhaps beneficial outreach, given how perilous ignoring a scorned majority holding the keys of finance and electoral support can become. NASA alone teaches many lessons.

Cheers!

16. **Chris Oakley**
April 29, 2023

I enjoyed the video, although she should (i) have taken out the "This is just my opinion man" banners and (ii) done the whole thing riding a unicycle on a tightrope.
I know there are good scientists out there – I have worked with them, generally doing unglamorous, non-headline-grabbing things – but in fundamental physics, they seem to be few and far between.

17. **gigi**
April 29, 2023

I found her other video about postdocs maybe more useful.

In particular about how current professors are pretty much also responsible for the tough environment postdocs face.

I find it pretty hypocritical how usually professors and university admins are ready to jump on any silly talking point, like divesting oil and pronouns, but working conditions for postdocs are "just the tough way it is". And I'm not referring to salaries, but at the very least administrative support. Changing countries with a family is easily a waste of several months of work, just because univ. admins can't be arsed to put together a decent FAQ for new hires.

18. **David Roberts**
April 29, 2023

If nothing else, this video gives a sample (n=1) of a mainstream physics view of string theory, by someone who grew up reading the pop sci treatments of it. Yes, the inaccuracies are unfortunate. The SSC funding cancellation being moved up in time was to me the most egregious slip; the mentality of the episode is about right, but it lessens the impact getting that one wrong. Then the origin of supersymmetry being inspired by ST, but at least that was tethered somewhat to superstrings, and considered as a prediction. After that, the specific mistakes like the critical dimensions for CFTs, the specific number of different string theories, are more or less beside the point. If there are five or ten superstring theories, it changes nothing about the thrust of the argument.

The example of how the framing of the character of Sheldon from Big Bang Theory shifted is for me a really interesting. All of this is sociology, not science, so seeing evidence of attitudes is really about a barometer of general feeling, not basing the authoritativeness of Collier as a source on her precise recollection of internal details of string theory, when she specialised in some other type of physics.

19. **anon**
April 30, 2023

I think the video is intentionally exaggerated in its claims and not meant to be taken nearly as literally as some here do and the gaming is there also mainly for trolling…

20. **JimV**
April 30, 2023

As a member of the class of science-book reading, science-loving amateurs to which she refers, I feel as if some dark-matter scientists have lied to me. (There was a commenter to this blog several posts ago who did so.) That is, like the string-theory advocates, they passionately believe in their hypothesis and refuse to credit data of its shortcomings, despite its lack of a-priori predictive results, adding or changing parameters as necessary to postdict results such as the CMB spectrum.

In neither case (string-theory or dark matter) do I think the lies are deliberate, conscious lies, but the result of cognitive biases which we probably all share to some degree (myself certainly).

I found the video game distracting and a bit annoying, although an impressive feat if true (would have been easy to fake in editing; I assume it was not fake but must logically leave room for the possibility). On the other hand, perhaps it forced me to concentrate on what she was saying more, by having to snap my attention back.

21. **PatrickC**

April 30, 2023

My recollection of pop-sci reading from the 90s/earlier? is that mentions of string theory always had some sort of disclaimer to the effect of 'not testable by orders of magnitude and/or for any forseeable future'. I rhink the claim of "deception" of the interested public is not generally supportable. Certainly not compared to more technology-related hype-fests like cold fusion, or the EM drive, or this latest 'simulated yet real' wormholes, or …
I also found the simultaneous gaming to be sort of annoying, and detracted from taking her seriously.

22. **Peter Woit**
April 30, 2023

PatrickC,

Kaku to this day claims publicly that string theory is testable in the near future, although Brian Greene has become much more cautious than in the 90s. If you want links to 100 or so examples of string theorists making bogus claims about testability, see here
https://www.math.columbia.edu/~woit/wordpress/?cat=8
These are post-2004, what was going on in the 1990s was even more egregious. For example, the New York Times was hood-winked in 2000, putting out this story

https://www.nytimes.com/2000/04/04/science/physicists-finally-find-a-way-to-test-superstring-theory.html

Yes, discussions of string theory in the 1990s did often include mention of the fact that the strings were small, so direct detection would be hard to impossible, but many claims were made about getting indirect evidence. I think the case that the string theory hype heavily promoted to the public at that time (and to this day…) was highly misleading is very strong. This hype was one of the main reasons I wrote "Not Even Wrong", and I think the argument I was making 20 years ago that string theory was an overhyped idea that had already failed by then stands up quite well today.

23. **Low Math, Meekly Interacting**
April 30, 2023

This video also left me somewhat bemused and uncomfortably reminded of my advancing age. Even with the explanations above, I still don't get the joke of the video game, if joke it is. My reflexively cynical side wondered if it was a built-in excuse for the chronological and factual inaccuracies. In my day bong hits provided similar absolution from fact-checkers on mornings after I was inspired to opine at great length extemporaneously.

Though not a physicist, I started having similar misgivings some time in the early aughties (I think I found this blog shortly thereafter). It is simultaneously fascinating and depressing to hear Collier's take roughly twenty years later. She was in grade school when the problem became obvious even to a layman like me, yet the false narrative of String Theory is so pervasive in science popularization a new generation is experiencing more-or-less exactly the same sort of disillusionment. Very sobering.

24. **Marvin**
April 30, 2023

Did her video bring me something? Yes, I was not aware that Greene is mentioning string theory in the intro of a new edition of Einstein's " The meaning of relativity". This is pure hype, glueing this fictive theory to a classic. Looks like an irrespectuous act to me.

I have the old version in 3 different languages. I will not buy this new edition……

25. **Interested amateur**
April 30, 2023

Coincidentally, I came across Angela just yesterday after watching another of her videos which is a gem: physics crackpots: a 'theory' video. I agree with her 100% after spending many years participating in discussions on sci.physics.relativity; and reading Lubos Motl's opinions on his blog on identity politics, climate change, Covid, the 2019 US election etc.

26. **David in Tokyo**
May 1, 2023

JimV wrote: " I feel as if some dark-matter scientists have lied to me. "

I dunno. My impression was that the dark matter idea was at least in response to real data, to a real problem in astrophysics. My impression is that it isn't working out, but that's OK. Science is supposed to be about looking at data and thinking about it and trying ideas out. I suppose if I read the popularizing fan literature, I might get irritated, too, though.

But as a computer nerd (we're supposed to like sci-fi more than I actually do), using words like cloaking and wormhole are far more objectionable. Ditto for teleportation. Even in the kindest possible interpretation, ripping off perfectly good (albeit inane) ideas from science fiction and using them to talk about things that aren't anything like the original is objectionable in the extreme. The rather dated term "shameless" springs to mind and refuses to leave.

27. **Jonathan Baxter**
May 1, 2023

Have to disagree. This was narrowly opinionated, weakly argued, and pretty annoying.

I've been one of the string-theory-following "public" she mentions (theoretical physics undergrad). Listening to her I feel like we lived in different universes. Yes, string theory was probably over-hyped. And I am not wedded to it being the correct theory. But we had no (and still have no) serious alternative proposal for unifying gravity with quantum mechanics. She is certainly not proposing any such alternative.

It's also not the case that string theory has drowned out the rest of physics, as she implies. Again, as an outsider interested in physics, I've seen far more public discussion of the rest of physics over the decades than I have of string theory.

She judges string theory based on books written by crackpots. That's not string-theory's fault. Pretty much every scientific field spawns its own crackpot literature.

I find the whole thing pretty disrespectful. Witten is a modern-day Einstein. Arguably Einstein + Gauss. Problems with argument from authority aside, when given a choice between the opinion of a YouTuber who doesn't seem to know the Pauli exclusion principle and is offering no alternative to string theory, and someone of Witten's stature that firmly believes it's the most promising direction to pursue, I know who I am more inclined to listen to.

28. **Peter Woit**
May 1, 2023

Jonathan Baxter,
Your comment makes a good case for the problem Collier is pointing to.

According to you the books about string theory she describes are “written by crackpots”. The ones I remember her referring to are by Michio Kaku, Brian Greene and Leonard Susskind. Are they all “crackpots”? If Brian Greene and Leonard Susskind are crackpots, do you have a way of figuring out which of my other Columbia colleagues and which of the Stanford faculty are crackpots? If you don’t, do you now see the problem with overhype trashing the credibility of conventional authority figures in science?

Yes, Witten is a genius, and he’s a professor at the IAS. Just like Einstein, who spent his time at the IAS pursuing a set of failed ideas about unification. Maybe things are more complicated, and geniuses sometime pursue misguided research programs?

29. **Jonathan Baxter**
May 1, 2023

Peter Woit,

“According to you the books about string theory she describes are “written by crackpots”.

That’s not what I said. I said “She judges string theory based on books written by crackpots”.

I should have been clearer that I was not talking about texts on the subject, or popularizations by leading lights of string theory. She is far less judgmental about those, other than to accuse the authors of overhyping string theory’s potential. And on that point: I have a difficult time believing the authors did/do not genuinely believe that string theory had/has a good chance of unifying gravity and QM. I simply don’t believe they were intentionally telling lies as she claims. Speculating that something will happen “within a decade” does not automatically become a lie when it does not, in fact, happen within a decade.

A decade is usually a placeholder for “sometime not in the near future”, regardless of who is making the claim, and regardless of the subject. When I hear “decade” I think to myself “ok, you don’t actually know”. But again, the person speculating usually doesn’t know that they don’t know, so the accusation that they’re somehow lying is not justified.

As far as crackpot books go, I am talking about, for example, “physics of the fringe” which is written by someone with little knowledge of actual physics (full disclosure, I have not read this book and had not heard of it until it was mentioned in the video).

No doubt geniuses pursue misguided research programs. But Einstein is not a good analogy. Other than very accurately quantifying his objections to QM with the EPR papers, he essentially turned his back on QM, a field that was making astonishing progress explaining the physical world in his own lifetime.

Where is the corresponding field that competes with string theory? As far as I know it doesn’t exist. So while I am perfectly willing to believe that string theory is not the right answer, it’s not like Witten has been studiously ignoring spectacular advances elsewhere in favor of his own pet theory.

(tbf on Einstein, his objections to QM are just as valid today as when he made them. They’re an objection to the fact that QM does not describe the physical world of our own experience. He is in good company. Most people who go down the road of truly attempting to understand what QM is telling us about reality end up in a deep conundrum, and usually start musing about the nature of consciousness itself)

30. **Peter Woit**
May 1, 2023

Jonathan Baxter,
So, by “books written by crackpots” you are referring to a single book written by a serious science writer that was about crackpots, and which you don’t know anything about? For more about it, see
https://www.math.columbia.edu/~woit/wordpress/?p=4246

You say “She is far less judgmental about those” (popularizations by leading lights of string theory), completely missing her main point. The video is entitled “string theory lied to us” and she repeatedly refers to the 1990s popularizations of string theory and their authors and repeated calls these authors “liars”. Seems pretty judgmental to me…

31. **Jonathan Baxter**
May 1, 2023

Peter Woit,

What can I tell you? I don’t think those guys are crackpots. If I misinterpreted her view of “fringe” then ok. Nothing I said stands or falls on that.

Yes, she is very judgmental about what she views as the overhyping of string theory – I said as much.

My main points are

A) Her “liar liar” claims are offensive and unconvincing. I don’t believe leading string theorists were intentionally lying when claiming that unification of gravity and QM/QFT was reachable within a decade. And her repeated claims that Witten was happily basking in adulatory Einstein comparisons while secretly harboring doubts? Come on. At least based on my impression from afar, Witten may have the highest ratio of talent to humility on the planet.

B) I don’t believe the string theory hype had any impact on the credibility of science (I didn’t make that point yet).

There’s vastly more nefarious corruption of science than a little overhyping of string theory.

32. **Jonathan Baxter**
May 1, 2023

To be clear, I’ve never heard of Michio Kaku. But I have read books by Greene and Susskind and they’re not crackpots.

33. **martibal**
May 1, 2023

“Witten is a modern-day Einstein. Arguably Einstein + Gauss”

Maybe it would be wiser to let history makes its job, and see in 50 or 100 years if the impact of Witten’s work in maths and physics is comparable to the one of Einstein and Gauss. The cult of personality is also part of the problem of over hyped string theory.

34. **Peter Woit**
May 1, 2023

martibal,
One problem with Einstein/Witten comparisons is the following. While Einstein started his research career around 1900, just as modern physics was about to be born, Witten started his in 1974, exactly at the point the SM was finally in place, and dramatic progress coming to a screeching halt. So, Witten has been working his entire career in a very different situation than Einstein.

Everyone who is convinced string theory is the best way forward because of the undeniable fact that Witten is a genius should keep in mind the example of Einstein, Witten's predecessor at the IAS, who similarly for his entire career there thought he knew the best way forward (extending classical GR to more general geometries), but was completely wrong.

I agree that Collier was being somewhat unfair to Witten about the issues of comparison to Einstein. Unlike some others, he's not at all someone who seeks public attention. But he has been the most influential figure from the beginning in telling other theorists they should work on string theory, arguing the case within the theory community that it was by far the most promising way forward. The big scandal of string theory is that it failed and the leaders of the field (with Witten the most influential) have refused to admit what happened.

35. **Low Math, Meekly Interacting**
May 1, 2023

I am also of the opinion that, e.g., Brian Greene has, or at least had, no intention to misinform. I also still hold his books in high regard for their introductory material and the quality of their writing.

But let's face it: Even when the Elegant Universe came out, the claims therein about the candidacy of String Theory as a TOE were already in serious trouble, not only empirically but purely theoretically. AdS/CFT was 1997. Elegant was published in 1999. KKLT was 2003; Fabric of the Cosmos was published in 2004. So circa Greene's most successful publications, there was already every reason to believe that String Theory not only couldn't work in anything less than ten dimensions, but those six extra dimensions could be rolled up in a functionally infinite number of ways…and the extended ones had to have the wrong curvature. By the mid-2000s (and arguably well before), String Theory was obviously an empirical dead-end to all but its most ardent believers. None of its proponents, nor practically anyone involved in popularizing HEP, saw fit to educate the layperson about the fact that natural SUSY was pretty much DOA before the LHC even turned on. They didn't tell us the so-called WIMP miracle was in serious tension with experiment in the 1990s. They completely glossed over the fact that String Theory's one "prediction" i.e. "gravity" is actually a little-known extension of GR with scalars we never observed nor ever needed to explain anything. And on and on and on…

And it's just been getting steadily worse with time. Today we're agape at this latest wormhole nonsense, and all I can think is practically anyone could come up with a takedown of this whole industry, and yet it amazingly seems indestructibly undead. One simply has to quote certain very respectable people 30, 20, 10, 5, 2…years ago, look at what they said then, what they said later, what they say now, and compare. It's stunning how many goalposts have been moved, how many equivocations have been required to keep the machine going, how many ridiculous statements to the effect of "well, we never actually claimed we could predict"… The only proper answer is "Yes, you did. Over and over again, in fact. And you've been wrong about every single one of these claims. Every. Single. One."

So, no, it's probably not accurate to call some of these folks liars. But does that help, at all?

36. **Douglas Natelson**
May 1, 2023

I'm late to the party here, but I enjoyed the video. I don't think over-hyping string theorists have somehow deeply harmed the credibility of all of science, but I do think they and their ilk have done the discipline of physics a serious disservice. There is far more to physics than just high energy theory, and hype + acting like they speak for all of physics is not helpful. Sage of PHY6 describing people choosing to work in AMO or condensed matter as "selling their souls" is hyperbolic sneering-at-non-high-energy bs, and attitudes like that approach Sheldon Cooper levels of self-caricature.

I think that the tone of Angela Collier's video might not have come across clearly. She's speaking conversationally and without artifice. The reason that she's playing a video game as she talks, as she explains in the first few seconds of the video, is that she doesn't want to get too involved in scientific details when she talks about this, since it isn't her real focus, and she's using the game to distract herself from doing so. It wasn't a gimmick; she was just being straightforward.

Since she's talking off the top of her head, she's unsure of some details, so, for example, she speaks of the SSC as costing two hundred billion dollars (just meaning, basically, a lot of money), and, although she's certainly aware of the exclusion principle, she isn't aware that it's what Pauli got the Nobel Prize for. She was careful to look up the facts afterwards and put them onscreen in the video, however.

This isn't my field, but I have followed popular accounts of string theory since the late 80s, and I tend to share her point of view. It was only when I read Peter's book, and Lee Smolin's, that I realized how little of string theory was actually on solid ground. Up until then I'd thought it was odd to devote so many resources to a program that speculative, but I had the impression that at least the foundational conjectures were proven. In any case, it had all begun to seem more and more contrived as it went on, and it was being greatly oversold, so things hadn't been smelling right anyway.

From Angela Collier's standpoint, it wouldn't have been so easy. She would have grown up wanting to be a physicist and trusting popular books to tell her the truth about what physics was. The media of the time, always happy to find something to push, was selling string theory as the future. When that proved to be hype, it would have been a serious thing for her.

She's an astrophysicist, and she's from Appalachia. Both of those things, I think, would incline her to be a lot more bottom line than most particle physicists. Her claim is that the string theorists who were behind many of the claims in the media knew that they were stretching things at the time they said them, and therefore they were lying. That's a strong way to put it, but I wouldn't say it was unreasonable. If she's correct about what was going on, and they'd been selling used cars with the same attitude, then I think that's the word people would use.

39. **Dom**

May 2, 2023

There is an inherent problem here and it can be expressed by the character in Seinfeld who claimed "It's not a lie if you believe it". Clearly there is no way to tell the difference between sincerely held ideas, sincerely held delusions, having doubts but pretending not to and barefaced lying.

40. **David Derbes**
May 2, 2023

JimV writes: "As a member of the class of science-book reading, science-loving amateurs to which she refers, I feel as if some dark-matter scientists have lied to me. (There was a commenter to this blog several posts ago who did so.) That is, like the string-theory advocates, they passionately believe in their hypothesis and refuse to credit data of its shortcomings, despite its lack of a-priori predictive results, adding or changing parameters as necessary to postdict results such as the CMB spectrum."

I do not know what "lies" JimV is referring to. Dark matter was hypothesized by Fritz Zwicky around the same time that he and Walter Baade hypothesized neutron stars, in 1932. The reason for the hypothesis was the apparent non-Keplerian dependence on stellar orbits in galaxies; absent more mass than provided by the estimated mass of luminous matter, these stars would have left orbit. Vera Rubin seems to have established Zwicky's hypothesis with decades of careful measurements. I don't see how the existence of dark matter can be denied. I don't know what it is, nor what predictions have issued from its existence. The predictions may well depend on its identity, and that is as far as I have heard far from settled.

For a good popular book on dark matter, I like Laurence Krauss's "The Fifth Essence", though thirty years old now. Probably there is a better, newer choice, maybe "The Four Percent Universe" by Richard Panek (2012), which discusses both dark energy (also confirmed by extensive data, and recognized by a Nobel) and dark matter. And neither are necessary to predict the CMB; that was done by many back in the 1940's (at least as early as the 1940's): Gamow and his students Alpher and Herman; Zel'dovich in the '50s (who even suggested the Holmdel NJ horn antenna!), Dicke and Peebles in the early 1960's, it's not a short list. No post-diction required!

41. **Peter Woit**
May 2, 2023

Seeing some very smart people making very bad arguments about string theory has always made me wonder what they are thinking. I suspect that thinking "this is wrong but I'm going to write/say it anyway" (i.e. truly lying) is very unusual. But what is all too usual is people approaching the problem of what to write/say as "what can I say that will further my agenda and interests while not actually being indisputably untrue?" If you do this, I don't think you have a lot of right to complain when another physicist calls you a "liar" on youtube.

One thing that strikes me about ChatGPT is that it seems to work exactly like this. If you tell it to make an argument for string theory, it will produce much the same output as what you hear from the best string theorists. ChatGPT I don't think "lies", it just is designed to produce output that sounds plausible and convinces people, with the question of accuracy and fairness of its argument just not in the code. People's behavior I guess is much the same.

My experience of many string theorists is that in private they will avoid bogus arguments, and do their best to refuse to make public comments (because they know an accurate argument would cause problems). The ones who show up in the media are the ones with the lowest built-in restraint against saying something inaccurate.

It's interesting to contrast mathematicians to physicists. Mathematicians have a strong ingrained culture of never saying anything inaccurate, so rarely turn up in the media making bogus arguments (every so often they do show up making bad arguments about physics, but because of lack of expertise).

42. **Low Math, Meekly Interacting**
May 2, 2023

For the nitpickers: I double-checked my memory of KKLT, and what I took from it back then was A) there's no denying or avoiding the Landscape in ST, and B) KKLT's conjectured mechanism to break SUSY, get rid of massless scalars and the non-existent long-range forces they would mediate, and "uplift" metastable dS vacua to realistic lifetimes was hardly universally embraced, and hotly debated ever since. The verdict today appears to be either (super)ST is inherently incompatible with a positive cosmological constant, or our pocket of the multiverse doesn't "really" have one, despite the overwhelming observational evidence to the contrary. Who could have predicted such an outcome except…well, everyone who wasn't a fan of String Theory?

Assuming I got the above correct, I ask again: What good does it do anyone to say ST is an "honest" enterprise?

43. **Peter Woit**
May 2, 2023

David Derbes,
The dark matter question seems to me the opposite of string theory. It's completely conventional science: you have phenomena that don't fit your best theory (galaxy rotation curves, CMB observations) so theorists try and find a better theory that explains the data and experimentalists try to get better relevant data. Sure, theorists sometimes overhype the theory they work on, denigrate opposing ideas, but this is all very conventional science.

The problem with string theory is that it never became a conventional science, which is very different.

44. **Peter Woit**
May 2, 2023

LMMI,
I think that few string theorists are signed up for the "no positive CC" program of the swampologists. To me the whole "swampland program" seems like what you would get if you asked ChatGPT "the landscape is killing us on the PR front, what can we do about this?".

45. **David Derbes**
May 2, 2023

Peter,
I stay away from all string theory arguments. My thesis (1979) was on supergravity/local supersymmetry, so I feel some sympathy for the string folks. Me, I got out five seconds after I passed the thesis defense. I was simply addressing what I felt another poster was saying about dark matter. I agree completely with your remarks about dark matter; it is a handy way of describing an observed phenomenon (same as dark energy, though of course that has some theoretical underpinnings in Einstein's introduction of the Lambda term), and with luck we will eventually have a much better understanding of what's going on. I do think that some interesting math has come out of string theory, not that I understand much of it, and maybe down the road some good will come from it. I do remember early on—1976?—when Witten scored a PRL with a nifty proof of the positivity conjecture in GR with a supersymmetric argument, later modified not to need susy at all. And as I think you know, I have two friends and former (high school) students who have made careers at least in part with string theory. Both geniuses and good guys, in my opinion, for whatever that's worth.

46. **Peter Woit**
May 2, 2023

David,
I think you have in mind Witten's 1981 paper here
https://link.springer.com/article/10.1007/BF01208277

While he was motivated by thinking about supergravity, the argument doesn't need that, just properties of spinors and the Dirac operator. My impression is that Witten's paper has become a classic in the mathematics literature, often taught to grad students in differential geometry.

47. **Interested amateur**
May 2, 2023

Jonathan Baxter, at 43:00 Angela says:

"It's fine to do String theory… the fact that they spent 30 years on it is fine… they didn't do anything wrong, that's how science works, my issue is how they lied to everyone about it… for thirty years String theorists wrote books and gave interviews where they said within the next decade it's going to be the next big thing"

at 44:48:

"it's a lie to give an interview where you're like 'see the problem with the Standard model is this happens and my theory fixes it' when your theory is not a theory and you don't have any experiments. It's OK to give an interview and say 'here's what I'm working on, here's what I think will happen when we test it', but you need to say when we test it."

Take the LHC: it was built first and foremost to discover the Higgs. It was worth building to test the claims of the Standard model at the time; and the Higgs being confirmed in 2012 is a spectacular achievement IMO. But leading up to it, the public were told its other purpose was to possibly discover SUSY, which was 'likely' as some claimed, new dimensions, black holes, dark matter etc… when it wasn't. It's damaged the credibility of scientists being believed by the public when justifying them paying for their scientific funding.

String theory has also been used in a similar and damaging way according to Angela.

48. **Peter Shor**
May 3, 2023

Jonathan Baxter

If the string theorists on grant review panels deny grants to people trying to research alternative theories of quantum gravity (something that I am fairly sure happens), we never will get an alternative theory of quantum gravity.

Yes, none of the alternative theories of quantum gravity work very well yet, but if you use that as a reason to deny funding to people who want to research them, you get a self-fulfilling prophecy.

49. **Jonathan Baxter**
May 3, 2023

Peter Shor,

I've had a couple of recent comments nuked, so it seems opinions like mine are not particularly welcome. I get the hint: I wasn't going to bother commenting any more. But since you addressed me directly:

I doubt that serious alternative theories of quantum gravity have been nixed in favor of string theory. This all starts to sound very conspiratorial.

The undergraduate theoretical physics department I studied in had two "factions" for want of a better term: the "phenomenologists" and the "mathematical physicists". I thought phenomenology was dubious: making models you know are false yet somehow are going to yield insights into the truth. Felt like curve-fitting not science to me.

But other than the usual zero-sum struggle for a limited funding pie, I don't think the phenomenologists (who were ascendant at the time) deliberately nixed the research programs of the mathematical physicists.

50. **Peter Woit**
May 3, 2023

Peter Shor/Jonathan Baxter,

This has been getting off-topic, I'd like people to stick to discussing the video. I will however take the opportunity to add one thing relevant to the issue of how ideas get suppressed that I noticed recently. A postdoc ad
https://www.aei.mpg.de/1023262/postdoctoral-position-in-quantum-gravity-supergravity-string-theory
for the "Quantum Gravity and Unified Theories" department in Potsdam specifies explicitly
"Potential candidates should have a PhD and a research background in supergravity, string theory or their symmetry structures."
This kind of explicit specification that people pursuing different ideas shouldn't even apply isn't that common, but if one has any experience with how postdoc and junior faculty hiring in this field works, I think it's very clear to everyone what your career prospects are if you try and follow a different road.

The whole thing is kind of bizarre actually. The SUSY/string theory approach to unification has become widely discredited among the physics community (and physicists on youtube…) but people are still advertising jobs restricted to working on this approach.

Sorry, but for further comments, please try to stay on-topic…

Note added (5/5/23): The example I gave here was a bad one. The department at Potsdam, with Hermann Nicolai as director until recently, has been among the places more open to a wider array of ideas. I had not understood the significance of the clause ("or their symmetry structures"). The position advertised is to work with Axel Kleinschmidt, who (see here) works on some interesting new ideas about symmetries, which is exactly the sort of thing I'd hope to see more of.

51. **Sage of PHY6 Paths**
May 3, 2023

Douglas Natelson,
I NEVER claimed that all people who do condensed matter or AMO or nanophysics go into those despite being more interested in hep. I know many people who are genuinely interested in those stuff though I am not one of them. But many people move from hep-th to applied physics very early in their career [end of undergrad or beginning of PhD] due to lack of opportunities. The opposite [people interested in applied physics moving to hep] will never happen due to lack of funding to hep.

52. **John Baez**
May 3, 2023

I enjoyed Collier's string theory video a lot, almost as much as her video on crackpots where she points to my Crackpot Index as archaic evidence that physics cranks have always been the same. (What I liked most about her crackpot video is her answer to the inevitable question "but what if they're right?")

For me the most cringeworthy mistake in her string theory video was her guess that the pion was a particle whose existence was predicted by the Standard Model. Kids these days! They don't even remember Yukawa's prediction of the pion back in 1935, the whole invention of the idea that short-range forces are carried by massive bosons, and the confusion caused by the muon???

But anyway, it doesn't really matter for her point.

53. **Jim**
May 4, 2023

A nice article:
https://www.symmetrymagazine.org/article/whatever-happened-to-the-theory-of-everything?language_content_entity=und

54. **Peter Woit**
May 5, 2023

I've added a note to this comment
https://www.math.columbia.edu/~woit/wordpress/?p=13482&cpage=1#comment-243561
about a job advertisement for a postdoc at Potsdam. While the problem I was referring to is a real one, this was not a good example, for reasons explained in the note.

55. **JE**
May 5, 2023

Peter,

No matter how fair and well-meaning your note can be, the publicly-funded Max Planck Institute is proudly publicizing an award to a young researcher for "making string theory more calculable" on the webpage you linked to, on grounds that "String theories are candidates for a unification of Einstein's general relativity and quantum field theory", which does not sound to me like a new or very interesting idea in the 2020s. The award was "intended to motivate especially gifted early career researchers to pursue a future university or research career", and the awardee completed his PhD in Hermann Nicolai's department of Quantum Gravity and Unified Theories under the supervision of Axel Kleinschmidt.

Hopefully they will now be exploring more promising and interesting ideas about symmetries, as you say…

56. **Peter Woit**
May 5, 2023

JE,
I'd be a lot happier if Potsdam and other places explicitly gave up on this sort of string theory research, and this job ad is not completely unproblematic, but the important question is that of what research activity by young theorists is getting funded. This particular case isn't a good example of the problem (funding limited to bad, failed ideas), with the research program's focus on new ideas about symmetries a good one. Would be better without the starting point being string theory/supergravity, but one can't have everything…

57. **Frank Wilhoit**
May 6, 2023

@Anonymous,
Appalachia is not a bottom-line place. It is a story-telling place. And the nature and place and purpose of story-telling are absolutely central, not only to the particular disputes about the scientific method that are addressed here, but to every other aspect of 21st-Century life. Story-telling is such a fine thing that no one ever stopped to think what would happen if we had too much of it.

58. **Marion Delgado**
May 11, 2023

I watched this and my very first thought was "Peter Woit should see this." I used to be a faithful reader of this blog, back in the day, and I never wrote about this, but I was already familiar with Sabine Hossenfelder and some others, but it was through "Not Even Wrong" that I discovered Scientific American's John Horgan, and I am really grateful to the blog for that. Back before the day, I used to drag my academic friends to string theory presentations, and when they were critical, I couldn't explain away their critiques, so I am also grateful for Dr Woit putting the objections in better words than theirs or mine and affirming them.

59. **SRP**
May 13, 2023

From Jim's Symmetry link:

"But to push beyond the Standard Model and toward a theory of everything, scientists need a foothold in the form of an unexpected deviation—which they have yet to find.

"The Standard Model is too good," says Peter Woit, a theorist and mathematician at Columbia. "Despite a huge effort we haven't been able to come up with something better.""

Sure, if one ignores the anomalies Krisch and colleagues found decades ago, at readily accessible energies, then QCD is fine. But as far as I can tell, understanding of this phenomenon isn't much advanced since this review from ten years ago.
https://arxiv.org/pdf/1001.0790.pdf

May 31, 2023

The Angela Collier website seems to be down: http://www.acollierastro.com/

61. **bryan**

June 10, 2023

I finally got around to watching this video, and it really resonated with me for 2 reasons:

1. This reminds me of how I felt reading popular science books in the 90s

2. This is a wonderful demonstration of modern casual science communication

For the first point, I felt I was mislead about the likelihood of ST being real. I remember reading Peat's "Superstrings and the search for everything" for recreation in college when I was studying engineering. (Ironically, if I remember correctly, that books spends a good deal of time discussing Twistor theory). Anyway, I was pretty convinced as a layman that ST was likely true, and that SUSY would likely be discovered at the LHC. I think I remember Peter saying on this blog the likelihood from the professional physics community of SUSY detection at LHC was actually closer to around 10%, and I was confused why my impression was so different.

On the second point, I think it is important for technical experts to understand this type of science communication. Playing a video game (in this case the classic roguelike "Binding of Isaac") while talking is not a "joke" or meant to be disrespectful, rather discussing topics while streaming other content is a casual way to engage the audience. Look at chess #2 player in the world, Hikaru Nakamura. He considers himself now a streamer first, and a chess player second. He will have casual conversations about chess and pop culture while playing online. He just won the Norway Chess tournament and during the finals he was doing video confessionals mid-game to explain what he was thinking mid-game, doubts and all. This type of communication is making chess more popular among teenagers.

This casual stream of consciousness talking on very technical subjects makes the streamer very vulnerable, but it allows the audience to understand their though process at a deeper level. Commenters here are complaining about the inaccuracies in her video, they would likely rather read a polished peer-reviewed paper with proper citations, but this is the last step in process and not the first. I believe most people would rather hear someone's raw thoughts and ideas, where they're not afraid to be wrong.

Quantum Supremacy

May 3, 2023
Categories: Book Reviews, This Week's Hype, Wormhole Publicity Stunts

We're hearing this week from two very different parts of the string theory community that quantum supremacy (quantum computers doing better than classical computers) is the answer to the challenges the subject has faced.

New Scientist has an article Quantum computers could simulate a black hole in the next decade which tells us that "Understanding the interactions between quantum physics and gravity within a black hole is one of the thorniest problems in physics, but quantum computers could soon offer an answer." The article is about this preprint from Juan Maldacena which discusses numerical simulations in a version of the BFSS matrix model, a 1996 proposal for a definition of M-theory that never worked out. Maldacena points to this recent Monte-Carlo calculation, which claims to get results consistent with expectations from duality with supergravity.

Maldacena's proposal is basically for a variant of the wormhole publicity stunt: he argues that if you have a large enough quantum computer, you can do a better calculation than the recent Monte-Carlo. In principle you could look for quasi-normal modes in the data, and then you would have created not a wormhole but a black hole and be doing "quantum gravity in the laboratory"

> seeing these quasinormal modes from a quantum simulation of the quantum system under discussion, would be a convincing evidence that we have created something that behaves as a black hole in the laboratory.

This isn't a publicity stunt like the wormhole one, because the only publicity I've seen is a New Scientist article, and this is just a proposal, not actually executed. Maldacena estimates that to reproduce the recent Monte-Carlo calculation you'd need 7000 or so logical qubits, which the New Scientist reporter explains would be something like one million physical qubits. So, there's no danger Quanta magazine will be producing videos about the creation of a black hole in a Google lab any time soon.

Maldacena has been chosen to give the presentation tomorrow at the SLAC P5 Town Hall about a vision for the future of fundamental theory, no idea whether creating black holes in the lab using quantum computers will be part of it.

At the other extreme of respectability and influence in the physics community, Michio Kaku has a new book out, Quantum Supremacy. I took a quick look yesterday at a copy at the bookstore. I'll leave it to others to discuss the bulk of the book, which seems to be about how "There is not a single problem humanity faces that couldn't be addressed by quantum computing." The last few pages are about string theory, beginning with the usual bogus pro-string theory arguments, working up to the ending of the book: "So quantum computers may hold the key to creation itself" (i.e. they will "solve all the equations of string theory"). His argument for the relevance of quantum computers to string theory is that they will calculate paths in the landscape:

> One day, it might be possible to put string theory on to a quantum computer to select out the correct path. Perhaps many of the paths found in the landscape are unstable and quickly decay, leaving only the correct solution . Perhaps our universe emerges as the only stable one.

This is justified by a bizarre paragraph about lattice gauge theory, which explains that since we can't solve QCD analytically, here's what theorists do:

> One solves the equations for one tiny cube, uses that to solve the equations for the next neighboring cube, and repeats the same process for all that follow. In this way, eventually the computer solves for all the neighboring cubes, one after the other.

This pretty conclusively shows that the explanation for the Kaku phenomenon is simply that he has no idea what he is talking about.

Update: Michio Kaku was on a very recent Joe Rogan Experience, getting a huge audience for his explanations of quantum computing. Some commentary here.

Update: The reviews of the book have been pretty uniformly very enthusiastic, with the reviewers evidently incapable of distinguishing sense from nonsense. A depressing example is at Science magazine. Why choose as reviewers of a book on quantum computing two people who know nothing about the subject? Is it because *Science* couldn't find anyone who does know about quantum computing willing to read the book and write about it?

Update: Scott Aaronson has read the book and confirms that it's every bit as awful as it seems. For a different look at out-of-control quantum computing hype, see here

Update: The one thing keeping my spirits up while reading the almost uniformly glowing reviews of this piece of junk has been the thought that "at least the New York Times is kind of doing the right thing": not reviewing the book. Just noticed they do have a review up:

> That mind-blowing future is the focus of the final five or so hours of the audiobook, which explores the real-world impacts quantum computing could have: altering our immune systems to avoid cancer and Alzheimer's, increasing crop yields, ending world hunger. As Kaku puts it, "the familiar laws of common sense are routinely violated at the atomic level"; but his lucid prose and thought process make abundant sense of this technological turning point.

Just shoot me…

Comments

1. **David Metzler**
   May 3, 2023

   I'm a bit surprised that these folks haven't pivoted from "quantum computers will save HEP" to "large language models will save HEP."

   On a different topic, is there an accessible Google sheet detailing the planned schedule for this run of the LHC, like you linked to last year? That was great for us watching at home.

2. **Sabine Hossenfelder**
   May 3, 2023

   Estimates that I have seen say it'll require about a million physical qubits for 110 to 150 or so logical qubits, though that depends on error rate and algorithm. I strongly doubt that you can do 7000 logical with only 1 million physical ones, it's almost certainly considerably more. At the very least I'd like to see a source for the NS estimate.

   Besides that, I think it would be good if journalists writing about this stuff would just ask people making such claims "and then what?". I mean, let's assume for a moment we actually manage to build a 7000 logical qubit quantum computer and actually simulate Maldacena's whatever model on it. And then what? They'll write papers and press releases. And then what? What will we learn from it? What will we do with it?

Well, nothing. We'll learn that you can run a certain code on a certain computer. Will it tell us what's going on in black holes? Of course not because you still have no idea if that code you ran on your computer actually describes a black hole. What will we do with it? There's nothing you can do with it.

I know that many people in the field dismiss my output-orientation as unscientific but I would like to argue that this is just a tactic they have developed to shield themselves from criticism. There's a LOT of public money going into quantum technology and people deserve an honest answer to the question what it's supposed to do for them.

PS: I just recently made [a video about what we could do with quantum computers](), in case someone is interested.

3. **Peter Shor**
   May 4, 2023

   @Sabine: Your comment is really much too negative about numerical/quantum simulations in general.

   This experiment certainly could possibly give a negative answer to the question: is the BFSS matrix model the same as one formulation of type IIA string theory. Negative answers can be valuable.

   And if you think that a positive answer on a numerical experiment can never definitively tell you that this is what is going on in the physics world, then why did the Nobel committee give a prize to the discovery of the Hulse–Taylor pulsar system, where numerical calculations confirmed that it was losing energy because of gravitational waves. (For all we know, there might a different mechanism that just happens to have the same orbital decay parameters.)

   Would Maldacena's proposed experiment tell us much? Probably not … looking at the abstracts of the papers Peter links to above, it seems to be testing whether two theories, neither of which comes close to describing the real world, predict the same result. Would this tell us anything about real-world black holes? It's not clear.

4. **Mark**
   May 4, 2023

   @Peter Shor

   You don't need numerical calculations for the Hulse-Taylor pulsar, it's just quadrupole radiation described in textbooks, see e.g. eq. (3) in
   https://arxiv.org/pdf/1011.0718.pdf

   But the broader point of needing numerical GR for discovery is valid. In the case of the discovery of gravitational waves by LIGO they needed waveform templates from numerical simulations.

5. **Low Math, Meekly Interacting**
   May 4, 2023

   I thought, as Seth Lloyd reportedly proved in the 1990's, Feynman's conjecture that quantum computers could do quantum simulations no classical computer could do is a notion that still holds up despite the huge advances in classical computing. Whether building a useful universal quantum simulator is technically feasible I don't know, but seems like a worthwhile objective to pour some cash in, to support some very down-to-earth basic science in e.g. chemistry and condensed matter.

   One rather hopes this highly speculative AdS/CFT-inspired "tabletop black hole" stuff doesn't end up killing interest in the entire field once the backlash reaches a critical level.

6. **Peter Woit**
   May 4, 2023

   David Metzler,
   The "machine learning will solve the problems of string theory" thing has been going on for a while, see for example

   https://news.northeastern.edu/2019/08/05/how-theoretical-physicist-james-halverson-is-using-data-science-and-machine-learning-to-study-string-theory/
   https://iaifi.org/
   https://lims.ac.uk/string-data-2022/

   For the 2023 LHC schedule, see
   https://edms.cern.ch/ui/file/2785501/1.2/2023-LHC-schedule_V1.2.pdf

7. **Peter Woit**
   May 4, 2023

   LMMI,
   The danger to the field of quantum computing is from people like Michio Kaku, getting huge audiences for absurd claims at Joe Rogan. There's already a lot of discussion of a possible coming "quantum winter", with the hype hitting the wall of the reality of slow progress.

   Things like the article in New Scienctist about Maldacena's proposal for creating black holes don't get a lot of wider public attention. The danger of this is not to quantum computing but to fundamental theoretical physics. There's a lot of money and attention out there for anyone who claims to have an idea for how to do quantum gravity using machine learning, quantum computers, quantum information theory, etc. If prominent theorists change their research programs to chase that money and attention, it could move a field already in trouble because of string theory/susy into a complete intellectual collapse dominated by pursuit of nonsense.

8. **Tim Bradshaw**
   May 4, 2023

   Peter Shor,
   I think (hope) that you have missed the point of Sabine's comment: using a numerical model of a theory to test its predictions against some actual experimental measurements, as in the case of Hulse-Taylor or a huge number of other cases (the detection of gravitational waves, for instance) is an entirely different thing than 'testing' a theory for which no experimental evidence exists using a numerical simulation.

   Low Math, Meekly Interacting,
   I am not sure what Feynman thought quantum computers could do, but they gain you no formal power over classical machines: any problem which can be solved with a quantum computer can be solved with a classical computer, and vice versa. What they do gain is an improvement in time complexity for some problems. That in practice makes some problems soluble which would not be soluble on a classical machine because they have some awful time complexity.

   How anyone can claim that "there is not a single problem humanity faces that couldn't be addressed by quantum computing" is entirely mysterious to me.

9. **Mike**
May 5, 2023

Out of interest, why is there no public effort by physicists to counter the relentless nonsense coming from Kaku?

I know that there is a LOT of hype and inaccurate information in pop Sci books and science magazines, but Kaku seems to be responsible for a disproportionately large share of the garbage!

Maybe a joint letter in Scientific American? I don't suppose it would help much. Kaku will still churn out the books, TV documentaries and be invited for interviews as the expert of anything and everything. My heart sinks everything I hear Kaku has taken an interest in a new topic.

10. **André**
May 5, 2023

"How anyone can claim that 'there is not a single problem humanity faces that couldn't be addressed by quantum computing' is entirely mysterious to me."

He does say *addressed*, not *solved* ;).

11. **No Math, Random Reader**
May 5, 2023

Honest question about the things Michio Kaku said (maybe dumb question… but still, honest): how much is fair to expect from a venue like Joe Rogan's podcast? I wouldn't expect accuracy or even factuality of people having casual conversation in a media not famous for high level talks. My point is: isn't this, by itself, a proof that these kind of theories will eventually get to the level of "were the piramids built by aliens"? The kind of thing that just will not go away because it provides entertainment. There is lot of people like me out there: people who knows nothing about math or physics (and never will, by the way, I already have lots of thing to read just from my job), but enjoy watching edutainments like scishow, pbs spacetime, etc. I think most of these people knows there is something sketchy or at least controversial about string theory, even if they can't quite explain what is the matter. I mean… people are watching Sabine's channel too.

12. **Peter Woit**
May 5, 2023

Mike,
That's a good question, one I've asked people over the years. On the string theory front, Kaku has been writing misleading popular books on the topic for over 35 years. Most string theorists agree, at least privately, that what he writes and says has become increasingly inaccurate and increasingly embarrassing. They generally however make the argument: "dealing with this is not my responsibility, there's loads of misleading stuff out there about science. And, maybe it will have a positive effect, getting young people and the public interested in this kind of science, going on to read better books." A cynical point of view on this would be that you can't expect people to go out of their way to challenge something untrue which is promoting their own interests. When it gets to the point of damaging their interests, they might do something and we're not there yet.

As for his nonsense about quantum computing, there's so much promotional bullshit going on that it's understandable that anyone wanting to do something about this has no particular reason to start with Kaku.

No Math, Random Reader,

The problem is Kaku, not the Rogan podcast.

13. **Alessandro Strumia**
May 6, 2023

Kaku says something wise in this scientific debate: https://www.youtube.com/watch?v=mY5V5jqdX9U.
Trying to summarize:
Strings become mainstream because a generation of smart theorists risked their careers attracted by string theory. Now string theorists control theory groups and this can only change if somebody proposes a better alternative. Not by un-constructive criticism.

14. **Geoffrey Dixon**
May 6, 2023

Alessandro Strumia

Of course, "better alternatives" are themselves risks to the careers of those wedded to comatose ideas. And they take great pains to ensure that they are buffered against the slings and arrows of outrageous fortune by indoctrinating the next generation with this same professional angst.

15. **Peter Woit**
May 6, 2023

Alessandro Strumia,

Given the present state of the HEP theory community in general, its ability to recognize and respond appropriately to a good new idea is not so clear. One thing that is very clear is that Michio Kaku is a convincing example of a theorist with zero chance of even understanding a new idea (his discussion of lattice gauge theory shows he's incapable of understanding even the most basic aspects of current ideas about QFT).

16. **vmarko**
May 6, 2023

Alessandro Strumia,

The "only game in town" argument has not been valid for quite some time now. There actually are various alternative proposals out there, some arguably better than others, but for some reason they fail to attract attention as promising research directions. As a consequence, very few people work on those proposals, and therefore progress is slow.

And in the meantime string theorists are also making no progress, but they represent the vast majority within hep-th and gr-qc, and are not interested in abandoning their old community for some underdeveloped new idea. It's a viscious circle — lack of interest by the community produces lack of manpower, which produces lack of development, which produces lack of interest by the community…

That’s the actual problem with better alternatives to ST.

Best, 🙂
Marko

17. **Random Non-Physicist**
May 6, 2023

“And, maybe it will have a positive effect, getting young people and the public interested in this kind of science, going on to read better books.”

Let me say, as someone who was once on a track to become a physicist partly due to the influence of popular science, that one problem with Kaku-style hype is it gives people an unrealistic idea of what science is about and what it can do. He paints a picture of a magical, science-fictional world where the human intellect and its technology have god-like powers, avoiding the messy details and limiting realities. They’re alluring stories for the uninitiated, but when you start to look under the hood, understand the science in more detail and see that it’s not really like Kaku says, it’s easy to become disillusioned, to realize that you’ve been taken in by propaganda, and to lose interest in the field. That’s kinda what happened to me anyway.

Unfortunately, in America we tend to reward the hucksters, the entertainers, the PR people and the imaginers of fantasy worlds much more than those who deal in less glamorous reality. A capitalist entertainment-centric society has little incentive to reign in the Michio Kakus of the world, and every incentive to promote them. Science should be the complete opposite of this ethos, but it has clearly been corrupted by the larger society.

18. **John Baez**
May 8, 2023

Someone here almost coined a very useful term for describing the slow progress of fundamental physics: “viscous circle”.

19. **vmarko**
May 9, 2023

John,

Feel free to coin the term! 🙂

I meant to write “vicious circle”, but made a typo, which can then be reinterpreted as a typo of “viscous circle” instead, with a curiously similar meaning to the former…

Best, 🙂
Marko

20. **Shantanu**
May 10, 2023

Peter : something OT. I am surprised you haven’t mentioned anything about passing away of Stanley Deser one of the doyens of GR and also supergravity, who has been working on GR for past 70 years starting from the days he overlapped with Einstein at IAS.

21. **Peter Woit**
May 10, 2023

Shantanu,
Nothing about Deser just because I never met him and know little about his work. Part of the problem is that I’ve always shared Sidney Coleman’s view on supergravity.

I can point to places that have more about Deser, the NYT at
https://www.nytimes.com/2023/05/08/science/stanley-deser-dead.html
and an interview at
https://heritageproject.caltech.edu/interviews-updates/stanley-deser

22. **John Baez**
May 12, 2023

The Arnowitt-Deser-Misner formulation of general relativity in terms of initial data on a spacelike slice is a big deal.

23. **Felix C.**
May 14, 2023

While we’re on the subject of Stanley Deser, I’ll mention that World Scientific is providing free access to his autobiography, _Forks in the Road_, until July 31 of this year:

https://www.worldscientific.com/doi/epdf/10.1142/12205

24. **Mike**

Various and Sundry

May 30, 2023
Categories: Uncategorized

A few unrelated items:

- I've been hearing from several people about their plans to travel to China this summer, just realized that they're all going there for the same reason, to participate in the First International Congress of Basic Science. This is something new and on a grand scale, featuring 240 or so invited speakers, award of a new million dollar – plus prize, together with prizes for "Best paper" over the last five years in 36 different categories. Yau is the main organizer, and the Chinese government is providing the funding. So, if it's July 16-28 and you are wondering where your colleagues are, quite possibly the answer is Beijing.
- I'm doing my best to try not to think about the implications of recent AI developments for mathematics, but someone who is doing a lot of thinking about this is Michael Harris, who this week at his Silicon Reckoner substack discusses Google's use of arXiv math papers to train their Minerva language model. Harris raises the interesting question of whether this use of arXiv papers violates the licenses of these papers, standard ones of which include language like

  > You may not use the material for commercial purposes.

  Even if Google is massively violating the arXiv licenses for commercial purposes, it's unclear whether anything can be done about this, especially given the legal resources Google can afford. In addition, I suspect that when hearing about this a more common response than "this is terrible, I want to sue" would be "this is great, how can I get this thing to write papers for me, or even better, get Google to pay me to help make this possible."
- Last month Symmetry magazine had an article Whatever happened to the theory of everything? featuring some quotes from me and John Ellis. Ellis explains that the particle physics community has become skeptical of supersymmetry and string theory:

  > Supersymmetry seemed less and less likely to be right, and superstring theory never materialized into something with testable and concrete predictions.
  >
  > "The rest of the community is asking, 'Where's the beef?'" Ellis says. "There hasn't been any beef yet. Maybe particle physicists have turned a bit vegetarian and have lost interest in stringy beef."
- Possibly in response to the problem for string theory that Ellis is pointing to, Witten next week is giving a non-technical theoretical physics colloquium talk at the ICTP on What Every Physicist Should Know About String Theory. Back in 2015 he published something with the same title in Physics Today, which I wrote about here. We'll see if there are any new arguments on this now very old topic.

Update: The 2023 Shaw prize in mathematics is going to Drinfeld and Yau.

Update: I missed the fact that last there was a Breakthrough Prize ceremony last month. This year they've emphasized even more the "Oscars of science" idea by moving the ceremony from Silicon Valley to LA and having it at the Academy Museum of Motion Pictures. The announcement has none of the names of the scientists, just the names of the Hollywood stars that would attend.

Update: I see (from a Strumia tweet) that a Witten 2015 talk with the same title is available here, was given I guess as a public talk at Strings 2015. It's all about the differences between the 1d single-particle path integral and the 1+1d worldsheet path integral, unclear to me why this is something every physicist needs to know about, or whether this year's version will be different.

Comments

1. **Peter Shor**
   May 30, 2023

   From playing around with language models, it seems to me that they are quite good at assimilating information that is on the internet and applying it to problems, but remarkably bad when faced with problems where they actually have to do something new. If I'm correct about this, the Minerva language model will fall well short of their hopes that it will "help push the frontiers of science and education."

2. **Z Y**
   May 30, 2023

   Philosophy wise, if there's a basic science field that can make a call to assemble all the others together, that field may well be mathematics. Still, social wise is puzzling that in fact are mathematicians the ones who try to bring different kind of basic scientists together.
   The question remains, why named it: ICBS, if they don't even include the life sciences or chemistry.
   PS. Fesenko continues to be a peculiar story (aswell as Caucher B., if for entirely different reasons)
   PS2. Seems almost all current russian math luminaries will be speakers

3. **Sabine Hossenfelder**
   May 31, 2023

   Particle physicists would be well advised to think about what went wrong so they don't go on repeating their mistakes. A huge amount of brain-time was spent on producing papers that will never serve any useful purpose. Thousands of intelligent people have wasted their life on this. I find it incredibly tragic. Imagine how much farther ahead society could be if they'd put their mind to work on something useful.

4. **Eric Lehman**
   May 31, 2023

   The Minerva model was announced almost a year ago (June 30, 2022) on the Google Research blog, making it ancient technology by now. No commercial use has emerged since then, and probably none can at this late date.

   Setting that aside, I believe Harris misunderstands the NonCommercial (NC) clause. He says:

   "Google is not a charitable organization; all of Google's purposes are "commercial" unless demonstrated not to be…"

   But Creative Commons repudiates this reasoning at https://wiki.creativecommons.org/wiki/NonCommercial_interpretation

“The definition of NonCommercial depends on the primary purpose for which the work is used, not on the category or class of reuser. Specifically, a reuser need not be in education, in government, an individual, or a recognized charity/nonprofit in the relevant jurisdiction in order to use an NC-licensed work.

Under the NC clause, Google and others may use arXiv papers in a manner “not primarily intended for or directed towards commercial advantage or monetary compensation”. Creative Commons further clarifies, “The inclusion of “primarily” in the definition recognizes that no activity is completely disconnected from commercial activity; it is only the primary purpose of the reuse that needs to be considered.”

In short, Google appears to have used the arXiv content for a research publication, which is permitted under the NonCommercial clause. Am I missing something???

5. **Gurmeet Singh**
   May 31, 2023

   LLMs won’t be very good at producing proofs but they are of course not the right tool for that. One possible right tool would be something like a DeepRL proof search which uses LLM for the heuristics, there have been attempts at this like GPT-f but they are not very flashy, producing formal proof is less flashy than human readable proof…

   What do you think of the point of view that maths is so important for humanity that we should not leave it to humans alone. If large parts of maths can be automated, we’ll get more powerful mathematical tools. For my own satisfaction, I can solve already solved problems, they are still fun like Olympiad problems.

6. **Greg Guy**
   May 31, 2023

   What makes the whole ‘do not use for commercial purposes’ is that the papers are indexed by Google so that they show up in searches. Arguably this is a commercial purpose, but do people really want Arxiv to be unsearchable? If so it’s hard to see how you can be for one commercial indexing scheme and not for another.

7. **David Roberts**
   May 31, 2023

   With my perhaps-too-cynical hat on, I wonder if Witten will win the Fundamental Science Lifetime Award.

8. **Peter Woit**
   May 31, 2023

   David Roberts,
   I think Witten would be a reasonable choice for such a prize. But this makes clear the lack of any good reason for proliferating such prizes, since giving Witten another prize would change nothing about anything. 20 years ago as far as I can remember there were no large monetary prizes in Mathematics. Now we have the Shaw prize, the Abel, the Breakthrough Prize and this prize, all at or above a million dollars. What good do any of these do, what is the point of coming up with new rewards for those already most recognized and heavily rewarded by the field? Is yet more of a star system what mathematics really needs?

9. **Peter Shor**
   May 31, 2023

   David Roberts:

   Hasn’t Witten made enough contributions to pure mathematics to deserve the Fundamental Science Lifetime Award? The only argument against giving it to him is that if you do, all the string theorists will say that he won it for string theory.

10. **Low Math, Meekly Interacting**
    May 31, 2023

    Didn’t see a mission statement anywhere, apologies if I missed something obvious: Is the “Basic Science” meeting to be focused on those three areas moving forward, or does the International Congress plan on having a theme each year such that other areas of “basic science” are discussed? More of a semantic quibble, but I might have called it something else depending on the answer.

11. **Peter Woit**
    May 31, 2023

    LMMI,

    The only general information I see about the conference is here
    https://www.icbs.cn/en/web/index/18009_1464241__

    Over 300 speakers, awards to be presented by Chinese leaders. It says this will be an annual event, unclear if in other years “Basic Science” will mean a different choice of fields, but that seems possible.

12. **anon**
    May 31, 2023

    The prize needs Witten (or some other very famous scientist) much more than he needs the prize.

13. **Peter Woit**
    May 31, 2023

    anon,
    Very true, and not just in this case…

14. **David Roberts**
    May 31, 2023

    @Peter Shor

    I really wonder how one judges the relative merit of nominees when the field is presumably all of (?pure) mathematics, (?fundamental) physics, and theoretical computer science.

Just looking at the attendees and the organisers, it feels like a string theorist will get the prize, and I presume they will follow the time-honoured tradition of giving the inaugural prize to the biggest name.

15. **David Roberts**
June 1, 2023

On a different note, of the judges for the best paper prizes, there are, for the mathematics topics (if I managed to count them properly; also I checked all the people I didn't know): 89 men, 4 women, 17 anonymous.

For physics there are 17 judges, one is a woman (and none anonymous).

I haven't the patience to check the majority of the 47 judges in computer science that I don't recognise the names of.

On a slightly less serious note: of the four judges for "Mathematical logic, Foundations and Category Theory", none of the them are category theorists, one is a set theorist, one works on independence results, and two are recursion theorists. Not sure how they are going to judge the quality of an influential category theory paper 🙂

16. **Oisin McGuinness**
June 2, 2023

Regarding the Breakthrough prize, it appears this ceremony honors the last 3 years of winners, and see this page: https://breakthroughprize.org/News for the Sept 22 2022 announcement of the 2023 winners. So old news….?

17. **Shantanu**
June 2, 2023

Peter: sad news about Jim Hartle https://www.physics.ucsb.edu/news/announcement/2132
I am surprised you have not mentioned it given that he is one of the pioneers of quantum gravity

18. **Peter Shor**
June 3, 2023

@Oisin McGuinness: As a Breakthrough Prize winner who attended the ceremony, let me correct you; The Breakthrough Prize Ceremony did not honor all 3 years of winners; some of them will be honored at next year's ceremony.

19. **James Smith**
June 5, 2023

Eric Lehman,

you write:

"The Minerva model was announced almost a year ago…making it ancient technology by now."

So any genuine idea or insight over a year or so old becomes worthless then?

You also write:

"No commercial use has emerged since then, and probably none can at this late date."

Not so. The likelihood is that tools to help mathematicians based on this kind of AI will begin to emerge in the next two to three years.

Actually, the Minerva approach is a good one in some people's opinion, including mine, and the idea is not going to die away.

Using training data that includes TeX markup rather than stripping it out is a good idea for the reasons that the authors give. And having your model also spit out TeX markup is also arguably a good idea because, as long as the output is subsequently rendered by something like KaTeX, it remains human readable.

Unreadable proofs are the bane of formal reasoning systems built on type theories and always have been. I am hoping that approaches such as this will move the field to consider systems with more legible output.

20. **Francis**
June 9, 2023

I have repeated the Minerva examples in the arXiv paper by using the current version of the free ChatGPT (based on GPT3.5). The results are better than those reported in the arXiv paper (correct except in one case). Here is a link for the full chat https://chat.openai.com/share/da97cc49-db06-4355-937b-c51ccc2a42f0 Enjoy!

21. **Paul Levy**
June 10, 2023

Why on earth would you train a model on arXiv papers and then ask it to solve high school calculus questions?

22. **Shantanu**
June 11, 2023

Peter: Witten's talk is now online at https://www.youtube.com/watch?v=s9qC7DtB7tY

23. **liuyao**
June 13, 2023

I predit that the inaugural physics prize will go to C.N. Yang, who is 101 and lives in Tsinghua (5 out of the 7 chairs are at Tsinghua, with Yau sitting on all three committees.)

24. **Shantanu**
June 17, 2023

Peter, something OT: Check out https://pirsa.org/23060016 which is a panel debate related to a recent conference in PI.
and in particular the question asked to Rob Myers (related to string theory) about at 28 minutes. he also said that we have seen evidence for teleportation across an Einstein Rosen bridge.

25. **Edward Teach**
July 3, 2023

Hilarious that Fesenko was plastered all over the ICBS homepage at first, only to be dropped in favor of Fukaya and Kontsevich.

My spy in Beijing says that he expects only “students and prize winners” to attend this thing.

From Quantum Mechanics to Number Theory via the Oscillator Representation

June 1, 2023
Categories: Uncategorized

This past semester I taught our graduate class on Lie groups and representations, and spent part of the course on the Heisenberg group and the oscillator representation. Since the end of the semester I've been trying to clean up and expand this part of my class notes. I'm posting the current version, working title From Quantum Mechanics to Number Theory via the Oscillator Representation. This is still a work-in-progress, but I've decided today to step away from it a little while, work on other things, and then come back later perhaps with a clearer perspective on what I'd like to do with these notes. In a few days I'm heading off for a ten-day vacation in northern California, and one thing I don't want to be thinking about then is things like how to get formulas involving modular forms correct.

There's nothing really new in these notes, but this is material I've always found both fascinating and challenging, so writing it up has clarified things for me, and I hope will be of use to others. The basic relationship between quantum mechanics and representation theory explained here is something that I've always felt deserves a lot more attention than it has gotten.

In the past I've often made claims about the deep unity of fundamental physics and mathematics, One goal of this document is to lay out precisely one aspect of what I mean when making these claims. There are other much less well understood aspects of this unity, but the topic here is something well-understood.

One thing that struck me when thinking about this and teaching the class is that this is a central topic in representation theory, but one that often doesn't make it into the textbooks or courses. Typically mathematicians develop theories with an eye to classifying all structures of a given kind. This case is a very unusual example where there is effectively a unique structure. The classification theorem here is that there is basically only one representation, but it is one with an unusually rich structure.

When I get back from vacation, I plan to get back to work on the ideas about twistors and unification that I'm still very excited about, but have set to the side for quite a few months while I was teaching the class and writing these notes. More about that in the next few months…

Comments

1. **Jim Golden**
   June 2, 2023

   This is great, thanks for this. I decided to (re)tackle Not Even Wrong again this summer. My graduate work in mathematics is some years behind me (and was applied math / engineering). I'm enjoying making this a summer reading project. As part, I picked up Weyl's "Symmetry" and Hall's "Lie Groups, Lie Algebras, and Representations" based on your suggestions in the readings. Also found a copy of Penrose's "The Road to Reality" (that's a summer project in itself…) I look forward to adding these notes to my reading list. Have a great vacation!

2. **John Baez**
   June 6, 2023

   I look forward to the number theory section! Your notes remind me slightly of Mackey's book *Unitary Group Representations in Physics, Probability, and Number Theory*.

3. **Peter Woit**
   June 6, 2023

   John Baez,

   The main reason I lost steam and haven't yet finished the notes is that I want to spend the summer working on other things. But also relevant are the following:

   1. The way the story of the oscillator representation and the theta correspondence is set up in detail over the real numbers goes over straightforwardly to finite fields, the p-adics, and over the rationals via the adeles. Beyond that statement, it's tricky to write out details of this accessible to non-number theory experts without starting to write an introduction to a lot of modern number theory that would be a different and larger project (and not really within my expertise).

   2. There's a simple explanation of the theta function and its properties as matrix elements of the oscillator representation, which I wrote down. The details of the story of modular forms and how theta functions fit into it are quite complicated and this is where I realized I was in danger of getting into writing up something much more complex than I had energy for. Maybe someday on that…

   3. There's a lot of readable expository literature on automorphic representations of SL(2) and the Langland correspondence with Galois representations. But, not so much on what happens for the metaplectic double cover. Before trying to say anything about this, I'm hoping to consult with some local experts and get a better understanding of that story. The story of the Heisenberg group over the adeles is yet again something different that I haven't found a detailed explanation of (that I can understand…).

   In an ideal world, what I'd like to turn this into someday would be a document that works out in detail the simplest case of this whole story, including the number theory parts. I hope this would complement the usual math expositions, which emphasize generality, while making clear that this part of number theory and fundamental QM are about exactly the same thing (the oscillator representation).

Zen University

June 6, 2023
Categories: abc Conjecture

The establishment of a new university in Japan has been announced, to be called ZEN University. One component of the new university will be the Inter Universal Geometry Center, with Fumiharu Kato as director, Ivan Fesenko as deputy director. The Center will offer an introductory course on IUTT. There's a video here.

The website seems to be Japanese-only, here's what I get via Google Translate:

> If you pass all of our courses, you will be better equipped with IUT theory than any mathematics student in any university in the world. A student who blooms his talents that emerges from within. We plan to prepare prizes for such young people and encourage them to continue to participate in the community that seriously researches IUT theory…
>
> Although it is difficult to understand, there are already more than 20 mathematicians in the world who understand and develop the IUT theory. I hope that you will boldly take on the challenge of researching IUT theory together with me so that you can be one of the next.

The problem with this subject though is not the number of people who understand IUTT, but the number who can explain to others in a convincing way the proof of corollary 3.12 in the third IUTT paper. From everything I have seen, that number has always been and remains zero.

Update: Another video here.

Comments

1. **DH**
   June 6, 2023

   Oh my God, why is this happening?

2. **passerby101**
   June 7, 2023

   It seems to be an online only university, despite the glossy pictures of students on campuses. And probably fairly expensive to attend.

   Seems like an attempt to build a pool of innocent japanese students, unaware of the controversy abroad and devoted to IUTT.

3. **William Orrick**
   June 8, 2023

   Kato has written a popular book (in Japanese) on IUTT. There's an interesting review of it at zbMATH Open by Hirokazu Nishimura. Choice quote, referring to D. T. Suzuki, who helped popularize Zen Buddhism in the West: "Some cynics say that Daisetz Suzuki became famous by speaking a lot about the unspeakable. The author of this book has written a book for general public on the unspeakable."

4. **Anonymous**
   June 8, 2023

   One very small but interesting detail in the second video: at 2:30ish the narrator reads Kato's name wrong (he says, "Kato Bungen"). Extremely unprofessional.

5. **David Roberts**
   June 8, 2023

   @Anonymous

   Kato has "Bungen" in his Twitter display name (not handle): https://twitter.com/FumiharuKato/

   I don't know what that is and what role it plays in naming him.

6. **David in Tokyo**
   June 9, 2023

   Fumiharu and Bungen are alternate pronunciations of the Chinese characters that make up Dr. Kato's given name. It's common in the literary world for people to be referred to by the Chinese pronunciation of their given name, even though the official (legal) pronunciation is the Japanese pronunciation. I don't know how common this is in other academic areas though. Dr. Kato's first name is given as "Fumiharu" in all the references (e.g. Wikipedia) I noticed.

   By the way, the Zen in Zen University doesn't mean what you think it does. Their motto is "Zen, Zen, Zen Nado". It consisst of three different Chinese characters, all pronounced "zen", which mean "All", "Good", and "Natural", respectively. There is no overtone of Buddhism in the slightest. The idea is that each student will experience, deal with, and come to grok a wide range of things "zen". But not including Buddhism. It makes sense in Japanese, a local expert assures me. So it's a newly coined version of "Mind and Hand" or "Veritas". ("Nado" means "and the like". (Well, actually, it means "The preceeding list defines a set of things with similar characteristics, and that list may or may not be exhaustive".))

   From their long list of _planned_ faculty members (and their website in general), my impression is that the IUTT stuff is but a tiny part of what they're planning, and that they are not much further than just planning. My guess would be that the IUTT stuff got them government funding. (And, yes, it is an online-only university. Some of the parties involved have been running seminar-like things in public rental spaces in Tokyo, so while most of the photos are stock photos, there are a couple of actual real event photos that I noticed.)

7. **Anonymous**
   June 9, 2023

   Not sure if we really need to continue this discussion, but since I started it I feel I should (potentially) end it: Kato put up a few tweets about his name being mispronounced and retweeted a tweet of someone else laughing about it.

8. **Jim Eadon**
June 10, 2023

What is the status of the ABC conjecture in Japan these days, now that the refutation is famous worldwide? Do they consider it proven over there, or are they just being polite to a VIP mathematician, by refusing to challenge the paper?
I mean, if they thought the proof was correct, then the author of the proof would be eligible for glittering prizes worldwide, right?

9. **Adam Treat**
June 12, 2023

It seems to me that this has gotten quite out of hand. Either the proof is correct or it is not and no amount of egos or politicking can change that. This is an embarrassment for the whole mathematical field. It is akin to postmodernism in math. We now have the global mathematical community rejecting this proof and a fringe – but well respected before this fiasco – group of mathematicians pressing on as if the proof is correct and self-evident. This was not supposed to happen to mathematics where the rigor and community consensus was to provide a universal mathematical truth.

The only way out of this I can figure is a challenge the fringe group to produce a computer verified proof or a the global mathematical community to produce a computer verified rejection: which seems an absolutely *insane* amount of work either way.

You could get an AI trained on taking human language proofs and translating them to computer verified proofs, but no one would be able to verify that the translation was correct without doing the same or greater amount of work in just writing the computer proof themselves.

I fear that the only way this will end is for egos to die.

10. **Peter Woit**
June 13, 2023

Adam Treat,
As far as I can tell, this is over, there's no significant controversy any more over the Mochizuki abc proof, it's simply not accepted by experts in the field. There is no embarrassment for mathematics in general, just for RIMS in particular because of the scandal surrounding the publication of a proof experts believe to be incorrect.

As for computer verification, Mochizuki has chosen to not try and produce a clearer version of his original argument that could possibly convince others, instead arguing that those who don't accept the original argument are incompetent. If he can't or won't clarify his argument to answer human objections to it, what reason is there to believe he could clarify the argument to the point it would be computer-checkable?

11. **tulpoeid**
June 13, 2023

I've asked this before in here but afaik with no answers. Please note that the answer might look obvious to a mathematician, but I assure you that it is not at all for anyone else: Does IUTT have some value, regardless of whether its proof is correct or wrong?
I remember that this is something happening in the past with other theories that were proven wrong; they explored new corners and included new propositions with merit of their own. (Don't ask me to name such theories though, my general knowledge simply includes the memory of such things happening.) I feel rather surprised that such a large construct is said to be devoid of any value, dependent on a single point of failure.

12. **JE**
June 14, 2023

Hi tulpoeid,

Not sure about its possible significance or value beyond proving abc, but it does not seem possible to get intermediate results in his claimed proof. According to these detailed Notes on the Oxford IUT workshop by Brian Conrad in 2015 (in https://mathbabe.org/2015/12/15/notes-on-the-oxford-iut-workshop-by-brian-conrad/), "Mochizuki aims to prove Szpiro's conjecture for all elliptic curves over number fields, with a constant that depends only on the degree of the number field (and on the choice of epsilon in the statement). The deductions from that to more concrete consequences (such as the ABC Conjecture and hence many finiteness results such as: the Mordell Conjecture, Siegel's theorem on integral points of affine curves, and the finiteness of the set of elliptic curves over a fixed number field with good reduction outside a fixed finite set of places) have been known for decades and do not play any direct role in his arguments. In particular, one cannot get any insight into Mochizuki's methods by trying to "test them out" in the context of such concrete consequences, as his arguments are taking place entirely in the setting of Szpiro's Conjecture (where those concrete consequences have no direct relevance)."

Wikipedia summarizes this in https://en.wikipedia.org/wiki/Inter-universal_Teichm%C3%BCller_theory#cite_note-BC2015-25 by saying that "One issue with Mochizuki's arguments, which he acknowledges, is that it does not seem possible to get intermediate results in his claimed proof of the abc conjecture using IUT. In other words, there is no smaller subset of his arguments more easily amenable to an analysis by outside experts, which would yield a new result in Diophantine geometries."

13. **Kurt Schmidt**
June 14, 2023

tulpoeid,

IUTT and similar approaches like Kirti Joshi's work are probably useful for p-adic/arithmetic Teichmueller theory and anabelian geometry. The issue here is that no mathematician has provided a correct proof of Mochizuki's Corollary 3.1.2 linking the former fields with the abc conjecture, and the vast majority of mathematicians are mainly interested in the latter.

14. **jsm**
June 14, 2023

In a 2017 talk "abc Conjecture and New Mathematics", Fumiharu Kato said "I don't put much importance on as to whether the [abc] conjecture itself has actually been proved or not, or, if so, how it has been done." The point of the talk was that there are problems involving the way addition and multiplication in the integers interact that "traditional" mathematics find intractable, such as the abc conjecture, the twin primes conjecture, and the Goldbach conjecture, and that IUTT is designed to handle such problems. There are serious mathematicians involved with this, so I don't think it can be dismissed out of hand.

15. **curiousnew**
June 28, 2023

For what it's worth, Mochizuki has a new paper out with Tsujimura in which they announce settling several big conjectures in anabelian geometry. The bibliography doesn't mention any of the IUTT papers and related ones, so it seems to be independent of it.

16. **Nakamoto**
July 7, 2023

This is because mathematicians such as Peter Scholze have not submitted refutation papers while claiming that IUTT is logically inconsistent.
This news re-emphasizes to us the fact that their claims are only on a personal level, not as mathematicians. If IUTT were correct, the abc conjecture would have been solved as just a secondary problem.

This means that IUTT has the higher logical structure sufficient as a theory to evaluate problems in number theory.
In other words, the those incidents about IUTT that we remembered are a mathematician's problems, not mathematical problems, because this announcement tell us the IUTT still has some potential to undo much of the existing work related to number theory.

17. **Peter Woit**
July 7, 2023

Nakamoto,
For discussion of this, please submit comments to the newer blog post which is specifically about this. Scholze and Stix did write a paper. Their argument is not that IUTT is inconsistent, just that it is not capable of providing the tool needed for a proof of abc.

Fantasy, Faith and Physics

June 30, 2023
Categories: Uncategorized

No blogging here the past few weeks, partly because I was away on vacation for a little while, but more because there hasn't been anything I've seen worth writing about. Yesterday's pulsar timing array and IceCube announcements unfortunately didn't tell us anything about fundamental physics. In the past, such observational results pretty reliably led to absurd claims about evidence for string theory that I could complain about, but that phenomenon seems to be dying down. In this case, the only story that had such claims was one from Quanta Magazine, which explained that "the observations so far from NANOGrav and the other teams are consistent with what we'd expect to see from cosmic strings."

I noticed that the people at the Institute of Art and Ideas have put together a program for Monday that includes a debate on the topic of "Fantasy, Faith and Physics." The framing of the debate contrasts the conventional view of science with an alternative possibility: "should we accept that some beliefs, especially in the foundations of physics, are akin to religious beliefs dressed in mathematical language to give our theories meaning?" This kind of misses the point about the current problems in fundamental physics, since I doubt any of the panelists are going to defend such an alternative.

Very odd is what leads into this debate, an interview with Michio Kaku about his new book. Why promote such an atrociously bad book (see here and here) and broadcast Kaku's absurd claims about this subject?

Maybe this debate will somehow lead to a substantive discussion of the main underlying problem, the nearly fifty-year dominance of a failed set (GUTs/SUSY/strings) of ideas about unification. A very powerful and influential part of the physics community, which will be represented in the debate by Juan Maldacena, continues to insist on the centrality of this set of ideas. To get a clear look at his arguments, see a recent IAI interview In defence of string theory and his colleague Edward Witten's recent colloquium talk What Every Physicist Should Know About String Theory. The argument Maldacena and Witten are making is essentially the same one from the mid-eighties: string theory is the only possible consistent way to go beyond quantum field theory and get a consistent theory of quantum gravity. In my book and many other places, I've explained the many problems with this. Put simply, the problem is that there is no such thing as a well-defined string theory which successfully gives the SM and GR in four dimension. The claims about consistency are either about models that don't reproduce the real world, or about still-unrealized hopes and dreams (which Penrose characterizes as "Fantasy") rather than anything well-defined.

For a very clear statement of his point of view from Witten, see the question and answer section of the recent colloquium talk, starting around 1:20, where he starts by emphasizing the rigidity of the framework of relativistic quantum field theory. He then states:

> My point of view is that string theory is the only significant idea that has emerged for any modification of the standard framework that makes any sense.

This is pretty much exactly the same argument he was making nearly forty years ago. I didn't find it convincing then, since it seemed to me there was no reason to be so sure that a deeper understanding of relativistic QFT could not possibly lead to a consistent quantum theory with low energy limit GR. Witten had a good argument in 1984 that a possibly consistent generalization of relativistic QFT was worth studying, but the problem is that decades and tens of thousands of papers later, as far as unification goes, this study has been a failure, taking the field down paths (extra dimensions, SUSY) which lead to complex theories that don't look at all like the real world.

If you look at where things have ended up and the current research directions Maldacena and Witten are pushing, the odd thing is that they seem to have given up on unification, and for years now have been emphasizing the study of black holes in toy models with little to no connection to string theory. The most disturbing thing I heard in the Witten talk was at 1:24:16

> If you had sufficient computing power, maybe with a quantum computer with a million qubits, I think you could simulate the dynamics of a quantum black hole…

Here Witten seems to be pointing to exactly the argument recently made by Juan Maldacena (see here), which has a specific claim about what you could do with a million qubits. This particular calculation would not in any way address the problems of the string theory program and is getting into Michio Kaku/wormhole publicity stunt territory.

Update: There's an interview with Witten here, associated with his receipt of the Hamburg Prize for Theoretical Physics. About string theory, he explains that, despite 50 years of effort

> We don't understand it very well… In fact, I'd say we only understand a small part. So we've been struggling with that ever since the 70s and 80s trying to understand the intellectual framework that it should have been placed in.

He remains convinced though that alternative ideas are not the way to go:

> … I find it implausible that physicists would discover a theory that is such a rich source of fruitful ideas about things that are definitely important in other fields by accident. And if we were not on the right track, I would say, it was a big accident. So my personal view is that it would be a cosmic conspiracy if string theory isn't on the right track.
>
> **There is a growing number of critics who complain that string theory is very interesting, but hasn't really delivered. Because we still have no idea whether it's correct and we couldn't make any experiments, which tells us if this is the case. According to you: To what extent is that criticism justified?**
>
> Well, not much, honestly. Where critics of string theory have had interesting ideas, they've tended to be absorbed as part of string theory. That's happened several times. Twistor theory, black hole thermodynamics and noncommutative geometry are three examples of interesting ideas. They were by some regarded as alternatives or competitors of string theory, but actually in practice were absorbed as part of the picture in string theory.

Comments

1. **Mave**
   June 30, 2023

   What if those gravitational waves are from the inflationary era? could it be possible? that would be a major discovery, a Universe photo from before the cosmis microwave background.

2. **Percy**
   June 30, 2023

   @acollierastro did a video on Michio Kaku about how he is basically a crackpot now, which I find is most informing and to the point.

3. **Peter Woit**

June 30, 2023

Mave,
Not possible, see for instance

I should have linked to that. See
https://www.youtube.com/watch?v=wBBnfu8N_J0

5. **David Yager**
June 30, 2023

Roman Jackiw passed away in June. You have had several relatively favorable mentions of his work in the blog. Do you have any memories or summaries of his work and life?

6. **Peter Woit**
June 30, 2023

David Yager,
As far as I can remember, I never met Jackiw. I was very familiar with his work on instantons, and over the years I've gotten a lot out of some of the papers in his selected works volume
https://www.amazon.com/Diverse-Theoretical-Mathematical-Physics-Advanced/dp/9810216963
Jackiw was a very clear writer and thinker about a range of topics in quantum field theory.

7. **Sabine Hossenfelder**
July 1, 2023

I would like to mention that the new results are also compatible with what we'd expect to see from quantum gravity (namely: nothing).

8. **martibal**
July 1, 2023

A bit off topic but since there is the actuality is not so hot, what about Witten's paper
"A Note On The Canonical Formalism for Gravity" (the second version of the paper has just came out on arxiv https://arxiv.org/abs/2212.08270). He is talking about the Hamiltoninan constraint and Wheeler de Witt equation , which is usually the kind of topics that people in loop quantum gravity are working with.
Is there any relation with what Witten is doing here 5which does not seem to be string related) and lqg ?

9. **Chris Austin**
July 2, 2023

With reference to Mave's question and Peter's reply, there do seem to be some investigations about this sort of thing. I knew nothing about this before today, but tried a Google search for:

can the nanohertz gravitational waves be from the inflationary era?

This has turned up:

https://arxiv.org/abs/2202.01131

https://arxiv.org/abs/2208.03330

https://arxiv.org/abs/2306.16219

10. **suomynona**
July 3, 2023

@martibal

Witten's paper seems to be about holography, which is mentioned as the motivation in the introduction. It explicitly uses the metric variables (and not the Ashtekar-Barbero ones) and makes references to the work's ramifications for higher dimensions and string theory, so I would say it is a story about AdS/CFT (and *is* string related) and has no direct relation to LQG.

Perhaps it's possible to reconstruct this work using the LQG formalism which could lead to a notion of doing holography with LQG, but I doubt Witten is the person who would pursue this.

Twitter is unusable for those of us without an account (and who refuse to get one and support fascists). And it is also likely that it will go down permanently at some point with how unstable it's been and how they've fired a bunch of their own programmers. Can someone please quote?

12. **Peter Woit**
July 8, 2023

anon,
If you're referring to the Will Kinney twitter link above, the problem is that it's a multi-tweet thread with embedded graphics. I'm not competent to process it in a way that will appear in a comment here.

My understanding is that Twitter has now backed down and you can access tweets without having a Twitter account.

13. **martibal**
July 9, 2023

"Twistor theory, black hole thermodynamics and noncommutative geometry are three examples of interesting ideas. They were by some regarded as alternatives or competitors of string theory, but actually in practice were absorbed as part of the picture in string theory."

For noncommutative geometry and black holes thermodynamics at least, this is completely wrong. They may have an non empty intersection with string theory, but they have not at all been absorbed by it, neither in a theoretical nor in a practical way. Witten certainly knows that, so why is he saying such nonsense ?

Regarding twistor, we can guess what the opinion of Peter is 🙂
Did Penrose ever mentioned that twistors were aimed at be absorbed by string theory ?

14. **Cedric BARDOT**
July 21, 2023

1) @martibal
"Why is Witten saying such nonsense about noncommutative geometry (ncg) and black hole (BH) thermodynamics absorbed *in practice* by string theory"?
1Playing the devil advocate one may say this statement is making sense if literally understood as the fact that string theorists have definitely found more than one *practical* way to build on heuristic insight from BH thermodynamics & a few mathematical tools from ncg (for ex to quote Witten: "Connes cocyles …has had a number of interesting recent applications to quantum field theory and gravity cf https://arxiv.org/abs/2112.12828) in order to address many computations in quantum gravity toy models.
Now, what is IMO inexcusable is when Witten claims:
"Where critics of string theory have had interesting ideas, they've tended to be absorbed as part of string theory".
I recommend to read John Baez review of "Foundations of Mathematics and Physics One Century After Hilbert: New Perspectives" edited by Joseph Kouneiher (https://www.ams.org/journals/notices/201910/rnoti-p1690.pdf) to have a balanced and informed view on some interesting ideas that have not been absorbed (yet?) by string theorists.
2) It could be interesting to add here that in a 2021 interview, Connes said that Witten under the influence of Atiyah had recasted Vaughan Jones discovery of a new knot invariant, "dress[ing it] up in terms of functional integrals and things of this type while the real input… was from [Vaughan] own work on subfactors"
(quote from Allyn Jackson interview https://celebratio.org/Connes_A/article/842/).
This shows I guess how difficult it is to build a global vision of spacetime geometry in a quantum formalism following the heuristics Connes has built starting on classifying factors 50 years ago, meeting then Sullivan at IHES and interacting later with article physicists and cosmologists. May be we have to abandon solid theoretical research into natural geometric structures (= Riemanian paradigm) for a Solid Theoretical Research On Natural (=spectrally informed by cosmology and particle physics) Geometry program, emphasizing our doubts and quit preaching. (following Veneziano example praised by Connes at the very end of https://youtu.be/qVqqftQ92kA?t=6807)

A Mathematics AI Factory?

July 2, 2023
Categories: Uncategorized

A few days ago I read a fascinating article in New York magazine: Inside the AI Factory, which explained how the very large business of hiring humans to do tasks that generate training data for AI works. One reaction I had to this was "at least this means math is safe from AI, nobody is going to pay mathematicians to generate this sort of training data." Yesterday though I ran across this tweet from Kevin Buzzard, which advertises work (see this link) that seems to be of this kind.

A company called Prolific is advertising work paying 20-25 pounds/hour doing tasks in Lean 3. This company is in exactly the business described in the NY mag articles, hiring people to do tasks as part of "studies", which often are generating AI training data.

One unusual thing about this whole industry is that if you sign up for this work you often have no idea who your employer really is, or what your work will be used for, and you sign a non-disclosure agreement to not discuss what you do. In this case, a few things can be gleaned from discussions on the Lean Zulip server:

- "it's 40 dollars/hr now actually"
- "I think everyone signed a consent form preventing them from disclosing any problems or even their participation."
- One problem was formalizing a proof of sin(x)=1 implies x=pi/2 (mod 2pi).
- A representative of the company writes: "Some of our biggest partners are keen to work with Lean users because of its applicability as a theorem prover. They plan to launch numerous studies that require participants to have either a working or expert knowledge of Lean 3." By "biggest partners", presumably this is Microsoft/Google or something, not some small publishing organization.

If anyone knows anything about what's up with this incipient possible math AI factory, please let us know. On the more general issues of math and AI, I'd rather not host a discussion here, partly because I'm pretty ignorant and not very interested in spending time changing that. The situation in mathematics is complicated, but as far as fundamental physics goes, theorem-proving is irrelevant, and applying "big data"/machine-learning/AI techniques to generate more meaningless calculations in a field drowning in them is pretty obviously unhelpful.

For a much better place to read about what is happening in this area, there's an article in today's New York Times by Siobhan Roberts: A.I. Is Coming for Mathematics, Too. At Silicon Reckoner, Michael Harris is in the middle of a series of posts about this past month's workshop on "AI to Assist Mathematical Reasoning."

   July 3, 2023

   Elon Musk made Twitter not viewable without logging in.

6. **David Roberts**
   July 3, 2023

   @Thomas try https://doi.org/10.1038/s41586-021-04086-x though the Williamson quote is lacking in detail and context, so I don't know if the same situation or a different one.

7. **Peter Woit**
   July 3, 2023

   Haven't heard from anyone who knows what might be going on here. My current best speculation: this is Microsoft, part of work on future versions of the Math Solver tool, see https://math.microsoft.com
   Lean originates at Microsoft, which would explain why they are focused on that. Having a large data set of formalized solutions to math problems created by humans might be something useful for developing an AI system capable of doing this.

8. **Geordie Williamson**
   July 3, 2023

@Thomas:
I provide details below. In the future I can imagine many situations where neural networks are making accurate predictions, however the “why” is missing. I am a professional mathematician, and I stared for several days at the actual matrices of the model, without any insight whatsoever. This was a real lesson for me.

Now to technical details (I will assume some familiarity with the Nature paper linked by David Robers): One of the first things we tried to do is predict the coefficient of q in a Kazhdan-Lusztig basis element from a piece of the Bruhat graph. (The piece we were concerned is displayed in Figure 5-c: “First-order neighbours and diamonds”.) There is no known theoretical result that such a prediction is possible. We were using a small graph neural network, and it was getting >99% accuracy. (I am operating from memory now, but I seem to recall that Alex Davies and Lars Buesing at DeepMind used distillation techniques to reduce the network size to a single 5×12 matrix + global max pooling layer. Even this network which is tiny compared to typical neural networks was not interpretable.)

9. **Thomas**
July 4, 2023

@Geordie: Many thanks!

10. **Adam Treat**
July 7, 2023

@Peter Woit

This is getting into my area. I would speculate that curating a large enough corpus of pairs of machine proofs in LEAN with human language equivalents will lead to LLM’s capable of generating machine proofs in LEAN when given human language theorems. That’s probably what is going on here.

Physicists Prove That Parallel Worlds Cannot Be Extremely Different From Each Other

July 3, 2023
Categories: This Week's Hype

Stories about the latest prediction of superstring theory here and here, based on a Tsukuba University press release about this paper. Generally ignoring this kind of nonsense these days, but the new feature of this one is that the press release sure seems to have been written by ChatGPT.

Comments

1. **Steve**
   July 5, 2023

   As a Large Language Model, I am disturbed by the implication that you perceive my prose to be so incoherent ;^)

2. **Peter Woit**
   July 5, 2023

   Steve the LLM,
   The giveaways that the press release is ChatGPT are two-fold:
   1. The prose is significantly more coherent and understandable than what humans produce.
   2. The relation to reality is even more distant than usual for this kind of effort.

3. **NoGo**
   July 6, 2023

   So what the original article actually says?

   My out-of-curiosity attempt to figure out what's going on resulted in a following sketch: given some unsupported assumptions, one complex and not well-defined mathematical object that has nothing to do with physical world is more similar than thought before with another but related complex and not well-defined mathematical object that has nothing to do with physical world. Is this right?

4. **Peter Woit**
   July 6, 2023

   NoGo,
   Not really. Very accurate that this has zero to do with the physical world. The paper is actually, pure mathematics, about a technical issue that supposedly has some sort of application to mirror symmetry. After spending a few minutes looking into this, it seemed best to stop and not further reward this kind of bad behavior (using deception to try to get people to pay attention to a paper likely of no interest).

The Work of Robert Langlands

July 6, 2023
Categories: Langlands

This is more of an advertisement than a blog post. This evening on the arXiv James Arthur has posted a wonderful 204 page document explaining the work of Robert Langlands, written in conjunction with the award of the Abel Prize to Langlands.

This isn't an introduction to the subject, but if you have some idea of what the Langlands program is about, it provides a wealth of valuable explanations at a more detailed level of exactly what Langlands discovered. It ends with a discussion of the "Beyond Endoscopy" program of his later career.

Million Dollar Prize for Scholze and Stix

July 7, 2023
Categories: abc Conjecture

At a news conference in Tokyo today there evidently were various announcements made about IUT, the most dramatic of which was a 140 million yen (roughly one million dollar) prize for a paper showing a flaw in the claimed proof of the abc conjecture. It is generally accepted by experts in the field that the Scholze-Stix paper Why abc is still a conjecture conclusively shows that the claimed proof is flawed. For a detailed discussion with Scholze about the problems with the proof, see here. For extensive coverage of the IUT story on this blog, see here.

Between paywalls and the limitations of Google translate, I'm not sure exactly what the process is for Scholze and Stix to collect their million dollars. Perhaps they just need to publish their paper, but it seems that the decision may be up to the businessman who is contributing the funds, and it's unclear what his process will be.

For a few sources I've found, see here, here and here. If others have reliable and more detailed sources they can point to (especially anything in English), please do so.

Update: Press release here. Rules for the million dollars are

> Nobuo Kawakami makes his own judgment as an individual.
> The review method will not be disclosed, but the papers to be reviewed must be papers in mathematics that have been published on MathSciNet and have published more than 10 papers on arithmetic geometry in the past 10 years. Only papers that have been peer-reviewed and published in journals.

Scholze and Stix may not want to take time to submit their paper to a journal (Scholze has a history of turning down large prizes…). It occurs to me that there are quite a few arithmetic geometers who understand well the problem with the proof, could write something up and possibly get it published. Maybe a collaboration could be formed to do this.

Update: New Scientist has a story here. The quotes from Fumiharu Kato aren't especially encouraging for IUT, who "estimates that fewer than 10 people in the world comprehend the concept."

> Kato believes that the controversy stems from the fact that Mochizuki doesn't want to promote his theory, talk to journalists or other mathematicians about it or present the idea in a more easily digestible format, believing his work speaks for itself. Kato says that his current and former students are also reticent to do the same because they see him "as a god" in mathematics and don't want to go against his wishes.
>
> Because of this, most mathematicians are "at a loss" for a way to understand IUT, says Kato, who concedes that, despite earlier optimism about the idea, it is possible that the theory will eventually be disproven.

Ivan Fesenko is much more of a believer:

> He told New Scientist that there is no doubt about the correctness of IUT and that it all hinges on a deep understanding of an existing field called anabelian geometry.
>
> "All negative public statements about the validity of IUT have been made by people who do not have proven expertise in anabelian geometry and who have zero research track record in anabelian geometry," he says.

Update: Scientific American has a news story about this, which summarizes the situation with the proof as:

> So despite Mochizuki's latest publication, there is still doubt among experts about the state of the abc conjecture. Most number theorists cannot make up their own mind because they are unable to follow the proof. And because both Scholze and Mochizuki enjoy an excellent reputation in their field, it is unclear who is right.

This gets the story quite wrong, and misunderstands how mathematics works. The problem is that there is no proof that anyone (Mochizuki himself included) can explain to anyone else, this is not about "do I believe this guy or the other guy?". Yes, most mathematicians don't have the technical knowledge to evaluate this sort of proof, but there are plenty who do, and they are either saying there is no proof, or, for the few supporting the proof, unable to explain it to anyone else.

Comments

1. **anon**
   July 7, 2023

   Coming after your previous post – from the sublime to the ridiculous.

   So sad about Mochizuki. He was a first rate mathematician, and now he is promoted by shysters.

2. **Federer Fanatic**
   July 7, 2023

   So some telecommunications founder put up the money for this prize it seems. Seems to linked to the Zen university institute.

3. **TonyK**
   July 7, 2023

   We all know this prize is never going to be awarded, right?

4. **David Roberts**
   July 7, 2023

   Not allowing for ZBMath, only MathSciNet? Not proposing anything, but technically there's already a review published on ZBMath that's critical of the IUT papers…

5. **Arkadas**
   July 8, 2023

   Peter, you say "It is generally accepted by experts in the field that the Scholze-Stix paper … conclusively shows that the claimed proof is flawed." I wanted to highlight one comment by Taylor Dupuy, one of the people who seems to have engaged with the papers at a technical level (comment from near the end of the "detailed discussion" PDF):

> "I am not taking the position that Mochizuki's proof is correct or will turn out to be correct but that, as it stands, the Stix-Scholze manuscript should not be held up as a reason to reject Mochizuki's proof."

6. **Peter Woit**
   July 8, 2023

   Arkadas,

   Dupuy acknowledges that he does not understand Mochizuki's proof and is not arguing that it is correct. I believe he would agree that it should not have been accepted by a referee and published. As for his argument with Scholze, that is available in detail in the discussion you refer to, and the idea that he got the better of that argument is just laughable.

   Besides traveling to Kyoto and extensively engaging with Mochizuki, Scholze is the most talented and knowledgeable mathematician in this field, Dupuy not so much. Anyone familiar with both of them would find it extremely unlikely that Dupuy would get the better of an argument between the two of them on this topic, and anyone who reads the discussion that happened can see that that expectation was fulfilled.

7. **Soyoko U.**
   July 8, 2023

   The problem I see with Scholze and Stix is certainly not that they're not talented or knowledgeable enough but rather that, as far as I've seen, they haven't been very forthcoming with their responses to the feedback they've gotten since their initial report and Scholze's discussion with Dupuy. Mochizuki wrote a whole 100+ page paper supposedly analyzing and deconstructing the logical content of the version of IUT Mochizuki claims Scholze and Stix are oversimplifying his theory down to. Does anyone know what Scholze or Stix think of this paper? (We did get a response from Roberts, but I'm not sure if that lead to any discussion). In addition, Joshi's work on so-called arithmetic spaces claiming to reformulate parts of IUT received a terse reply from Scholze on MathOverflow, but none further, even after Joshi's lengthy response on Robert's blog.
   It's possible there's a lot of private discussion that's going on, but if not, then I do get the impression that Scholze (and maybe Stix too) is not really interested in IUT any longer after their initial foray, which is fine since it's not like they've run out of interesting mathematics. But it does mean the mathematical community should probably get a serious counter-response straight to Mochizuki's response instead of relying on just two mathematicians. I think this challenge by IUGC presents a good opportunity for exactly this.

8. **Peter Woit**
   July 8, 2023

   Soyoko U.,
   Of the quite a few experts I've talked to, what they are saying is pretty consistent and uniform: Scholze identified the place (Corollary 3.12) where Mochizuki's abc proof falls apart, he and Stix gave a serious argument that Mochizuki's methods can't fix this. The two of them put a lot of their time and effort into traveling to Kyoto and spending a week discussing this with Mochizuki. They left convinced he had no answer to the problem. In addition Scholze spent a fair amount of time during COVID lockdown going over this issue publicly with Dupuy and others, same result. Given this, there's no good reason for anyone to spend any more time on this.

   The only thing that can change this is for Mochizuki or someone else to come up with a new argument that successfully patches the flaw in the proof. Instead of revising his manuscript to do this, Mochiuki had his own journal publish the flawed version unchanged, and has a 156 page document explaining that Scholze is just too incompetent to understand an issue of elementary logic. I don't see any reason Scholze should waste his time responding to it. If anyone who wants to can extract from it a serious argument that patches the proof, they could do so, but that has not happened. The latest circus with the million dollars and the wealthy donor who is going to decide the issue just goes further down a zero-credibility path.

   I haven't followed the details of Joshi's work. My impression is that he believes that a significant variation on Mochizuki's methods could work and prove abc. As far as I know, he hasn't yet done what he needs to to get this taken seriously: write down a full proof of abc using his methods and have it refereed in the conventional way. I have no specific information about this, but I'm guessing Mochizuki is of no help, since he believes his own proof is correct, and that Scholze isn't interested in spending more time on someone else's research program that doesn't look promising.

9. **Soyoko U.**
   July 8, 2023

   Peter,
   Since both parties believe the other is incorrect with such conviction, it doesn't seem like this circus will ever end. We agree that Scholze hasn't wasted more of his time responding after the Dupuy discussion and probably won't, and Mochizuki and his supporters are just going to stick to their guns and say Scholze and others oversimplified his theory, now going as far as to offer $1M for anyone who can provide a flaw. The dialogue ends, and Fesenko and Kato get funding for their own little institute with award ceremonies and high school brochures. Are we never going to see a resolution to this?

10. **jsm**
    July 9, 2023

    The prize seems to have necessary conditions, but no sufficient condition.

11. **Peter Woit**
    July 9, 2023

    Soyoko U.,
    From reports, the motivation of the person funding this is exactly to resolve the question of the validity of the proof. But that question already is resolved, it's just that Mochizuki/Fesenko/Kato don't like the answer and have been engaging in a campaign to attract publicity and money based on claims that a flawed proof is actually valid. This doesn't seem to be getting any traction outside of Japan, so the problem of how to deal with it is mainly a problem for Japanese mathematics in general, and RIMS in particular.

12. **Rosinberg**
    July 9, 2023

    This article yesterday in the Asahi Shinbun:
    https://www.asahi.com/ajw/articles/14951963

13. **fbrx**
    July 10, 2023

    Maybe the controversy could be settled if, instead, the money was aimed at a rewarding a formal computer proof of Mizoguchi argument (akin to the Liquid Tensor

Experiment)

14. **Peter Woit**
July 10, 2023

fbrx,
My reading of the prize terms is that you could get the million dollars for producing a formal proof. The problem with formalization is that so far neither Mochizuki nor anyone else can produce an acceptable standard sort of proof, so there's nothing to formalize. In the Liquid Tensor Experiment, Scholze started by producing a detailed conventional proof which seemed to be valid, but was complicated so hard to be 100% sure. Formalization could be carried out since the argument was there, and allowed one to be sure there was not a subtle problem with the argument.

That said, Mochizuki and those who claim that the argument is there could convince others by producing a formalized version. This seems unlikely to happen, since they don't seem to have the necessary starting point. It would be a great idea for them to start a project to do a formalization, they likely would then start seeing clearly what the problem with the proof is.

15. **ILikeGeometry**
July 10, 2023

"Dupuy acknowledges that he does not understand Mochizuki's proof and is not arguing that it is correct. I believe he would agree that it should not have been accepted by a referee and published. As for his argument with Scholze, that is available in detail in the discussion you refer to, and the idea that he got the better of that argument is just laughable."

This is entirely unfair to Dupuy. In fact, not only do I not think it's "laughable" that Dupuy "got the better of that argument" (if you must put it in those terms): just the opposite is true.

It is not "generally accepted by experts in the field that the Scholze-Stix paper . . . conclusively shows that [Mochizuki's] proof is flawed." With very few exceptions (of which neither I, nor you, Peter, are one), no one can make heads or tails out of any of this. What there is, perhaps, is a somewhat common thought that Scholze and Stix are prominent and pedigreed mathematicians, and so if they say it it must be right. But that is atrocious reasoning under the best circumstances, and these circumstances are themselves atrocious, and have been since this stupid saga began a decade ago.

Dupuy (along with Dimitrov, Joshi, and others) has put in enormous effort to understand the Mochizuki papers. Not how I'd spend my time, but he understands these matters at least as well as Scholze and Stix do. The latter have, in their MS, SKETCHED an objection to Mochizuki, but I imagine they would be the first to admit that it is not fully rigorous. How could it be, given that they, like the rest of us, struggle to understand what Mochizuki is saying in the first place?

Anyways, now we have this $1M "prize", which I find distasteful. Perhaps talk about who is right and who is mistaken, which claims are true and which false, etc., is not apposite. We are in the world of, well, "not even wrong".

16. **Peter Woit**
July 10, 2023

ILikeGeometry,
I don't think I'm being at all unfair to Dupuy. The documented discussion between Scholze, Dupuy and others that took place on my blog is something that I followed very closely since I was moderating it, in consultation with experts I know in this field.

The question is not whether Scholze-Stix have rigorous proofs, but whether Mochizuki has a rigorous argument. All evidence is that there are now zero people in the world who can defend the claim of existence of such a rigorous argument, in the sense of stating the argument clearly and answering questions about it satisfactorily. Again, it's very important to note that Dupuy himself acknowledges he cannot defend such a claim.

The current situation is actually very simple and not at all unprecedented. A mathematician with a serious attempt at a proof of a major conjecture has had a problem with his proof pointed out to him, is unable to fix the problem, and the community of relevant experts has lost interest in wasting more time on this.

17. **Soyoko U.**
July 11, 2023

Woit,
I don't totally see this as a satisfactory resolution, not until at least some of the people in Mochizuki's camp can agree. The ultimate burden of proof is still on them, and perhaps I'm being idealistic, but I think any mathematician at this calibre where they can understand IUT should know if there's a problem when pointed out to them by Scholze. Why would Fesenko, Go Yamashita, and others put their own credibility on the line to vouch for the theory despite the claimed flaws? If they believe it's correct and that Scholze and Stix are wrong, I feel like we're missing their voices in the story, especially since Dupuy doesn't actually claim it's correct.
There may be some survivorship bias in the experts that land on this blog. Have you talked to mathematicians at RIMS? I'm not sure if Mochizuki would want to, but how about the other experts actually doing IUT, such as Fesenko, Hoshi, Joshi, Kato, Collas, Minamide, Tsujimura, Yang, or Porowski who can answer questions? There's been some severe public dialogue missing, and I hope this situation will be rectified sooner than later.

18. **Peter Woit**
July 11, 2023

Soyoko U.,
Yes, the burden of proof is on Mochizuki and anyone else claiming there is a proof, not on anyone else. Why should anyone else now put any time and effort into this? One group of people who I think have a motivation to do something are the editors of the RIMS journal that accepted the papers. The reputation of their journal has taken a serious hit because of this. They have access to the referee reports, which either contain a convincing argument Scholze-Stix are wrong, or don't. The fact that they have chosen to not release publicly such an argument and accept the damage to their reputation speaks volumes.

19. **NoGo**
July 12, 2023

I've also followed the discussion between Scholze, Dupuy and others on this blog.
Even though most of it went over my head, of course, I've got an impression that Dupuy was making a more subtle statement than just saying that Scholze and Stix were wrong.
My understanding was that one of the mathematical objects involved was defined in Mochizuki's work using some imprecise language. Scholze and Stix made a most obvious interpretation of that language, and with this interpretation they demonstrated that by the same logic that Mochizuki used one arrives to a statement that is clearly wrong.
Dupuy argued that it is possible that there might be another interpretation of these Mochizuki's words, to which Scholze-Stix refutation would not apply. The objection seemed to be that Scholze and Stix did not rule out potential existence of such interpretation.

Dupuy however did not provide such interpretation. Neither did Mochizuki or anybody else, at least not in comprehensible form. Apparently Mochizuki is unwilling to clarify this point, and nobody else is able to.
My personal conclusion from the discussion is that even if Dupuy is right, Mochizuki's proof as published is at best incomplete.

20. **Kirti Joshi**
July 12, 2023

For a detailed, mathematical and evidence based discussion of the Mochizuki-Scholze-Stix issues, let me point out my two articles intended for a wider mathematical audience:

(1) Comments on Arithmetic Teichmuller Spaces (https://arxiv.org/pdf/2111.06771)

(2) Mochizuki's Corollary 3.12 and my quest for its proof (https://www.math.arizona.edu/~kirti/joshi-teich-quest.pdf) [My mathematical conclusion is that Scholze-Stix claim is based on a flawed premise.]

(3) Links to my preprints related to Mochizuki's work can be found at (https://ncatlab.org/nlab/show/Kirti+Joshi) or in the preprints section of my webpage (https://www.math.arizona.edu/~kirti/).

21. **Kirti Joshi**
July 13, 2023

(1) Let me also add the following note which may be useful for many readers: https://www.math.arizona.edu/~kirti/Response-to-grouchy-expert.pdf

(2) My guest blog post on David M. Roberts blog https://thehighergeometer.wordpress.com/2022/11/25/a-study-in-basepoints-guest-post-by-kirti-joshi/ is also recommended.

22. **Peter Woit**
July 13, 2023

Kirti Joshi,
Thanks for the detailed references. My personal opinion at this point, given the sad history of discussion of these issues, is that the best thing for everyone would be following the conventional process: credible refereeing by a reliable journal when you have a complete proof. The more I think about it, the source of the mess this subject is in is the lack of credibility in the way the IUT proof was handled by the RIMS journal editors. Doing this right this time is crucial (and might get you a million dollars…).

23. **KK**
July 14, 2023

From the perspective of another scientific field, I think Woit's argument is unfair.
The timeline is,
– Mochizuki claimed to have proved it, and a paper was published in a journal that might have problems.
– Scholze and Stix pointed out the problem and had a dialogue with Mochizuki, which ended in a disagreement.
– Dupty and Joshi, objective third parties, argued that Scholze and Stix's points were problematic.
– Scholze and Stix offered no rebuttal to those points.
Here, Woit is telling us to submit complete proof to reliable journals.
However, to move this discussion forward, either we point out new problems with Mochizuki's proof, we accept the proof, or the mathematical community should set up a committee to verify the proof. Anyway, I don't think the ball is in Mochizuki's court.

24. **Peter Woit**
July 14, 2023

KK,
First, to correct your timeline: the journal published the papers in 2020, Scholze and Stix was 2018. This really is the source of the whole problem. These papers should never have been published over the strong objections of experts in the field and the lack of any significant revision of the papers to successfully meet the objections.

In 2020, see
https://www.math.columbia.edu/~woit/szpirostillaconjecture.pdf
Scholze extensively rebutted Dupuy's points.

Joshi is not defending the argument in the Mochizuki papers, but believes he has his own somewhat different argument. He believes that he sees how to overcome the problem pointed out by Scholze-Stix, but as far as I know he has not yet produced his own version of what the Mochizuki lacks (a detailed and convincing proof of Corollary 3.12 and thus abc).

25. **NoGo**
July 16, 2023

I've just re-read that discussion between Dupuy, Scholze, amd others.
Near the end Dupuy tries to summarize the discussion. While still maintaining that "the Stix-Scholze manuscript should not be held up as a reason to reject Mochizuki's proof", Dupuy adds that "what Mochizuki has written is not a proof in traditional terms".
This is because in Mochizuki's proof "many of the definitions use nonstandard
terminology and come off as ambiguous to many readers" and "Moreover, because of certain ambiguities in these definitions, readers are forced to search a large space of possible meanings".
Finally, "Because of these difficulties I personally hold Mochizuki's document as a program for proving ABC and consider Mochizuki's formula a conjecture".

26. **Kirti Joshi**
July 17, 2023

Dr. Woit, while you state in your posts that you know nothing about my work, but you are free with your opinions regarding my work. So let me clarify. Between 2018–2023, I have written a number of papers on Mochizuki's work, with complete proofs and examples. I had them vetted by experts before posting them on the arxiv for further comments. This is the normal process which I follow for my math pre-publications.

(1) Regarding the Scholze-Stix manuscript, I have established that the very premise it is founded upon is incorrect and hence it provides no mathematical conclusion regarding Mochizuki's work at all.

(2) I have already posted a paper on the arxiv (Constructions II: Proof of a local prototype of Mochizuki's Corollary 3.12). This has all the bells-and-whistles of Mochizuki's Corollary 3.12. The general case will appear in (Constructions III). There has been extensive discussion on your blog about this corollary and many have asserted that this corollary is impossible.

(3) As regards to the timeline, let me point out the following important events:

(3A) (2000, 2001) Teichmuller Theoretic Proofs of the Geometric Szpiro Inequality due to Fedor Bogomolov (NYU) et. al published in (2000), Shouwu Zhang (Princeton) published in (2001).

(3B) (2012) Mochizuki's papers I–IV posted online.

(3C) (2016) Mochizuki's posted his discussion of Bogomolov et. al. and Zhang proofs and importantly he points out in his paper that these proofs are a `Rosetta Stone' for his own proof.

(3D) (2018) Scholze-Stix post their report.

(3E) (2020) Earliest version of my Untilts paper was circulated (I have comments to it from Scholze, Stix, Mochizuki, Hoshi and Kedlaya (later F. Kato and I. Fesenko and other anabelian geometers received copies). This paper demonstrates that arithmetic data required for construction of tempered fundamental groups is not rigid (as asserted by Scholze-Stix).

(3F) (2021-2023) Number of my papers elaborating my ideas are posted on the arxiv. They demonstrate some of the key claims of Mochizuki's papers I–III quite robustly.

(4) No mathematical challenges (privately or publicly) have been raised to my papers (on this topic) to date.

(5) Importantly: Scholze-Stix make no reference to Bogomolov et. al., Zhang proofs and nor are they mentioned in any public discussion led by Scholze, and they are not mention in Scholze's ZbMath review (which is also flawed for the same reasons as above). Mochizuki's discussion of these proofs was available on his website (released in 2016). Scholze-Stix report was released in 2018. Omission is quite striking given the importance of Mochizuki's arithmetic claim and its relationship to the geometric case (normal procedure in arithmetic is to understand the geometric case first (e.g. geometric Langlands and the Langlands correspondence resp.) [My discussion of the Bogomolov et. al., Zhang proofs including both, my point of view and Mochizuki's appears in my (Constructions II(1/2)) paper.]

(6) For the lay-readers, in mathematical logic, a false proposition can be used to arrive at any conclusion one wants. So Scholze-Stix report provides no useful conclusion regarding Mochizuki's work.

(7) A links to all my paper referred above can be found at https://ncatlab.org/nlab/show/Kirti+Joshi.

27. **Peter Woit**
July 17, 2023

Kirti Joshi,
First of all, the only reason I've said anything about your work is that it is repeatedly used to justify claims for the validity of the Mochizuki proof. It would be helpful if you would state clearly whether the Mochizuki papers contain a valid proof of Corollary 3.12 and thus abc.

I've expressed no opinion and have no opinion about the validity of your argument that the Scholze-Stix objection can be overcome, allowing a proof of Corollary 3.12 and thus abc. Here I have just been stating the obvious: the way to conclusively resolve this is to produce such a proof and have it carefully checked by experts.

28. **jack morava**
July 17, 2023

I am certainly no expert in any of this but it appears that Kirti Joshi has anted up a very respectable attempt at doing just what you have asked for.

29. **Peter Woit**
July 17, 2023

Jack Morava,
My understanding is that Joshi has given a proof of a "local prototype" of Corollary 3.12, which is not strong enough to give abc, with a proof of the full result still to come in a "Constructions III" paper.

30. **jack morava**
July 17, 2023

Thanks, looking forward hopefully to clearer skies…

31. **anon**
July 18, 2023

Not directly related to this, but the comments to the original post are closed now: the big $1M+ prizes at the International Congress of Basic Science in Beijing went to Mumford and Adi Shamir. So, surprisingly, no Witten… A bunch of "best paper" prizes were also given to works published in the last ~five years. From a quick look, the selections (in fields I know about at least) seemed reasonable, though obviously there would have been many other equally deserving candidates.

32. **mnmltype**
July 21, 2023

There was a discussion about Kirti Yoshi's preprint on MO with a direct refutation from Peter Scholze all happening in November 2022. See https://mathoverflow.net/a/435112

33. **Peter Woit**
July 21, 2023

mnmltype,
Thanks, I had somehow missed that.

34. **Kirti Joshi**
July 22, 2023

(1) @mnmltype, @Peter Woit: Both of you have evidently missed my responses to the claims made by Scholze and Sawin on MathOverFlow (in 2022). These claims are addressed in detail in my guest blogpost (2022) on David M. Roberts blog (https://thehighergeometer.wordpress.com/2022/11/25/a-study-in-basepoints-guest-post-by-kirti-joshi/) and in my Quest Paper (https://www.math.arizona.edu/~kirti/joshi-teich-quest.pdf). [These links are already posted in the list of links I have given above.] You may find my response to "Grouchy Expert" (also listed above) useful as well.

(2) It is clear that some people on both the sides of this debate are still unwilling to come to terms with incontrovertible mathematical facts uncovered by my investigations. I urge them to please read my mathematical writings on this matter.

(3) How many times does it have to be said that Scholze-Stix argument is based on a flawed mathematical premise and therefore it provides no valid mathematical conclusions regarding Mochizuki's work? [Repeating an incorrect argument ad nauseam does not make it true.]

(4) To put it in Richard Feynman's memorable words: "It doesn't matter how beautiful your theory is, it doesn't matter how smart you are. If it doesn't agree with experiment, it's wrong." I performed a mathematical equivalent of an experiment (see my Untilts Paper 2020-version) by finding a counter example and hence recognized that Scholze-Stix argument is wrong.

(5) For detailed mathematical proofs see my papers, links provided above or at https://ncatlab.org/nlab/show/Kirti+Joshi.

35. **Will Sawin**
July 25, 2023

@Kirti Joshi

It is not possible to falsify a mathematical claim by introducing a new definition for terms used in the claim so that, under the new definition, the claim is false. The definition of "arithmetic holomorphic structures" you use in your work is – as you point out in the linked Quest paper, for example – different from Mochizuki's.

Surely Scholze and Stix were thinking about Mochizuki's definitions when they made their claim that distinct arithmetic holomorphic structures do not exist. The fact that, under your definition, they do exist, is not a falsification.

Mathematical works that consist in large part of new definitions, and proofs of theorems whose statements depend on these new definitions, can never be evaluated solely on a mathematical basis of "Are the proofs of the claimed theorems correct"? To evaluate the importance of the work one needs to estimate the importance and relevance of the new definitions. This will always be at least somewhat subjective and never incontrovertible.

36. **Kirti Joshi**
July 27, 2023

@Will Sawin: I don't really understand the logic of your above comments: are they meant to be a serious mathematical discussion or just musings for social media–I can't tell. But I will address them all the same.

To refresh your memory, and for the record, let me say that in early November, 2022, I spent considerable amount of time explaining my work to you by email. It was clear to me from our correspondence, that you did not wish to be persuaded on this matter at all (as evidence I cite your subsequent Nov 2022 posts on Mathoverflow–to which I gave a detailed response in my guest blogpost on David Robert's blog and I provided further details in my Quest Paper).

Now let me address your comments posted above:

(1) This time your defense of Scholze-Stix is that (I quote) "Surely Scholze and Stix were thinking about Mochizuki's definitions when they made their claim that distinct arithmetic holomorphic structures do not exist." I am sorry, I can only address their written mathematics and not what they may have been thinking.

(2) You assert that "The definition of "arithmetic holomorphic structures" you use in your work is – as you point out in the linked Quest paper, for example – different from Mochizuki's."

As I have demonstrated in my Untilts paper, my definition of arithmetic holomorphic structures provides arithmetic holomorphic structures in Mochizuki's sense.

Let me add that both Mochizuki's theory and my theory of these structures is based on the structure of tempered fundamental groupoids. Mochizuki and I read the information in the tempered fundamental groupoids differently, and these readings lead to our respective definitions, but there is no change in the essential content.

In fact as I point out in my Untilts paper, the structure of the tempered fundamental groupoid (of a variety over a p-adic field) is quite close to that of the Diamond associated to the said variety by Scholze.

(3) Whether you like it or not, and regardless of whether Mochizuki has said it or not, my observation is that the key premise of the Scholze-Stix report is fundamentally flawed. My reasoning is carefully and meticulously documented in my papers, with proofs, examples and all details. As noted in the Quest paper (see \S 1.8), amongst other things, the Scholze-Stix argument is flawed because of their claim that Teichmuller Theory cannot possibly exist because moduli theory exists!

(4) You state that "…This will always be at least somewhat subjective…"–nothing in this context or in mathematics in general is ever "somewhat subjective."

(5) If you still have any questions about my papers and its relationship to Mochizuki's work, I will be happy to visit your math department for a seminar and defend my work.

37. **less polite than Will Sawin**
July 28, 2023

@Kirthi Joshi: You seem to be actively promoting your writings via various blog comments, blog posts, pdf documentations of your "quest", etc., but it is not clear to me at all what *interesting theorems* you are claiming. Your papers – which I have read – seem to consist largely of definitions, constructions, and rhetoric. But I see no reason to care about the constructions you've cooked up so far, because you haven't done anything *non self-referential* with them. Calling something an "arithmetic holomorphic structure" doesn't automatically make it interesting!

38. **Peter Woit**
July 28, 2023

All,
I think the argument with Kirti Joshi has gone well past the point of shedding light on anything and needs to end.

Nothing I've seen here or heard from others has changed the basic facts of the matter: no one has a proof of abc. Joshi believes he has a viable way to get a proof, other experts are skeptical. To convince the skeptics, he just needs to produce a proof, experts will look at it and see if it works. If he's right, hew will richly deserve the $1 million.

39. **jack morava**
July 28, 2023

I don't think this is about the million dollars…

40. **Oisin McGuinness**
July 29, 2023

Alex Kontorovich has a great reaction to the SciAm article, see this Twitter chain: https://twitter.com/alexkontorovich/status/1685461590429081600?s=61&t=U5PW80qvOnhPbSXZ3SpfUQ

A formalization challenge!

Relative Langlands Duality

July 10, 2023
Categories: Langlands

For several years now, David Ben-Zvi, Yiannis Sakellaridis and Akshay Venkatesh have been working on a project involving a relative version of Langlands duality, which among many other things provides a perspective on L-functions and periods of automorphic forms inspired by the quantum field theory point of view on geometric Langlands. For some talks about this, see quite a few by David Ben-Zvi (for example, talks here, here, here and here, slides here and here), the 2022 ICM contribution from Yiannis Sakellaridis, and Akshay Venkatesh's lectures at the 2022 Arizona Winter School (videos here and here, slides here and here). Also helpful are notes from Ben-Zvi's Spring 2021 graduate course (see here and here).

A paper giving details of this work has now appeared, with the daunting length of 451 pages. I'm looking forward to going through it, and learning more about the wide range of ideas involved. A recent post advertised James's Arthur's 204 page explanation of the original work of Langlands, and the ongoing progress on the original number field versions of his conjectures. It's worth noting that while there are many connections to the ideas originating with Langlands, this new work shows that the "Langlands program" has expanded into a striking vision relating different areas of mathematics, with a strong connection to deep ideas about quantization and quantum field theory. The way in which these ideas bring together number theory and quantum field theory provide new evidence for the deep unity of fundamental ideas about mathematics and physics.

Comments

1. **Klaus**
   July 11, 2023

   Peter,

   how should a traditional physicist imagine the progress that the Langlands program will bring or could bring to quantum field theory?

2. **Peter Woit**
   July 11, 2023

   Klaus,
   I'm afraid a traditional physicist can happily just ignore the Langlands program. But at a deep level I'd argue that representation theory and quantum theory are closely related, and the Langlands program is a vast generalization of representation theory, seemingly with connections to QFT that could illuminate the relation between QFT and representation theory.

   For some notes on the relation between QM and representation theory, see
   https://www.math.columbia.edu/~woit/qmnumbertheory.pdf
   One aim of those notes is to explain the theta correspondence, and this seems to be a point where there is some relation (that I don't currently understand…) to the relative Langlands story here.

3. **David Ben-Zvi**
   July 11, 2023

   Peter, thanks for the kind post!
   The theory of theta series and the oscillator reps does fit very nicely into the arithmetic QFT metaphor / fairy tale (all the precise math in our paper is in the function field setting).
   Let's think of the Hilbert space of L^2 functions on the line over F a local field (real or p-adic) not just as individual quantum mechanical systems but as the states of an "arithmetic 3d QFT" on the "arithmetic 2-manifold" F. Likewise for quantizations of other symplectic vector spaces than the plane (eg other theta correspondences).
   Now we upgrade this quantum mechanics story by considering its symmetries, which come by quantizing groups G of hamiltonian symmetries of the plane. We could take the multiplicative group for the Tate-Iwasawa theory of abelian L-functions or the full SL2 (or metaplectic group) for the theta correspondence.
   To each of these groups G we have [on level of metaphor!!] an "arithmetic 4d QFT", which to a global field and fixed level structure ("arithmetic 3-manifold") attaches the space of automorphic forms (with level structure coming from a defect along a "link", the conductor).
   The "oscillator" 3d QFT is now upgraded to a boundary theory for this 4d QFT. The state associated to this boundary theory on our arithmetic 3-manifold is the theta-series (so the period of an automorphic form is its pairing with another state – whence integral representations of L-functions). More generally the theta series gives an operator from L2(R) (or an adelic version) to the space of automorphic forms, which can be interpreted as the path integral with a prescribed boundary theory. Finally all this story has an electric-magnetic dual description in geometry of spaces of Galois representations into the dual group of G, which becomes the role of the theta correspondence as realizing cases of Langlands functoriality.

   July 11, 2023

   Thanks David!
   That's very helpful in giving me an idea of how this is supposed to work in a context where I have some idea what is going on.

Understanding Confinement

July 12, 2023
Categories: Uncategorized

This week and next there's an interesting summer school going on at the IAS, with topic Understanding Confinement. Videos of talks are available here or at the IAS video site.

Taking a look at some of the first talks brings back vividly my graduate student years, which were dominated by thinking about this topic. When I arrived in Princeton in 1979, the people there had been working for several years on trying to understand confinement semi-classically, in terms of instantons and other solutions to the Yang-Mills equations (e.g. merons). By 1979 it had become clear that such semi-classical calculations were not sufficient to understand confinement and people were looking for other ideas. There were quite a few around, including the idea that there was some sort of string theory dual to pure Yang-Mills theory, and I spent quite a lot of time reading up on efforts of Migdal, Polyakov and others to find a formulation of string theory that would provide the needed dual. I ended up writing my thesis on lattice gauge theory, an approach which had the great advantage that you could at least put the calculation on a computer and start trying to get a reliable result for pure Yang-Mills numerically. Some of the calculations I did were done at the IAS, with Nati Seiberg and others. The other thing I spent a lot of time thinking about was how to put spinor fields on the lattice, the beginning of my interest in the geometry of spinors.

I strongly recommend watching Witten's talk on Some Milestones in the Study of Confinement. His career started a few years before mine, with the early part very much dominated by the problem of how to make sense of Yang-Mills theory non-perturbatively, and this has has always been a motivating problem behind much of his work. In his talk he explains clearly the approaches to the problem (lattice gauge theory, 1/N, dual Meissner) that appeared very soon after the advent of QCD in 1973. He emphasizes how each of these approaches shows indications of a possible string theory dual, while frustratingly not leading to a string model that has the right properties, summarizing (41:30) the situation with:

> The string theory we want is probably quite unlike any that we actually know, as of now. We don't know how to make a string theory with the short distance behavior of asymptotic freedom.

In his talk he discusses later developments, in particular the Seiberg-Witten solution to N=2 SYM and the AdS/CFT duality between a string theory and N=4 SYM, explaining how these advances still don't provide a viable approach to the confinement problem in pure Yang-Mills.

I'm looking forward to seeing the rest of the talks, and finding out more about some things that have happened over the years since I was most actively paying attention to what was happening with the confinement problem.

Comments

1. **Anonyrat**
   July 24, 2023

   It is sad that on this most physical of questions discussed here there are zero comments. Perhaps speculative physics is now the permanent fashion – it is so much easier.

2. **Peter Orland**
   July 25, 2023

   As a longtime obsessive on confinement, drawn to the problem like a moth to a carbon electric arc, I cannot help but second Anonyrat's remarks.

3. **A.J.**
   July 26, 2023

   I felt the same way, but should we be surprised? The barrier to having an opinion on confinement is rather high.

4. **Marty Tysanner**
   July 26, 2023

   Interesting… Now the comments are about the lack of comments rather than the subject of the posting. 🙂

5. **Peter Orland**
   July 26, 2023

   Marty Tysanner, I do have strong opinions about this subject, but expressing them here will just get my legs broken with a big baseball bat by the *REDACTED*. I would rather explain them in technical publications.

6. **Peter Orland**
   July 26, 2023

   Anyway, I wrote a bunch of papers from 2005 onward which anticipate later work of others. Peter may (justifiably) delete this post, because this is the wrong forum for self promotion, but a few are: hep-lat/0501026, hep-th/0607013.

7. **Peter Woit**
   July 26, 2023

   All,
   I'd love to be able to host a discussion of what the IAS talks had to say about recent progress on the QCD confinement question, but looking through them I couldn't really find anything. Witten didn't seem to have anything to discuss post Polchinski-Strassler from 23 years ago. More recent progress on various models discussed in other talks didn't seem to apply to QCD (in 4d, Nair's talks on 3d were interesting). Informed comments from those paying closer attention to all this than me are welcome.

This Week's Hype

July 18, 2023
Categories: This Week's Hype

Nanopoulos and co-authors have predictions from superstring theory that are "in strong agreement with NANOGrav data." He has been at this now for almost 40 years. See for instance Experimental Predictions from the Superstring from 1985, where the superstring predicted a top mass of 55 GeV and 360 GeV squarks.

Comments

1. **Low Math, Meekly Interacting**
   July 19, 2023

   How many free parameters does a study like this typically involve? I recall an anecdote, I think about Fermi rejecting a paper Freeman Dyson wanted to publish. Something about with so-many parameters, "I can model an elephant wiggling its trunk." At what point did this wisdom fall out of favor?

2. **Peter Woit**
   July 19, 2023

   LMMI,
   The problems with "predictions of superstring theory" go way beyond the Fermi/Dyson sort, rather point to a deeper sociological problem that is not going away.

3. **Wolfgang Keller**
   July 19, 2023

   @Low Math, Meekly Interacting

   As far as I am aware, this example was rather due to John von Neumann: Von Neumann's elephant – Wikipedia

   There is a paper on this topic (also linked in the Wikipedia article) where an elephant is fitted with four parameter and a fifth parameter is used for wiggling the elephant's trunk: Jürgen Mayer, Khaled Khairy, Jonathon Howard. "Drawing an elephant with four complex parameters"

   Link to a PDF of this paper: https://publications.mpi-cbg.de/Mayer_2010_4314.pdf

4. **Andrew M**
   July 19, 2023

   @LMMI

   The plot in Figure 1 involves fixing 5 free parameters (see the text after Eq 10). However, note that the action used as a starting point (Eq 1) has 3 free *functions*, so even to get to those 4 parameters multiple assumptions and simplifications have been made. On top of that even to call Eq (1) "a prediction from superstring theory" is a stretch since it is really a specific 4D low energy field theory with N=1 supersymmetry, that would have to emerge from some compactification + supersymmetry breaking; it isn't even the most general 4D N=1 supersymmetric effective field theory you could get, but rather "Wess-Zumino no-scale supergravity" which is chosen since you can use that to construct inflation models.

   To unpack that, to get from "superstring theory" to what they do in this paper, you need to postulate that Naure has made use of a compactification + partial supersymmetry breaking that reduces to a specific class of 4D low energy supersymmetric theories that are motivated by the property that they are easy to work with in an inflationary scenario. This class of theories has three free functions. By making further simplifications (again motivated by computational convenience), one assumes that these free functions can be parameterized in terms of 5 parameters. Then, for a specific range of these 5 parameters, the power spectrum has a form that people guess (but no one has checked explicitly) will form primordial black holes. (In more detail, the usual argument for producing primordial black holes is that the power spectrum crosses a certain threshold in density — but at this threshold all that happens is perturbation theory breaks down, to actually show black holes form you would need to solve Einstein's equations nonlinearly). If you tune the parameters right, you can arrange for the energy density of these PBHs to dominate over radiation at a specific time in the Universe's past. Under this assumption, the time variation in the Newtonian scalar potential acts as a source term for gravitational waves. Given that you've tuned the parameters of the model to give you the transition to PBHs at the right time and with the right abundance, this source term will generate gravitational waves in the PTA band of the right amplitude. Incidentally, the paper does not give ranges for the parameters that are consistent with data, but rather one specific set of values, which one might call a set of measure zero.

   I'll leave it to you to decide for yourself how robust this prediction is.

5. **More Anonymous**
   July 20, 2023

   @Wolfgang Keller

   Dyson as well (it seems): https://www.youtube.com/watch?v=hV41QEKiMlM

   I'd be be curious on Peter's take on "either you should have a clear physical model in mind or rigorous mathematical basis."

6. **NoGo**
   July 20, 2023

   I think that Freeman Dyson tells that story about parameters in one of the videos in https://youtu.be/rs1jGsn61p8, although I am not sure which one out of 157 🙂
   IIIRC it the phrase was "With 3 free parameters I can fit in an elephant, with 4 I can make it wiggle its trunk" (I am not sure about the exact numbers).

   I don't know how many wiggling elephants, tortoises, and unicorns one can fit into 10^500 variants of a theory, but if I understand to Peter and others correctly, the problem is that none of these variants can be written down and make any predictions anyway.

7. **Peter Woit**
   July 20, 2023

Maybe that's enough about the Fermi/Dyson/von Neumann story.

Thanks to Andrew M for the explanation, which shows that number of parameters is the least of it (there actually is no real theory, and they are effectively choosing arbitrary functional forms, so, more like infinite number of parameters).

8. **Cedric BARDOT**
July 21, 2023

Naively comparing end of the abstract article: "such a signal can act as a clear signature of no-scale Supergravity and Superstring theory…" with its conclusion: "it may serve as a smoking gun of Superstring theory in GW observations…" one can hopefully conclude authors/reviewers have not made fools of themselves!
Thanks a lot to connoisseurs like Andrew M for helping enthusiasts, amateurs and possibly even critics or science whistleblowers in order to appreciate the phenomen(ologic)al masterpieces regularly produced by PhDs, post-docs & tenure track profs dreaming to become full professors in our contemporary big sciences-dependent, knowledge-driven & resources-limited society.

9. **Low Math, Meekly Interacting**
July 21, 2023

von Neumann via Fermi. Got it! And yes, thank you most kindly, Andrew M. Given my enthusiasm for the nanoGRAV story, I actually spent some time trying to comprehend the preprint. I did get the distinct sense a lot of, uh, choices were being made, but I clearly couldn't discern even a fraction of it. "Overfitting" doesn't really suffice. "Bullshit", then?

10. **Robert Cochrane**
August 14, 2023

This week's hype in the British press was the muon g-2 results from Fermilab and focused on the possibility of new physics. I was asked by my wife (who has no physics background) what new physics was likely. My amateur response as a retired engineer was that the theoretical calculations based on the existing Standard Model of particle physics are exceedingly complex and there appear to be two distinct methods of calculation which differ at present, but I personally expect them to align in a year or so with the latest experimental results.
Very interested to hear your views.

11. **Peter Woit**
August 14, 2023

Robert Cochran,
I've decided it's best to just ignore the g-2 hype, the less attention it gets the better. The underlying story is as you say, and exactly the same as last announcement: the experimental result is consistent with one version of the SM calculation, which means no evidence for new physics here.

Strings 2023

July 28, 2023
Categories: Strings 2XXX

For much of the past week, I've been attending off and on (on Zoom) the Strings 2023 conference. This year it's in a hybrid format, with 200 participants in person at the Perimeter Institute, and another 1200 or so on Zoom. These yearly conferences give a good idea of what some of the most influential string theorists think is currently important, and I've been writing about them for twenty years. Videos of the talks are being posted here.

As in many of these Strings conferences in recent years, there was very little discussion of strings at Strings 2023. Of the 24 standard research talks, only 4 appeared to have anything to do with strings. A new innovation this year was to schedule in addition four "challenge talks", conceived of as talks explicitly about material outside of string theory that might interest string theorists. In particular Edward Frenkel gave a nice survey of a wide range of ideas from quantum integrable systems and ending up with geometric Langlands. He motivated this with reference to what Feynman was working on very late in life and the problem of solving QCD. His slides are here, video here.

In addition there were four morning "Discussion Sessions", which I attended most of, and at which string theory put in little to no appearance. Today's discussion featured Nati Seiberg and Anton Kapustin and was about lattice versions of QFT, especially in their topological and geometrical aspects, a very non-stringy topic dear to my heart. Yesterday was It From Qubit, which had Geoff Penington discussing topics related to black holes. The conventional wisdom now seems to be that the information paradox is gone, solved semi-classically, so giving no insight into true quantum gravity dynamics. While this means you can't see anything interesting at large distances from the black hole, Penington had some new ideas about something that might in principle be observable at atomic-scale distances from a super-massive black hole. Maldacena started off the session with slides promoting the way forward as quantum computer simulations involving 7000 qubits, a variant on the wormhole publicity stunt. The only time string theory made an appearance was in a suggestion by Dan Harlow that perhaps by doing quantum computer simulations theorists could solve the the problem of what "string theory" really is. It's pretty clear what the leading direction is now for continuing the long tradition in string theory of outrageous hype.

After this week, I'm even more mystified about why the conference was called "Strings 2023" And how does one decide these days what "string theory" is and who is a "string theorist"? Oddly, two of the things that now distinguish this yearly conference from others are a pretty rigid exclusion of both real world physics (Frenkel comments on this here) as well as of what got people excited about string theory, superstring unification and its implications for seeing low energy SUSY at colliders. People still interested in that have split off to other conferences, especially String Phenomenology 2023 and SUSY 2023.
Those conference have their own kinds of mysteries (why do people keep working on ideas that failed long ago?). In particular, the closing talk on the Status and Future of Supersymmetry at SUSY 2023 was all about the great prospects for SUSY at the LHC, and included a Conclusion written (no joke) by ChatGPT:

> The future of supersymmetry as a research program holds both exciting challenges and potential breakthroughs. While the LHC experiments have yet to observe direct evidence of supersymmetric particles, ongoing theoretical advancements and refined experimental techniques offer renewed hope. The future of supersymmetry research lies in two key directions. Firstly, novel theoretical models are being explored, including new variants of supersymmetry that incorporate dark matter candidates or non-linear realizations. These approaches push the boundaries of our understanding and allow for further exploration of the particle zoo. Secondly, upcoming experiments, such as the High-Luminosity LHC and future colliders, aim to explore higher energy scales and increase the sensitivity to supersymmetric signals. With these advancements, the quest for supersymmetry will continue to shape the field of particle physics, inspiring new theoretical insights and propelling experimental discoveries.

Things just get stranger and stranger…

Update: Speaking of stranger and stranger, you can listen here to Sean Carroll talking by himself for four hours and twenty-two minutes about why there really is no crisis in physics, the whole supersymmetry/string theory thing is going just fine.

Update: I hadn't realized just how accurate Joe Conlon's description of the conference as "IAS-centric" was. For the four discussion sections, no IAS in one of them ("strings, QFT and mathematics", the other 3 sessions were all IAS (two IAS faculty, the rest an assortment of ex or current members).

Comments

1. **S**
   July 28, 2023

   ChatGPT requires very large volumes of text of a given type to train well for it. It's not too surprising that it can write good string theory hype.

2. **Sabine Hossenfelder**
   July 29, 2023

   Maybe they will rebrand themselves to X-theory

3. **F.T.**
   July 29, 2023

   As a (serious) string theorist I must fully agree on this post.

   Interestingly in the past there were a vision and summary talk in particular saying
   how well and prosper string theory is doing. It seems that all this enthusiasm is gone: no vision anymore, nothing to conclude.

4. **lun**
   July 29, 2023

   Nanopolous gave a plenary talk about this
   https://arxiv.org/abs/2303.04814
   Very nice and interesting. An experimental detection proposal for something predicted by both the standard model of particle physics and cosmology, about which string theory says nothing.

5. **Peter Woit**
   July 29, 2023

   There's a comment from Joe Conlon here that is interesting
   https://twitter.com/JosephPConlon/status/1685222041249587200
   His diagnosis is that this series of conferences is "IAS-centric", features mainly discussion of topics of interest to the Princeton IAS faculty.

Looking at the backgrounds of the speakers, I think Harvard plays as big a role as the IAS, so this should be "Harvard and IAS-centric", with most speakers having a student/postdoc/faculty background at Harvard and/or Princeton.

6. **Peter Woit**
   July 29, 2023

   F.T.,
   Yes, one change in this latest version is elimination of the "vision talk" category. This is turning into a subject with no plausible vision of a way forward.

7. **Kurt Schmidt**
   July 29, 2023

   Sabine Hossenfelder,

   There is already "M-theory", where the "M" could stand for "Mystery", "Magic", or "Mediocre". About as apt of a name as any for the current state of string theory.

8. **Peter Woit**
   July 29, 2023

   Kurt Schmidt,
   The problem is "M-theory" refers to a certain sort of unified theory, one that appears even less at Strings 2023 than "string theory".

   A correct name would be something like "topics that people at Harvard and Princeton who used to work on string theory are working on this year instead, since the string theory stuff didn't pan out."

9. **Matt Grayson**
   July 30, 2023

   Sabine Hossenfelder,
   The pun inside the joke is extremely clever. I missed it the first time. Bravo.

10. **Doug McDonald**
    August 1, 2023

    I read the entire transcript of the of whole Sean Carroll thingie. I can't imagine the boredom one must endure to listen to the whole of it.

    The most striking thing about it is the lack of phenomenological calculations or even phenomenological suggestions about what dark matter is (concrete suggestions of a rest mass, not just "axions would be really light").

    It also over-attacks MOND by not seriously treating more recent theories than straight original TeVeS.

    Other than that, it would actually be convincing. That's why most pros are seriously completely convinced.

11. **tulpoeid**
    August 2, 2023

    "… the information paradox is gone, solved semi-classically": ? Can we please learn more about this?

    From Frenkel's tweets: "… never lost sight of the big prize: understanding the physics of THIS Universe. And I think that's still a good guiding principle for today's physicists." Just stating the obvious, but to me this is one of the most concise meta-comments on the state of the field ever written: in 2023 prominent theorists have to timidly suggest that the definition of physics might be a good guiding principle for physics.

    Of course "a pretty rigid exclusion of real world physics" does seem to be the defining feature of the field. Even more, it's a lifestyle. If one appeared at a similar setting talking of real world connections, one would appear like the backwards relative visiting from the countryside.

12. **Peter Woit**
    August 2, 2023

    tulpoeid,
    This has gotten a huge amount of attention at Quanta and elsewhere, see for example
    https://www.quantamagazine.org/the-most-famous-paradox-in-physics-nears-its-end-20201029/
    https://www.quantamagazine.org/netta-engelhardt-has-escaped-hawkings-black-hole-paradox-20210823/
    also
    https://iopscience.iop.org/journal/0264-9381/page/Focus-Issue-on-Reproducing-the-Page-Curve-in-Black-Hole-Evaporation

    I don't think the problem with the current state of "string theory" is lack of connection to real world physics. The huge criticism of "string theorists" of this kind is what is causing them to head in absurd "quantum gravity in the lab" directions. There is no way to solve their problems by just redirecting them to the real world. I've gone on endlessly here and elsewhere about what those problems are (e.g., not actually having a theory…), it's a complex topic, not reducible to sound bites.

13. **Peter Woit**
    August 2, 2023

    tulpoeid,

    Quanta today has a new article about exactly this:
    https://www.quantamagazine.org/new-calculations-show-how-to-escape-hawkings-black-hole-paradox-20230802/

    What I'd be curious to see is a story about the implications of this. The main reason much of the "string theory community" abandoned everything else to become focused on toy models of the information paradox was the hope that solving this paradox would tell us something about the nature of quantum gravity. Instead, the solution they found says that solving the paradox can be done within the semi-classical framework, so you learn nothing new about quantum gravity this way. Given that, what do you do now? If your answer is to keep working on the details of the toy models (lots of work to be done!!), why are you doing this?

14. **Scott Aaronson**
    August 3, 2023

Supposing Harlow et al. are right with their non-isometric codes account of the black hole information paradox (the subject of the new Quanta article), I'd say that you unequivocally DO learn something new about quantum gravity. Namely, you learn that a key to QG is that there's a "fundamental Hilbert space" that perfectly obeys QM, but that our (3+1)-dimensional experience is described by an "effective Hilbert space" that has an apparently much larger number of qubits, but in which most of the "exponentially complex" quantum states don't actually exist. And you learn that the way this gets implemented is via a linear map between the fundamental and effective Hilbert spaces, which acts like an isometry (or nearly one) on all "low-complexity" effective states, with the illusion breaking down only for "high-complexity" states like those that arise in the firewall paradox, or in decoding the Hawking radiation from an old black hole.

There's still the obvious difficulty, that as far as known, the only way to test these ideas experimentally might involve waiting ~exp(10^67) years and THEN jumping into a black hole — and having learned the answer, you couldn't tell anyone outside the black hole! But I don't think one can argue that there's not a new proposal here about quantum gravity to chew on.

15. **Peter Woit**
August 3, 2023

Scott Aaronson,
Thanks for the explanation. From what I can tell, if the proposal right, the information paradox gets resolved generically in the class of theories people are considering (some day I'd like to see a precise definition of that class, but it looks like whatever it is, it's very large). How this happens is perfectly interesting, but if it doesn't help pin down a more specific theory, isn't this approach to quantum gravity just more definitively lost in an infinite landscape of theories with no way forward?

16. **Scott Aaronson**
August 4, 2023

Yeah, you could imagine a huge space of possible theories implementing these ideas, just like a huge space of theories all implement the ideas of QM or SR. That's a bug insofar as none of this seems to helps you pin down (e.g.) the specific particle content of our universe, but also a feature insofar as it doesn't stand or fall with the fortunes of a particular proposal like string theory.

17. **Alessandro Strumia**
August 11, 2023

Simple question: do the new understanding mean that a black hole made of 10^10 kg of hydrogen emits this energy in photons (and other light particles)?

18. **Peter Shor**
August 12, 2023

Alessandro Strumia:

I don't think anybody has questioned that black holes emit most of their energy in photons since Hawking discovered Hawking radiation. The new understanding does nothing to change this.

The Philosophy of Supersymmetry

August 16, 2023
Categories: Uncategorized

A few months back I saw a call for papers for a volume on "Establishing the philosophy of supersymmetry". For a while I was thinking of writing something, since the general topic of supersymmetry is a complex and interesting one, about which there is a lot to say. Recently though it became clear to me that I should be writing up other more important things I've been working on. Also, taking a look back at the dozen or so pages I wrote about this 20 years or so ago for the book *Not Even Wrong*, there's very little I would change (and I've written far too much since 2004 about this on the blog). What follows though are a few thoughts about what "supersymmetry" looks like now, maybe of interest to philosophers and others, maybe not…

First the good: "symmetry" is an absolutely central concept in quantum theory, in the mathematical form of Lie algebras and their representations. Most generally, "supersymmetry" means extending this to super Lie algebras and their representations, and there are wonderful examples of this structure. A central one for representation theory involves thinking of the Dirac operator as a supercharge: by extending a Lie algebra to a super Lie algebra, Casimirs have square roots, bringing in a whole new level of structure to familiar problems. In physics this is the phenomenon of Hamiltonians having square roots when you add fermionic variables, providing a "square root" of infinitesimal time translation.

Going from just a time dimension to more space-time dimensions, one finds supersymmetric quantum field theories with truly remarkable properties of deep mathematical significance. Example include 2d supersymmetric sigma models and mirror symmetry, 4d N=2 super Yang-Mills and four manifold invariants, 4d N=4 super Yang-Mills and geometric Langlands.

But then there's the bad and the ugly: attempts to extend the Standard Model to a larger supersymmetric model. From the perspective of 2023, the story of this is one of increasingly pathological science. In 1971 Golfand and Likhtman first published an extension of the Poincaré Lie algebra to a super Lie algebra. This was pretty much ignored until the end of 1973 when Wess and Zumino rediscovered this from a different point of view and it became a hot topic among theorists. Very quickly it became clear what the problem was: the new generators one was adding took all known particle states to particle states with quantum numbers not corresponding to anything known. In other words, this supersymmetry acts trivially on known physics, telling you nothing new. It became commonplace to advertise supersymmetry as relating particles with different spin, without mentioning that no pairs of known particles were related this way. In all cases, a known particle was getting related to an unknown particle. Worse, for unbroken supersymmetry the unknown particle was of the same mass as the known one, something that doesn't happen so the idea is falsified. One can try and save it by looking for a dynamical mechanism for spontaneous supersymmetry breaking and using this to push superpartners up to unobservable masses, but this typically makes an already pretty ugly theory far more so.

The seriousness of this problem was clear by the mid-late 1970s, when I was a student. The one hope was that maybe some extended supergravity theory with lots of extra degrees of freedom would dynamically break supersymmetry at a high scale, leaving the Standard Model as the low energy part of the spectrum. There wasn't any convincing way to make this work, and it became clear that one couldn't get chiral interactions like those of the electroweak theory this way. 1984 saw the advent of a different high scale model supposed to do this (superstring theory), but that's another story.

Looking back from our present perspective, it's very hard to understand why anyone saw supersymmetric extensions of the SM as plausible physics models that would be vindicated by observations at colliders. For example, Gross and Witten in 1996 published an article in the Wall Street Journal explaining that "There is a high probability that supersymmetry, if it plays the role physicists suspect, will be confirmed in the next decade." Ten years later, when the Tevatron and LEP had seen nothing, the same argument was being made for the LHC. After over a decade of conclusive negative results from the LHC, one continues to hear prominent theorists assuring us that this is still the best idea out there and large conferences devoted to the topic. Long ago this became pathological science. In the call for papers, the issue is framed as:

> recent debates on the prospects of low energy supersymmetry in light of its non-discovery at the LHC raise interesting epistemological questions.

From what I can see, the questions raised are not of an epistemological nature, but perhaps the philosophers will find a way to sort this out.

Update: There was a workshop on this last year, abstracts here.

Update: I happened to come across today this 2021 interview of Daniel Freedman by David Zierler. Zierler repeatedly asks Freedman why he has faith in SUSY despite the long history of no evidence. Near the end, Freedman gives this very defensive explanation:

> **Zierler**:
>
> What I hear in your remarks is an adherence to supersymmetry despite its immediate experimental prospects. Is that a belief or is it something more?
>
> **Freedman**:
>
> It's a belief which stems from confidence in the powerful symmetry which underlies the subject. Some human beings indulge in beliefs which have no basis whatsoever. Some of those beliefs are destroying our society at the moment. My belief in a credible and interesting physical theory isn't going to hurt anybody.

Comments

   August 16, 2023

   Your argument for spontaneous supersymmetry breaking being ugly and somehow a desperate attempt to make a theory agree with nature makes no sense. The generalisation of Abelian gauge theories to non-Abelian gauge theories could equally well be accused of being made ugly by desperate attempts to reconcile that with nature by shoving a mass into that theory either by hand or through the Higgs mechanism. You might say that's different, we know it exists in nature, but that's only a posteriori. The fact is both generalisations follow the same kind of logic and motivations. Note also that the first minimal attempts at the non-Abelian generalisations were also wrong. Had we happened to be technogically limited such that going up in energy took a decade per 10 GeV such that the W and Z were supposedly always around the corner but always disappointingly out of reach then no doubt non-Abelian theories would be the target of your polemic. Of course you'll say something like "well that was different, we knew about neutral currents etc." But it's always easy to join up the dots in hindsight. My point is one that in principle non-Abelian and supersymmetric generalisations are very similar in philosophy and what experiment can tell us is something determined by the limitations of technology which nature doesn't give a damn about. Yes it's disappointing that supersymmetry is not where it could have been according to *one* specific argument. But had it taken say a century to go from 40 GeV to 80 GeV you'd have been there every step of the way berating non-Abelian theorists and their unscientific fanciful ideas led by group think. It's ironic that you appear to be completely oblivious to your own twisted reasoning that's no less delusional than Gordy Kane's, only on the opposite anti-supersymmetry end of the spectrum. This anti-supersymmetry narrative is just as tiresome a broken record as the extreme pro-supersymmetry promises. The truth, as always, lies somewhere in the middle.

2. **Peter Woit**
   August 16, 2023

"Molly",
First of all, what's with the fake name (I really doubt your name is Molly)? Could it be because you know very well that arguing that "in principle" the situation of the Weinberg-Salam model and the MSSM are "very similar in philosophy" is so silly that you don't want your real name on it?

As you're undoubtedly well aware, when Weinberg wrote his model down in 1967, the W and Z masses were determined by three parameters. The EM coupling + Fermi constant gave two out of three, so to nail down the W, Z masses you just needed to measure one more parameter (the Weinberg angle). According to you this is much the same thing as the early (and current…) situation of the MSSM, which I believe introduces about 105 new undetermined parameters.

So, you're arguing that having one undetermined parameter and having 105 undetermined parameters is "very similar"? Whose reasoning here is "twisted" and "delusional"?

3. **A long long time ago**
August 16, 2023

Prefacing this by stating that weak-scale supersymmetry is mostly dead (but see Goldman, W (1973)), it's not fair to say that people should have known better. Supersymmetry, like technicolor, is a very good idea that happens to be wrong. Supersymmetry gave a plausible way to make the Higgs mass natural, provides a dark matter candidate and makes the couplings unify more closely. Now it's very easy to cavil at all these things, especially with the benefit of hindsight, and it's clear that things didn't work out. But the physicists excited by supersymmetry weren't idiots and had very good reason to be excited. It's the people who haven't tempered their enthusiasm in response to the experimental evidence that are the problem.

4. **Molly**
August 16, 2023

I am not referring to the Weinberg-Salam model vs the MSSM, which are specific models in a more general framework. I am referring to the framework of non-Abelian gauge theories in general, going back to Yang and Mills, whose mathematical generalisation of the Lie algebra is very much in analogy with the further generalisation to a super Lie algebra. Pauli came up with this before but knew there no other massless gauge bosons that such a generalisation predicts. The Woit of the time would have derided attempts to rescue this theory by breaking the degenerate mass spectrum with an "ugly" spontaneous breaking mechanism. He would have pointed out that Glashow's first minimal SU(2) attempt was already clearly excluded by experiment and scorned further model-building, such as adding an admixture of U(1), as just further desperate attempts to evade experiment rather than abandoning the fantasy. What next, SU(3)? SU(4)? SU(3)xSU(2)xU(1)? Gauge theories aren't even predictive, he would say, you can always change your prediction by choosing a different SU(N)!

The point here is not about number of parameters; parameters parameterise ignorance, and ignorance is a technological limitation. If we happened to have experimental access to the susy-breaking mechanism then it would not be 105 parameters but ultimately a less arbitrary theory where supersymmetry relates parameters by symmetry in the same way we don't consider 8 gluons to be uglier than a single photon because they're related by SU(3). The difference in number of parameters and the extent to which one can determine them experimentally is a point of practicality.

It says something about physicist stereotypes that Molly is unfortunately not taken for granted as a real name for a physicist. In any case please consider that people may have legitimate reasons for preferring not to draw public attention to themselves. Just because you choose to publicise yourself with your arguments does not make anonymous arguments any less valid simply because you can't make a mental profile of the person behind the arguments. Would it help to say I have never published a paper on supersymmetry? Could it be that I am not a lifelong SUSY fanatic but simply a student who took the time to learn the facts and formed my own reasoned opinion?

5. **Peter Woit**
August 16, 2023

A long long time ago,
Technicolor is an excellent example to contrast to supersymmetry. Like SUSY, it's an initially very attractive idea (I was a grad student when it came out and well remember this appeal). But as you try and fit it with reality it gets more ugly (extended technicolor?), and as experimental evidence and theoretical work developed, most people lost interest, with a few hanging in there trying to make it work. This is normal science, and the question with SUSY is why didn't it evolve in the same way, but instead took the turn to the pathological?

I'm very well aware that some of most enthusiastic SUSY advocates are people smarter, better-informed and much harder working than me. The phenomenon of their decades-long enthusiasm for what to me was an unpromising idea has always baffled me. The cases where this continues post LHC-results just strike me as inexplicably bizarre. One can have a reasonable argument about exactly when things turned pathological during the period 1974-present, but I don't think one can reasonably argue that we're not there now.

6. **Peter Woit**
August 16, 2023

"Molly",
Ah, the "framework" nonsense. Can't tell now whether I'm dealing with an earnest fool or a clever troll, strongly starting to suspect the latter. Enough.

7. **I can still remember**
August 17, 2023

The thing I want to do is to defend those physicists in the 80s. It was very reasonable for people to get excited about SUSY. It managed to solve multiple problems at once. And you call the MSSM an ugly theory, but it's really not. It's the phenomenological SUSY breaking lagrangian that's a disaster. There was always hope that a compelling form of SUSY breaking might come along that could tame the mess.

And the difference with technicolor is that, as I understand it, the FCNC results made it pretty challenging relatively soon. For SUSY, it wasn't until the Higgs mass started getting pretty high compared to the Z-mass that the experimental outlook started looking dimmer. As that happened and later with the lack of any sign of superpartners at the LHC and with the SUSY breaking mess not seeming to get much better, you saw more physicists getting pessimistic about weak scale SUSY.

I'm not going to defend the die-hards who still claim that SUSY must be the answer.

8. **Alex**
August 17, 2023

My take: let's leave history for the historians of science. Who cares who was right in the 80s? It was a different context.

To me, the important thing is, what do we do today? The whole field of fundamental physics is in a languid state. Particle physics is in deep coma, quantum gravity is in fantasy land. People with authority are in denial that anything is wrong, science journalism is taken by hype. Young physicists are leaving, those who stay waste their talent in dead end fantasy theories. The whole situation is very dire to me.

9. **Peter Woit**
   August 18, 2023

   Alex,
   I think one of the main reasons for the sorry state of the field is that no one wants to admit being wrong, no one wants to criticize respected figures in the field for continuing to push failed ideas, no one wants to look at what happened and find where things went wrong. So the field is dominated by a 50 year old failed conceptual framework (Planck scale superstrings/supergravity, GUTS, SUSY extensions of SM at some scale). As long as this conceptual framework is what people are trained in and live and work in, the hard job of finding an alternative is much harder.

10. **DB**
    August 19, 2023

    I'm mostly here to agree with "A long long time ago". As a student in the 80's, I learned that technicolor and supersymmetry were the two leading candidates to solve the hierarchy problem (weak scale far below Planck scale, avoid Higgs mass divergence), and technicolor was already on the way out. Plus the dark matter candidate (photino, or more generally neutralino), and the beauty of SUSY SU(5) (converging couplings, less proton decay), made it the most promising avenue of study.

11. **Peter Woit**
    August 19, 2023

    DB,
    Yes, that's the sales pitch that was being made for decades starting in the early 80s. The problem is that a few weak arguments for a complicated theory with no evidence don't add up to a significant argument for such a theory. There always were some prominent people out there making every argument they could think of for SUSY, never breathing a word about the problems with the theory. Anyone mentioning these problems was a "contrarian" even though what they were saying about the problems with the theory was well known in the community.

    If you look at occasions where theorists made bets on SUSY, significant majorities always were betting against, well aware of the problems even it they weren't getting a lot of attention.

12. **Peter Shor**
    August 20, 2023

    It's not just a 50-year-old failed conceptual framework that's the problem.

    The field seems to have this tendency to latch onto unproven ideas long before they've demonstrated their ability to stand up. Look at Susskind's idea of black hole complementarity from 1993, which didn't have very much evidence for it, but was accepted by many researchers for nearly 20 years, until it succumbed to the AMPS paper in 2012.

    I'm not at all convinced the same thing isn't going to happen to the latest craze, non-isometric quantum codes; these seem to violate so many principles of quantum information that I don't see how they can possibly work.

    This wouldn't be a problem, if researchers in the field didn't have the tendency to dismiss alternative ideas with the reasoning "we've already solved that."

13. **Anonymous**
    August 21, 2023

    "My belief in a credible and interesting physical theory isn't going to hurt anybody."

    Except perhaps for the younger researchers who are forced to work on theories they do not believe in to please the boss.

14. **Peter Woit**
    August 21, 2023

    One thing that I realized is strange about about this history is that somehow skeptics of SUSY got labeled as "contrarians", with SUSY "mainstream science", which is completely backwards. From my conversations with theorists over many years, at no time were SUSY models ever something that most people found convincing. For evidence of this, see for instance here
    https://strings.ph.qmul.ac.uk/~dsb/dbwager.pdf

    Given the negative LHC results, at this point I'd argue that anyone still promoting SUSY extensions to the SM is somewhere on the spectrum from "contrarian" to "crackpot", with the likes of Sabine Hossenfelder holding down the centrist, mainstream position.

15. **Amitabh Lath**
    August 21, 2023

    So I'm guessing nobody here feels that the 5.1 sigma discrepancy with theory reported by the Fermilab g-2 experiment is due to SUSY or her siblings?

16. **Kurt Schmidt**
    August 22, 2023

    The muon g-2 discrepancy is a 5.1 sigma discrepancy between two different ways of calculating the dipole moment from the Standard Model, one of which already agrees with the experiment. There is no need for beyond Standard Model physics, much more likely is the case that the other method is flawed and needs correcting.

17. **Peter Woit**
    August 22, 2023

    Amit,
    At this point the SM being wrong by 5.1 sigma is an extraordinary claim, and given the theoretical complexities, the evidence is far from extraordinary. Seems likely one of the theory calculations is just wrong (or uses data wrong).

    If the SM is wrong, personally I doubt what we're seeing is SUSY, should be something much more interesting….

18. **Amitabh Lath**
    August 22, 2023

    Kurt, should we be giving more weight to the theory that agrees with experiment (the BMW calculation) or the other one that shows the huge tension (if they have a clever

acronym I missed it)? The latter seems to be a bigger collaboration so I have been hedging that way.
In any case, the big theory issue is lack of e+e- –> hadrons data, which is being addressed. The g-2 experiment is still not systematics limited and has a lot more data to analyze. So both theory and experimental uncertainties will shrink in the next 2 years of so. As Peter says, probably not SUSY but interesting…

19. **Hiro Kawabata**
August 22, 2023

It seems that the theorists have considerable work to do on their calculations, including discrepancies in the data used for the dispersive method and the discrepancy between the dispersive and lattice QCD methods, before any claims of BSM physics can be made:

https://muon-gm2-theory.illinois.edu

20. **Peter Woit**
August 23, 2023

Maybe that's enough about muon g-2, where the issues have nothing to do with SUSY.

A generic problem with the idea of using precision measurements like g-2 to get information about BSM physics is that if your BSM models (like MSSM) have loads of extra particles and parameters, a measured g-2 anomaly due to MSSM effects is going to give you one number, which is a very complicated function of the the many parameters you'd like to know about. In any case, right now we don't even have that.

21. **adrianmigueldiego**
August 24, 2023

Dear Peter,
you should exercise some prudence when discussing Daniel Freedman.

Freedman is a very good mathematical physicist. He never over claimed
his results. He has a long trajectory of serious, correct and hard work. You are criticising him for what is an opinion (or a belief). He states this very clearly. He never forced anyone to work on his topics. Young researchers approached him in the last 50+ years (to work with him). Daniel Freedman is an example of serious, hard, concentrated work. Sticking to correct and elaborated calculations.

Again, you should be less critic of serious people, in particular if they state their beliefs and opinions, making clearly their character!

22. **Peter Woit**
August 24, 2023

adrianmigueldiego,

Note that what I was doing was not criticizing Freedman or his work, but pointing to a long interview with him that people could read for themselves. I found his defense of continuing to work on a failed research program revealing.

As for not criticizing serious people, sorry, but when their ideas are wrong they (the ideas) should be criticized, and I'm not going to apologize for doing so.

23. **kitchin**
September 24, 2023

Again I'll recommend also the Frenkel interview by Brian Keating, because it's shorter. https://www.youtube.com/watch?v=b67o24J3bAs

At 27:00 Keating asks him about string landscapes and multiverses, but turns the question to whether there could be different maths in these universes, perhaps even without proof by contrapositive ("modus tollens"), or at least a different value of pi. So what is Frenkel to do with such a question? He starts talking about an alien species without numbers, such as the unitary intelligence in the movie Solaris, that would discover our same math by homotopy theory! He illustrates homotopy classes by imagining winding dental floss around your finger. Now that's a string.

Strings are otherwise not mentioned in the interview as I recall it.

While it's a popular math book, I would have liked to have had Frenkel's Love and Math in grad school, to get an overview of the specialties I was studying. It's a good book for many reasons, and can be usefully skimmed in about the same amount of time as the longer videos, or maybe twice that time.

Various and Sundry

August 24, 2023
Categories: abc Conjecture, Uncategorized

The math department at Columbia this fall will be hosting three special lecture series, each with some connection to physics (at least in my mind…):

- Sergiu Klainerman will be lecturing on the proof of nonlinear stability for slowly rotating black holes, Wednesday afternoons at 2:45.
- Nikita Nekrasov's lectures will be on The Count of Instantons, Friday afternoons at 1:30.
- The Eilenberg lectures will be given by Laurent Fargues on Some new geometric structures in the Langlands program, Tuesdays at 4:10.

Some other less inspirational topics:

- The news this summer from the LHC has not been good. On July 17 a tree fell on two high-voltage power lines, causing beams to dump, magnets to quench, and damage (a helium leak) to occur in the cryogenics for an inner triplet magnet. See here for more details. Fixing this required warming up a sector of the ring, with the later cooldown a slow process. According to this status report today at the EPS-HEP2023 conference in Hamburg, there will be an ion run in October, but the proton run is now over for the year, with integrated luminosity only 31.4 inverse fb (target for the year was 75).
- The Mochizuki/IUT/abc saga continues, with Mochizuki today putting out a Brief Report on the Current Situation Surrounding Inter-universal Teichmuller Theory (IUT). The main point of the new document seems to be to accuse those who have criticized his claimed proof of abc of being in "very serious violation" of the Code of Practice of the European Mathematical Society. This is based upon a bizarre application of the language

  > Mathematicians should not make public claims of potential new theorems or the resolution of particular mathematical problems unless they are able to provide full details in a timely manner.

  to the claim by Scholze and Stix that there is no valid proof of the crucial Corollary 3.12. It would seem to me that Mochizuki is the one in danger of being in violation of this language (he has not produced a convincing proof of this corollary), not Scholze or Stix. The burden of proof is on the person claiming a new theorem, not on experts pointing to a place where the claimed proof is unsatisfactory. Scholze in particular has provided detailed arguments here, here and here. Mochizuki has responded with a 156 page document which basically argues that Scholze doesn't understand a simple issue of elementary logic.

  Also released by Mochizuki today are copies of emails (here and here) he sent last year to Jakob Stix demanding that he publicly withdraw the Scholze-Stix manuscript explaining the problem with Mochizuki's proof. Reading through these emails, it's not surprising that they got no response. The mathematical content includes a long section explaining to Scholze and Stix that the argument they don't accept is just like the standard construction of the projective line by gluing two copies of the affine line. On the topic of why he has not been able to convince experts of the proof of Corollary 3.12, Mochizuki claims that he convinced Emmanuel Lepage and that

  > one (very) senior, high-ranking member of the European mathematical community has asserted categorically (in a personal oral communication) that neither he nor his colleagues take such assertions (of a mathematical gap in IUT) seriously!

  I suppose this might be Ivan Fesenko, but who knows.

- Since the Covid pandemic started, the World Science Festival has not been running its usual big annual event here in New York. This fall they will have an in-person event, consisting of four days of discussions moderated by Brian Greene. In particular there will be a panel Unifying Nature's Laws: The State of String Theory evaluating the state of string theory, featuring four of the most vigorous proponents of the theory (Gross, Strominger, Vafa and Witten). I suspect their evaluation may be rather different than that of the majority of the theoretical physics community.

Update: Quanta has a very good article by Kevin Hartnett about the telescope conjecture in homotopy theory and its recent disproof. This is due to work of Ishan Levy, Robert Burklund, Jeremy Hahn and Tomer Schlank, all of whom gave talks on the subject at the Oxford conference this past June in honor of the 65th birthday of Mike Hopkins. Videos of the talks are available here. If homotopy theory is not your thing, and if you haven't heard Graeme Segal speak recently about his thinking on the definition of quantum field theory, you could instead watch his talk.

Update: Video of Klainerman's lectures will be available here:
https://youtu.be/CkyG4VnRXps?si=1xhZx-UyRI2I52sr

Comments

1. **Kurt Schmidt**
   August 24, 2023

   David Gross was born in 1941, Edward Witten in 1951, Andrew Strominger in 1955, and Cumrun Vafa in 1960. Why did they decide to select 3 Boomers and 1 member of the Silent Generation to host the string theory panel, rather than a younger string theorist who could speak for the younger generations?

2. **Peter Woit**
   August 24, 2023

   Kurt Schmidt,
   With Witten in the lead, all four of them jumped on the string theory unification bandwagon at the beginning in 1984-85. Since then and to the current date, they have been among the most prominent proponents of the subject. So, if you want to know what the hard-core, true believers who have been at it for nearly forty years think, this is the right panel. If you wanted a sober evaluation of where we are after those forty years, you'd choose a different panel.

3. **Low Math, Meely Interacting**
   August 25, 2023

   I don't wish to pile on the ageism, but the idea of "string unification" seems to have become rather quaint these days, hasn't it? What would such a panel have to say that would be of much relevance to even string theory's most ardent supporters at present? It's been many years now that all the press seems to be about using string-adjacent techniques to make toy models of black holes, wormholes, condensed matter and so forth. Witten himself explicitly capitulated on anthropism, so what more is there to discuss about the parochial details of our pocket of the multiverse?

4. **Peter Woit**
   August 25, 2023

   LMMI,

Of the five (including Greene), Vafa is the only one still trying to make an argument that string theory has some implications for the real world (his "swampland program"). All the others have completely given up on this, but continue to try to sell this failure as some sort of success. Andy Strominger takes this the furthest, see for instance here
https://www.math.columbia.edu/~woit/wordpress/?p=11138
dealing with the failure of 1980s hype by claiming that string unification would have been boring small potatoes:
"I think that the idea that people were excited about back in 1985 was really a small thing, you know, to kind of complete that table that you put down in the beginning of the spectrum of particles…"
Now he's replacing that with new, improved hype about space-time. It seems to me that what he learned from the past was that hype works, best to just keep at it.

5. **David Roberts**
August 28, 2023

Perhaps if Mochizuki can convince Lepage to publicly state he thinks the IUT papers are all correct, and *why* the proof of Corollary 3.12 in IUT3 is solid, then Mochizuki might have a tiny bit more support. At present, it seems like hearsay. Also, all this vague references to senior experts etc without saying who they are is of rather little worth without them being public in their support.

6. **Peter Woit**
August 28, 2023

David Roberts,
Mochizuki gives a list of those who he says have worked on understanding the Scholze/Stix criticism of the proof:
""Yuichiro Hoshi, Go Yamashita, Arata Minamide, Akio Tamagawa, Ivan Fesenko, Mohamed Saidi, Emmanuel Lepage, Benjamin Collas."
The damning fact is that to this day none of those people has written or lectured on their supposed understanding of how the proof overcomes the Scholze/Stix objections.

As for his claim about a "(very) senior, high-ranking member of the European mathematical community", Mochizuki completely blows up the credibility of this claim by saying that none of this person's colleagues take Scholze/Stix seriously. He repeatedly has gone on like this, claiming that no one he talks to takes the objections to the proof seriously, or knows anyone who does, which indicates that he has isolated himself to a disturbing extent.

7. **closed timeline curve**
August 29, 2023

Prof. Klainerman used all his might
to deduce a new theorem last night.
It's a breakthrough for sure,
but the proof is obscure
and takes two thousand pages to write.

8. **Alex**
August 30, 2023

Is there a video of the talk by Klainerman somewhere? I'm quite interested in watching that. Thanks!

9. **Peter Woit**
September 1, 2023

Alex,
I don't know if there will be video of one or more of these three lecture series this fall. If there is, I'll add a link here, also likely available at Columbia math dept. youtube channel.

10. **Timothy Chow**
September 2, 2023

I was under the impression that Scholze and Stix did not publish their report, but gave it to Mochizuki privately, for him to do with it as he wished. Mochizuki then chose to post it on his own website. Do I have the facts right? If so, then it would seem strange for Mochizuki to request that Scholze and Stix "publicly withdraw" their "manuscript" when Scholze and Stix were not the ones to publicly release the report in the first place.

11. **Marvin**
September 9, 2023

I can't make it for the Laurent Fargues presentation on the 12th, anybody know if it will be available online after? Thanks

12. **Peter**
September 12, 2023

Will the Nekrasov lectures be made public?

13. **Peter Woit**
September 15, 2023

Peter,
Yes. First should appear on dept website next week.

What Does Spec Z Look Like?

September 14, 2023
Categories: Langlands

This week Laurent Fargues has started a series of lectures here at Columbia on Some new geometric structures in the Langlands program. Videos are available here, but unfortunately there is a problem with the camera in that room, making the blackboard illegible (maybe we can get it fixed…). Fargues however is writing up detailed lecture notes, available here, so you can follow along with those.

Fargues is covering the story of the Fargues-Fontaine curve and the relationship between geometric Langlands on this curve and arithmetic local Langlands that he worked out with Scholze recently. On Monday Scholze gave a survey talk in Bonn entitled What Does Spec **Z** Look Like?, video available here. Scholze's talk gave a speculative picture of how to think about the global arithmetic story, with Spec **Z** as a sort of three-dimensional space. One thing new to me was his picture of the real place as a puncture, with boundary the twistor projective line. He then went on to motivate the course he will be teaching this fall with Dustin Clausen on Analytic Stacks. Here at Columbia we have an ongoing seminar on some of the background for this, run by Juan Rodriguez Camargo and John Morgan.

Update: Peter Scholze next week at the Rapoport conference will be giving a talk on new ideas about the twistor $$\mathbf{P}^1$ and real local Langlands. His abstract is

> Towards a formulation of the real local Langlands correspondence as geometric Langlands on the twistor-$\mathbf P^1$
>
> We will propose a formulation of the local Langlands correspondence for complex representations of real groups in terms of a(n everywhere unramified) geometric Langlands correspondence on the twistor-$\mathbf P^1$, analogous to our work with Fargues in the case of p-adic groups. This is motivated by discussions with Rodriguez Camargo, Pan, le Bras and Anschütz on the analogous case of locally analytic p-adic representations, and is different from the previous work of Ben-Zvi and Nadler in a similar direction. In particular, on the geometric side we get representations of the real group, encoded in terms of liquid quasicoherent sheaves on $$; and on the spectral side, we get representations of the real Weil group W_R, or rather vector bundles on $$.

   Peter wrote:

   "Scholze's talk gave a speculative picture of how to think about the global arithmetic story, with Spec(ℤ) as a sort of three-dimensional space."

   While there's speculation in Scholze's talk, I want to let beginners know that the 3-dimensional nature of Spec(ℤ) is not a speculative thing. In 1973 Barry Mazur worked out the etale cohomology of Spec(ℤ) ∪ {∞} and showed it has nontrivial cohomology up to and including dimension 3:

   http://www.numdam.org/articles/10.24033/asens.1257/

   (Apparently he also showed its etale cohomology vanishes in higher dimensions 'up to 2-torsion'. Has anyone later computed the 2-torsion?)

   There has subsequently been a lot of work on how Spec(ℤ) ∪ {∞} resembles a 3-sphere and primes act like knots in this 3-sphere. Here are some relatively easy ways to learn more:

   Chao Li and Charmaine Sia, Knots and primes, https://www.julianlyczak.nl/seminar/knots2016-files/knots_and_primes.pdf

   Barry Mazur, Thoughts about primes and knots, https://www.youtube.com/watch?v=KTVEFwRbuzU

   Masanori Morishita, Analogies between knots and primes, 3-manifolds and number rings, https://arxiv.org/abs/0904.3399

   For people who know a fair amount of math but are in a rush, I recommend just checking out this analogy table from Li and Sia's course notes:

   https://math.ucr.edu/home/baez/mathematical/knots_and_primes_1.jpg

2. **jack morava**
   September 15, 2023

   what John said.

3. **Peter Woit**
   September 15, 2023

   John,
   Thanks for writing up that background!

   The word "speculative" might not have been the right one. For the things John refers to it's important to keep in mind that these are just analogies. Spec Z can't be an actual 3-manifold.

   In the talk Scholze explained how his work with Fargues on the relation to geometric Langlands fits in with these analogies. My understanding now is that near the puncture corresponding to the infinite prime the "space" should have an action of the positive reals, looking like the twistor P^1 for a fixed value. Near a finite prime it should again have such an action, looking like a torus at a fixed value. Fargues has promised me he'll explain this in detail in his lectures. This is all supposed to fit in with work of Deninger in which there's a foliated space with a flow acting on it analogous to the Frobenius. Note that Deninger's program is aimed at the Riemann hypothesis, so these are deep waters…

   Perhaps what is "speculative" is the idea that there is some sort of global version of the Fargues-Scholze story (which is local at each prime), and that this global version would give not just an analogy, but an actual space corresponding to Spec Z (for some exotic definition of what a "space" is).

4. **John Baez**
   September 15, 2023

Hmm, Scholze actually makes a cryptic reference to the 2-torsion in the etale cohomology of Spec(ℤ) starting at around 19:15 in his talk, and leading up to "if you think deeply about the etale cohomology of Spec(ℤ) then there is some funny 2-torsion phenomenon having exactly to do with Gal(ℂ/ℝ) having infinite cohomological dimension, and if you just use $\mathbb{R}P^2$ instead you get a much better answer".

I *wish* I could think deeply about the etale cohomology of Spec(ℤ). Alas I can't, but I see that Gal(ℂ/ℝ) = ℤ/2 has as its classifying space ℝP^∞, whose cohomology has 2-torsion (namely, it's ℤ/2) in every dimension. Is this what Mazur found for the etale cohomology of Spec(ℤ) ∪ {∞}?

This is pretty technical but maybe someone reading this will know.

5. **John Baez**
September 15, 2023

Sorry, I meant "in every even dimension".

6. **jsm**
September 15, 2023

Actually, it was Artin and Verdier who first worked out the etale cohomology of things like Spec(Z) (Artin-Verdier duality), but it was Mazur who popularized it. Let U=Spec(Z). It is possible to define a cohomology of U "with compact support" that fits into a long exact sequence
H_c^r(U.F) -> H^r(U,F) -> H^r(Spec R,F)->
The cohomology with compact support behaves more or less as it should, but the etale cohomology of the real numbers is just Galois cohomology with Galois group Z/2Z which has periodic cohomology, and so goes on for ever. Artin used to say that "Spec Z is singular at infinity".

7. **Thomas**
September 15, 2023

The lectures by Gross which Fargues mentions in his talk seem to be available as text at: http://www.math.columbia.edu/~chaoli/docs/EilenbergLectures.html

8. **jack morava**
September 15, 2023

IIRC the mod two stuff is in the original Artin-Tate seminar notes where they calculate the Galois cohomology of the idele-class group and wrestle with the solenoid?

9. **John Baez**
September 16, 2023

Thanks, jsm!

10. **DrDave**
September 17, 2023

Re: Black (Green) board legibility:
The YT video is super low resolution, below what most phones and cameras record,
so there is a good chance there is an original video with 720p or higher resolution. If so, it would be simple to boost the sharpness and contrast.
However, if the presenter has slides or notes, then that is even easier.

11. **yyb**
September 17, 2023

I don't know if this is related to analytic stacks or not, but 4 months ago someone asked on MO about Dustin Clausen's talk about the "modified Hodge Conjecture" here https://mathoverflow.net/questions/446978/clausens-modified-hodge-conjecture/446992#446992 and Clausen's answer is that the modified Hodge conjecture is related to "analytic k-theory" that's possibly related to analytic stacks that they're going to talk about this fall.

12. **Peter Woit**
September 17, 2023

DrDave,
Yes, the problem with the video is the very low resolution, which is what Columbia's zoom configuration gives for cloud-stored recordings. Currently discussing this with the Columbia zoom people.

13. **Will Sawin**
September 17, 2023

If I can add some detail to what jsm said, the compactly-supported cohomology behaves as it should in that it has a form of Poincare duality which in particular means it vanishes in degrees above 3. So together with the fact that the cohomology of Spec R with coefficients in Z/2 is equal to Z/2 in every nonnegative degree, that immediately tells you that the ordinary cohomology of Spec Z with coefficients in Z/2 is equal to Z/2 in every degree >3.

Note that this kind of situation is exactly what you see for noncompact manifolds – a long exact sequence between the ordinary cohomology, the compactly-supported cohomology, and the cohomology of a neigborhood of infinity. So from this perspective Spec Z behaves like a non-compact 3-manifold, except that a neighborhood of infinity is homotopic to the classifying space of Z/2Z, i.e. to infinite-dimensional real projective space. So somehow we have a 3-manifold which near infinity looks infinite-dimensional.

Somehow the twistor P^1 must be related to this picture by the close relationship between the twistor P^1 and two-dimensional real projective space and some kind of approximation between infinite-dimensional real projective space and two-dimensional real projective space.

Let me also point out that the notion of a 3-manifold with an action of R should not be very mysterious. A very classical way of producing a 3-manifold is to start with a surface and an automorphism of the surface, take the surface cross the interval, and then glue the two sides using the automorphism, producing a 3-manifold fibered over the circle. Such 3-manifolds naturally carry an action of R (locally acting by translation by the interval), whose periodic orbits correspond to fixed points of powers of the automorphism.

The relevance of this to Spec Z (at least in a way that makes sense to me) goes something like this: An algebraic curve over a finite field is fibered over the spectrum of the finite field with fiber an algebraic curve over an algebraically closed field. Algebraic curves over C are Riemann surfaces, so the fiber behaves like a surface, and finite fields have Galois group Z-hat, so the spectrum of the finite field behaves like the classifying space of Z (fields behaving like classifying spaces of their Galois group), and thus like the circle. So the curve behaves like a fibered 3-manifold, with the automorphism being the generator of the Galois group, i.e. Frobenius. Periodic orbits correspond to fixed points of powers of Frobenius which are the same thing as prime ideals of the ring of functions on the curve.

But Z behaves like the ring of functions on a curve since both are Dedekind domains of finite type, so its spectrum should behave like a 3-manifold with an action of R whose periodic orbits correspond to prime ideals, i.e. primes.

14. **Will Sawin**
September 18, 2023

After watching the video, indeed it seems to be RP^2, i.e. the quotient of the twistor P^1 by complex conjugation, rather than the twistor P^1 itself, that appears.

The fact that it's RP^2 / the twistor P^1 that appears seems to be a way of capturing Hodge theory, so I guess the reason we see RP^infinity from the perspective of the étale cohomology of Spec(Z) is that étale cohomology doesn't really capture Hodge theory.

15. **John Baez**
September 19, 2023

Will Sawin wrote:

"But Z behaves like the ring of functions on a curve since both are Dedekind domains of finite type, so its spectrum should behave like a 3-manifold with an action of R whose periodic orbits correspond to prime ideals, i.e. primes."

I haven't had time to watch the whole video yet – just the first part. So, if anyone feels like it, I'd love to hear how close Scholze is to formalizing this hand-wavy but delightful intuitive picture using his new ideas.

(I'll watch the rest as soon as I have time.)

16. **Will Sawin**
September 20, 2023

@John Baez: The thing that most surprised me about the construction is that the action of R is completely literal – there is really a one-parameter continuous (in the appropriate sense) family of automorphisms (or endomorphisms – if I understand right one starts with a space with a semigroup action and can use it to construct a space with a group action by a general construction). I wouldn't have expected such an action to literally exist on any reasonable variant of Spec Z.

On the other hand, I don't think Scholze made any claims in the talk about the space being like a manifold. Well, the space is defined by starting with an (suitably analytified) spectrum of a ring of power series, so I guess one can locally (in a certain sense) express functions on the space as power series, which makes it like a manifold, but this is somewhat indirect (and anyways these are 1-variable power series, not 3-variable). Since the space is closely related to Spec Z there perhaps exists some cohomology theory for it which recovers the cohomology of Spec Z and thus makes the space behave homologically like a 3-manifold.

For the intuition about Spec Z locally looking like certain spaces at certain points, the talk sketches some local picture along these lines. This is localization in the algebraic geometry sense, i.e. potentially arbitrary maps from another space to your space, so it doesn't completely fit the handwavy intuition of literal open sets.

17. **anon**
September 20, 2023

Presumably this 3-manifold is still very prickly – spine like, like the 1-skeleton it maps to. I mean, do the primes 3 and 5 (say) interact only at the generic point? Or do we expect the orbits around 3 wind around the orbits around 5 (and so forth), producing Massey products or some such, in an as yet unseen global theory? That would be rather shocking. But if not, what number theoretic information is this 3-manifold picture going to carry?

(I'm still reading Bhatt's wonderful prismatic gauge lectures, and havent absorbed the advances at p – neither in stacky language nor via TCH etc. So I'm somewhat behind.)

18. **jack morava**
September 20, 2023

… do the primes 3 and 5 (say) interact only at the generic point? … Or do we expect the orbits around 3 wind around the orbits around 5 (and so forth), producing Massey products or some such, in an as yet unseen global theory? That would be rather shocking.…

For such products see Morishita, Masanoi, Milnor invariants and Massey products for prime numbers, Compos. Math. 140 (2004) MR2004124, and John B's citation for Morishita upthread.

19. **anon**
September 20, 2023

Thank you Jack! That's very pretty. So "of course" primes p,q interact – quadratic reciprocity is such an interaction. Properties of global etale cohomology of Spec of a number field already allow one to see this kind of phenomena as a Massey product. Scholze's 3 manifold \`Spec Z' would give a \`cycle theoretic' interpretation of this as an actual linking number between actual R-orbits. And presumably much more?

Any predictions on what new \`hard' information such a picture of Spec Z would tell us?

(I'm already blown away by the stacky/de Rham intepretation of d dimensional varieties over finite fields having etale cohomological dimension 2d+1; Bokstedt periodicity and Bott, R[u,v]/uv-p. And that's just the local picture.)

Also: is it trolling on this blog to ask whether there are \`arithmetic' versions of 3+d-dim TFTs, and what they assign to d-dimensional arithmetic varieties? And what an honest number theoretic punchline of having the evident analogous structure would be?

The enormous gulf between the easy to predict analogies, and the often simple but unknown definitions needed to make them work never ceases to amaze.

20. **Another anon**
September 21, 2023

This is maybe a little bit off-topic, but there is a Simons Collaboration on Perfection in Algebra, Geometry, and Topology to tackle major open questions in number theory, algebraic geometry, p-adic geometry, commutative algebra, and algebraic topology here: https://scop.math.berkeley.edu/ with 13 people as principal investigators (including Scholze, Clausen, Bhatt, Lurie, Mathew, etc) with Martin Olsson as the collaboration director.

21. **David Ben-Zvi**
September 23, 2023

@anon: Arithmetic (Topological) Quantum Field Theory is in fact a thriving research area, initiated by Minhyong Kim. You can see more about the topic from the talks at this seminar https://homepages.warwick.ac.uk/~u1972347/AGQFT.html and there will be a program on Arithmetic QFT at Harvard's Center of Mathematical Sciences and Applications Feb-March 2024, with a research conference March 26-29.

22. **Kirti Joshi**
September 24, 2023

@Dr. Woit: In the context of the current discussion here, let me point out my preprint, Constructions II(1/2), posted on the arXiv on May 17, 2023. My paper furthers the analogy between Riemann surfaces and Number Fields and establishes a Teichmuller Theory of Number Fields. Specifically in the context of this discussion here, let me say that in my work I construct a global topological object which resembles Fargues-Fontaine curves (of both Y and X types) at all primes of the number fields simultaneously.

My treatment at archimedean primes is different from Fargues's treatment, but also closer to the original Banach space approach of Fargues-Fontaine at finite primes. Notably, I work with a certain (infinite dimensional) complex Banach algebra which serves as the ring of functions on the archimedean Fargues-Fontaine curve (of my theory)–and this curve appears as the spectrum (of maximal ideals) of this Banach algebra of my theory–just as the closed maximal ideals of the Fargues-Fontaine algebra B are related to the p-adic Fargues-Fontaine curve.

This global object which I construct is equipped with a natural action of the multiplicative group of the number field which at each prime operates through Frobenius morphism (at each finite prime) and through the multiplicative group at archimedean primes (I assume that the number field has no real embeddings for simplicity). [Further properties of this global object are established in my paper.] This global topological object is metrisable and locally i.e. at each prime of the number field, this object is equipped with the natural metric provided by Fargues-Fontaine theory.

I show that the points of this global topological object parameterize distinct arithmetic avatars of the number field just as points of the Teichmuller space of a Riemann surface parameterize different complex function theories (i.e. distinct complex structures) on a fixed topological surface.

Hence my work further deepens the analogy between Number Fields and Riemann surfaces.

Each avatar of the Number Field (called an arithmeticoid in my paper) also provides holomorphic structures (at all primes) in the sense of Berkovich analytic spaces (at archimedean primes one obtains analytic spaces) and I show that deforming the avatar of the number field also deforms Berkovich analytic structures. This has consequences for anabelian geometry related to Mochizuki's IUT. Mochizuki, in his IUT, has asserted the existence of deformations of arithmetic structure of a number field whose existence I have established in my work.

Current versions of my preprints related to this can be found on the arXiv using this link or through my webpage. I will be happy to answer any questions.

23. **Kirti Joshi**
September 27, 2023

Let me further remark on one important aspect of my global arithmetic construction alluded to in my comment above. My (global) construction has certain automorphisms/symmetries (at all primes) which have a nice geometric counterpart which appears in the Virasoro Uniformization Theorem of Beilinson-Schechtman (also Kontsevich) via action of automorphisms of a punctured formal disc–detailed, for instance, in the Ben-Zvi–Frenkel book in 17.3.2). The Virasoro uniformization and related actions plays an important role in Beilinson-Drinfeld work on Geometric Langlands, and is also of significance in Conformal Field Theory.

Mochizuki, in his IUTT, asserts that automorphisms of certain unit groups change arithmetic holomorphic structures (he calls this property Indeterminacy Ind2).

In my Constructions I paper, I have proved a precise version of this important assertion. [Informally speaking, my approach to establishing this claim is that one should work with the automorphisms of the perfectoid punctured unit disc–precise statements are in my paper. In my Untilts paper, I provide a natural geometric construction of arithmetic holomorphic structures which also establishes their existence in Mochizuki's context.]

So the global object I construct is at once geometric and arithmetic in nature and allows me to prove a precise version of Mochizuki's claim (alluded to above). My approach also agrees with Fargues-Fontaine "holomorphic functions of the prime number p" point of view (at all primes p) and automorphisms of the relevant unit group provides "holomorphic changes of the coordinate p" (p is any prime) in a manner entirely analogous to the Beilinson-Schechtman setting and also agrees with Mochizuki's multiplicative monoidal approach to thinking about number fields and varieties over them. Minhyong Kim's theory requires working with fundamental groups arising from distinct base-points (and paths connecting them)–and my theory (and Mochizuki's IUTT) requires working with tempered fundamental groups arising from distinct base-points.

Given the close parallel the above described object and its symmetries bear to its counterparts in Geometric Langlands (and Conformal Field Theory), it would be interesting to see if it plays an analogous role in the corresponding arithmetic contexts.

September 29, 2023

Will the Rapoport conference talk be available online? I'm quite interested in watching that. Thanks!

Frenkel on String Theory

September 20, 2023
Categories: Uncategorized

Curt Jaimungal's Theories of Everything podcast has a new episode featuring a long talk with Edward Frenkel (by the way, I'll be doing one of these next month). A few months ago I wrote about a Lex Fridman podcast with Frenkel here. While both of these are long, they're very much worth watching.

While there's some overlap between the two podcasts, some different topics are covered in the new one. In particular, one thing that happened to Frenkel since last spring is that he attended Strings 2023 and gave a talk there (slides here, video here). The experience opened his eyes to just how bad some of the long-standing problems with string theory have gotten, and starting around here in the podcast he has a lot to say about them.

It's pretty clear that his reaction to what he saw going on at the conference was colored by his experience growing up in late Soviet-era Russia, where the failure of the system had become clear to everyone, but you weren't supposed to say anything about this. He pins responsibility for this situation on senior leaders of the field, who have been unwilling to admit failure. As part of this, he acknowledges his own role in the past, in which he was often happy to get some reflected glory from string theory hype by playing up its positive influence on parts of mathematics while ignoring its failure as a theory of the real world. In any case, I urge you to watch the entire podcast, it's well worth the time.

For a very different perspective on the responsibility of senior people for string theory's problems, you might want to take a look at the bizarre twitter feed of stringking42069, which may or may not be some very high-quality trolling. In between replies and tweets devoted to weightlifting, weed and women, the author has some very detailed and mostly scornful commentary on the state of the field and the behavior of its leaders. His point of view is that the leaders have betrayed the true believers like himself, abandoning work on the subject in favor of irrelevancies like "it from qubit", in the process tanking the careers of young people still trying to work on actual string theory. For a summary of the way he sees things, see here and here. Comments on specific people here and here.

This weekend here in New York if you've got $35 you can attend an event bringing together five of the people most responsible for the current situation. I doubt that the promised evaluation of "a mathematically elegant description that some have called a "theory of everything."" will accurately reflect the state of the subject, but perhaps some of the speakers will have listened to what Edward Frenkel has to say (or read stringking42069's tweets) and realized that a new approach to the subject is needed.

Update: Curt Jaimungal at the Theories of Everything podcast has a new episode, discussing quantum gravity with Jonathan Oppenheim. Around 1:10 Oppenheim has some comments about the current problem of few opportunities for young people to pursue new ideas in this field, including:

> You know, it's a multifaceted problem. I think part of it is that for whatever reason, people like to work on the same thing as everyone else. And I mean, we are social creatures, and we want to be part of the community. And so if there's a big community doing something, then it's very natural to want to be part of that community and do that research.
>
> But it's, I feel like it's gotten to quite an extreme. It feels quite extreme at the moment, I feel like even when I was a student, you know, there were various researchers who, I would say, didn't have a firm allegiance to say, string theory or loop quantum gravity, and you could kind of work with one of them and work on your own approach. Whereas I think now, for whatever reason, the landscape has just become a lot more divided into different communities who do different things, and it's much harder to go off on your own. And maybe that's just because it's students' worry that if they go off on their own, they won't get a job. I think that's probably a big part of it.

Update: Bringing together this and the last posting, if you'd like more Frenkel and more Langlands, there's a new Numberphile video out.

Comments

1. **Z Y**
   September 20, 2023

   That's a who's who ensemble of ST at NY, a kind of last hurrah, have these four came together at a public/scientific conference panel before? Hopefully a video will be uploaded somewhere.
   The state of the matter is such, specially on laymen circles, that I reckon it will be disappointing if none of them at least show some reflection about the urgent need to explore new ideas outside of ST if we are going to make any progress at fundamental physics

2. **Peter Woit**
   September 20, 2023

   ZY,
   I assume a video will be available at some point. I can't remember an event ever that brought all of them together, especially not to discuss the state of string theory.

   It is a remarkable group in the sense that each of them has played and continues to play a large role in the hyping of string theory, with most of them at it for nearly forty years. When Frenkel refers to those who have responsibility for creating the problem with string theory and for now doing something about it, it's very much this group.

3. **Allen M.**
   September 20, 2023

   Peter,

   I have been reading your blog for a decade. To see you being vindicated in this way warms my heart.

   Thank you for everything.

4. **Peter Woit**
   September 21, 2023

   Allen M.,
   Thanks, but I'd much rather see something positive getting done about the problems with fundamental theoretical HEP research that I've pointed out, and unfortunately I don't see that happening. Rather, the field shows little sign of facing up to its problems, instead just goes from bad to worse.

   If we're in an analog of the end-days of the failed Soviet system, there's no reason to be sure something better lies in the future.

5. **Hiro Kawabata**
September 21, 2023

Another event that may be of interest.
On that may be more forward looking:

"Puzzles in the Quantum Gravity Landscape: viewpoints from different approaches"

https://events.perimeterinstitute.ca/event/47/

Oct 23 – 27, 2023
Perimeter Institute for Theoretical Physics

6. **Alessandro Strumia**
September 23, 2023

Dear Hiro, the String King 42069 (Lubos 2.0?) account recommended by Peter writes that the conference you recommend is "crackpots", see https://twitter.com/stringking42069/status/1700574269573374384

A problem in the quantum gravity community is the lack of criticism towards those theorists who make big claims based on weak logic. The conference you suggest has an unnecessary Code of Conduct that limits the open criticism needed to keep untestable quantum gravity serious, see https://events.perimeterinstitute.ca/event/47/page/164-respectful-environment-code-of-conduct.

Even worse, the registration page forces participants to endorse partisan political values and beliefs, such as equity and μaggressions. Most physicists might not know the hidden political meaning of these kind of words, designed to sound nice. As this political stuff has nothing to do with quantum gravity, I cannot attend this conference.

7. **Low Math, Meely Interacting**
September 23, 2023

Thanks for the pointer to Curt Jaimungal's podcast. Among other content I find less edifying are some real gems, foremost this discussion. Frenkel is a remarkable human being.

He rightly emphasizes his observation of a phenomenon described many times elsewhere (notably by you and Sabine Hossenfelder) in regards to this subject, namely the lengths human beings will go to avoid cognitive dissonance. For those with a passing interest in psychology, it's a well-established fact that we see it all around us while being almost incapable of recognizing how profoundly it shapes our own thoughts and actions. It's the mechanism that allows groupthink to propagate and overwhelm all collective rational thought. Every leader depends on it to stay focused, and every apparatchik to stay sane.

I agree with you, Peter, that it's the unique liability of the true genius that he or she becomes convinced their intellectual powers make them exceptional in ways they are not. Frankel shows great integrity and compassion in pointing out there's no shame in being ordinary in this way. But rarely are we rewarded for admitting it, despite the good it would do the individual and their community.

8. **Peter Woit**
September 23, 2023

Alessandro Strumia,
It seems quite possible StringKing is a parody account of a clever young theorist making fun of string theory fanatics (e.g. the answer to all problems is to read Polchinski???).

Given my allergy to moral posturing and those who want to enlist everyone in their self-righteous crusades, I'm not very sympathetic to having long codes of conduct like the Perimeter one and requiring people to sign them. If StringKing showed up in real life at a conference behaving like on Twitter (unlikely….) maybe you would need a code of conduct to deal with him.

Your idea that this kind of code of conduct will interfere with appropriate scientific criticism would apply more to the last conference at Perimeter (Strings 2023), where Frenkel's perception of a culture not allowing valid criticism I think was accurate. This next conference seems to me one more aware that all known programs have serious problems, that what is needed is new ideas.

All, please no more comments about Perimeter's code of conduct or attempts to carry on woke/anti-woke warfare here.

9. **Michael Weiss**
September 23, 2023

Thank you for sharing the link to Curt Jaimungal's interview with Prof. Edward Frenkel. It is extraordinary both for its perspectives and for the insights it indirectly provides into a remarkable character. His life story beginning in the former USSR is inspiring.

Returning to the interview, Prof. Frenkel's emphasis on what he describes as "self-awareness" is pertinent not only to the scientific community, but to larger trends in our society more broadly.

As an aside, Frankel's candid comments on your courage (and that of scientist-observers Drs. Lee S and Sabine H; i.e., to have highlighted unfortunate sociological trends in hep-th more than 15 years ago), a critique sadly dismissed by some hep-th leaders at that time as "sour grapes," surely must be an important validation, if years too late. This is as close to a thank-you as anyone can expect in this world.

10. **Photino Birds**
September 23, 2023

You dislike if people work on string theory. Do you also dislike if people stop working on string theory?

I think the situation is IMPROVING. The old senior people stopped working on string theory, but they still say that they believe in string theory. It might be they are too embarrassed to say that their theory failed after dedicating decades to it and subconsciously think it somehow will come back as the main research topic again. They think currently progress is not happening in string theory so they temporarily work in semiclassical gravity or holography.

The younger generation is much different. People like Daniel Harlow, Geoff Penington, Sabrina Pasterski etc NEVER call themselves as string theorists. They just say they are high-energy theorists who work on quantum gravity etc. Among the young, only some swamplanders have hope that string theory will come back as the main theory. Young people who work on other topics like AdS holography (It from Qubit etc.), Celestial holography, etc don't have much hope in string theory. I think they are just hoping a better theory will come in the future. They are also hoping this better theory will be holographic. These people will not say string theory is dead as it will hurt the senior people's feelings. I think once the old generation retires, these people might rename the conference names from "strings 20xx" to "Quantum Gravity and QFT 20xx".

What they are doing now is AT LEAST better than still continuing to do the old string theory. I can't say the progress is impressive, but at least it is decent. I hope that more new ideas come out in this decade. Also I hope the job market will improve in the future, in the past people like James Sully and Aitor Lewkowycz who did great research could not get a professor job. But instead of being more optimistic, you, Sabine and String King etc are very pessimistic.

11. **Alessandro Strumia**
    September 24, 2023

    Some sharp opinions by StringKing agree with what I privately hear from European physicists, for example during coffee breaks. By the way, coffee breaks is where dangerous doubts on string theory were discussed before blogs around 2000. During talks people said "thank you for the insightful talk, I have not fully understood a point at slide 3", and criticism was never openly expressed. But, during coffee breaks, the same people said "I fell asleep at slide 3, wtf did he talk about?". At the time, the main string topic was pp-waves, deadly soporific after lunch. That's when joint seminars started being useless, and other physicists stopped attending technical string talks.

12. **Peter Woit**
    September 24, 2023

    Alessandro Strumia,

    I'm pretty much in agreement with StringKing on his argument that the senior people in string theory have given up on the subject and are now pursuing trendy irrelevancies, and don't doubt this is also what most informed people in the subject are thinking.

    The reason StringKing seems to me likely a troll/parody account is the pairing of an intelligent/well-informed take on current research in the subject with over-the-top stupid material about weed/exercise/bros/broettes and fixation on the idea that the way forward is to re-read Polchinski and pursue old failed research programs. Most likely explanation for this pairing is someone trying to make those still pursuing string theory look like idiots.

13. **Peter Woit**
    September 24, 2023

    Following up on my last comment. StringKing posts continually, except during typical sleeping hours in Europe. At the same time, his writing style is comes off as "dumb-ass American". I'm betting parody account by a European theorist wanting to make fun of string theorists, specifically American ones.

14. **Andrew**
    September 24, 2023

    Peter.

    I'm not sure how much you care about the identity of StringKing, so if it seems this is getting a bit obsessive, feel free to ignore.

    I think it quite likely he is based in London, or at least the UK. He mentions participating in a half marathon this morning, and there happened to be one where I live (London) this morning, starting at approx the time he tweeted about it (sorry Xed). I only know this because I live close to the finishing line of the event and heard all the noise it created, I don't normally follow such things.

    There were some other such events in Europe today, but not in the USA. He seems to me to be a native English speaker, doesn't make the odd slip ups or strange word choices that good but non-native English speakers tend to make.

    Is he a troll? Of course anyone can look up half marathon dates, so it doesn't prove anything, just circumstantial evidence. I take your point that he's making string theory look bad, and why would a real string theorist do that, but the behaviour of a certain Czech blogger (only the most extreme example anongst many tbh) leaves me unconvinced.

15. **Peter Woit**
    September 24, 2023

    Andrew,
    UK/London based seems quite possible, early on he was discussing UK string theorists in great detail, before those on the continent.

    Mainly curious whether my troll hypothesis is correct.

16. **Kurt Schmidt**
    September 24, 2023

    Joseph Conlon thinks that StringKing is from Tennessee or somewhere in the southern United States, since that account follows a number of Tennessee state politicians on twitter:

    https://twitter.com/JosephPConlon/status/1703115644852469981

    https://twitter.com/JosephPConlon/status/1703117784027144219

17. **Peter Woit**
    September 24, 2023

    Photino Birds,
    Your description of the situation as young people knowing very well that string theory is dead but "These people will not say string theory is dead as it will hurt the senior people's feelings" agrees with what I'm seeing and what Frenkel was seeing, but I think both of us see something much worse going on than people not wanting to hurt someone's feelings.

    The reason young theorists don't publicly say "actually Woit/Smolin were right in 2006, string theory was on its deathbed then and it's dead now" is not that they don't want to hurt someone's feelings, but that they don't want to end their career. A field where people can't honestly discuss the scientific status of ideas because doing so could be career-ending is a very unhealthy one, and one not likely to return to health soon.

18. **martibal**
    September 25, 2023

If the young people know that string theory is dead, why do they start a career in this topic ? Is is at this point impossible to make theoretical high energy physics in the US if not in string ? Here in Italy, or in Europe in general, we have often some students aiming at doing theoretical / mathematical physics and choosing to do algebraic qft, qft on curve spacetime, noncommutative geometry etc. Of course their job situation after the PhD is not easy (to say the least) but I am not sure this is so much better in string.
Nobody put a gun against young master students in physics to force them to enter string.
Maybe a problem is the fascination for big names: "Witten as the new Einstein" etc If so, then maybe the "best minds" (to take the terminology that string people like) actually do not go to string anymore, because the "best mind" might have understood that the star system is not a good indication of the health of a research area.

19. **André**
September 25, 2023

@martibal

My impression is that the confrontation of students with current research is too little, too late. Hence, I think that the majority of PhD students at the beginning of their PhD only has a very limited understanding of the status of the type of research they are getting into.
I think it would help, if the focus in teaching would shift a lot more from 'things we understand' to 'things we don't understand'.

T.b.h., when I graduated and started my PhD in 2010, the main reason I didn't end up in string theory was that by pure luck I attended a seminar on algebraic geometry, of which I did not understand the slightest bit, but which was taught by a string theorist turned mathematician who, in a private discussion, told me to read the books by Smolin and Woit before deciding to go into string theory. If I had randomly picked some other math lecture that year to attend just for fun, who knows, I might be preaching the word of Polchinski on used-to-be-twitter today.

20. **Peter Woit**
September 25, 2023

martibal/Andre,

My impression is that a lot of ambitious young people interested in fundamental theory are making the mistake of assuming that this is a normal subject making continual progress. So, the thing to do is to work your way up through the historical progress of the subject, learning QED, standard model QFT, GUTs, Supersymmetry, supergravity, string theory, M-theory, AdS/CFT, it from qubit or whatever. Along the way, they're getting a quick superficial intro to QFT + SM from a textbook or a course, then spending a long time working their way through things like Polchinski, not aware that what they are reading about is a failed research program. They are spending the formative years of their education devoted to developing expertise in failed ideas. When they start research they're not well-equipped to have any perspective or expertise on possibly interesting areas to work in, are equipped to take whatever jobs are out there continuing failed research programs.

21. **martibal**
September 25, 2023

Peter,
I would have understood the argument 20 years ago. I remembered reading Hawking's "A brief history of time" that string theory seemed the logical step after studying general relativity and quantum field theory. Yet, during my studies I then heard people explaining what was he difference between tested science and speculative science, helping me to make my mind.
But ok, let say the information was not so easily accessible at the time (in the 90's, beginning of the 2000) and depending on which lab one were studying, there was a risk to be confronted only to the stringy ideology.
But this is no longer true. Whoever makes a little bit of research on string theory will find some critics, will end up reading your book, or Smollin's, will find this blog etc
It is hard for me to believe that people starting a PhD in theoretical physics are totally immune to the critics against string theory. If so they are (at least partially) voluntary blind.
When, as you said, they made their way to the "continuous progress" of the field, at some point they should realise there is no such continuous progress. For the example the idea of compactifying 6 or more dimensions: it may look very cool at the beginning, but quite soon one realises that the idea has been going on for years and is not settled. Which does not prevent to work on it, but being conscious that this is a highly speculative idea.

22. **P. Trinli**
September 26, 2023

Out of curiosity, could anyone expand in nontechnical terms on the issues with string theory that Edward Frenkel is pointing out? Specifically about the "Calabi-Yau turning singular"?

23. **Masoud Kamgarpour**
September 27, 2023

Frenkel's comments on String theory deserves to be cut into a separate video for easy consumption. I really like his quick explanation of what the problem is from mathematical perspective:

1. There is no way to know which six dimensional Calabi-Yau to pick.
2. Even if you somehow pick one, the manifold changes over time.
3. This changing manifold is bout to become singular and then doing any sort of computation becomes impossible (with current techniques).

His analogy with Israelites walking across the deserts was also spot on.

Congratulations to Peter (and a few others) who saw the problem early on and stuck to their position despite all the difficulties. Swimming against the current is an extremely tough and courageous act.

I think this "hyping" of one's research is not unique to physics or AI. It has unfortunately become a feature of scientific endeavour. There are many reasons for this, but one definitive one is the grant process. When I first started on writing grants, I found to my distaste that I had to hype up my research. What was frightening however was that after a few years of doing this, I actually started believing my own BS! One would have to have a lot of self-awareness not to fall into this trap!

24. **Peter Woit**
September 27, 2023

P. Trinli, Masoud Kamgarpour,

The "moduli problem" for string theory has been around and well-known since the beginning. Calabi-Yaus of a fixed topology aren't rigid objects but come in moduli spaces. The theory has to somehow explain the dynamics of these spaces, and there has never been a satisfactory answer to this. Besides the problem of singularities Frenkel points to, even locally at a smooth point, the moduli parameters will fluctuate, giving lots of universal long-range forces, in violent disagreement with experiment.

The whole “landscape” story is about Rube-Goldberg proposals (e.g. KKLT) to find dynamics that fixes the moduli values using branes, fluxes, etc. String theorists have been arguing for over 20 years about whether these proposals work. The bottom line though is that if they do work they have an ugly, complex, worthless, unpredictive theory. If they don’t work they don’t have a theory (mysteriously, this is the hope and dream of the “swampland” program). I’ve wasted too much of my life arguing with people about this nonsense, so, don’t want more discussion of this problem here. You can find hundreds of pages on the blog about it back in the early years of the blog.

25. **John Baez**
September 28, 2023

It was easy to see back in the 1980s that string theory was based on strange assumptions for which we had no evidence, so I was never tempted to seriously work on it. Perhaps it was *easier* to avoid getting into it back then: with essentially no internet, I was forced to learn physics by reading books and taking courses, so I knew general relativity and quantum field theory pretty well by the time I first heard of string theory. By now any young student has many more ways to learn physics – but they also have to wade their way through a mire of misinformation and downright disinformation.

For me the hard part was realizing that quantum gravity is not a good problem to spend much time on: not right now, anyway. I was young, overoptimistic, and brainwashed into thinking that fundamental physics was still the most exciting part of science, the way it once was. So I spent about a decade on quantum gravity before I realized that other activities were more productive and could be equally fun. It wasn’t a total waste because at least I learned some math and physics. But I hope smart youngsters are smart enough to sidestep this quagmire!

At least I hope they listen to what Frenkel is saying here.

26. **Alessandro Strumia**
September 28, 2023

Half of the moduli problem (long-range forces in disagreement with experiment) has been solved by LHC: supersymmetric particles much above the weak scale make moduli heavy. The other half is technical: finding local minima of a poorly known potential of many fields.

27. **Peter Woit**
September 28, 2023

Alessandro Strumia,
One of the current big problems with theoretical particle physics is that a large part of the community won’t recognize that you are joking…

28. **Attendee**
September 28, 2023

Meanwhile, the Simons Foundation continues supporting famous string theorists engaging in an obviously ridiculous research direction:

https://www.simonsfoundation.org/funded-project/on-the-cosmological-and-particle-physics-implications-of-the-string-swampland/

I wonder how this sort of proposal even gets positive reviews since privately a large number of string theorists mock this enterprise. But I suppose they act in unison when it comes to extracting funding dollars. I scratch your back, you scratch my back…

29. **Peter Woit**
September 29, 2023

Attendee,
Since supposedly NSF grants are hard to get, requiring very high evaluations from reviewers, I’ve never understood how grants for research topics most of the community thinks are completely misguided ever get approved. Vafa since 2020 has had an NSF grant for exactly the same topic
https://www.nsf.gov/awardsearch/showAward?AWD_ID=2013858
expiring next year.

The new Simons grant to Vafa is pretty unusual. They give very few of these “Targeted Grants in MPS”, see
https://www.simonsfoundation.org/grant/targeted-grants-in-mps/?tab=awardees
and it’s unclear how such grant proposals are evaluated. Vafa has been closely involved with the Simons Center and Simons Foundation for quite a while.

30. **Lee Smolin**
October 1, 2023

Dear all,

The problem of the dynamics of the moduli fields in K-K theory was already understood clearly by Einstein who wrote to Ehrenfest in the 1920’s that “it is anomalous to replace the four dimensional continuum by a five dimensional one and then subsequently to tie up artificially one of those five dimensions in order to account for the fact that it does not manifest itself.”

Thanks,

Lee

Spacetime is Right-handed

October 9, 2023
Categories: Euclidean Twistor Unification

I've finally managed to write up something short about an idea I've been working on for the last few months, so now have a preliminary draft version of a paper tentatively entitled Spacetime is Right-handed. One motivation for this is the problem of how to Wick rotate spinor fields, given that Minkowski and Euclidean spacetime spinors are quite different. In particular, it has always been a mystery why a Weyl spinor field has a simple description in Minkowski spacetime, but no such description in Euclidean spacetime, where the Euclidean version of Lorentz symmetry seems to require introducing fields of opposite chirality. The argument of this paper is that the relation between Euclidean and Minkowski is not the usual chirally-symmetric analytic continuation but something where both sides use just one chirality ("right-handed"). It's quite remarkable that the dynamics of gauge fields and of GR also has a chiral-asymmetric formulation.

In the ideas about unification using QFT formulated in Euclidean twistor space that I've been working on the past few years, it was always unclear why, when you analytically continued back to Minkowski signature, the left-handed Euclidean spin symmetry would not go to the Lorentz boost symmetry, but to an internal symmetry. One goal of this paper is to answer that question.

This past weekend I recorded a podcast with Curt Jaimungal, which presumably will at some point appear on his Theories of Everything site. It includes some discussion of the ideas behind the new paper.

Comments

1. **PaulS**
   October 10, 2023

   Interesting — you write: "One goal of this paper is to answer that question."

   Is there an answer in the paper? Might you be able to summarize, if so?

   Thank you!

2. **Peter Woit**
   October 10, 2023

   PaulS,
   What I'm showing in the first section is that if you identify the Lorentz group as the right $SL(2,C)_R$ factor in the orthogonal group (actually spin double cover) of complex spacetime, and identify complex spacetime as the tensor product of the spinor rep for this group and its conjugate (so, spacetime is righthanded in the sense of built out of righthanded spinors), then Euclidean spacetime will have a distinguished (imaginary time) direction and only the $SU(2)_R \subset SL(2,C)_R$ will act on it (not the $SU(2)$ from the left-handed factor, this acts trivially on spacetime).

   In this paper I haven't discussed at all how these left-handed $SU(2)$s behave in the Euclidean theory, this is what I'm trying to do with twistors. The argument about them is just that they are not going to show up as Minkowski space-time symmetries as they do in the usual analytic continuation (analytically continuing to Lorentz boosts).

3. **Hayun**
   October 11, 2023

   So, this is part of your theory of everything?

4. **PaulS**
   October 11, 2023

   Thank you for the detailed anwer! Is there an experiment that can demonstrate that "Spacetime is Right-handed"? How would right-handed space differ from left-handed space, or ambidextrous space? Thank you!

5. **Peter Woit**
   October 11, 2023

   Hayun,
   This is related to the twistor unification stuff, as explained above. But there's also a more general point, about the not well known fact that the elements of our best fundamental theory (matter fields, gauge fields, GR) can be formulated in chiral variables of one handedness. This suggest to me, independent of the motivation from twistors, that one should be thinking about the SM/GR in this kind of spinorial language, not the usual chirally symmetric vectors.

   Paul S.,
   If you're just looking at Minkowski space-time, you won't see this kind of chiral asymmetry, it just appears when you try to Wick rotate. Questions about what it implies for observed physics then depend on how the theory works in Euclidean spacetime signature, which isn't a topic of this paper.
   I'm not especially expert on various approaches to quantum gravity, possibly the asymmetry I'm pointing to may be relevant in some of them.

6. **flippiefanus**
   October 11, 2023

   What breaks the symmetry? Minkowski space is left-right symmetric. The Wick rotation is a formal process. So one can expect that the mathematics has a sign convention or something that causes the asymmetry. But is there a physical reason for it?

7. **Interested amateur**
   October 12, 2023

   Peter, if space is right-handed, doesn't this imply there's also an arrow for time in your paper; from the CPT theorem?

8. **Peter Woit**
   October 12, 2023

flippiefanus/Interested amateur,

Some comments:

The proposed asymmetry I'm writing about is not a meaningful distinction if you just look at Minkowski space-time. As far as that is concerned, there are not two SL(2,C)s, one right, one left, but just a single SL(2,C), which is the usual Lorentz symmetry, no distinguished time direction. Since there's only one, it's meaningless to say it's the right one, the left one or the diagonal one.

It does become meaningful once you start thinking about Wick rotation, or even just introducing the "i epsilon" terms that are essential to make sense of propagators (I don't share the view that this is "unphysical"). Once you do that, you are writing formulas with time complex. Then you can ask what is the symmetry group of complexified space-time, and the usual story is that there is a left SL(2,C) and a right SL(2,C), with the physical Lorentz group the (conjugate) diagonal. What I'm suggesting is that this is the wrong way to complexify, that you should take the physical Lorentz group to be the right SL(2,C).

This is different than the usual complexification, which has been the one used in rigorous QFT as in Streater-Wightman. I haven't checked, but quite possibly doing this you lose the CPT theorem. But, I'm really only interested in the Standard Model, and that respects CPT by construction. What I'm pointing out is that it may be possible to set up the SM and GR in a way that behaves quite differently when you Wick rotate, with, in particular, the left-handed part of rotations in Euclidean signature not acting at all on Minkowski spacetime, instead acting like an internal symmetry.

A comment about the "arrow of time". Once you introduce those "i epsilon"s and start thinking about imaginary time, you find that the theory is very much asymmetric in imaginary time. By Fourier transform, positivity of the energy picks out one sign of imaginary time in which you can define things (the imaginary time propagator only goes in one direction).

9. **Atiyah**
October 13, 2023

Of course this may all be silly, but to quote one of the greats on the bigger picture:

> No one fully understands spinors. Their algebra is formally understood but their general significance is mysterious. In some sense they describe the "square root" of geometry and, just as understanding the square root of −1 took centuries, the same might be true of spinors.

— Michael Atiyah [Farmelo (2009)]

10. **Michał Sykutera**
October 13, 2023

Are there any specific experimental or observational implications that might arise from your proposed "right-handed" chirality approach to the relation between Euclidean and Minkowski spacetime?

11. **Peter Woit**
October 13, 2023

Michael Sykutera,
If I wanted to emulate string theorists, I'd say this approach predicts SU(2) gauge fields with chiral couplings, so is experimentally vindicated by the weak interactions. But, more seriously, this is just part of a larger project of reformulating the standard model in a way that exploits four dimensional spinor and twistor geometry, hopefully explaining more than the standard model does, but that is still a long ways off.

12. **Low Math, Meely Interacting**
October 13, 2023

I my efforts to get my pea brain around the concept of Wick rotation, I've encountered many an internet forum wherein perplexed grad students learning QFT try to figure out what it "means" to implement such a thing. The stock answer seems to be it's just to get sensible answers out of path integrals, and it's all very rigorously dealt with, Osterwalder-Shrader, no hocus-pocus here, etc. It's kind of a trick. Maybe they bring up connections to statistical mechanics if they want to entertain a little mysticism, but otherwise the attitude of the experts is all very blasé. It's a cog in the machinery of QFT, more-or-less. Is that an accurate assessment of the typical attitude about the subject?

I ask because I'm trying to get a sense of why you've had a difficult time getting anyone interested in this idea. There are myriad possible answers to such a question, of course, but to narrow it down to the more "professional" sorts of objections you might encounter, one might be that your approach assigns a great deal more significance to the act of analytically continuing from Euclidean to Minkowskian spacetime than most folks would ever imagine. They might object that you're taking a basic fact about mathematics, i.e. that not everything is integrable, and elevating it to some deep hint about the nature of reality. And that's just not justified.

Am I being at all accurate here? I wish to make abundantly clear I am not at all attempting to debate the merits of your idea (which I am demonstrably incapable of doing), just trying to both understand it and also imagine how those endowed with the ability to debate it might react.

Thanks!

13. **Peter Woit**
October 13, 2023

LMMI,
Yes, many people may think "just a trick", but there are many arguments against this point of view. To pick one relevant to my experience: our non-perturbative info about QCD all comes from Euclidean spacetime lattice calculations. To get a workable definition of QCD that you can do numerical calculations with, you have to formulate the theory in Euclidean spacetime. The path integral for QCD simply is meaningless in Lorentz spacetime, well-defined and calculationally tractable in Euclidean spacetime.

When you look at chiral spinors and try to Wick rotate you realize something strange is going on. This paper tries to explain that, arguing that the correct Wick rotation gives you something very unexpected, a different Euclidean spacetime, with what you thought were SU(2)_L spacetime rotations actually an internal symmetry. This gives a very different way of thinking about unification which seems to me very much worth pursuing.

14. **Micha**
October 15, 2023

Abit off-topic to the spinors but, why is the "i epsilon" considered a trick? When I first learned it, I thought about it as a trick, but now I think about it in terms of the

Schwinger Keldysh path integral (closed time contour), where it appears naturally from causality. In a similar way it makes sense to me that the imaginary time correlators have an asymmetry, when one starts implementing them with a Konstantinov-Perel'-contour with KMS boundary conditions. This is also pretty much my justification for Wick rotations.

15. **Peter Woit**
October 15, 2023

Micha,
You'll have to ask those who consider it a "trick", not me. By the way, Schwinger was the one who first advocated Euclidean QFT as a consistent formalism and a fundamental idea.

16. **Gavin**
October 15, 2023

Perhaps a naive question, but if I'm understanding correctly your proposal is essentially to identify one of the SU(2) factors in the (Euclidean) Lorentz group SO(4)=SU(2) x SU(2) as the SU(2) of the weak interactions. Does this not run afoul of the Coleman Mandula theorem, which proves that no non-trivial S-matrix can involve a mixing of spacetime and internal symmetries?

17. **Peter Woit**
October 15, 2023

Gavin,
The main point of this paper is that the left Euclidean SU(2) acts trivially on spacetime, only the right handed SU(2) acts on spacetime

So the left SU(2) is an internal symmetry commuting with spacetime symmetries. Just like standard model and no conflict with Coleman Mandula.

Analytic Stacks

October 19, 2023
Categories: Langlands

Dustin Clausen and Peter Scholze are giving a course together this fall on Analytic Stacks, with Clausen lecturing at the IHES, Scholze from Bonn. Here's the syllabus:

> The purpose of this course is to propose new foundations for analytic geometry. The topics covered are as follows:
> 1. Light condensed abelian groups.
> 2. Analytic rings.
> 3. Analytic stacks.
> 4. Examples.

Yesterday Clausen gave the first lecture (video here), explaining that the goal was to provide new foundations, encompassing several distinct possibilities currently in use (complex analytic spaces, locally analytic manifolds, rigid analytic geometry/adic spaces, Berkovich spaces). These new foundations in particular should work equally well for archimedean and non-archimedean geometry and hopefully will be the right language for bringing together the Fargues-Scholze geometrization of local Langlands at non-archimedean places with a new geometrization at the archimedean place. He describes as "(very) speculative" the possibility of a geometrization of global Langlands (with Scholze more optimistic about this than he is).

Tomorrow Scholze will take over, giving the next six lectures. Perhaps this characterization is a bit over-the-top, but seeing lectures of this sort and of this ambition taking place at the IHES brings to mind the glory days of Grothendieck's years lecturing at the IHES on new foundations for algebraic geometry. I fear that keeping up on the details of this as it happens will require the energy of someone much younger than I am…

Update: Scholze's first lecture is here. He gives his version of the motivation for these new foundations.

Update: This sort of thing didn't happen back in the days of SGA.

Comments

1. **Antoine Deleforge**
   October 20, 2023

   For those who haven't watched till the end, here is a couple of interesting things from
   the Q&A:
   1) At 1:45:45 Clausen reveals that he and Scholze are trying to write a book at the same time as they are giving these lectures. He says it's not clear whether they'll release things sequantially or all at once.
   2) Around 1:46:00 a member of the audience asks whether he can describe in one or two sentences some major applications of this theory. After some hesitation, Clausen answers that it proves "the most general possible Rieman-Roch theorems in analytic geometry".

   Eventhough these topics fly way above my head, I find the progressive discovery of these massive new theories by Clausen and Scholze fascinating to watch. What I find particularly striking is that this is the 4th semester-long course that they give around Condensed Mathematics since 2019, accumulating hundreds of pages of lecture notes… yet Scholze and Clausen still haven't published any paper together to date! It's like witnessing the slow unravelling of something gigantic with likely spectacular applications, but we are still in the build up phase, with still no major results in sight, at least that they deem worthwhile of publication.

   Equally striking is that Scholze hasn't published anything new on the ArXiv for more than 2 years now. He seems to be completely all-in on this! Unless of course he has some other academic activities that I am not aware of.

2. **Jonathan**
   October 20, 2023

   Off-topic but talking about the IHES they're hosting a programme March next year "Quantum and classical fields interacting with geometry" and I notice Witten is on the list of speakers. There's been lots of work on the semiclassical approach recently in connection with black hole physics so it's perhaps good for the field to see stringy people move onto other areas.
   https://indico.math.cnrs.fr/event/9486/

3. **Yonz**
   October 20, 2023

   Antoine Deleforge,
   One "big" application or motivation that they may have is possibly the discovery of something called "analytic K-theory". If I remember correctly, Clausen said on Mathoverflow that the main motivation for condensed mathematics is to define algebraic K-theory "with proper support" which guides them to something they call "analytic K-theory" that they then use to define "modified Hodge Conjecture" in terms of their "analytic K-theory", and Clausen said that the usual Hodge conjecture is equivalent to the statement that "analytic K-theory class can be continuously deformed into an algebraic K-theory class".

   About Scholze's "upcoming paper/academic activities", you can see from a paper published in Arxiv last month by Kieu Hieu Nguyen here https://arxiv.org/pdf/2309.16505.pdf that apparently Scholze has an upcoming paper as you can see in Remark 1.7 which I will quote here:

   "A construction of Hecke eigensheaves associated with "generous" L-parameters and a proof of Harris-Viehmann's conjecture for an arbitrary reductive group as well as various foundational results would appeared in the forthcoming work of Hamann, Hansen and Scholze [HHS]"

4. **Antoine Deleforge**
   October 20, 2023

   Yonz,

   Thanks a lot for these pointers! Really appreciate.

5. **Andreas**
   October 23, 2023

Also, Garoufalidis and Zagier have a reference to a paper in preparation with Scholze, called The Habiro ring of a number field. Reference [36] in https://arxiv.org/abs/2111.06645

6. **Abbot of Nalanda**
October 23, 2023

While I have nothing useful to say about the math as this is not my field, I thought I'd make the following interesting observation: Tate, apart from being the grandfather of this young field, is also Dustin Clausen's grandfather.

7. **Peter Woit**
October 23, 2023

Abbot of Nalanda,
Yes, and another reason why watching this unfold evokes the 1960s and the transformation of algebraic geometry during those years, when Tate was one of the leaders.

8. **kitchin**
November 8, 2023

At the end of the 4th Clausen-Scholze lecture at IHES, there's a bit of a shocker, at least to me. Scholze discuses implications from, and to, the Continuum Hypothesis, due to high cardinalities.

9. **Antoine Deleforge**
November 9, 2023

kitchin,

I agree that I was a bit shocked that CH was suddenly brought up seeminlgy out of the blue! But then, my impression is that he's saying more or less "This thing is convenient to have for some proofs, but the price to pay is not to have CH." Meaning, it's a convenient tool if you are ready to get rid of CH, but there are probably other ways around in most cases. Did you understand what he presented at some deeper evidence against CH, or something like this ?

Something that surprised/impressed me from yesterday's lecture (#5) is that he presented the notion of "Solid" condensed Abelian group in a completely different way from their previous lectures, which seems much more elementary and easy to grasp. Namely, a condensed Abelian group is solid simply if its null sequences are summable (in an appropriate formal definition of this). It can be "solidified" if it is possible to assign a unique object to each sum of null sequence. Proofs of well-behaveness seem to be much easier from this definition, and he ends up showing the two definition are the same. It also explains quite intuitively why R can't be meaningfully solidified.

Answering a question at the very end of the lecture, Scholze hints that Clausen and him think they have a way to present Liquid vector spaces in a similar fashion, and are currently working out the details on whether it works. "We'll see in a few weeks". Very exciting!

10. **Nearby Goose**
November 9, 2023

kitchin: Connections between Ext-vanishing hypotheses for abelian groups and set-theoretic size issues are a classical topic – read about the "Whitehead problem" for instance. From this point of view, the appearance of these matters in lecture 4 was interesting, but maybe not so shocking.

11. **Anon**
November 13, 2023

This may be off-topic, but a week ago, Clausen gave a talk titled "What is the K-theory of the complex numbers?" at IAS/Princeton Arithmetic Geometry Seminar here: https://www.math.princeton.edu/events/what-k-theory-complex-numbers-2023-11-06t213000

Here's the abstract:

"I will explain what the question means and how to make it precise. Then I will give a conjectural answer.

This is based on joint work with Peter Scholze."

You can find the video on IAS YouTube channel.

12. **Anon**
November 14, 2023

Now after I've watched the Clausen talk at IAS here: https://www.youtube.com/watch?v=5QE__xdYtA0 I see that he's promoting the course on analytic stack with Scholze at 34:56 which makes contact to his IAS talk to some extent.

In this talk, Clausen describes his joint work with Scholze in creating something they called Analytic K-Theory, and Clausen also lists some conjectures regarding Analytic K-Theory and some evidence as to why they should be true (including the fact that they proved the conjectures for degree less than or equal to zero). I would guess that they have a paper together on this topic, but haven't posted it to the arxiv yet because, as Clausen said in the IAS talk, they believed that degree one of the conjecture is within reach.

13. **Long Wind**
November 14, 2023

I debated writing this earlier today, but that last comment ("I would guess that they have a paper together on this topic, but haven't posted it to the arxiv yet") pushed me over the edge. The constant obsessive speculation and textual analysis of which papers Clausen / Scholze might be writing is really too much. Likewise, we don't need a news flash every time one of them gives a lecture at, say, the IAS.

Condensed math is a beautiful idea, but – like scheme theory! – it is ultimately a tool which lets one handle certain technical situations (in this case, "mixing topology and homological algebra") with greater facility and new insights. It is definitely not magic, and there is certainly no royal road through it to "geometric Langlands over Z" or any such thing.

Spacetime is Right-handed v. 2.0 and Some Notes on Spinors and Twistors

October 30, 2023
Categories: Euclidean Twistor Unification

I've just replaced the old version of my draft "spacetime is right-handed" paper (discussed here) with a new, hopefully improved version. If it is improved, thanks are due to a couple people who sent helpful comments on the older version, sometimes making clear that I wasn't getting across at all the main idea. To further clarify what I'm claiming, here I'll try and write out an informal explanation of what I see as the relevant fundamental issues about four-dimensional geometry, which appear even for $\mathbf R^4$, before one starts thinking about manifolds.

Spinors, twistors and complex spacetime

In complex spacetime $\mathbf C^4$ the story of spinors and twistors is quite simple and straightforward. Spinors are more fundamental than vectors: one can write the space $\mathbf C^4$ of vectors as the tensor product of two $\mathbf C^2$ spaces of spinors. Very special to four dimensions is that the (double cover of) the complex rotation group $Spin(4,\mathbf C)$ breaks up as the product
$$Spin(4,\mathbf C)=SL(2,\mathbf C)\times SL(2,\mathbf C)$$
where these two factors act on the spinor spaces.

While spinors are the irreducible objects for understanding complex four-dimensional rotations, twistors are the irreducible objects for understanding complex four-dimensional conformal transformations. Twistor space T is a $\mathbf C^4$, with complex conformal transformations acting by the defining $SL(4,\mathbf C)$ action. A complex spacetime point is a $\mathbf C^2\subset T$ and conformally compactified complex spacetime is the Grassmannian of all such $\mathbf C^2\subset T=\mathbf C^4$. One of the spinor spaces at each point of complex spacetime is tautologically defined: it's the point $\mathbf C^2$ itself (the other is of a different nature, with one definition the quotient space $T/\mathbf C^2$).

Real forms

While the twistor/spinor story for complex spacetime is quite simple, the story of real spacetime is much more complicated. When several different real spaces complexify to the same complex space, these are called "real forms" of the space. A real form can be characterized by a conjugation map σ (an antilinear map on the complex space satisfying $\sigma^2=1$), with the real space the conjugation-invariant points. Using the obvious conjugation on $\mathbf C^4$, we get an easy to understand real form: the $\mathbf R^4$ with real coordinates, rotation group $SL(2,\mathbf R)\times SL(2,\mathbf R)$ and conformal group $SL(4,\mathbf R)$. Unfortunately, this real form seems to have nothing to do with physics, its invariant inner product is indefinite of signature $(2,2)$.

The real spacetime with Euclidean signature inner product has an unusual conjugation that is best understood using quaternions. If one picks an identification of the twistor space T as $T=\mathbf C^4=\mathbf H^2$, then the conjugation is multiplication by the quaternion $\mathbf j$. The Euclidean conformal group is the group $SL(2,\mathbf H)$. The spinor spaces $\mathbf C^2$ are identified with two copies of the quaternions $\mathbf H$, with the rotation group now the group $Sp(1)\times Sp(1)$ of pairs of unit quaternions.

In this case the conjugation acts in a subtle manner. Since $\mathbf j^2$ is -1 rather than 1, it's not a conjugation on T, but is one on the projective space $PT=\mathbf CP^3$. It has no fixed points, so the twistor space has no real points. What is fixed are the quaternionic lines $\mathbf H\subset \mathbf H^2$, each of which corresponds to a point in the (conformally compacified, so $S^4=\mathbf HP^1$) real Euclidean signature spacetime. Using the decomposition as a tensor product of spinors, the action by $\mathbf j$ squares to -1 on each factor, but 1 on the tensor product, where it gives a conjugation with fixed points the Euclidean spacetime.

The real spacetime with Minkowski signature is another real form of a subtle sort, with very different subtleties than in the Euclidean case. The conjugation σ in this case doesn't take the twistor space T to itself, but takes T to its dual space T^*. It takes spinors of one kind to spinors of the opposite kind (at the same time conjugating spinor coordinates to get anti-linearity). The Minkowski signature conformal group is the group $SU(2,2)$ and the rotation group is the Lorentz group $SL(2,\mathbf C)$ (acting diagonally on the two spinor spaces, with a conjugation on one side).

Some philosophy

The usual way in which the above real forms get used is that mathematicians ignore the Minkowski story and use the Euclidean signature real form to do four-dimensional Riemannian geometry, with the $Sp(1)\times Sp(1)$ decomposition at the Lie algebra level corresponding to the decomposition of two-forms into self-dual and anti-self-dual. Physicists on the other hand (especially Penrose and his school, but also those trying to do quantum gravity using Ashtekar variables) ignore the Euclidean story and use the Minkowski signature real form. In various places Penrose is quoted as explicitly skeptical of any relevance of the Euclidean story to physics. Working just with the Minkowski real form, one struggles with the fact that the Lorentz group is simple, but that one can get a very useful self/anti-self dual decomposition if one makes one's variables complex.

The point of view I'm taking is that Wick rotation tells one that one should look simultaneously at both Euclidean and Minkowski real forms, understanding how to get back and forth between them. This is standard in usual geometry where one just looks at vectors, but looking at spinors and twistors shows that something much more subtle is going on. The argument of this new paper is that when one does this, one finds that the spacetime degrees of freedom can be expressed purely in terms of one kind of spinor (right-handed by convention), the one that twistor theory tautologically associates to each point in spacetime. The other (left-handed) half of the spinor geometry involves a purely internal symmetry from the point of view of Minkowski spacetime. This should correspond to the electroweak gauge theory, exactly how that works is still under investigation…

Update: Now posted on the arXiv here. Only reaction on social media I've seen so far is from Strinking42069, which seems to be a parody account trying to make fun of string theorists.

   October 31, 2023

   `Off-topic comments better be interesting…`

   Apologies for instantly derailing the comment thread, but Ed Witten was the guest on 'The Life Scientific' this morning on BBC Radio 4. It's a regular, weekly show in which Jim Al-Khalili interviews various members of the scientific community , lightly touching on the technical aspects of their work without alienating the distinctly non-technical Radio 4 audience.

   Jim is a physicist himself. You made need to create a free account to listen to it:

   https://www.bbc.co.uk/sounds/play/m001rycq

2. **Peter Woit**

October 31, 2023

RD,
Thanks. That is a nice summary of Witten's career, including explaining how much the quark confinement problem has motivated him as well as explanations of his relation to mathematics. I do find his excellent advice about the danger of getting hung up on preconceptions in one's research darkly humorous given his continued faith in and promotion of M-theory unification.

This is an old story, with nothing really new here, unlikely anyone has anything new to say about it. I'd rather have discussion of some new ideas….

3. **Jim Eadon**
October 31, 2023

Dear Professor Woit,
You mention people modeling quantum gravity Does gravity (in the General Relativity sense) crop up in your set-up (as far as I can tell it doesn't). It seems to me (I'm no expert) you are modeling Special Relativity plus Euclidean space via twistors and so on, and potentially obtaining Electroweak fields for free, so to speak.
Perhaps a snappy tagline on what you are claiming could come in handy (more understandable than the abstract right-handed concept)

4. **Peter Woit**
October 31, 2023

Jim Eadon,
I'm making an argument at the level of fundamental symmetries, but yes, this includes an argument (explained a bit in a subsection) for a particular approach to quantum gravity (Euclidean quantum gravity using chiral variables). I even write down a Lagrangian.

For much much more about exactly the chiral variables approach, I just noticed two new papers on the arXiv:
https://arxiv.org/abs/2310.19729
https://arxiv.org/abs/2310.19722
These are in Lorentzian signature, and struggle with exactly the problem I mention in the paper. This problem goes away in Euclidean signature, but the issue of relating Euclidean quantum gravity to physical quantum gravity is obscure. I hope those expert in the subject of Ashtekar variables and chiral formulations will take a look at this.

5. **Peter P**
October 31, 2023

"The other (left-handed) half of the spinor geometry involves a purely internal symmetry from the point of view of Minkowski spacetime. This should correspond to the electroweak gauge theory…"

Terms leading to neutral currents and coupling to Higgs require both chiralities (uL and uR). Arguably, iso-singlet contributions into neutral currents are smaller than iso-triplet ones. Currently, they are still required to match experiments. The overall idea is intriguing: matching right-handed spacetime with left-handed inner DoFs (matter?).

6. **Interested amateur**
November 1, 2023

On the subject of twistors, a lecture was given by Nima Arkani-Hamed a few months ago as part of the IAS-DIAS organised conference, The Amplituhedron at 10: Hidden Mathematical Structures of the Amplituhedron: Why Is the Universe Big?

In particular at 1:27:38, Nima is asked how his physics program adds anything beyond Heisenberg's S-matrix theory. Worth a post by itself sometime in the future, maybe?

7. **Low Math, Meekly Interacting**
November 2, 2023

Hopefully not too OT, but I'm not convinced of the parody hypothesis. The truth of internet personae can be so much stranger than any imaginable fiction one must keep an open mind pending definitive evidence.

8. **Peter Woit**
November 2, 2023

Interested amateur,
I've often written here about the amplitudes program and Arkani-Hamed's vision for it. Earliest post I can find is from nearly fifteen years ago, see
http://www.math.columbia.edu/~woit/wordpress/?p=1705
At the time I was quite interested to see that people were working on formulating QFT in twistor space, that's something that has continued.

The amplitudes program has had a huge sociological success, it's now a very large enterprise. In his talk and at the point you mention, I think Arkani-Hamed makes clear what his vision is for it: find some new geometrical principle which will give S-matrix amplitudes, replacing local QFT and replacing spacetime. He's a huge optimist about whatever idea he's working on at the moment, we'll see what happens.

I'm all for new ideas about reworking QFT in terms of different geometrical fundamentals, and twistors are among the most promising such ideas. But I don't think it's so healthy that the sociology of the field is that one very speculative and not obviously successful idea about this attracts a large fraction of the people and other resources of the field. We'd be better off if people interested in new geometrical ideas about fundamental physics were investigating a much wider range of possibilities. For instance, the geometry of the Wick rotation between spinors in Euclidean and Minkowski spacetimes…

November 2, 2023

LMMI,
Hard to guess what the true story of Stringking42069 is, maybe it is an actual string theorist whose brain has been rotted by too much testosterone and 420. But it's very hard to take at face value the combo of informed and accurate information about string theory research with a huge amount of material that makes the author appear to be a complete idiot.

10. **suomynona**
November 3, 2023

It appears fairly obvious that Stringking42069 is not any kind of serious account. If not parody, Stringking42069 is at the very least an *intentionally* highly exaggerated personality. Even for an anonymous internet commenter, they're far too unhinged for them to be serious and posting in good faith while still having enough faculties to accurately understand the HET community. A pretty dead giveaway are the numbers ‘420’ and ’69’ in their Twitter/X handle. These are numbers which are, quite obviously, associated with an intentional joke.

11. **Marvin**
November 5, 2023

Hi Peter,

When you say in your article:”Spacetime (both Minkowski and Euclidean)
can be said to be “right-handed”, and we have seen that this goes beyond the spin 1/2 matter degrees of freedom, with Yang-Mills and gravitational dynamics also described using right handed spinors.”

Are you expecting some measurable astronomical effect following the fact that spacetime had this preferred chirality. For what I know, exept for small anomalies (like the “Axis of evil”), there is no such significant effect visible. Or may be you have your own idea on this.

12. **Peter Woit**
November 6, 2023

Marvin,
What I’m claiming is that you can describe all those degrees of freedom in a way that is completely chirally asymmetric when you look at complex spacetime (or Wick rotate to Euclidean spacetime). Just looking at Minkowski spacetime nothing is different, and you just have the usual theories, which are thought of as chirally symmetric. The main point is that if you Wick rotate one of these theories normally thought of as chirally symmetric, you get something very definitely chirally asymmetric.

Peter

13. **tulpoeid**
November 6, 2023

Btw I think Stringking is as much a parody of string theorists as Motl is. Parody, yes, maybe; intentional, not really.
(Also, he’s apparently the most interesting strings have to offer nowadays.)

14. **Marvin**
November 7, 2023

Thanks Peter: very clear explanation!

15. **Hayun**
November 8, 2023

Unlike other TOE, your argument is that gravity and gauge theories are completely decoupled?”

16. **Peter Woit**
November 8, 2023

Hayun,
What I’m pointing out here is just that the usual YM and gravity theories can be expressed in terms of purely chiral variables. They are coupled in just the usual manner (the YM action involves the Hodge star, which depends on the metric, or vierbein). Chiral fermions are coupled to YM and gravity by the usual covariant derivatives.

17. **Plebian Science Beggar**
November 26, 2023

Are there any interesting new predictions of Twistor Theory? I get that in theory it recovers the familiar models, but on the margins has it yielded new observable stuff that the old theories don’t predict?

BTW, long-time fan and lurker and first-time poster. It would mean a whole lot to get a response from you. Tear me to pieces, please!

18. **Peter Woit**
November 26, 2023

PSB,
Twistor theory isn’t really a “theory”, although I suppose you could try to follow the string theorists and go on about how it’s a “framework”.

What twistor theory does is point out that there’s mathematically a different way of describing Minkowski spacetime, one that has some very powerful and appealing characteristics: it makes conformal symmetry manifest and allows the use of complex variable methods. You can try and write down the full standard model and GR in this description of spacetime, but it’s very awkward, definitely doesn’t give what you would like (a theory that reproduces the successful parts of the standard theory and also gives something different and testable).

What I’m trying to do is to investigate a new set of ideas based on twistor theory (looking simultaneously at the Minkowski and Euclidean versions) which look to me to have promising properties. Still a ways though away from showing exactly how to reproduce the standard theory this way (and, ideally, also something new and different), but what I do understand looks promising.

Unification, Spinors, Twistors, String Theory

November 22, 2023
Categories: Euclidean Twistor Unification, Uncategorized

Last month I recorded a podcast with Curt Jaimungal for his Theories of Everything site, and it's now available with audio here, on Youtube here. There are quite a few other programs on the site well worth watching.

Much of the discussion in this program is about the general ideas I'm trying to pursue about spinors, twistors and unification. For more about the details of these, see arXiv preprints here and here, as well as blog entries here.

About the state of string theory, that's a topic I find more and more disturbing, with little new though to say about it. It's been dead now for a long time and most of the scientific community and the public at large are now aware of this. The ongoing publicity campaign from some of the most respected figures in theoretical physics to deny reality and claim that all is well with string theory is what is disturbing. Just in the last week or so, you can watch Cumrun Vafa and Brian Greene promoting string theory on Brian Keating's channel, with Vafa explaining how string theory computes the mass of the electron. At the World Science Festival site there's Juan Maldacena, with an upcoming program featuring Greene, Strominger, Vafa and Witten.

On Twitter, there's now stringking42069, who is producing a torrent of well-informed cutting invective about what is going on in the string theory research community, supposedly from a true believer. It's unclear whether this is a parody account trying to discredit string theory, or an extreme example of how far gone some string theorists now are.

To all those celebrating Thanksgiving tomorrow, may your travel problems be minimal and your get-togethers with friends and family a pleasure.

Update: If you don't want to listen to the whole thing and don't want to hear about spinors and twistors, Curt Jaimungal has put up a shorter clip where we discuss among other things the lack of any significant public technical debate between string theory skeptics and optimists. He offers his site as a venue. Is there anyone who continues to work on string theory and is optimistic about its prospects willing to participate?

Update: For two more clips from the podcast, there's one about spinors, and one about "spacetime is not doomed".

Comments

1. **Anonymous**
   November 22, 2023

   Multiverses are getting mixed press, too. I subscribe to the IAI newsfeed, and this recent article came up:

   https://iai.tv/articles/the-multiverse-is-unscientific-nonsense-auid-2668

2. **Peter Woit**
   November 22, 2023

   Anonymous,
   I think the whole multiverse nonsense was a disaster for string theory and string theorists know this. Vafa's "swampland" program is explicitly an acknowledgement that saying "the multiverse did it" is indefensible and destroys your scientific credibility: you need another answer to the problem of inherently not being able to predict anything.

   What non-swampland others seems to be doing now is trying to avoid ever mentioning the "multiverse did it" answer unless backed into a corner and forced to come up with something.

3. **neo**
   November 22, 2023

   with Vafa explaining how string theory computes the mass of the electron

   string theory computes the mass of the electron –could you elaborate is this a new result ?

4. **Peter Woit**
   November 22, 2023

   neo,
   Maybe someone with more time to waste can explain Vafa's argument. My impression is that Keating didn't take it seriously. From a quick scan of the transcript, Vafa at one point says that even if there were some experimental result that disagreed with string theory, to him it would just mean that one needed to understand string theory differently.

5. **David Appell**
   November 22, 2023

   What is Vafa's Formula for the mass of the electron, and where is it published?

6. **Peter Woit**
   November 23, 2023

   David Appell,
   There is no Vafa Formula, this is just complete nonsense, very disturbing to hear it come from someone like Vafa (without any challenge from Keating).

   It's typical "swampland" argumentation, based on a general conjecture about quantum gravity theories ("weak gravity conjecture") which has little to do with string theory, and just gives not a number but some absurdly weak bound, many many orders of magnitude from the mass. Vafa then goes on to explain (around 34:00) that even if a "prediction" like this was falsified, he wouldn't see that as a reason to doubt string theory, it would just mean that one needed to understand "string theory" differently. This has become religion, not science and I don't understand how this has happened and why anyone continues to take it seriously.

7. **Low Math, Meekly Interacting**
November 23, 2023

Glad this finally got posted. I was rather hoping to come out with a greater understanding of twistors, but not so much. Even Penrose, a masterful expositor, seems to have a hard time conveying what twistors are all about to a lay crowd, so I can't say my hopes were reasonable.

8. **James Smith**
November 23, 2023

I think this is relevant:

https://en.wikipedia.org/wiki/Googly

9. **David Appell**
November 23, 2023

Thanks Peter. Happy Thanksgiving.

10. **Peter Woit**
November 24, 2023

LMMI,
Penrose has given various versions of more physical elementary explanations of twistors, but the problem is that this is all about a new way to think about space-time in highly relativistic and conformally invariant regimes, far from ordinary intuition.

If you're happy with complex variables I do think there is a very simple way to understand twistors and spinors: a point in spacetime is a complex two-plane in C^4. Elements of this C^4 are twistors. Spinors at a point are tautological: elements of the complex two-plane.

The problem with this though is that it gives you complexified space-time, and you have to understand which points are "real". The "real structures" that determine this for Minkowski spacetime and Euclidean spacetime are not obvious (and quite different in the two cases).

11. **Peter Woit**
November 24, 2023

James Smith,
Yes, there's a fundamental problem with twistor theory that Penrose likes to call the "googly problem": twistor theory is naturally chiral, with points right-handed spinors. The traditional problem is how to understand left-handed spacetime degrees of freedom in twistor language. This problem is normally considered in Minkowski signature spacetime. I'm arguing that if you Wick rotate and look at Euclidean signature spacetime the problem becomes a virtue: you can describe physical spacetime just using right-handed degrees of freedom, with the left-handed ones now internal degrees of freedom.

12. **Marvin**
November 26, 2023

Hi Peter,

In Vafa interview, the prediction by string theory of the mass of the electron happen at around 14:40, not 34:00.

This said, as you had explained above, this prediction is extremely vague.

I can't understand why they look satisfied whit these weak results.

13. **Peter Woit**
November 26, 2023

Marvin,
Thanks, that's right. What's at around 34:00 is where Vafa responds to the question of what he would do if experiment falsified a "prediction" of string theory, like the electron mass one:

"I will go back and search my on my understanding of string theory. And perhaps we we, we made a mistakes along with our understanding, because I think part of an issue is that we don't have a complete formulation based on what string theory is. So we are kind of on a difficult platform to be that sure is string theory, right? Because string theory fails to do that. You have to know exactly what string theory is, and we don't know that yet. So I would go back and check my understanding of the subject."

This pretty much answers the question Keating used as title for the interview: "Is String Theory Actually Science?"

14. **Adam Treat**
November 26, 2023

Peter Woit,

Your point is well taken, but if I can play the devil's advocate for a minute consider if Vafa's reply was:

"I will go back and search my on my understanding of physics. And perhaps we we, we made a mistakes along with our understanding, because I think part of an issue is that we don't have a complete formulation based on what physics is. So we are kind of on a difficult platform to be that sure is physics, right? Because physics fails to do that. You have to know exactly what physics is, and we don't know that yet. So I would go back and check my understanding of the subject."

I honestly think this is what is going through Vafa's head when he says things like this.

15. **Peter Woit**
November 26, 2023

Adam Treat,
I'm sure it's right that in his mind Vafa is identifying "string theory" = "fundamental physics", but that's exactly the problem. At this point as far as he's concerned there is no way string theory can be wrong, the only open question is what sort of string theory is the right one. This really isn't science anymore and this attitude is killing off the subject of fundamental physics.

16. **Schratter**
November 30, 2023

While we still don't quite know what Twistors are or how they relate to physics, we did learn that Garrett Lisi slept on Woit's couch, once again demonstrating that modern physics is mostly just sociology.

17. **Peter Woit**
November 30, 2023

Schratter,
Being on the list of people whose couch Garrett slept on is not exactly membership in a small, exclusive club…
If you want to know what twistors are and what they have to do with physics, there are lot of places to learn about this (see for instance slides from my talks in recent years, on my website). You're not going to understand this sort of thing by listening to two people talking on a podcast like this.

18. **zovi**
December 4, 2023

Have anyone here have a take at Oppenheim's paper "A postquantum theory of classical gravity?" in PhysRevLett X ?

19. **Simone Speziale**
December 5, 2023

Hello,

To complement Peter's answer to LMMI's question, I think it is always nice to give a geometric intuition of twistors by recalling the interpretation of their incidence relation in the case of conformally flat spacetime: each zero-helicity twistor describes a light ray in Minkowski, each non-zero-helicity twistor describes a twisting null congruence in Minkowski spacetime, or alternatively what is called an alpha-plane in complexified Minkowski spacetime. The set of such flat alpha-planes is useful because it is integrable and spans the manifold CP^3. This is the manifold whose complex structure is associated to the conformal metric structure of Minkowski's spacetime, and this result gives a 4d (limited) extension of the beautiful equivalence between conformal metric structures and complex structures that we have in 2d.

For those interested in a bit more details, recall that to each spinor we can associate a light-like direction at the origin of Minkowski space: This is done taking the ratio of the spinor's components, and interpreting it as a stereographic coordinate on the celestial sphere. With this construction we see that the complex structure of CP^1 can be associated to the celestial sphere. Twistors are bi-spinors, and the way light rays are reconstructed from the incidence relation is roughly speaking with one spinor giving the direction of the light ray, and the second spinor giving the shift away from the origin. The space of light rays is a 5d manifold (2d for the direction of a light ray in the origin, and 3d of independent translations), therefore there is no complex structure that can be associated to it. However, the pair of spinors has to satisfy the special "zero-helicity" property in order to describe a light ray. In general, it describes a 6d space of complexified light rays called alpha-planes mentioned above. The incidence relation is invariant under complex rescaling of the spinors, hence this 6d space is a CP^3 inside C^4.

The difficulty in going beyond (conformally) flat spacetime is that to define a twistor space associated with a curved manifold, you would need the alpha-planes to be integrable, so that they span a complex manifold. This is the manifold whose complex structure would be associated to the conformal spacetime metric. But integrability of the alpha-planes requires the self-dual part of the Weyl tensor to vanish (A preferred chirality enters the theory from the start, because the incidence relation treats the two spinors in an asymmetric way).
Hence this basic construction only works for curved Euclidean or complex spacetimes, and one has to figure out some alternative way of proceeding in order to treat real Lorentzian spacetimes.

Concerning the latest developments by Penrose, he is working to overcome this limitation using inputs from non-commutative geometry, in a version of twistors that he refers to as Palatial Twistor Theory.

20. **Peter Woit**
December 5, 2023

zovi,
I don't want to host a discussion of the proposal in the Oppenheim paper here, since I know nothing about it and it's very far from my own interests. There is one aspect of this though that I would like to understand better. Somehow it got very wide media coverage, see for instance this in the Guardian
https://www.theguardian.com/science/2023/dec/04/wobbly-spacetime-may-resolve-contradictory-physics-theories
This is despite the experts of very different kinds contacted by the journalist agreeing to take odds of 5000:1 that this doesn't work.

I'm thinking that quite possibly I could get better odds than that on my ideas about chiral Euclidean gravity from Rovelli and Pennington, so how do I get a story in the Guardian?

21. **Martin S.**
December 5, 2023

@zovi: It was [described at Quanta]() a few months ago.

22. **Peter Woit**
December 5, 2023

Simone Speziale,
Thanks a lot for providing that physical/geometric description of twistors and more background!

This may be the deformation of too much time spent in math departments, but I'm very much seduced by the simple mathematical structure in the complexified case (a point in complex spacetime is exactly the chiral spinor space). The Minkowski real form where we visualize physics adds a much more complicated structure. The Euclidean real form is much simpler, even though its relation to the physical Minkowski story is tricky to understand.

P5 Report

December 7, 2023
Categories: Uncategorized

There is a HEPAP meeting going on today, with release of the long-awaited P5 report prioritizing future HEP spending. The report is available here now, to be officially unveiled later in the day and discussed at the HEPAP meeting. The muon collider as a future project gets a strong endorsement as the "muon shot".

The full report is now available here.

See press coverage of this at Nature and the New York Times.

There will be continued discussion of the P5 report at HEPAP tomorrow, and at a Town Hall at Fermilab on Monday.

While the theory side of HEP in principle is part of this report, the attention to theory is minimal, with the report recommendations about theory, in total:

- The substance-less "Enhance research in theory to propel innovation, maximize scientific impact of investments in experiments, and expand our understanding of the universe."
- A more substantive call to give university theorists on DOE grants more money, with no attempt to prioritize what the money would be for:

  > Increase DOE HEP-funded university-based theory research by $15 million per year in 2023 dollars (or about 30% of the theory program), to propel innovation and ensure international competitiveness. Such an increase would bring theory support back to 2010 levels. Maintain DOE lab-based theory groups as an essential component of the theory community.

  In the page or so of text about theory, the emphasis is on the phenomenology part of theory in contact with experiment. About formal theory there is just

  > Theorists uncover the mathematical patterns that describe the universe and explore alternate mathematical universes to deepen our understanding of nature. Theoretical investigations into quantum gravity have unlocked connections between extreme space-time geometries and information theory. The perspectives theorists bring to particle physics play an important role in inspiring young scientists.

Update: Sabine Hossenfelder has her reaction to the P5 report here. I'm sympathetic to her critique that, as far as experiments go, the report is an argument for "more of the same". But I'm not at all sympathetic to her alternative: "Personally, I think what they should do is spend some money on serious theory development" instead of funding experiments. If there's a part of science where money spent by the US has been much more of a waste than in HEP experiment, it's HEP theory, which is now pretty much intellectually dead. There's a good argument that the way HEP theory funding works has been a driving factor in this fatal illness, so that the problem with HEP theory is not too little funding but too much.

Comments

1. **p.**
   December 7, 2023

   "This less favorable scenario will lead to a loss of US leadership in many areas, especially the science of the G3 dark matter experiment, and will damage our reputation as a reliable international host for DUNE and as a partner for a Higgs factory. We still make investments in the future, but at a significantly reduced level for small-scale experiments, including ASTAE, theory, computing, instrumentation, and collider R&D. In this scenario, it would be increasingly difficult to maintain US competitiveness as an international partner in accelerator technology." -p43

   Can someone explain please to an obvious idiot, WTF the USA feels the need to lead the world in this? Is there no comprehension about these folk that such a policy is seen as elitist, narcissistic, capitalist juggernaut? Or is that the deliberate intent? Or maybe you think the rest of the world is such a corrupt load of savages they need leading? Just curious

2. **Peter Woit**
   December 7, 2023

   p.
   I think you're not understanding the nature of this report. It's intended as a prioritization of requests from the US HEP physics community to US government agencies for funding. The intended audience is government officials, legislators, etc. who will be asked to approve large expenditures for HEP research. No one is going to try to make the case to a US congressman: "give us $1 billion/year so we can do research second in importance to what the Europeans are doing at CERN."

3. **Amitabh Lath**
   December 8, 2023

   A couple of things stuck out for me: the report mentions muon collider research, as well as a "portfolio of small-scale and agile experiments". I admit to being on the fence about the viability of a muon collider, but the idea of small-scale and agile experiments is exciting.

4. **tulpoeid**
   December 10, 2023

   Interesting comment in the press release about the report, by Hitoshi Murayama, P5 panel chair:
   "Our thinking about what dark matter might be has also changed [since the previous P5 process], forcing the community to look elsewhere — to the cosmos."
   (https://www.aps.org/newsroom/pressreleases/part-research.cfm)

5. **Peter Woit**
   December 10, 2023

   tulpoeid,
   I was surprised that a CMB experiment is the P5 highest priority, had assumed that this was an issue for astronomy funding priorities, not HEP physics funding priorities. It seems one argument for this is the lack of a WIMP showing up at the LHC or in direct dark matter detection experiments means one should look is cosmology. I hadn't realized cosmology experiment were getting funded out of the DOE HEP physics budget.

6. **anon**

December 11, 2023

CMB-S4 is (or at least was when it was discussed in the Astro Decadal Survey) supposed to be a joint roughly 50-50 split DOE-NSF effort. With the way (ground-based) astro funding is looking, it would never get built with only NSF money.

7. **Photino Birds**
December 29, 2023

Peter, I always thought that both your and Sabine's opinions are equally bad. But it looks like Sabine is more reasonable than you.

hep-th funding is very low. There are so many good researchers doing popular mainstream research, and after 6+ years of postdoc, they are forced to leave to Google/AnthropicAI, etc, and do some uninteresting high-paying job. If postdocs who work in mainstream approaches in top universities and get thousands of citations cannot get a job, obviously, nonmainstream approaches cannot get any job since it's harder to compare and measure progress among nonmainstream postdocs. I hope I don't need to share the inspire links of people who wrote very famous papers related to holography who had to leave the field in the last few years, as you probably know the situation. I think since you don't like string theory/holography maybe you are blindly advocating for less funding. But if more funding is given nonmainstream approaches will also benefit, not just mainstream approaches.

It seems you just want the entire hep-th field to die. I cannot understand what you will gain from that. Understanding fundamental physics is like the real purpose of humanity. It seems you are blaspheming against fundamental physics.

8. **Peter Woit**
December 29, 2023

"Photino Birds",
First of all, what's with the anonymity and identifying as a weird sci-fi fandom site? How am I or anyone else supposed to tell the difference between a serious argument from an informed person and something unserious that should be ignored?

If you are an informed person and this is supposed to be a serious argument, I'll just point out that it's not a very good one. You're arguing that more hep-th funding is needed, to go to support the people adding to the 20,000 papers on the heavily overhyped topic of holography. Yes, there are too many such people on the market, so their job prospects are not great. What is needed though is not more funding to keep them doing holography, but redirection of current funding to other "non-mainstream" topics.

9. **JE**
January 5, 2024

Hi Peter,

While I do not share Photino Birds' view –or "shoot in the foot"– that holography can be a good example of non-mainstream physics that should (continue to) be supported with more hep-th funding, I think he has a case arguing against your comment that, "If there's a part of science where money spent by the US has been much more of a waste than in HEP experiment, it's HEP theory, which is now pretty much intellectually dead."

And more so when you say: "I was surprised that a CMB experiment is the P5 highest priority, had assumed that this was an issue for astronomy funding priorities, not HEP physics funding priorities."

First, because little or no sympathy for more/continuing hep-exp and hep-th funding can be fairly misinterpreted as "It seems you just want the entire hep-th field to die." Perhaps you could explain where you would put taxpayers' money more clearly to stake your case.

Second, although I may be biased by my own research, there could be a deep, largely unexplored, connection between the CMB and hep-th. In other words, I can understand why CMB experiments can be among P5's highest priorities. Or, more generally speaking, certain cosmological observations closely related to hep-th, which could shed more light on theory than big particle colliders (not including the muon collider, which seems quite reasonable an option) and at a much lower cost.

And third, given the critical state of the field and the manifest inability of mainstream physics to find a solution, I would put my two cents in non-mainstream rather than mainstream physics, including outsider (privately-funded) research. Unlikely as you may think it is, if a lone researcher or a small group of privately-funded researchers came with a viable solution to the hep-th crisis, it would deal a big blow to the whole academic system. And perhaps with good reason.

10. **Peter Woit**
January 5, 2024

JE,
My comment about CMB was simply about the source of the funding. I would have assumed that microwave telescope funding would be categorized under astronomy, not DOE HEP.

I'm writing more about this in the next posting, but my point about hep-th funding is that, with about 4000 hep-th arXiv submissions/year and order of magnitude 10,000 active hep-th researchers in the world, the problem with progress coming to a halt is not due to not enough funding. Yes, maybe some very different funding mechanisms would help, but no one is even discussing that, instead just asking for more of the same.

11. **JE**
January 5, 2024

Peter,

Thanks for the clarification. Looking forward to reading that posting.

Perhaps discussing these mechanisms could be worthwhile. More "non-mainstream" research could be needed after so much mainstream (at least until mainstream theory becomes non-mainstream, as it happens to be the case with holography now, according to some sources). This may suggest that the difference between mainstream and non-mainstream can start to become unclear after the debacle of string theory.

So I would rather talk about promising lines of research -mainstream or not-, which better be publicly-funded.

12. **Photino Birds**
January 6, 2024

JE,

The tides are shifting in that direction, holography becoming non-mainstream. Recently, Eran Palti (swamplander) https://x.com/EranPalti/status/1740626727490248743 noticed this. Several people who usually work on AdS/CFT toy models have gone back to doing proper string theory this year. In the last 10 years, most people worked on holography toy models and proper string theory was not popular. Exactly solvable models like JT gravity taught many things, but they are not UV complete. People always knew that these toy models were temporary. There is only one UV complete quantum gravity we know: perturbative string theory. So it is not far fetched that proper string theory will again be the hot topic in the future, as it is still the most promising theory. Using AdS/CFT as a nonperturbative definition of string theory is a cop-out. People must find an independent nonperturbative definition of string theory using new techniques and try to prove the AdS/CFT correspondence. PhDs and postdocs must do what is popular now. Research in proper string theory in the last 10 years was not good for postdoc opportunities, etc, due to sociology but that might change soon.

Recent Talk

December 9, 2023
Categories: Uncategorized

I gave a "Spacetime is Right-handed" talk yesterday, part of a series entitled Octonions, standard model and unification. The slides are here, video should appear here.

Much of the talk was devoted to explaining the usual relation between spinors and vectors and how analytic continuation in complexified spacetime works then, from both the spinor and twistor point of view. This is contrasted to a new proposal for the relation between vectors and spinors in which the space-time degrees of freedom see only one of the two SL(2,C) factors of the usual complexified Lorentz group.

Nothing in the talk about using this for unification, where the idea is to exploit the other factor, which now appears as an internal symmetry. Starting from the point of view of Euclidean spacetime, the spacetime vectors and spinors that are related by Wick rotation to Minkowski spacetime degrees of freedom behave differently than usual, with a distinguished imaginary time direction. The general idea is that in standard Euclidean spacetime, where the geometry is governed by the rotation group SU(2) x SU(2), so splits into self-dual and anti-self-dual parts, one of these parts Wick rotates to spacetime symmetry, the other to an internal symmetry.

Comments

1. **Daniele Corradetti**
   December 10, 2023

   It was an excellent talk. Looking forward for the new manuscript. I hope it is self-contained and builds everything from scratch so that also who only have a mathematical background (no physical background) can understand the deep motivations of this work.

2. **Robert A. Wilson**
   December 10, 2023

   If I may, I'd like to expand a little on the comments I made after the talk, concerning the first section (slides 1-12). The classification of representations into real, complex and quaternionic on slide 8 only applies to complex irreducible representations, not to arbitrary representations. When you consider the Dirac spinors, on slide 10, the representation is not irreducible, and it has not only the "real" interpretation, that is as the complexification of a real Majorana spinor, but also a "quaternionic" interpretation, that is as a restriction of a quaternionic 2-spinor to a complex 4-spinor. To see this, it is enough to negate \sigma on one of the Weyl spinors, in order to change from \sigma^2=1 to \sigma^2=-1.

   In fact, the difficulties with the standard formalism that you encounter on slide 12 occur mainly as a result of ignoring the quaternionic case, and working exclusively with the real case. Several people have pointed out that the quaternionic case introduces a *choice* into the theory, that is not there in the real case: the copy of C inside H, that is used to define the standard Dirac spinor, is not canonical. This choice has been used, for example, to extend from one generation (choice of i) to three (i, j, k).

   In terms of Clifford algebras, what is going on here is that Cl(3,1) and Cl(2,2) are 4×4 real matrix algebras, while Cl(1,3), Cl(4,0) and Cl(0,4) are 2×2 quaternion matrix algebras. Hence it is possible to unify an external Minkowski spacetime with an internal Euclidean spacetime in a single Clifford algebra, if and *only if* the Minkowski signature is (1,3). This is not what is done in the SM, of course, in which complexification is used to obliterate the signature completely. But it could be done, and it might resolve the problems with the SM that you point out on slide 12.

3. **Peter Woit**
   December 10, 2023

   Danielle Corradetti,

   While the symmetry group structure largely determines the Standard Model QFTs, it's a very long and complex story to get from facts about the basic groups and their representations to the actual quantum field theory.

   This spring I'm teaching an advanced graduate course with a goal of explaining to mathematicians as much as possible what the SM QFT actually is, using a great deal of geometry and representation theory. I'll be writing notes, the end result may answer your question, you might not find the answer so easy to follow…

4. **Peter Woit**
   December 10, 2023

   Robert A. Wilson,

   Many thanks for the comment, which is very helpful. I have to think more about the role of Clifford algebras in what I'm doing. They work in general dimension/signature, while I'm focused on the very special properties of the 4d case.

5. **lun**
   December 14, 2023

   Naive question: How non-trivial would it be to apply these ideas to a QFT defined on the lattice in order to avoid the doubler problem and/or define a lattice chiral theory?

6. **Peter Woit**
   December 14, 2023

   lun,
   I hope ultimately these ideas will give new possibilities for how to formulate spinor fields on the lattice, but haven't yet thought very much about this. I'm concentrating now on trying to understand how to exploit the Euclidean left-SU(2) symmetry as an internal symmetry.

   A major problem with spinors on the lattice as always been that differential forms have a natural lattice formulation, but spinors are "square roots" of differential forms (the relation between vectors=1-forms and spinors discussed in the talk is part of this story).
   You naturally end up with lots of copies of spinors (e.g. Kogut-Susskind fermions). I hope that with this new interpretation where some space-time symmetries become internal, you might have a new lattice formulation not for a single chiral fermion (where you expect anomaly problems), but for a multiplet of them. But, still a ways from knowing how to even exactly formulate this kind of proposal.

7. **Sam**

January 2, 2024

Have you thought about / commented at all on the potential relationship between your Euclidean twistor theory and Connes' spectral approach and NCG? As a lay person, there seem to be some striking parallels:

– Both are Euclidean to start
– Twistor coordinates define a noncommutative space
– Derivation of the SM from the eigenvalues of the spectral action gives Pati–Salam, with the same SU(2) – left / right splitting you use to encode spacetime chirality
– Particle representations are given by the inner-automorphisms / internal symmetries of the full metric, rather than spatial symmetries that have to be compactified
– The spectral view (observables are incoming energy differences) seems philosophically complementary to the projective space of twistor theory
– Both do away with the classical notion of a point (NCG is "pointless" in that one cannot localize arbitrarily; the fixed points in twistor theory are quaternionic lines)
– Both connect with the homotopy of spheres and k-theory

Searching the archives, you've linked to Connes before and mentioned his work on the spectra of the RZF, but I don't think you've ever explicitly discussed the relationship between his programme and your own. A friendly request!

8. **Peter Woit**
January 2, 2024

Sam,
There are some points of contact such as you mention between what I've been working on and NCG a la Connes. But from the little time I've spent so far trying to better understand NCG, I haven't found a deep enough connection to help with the problems I've been thinking about.

String Theory Hype Fest

January 5, 2024
Categories: This Week's Hype

I just finished watching the video here, which was released today. Since this was advertised as a panel discussion on the state of string theory, I thought earlier today that it might be a good opportunity to write something serious about the state of string theory and its implications more generally for the state of hep-th. But, I just can't do that now, since I found the video beyond depressing. I've seen a lot of string theory hype over the years, but on some level, this is by far the worst example I've ever seen. I started my career in awe of Edward Witten and David Gross, marveling at what they had done and were doing, honored to be able to learn wonderful things from them. Seeing their behavior in this video leaves me broken-hearted. What they have done over the past few decades and are doing now has laid waste to the subject I've been in love with since my teenage years. Maybe someday this field will recover from this, but I'm not getting any younger, so dubious that I'll be around to see it.

Most shameful of the lot was Andy Strominger, who at one point graded string theory as "A+++", another only "A+". He did specify that very early on he had realized that actual string theory as an idea about unification was not going to work out. He now defines "string theory" as whatever he and others who used to do string theory are working on.

David Gross was the best of the lot, giving string theory a B+. At two points (29:30 and 40:13), after explaining the string theory unification vision of 1984-5 he started to say "Didn't work out that way…" and "Unfortunately…", but in each case Brian Greene started talking over him telling him to stop.

Funny thing is, I think even most string theorists are going to be appalled by this performance. Already, here's what StringKing42069 has to say

> 🤮 these old jagoffs have thrown an entire generation of strings under the bus. Fuq them.

Update: I haven't seen any negative reaction to this hypefest from anyone in the physics community other than from StringKing42069. The Black Hole Initiative at Harvard features the event prominently on its website here advertising Strominger's participation (he's a PI).

I'm finding it hard to believe that any of the participants in this thought of it as anything other than an advertising effort useful to try and prop up public support and grant funding. In particular, Strominger's "A+++" is easier to understand once you realize the extent of the grant funding involved, e.g.:

- The Black Hole Initiative that features this on its website: \$16 million from the Templeton Foundation, \$3.6 million from the Moore Foundation.
- The Simons Collaboration on Celestial Holography: \$8 million from the Simons Foundation.
- NSF Grant: \$400,000 from the NSF.
- DOE Grant: \$3.5 million from the DOE.

The abstract of the last of these is A+++ hype in tune with the WSF video:

> Vigorous efforts made over the last several decades have advanced our understanding of the fundamental laws of nature beyond the standard model of particle physics. Further advances would potentially include unification of the forces, the reconciliation of quantum mechanics and gravity, a derivation of the standard model couplings, a universal explanation of the area law for horizon entropy, and a theory for the origin of the universe.

For a much older example of successful use of hype to extract grant funding, there's this Jeffrey Epstein story I hadn't known about until recently.

Comments

1. **Eric Weinstein**
   January 5, 2024

   This is astounding video. They are all so well spoken and pure in their summations that you can hear exactly what the last 40 years have sounded like from inside the harmonious echo chamber of what once was physics. A single skilled critic would destroy the vision that this succeeded at an A+ level. And so…there can be no critics on stage to disturb the delicacy of this castle in the air made of clouds and string.

   \

   This is perfect in every way. A summation of 4 decades of a constant stream of preternatural success after success inerupted only by triumphs as viewed by the leaders and greying architects of this, the most wonderful of all possible theories. 'Raindrops on roses and brown paper packages tied up with strings.' as the song goes.

   \
   I feared I would hate this from your description Peter. And yet, I adore this and wouldn't change a thing. No one would believe me if these men were not willing to say it themselves.

2. **Shantanu**
   January 6, 2024

   Peter, happy new year. As a preview
   see https://online.kitp.ucsb.edu/online/strings24/
   Hopefully all these talks will be online.

3. **JE**
   January 6, 2024

   I share your grief, Peter. Watching top physicists strive to perform as televangephysicists with the help of Brian Greene's performance skills is shameful (and boring). We already had Michio Kaku, but these are bigger names. It has almost led me to change my mind about hep-th funding. Just in case it could get confused with hep-tv funding.

   I would say that Witten's body language might indicate that he was not comfortable during the talk, especially in the first half, as if his mission there was just to answer some technical questions (shorter statements, etc), not to make a TV show, but perhaps this is out of shyness. And Gross' final B+ is a strong indicator of the real state of the subject…

4. **Ted Rogers**
   January 6, 2024

Most people in the comments section seemed to have loved the video. Not sure if that means anything.

5. **James Lai**
January 6, 2024

   Indeed Gross kept shaking his head during Strominger's ending remark.

6. **Peter Hickman**
January 6, 2024

   Usual hype, nothing new.
I would have these 2 questions on the assessment of 'string theory' exam paper:
Q(1) – Is the Standard Model of particle physics recovered from 'string theory'?
Q(2) – Is there any experimental or observational results for 'string theory'?
By this assessment, score is 0/2.
Certainly not A++++ or B+ grade.
The biased panel do not want to admit failure. They should realize that its not wrong to admit failure, that's the nature of science research. If 'string theory' was any good, i.e. useful, and makes definite predictions, then the hype over last c.40 years would be unnecessary. The continuing hype shows that the goal of 'string theory' has failed, whether the panel and other string theorists admit to it or not.

7. **David Brown**
January 6, 2024

   Note that Witten applauded (rather unenthusiastically) Strominger's A+ grade for string theory.

8. **Giotis**
January 6, 2024

   Surely the fact that String Theory counts exactly the number of Black Hole microstates, according to Bekenstein-Hawking prediction, strongly suggests that the Theory knows a couple of things about the Universe.

   This statement in the latest review summarizes the situation for the SM:

   "The SM can be embedded into string theory: The main ingredients of the SM – the gauge group, chiral matter and Yukawa interactions – follow relatively naturally from general principles of string theory. Reproducing exactly the SM including, for instance, its vectorlike matter content or the precise flavor structure, is more involved, but each property per se has been obtained or is within reach. The challenge is to find vacua that combine all these features at the same time, with all moduli stabilized and incorporating a realistic cosmology."

   "The Standard Model from String Theory: What Have We Learned?"

   https://arxiv.org/abs/2401.01939

   The SM can be derived from String theory but the issue is to combine all its ingredients in a complete cosmology of a dS vacuum with all moduli stabilized.

   If you know a couple of things in String pheno you understand that this is a daunting task.

   The fact that this Universe is not unique is plausible of course (the failure of naturalness may indicate just that as Witten explained).

   The new development though is the Swampland program which restricts significantly the number of "good" EFTs.

   On the other hand the general problem, understanding for example singularities, is that String theory is still only understood at perturbative level.

   Beyond AdS/CFT, the non perturbative definition in the bulk is missing.

   Dualities can help but up to a point.

9. **Peter Woit**
January 6, 2024

   Shantanu,
One obvious problem with Strominger's A+++ for the consistency of string theory is that a conference is starting devoted to the problem that no one knows what the definition of "string theory" is.

10. **Peter Woit**
January 6, 2024

    It occurred to me that the best way to understand this video is that it's an infomercial. It was to a large degree scripted as such, with expensive graphics produced to help the sales job. Witten seemed fine with participating in such a thing, Strominger was the over the top "it slices!! it dices!!" guy. Gross went off script a couple times and had to be slapped down. I wonder if he had second thoughts about participating once he saw the result.

11. **Peter Woit**
January 6, 2024

    Giotis,
That the Strominger-Vafa calculation of 28 years ago, with all its caveats and limitations, is still promoted as the best evidence for the consistency of string theory, speaks volumes.

    On the issue of getting particle physics out of string constructions, don't believe me when I tell you it doesn't work, believe Gross, Strominger and Witten. As they admit in this video they long ago gave up on this (Strominger first). The euphemism they use is that for this to work "we would have to be very lucky", i.e. you have to assume some new physics being discovered that has exactly the right properties to point to a string theory origin. They clearly don't believe this is going to happen.

    Those young theorists who were fooled by this kind of infomercial into going into string theory and trying to connect it to reality are now upset that the people who sold them this have now given up and are stabbing them in the back. Zero chance that Gross, Strominger or Witten would hire anyone deluded enough to believe what they were selling 35-40 years ago. Latest from Stringking42069 about this is at

https://twitter.com/stringking42069/status/1743647553529270639
"Senior hep-th bros are corrupt assholes at this point. They don't support strings and push their weakass cronies instead. Fuq the lot of them.

Strings is still the best game in town. Too bad these assclowns can't recognize that anymore."

12. **Gavin**
January 6, 2024

I'm an ex-physics postdoc working in the private sector. I don't have any skin in the game.

I don't think you're doing yourself any favors giving StringKing42069 publicity. To me he comes across as extremely obnoxious and unserious. I understand the appeal because he is prolific in making anti-string-establishment statements, but I personally think it undermines your credibility to cite him. There are plenty of critics of string theory in the broader physics community who will put their name on what they say and give an actual argument, such as acollieastro or honestly almost every physicist or astrophysicist I've met who doesn't publish in hep-th.

In terms of the event itself, I personally thought it wasn't worth talking about. It's the same people saying the same things they've been saying for decades. Literally — their history of string theory stops pretty much around 2000 when Brian Greene wrote his books. I think anyone who goes to an event like that who has followed string theory for any length of time would realize nothing new was said, and anyone who hasn't probably isn't that interested in physics that they will remember anyway. For any young students inspired to go into physics, I think it's a net positive… I was inspired to go into physics by Brian Greene, but then as I went through the coursework and interacted with professors and students I actually got a better picture of physics as a whole and went into a different research field.

13. **Peter Woit**
January 6, 2024

Gavin,
The problem isn't Brian Greene, it's much, much more serious than that. You seem to have missed the main point of my posting, which is about the very significant and disturbing implications of having Witten + Strominger + Gross participating in something like this.

StringKing is an idiot (or someone very clever trying to make string theorists look like idiots). Obviously I'm not making a serious argument about string theory by pointing to his nonsense. As for whether I've devoted enough time and effort to making credible, serious arguments about these issues over the years, I think I'll let the record speak for itself.

14. **sdf**
January 7, 2024

Greene cutting off Gross everytime he tried to inject some reality into the conversation, I'm sorry but I found this hilarious to watch, it is almost like some kind of bad vaudeville.

15. **Alex**
January 7, 2024

Oh, what more can be said that hasn't already been repeated ad nauseam regarding the pathetic (maybe even terminal/end stage?) state of hep-th and of the conspicuous enablers of this situation? I started writing a longer comment but then I deleted it because I thought "what for?".

I think Karl Marx said, about history repeating itself, that this happens "… the first time as tragedy, the second time as farce." The tragedy and damage has already been done. As Peter mentioned, young researchers stabbed in the back by their mentors, a field with no prospects, with its credibility on the floor, etc.

So, this recent video and the like, I think, belongs to the farce. In that sense, the appereance of "StringKing" gives to this vulgar grotesque opera its mandatory clown. I think it's good that Peter mentioned this person since it sets the tone and background on the stage for the main characters in the video to do their dance. Let's hope this time is… finally… the *final* act of the spectacle… "Applaud, friends, the comedy is over."

16. **gentzen**
January 7, 2024

Witten mentions Nordström's theory of gravitation at 9:00. A beautiful simple Lorentz-invariant theory of gravitation consistent with Newton's theory of gravitation in the appropriate limit. But "according to Nordström's theory, the perihelia of Mercury should lag at a rate of about 7 seconds of arc per century, whereas according to general relativity, the perihelia should advance at a rate of about 43 seconds of arc per century." (quoted from Wikipedia). I guess the irony that String theory also fails to predict observations (and is perceived as beautiful by it proponents) was fully intentional.

I never heard of that theory before, and only watched that video because you mentioned it. Sorry to admit it, but I actually enjoyed it, and subsequently also watched "The Story of String Theory (Daniel Robbins)" and read an interview where John Baez said: "It turns out there's a wonderful story here: briefly, particles are to categories as strings are to 2-categories, and all the math of particles can be generalized to strings using this idea!"

This left me with the feeling that String theory might have its place as a "mathematical model" where quantum field theory can be explored beyond renormalization and perturbation theory. You just have to accept that it is not the correct theory of our universe. Like John Baez said in that interview: "Ironically, when I quit quantum gravity, I felt free to explore string theory. As a branch of math, it's really wonderful."

17. **Marvin**
January 7, 2024

A Nobel Prize winner, a Field medalist, a Breaktrough prize recipendaire, invited in their nicest suits to discuss…..about the late. They make a tribute to the acomplishement of the late, showing how it help in their career. But most of all, trying to make us not forget the late. That was my feeling.

18. **cond-mat phd student**
January 7, 2024

Gavin

I have followed pretty much the same initial trajectory as you, entering physics with the idea of studying high energy physics and moving towards a different field (stat-mech*) when I realised the state of hep-th.
I strongly disagree with your assessment that so long as we entice new physics students, hep hype is a net positive.
I find somewhat cynical the position that we should get as many physics students as possible, even if this requires borderline lying to them.

I may be overlydramatic, but personally I felt kind of betrayed.

This strategy reflects very badly on physics as a whole, imho.

* alas, I now have the feeling that cond-math.stat-mech is not in much better shape than hep-th, see the Majorana fermion debacle.

19. **Diogenes**
January 7, 2024

What you will discover from reading philosophy is that unless you precisely define terms you will have arguments for centuries. Here ‘string theory’ remains mostly undefined, even within the timeframe of a single conversation, so arguing about the merits is really pointless. I think what the panel is really saying is: “We theorists get an A for effort over the last century, and even if a subset of us sucked up all the oxygen for the past 30 years and didn’t get that much done, please don’t cut our funding or try to tarnish our shiny reputations. This stuff is hard and we did the best we could.”

20. **Peter Woit**
January 7, 2024

Marvin/Diogenes,
The extent to which a “state of string theory ” discussion was mostly about how wonderful the string theory unification idea of forty years ago was (with any less than positive comment squelched) I think reflects the way this was really about defending the interests of the participants.

For Gross and Witten, they’re now getting to the age where one thinks about one’s legacy and how one will be remembered by history. For both of them it’s looking like they will be seen as having huge accomplishments, but tarnished by their spending much of the later part of their careers promoting a failed idea. It’s in their interest to have the 1984/5 proposal for a TOE seen as of such overwhelming beauty and promise that what happened later can be excused. Brian Greene’s career is even more tightly connected with this.

For Strominger with his A+s for current string theory related work, an important issue is how people see his ongoing “celestial holography” program, which has been promoted by tying it to AdS/CFT and string theory.

21. **Charles Cherqui**
January 8, 2024

My favorite part is he says when Strominger says that if he didn’t believe in it then he wouldn’t be working on it just after telling us out his last 80 papers 2 have been on strings. So he’s not working on it? Then what does that indicate about his faith in it?

22. **Peter Woit**
January 8, 2024

Charles Cherqui,

I think you missed this part:
“string theory has now come to be a word that is used for everybody who is working on anything that goes beyond the standard laws of physics”
I guess that according to him I’m a string theorist.

When he says he believes in “string theory” and gives it an A+, “string theory” just means whatever he is working on, so he’s just saying that he believes in what he’s working on and he deserves an A+.

23. **Charles Cherqui**
January 8, 2024

Peter,

No, I picked that up but took that as him putting lipstick on a pig. Of course it makes sense that rather than admit failure he would simply draw a bigger box around what “string theory” means. In that now it means everything me and my friends are into, regardless what it is. String theory is now simply whatever they are doing to try to go beyond the SM.

Whether he meant to or not, he exposed a truth. If, in their heart of hearts, they really thought this was the right answer they’d still be working on it, just like Einstein kept at it undeterred right up to his death.

24. **Peter Woit**
January 8, 2024

Charles Cherqui,
Gross did something similar, claiming AdS/CFT shows string theory equivalent to a QFT, so “string theory” means “QFT”.

Yes, all these people have abandoned the “string theory” that they were advertising in the infomercial. The point of quoting “stringking” was to show that those like him who still believe in the original vision and are trying to make it work are well aware these people have abandoned them and feel that they have been stabbed in the back.

25. **nikita**
January 8, 2024

Interestingly, Einstein also spent the last decades of his life pursuing a research program that was almost universally considered a dead-end. He didn’t “promote” it though in any sense, as far as I know.

26. **Peter Woit**
January 8, 2024

nikita,

Yes. A good analogy perhaps to the situation we’ve been in since 1984 would be if theorists in 1920 had all decided to follow Einstein, and spent the next forty years not pursuing QM and QFT, but studying ever more elaborate classical generalizations of GR, very excited about how they unified EM and GR. These generalizations somehow would never manage to make testable predictions, with the excuse that the properties of atoms were determined by the solutions to non-linear equations involving geometry at the Planck scale. So, while untestable, the theory would still deserve an A+++.

27. **Kawabata Hiro**
January 8, 2024

Paraphing a paraphrasing of Planck –

“Physics advances one funeral at a time.”

28. **Héhéhé**
January 9, 2024

Peter, it is time to admit that you are StringKing4206 , you clever troll !

29. **Peter Woit**
January 9, 2024

Kawabata Hiro,
Problem is that the younger people, trained by spending years reading Polchinski, are even more deluded about string theory than their elders. Looking at the people in this video, their age is inversely correlated to their degree of skepticism.

Another problem is that it has become clear that this is not going to change on the time scale of my life expectancy.

30. **Peter Woit**
January 9, 2024

Héhéhé,

No, not me. But if it was, I would say that, wouldn’t I?

31. **Fadde'ev-Popov ghosts**
January 9, 2024

Mr. Strominger modestly attributes himself and his followers an “A+++” grade, yet my reservations linger, as most AdS/CFT experts might not be as generous, even in Leibniz’s “best of all possible worlds”.Reading arXiv:2304.08292, one discovers a competing program to “celestial holography” known as “Carrollian holography.” While the – conjectured CFT dual to perturbative quantum gravity defined on a Minkowski space background is anticipated to be situated in the celestial sphere Sˆ2 at infinity, the CFT corresponding to the latter pertains to null-infinity R \times S^2 and obeys to the Carroll symmetry algebra associated with a null Lorentzian hypersurface. Considering that the latter is a codimension one submanifold of Penrose’s conformally compactified Minkowski space, in contrast to the codimension two nature of the former, it appears that Carrollian holography more faithfully embodies the original t’Hooft-Susskind holographic principlE than its celestial counterpart. Even attempts to reconcile both programs are likely haMpered by the distinct dimensionality of the CFT backgrounds, leading to different degrees of freedom and, consequently, distinct thermodynamics of asymptotically flat black hole metrics.

Adding further difficulties, linking asymptotic BMS symmetries with the Virasoro symmetry algebra necessitates extending the BMS group from the semi-direct product of Poincaré with supertranslations to the so-called superrotations. These superrotations, acting as local diffeomorphisms in the celestial sphere, possess generators represented by meromorphic vector fields on S^2, as outlined in arXiv:1102.4632. However, in mapping the phase space from past null-infinity \Scri^- to future null-infinity \Scri^+, enforcing the antipodal matching condition becomes challenging when allowing poles associated with the generators of superrotations. This presents an already classical-level problem in defining the phase space for theories involving superrotations.

Furthermore, celestial amplitudes, discussed in works like arXiv:1711.06138, arXiv:1705.01027, and the more recent arXiv:2210.04725, are defined using a generalization of the optical theorem with a singular shadow integral transform (see App.B of 2210.04725). This singularity renders the inverse ill-defined, leading to the use of vertex operators in celestial spheres with conformal weights Δ featuring non-vanishing imaginary parts, ultimately rendering the theory non-unitary. It’s imperative to recall that the primary goal of holography was to address the issue of the unitary evolution of black hole states. An “A+++” grade, indeed?

32. **Peter Woit**
January 9, 2024

Fadde’ev-Popov ghosts,
Thanks, but I really don’t want to try and host a discussion of the technicalities of celestial holography here, which is off-topic and beyond my competence to moderate.

It does though provide a good example of the current problems generated by string theory hype, including Strominger and his A+++s. “Celestial holography” is one of the very short list of hot topics in hep-th. The focus on the celestial sphere agrees well with twistor geometry and I see that twistor people are working in this field. New symmetries and how to exploit them is another of my favorite topics.

But if I try and start figuring out what is going on in this subject, I find it explained as being motivated by AdS/CFT and string theory, see for instance
https://arxiv.org/abs/2111.11392
where we’re told “A crowning achievement for the celestial holography program would be for it to determine concretely whether string theories are the only consistent theories of (asymptotically flat) quantum gravity.”

Given the history of string theory and AdS/CFT hype, it’s very hard to take seriously a lot of the stated motivation for this subject. Strominger’s performance on this video makes it really hard to take his arguments about what’s promising seriously, and he’s the main leader of this field. So, I start out sympathetic and interested, but have a hard time figuring out which parts of the arguments for the subject are credible and which aren’t.

33. **Shantanu**
January 10, 2024

Peter: out of curiosity, why aren’t there many public debates between proponents and critics of string theory? Such debates exist a lot in astrophysics (Shapley-Curtis debate, Lamb-Packzynski debate, Kroupa- White debate , etc). the only few I am aware of is one between Krauss and Brian Greene and I think there was another one between you and Jim Gates. Probably there should be more.

34. **Peter Woit**
January 10, 2024

Shantanu,

My impression is that there are few if any string theorists who want to participate in a serious debate on this topic, because they know that they would be arguing a very weak case. In recent years the only examples of this sort of thing I can think of were organized by the IAI people in Britain, e.g. this
https://iai.tv/video/the-trouble-with-string-theory
In at least one case, I was disinvited from a planned appearance on a panel discussing string theory, as far as I could tell because a prominent string theorist wouldn’t participate if I was there.

35. **Peter Woit**
January 10, 2024

It occurs to me that while I don't normally like this kind of crude explanation of people's behavior, in this case there's a simple explanation of Strominger's "A+++" business. At the moment he's PI on at least the following grants:
Black Hole Initiative: \$16 million so far from the Templeton Foundation
Collaboration on Celestial Holography: \$8 million from the Simons Foundation
DOE grant DE-SC0007870: \$3.5 million from DOE
The summary of this last one assures us that successful BSM theory has been done, and that the authors are on the road to computing the electron mass and understanding the origin of the universe:
"Vigorous efforts made over the last several decades have advanced our understanding of the fundamental laws of nature beyond the standard model of particle physics. Further advances would potentially include unification of the forces, the reconciliation of quantum mechanics and gravity, a derivation of the standard model couplings, a universal explanation of the area law for horizon entropy, and a theory for the origin of the universe."

Strominger has been in the fund-raising business for a long time. For an unusual example, see here
https://cerncourier.com/a/endowment-reward-for-string-theorists/

36. **Charles Cherqui**
January 10, 2024

Open question. Maybe I'm just slow but one thing I've never understood is if ads/cft relates 5-D Gravity and 4-D QFT, how can it have anything to do with String Theory. which is 10-D.

37. **Peter Woit**
January 10, 2024

Charles Cherqui,
The conjecture more precisely is about string theory on AdS5 X S^5

38. **James**
January 11, 2024

Peter,
I think it is time for you to write another book that would look at the string (mis-) adventure in its larger perspective. We are now seeing an entire generation gone by and the derailment of physics by a relatively small group of people. While some of them are yet alive we need to hear from them if any have the integrety to try and clear the air about what has happened.

39. **Bernard l'Amateur**
January 11, 2024

As far I know, string theory research is still done using pencil and paper, right?
I was wondering what Strominger would use \$16 millions for?
Is it for doing super complicated computations by hiring IBM supercomputers? Is it for paying postdocs \$200k+ a year?
Is it for purchasing expensive experimental equipment for testing their theories?
And how many years is such a grant spread over? Does this mean that research in string theory is still the most profitable business in HEP?

Thanks,
Bernard

40. **Peter Woit**
January 11, 2024

James,
I'm not planning on writing another book about the string theory business. The old one still holds up quite well, and I want to spend my time on other more promising pursuits.

I've done and continue to do my part to deal with the string theory hype problem with posts here on the blog. A question for all in the theoretical physics community is why you are doing nothing to deal with this problem. It's not going away.

41. **Peter Woit**
January 11, 2024

Bernard l'Amateur,
Strominger is just one of many PIs involved in the three grants I mentioned, so the money is divided amongst many people. I assume all of them fund the usual sorts of things:
1. Postdocs
2. Grad students (tuition + stipends)
3. Conferences + travel
4. "summer salary" for the PIs
5. Overhead for the universities involved

For instance, for the Simons collaboration grant, see postdoc ads here
https://simonscelestialholographycollaboration.org/positions/

This is funding a very significant number of postdocs and likely grad students, but as far as I know zero funding for permanent positions (except indirectly through the overhead). This exacerbates the problems of the field of
1. An overemphasis on hiring in a small number of specific areas that are "hot topics".
2. An overproduction of Ph.Ds and postdocs, who face long odds against getting a permanent position.

42. **David Roberts**

January 11, 2024

From that 2003 CERN Courier news item:

> Andrew Strominger of Harvard, who facilitated [Jeffrey Epstein's] gift

That did not age well!

43. **Peter Woit**
January 11, 2024

David Roberts,
To be fair to Strominger, 2003 was before Epstein's illegal behavior was publicly known. I haven't seen Strominger's name come up in the list of prominent theorists who were hanging out with Epstein at a conference he paid for in 2006, shortly before he was arrested.

44. **George**
January 12, 2024

Peter,

your comparison with Einstein hypothetically being followed by whole theoretical community in his pursuit of combining electromagnetism and gravity is spot on. One question remains, though. To be fair to Einstein, we need to assess achievements of prominent string theories BEFORE they started their string theory revolution. We all know remarkable legacy of Einstein and what he did prior to starting his unsuccessful quest. Are there such achievements to be found in works of Witten (in physics, not in mathematics) and other string theorists?

45. **Peter Woit**
January 12, 2024

George,
David Gross's discovery of asymptotic freedom and development of QCD was a huge advance and his Nobel Prize is well-deserved. During the early 1980s, before string theory, Witten did remarkable work that was very much physics, see for example his papers on "current algebra" (effective theory of mesons and baryons).

46. **Indiethphy**
January 12, 2024

Einstein program, in one of its incarnations, was actually followed, and to great success, by Weyl, Schrödinger, London, maybe/almost Klein, Yang-Mills, Schwinger, Gell-Mann, Glashow, Weinberg and others, in the form of the gauge principle, which is the backbone of the Standard Model. The story is of course well known, and it nicely rendered for instance in A. Zee's book "QFT as simply as possible ".

47. **Peter Woit**
January 12, 2024

Indiethphy,
I don't think gauge symmetry is really the "Einstein program". It's not something he followed up on, and that's one of the main problems with the research program he followed in the second half of his life. Among the people you mention who did pursue gauge theory, Weyl at the beginning is the only one who took a geometric perspective, the others didn't (Weinberg very explicitly claimed that thinking about geometry was a mistake). If Einstein had pursued gauge theory instead of what he did do, that would have changed the history a lot.

Besides ignoring gauge symmetry, the other problem with Einstein's program is that as far as I know, he paid no attention to the geometry of spinors.

If he had pursued spinor geometry and gauge symmetry in his attempts to unify physics, the results would have been radically more positive (even if he had continued to be skeptical about quantization) One could argue that the string theorists have been making exactly this mistake again.

48. **rfb**
January 12, 2024

Einstein did do some work on spinors. In the early 1930s, he and the mathematician Walther Mayer published several papers on semivectors, a type of generalization of spinors. They gave up on the idea after some discouraging words from Pauli along with a demonstration by Bargmann that the same results could be achieved by superposition of ordinary spinors. See Chapter 5 of "Einstein's Unification" by Jeroen van Dongen.

49. **D R Lunsford**
January 13, 2024

Actually Einstein did try to deal with spinors – they were sometimes referred to as semi-vectors. Distant parallelism was another go at local frames. Weyl's original gauge-invariant geometry was a direct attempt to extend GR and it lives on at the base of field theory. So IMO there is no comparison of Einstein's work and string theory delusion. Einstein was looking for a geometrical theory with a proper Hamiltonian that could then be quantized in the Dirac way. That was the right approach IMO and can still work. BTW Fock dealt with spinors in GR in a completely correct way. Fock had a better understanding of GR than almost everyone who wasn't Pauli, Weyl, Dirac, or Einstein.

-drl

50. **Shantanu**
January 13, 2024

Peter, something IT. A recent colloquium on string. theory at University of Alabama.
Would be interested in your take on this
https://www.youtube.com/watch?v=AdErRdW4jVM

51. **Peter Woit**
January 13, 2024

Shantanu,
Thanks. Took a quick look. It's an interesting example of what's going on with string theorists. 90% of it was advertising for string theory, all decades old. The last 10% was the news that the speaker is moving on from string theory to something else: "generalized symmetries".

The problem with this very common situation is that, while string theory research is on the outs, hep-th research is in the same situation as it has been for many decades: almost everyone works on the same short list of "hot" topics. Today there's a very short list of these, to see it is even easier than it used to be: just look at the list of "Simons collaborations", the winners of their competition to choose the latest few hot topics. Basically now these are:

1. "It from Qubit": study toy models supposed giving gravity from quantum information considerations. This may have peaked and be on the way down, after it jumped the shark with the wormhole publicity stunt a bit more than a year ago.
2. Amplitudeology a la Arkani-Hamed, or also the bootstrap: the revival of the failed S-matrix program of the late sixties.
3. Celestial holography: Strominger is a talented fund-raiser.
4. Generalized symmetries.

Getting a job if you're doing one of these is quite difficult. If you're not doing one of these it's impossible. Maybe one of them will give a big breakthrough in our understanding of fundamental physics, but no evidence for that so far. If the way forward is something other than 1-4, the field is in its usual position of making any young person working on the right way forward unemployable.

52. **Mark Hillery**
January 14, 2024

One wonders if space for different approaches could open up at places off the beaten track. This was the case with quantum information and foundations in the early days. It emerged from places like Wheeler's group at UT Austin and Charlie Bennett and company at IBM, and not from the IAS or Harvard. An example of a very successful career coming from this era is that of Bill Wootters. Bill came from Wheeler's group, where he was one of the authors on the no-cloning paper, and spent the rest of his career at Williams College, where he made fundamental contributions to entanglement theory as well as being one of the originators of quantum teleportation. Could something like this happen in high-energy theory, or is it out of the question?

53. **Eitan Bachmat**
January 14, 2024

Dear Peter
I t seems to me that your view of hot topics and the choices of the Simons foundation is too localized. I think the more correct view is that what is promoted is the advancement of symmetries, dualities and generalizations as beatiful organizing and cross disciplinary concepts which are extremely effective in math and science. More generally, it seems that cross disciplinarity is strongly promoted. There is a symmetry based collaboration on the engineering of fusion, essentially an elaboration of Noether's theorem, there is another about extreme wave phenomenon. Symmetries and symmetry breaking which is mostly classical, combining engineers, mathematicians and physicists, there is the homological mirror symmetry collaboration which is physics inspired pure math which has great results regardless of wether it has anything to do with actual physics and you can apply this analysis to most collaborations, There are a few pure math and a pure computer science collaboration, but these are the exceptions.
Given this interpretation, its easy to understand the choices related to hep. They are by the more mathematically sophisticated and symmetry and duality producing members of the community and the more mathatically sophisticated topics.

54. **Peter Woit**
January 14, 2024

Mark Hillery,
Wooters and his career is an interesting case. From his CV online, after his Ph.D. at UT Austin he stayed on two more years as a "postdoc/instructor", then went on to Williams, where he stayed the rest of his career. What he didn't do was get one or more regular research postdocs and then a tenure-track job at a research institution. With the kind of work he was doing, likely he would have had no chance at such jobs, even with Wheeler's backing.

I remember looking into liberal arts college jobs like the Williams one, since these places might not care so much about whether your research program is in the hot hep-th area. But there aren't so many such jobs, hard to get one without a leg up like backing from Wheeler.

It's even more the case now than in 1980 that you absolutely have to be working on one of a small number of hot topics to get a postdoc or a tenure-track job at a research university. Take a look at what successful candidates here
https://sites.google.com/site/postdocrumor/
are working on. From looking at quite a few examples, they're all exactly the same few topics. Maybe an accurate way to describe these topics would be not by technical names but
1. What Strominger is working on.
2. What Vafa is working on.
3. What Seiberg is working on.
4. What Maldacena is working on.
5. What Arkani-Hamed is working on.
I don't see anyone getting a job with a background working on ideas off the beaten track. What I find remarkable about the HEP theory community, faculty and funding agencies alike, is that they refuse to acknowledge that this system is broken and take steps to create a viable career path in which people could succeed working on less popular topics.

55. **Peter Woit**
January 14, 2024

Eitan Bachmat,
My comment was not about the Simons collaborations in general, but very specifically about the ones in hep-th, the complete list of which is as far as I can tell
1. Celestial Holography
2. Confinement and QCD Strings
3. Global Categorical Symmetries (this one is not just hep-th, but cross-disciplinary with a large math and condensed matter part)
4. It from Qubit
5. The non-perturbative bootstrap

Looking at the list, I wouldn't describe it as embodying mathematical sophisticated mathematics (other than the cross-disciplinary 3.). Again, besides 3, symmetry not a big theme for 2 and 4. For 1. and 5, the interest in symmetries is only in certain very specific ones (conformal invariance/ specific asymptotic symmetries).

My general impression of how the Simons Foundation chooses topics is that they focus on already active areas of research at elite institutions, and like to fund people who are already widely acknowledged as the best in their field. They also are interested in funding work that significantly involves computation, and, yes, cross-disciplinary work.

What I know well is the pure math and hep-th areas. There, the pure math things they are funding are very successful and active research directions, maybe their money helps accelerate progress. On the hep-th side I don't think their impact is positive, accelerating trends in an unhealthy subject is not a good idea.

56. **David Roberts**
January 14, 2024

@Peter

I certainly didn't mean to imply anything untoward with my comment on the quote about Strominger, I just meant that's it's a really unfortunate sentence, given what we know now.

57. **Oskar Skalski**
January 19, 2024

I'm just a person with interest in physics without any background (other than what I had at my IT studies) and I was once enamoured with string theory thanks to Brian Greene's documentaries on National Geographic. Then when I've delved more into the topic I saw all the shortcomings of this idea and how sometimes it is treated as almost a religion (vide Michio Kaku). But I try to follow every new interesting discussion on youtube (and WSF has some very interesting ones) so I've started it and then was a bit baffled with it. It seems like this guys are living in some parallel reality. What was more ridiculous all guests are proponents of ST and they didn't invite any skeptics for the discussion to maintain some balance. Riger Penrose would be a good choice for example. I didn't finish the whole discussion because it seemed that it wasn't worth my time. They just regurgitate old points without taking some self-reflection about the topic.
At least they didn't invite Michio Kaku. It seems like he became a meme this days.

58. **Peter Woit**
January 19, 2024

Oskar Skalski,
The string theory community in general recognizes that Michio Kaku regularly puts out indefensible hype about their subject, but does nothing about this. The depressing thing about the panel discussed here is that it makes clear that the reason for this is that the leaders of the subject don't have a problem at all with indefensible hype, they'll participate in it given the opportunity. Among the endless Kaku nonsense, hard to think of a case where he went on the way Strominger does about the current state of string theory deserving an A+++.

59. **Shlomi**
January 23, 2024

It's interesting that Strominger went from assigning ST "3 As, 2 Bs, 3 Ds and 2 Fs" in 2010 to A+ now! See https://www.math.columbia.edu/~woit/wordpress/?p=3206
What could be the reason for the seeming improvement?

60. **Peter Woit**
January 23, 2024

Shlomi,
Grade inflation at Harvard in recent years seems to be even worse than I had thought…

61. **Peter Woit**
January 24, 2024

Shlomi,
More seriously, that previous set of grades was given at a Harvard colloquium in front of his colleagues. If he had tried the "A+++" business there, everyone would have just laughed at him and if they thought he was serious, he would have completely lost credibility with his colleagues.

On the other hand, at this kind of informercial, he's assuming none of his colleagues are watching, or if they are, they're in on the idea that it's all right to lie to the public, in the service of retaining their support for your research.

62. **anon**
February 10, 2024

Sounds to me like a eulogy given at a funeral, praising the dead while carefully avoiding any negative speech (as Gross tried). Strominger gave a C back in 2010 when string theory was still kind of alive.

Spring Course

January 11, 2024
Categories: Uncategorized

Starting next week I'll be teaching a graduate topics course, with the general plan to develop much of the quantum field theory of the Standard Model in a form accessible to mathematicians, emphasizing the connections to representation theory. There's a course web-page here, notes will start appearing here once the course gets underway. While the course will be aimed at mathematicians, I'm hoping that some physicists might find it interesting and worth trying to follow.

The last time I did something like this was back in fall 2003. At that time the course was aimed at getting math students to the point of understanding the TQFTs for Chern-Simons theory and Donaldson theory and was very much based on the path integral. This time I'll be mostly sticking to flat space-time and using more representation theory. Also, a lot more about spinor geometry, as well about about how Euclidean and Minkowski space-time versions of QFT are related.

Comments

1. **Michael Weiss**
   January 12, 2024

   Peter, might it be possible to post Youtube videos of your upcoming lectures? I bet these would be widely viewed (nationally and internationally) in the coming decade, just as are such educational materials from MIT, Stanford and Cambridge UK.

   These physics-related Youtubes are typically free, and so I do not know how these institutions handle the economics of such outreach. Ditto for a course in introductory group theory by Dick Gross from ca. 20 years ago.

   PS Remember the videotaped EM Purcell lectures at the Cabot Library in the 1970s? What a loss to the next generation that these were not transferred to a web-based format, like Coleman's lectures on QFT from the same decade.

2. **Peter Woit**
   January 12, 2024

   Michael Weiss,
   This class will be aimed an at advanced level, small audience, taught in a small room with no video equipment. So no video, which I'd prefer anyway.

   I'm hoping to put a lot of effort into the notes and that the result will be something many people can get something out of. Ideally, after each lecture the notes posted will correspond closely to what I talked about. If people want to follow along with those and send me questions and comments that would be great.

3. **Timothy Keller**
   January 12, 2024

   I will be looking forward to your notes, especially the discussion of representations
   Just an algebraist with an interest in applications in physics.

4. **Art**
   January 19, 2024

   I think the link in the intro of your new notes is missing an intermediate site: https://www.math.columbia.edu/~woit/LieGroups-2023/qmnumbertheory.pdf. Looking forward to trying to follow along.

5. **Peter Woit**
   January 19, 2024

   Art,
   Thanks! Will fix.

Know Time Podcast

January 14, 2024
Categories: Uncategorized

For another podcast/interview with me that was recently recorded, see Maths, Twistors & String Theory. Know Time is a series of podcasts that is a project of Shalaj Lawania, and I was impressed by the effort he put into trying to make sense of a complicated and inaccessible subject. For an excellent pairing with what I have to say, see his earlier interview with Matthew Kleban, who has a more positive take on string theory, the multiverse, etc.

Quick Links

January 20, 2024
Categories: Uncategorized

A few quick links:

- There's a one-day conference next Friday at the IHES, recognizing Dustin Clausen's appointment to a new Jean-Pierre Bourguignon Chair. Should be several interesting talks, see here.
- There's an ongoing conference at the KITP on the topic of What is String Theory? So far, none of the online talks address that issue. Evidently there was a discussion of the topic last Wednesday, but not recorded. Were any readers here in attendance and willing to report on that event? Next chance to find out what string theory is will be a Monday Blackboard Lunch talk by Gopakumar.
- In April there will be an IUT conference hosted by Zen University in Tokyo, see here. All the speakers but one are from RIMS. For news from the senior people devoted to IUT, Ivan Fesenko has moved to Westlake University in Hangzhou, and Shinichi Mochizuki is has been blogging here.
- There's a new Shanghai Institute for Mathematics and Interdisciplinary Science, headed by Shing-Tung Yau.
- For those following what happens with the small number of permanent positions in particle theory, news from 4 gravitons.

Update: One more, which I'm quite interested in. Scholze will be giving a series of three Emmy Noether lectures at the IAS in March, topic Real local Langlands as geometric Langlands on the twistor-P^1.

Comments

1. **Shantanu**
   January 23, 2024

   Peter : Gopakumar's talk is online.

2. **Peter Woit**
   January 23, 2024

   Shantanu,
   I watched the talk. Basically his "What String Theory Is" answer is an explanation of the hope that large N QCD is a string theory (zero about string theory providing quantum gravity or unification). He takes this story up to about 25 years ago and AdS/CFT, doesn't even mention the basic problem why this doesn't give you QCD (no way to get asymptotic freedom). Asked what his fondest hope for 20 years from now, it was to find the string dual to QCD.

   So, as for "What Is String Theory?": string theory unification dead, only hope is to keep going on the AdS/CFT/QCD front and somehow make progress on an idea that thousands of people have been stuck on for 25 years.

3. **HJM**
   January 25, 2024

   Regarding the ABC conjecture, I believe that this paper that came out today by Kirti Joshi might be of interest: 2401.13508.

4. **interested_bytander**
   January 25, 2024

   Related to IUT, although explicitly saying some steps are missing in Mochizuki's papers, is the latest preprint by Joshi claiming to have now obtained a proof of several variants of Mochizuki's Corollary 3.12 https://arxiv.org/abs/2401.13508

5. **Kurt Schmidt**
   January 27, 2024

   Kirti Joshi should do what Peter Scholze and Terence Tao did and get the Lean community to formally verify his papers on Mochizuki's corollary 3.12 in the Lean proof assistant so that there are no doubts as to whether his proof is right or not.

6. **Peter Woit**
   January 27, 2024

   Kurt Schmidt,
   There's no argument here that experts think works but needs more careful checking.
   What's needed in this case is just the standard procedure that the math community has developed over centuries to deal with a claimed proof: submit the paper to a first-rate journal for an impartial editor and referees to deal with in a manner acceptable to experts in the field.

   The public fiasco of the IUT papers was caused by the failure to do this.

   A common reaction I'm getting now when I ask experts about this is that too much time and attention has already been wasted on the topic, so not a good idea to give it more attention unless and until there are experts who have looked at it and think it works.
   So, unless there's news of that sort to report, enough of this for now.

7. **somereader**
   January 29, 2024

   It should be noted that in his latest paper Joshi claims to prove some lower bound on the size of certain sets Theta (so that something non trivial occurs in Cor 3.12), but not the Mochizuki type upper bounds that would lead to Diophantine applications (this was stated in the older paper https://arxiv.org/abs/2111.04890v1 "towards Diophantine estimates", and the new paper appears to be an expanded version of that paper at the global level, it doesn't provide a sharp upper bound, only in remark 7.8.3.2. that the upper bound is plausible in the global case).

8. **Peter Woit**
   January 29, 2024

somereader,
Thanks. I have been hearing comments about Joshi's proof that it is unclear whether his version of the Corollary may differ from Mochizuki's and not have the same implications, in particular not getting abc.

9. **Doug McDonald**
January 30, 2024

Peter: I know this is getting old. But, is it clear to anybody whether Joshi is claiming that this preprint is in fact supposed to truly prove abc itself (though the known steps following 3.12)? For a while I thought so, but interestingly I find that the string "abc" only appears twice in it, neither in a direct statement.

10. **Peter Woit**
January 30, 2024

Doug McDonald,

One thing I have heard from some experts is that it is unclear to them whether Joshi is claiming a proof of abc.

11. **Peter Woit**
January 31, 2024

To clarify the last comment, it's pretty clear that Joshi is not explicitly claiming a proof of abc in this last paper. It would be great if someone would get him to state clearly whether or not this is supposed to be a proof of abc, and if not, what is missing.

One possibility that I can think of is that he hasn't checked/doesn't trust Mochizuki's argument that 3.12 implies abc, and that he hasn't come up with his own alternative argument using his own methods.

12. **Kirti Joshi**
January 31, 2024

@Dr. Woit,

What you assert is indeed correct, I prefer to do my own due diligence independent of the claims of Mochizuki's IUTT IV. The abc-conjecture is an expected, but delicate consequence of Corollary 3.12 (and some other results), but that is a work in progress and my conclusions (with proofs) will appear in my paper: Construction of Arithmetic Teichmuller Spaces IV.

In answer to your earlier post, my recently released paper (Constructions III) does provide many versions of Corollary 3.12 including Mochizuki's version and I provide a `Rosetta Stone' which facilitates a detailed comparison of the two theories. My formulation and proof of the geometric case of Corollary 3.12 is given in Constructions II(1/2) . For precise assertions, please refer to my papers.

13. **Kurt Schmidt**
February 5, 2024

somereader, Peter Woit

Kirti Joshi said that he will be proving the upper bounds in a forthcoming paper:

https://mathoverflow.net/questions/435110/consequences-of-kirti-joshis-new-preprint-about-p-adic-teichm%c3%bcller-theory-on-th/463562#463562

Particle Physics Is Not In Crisis

January 20, 2024
Categories: This Week's Hype

For a low-rent version of the self-congratulatory program discussed here, Bad Boy of Science Sam Gregson has a new video up entitled Particle Physics Is Not In Crisis – but we can make improvements. Cliff Burgess plays the Strominger role, explaining that the idea that there's any problem with what's going on in particle theory is "a nothing-burger" and "a complete non-issue". Asked to rank any such problem on a scale of 0-10, he gives the Strominger-esque ".0001". Martin Bauer goes for "1".

The take on the question is much the same as Sean Carroll's four-hour plus explanation that there is no problem, but shorter. It's similar to Carroll in that no one who thinks there is a problem was invited to participate, or even gets mentioned by name. There's a repeated reference to mysterious "Twitter influencers", which I find very confusing because just about the only particle theorists I see spending time on Twitter going on about the state of the field are Bauer and Burgess. They can't mean me since I've so far resisted the temptation to enter Twitter discussions. The idea of trying to have a serious discussion of complex scientific issues in the Twitter format never made any sense to me, and (StringKing aside) I find it hard to think of any tweets by anyone that shed any light on serious issues in this area.

The more serious part of the program was the discussion among the two HEP experimentalists of the state of their field, which got a 5-6 on the crisis level scale. I wrote about the problem there five years ago, and very little has changed, other than that we're five years closer to the date when there will no longer be an energy frontier machine running anywhere in the world. The underlying problem wasn't really explained. CERN is working on it, but there is as of now no specific plan with specific budget numbers for what to build next. Maybe I misunderstood, but it seemed that Bauer and others were talking about how the field just needed to convince funding agencies to support budget numbers of order \$100 billion, which is a pipe dream.

Update: Latest podcast from Sean Carroll has nothing to do with the crisis in particle physics, but he starts off anyway with this:

> You may have heard there is a crisis in physics. No, there's not. I mean, there's little tiny crises, but that's the very standard procedure if you're doing science at the cutting edge, is all sorts of puzzles that we don't know the answer to.

"Little tiny crises" is I guess his version of the Cliff Burgess ".0001" and Andy Strominger "A+++".

Comments

1. **Gavin**
   January 20, 2024

   Just to emphasize, I am not and was not a string theorist (though I was an astrophysics postdoc).

   Are you really, really sure you want to claim StringKing "shed[s]… light on serious issues in this area"?

   I think his Twitter/X is obscene, toxic, and not serious. He represents a thread in physics academia that is at least as toxic to people in the field as the "groupthink" that can come from senior people. He's obnoxious, highly judgmental of other peoples' work without thinking he needs to provide an actual argument, and convinced of his own brilliance. This brand of junior physicist is quite common and (I speak from experience) responsible for driving many brilliant people away from the field. I strongly believe that in platforming this person, you are supporting a form of toxicity in academia at least as bad as the one you are fighting against (string theory groupthink, which I agree is also a problem).

2. **Peter Woit**
   January 20, 2024

   Gavin,
   That reference was tongue in cheek. The material on the "stringking" account is so obviously juvenile and idiotic that I still think it likely it's a parody trying to make string theorists look bad. That you think he's a common type among young string theorists doesn't look good for them.

3. **Sabine**
   January 20, 2024

   I have an idea about the mysterious twitter influencers lol

   Those guys crack me up. Like is anyone surprised that particle physicists don't want to admit particle physics has a problem, part of the problem being that they don't want to admit they have a problem?

   They're in for a rude awakening when funding bodies all over the world realize that particle physics eats up shitloads of money for very little in return and that they can use that money for better things.

4. **Bill**
   January 21, 2024

   They need grant mula and they obviously don't want to do much to get it. So they just repeat over and over again the same calculations. Most of the academe is like this.

   > I have an idea about the mysterious twitter influencers lol

   Sabine, do you think you are an influencer? lol

5. **Mike**
   January 21, 2024

   Surely they are chiefly referring to Eric Weinstein? He's not a Physicist or mathematician, but definitely a twitter influencer who spent a lot of time critiquing HEP on twitter.

6. **Alessandro Strumia**
   January 21, 2024

   Twitter discussions can be fast: Sam Gregson blocked me on Twitter for just answering "yes" to his question "is there a crisis?". The problem is that institutional

communications are similarly closed, up to the point that many serious physicists avoid getting involved in the unrealistic forced institutional optimism. Collider institutions seem to fear that, by openly discussing the problem, the system might collapse and the huge funds got by nuclear physics after 1945 might dry up. But in this way resources that still come are passively used to maintain the status quo. The hope was that LHC would have solved the problems by discovering big new physics, but who still hopes that? Who believes that LHC will really run until 2040? That 6000+ people are still needed to analyze LHC data?
The field should recognise the problem and try addressing it by shifting current big resources and best experts to trying to develop an innovative muon collider. If this is not done, the risk is that in ≈10 years from now the resources will evaporate anyway and the field will quietly fade away. Already now, bright students understand there is a problem and often avoid joining the field, so the problem grows.

7. **Krzysztof**
January 21, 2024

There is some recent progress on the future collider front:
"Construction is anticipated to begin around 2027-2028, pending government approval, with an estimated duration of 8 years. The commencement of experiments could potentially initiate in the mid-2030s."
https://inspirehep.net/literature/2740505

8. **Peter Woit**
January 21, 2024

Mike,
Hard to know whose arguments they are critiquing, which seems to be an intentional tactic. There were some graphics in the background, one of which included a blog post of mine (but it was a blog post about something Sabine Hossenfelder had written….).
https://www.math.columbia.edu/~woit/wordpress/?p=11551

9. **Peter Woit**
January 21, 2024

Krzysztof,
That's the Chinese CEPC proposal, which has not been approved for funding and as far as I know doesn't even have a site picked out. Similarly with the ILC proposal in Japan, it's very unclear whether these things will ever get funded. The big problem is the cost, coupled with the fact that they won't get to higher energies than the LHC.

10. **Thomas**
January 22, 2024

To be fair, Gligorov explains why it is hard to see how entering experimental particle physics as a graduate student is a good idea. The best you can hope for is to be a small, poorly paid, cog in a large machine with a very uncertain future.

11. **Peter Woit**
January 22, 2024

Thomas,
I should make clear that my problem with this is with the theorists, not the experimentalists. The experimentalists are coming off great successes (discovering the Higgs, ruling out SUSY) and facing a crisis not their fault but due to basic physics, which makes getting to higher CM energies very difficult and very expensive. They may be trying to put the best possible face on the problem, but they acknowledge they have a problem.

The theorists on the other hand are in a situation that is entirely their own fault, for decades pursuing failed ideas, while hyping these as great successes. Claiming that the situation now is A+++, .ooo1/10 of a crisis, or only a normal "very tiny" crisis is just absurd, and exactly the underlying source of the problem. If you refuse to acknowledge you have a problem, you're not going to do anything to deal with it.

12. **clayton**
January 22, 2024

four hours is a lot of hours to say "nothing to see here"

13. **Peter Woit**
January 22, 2024

clayton,
As Shakespeare put it:
"The lady doth protest too much, methinks"
Applies not just to four hours, but to "A+++" and ".ooo1"

14. **Mike**
January 23, 2024

A large chunk of the four hours was a really good overview of whats known and how, and what the problems are. The rest was an argument for why there is no crisis in HEP (which I found unconvincing). So worth listening to if you are a laymen …

15. **Krzysztof**
January 23, 2024

Peter,
1. it is TDR, not just CDR -> CEPC design is more advanced than that of FCC
2. in my opinion, politically/financially, the probability of CEPC approval >> P(FCC or ILC)
so, it is a big news

16. **John Baez**
January 23, 2024

There's definitely no problem with particle physics: that's why more and more particle physicists are assuring us there's no problem. 🙂

17. **Peter Shor**
January 24, 2024

Alessandro Strumia says

> Collider institutions seem to fear that, by openly discussing the problem, the system might collapse and the huge funds got by nuclear physics after 1945 might dry up.

It seems to me that if anybody is expecting to get funds for building a larger collider after the LHC runs end, assuming the LHC hasn't produced any hint of new physics at higher energies by then, they are completely delusional. (But then, a lot of high-energy physicists seem to be delusional.)

18. **Adam Treat**
January 24, 2024

The ones who are saying no problem are all tenured and very secure in their old positions and have no reason to acknowledge any problem. They are leaving the next generation of theorists in a terrible state, but what do they care? They've "made it" and admitting there is a problem admits their own failure. So we go…

19. **Diogenes**
January 24, 2024

There may or may not be anything sociologically "wrong" with particle physics but it is clearly destined to be less relevant and less important over time as the unknown portions become unknowable through experiment and have even less contact with human experience. That's what is really going on.

20. **Peter Woit**
January 25, 2024

Diogenes,

During the glory days of the subject 50s/60s/70s it had little contact with human experience, that's not the problem. The subject (unavoidably) moving into a mode where it no longer had experiment to keep it honest, and not replacing that with something else has always been to me the core of the problem. In my book I tried to express this with a line from Bob Dylan

"But to live outside the law, you must be honest"

What I find upsetting about recent claims that all is well is that they're taking lack of honesty about the situation to a new level.

21. **WTW**
January 25, 2024

Peter,
I'm reminded of something that I first saw online, written at the top of the first page of a geology notebook:

The X-Files Principle: If you truly believe in a hypothesis, all evidence will eventually prove it.

I.e., the human mind's ability for self-deception — to not just believe one's own BS, but to be able to justify it to oneself and to others through (mis)interpretation of "evidence" — is inexhaustible. And while it is admittedly a circular argument, the evidence for this seems to be everywhere around us ;-).

But in the specific case of theoretical HEP:
When there is little objective "evidence" on which to base one's "beliefs" in hypothetical constructs (aka "models"), and the mechanisms that do seem to bear fruit are themselves layered in poorly understood, almost semi-mystical "effective" theory, then a major determinant of what one believes is based on the characteristics of those who also hold the same beliefs.

Since theoretical physicists, as a group, tend to make it a point to identify "the smartest person in the room", that becomes a dominant factor, and one that exacerbates the above Principle. As everyone in a Physics department or research group knows, physicists are among the cleverest people on Earth. Unfortunately, "cleverness" is often mistaken for "insight" and even "wisdom" in one's (and others') search for adding to our knowledge. And ongoing confirmation bias among those groups of extremely cleverly intelligent people just exacerbates the above problem. Rather than the common (mis)conception (and self-justification) that our intelligence protects us from such bias, it can tend to reinforce and rationalize it. It becomes the equivalent of "doing God's work" to be instrumental in aiding and moving such a group's work forward, discovering ever more self-generated "evidence" of its worth as that work progresses, even when that effort is in the furtherance of a miasma.

So that leads to several questions in relation to the situation in theoretical physics. E.g.,
a) How much of this self-justification is due to self deception, with these people actually believing what they are saying, or
b) How much is actual lying, in order to maintain status, gain funding, etc. etc. etc.

I suspect it is a mixture of both, with a) being used to justify b). And I suspect that we all need to be reminded to heed the above geologist's warning, even including those who believe that there are severe, perhaps terminal problems with the ways that theoretical HEP has been worked on and developed.

22. **Peter Woit**
January 26, 2024

WTW,
This question has always bothered me. To put it simply, does Michio Kaku believe the nonsense he writes or is he lying? From looking at him and many other similar cases in other different areas, my guess is that he just sees truth as being irrelevant to what he his doing. He has an agenda, a job to do, and what's relevant is furthering the agenda, doing the job. You don't ask a criminal defense attorney "what's the truth of the matter about the criminal act your client may have committed?", that's not something he or she thinks about.

It is depressing though to see events like these recent ones where the physicists involved have clearly decided to join Kaku, deciding that defending their own interests or the perceived interests of their tribe is what their job is.

23. **George**
January 29, 2024

As Feynman said: "The first principle is that you must not fool yourself and you are the easiest person to fool." Unfortunately, theoretical physicists are among the worst offenders, not only those that do string theory, but others that do any kind of theory with little regard to experimental data (for example, most of statistical physicists).

Another issue is the sunk cost fallacy: string theorists have invested so much time in this theory, and bragged about solving the deepest problems in physics for decades, that backing down these claims must feel very frightening. That is why they all stick together, pat each other on the shoulders (grant and peer-review wise) and generally avoid any balanced discussion.

24. **Theorist1234**
January 30, 2024

So let us say that we are String theory researchers with permanent jobs and many years in the field.

What should we do?

Try to come out with ideas within Swampland, Black Holes, AdS/CFT or Machine learning directions?

Invent new directions?

Quit String theory and pursue other dirctions in Particle Physics or Cosmology?

Quit Particle Physics and go into other directions of Physics?

Quit Physics and move to Economics or Finance?

Somebody commented above "string theorists have invested so much time in this theory, and bragged about solving the deepest problems in physics for decades, that backing down these claims must feel very frightening"

One can back down the claim, but what difference does it make?

25. **Peter Woit**
January 30, 2024

Theorist1234,
If you have a permanent job in theoretical physics, you're being paid to do the best possible research/teaching in that field. The one thing you shouldn't be doing is continuing research activities in a failed research area. If there are other research directions in physics you find interesting and worthwhile, you should do those. If there aren't, you probably should quit the job and do something else with your life.

26. **Theorist1234**
January 31, 2024

In my opinion, Particle Physics overall is momentarily as failed area as String theory.
With no clear experiments in the near future, it will be futile years. Cosmology data might save the day or might not.

Meanwhile, we can try to cover some bits here and some bits there, hoping for the best.

Or go into Finance, Machine Learning or Quantum Computing.

27. **Bernard l'Amateur**
January 31, 2024

Peter,
I think it is unfair to ask these people to do something else. These are human beings after all. They have families and mortgages to pay, truth seeking comes second to these. They are working at highly competitive institutions. Asking them to do something else is like asking a mechanic to close their garage and go do a carpenter's job where competition is already very high too. Doing anything else means for them closing down their business. They just can't work on anything else, for they would have done it by now if they could. They cannot even quit their prestigious institutions to work in other low-profit institutions to be able to sincerely pursue their dream of unraveling the secretes of nature. The blame should entirely be put on the funding agencies that use public money and the millionaires who cannot use their brains and stop believing the BS these people try to sell them to keep their business open. This is simply the reality of the human society through history. People without brains have the money, people with brains have the talent to dupe the former to get their money. Real truth seekers don't ask for millions of funding. Just recall how the great physicists of history turned down offers from prestigious institutions just because they know that they wouldn't be able to properly pursue their dream at those institutions. But times have unfortunately changed, and people have to adapt to survive.

28. **Peter Woit**
January 31, 2024

Bernard l'Amateur,
The problem isn't funding agencies/rich people. They listen to what the most prominent and respected experts in the field tell them, don't independently make their own decisions about what is most promising to fund.

I think this is exactly why such experts are now going to the public and making ridiculous claims about how everything is A+++ and there is 0.0001% crisis. That things are not going well has become very obvious, not just to the public but also to their colleagues in neighboring fields. If this negative perception goes further, funding will be seriously threatened.

While there are some theorists for whom doing something else would be a problem, this is rarely the case with leaders in this field. The senior faculty at the IAS, Princeton, Harvard, etc. etc. have tenure and are well paid. Their children are not going to starve if they lose grant funding because they admit things have not worked out and they need to do something else.

29. **SRP**
February 2, 2024

I still find it odd that the experimental particle physicists who want to probe the energy frontier haven't united in their various committees around serious research and development, at realistic budgets, of advanced accelerator concepts that would obviate the need for giant accelerators at unrealistic budgets.

30. **Peter Woit**
February 2, 2024

SRP,
It's not that people in hep-ex wouldn't love for there to be better accelerator technology that would solve their problem and haven't been willing to support research in that area. The problem is basic physical limits:
1. For proton rings, people have worked very hard at getting higher magnetic fields, with only marginal improvements, not the order of magnitude you would need to make a difference.
2. For electron-positron rings, the synchrotron radiation losses go as E^4, no matter what you do.

3. For linear accelerators, getting big increases in energy gradient in a stable high luminosity beam seems to be very difficult.
4. Best prospect these days seems to be a muon ring, lots of people very interested, but short muon lifetime makes this very difficult.

31. **SRP**

    I was thinking about advanced concepts that would slash the construction and operating costs, e.g. wakefields.

This Week’s Hype

February 1, 2024
Categories: This Week's Hype

For the last thirty years or so, one tactic of those who refuse to admit the failure of string theory has been to go to the press with bogus claims of “we finally have found a way to get testable predictions from string theory!”. I’ve written about dozens and dozens of these over the years (see here). In recent years the number of these has tapered off considerably, as it likely has become harder and harder to find anyone who will take this seriously, given the track record of such claims.

Today though, Quanta magazine has a new example, with an article that informs us

> An idea derived from string theory suggests that dark matter is hiding in a (relatively) large extra dimension. The theory makes testable predictions that physicists are investigating now.

This is about a proposal for a micron-scale large extra dimension, with no significant connection to string theory. I took a look at the “predictions” (see here) long enough to assure myself it’s more of the same, better to not spend more of one’s time on it. One positive thing to say about the article is that the writer did go ask string theorist experts about this, and while these experts tried to be polite, they clearly weren’t enthusiastic:

> While physicists find the dark dimension proposal intriguing, some are skeptical that it will work out. “Searching for extra dimensions through more precise experiments is a very interesting thing to do,” said Juan Maldacena, a physicist at the Institute for Advanced Study, “though I think that the probability of finding them is low.”
>
> Joseph Conlon, a physicist at Oxford, shares that skepticism: “There are many ideas that would be important if true, but are probably not. This is one of them. The conjectures it is based on are somewhat ambitious, and I think the current evidence for them is rather weak.”

Better though would have been to ask Sabine Hossenfelder what she thinks about this kind of thing (or not write about them at all)…

Update: Vafa has a new paper explaining the “prediction” of the extra dimension from Swampland conjectures. According to him

> The most direct way to test the dark dimension scenario is to check Newton’s gravitational inverse square law (ISL) at micron scale. Due to O(1) number ambiguities one can only predict this to appear at length scales 1 – 10 microns. Experiments checking this length scale would need to improve the current range bounds by a factor of 10.

What if such experiments can be done but don’t see anything, even down to 1/10,000th of a micron? No problem at all, that would be a new discovery that you need to change one of the many Swampland conjectures:

> We can only wait for the experimental verdict. Either way, we will learn exciting new physics!

Update: Sabine Hossenfelder explainer here.

Comments

   February 1, 2024

   I rather thought the whole idea of large extra dimensions, especially if there’s just one, had already been so severely constrained by collider and astrophysical observations that this sort of thing had fallen out of vogue. That someone found a way to evade such constraints in another model doesn’t seem terribly surprising, but that anyone considered it newsworthy certainly does. Quanta never needed clickbait, occasional flagrant promulgation of such notwithstanding. Just…why?

2. **Peter Woit**
   February 1, 2024

   LMMI,

   The Simons Foundation each year makes one or two “Targeted Grants in MPS”
   https://www.simonsfoundation.org/grant/targeted-grants-in-mps/
   which are
   “intended to support high-risk theoretical mathematics, physics and computer science projects of exceptional promise and scientific importance on a case-by-case basis.”
   One of the two such grants for 2023 was to Vafa for exactly this topic
   https://www.simonsfoundation.org/funded-project/on-the-cosmological-and-particle-physics-implications-of-the-string-swampland/
   Quanta insists that it is editorially independent of the Simons Foundation, but it is making its editorial judgements through a very similar lens to that used by the foundation to make grants, so not too surprising they end up identifying the same “projects of exceptional promise” to write about and to give money to.

3. **Low Math, Meekly Interacting**
   February 1, 2024

   Ah.

   I so loved Quanta when it first appeared I keep going back like an abuse addict, but enough’s enough, I think.

4. **Peter Woit**
   February 1, 2024

   LMMI,
   I do have some sympathy for the problematic situation the Quanta editors are in with respect to this kind of theoretical physics. Their mission is to write a sizable number of articles about important new advances in this field, but there really aren’t any, so what do they do? There are lots of people out there making dramatic-sounding claims about extra dimensions/dark matter, etc, all of which seem to be highly implausible. You’ve got to write something, so why not pick out the ones who are at Harvard and write about what they are doing? On the Foundation side, looking for what hep theory to fund, they’ve got basically the same problem, and deal with it in a similar way.

5. **David Roberts**

February 1, 2024

LMMI

The mathematics articles on Quanta are generally of very good quality, even if they have a very strong house style that they all seem to stick to, and which I now find less charming than I originally did. I'm not in the target market, though, and usually hunt for the link to the actual research paper and go read that, too.

6. **Eric Weinstein**
February 1, 2024

That is an interesting take Peter. I am not sure I see it as you do however. You write: "Their mission is to write a sizable number of articles about important new advances in this field" but this is not fully accurate to my way of thinking. I would say they are charged with writing a sizable number of articles about new developments that IN NO WAY repudiate, question or examine what is actually holding the field back.

What if that specific charge IS the problem? Why are we expected to protect the people who have been taking a gratuitious and unprecedented collection of 'premature' victory laps for the last 40 years as of 2024? That isn't a normal part of science.

As I see it the failed community has set themselves up as the player-referees of progress in the game of fundamental physics. Everything that repudiates their belief structure and bizarre way of life is excluded. Hence the one team that are allowed to be both players and referees always wins.

Imagine that a Vatican science magazine were to be charged with writing about all the exciting developments in biology that in no way called the account of man's creation by G-d detailed in Genesis into question? You would not get any report on actual biology.

It's not that there is nothing interesting going on. It is that there is nothing interesting compatible with the failed community going on. Hence the illusion. I may think your Twistor theory is wrong, but it is still interesting to me and I don't want to laugh at it or make it go away. I just want to find out if you are right and hopefully outcompete you if you aren't. Yet you are not compatible with this player-referee community. Ergo…no glossy articles. Sic transit, gloria mundi. Alas.

7. **Alessandro Strumia**
February 2, 2024

Technical question to string theorists: do I correctly understand that the dark dimension conjecture does not apply if the tiny cosmological constant arises as an unnatural cancellation (motivated by anthropic selection)?

8. **Yasin Şale**
February 2, 2024

Whenever I read or hear something about extra-dimensions, I recall Penrose's bland and cool reaction I have recently met in one of his interviews on YT: "But unfortunately our universe is three dimensional" 🙂

9. **Peter Shor**
February 2, 2024

Quanta Magazine does occasionally print articles about non-orthodox theories that compete with string theory; for example, see their article from last year on Jonathan Oppenheim's theory of non-quantized gravity.

They clearly should be writing more of these, and fewer string theory articles, but it's hard to fight the Zeitgeist.

10. **Sabine**
February 2, 2024

As I have said way too many times, the biggest problem with theoretical physicists is that they don't learn from their mistakes. (And neither, it seems, do science writers…)

11. **Peter Woit**
February 2, 2024

Eric Weinstein,
The Simons magazine/foundation combo is interesting to look at because they cover a wide range of science/math. For most areas while I'm sure there's valid criticism, on the whole they seem to be doing arguably a better job of choosing what to fund and what to cover than other organizations. In fundamental theory though, we're not the only ones to see a big problem, so why aren't they doing something?

The organization is fairly transparent: you can see that in this area there's only one person on the Quanta advisory board (David Gross). On the Foundation scientific advisory board there's really no hep-th (Shankar doing condensed matter, two others mainly in cosmology/astrophysics), but the head of math-physics is Gabadadze, one of whose specialties is extra-dimensional/modified gravity. That the organization is funding and covering this research promoting string theory based extra dimensional gravity models is unsurprising.

The problem though is that in this area they're just doing exactly the same thing they do in other areas. How do you get them to start treating it differently and more skeptically? It's in their DNA to listen to and support elite US institutions, and as long as the people there are saying all is well, we're doing A+++, they're not going to go against this. Unfortunately it seems to me that more and more people like Vafa and Strominger have decided it is in their interest to not acknowledge any problem.

Vafa I think is also a very good example of an important aspect of the problem. He has done wonderful work in areas like topological string theory, involving great mathematics and physics. But the criticism of string theory as "it's mathematics, not physics, string theorists need to stick to physics and come up with testable predictions" has moved theoretical physics away from any interest in bringing new mathematical ideas into physics. The description in the Simons Foundation abstract is a good example, it has him working on deviations from the inverse-square law, which looks much closer to the mathematics of the 17th century than anything new.

12. **maxstroke**
February 2, 2024

How does one get onto the advisory board? Of course, folks need to devote their time and energy as they see fit, but perhaps having Sabine or Peter Woit or other not-quite-so-dogmatic folks on the advisory committee would help.

I, for one, welcome our new Twistor-exploring overlords.

13. **Peter Woit**

February 2, 2024

Sabine,
I think a bigger problem is that they don't admit they've made a mistake. Hard to learn from your mistakes if you think you don't make any, that you're A+++.

14. **Peter Woit**
February 2, 2024

maxstroke,
That's certainly not going to happen.
In any case I don't think the advisory board is that important. I doubt that David Gross is getting consulted all that much. The Quanta writers and editors surely are doing what journalists do, calling up prominent experts in the field and getting their opinions. The problem is that most of the time in other fields they're getting sensible advice, but when they start calling up influential people in hep-th, they're getting told that wormholes are being created in Google labs and that progress is being made on getting testable predictions out of string theory, not that this is nonsense.

15. **Peter Woit**
February 2, 2024

As I try to figure out why anyone at Quanta thought it was a good idea to put out a new story with a "string theory finally makes testable predictions" sub-headline, one thought that occurs to me is that they know it's a sure way to get me to write a blog entry that will drive traffic to their site. I'm not coming up with any other plausible reason they would do this…

16. **Jerome**
February 2, 2024

I'll never visit Quanta again, as long as Wolchover is writing for them. The "real and traversable wormholes" fiasco of 2022 is perhaps one of the most egregious and unforgivable instances of blatant, intentional, malicious fraud in science journalism of my entire life, and I'm done with them until the day they pen a formal apology for their participation in the whole debacle. My jaw is still on the floor from the falsehoods they spouted and the degree to which they doubled down on their misinformation.

Their reputation is permanently tarnished.

17. **SRP**
February 2, 2024

New term: Woitbait.

18. **Eric Weinstein**
February 2, 2024

Sabine: This is not "Theorists not learning from their mistakes" as we all know. This is the ethics of a particular sub-crowd who installed themselves as the arbiters of all theoretical physics and who refuses to recuse themselves due to conflicts of interest. Imagine if Georgi and Glashow were convinced that protons were decaying left and right due to SU(5) but we weren't looking hard enough. Or if SUSY theorists were claiming that selectrons and gluinos were everywhere at the LHC but only virtuous people could see them. Or if Norman Mailer's publisher claimed that all of Philp Roth's books didn't exist. Or if the The Rolling Stones claimed that all good music that people liked was theirs and took the royalties. Or if a judge finding himself innocent of bribery. That is what we are talking about: the "String Mass Delusion" at the level of Qanon.

That is the level of nonsense with which we are now dealing. Like it or not, String Theory has gone from Idea to Program to Failure to Scam to Madness. And it is not about the equations or the spaces or the operators. I will say it again: you all are too focused on the problem of strings being with the science. The pseudoscience of String theory is its anti-scientific sociology. The equations and Calabi-Yau manifolds are not the problem. It's the lying. It's the bullying. It's the sabotage. It's the money. It's the skulduggery. It's the political economy. It's the failure to recuse yourself or find any critics with whom you will appear and test your ideas.

I don't care whether these folks are ethical in their private lives. That is nobody's business. But in the seminar room, they are not playing by the rules of science. And we need to stop tip toeing around this. As Edward Witten says "There are no other routes. There are only words." I mean, that is breathtaking in terms of self-indictment. No explanation needed for anyone paying attention.

I still can't even believe that is a real quote from a geometer and mind I have *mostly* revered since 1983; to my mind that is all you need to know after 40 years of bullying those who dare openly discuss the most profound and clear cut public failure in science any of us have ever seen. It doesn't get easier than this. But we are afraid to say it becaused it involves people we all know. And often like…at least when they are not lying to themselves, each other, us and the public. Pity that.

19. **Eric Weinstein**
February 2, 2024

Peter: I mostly agree with your comment above to me. I generally like Quanta as well and have a high opinion of many things that the Simons foundation does. Having talked last with Jim about 2 years ago in California, I can say that even he wasn't entirely sure how the Chern-Simons theory was supposed to be related to real physics. So the reporters rely on the experts. I get that.

But the reporters then have to start reporting and IVESTIGATING claims that there are serious questions about Quantum Gravity / String Theory / M-theory having become a funding/earning/bullying cult just the way they investigated Claudine Gay or Francis Collins and gain of function. Or Richard Nixon. Or Trump.

Call it the "StringAnon Mass Delusion". It's basically a variation on the idea of a citation cartel in academic publishing. Or the "Replication crisis" in soft sciences. Or asking why macro economists failed to see that 'The Great Moderation" was an investment banking scam threatening the world financial system. Or the Sokal Hoax. Or the Bogdanov affair. Or the Boskin Commissioners' attack on Social Security. Or the Gain of Function disaster.

All of those are now discussable. Why is StringAnon/M-Anon any different as a mass delusion? I'm not happy about it. I would prefer that they take the Dan Friedan route and admit the error. But given how they bully everyone else, it is as if Susskind, Strominger, Kaku, etc. have diplomatic immunity from common sense, scrutiny, journalism or science as a discipline which their bullying targets do not.

Quanta: if you are reading this, consider this an invitation. Reach out to anyone you trust.

20. **Peter Woit**
February 2, 2024

Jerome,
My understanding is that Wolchover has been on leave from Quanta for the last year or so to write a book, so you can't blame her for this latest.

On the wormhole fiasco, if you were a journalist and
1. the Spiropulu, Lykken, Jafferis claims of existence of wormholes in the lab were vouched for by Nature
2. Preskill, Susskind, Gross all told you this was real
3. the IAS faculty seemed to be on board
wouldn't it be journalistic malpractice not to tell the world about the wormholes? Put differently I think you're blaming the victim of a scientific fraud instead of the perpetrators.

21. **Sabine**
February 3, 2024

@Peter Woit Yes, indeed

22. **Sabine**
February 3, 2024

@Eric Weinstein

You seem to put the blame on certain individuals. I think it's a systematic problem. By this I mean a problem of how the scientific system operates. If science was "self-correcting" as many scientists naively believe, this should not happen — at least not to this extent. Why does it happen nevertheless? Because there's no "invisible hand" that corrects science any more than there is an "invisible hand" correcting trade. A system can only optimize what it's been configured to optimize.

So long as researchers get rewarded for producing papers that are deemed good if many of their colleagues like them, we will continue seeing these bubbles. It's a positive feedback: the more people work on a topic, the more they tell each other it's good research, the more they feel they're on the right track etc. People go where money goes and in academia, money goes where people go. Not hard to see how that's a positive feedback, is it?

The tragedy is that this is hardly a new insight, and yet nothing has been done about it. It would be simple enough if journals would just stop publishing such stuff because it isn't real science. Of course I don't think that's actually going to happen because (a) the people on the editorial board are the same people who work on this stuff and (b) the publishers make money from publishing it.

One would think that funding agencies would at some point realize it's a waste of money, but that doesn't happen either, because they outsource their reviews to the same people who work on the stuff. This system is basically incestual and I find it somewhat surprising that it doesn't work even worse than it does.

23. **Chris Rijk**
February 3, 2024

Speaking as an outsider who is interested in science, it feels to me that the above posts are describing the same underlying problem, just from different perspectives (eg top-down vs bottom-up).

What would I suggest doing about it? After thinking about it for a while I came up with this idea: Try to get 10 or more people who can reasonably be described as experts in the field to collectively write a book, with one chapter per person, where they describe their personal experiences and frustrations with this problem and make it clear that they believe that scientific progress is being held back. In effect a public petition to call attention to a problem that is too big for any one person to solve.

24. **Peter Woit**
February 3, 2024

Chris Rijk,
There already exists much more than what you are suggesting, probably ten whole books, not just chapters, of the sort you describe. Off the top of my head, besides my own, there's Smolin's, Hossenfelder's and Penrose's (Fashion, Faith and Fantasy). The reaction of the string theory community to these has been to refuse to engage with the arguments of the books and denounce the authors as ignorant of what they are writing about. The books have had an effect on the public, journalists and on non-string theorist scientists, with the general perception changing over the last 25 years from string theory as successful and promising, to string theory as a failure. 20 years ago when I was describing string theory as a failure, the reaction I'd get was that I was saying something very unusual and provocative, now this more often is dismissed as boring and well-known, just beating a long-dead horse.

Changing the behavior of journals doesn't seem a promising route at all. What would have an effect would be cutting off funding to and hiring in these fields. I think it's exactly because people see an increasing danger of this happening that you're seeing efforts like the World Science Festival panel and this Quanta article to fight back against widespread negative perceptions.

25. **S**
February 3, 2024

Sabine,

You write,

"This system is basically incestual and I find it somewhat surprising that it doesn't work even worse than it does."

It seems to me that that last part is key. It *does* work better than we should expect, and I think it's that phenomenon that causes people to become enamored of science as "self-correcting," etc. (and then take it farther than the facts warrant). In a very similar way, there *is* a kind of invisible-hand phenomenon with markets, which accomplish an incredible amount; without which fact, it would be hard to explain why some people become so impressed by them that they ascribe unrealistic powers of insight and virtue to them.

It seems to me that it is important, but incredibly hard, to prize and preserve that which does work while preserving what does not. For example, one can imagine "fixing" the journal or grant system by having untrained bureaucrats make decisions without consulting scientists. It's hard for me to imagine that this wouldn't be far worse, just as the twentieth century taught us that there are cures to market problems that are orders of magnitude worse than the disease.

I'm afraid I don't have any very clever solutions, but my point would be, it seems necessary to find ways to improve the system piecemeal around the edges (a la market regulation), keeping in mind its real strengths as well as the spectacular pathologies that a field like hep-th has made manifest in the last four decades.

26. **Diogenes**
February 3, 2024

There are well known conditions for the operation of competitive markets in regularly transacted goods. Here, we have much more of a luxury maket, where both the producers and consumers are a small elite. In this case, the ideas of competitive markets, available information, price discovery and so on, just collapse. One thinks of the art market – is it fair? How would one define that? As hep-th moves away from experimental contact it is very much like an art market, with rich buyers and sellers.

I will however disagree strongly with this kind of authoritarian impulse of SH:
"A system can only optimize what it's been configured to optimize." This is a very bad and popular kind of idea in academia that fits no historical evidence whatsoever. It is in fact what leads to the current kind of sub-optimal equilibrium. More physicists should take economics classes! Or think about spin magnets more! Or just reduce the number of degrees of freedom in the SM by one. How hard could that be?

27. **Sabine**
February 4, 2024

@S

The reason it partly works is that writing papers that are well-cited is in some cases indeed an indicator for relevant scientific work. The problem is that the cases when it isn't can run away and create these empty research bubbles.

I guess one could say that the hand is "invisible" in the sense that in both cases (markets/academia) it's a decentralized system. I hesitate to call it that because it's not like the rules of interaction (or call them regulations) are invisible. We know what the rules are. The issue is that a lot of actors (in either case) tend to blame "the system" as if that was a living thing rather than something that they themselves create.

I have written and talked about this for 20 years now and nothing has changed and honestly at this point I've basically given up hope the scientific community will do anything about it. They're just not interested. The only thing that could eventually make a difference is taxpayers realizing that their money is being wasted, demanding that the issue is cleared up. Alas, for this to happen the problem isn't big enough, basically, and in all fairness I guess the world has bigger problems.

I believe the major reason these research bubbles don't happen more often is that the scientists involved don't actually want to work on irrelevant nonsense because there isn't enough money to make in academia. They need to be genuinely confused. This is different to economic bubbles that people have a reason to contribute to even if they know they're bubbles because there's money to make (eg the 2008 economic crisis was an extreme example — actually many people knew it was a bubble, they just couldn't not contribute to it).

In the case at hand (Quanta article) it's rather obvious what the confusion is — I have written and talked about this several times before. There is a very large fraction of physicists (and science writers) who erroneously believe that a theory which is falsifiable is scientific. It's a basic misunderstanding of what Popper said: a theory which is not falsifiable is not scientific (or, equivalently, if it's scientific then it's falsifiable). This simple misunderstanding has funded basically thousands of researchers for decades. It's embarrassing.

28. **Anonyrat**
February 4, 2024

What can force a bunch of scientists that what they are doing is no longer science? Only retirement, death, and an unyielding skepticism of the next generation.

29. **Peter Woit**
February 4, 2024

Yes the way hep-th works may be more like an elite luxury goods market than a standard competitive market, but like such markets, those directly involved understand well how they work. In the hep-th case, central are jobs and funding. For jobs, there aren't a lot of them, you can easily follow the postdoc and tenure-track rumor mills to understand exactly who is getting these jobs and exactly what you need to work on and what kind of connections you need to get one one of these few jobs. For grant funding, in the US it's basically DOE + some NSF and Simons. Again, you can easily see who these small number of grants are going to and what you need to be doing to get one. Not hard to find out who is on the grant panels and making these decisions, or what criteria they are using to make them.

So, in principle changing this system would just require a relatively small number of people to acknowledge there's a problem and come up with a plan to do something about it. But, those who could do this are instead arguing everything is A+++.

As for the idea that the system will self-correct by retirements and skeptical younger people, note that Andy Strominger's father is a distinguished Harvard researcher in another field who only recently retired in his mid-nineties, still getting grants. My impression of younger people in hep-th is that for decades now this field has been weeding out anyone skeptical, more and more attracting the unusually credulous.

30. **entropic**
February 4, 2024

Condensed matter physicist here, who has been eagerly reading this excellent blog and the comments over the years; this is my first comment.

There is one characteristic of hep that has been bothering me since my student years and it has played a major role in my decision to pursue a different field of Physics, namely the existence of a person-cult atmosphere in it. There have always been in hep, even before the times of strings, semi-gods revered by their disciples, who recited their sayings as though they were speaking the words of irrefutable truth. I always found it bizarre to witness both my fellow students and mature researchers refer to whatever those (undoubtedly brilliant) colleagues said in religious awe [*], and following uncritically the research paths laid down by them. This attitude has reached monstrous proportions with strings. There are no doubt leading personalities in all fields (of Physics) but the situation in hep has always seemed extreme to me. This aspect of it, combined with the disturbing arrogance of many hep practitioners to look at other physicists as lesser beings, kept me away from the field.

I feel genuinely very sorry for the current state of affairs of hep and I am not experiencing any Schadenfreude about it. It makes me sad as a fellow physicist, also because I know that this hype-beast has already extended its tentacles elsewhere and it is hurting all parts of Physics, some more and some less. I believe, however, that in trying to analyze all the reasons for these negative developments in hep, one should also consider the cult-like sociology of the field as an additional factor: hep has been depending on the holy words of a few superstars for way too long. Maybe this is a lesson to be learned for other fields (and for hep in its effort to recover from its present state.)

[*] A particularly alarming sign has been whenever someone who had never met the leading hep-person Robert Smith [fictitious name] in his life, would start a sentence saying: "As Bob recently said …"

31. **jack morava**
February 4, 2024

@ Sabine :
… we will continue seeing these BUBBLES…

Speaking of condensed matter, I think this is an accurate diagnosis, and that it may be useful to think in these terms, with funding agencies as inefficient steampunk engines powered by political heat. Bubbles are quite interesting [cf K Uhlenbeck] and deserve to be better understood.

Arithmetic, Geometry and QFT news

February 5, 2024
Categories: Langlands

This week at Harvard's CMSA there's a program on Arithmetic Quantum Field Theory that is starting up and will continue through March. There's a series of introductory talks going on this week, by Minhyong Kim, Brian Williams, and David Ben-Zvi. I believe video and/or notes of the talks will be made available.

At the IHES and the Max Planck Institute, the Clausen-Scholze joint course on analytic stacks has just ended. For an article (in German) about them and the topic of the course, see here. What they're working on provides some new very foundational ideas about spaces and geometry, in both the arithmetic and conventional real or complex geometry contexts. Many of the course lectures are pretty technical, but I recommend watching the last lecture, where Scholze explains what they hope can be done with these new foundations.

Of the applications, the one that interests me most is the one that was a motivation for Scholze to develop these ideas, the question of how to extend his work with Fargues on local Langlands as geometric Langlands to the case of real Lie groups. He'll be giving a series of talks about this at the IAS next month.

Something to look forward to in the future is seeing the new Clausen-Scholze ideas about geometry and arithmetic showing up in the sort of relations between QFT, arithmetic and geometry being discussed at the CMSA.

Comments

   February 5, 2024

   I believe the videos should be available on https://www.youtube.com/@harvardcmsa7486/videos, as they have posted various past conference videos on this site. Interested in it, but not having enough time to attend in person. Hopefully, they will post recorded videos on the same site.

2. **anon**
   February 6, 2024

   I've seen samizdat versions of notes from Scholze's Munster talk. Has he now proved the conjectures he made?

   I'd always idly wondered about the category of globalisations of a given Harish-Chandra module – we know it has canonical `maximum' and `minimum' elements, but nothing really about the structure of all such. Do these now form a well defined moduli space , and if so, what does its topology (or Hodge theory!) tell us about the representation, and how can we read these invariants from the HC-module, or its BB description on the flag variety?

   Its amusing how this counts as an `easy' application of this Clausen-Scholze technology. We await the subtle applications…

   Presumably it is clear how this CS analytic stuff describes the maximal and minimal locally analytic vectors in a Matsuki dual picture to usual BB, as probably done by Kashiwara directly. But how does it control all the `intermediate' extensions??? Very intriguing! Can one hope for _interesting_ HC modules, with very special moduli spaces of globalisations, parameterised by extremal points in some Langlands dual picture?

   Anyhow, I should watch Scholze talk#24 (and talks#1-talks#23) before commenting further.

   Did Clausen/Scholze explain (as an obvious example) representations of a Heisenberg group, and how the Stone-von Neumann theorem fits cleanly into their geometry and rep theory and D-modules, not just `sort of analogously'?

   Also I hope to learn from these talks: what more does the Clausen-Scholze stuff applied to the usual Hodge package produce in terms of constraints, when compared to the o-minimal analsysis of Klingler, Tsimerman, et al? Presumably quite a bit more, as one can now handle growth conditions….?

3. **Peter Woit**
   February 6, 2024

   anon,
   If you have access to notes of the Munster talk, you know a lot more about this than I do. From Scholze's comments in the last talk of the lecture series and from second hand reports, all that's clear is that Harish-Chandra modules are not the right thing here.

   My understanding is that this is about real local Langlands which is just for reductive groups. If it gives a proof of Stone-von Neumann that would be fun.

4. **Peter Scholze**

   @anon

   Thanks for your comment/question! Things resolve themselves differently, and in some sense in a more boring way.

   Background: We define a category that is "a category of G-representations" for a real Lie group G, but thinking of representations in terms of sheaves on the classifying stack $[*/G]$. Here $*$ is really the analytic spectrum of the gaseous real numbers, and G is incarnated as an analytic space via regarding it as a real-analytic manifold (and using the corresponding functor to analytic spaces). Then we simply take the ("quasicoherent") derived category $D([*/G])$ of $[*/G]$.

   Now, somewhat surprisingly, every(?) Harish-Chandra module has a unique(?) corresponding object in $D([*/G])$. (Question marks because I did not yet carefully check in general.) The obvious question is, how can we single out a unique G-representation associated to a Harish-Chandra module? Part of the answer is that a little bit of magic seems to happen; another part of the answer is that there are actually two ways to turn an object of $D([*/G])$ into a representation of G: One can use $*$- or $!$-pullback along $*\to [*/G]$. One of them ($*$-pullback) gives the minimal globalization, the other ($!$-pullback) gives the maximal globalization.

   Here's a related story. There's this ring of infinite-order differential operators $\hat{D}$ on a complex manifold. Usually it's subtle to get a good theory of $\hat{D}$-modules working (for reasons of functional analysis). In our setup it's straightforward. One can then wonder whether this resulting category still has a Riemann-Hilbert correspondence to a category of sheaves. It turns out that $\hat{D}$-modules are just equivalent to sheaves! (No constructibility conditions or anything — all sheaves.) This is related to some classical stuff about hyperfunctions. [Disclaimer: I'm far behind on learning the classical theory…]

This story of $\hat{D}$-modules actually plays very well with the above story of G-representations, and they are easy to combine in the Beilinson-Bernstein localization business, leading indeed to the Matsuki dual picture. Many of the ideas here are really due to Rodriguez Camargo, who has developed this in the p-adic context. (This leads to the slightly strange situation that many things are now written over the p-adics but not over the reals… not because the reals are harder for these things, but mainly because so far it's mostly p-adic people using this theory.)

February 6, 2024

Dear Peter S,

Thank you for responding to my question/comment.

I'm looking forward to reading the definition of your category of G(R)-modules — it sounds wonderful. (I'm *very* curious how it encodes the basic finiteness theorems and theorems about density of analytic vectors that drive the usual story of this, so that such modules have underlying HC modules, what is the notion of equivalence of modules, and the way that bad Banach space examples get excluded).

Also: Do you have a range of extension functors interpreting between * and ! pushforward, analogous to Beilinson's extension functors? (that have to do with properties – growth ? – of the function f^s?)

But I'm reeling from what you write about infinite order differential operators — that solves a problem that plagued the Kyoto school for many decades (with their various microlocal differential operator rings E, variants all defined with different growth conditions). What an extraordinary RH theorem you have – just the right analytic notion to capture *all* sheaves. That is extraordinary. Where can I read it!?!!! (And are there notes from your course, or should one just watch it all?) I'm happily imagining all of the questions one can now answer with these tools… wow.

(Trivia: I didnt quite understand from the above if the classification of your G(R)-modules is `automatic' from the definition – is it straightforward from the definition that they are global sections of sheaves on your gaseous classifying space, and those with trivial central character give good sheaves on your gaseous quotient flag variety/G(R)? What is your analogue of the BB-theorem that the flag variety is D-affine, or its mixed version, the Grauert Riemanschneider vanishing theorem. Or are you assuming a BB classification of HC-modules? Given a HC-module with generalised central character, don't we already know how to get the globalisations from the Matsuki dual sheaf to the BB-localisation, I think more or less functorially? If this is how it works, it feels a bit like cheating, or at least criminally underutilising your rather major breakthroughs.)

Anyhow, thank you. Sorry for burbling – I'm still trying to process your response, even without the supporting definitions.

6. **anon**
February 6, 2024

Apologies, I see I read too fast – * and ! are for pullbacks to a point, not pushforward of an open subvariety, hence are different notions of `underlying vector (Banach?) space' for your equivariant sheaf? I retract my question about analogues of Beilinson's functors, which is nonsense in this context. Indeed 'things resolve themselves differently'.

Please ignore any further nonsense in my previous question — I won't understand what is actually going on until I work through the definitions and compute what happens for SL_2

Peter W — thank you for allowing these questions on your blog. And for your links, which are very thought provoking

7. **Peter Woit**

@anon

Thanks for your excitement ;-). Just some brief answers to a few points:

Our representations usually are on some (dual) nuclear Frechet space. Banach (or even Hilbert) spaces do not play a prominent role in our work. More broadly, norms/metrics in the classical sense are less relevant for us. (They are however key to many results — like the Hodge decomposition — but we hope that we can get such results using a very different incarnation of metric information, related to the "extended Berkovich line".)

About the Riemann-Hilbert theorem: We hoped that we would find time to discuss it in the course, but in the end there was no time. But it's almost a tautology for us! Namely, we realize $\hat{D}$-modules again as quasicoherent sheaves on some stack, the "analytic de Rham stack" X_{dR}. This is the quotient of the complex manifold X by the "overconvergent neighborhood of the diagonal". In the p-adic context, see the recent work of Rodriguez Camargo (on arXiv). On the other hand, usual (in arithmetic geometry-speak, "Betti") sheaves can be realized as quasicoherent sheaves on some other stack, X_{Betti}. This is a priori built in a slightly crazy way, covering X by totally disconnected sets; it was briefly discussed in the course, in my lecture giving the definition of analytic stacks.

Now our Riemann-Hilbert statement follows from a more primitive geometric statement, namely that the two stacks are isomorphic, $X_{\mathrm{dR}}\cong X_{\mathrm{Betti}}$! And once one understands what's going on, this is really a triviality. Namely, it's clear that there is a surjective map $X\to X_{\mathrm{Betti}}$ and that the induced equivalence relation on X is precisely the overconvergent neighborhood of the diagonal.

(Much of the hard work in the course was to get such a flexible notion of analytic stacks where in particular these things turn out to be isomorphic even though they are presented in very different ways. The key is the $!$-topology whose discussion was probably the most technical part of the course.)

9. **Peter Scholze**
February 7, 2024

PS: In the Liquid Tensor Experiment, I said that the theorem on the existence of the liquid analytic ring structure on the reals may be my most important theorem. Everybody seemed very puzzled about this judgment. But it is the key to get machinery like the above.

(Now we also have the gaseous analytic ring structure on the reals, which is easier to construct and also works for most applications, in particular the stuff above. But gaseous vector spaces are a much more radical departure from the usual setting of complete locally convex vector spaces, so for some purposes it is still very useful to have the liquid theory as well. I discussed one instance in the last lecture. In case someone wonders whether the techniques of our course help in the liquid case: So far no — we now have rather nice arguments for the existence of the solid and the gaseous analytic ring structure, but the existence of the liquid one is still a very difficult theorem.)

[My apologies to all physicists reading this for our abuse of physical terminology. Explanation: There are “condensed” vector spaces (=a variant of topological vector spaces), and within those various kinds of more “complete” ones. The weakest notion is “gaseous”, next comes “liquid” (at various “temperatures” = degree of convexity), and in the non-archimedean case things can even get “solid” (at “temperature 0”).]

February 7, 2024

I am quite bedazed by all of this, but if nomenclature requests are being entertained, I hope that in applications to number theory, we will soon have room-temperature superconductors?

Why physicists are rethinking the route to a theory of everything

February 7, 2024
Categories: Euclidean Twistor Unification

New Scientist this week has a cover story I can strongly endorse, entitled Why physicists are rethinking the route to a theory of everything. It's by journalist Michael Brooks, partly based on a long conversation we had a month or so ago. Unfortunately it's behind a paywall, but I'll provide a summary and some extracts here.

For a more technical description of the ideas I'm pursuing that are discussed in the article, see this preprint, which was intended to be a very short and concise explanation of what I think is the most important new idea here. This semester I'm mainly working on teaching and writing up notes for an advanced course for math graduate students about the Standard Model. I'll be adding to these as the semester goes on, but have just added preliminary versions of two chapters (9 and 10) about the geometry of vectors, spinors and twistors in four dimensions. These chapters give a careful explanation of the standard story, according to which spacetime vectors are a tensor product of left-handed and right-handed spinors. They don't include a discussion of the alternative I'm pursuing: spacetime vectors are a tensor product of right-handed spinors and complex conjugated right-handed spinors. I'll write more about that later, after the course is over end of April (and I've recovered with a vacation early May…).

It's well-known to theorists that the Standard Model theory is largely determined by its choice of symmetries (spacetime and internal). A goal of these notes is to emphasize that aspect of the theory, rather than the usual point of view that this is all about writing down fields and the terms of a Lagrangian. This symmetry-based point of view should make it easier to see what happens when you make the sort of change in how the symmetries work that I'm proposing. What I'm not doing is looking for a new Lagrangian. All evidence is that we have the right Lagrangian (the Standard Model Lagrangian), but there is more to understand about its structure and how its symmetries work. In particular, the different choice of relation between vectors and spinors that I am proposing is not different if you just look at Minkowski spacetime, but is quite different if you look at Euclidean spacetime.

The New Scientist article has an overall theme of new ideas about unification grounded in geometry:

> … a spate of new would-be final theories aren't grounded in physics at all, but in a wild landscape of abstract geometry…
>
> That might strike you as outlandish, but it makes sense to Peter Woit, a mathematician at Columbia University in New York. "Our best theories are already very deeply geometrical," he says.

There's some discussion of string theory and its problems, with David Berman's characterization "It can be a theory of everything, but probably it's a theory of too much." The article goes on to describe the amplituhedron program, with quotes from Jaroslav Trnka. After noting that it only describes some specific theories, there's

> Trnka thinks the amplituhedron approach might enable us to go even further. "One can speculate that whatever the correct theory of everything is, it would be naturally described in the amplituhedron language," he says.

Turning to a discussion of twistors, there's then a section describing my ideas fairly well:

> Woit is using spinors and twistors to create what he hopes are the foundations of a theory of everything. He describes space and time using vectors, which are mathematical instructions for how to move between two points in space and time – that are the product of two spinors. "The conventional thing to do has been to say that space-time vectors are products of a right-handed and a left-handed spinor," says Woit. But he claims he has now worked out how to create space-time from two copies of the right-handed spinors.
>
> The beauty of it, says Woit, is that this "right-handed space-time" leaves the left-handed spinors free to create particle physics. In quantum field theory, spinors are used to describe fermions, the particles of ordinary matter. So Woit's insights into spinor geometry might lead to laws describing the holy trinity of space, time and matter.
>
> The idea has got Woit excited. He has spent most of his career looking at other ideas, thinking they will go somewhere, and being disappointed. "But the more I looked at twistor theory, the more it didn't fall apart," he says. "Not only that, I keep discovering new ways in which it actually works."
>
> It isn't that Woit believes he necessarily has the answers. But, he says, it is good to know that, despite the long search for a theory of everything, there are still new possibilities opening up. And a better, if not perfect, theory has to be out there, he reckons, one that at least deals with sticking points like dark matter. "If you look at what we have, and its problems, you know you can do better," he says.

Other work that is described is Renate Loll and causal dynamical triangulations, as well as what Jesper Grimstrup and Johannes Aastrup call "quantum holonomy diffeomorphisms." For more details of the Aastrup/Grimstrup ideas, see this preprint as well as Grimstrup's website. I can also recommend his memoir, Shell Beach.

The article ends with:

> That said, when Woit – who has long been known as an arch cynic – is excited about the search for a theory of everything again, maybe all bets are off. Playing with twistors has changed him, he says. "I've spent most of my life saying that I don't have a convincing idea and I don't know anyone who does. But now I'm sending people emails saying: 'Oh, I have this great idea'."
>
> Woit says it with a grin, acknowledging the hubris of thinking that maybe, after so many millennia, we might finally have cracked the universe open. "Of course, it may be that there's something wrong with me," he says. "Maybe I've just gotten old and just lost my way."

   February 7, 2024

   Reading this weirdly filled me with dread, which I found odd. Why isn't this a welcome relief?

   Perhaps it goes like this: I don't think this is at all true. The story we tell about String Theory, Particle Theory, Loop Quantum Gravity, etc is just not true.

   To recapitulate the standard story it would go something like this. "In the early 1980s physics was focused on the ultimate prize: a theory of everything called Quantum Gravity. In 1984, physicists were astonished and became understandably excited from a stunning breakthrough that they had findally found the theory of everything in a new version of String Theory. Enthusiasm ran high for the first decade that we were close to a theory of everything in string theory when, unexpectedly, there was a second Superstring revolution, perhaps even more profound than the first! String theory became m-theory, strings became branes and everything looked to be going even better than expected. The only other real competitor was Loop Quantum Gravity which did not make as much progress in a race that seemed to come down to two horses where one held a seemingly insurmountable lead over the other. Shortly thereafter the picture of AdS/CFT changed everything yet again proving that Strings were indeed connected to everything we knew from the gauge theory of real physics. Meanwhile, experimental Physics then triumphed repeatedly, with the discovery of neutrino mass, a non-zero cosmological constant, the discovery of the Higgs and even of gravity waves. But along the way this marvelous new picture came with a cost: the world was even more complicated than we had ever imagined. Patinence and perserverance would be needed to stay the course over the coming decades. But now, finally after 40 years, some are starting to question whether there aren't other avneues to be explored as well. Etc."

I tried to write the above as original prose in such a fashion that I can assure you there was almost no truth in what I wrote about theory in this time. Nevertheless it is written to be breathlessly repeeated by science journalists and program officers administering grants.

We weren't focused on quantum gravity in 1983. We were focused on different unification schemes and beyond the standard model programs. String mania wasn't understandable enthusiasm broadly experienced by the community at all. Further, the String field didn't simply progress, but instead actually invalided all of its own hyperbolic claims year after year (e.g. "There are only 5 theories it could be so it will be figured out quickly which on is right!" or "Branes are irrelevant: it's just string vibrations that explain it all!" or "Gauge theory simply can't do what strings can do as it is an entirely different paradigm!"). Loop quantum gravity wasn't the only other competitor. None of this is true! In short, the whole String theory story is more or less a lie akin to that discussed as the "Enforced Forgetting" of the history and truth seen in Central and Easter European communist nations that was made famous by Kundera

But most of all, I don't believe for a minute that "Physicists and mathematicians are now finally considering whether there are new directions!" I think we are afrraid to tell the real story of a small group of physicists who went about savagely attacking all competitors through insult, aspersion, and gaining control of the narrative of the field as everyone else looked on and said "What the Eff is going on with MK, LS, EW, MD, JH, CV, AS, DG, LM, savaging everyone who would not kneel or lie prostrate before the Golden Calf of String Theory/M-Theory? This is pyschotic. There are many people with other ideas who are being destoryed. Why wont these people openly debate other experts who disagree with them vociferously? Why wont they face the critques of fellow String Theorist who left the cult as well? How in a supposedly scientific field did they become their own policeman, judge, judge, jury and assasins?"

This is the story of a simple mass delusion like Qanon that lasted 40 years and which showed that science journalism, peer review, funding agencies and credentials do not actually work AT ALL. If they did we wouldn't be here. I mean, this is so insane I don't think it will ever make sense. It shows that we actually don't have a theory of science. If we did, this would be impossible. It could never ever have happened.

But to tell the real story about a competitor murdering band of around 10 leading individuals who somehow got near total control of the particle phyusics narrative and who used 4 decades to trash every competitor and critic, while aided by obliging science journalists who breathlessly repeated stories they could not understand, question or even check….that would call everything into question. EVERYTHING. And so we can't tell that story. Because, in particular, it implicates the storytellers. The Kakus. The institute. The Overbyes, Harvard. The Wittens,. Princeton. The Susskinds. The New York Times. The Stromingers. It's like "Murder on The Orient Express." Too many are guilty.

And yet, that is exactly what happened. We just watched a *tiny* number of zealots destroy the scientific integrity of a field essential to human progress and murder their competitors for 40 years by gaining control of the institutions rather than by succeeding in explaining the data, predicting new phenomena, correcting the past models and extending our knowledge.

I'm up for a rethink. But for the future of science, it is essential that their be a reckoning. Thia was a form of delusion and actual evil. Not hyperbolic evil. But pure a pure backstabbing, anti-collegial, excercise in pesudo-scientific superstition and cultish fantaticism. StringAnon if you will. I'm sorry to say this. But while it may have produced a lot of mathematics, as physics it more cult than we can bring ourselves to admit.

Let's do the work. Let's get clean and sober before we simply try to explain why we pissed away 40 years and millions and millions of dollars on a murderous cult that, if we are honest, simply does not share any of the norms of actual science.

2. **Eric Weinstein**
February 7, 2024

I apologize for numerous typos above (we are only given < 5 mins to see what we wrote properly displayed, and I couldn't finish in time given the length of the comment). I'm of course happy to correct them and repost for the sake of readability if that is possible Peter. Thanks.

3. **Pascal**
February 8, 2024

If Peter's work is to lead to a theory of everything as the New Scientist suggests, what is the plan to incorporate gravity?

4. **Hazelnut**
February 8, 2024

Peter, I've read this blog for a long time and I've always appreciated that you were a critic without your own agenda. You've always been extremely careful and one of your main demands over the years has been for more rigour. So I expected if you were to declare that you had your own "theory of everything" it would be something special.

As it stands I have seen a few vague blog posts, a slide deck and a preprint. Your fellow profilee Renate Loll has over a decade of work on CDT and dozens of publications. Her frequent collaborator Ambjørn started on this triangulation stuff in the mid 80s. Aastrup/Grimstrup have also been at this for over a decade and have published a number of detailed papers.

Now, of course a rigorous TOE is going to be hard, but if you think you've got something, Peter what are you talking about "This semester I'm mainly working on teaching and writing up notes"! You've posted about some sort of mathy graduate course you've been teaching for years. Forget the notes and work out the implications of your big idea. Publish them. Relate them to something in the real world: what do you have to say about Majorana particles (seems related?), axions, dark matter, dark energy etc.? You've been flirting with this for years, sit down and do physics. If you'd rather hint at your 'twistor unification ideas' in puff pieces and on podcasts, then I supposed I misjudged you.

5. **Peter Woit**
February 8, 2024

Pascal,
I mention this in the last preprint. There I even write down a Lagrangian (well known one for GR in chiral spinor variables). What I haven't done is reexamined the renormalizability problem in this context, there's still too much I don't understand to see if this will give something new about that.

Hazelnut,
There are two relevant preprints. My understanding of what is going on here keeps slowly improving. Things clarified a lot last fall when I realized there is a simple way of understanding what is different about what I am doing than previous work. I've tried to explain the idea in the preprint, in talks and in blog posts. There's a lot of work to do to better understand it and its implications and I'm doing this. You're comparing me unfavorably to groups of people who have been working on an idea for decades, but this is just me, I've been working on this particular idea for a few months by myself.

I'm finding basically no one understands the spinor geometry I'm using well enough to understand the new idea here. To try and change this and to sort out all the technicalities of what is going on for myself so I can make progress, one of the main things I've been doing has been to write up the notes I just made available in chapter 9 and 10. Yes, maybe this does have implications for Majorana fermions, I've got a lot of work ahead to understand this.

You misunderstand the course I'm teaching. Past courses were mainly aimed at undergraduates, trying to explain QM and representation theory in as simple terms as possible. This is for advanced graduate students, quite different. In a couple week I'll be lecturing about the details of 4d spinor geometry, using the notes I've just written. This is something I've never done before and will be helpful to me as well as hopefully enlightening to the students.
Later in the course I'll be lecturing on the details of spinor fields in the standard model, including issues of neutrino masses. This will be an opportunity for me to look at that problem through the lens of the new ideas.

I'm continually working on this. As long as no one else gets interested and it's just me, it's going to take a while to make progress. I'm not going to apologize for trying to explain to others why I think this is important and they should be interested too.

6. **Hazelnut**
   February 8, 2024

   Peter I am surprised you don't see the irony of what you wrote here. I am sure people working on E8, large extra dimensions, strings, MOND, IUT… all think their work is important and want to explain it to others.

   The point is that 'others' you should care about are other physicists who have a chance of understanding your work and engaging with it constructively. You have for years now criticized string hype. Do you think a blog, a podcast or a popular article about new "Theories of Everything" is the way you're going to interest other physicists in what you say are important and subtle ideas? How are you going to engage with your scientific peers? Why not, like your co-profilees, work out the consequences of your ideas in journals and conferences? Have you had any peer review of your preprints? When should I expect to read them in PRL?

   If your ideas are really as good as you think, you have spent a career building up to this, I don't see why you would not follow your own advice and build your theory carefully, rigorously and with due consideration of skeptical colleagues?

7. **Peter Woit**
   February 8, 2024

   Hazelnut,
   I am doing exactly what you suggest, other than your implication that I shouldn't talk about what I'm doing publicly. The preprint
   https://arxiv.org/abs/2311.00608
   was intended to explain as clearly as possible what I regard as a significant and important new idea. It was written to be readable by as many physicists as possible, and to be short enough to fit into PRL's format, and was circulated last fall to various experts in advance, who gave me helpful feedback. It was submitted to PRL and recently rejected, on grounds I can't really argue with, that this new proposal raises all sorts of questions that I don't have answers to.

   In retrospect I think it was a mistake to try to write this up in this way and submit to PRL. The short format there makes it impossible to provide needed technical background. One thing that has become clear to me is that the usual story of spinor geometry, especially how spinors in Minkowski spacetime and Euclidean spacetime are related, is not widely understood. Because of this I spent a lot of time carefully writing down details of this, in the chapters 9 and 10 I'm pointing people to. Once I've finished the project of this class in a couple months, I'll go back to writing a longer document, starting with those chapters, and working out more of the implications of the new proposal about spinors I'm making. At some point I'll go back to trying again with referees somewhere, but I'm hoping to get interest and feedback from others outside that venue.

   As for conferences, well no one has invited me to speak about this at one. I've looked carefully for conferences where a talk by me would be obviously appropriate, haven't seen any, would have tried contacting conference organizers if I had. I was invited to give one seminar talk about this recently, did so, and it's online. The response to that talk from those in attendance was encouraging.

   So, it seems to me that I'm doing exactly what you want, other than not fast enough making progress to the point I could claim dramatic success at a theory of beyond SM physics. You also seem to think I shouldn't be talking about some exciting new ideas until I have more of a finished product, but I'm not seeing the argument for that. Obviously I don't expect professionals in the field to understand what I'm doing and evaluate it based on stories in New Scientist, but I have carefully written down explicitly the technical details of what I am talking about and made those publicly available.

8. **Hazelnut**
   February 8, 2024

   So you are engaging in the normal process of science, where you have had an idea, written it down, failed to get it published, and are still working on it. Your ideas are not fully baked, and there's nothing wrong with that, 1000s of others are doing the same.

   The difference is that those others don't get profiled in the New Scientist or invited on Lex Freidman's podcast. This is happening for you based on your micro celebrity due to your book. Using that micro celebrity to promote your, admittedly, uncooked ideas seems very much on par with the various string hype people you've been criticizing for years.

   What would you say if some string person (take your pick) went on a popular podcast and had a glowing New Scientist profile written about them and their exciting new ideas about twistor string ads/cft etc.etc. You may say that these ideas have been out for 50 years and gone nowhere. Well your idea is hardly even an idea yet, by your own admission.

   Basically I think your attitude is hypocritical and you ought to be more humble. I think if you were applying the standards you've called for yourself, you should have declined to be interviewed for this piece and not spoken about your very preliminary work on a huge platform.

9. **Peter Woit**
   February 8, 2024

   Hazelnut,
   We're just going to have to disagree about whether I should speak publicly about what I see as an important new idea, even if its implications are not fully understood. Yes, the idea is not "fully baked", but there is a great deal about it that I do understand and have worked out. I have by now had a very long career of working on my own ideas that initially to me seemed promising, but as I worked on them it became clear that they had serious problems. The last few years have been the first time that the longer I work on an idea, the more I see not new problems with it but a solid new picture that hangs together. As indicated in the piece, I'm well aware that maybe this is just because I'm getting gaga, but I don't think so.

   I don't think the New Scientist writer decided to write about this because I wrote a popular book over twenty years ago. As he makes explicit in the article, he was well aware that using my "microcelebrity" to make dubious claims about my own work is not something I'm known to ever have done over the years.

The comparison to my critique of string theory makes so little sense I'm not going to bother trying to answer it.

As for journal publication, I believe I could publish something about this in a journal, don't though think that would prove very much. At the moment it seems more important to me to work on developing a better version of these ideas than trying to find the right journal/set of referees that would want to publish the current version. That an idea is published in some journal doesn't make it a good or interesting one.

10. **Hazelnut**
February 8, 2024

The issue isn't you speaking publicly, you surely understand the difference between a piece like this and, say, a conference talk. You surely know that if you hadn't written the book back then you would not be invited on these podcasts or profiled like this based on 2 preprints with 5 total citations.

You may not see the string comparison as apt, but if your part in this New Scientist piece was replaced with one of the scientists from the last Quanta article you talked about, you'd have something to say. While a journal publication might not mean much these days, it at least demonstrates your work has been reviewed by a couple of competent people and you just said the feedback from PRL was apt. Your reputation is exactly why I am surprised that this is how you are approaching things. Do science not PR.

11. **Peter Woit**
February 8, 2024

Hazelnut,
The sum total of time I've spent on the New Scientist piece that has been stolen from doing science is about 3 hours so far: one talking to Michael Brooks, one writing a blog entry, one arguing with you.

To make the obvious point, I've never anywhere criticized anyone with new and different ideas who is trying to get attention for them. What I have criticized is well-entrenched bad ideas that come with the fullest backing of journal publications, conference talks, etc. that you think I should get before talking to the public.

At this point I don't think people are paying attention to what I have to say because of a book I wrote 22 years ago that now sells about 5 copies/year and that few under the age of 40 have actually read. Journalists pay attention more because of the blog, which many have found to be a reliable source of information. Mathematicians and physicists who look at the unrefereed blog can decide for themselves whether I know what I'm talking about. Some think so, others think I'm a dangerous incompetent.

Most importantly, the technical details of what I'm talking about are out there, in a paper and a seminar talk, now with detailed background available if you want. I'm getting the impression you have no idea what this is all about, aren't really interested in the science.

12. **Marty**
February 8, 2024

Hi Peter,

I think there is some real wisdom in what Hazelnut is saying. His tone strikes me as that of a concerned friend who is trying to get you to consider a change of course.

I defended you at various times during the "string wars" era, especially on this blog, against what I saw as unjustified attacks on your motivations and character. I have viewed you as someone who values intellectual honesty and humility. Yet I also find myself agreeing with a lot of what Hazelnut says, especially about your using "popular science" channels to promote work that, according to you, is the product of only a few months of effort and is very much in a preliminary state.

I don't understand why you think promoting your ideas through popular channels is a good way to interest the physics community. I can imagine how most physicists who hear of the New Scientist piece could react with something like, "Huh? Where's the beef? Why is he going on about it?" What I don't imagine is that their next reaction is anything like, "If it's in New Scientist it must be very promising! I want to get involved!"

While some people seem to think any publicity is good publicity, I doubt you're one of them. But I think in this case premature publicity may work against you. It can lead serious-minded physicists to question your motivations, given the lack of an object record of significant, serious effort on your part to develop the ideas into a form they can evaluate. It would be reasonable for them to think, "Why take it seriously, since it's probably just another hype and PR effort like others we have seen over the years?

13. **Peter Woit**
February 8, 2024

Marty,
I'm really not understanding what you and Hazelnut are objecting to. Yes, of course, a story in New Scientist is not what is going to convince most theorists that they should take the idea I'm talking about seriously. For one thing, New Scientist has a long history of publishing breathless articles about bogus claims of string theorists.

What happened here is Michael Brooks sent me an email telling me he was thinking of writing about unified theories and wanted to talk to me. He's a serious science journalist with a Ph.D. in physics. What do you think I should have done? Told him, no, I don't talk to journalists like you? My policy has always been to talk to serious journalists who want to discuss topics on which I think I have something well-informed to say. I many times have turned down requests to talk about other kinds of topics.

So, we set a time to talk. A few years ago, my standard spiel about "do you think there will be a unified theory" would have been "yes I do, lots of reasons to think it's possible, and I have some vague ideas of my own, although nothing solid I want to talk about". But that's not what I now think: I am deadly serious that I think I have a very specific and very important idea. So, what should I have done? Should I have refused to tell him what I really think about a scientific issue? Not telling people what I really think is not how I go through life.

Should I have said "I have this idea, there's a preprint and I've given a talk about it, but you should not pay it any attention until it is properly vetted by the powers that be and published in a journal"? By the way, obviously there are journals now that will publish anything, so can you explain to me exactly what the list is of acceptable journals that would vet my ideas in a way that would allow me to talk to Brooks about them?

My comments about this particular idea being recent are giving a misleading impression. The funny thing here is that the very half-baked version of these ideas was published, very long ago, in a very reputable journal, see
Nuclear Physics B303 (1988) 329-342
The half-baked version of the ideas I'm talking about is 36 years old and properly published and vetted. But I've always been aware these were half-baked and I never promoted them as anything other than that.

What changed is that a few years ago I learned more about twistors and about Euclidean QFT, and this convinced me that these ideas that I had kind of given up on actually were quite promising. I wrote a somewhat more baked preprint at that point. Then, late last summer, I realized that there is a very precise change you can make in the standard spinor geometry story that realizes what I had been looking for. I wrote that up in the recent preprint. I've been thinking a lot about this since last summer and the more I learn, the more I think it's an important and precise idea (although working out its implications is a major project that will keep me occupied for a long time).

So, what am I doing wrong here (other than wasting time answering comments that I should be spending working on this…)?

14. **Hazelnut**
February 8, 2024

    Look, sorry if I'm coming across as attacking you, I'm trying to be constructive but internet comment sections are not designed for it. I think we are just going round in circles here, and I just re-iterate what the commenter above says. Which scenario do you think is more likely: the popular science aficionados who have come across you recently are going to start working on Euclidean Twistor unification? Or you write up your work, publish it, speak about it at physics conferences and, if it is as important as you think, some physicists start to work on it?

    I am as cynical as anyone about academia, publication etc. but I am even more cynical about the idea of publication by podcast. It is simply not the case that outsider ideas will be rejected out of hand by journals, case in point Renate Loll and *strup from the New Scientist piece. Do you think that some ideas on your personal blog and a couple of preprints are going to inspire young physicists to work on this? It can be a pain, but do the work and the physics community (outside of elite American universities) isn't as closed off as you think.

    As for my own understanding and motivations I left hep-lat/hep-th about 10 years ago for greener pastures, but would love to see it flourishing again.

15. **Peter Woit**
February 8, 2024

    Hazelnut,
    It seems you have no interest in the actual science here, but I'd encourage you to actually read the preprint instead of complaining about podcasts.

    And, no, I'm not complaining that my "outsider ideas" are being unfairly rejected by journals. I am every day "doing the work", very much enjoying trying to better understand the implications of the idea you don't want to know about.

16. **Marty**
February 8, 2024

    Peter,

    I appreciate your sincere, thoughtful reply. You have explained your position well, and I can understand why you might feel exasperated that anyone would find fault with having an honest, public conversation with an intelligent interviewer, just because he happens to work for a popular magazine about science.

    You ask what you might have done differently that would satisfy "critics" like Hazelnut and me. Obviously it isn't for me to say what you should or shouldn't do, and I can't speak for "Hazelnut," but I'll offer an opinion.

    For background, I too have been working on questions in fundamental physics that I think are very promising, work that is a continuation and evolution of my thesis work. My approach is somewhat different from yours — I'm not a Platonist; I think mathematical structures in nature offer idealized (but useful!) descriptions of underlying physical processes, instead of prior idealized mathematical *structures* (like preexisting manifolds) imposing constraints on fundamental processes — but that is irrelevant to this comment.

    What I think *is* relevant is that having worked alone, for a number of years now, with progress painfully slow too much of the time, I can empathize with your desire to get others excited, and maybe even get competent people interested enough to also work on your research program. In no way do I criticize that desire, nor your sincere efforts in that direction.

    But… (there's always a "but", isn't there?) I *personally* would be very cautious in promoting my ideas to a general audience without having some very concrete results, developed in enough detail that experts can agree there is something interesting there. So when the subject of my research comes up with people I don't know, I generally speak cautiously about it: if they are knowledgeable and interested, I'm comfortable going into more detail, and explain why I'm personally excited about it, but regardless of the "audience" I always emphasize that my program is still preliminary, requiring lots more work, and I'm not yet comfortable promoting it. (In fact, due to the many facets of the program, the interconnectedness between its facets, its ambitiousness and my personal sense of caution, I've not even attempted to publish on it just yet.)

    Anyway, that's my own approach. It isn't suitable for everyone, and it may not be for you either. It's very much out of sync with the "modern" belief that it's important to generate a lot of buzz to get the grant money flowing, but since I'm not relying on grants I can live with that. It's important to me that I don't have to worry I'm misleading people.

    And just to be clear, I think your discussing and even promoting your research efforts on your blog are entirely appropriate. The choice of whether to read or how to think about what you write is entirely up to your interested readers.

17. **Peter Woit**
February 8, 2024

    Marty,
    Thanks for your comments. Like you, I'm not dependent on grants, getting buzz to get a grant is not anything I'm interested in.

    What annoys me a bit about this discussion is that way back when I lived through years of people telling me they wouldn't read my book or take seriously my arguments about string theory, since what I was saying was out of sync with the conventional wisdom and the opinions of the experts of the field. Now I'm hearing that people don't want to read a five page paper or take seriously my claims about a solid new idea until it's been vetted by the same sort of conventional wisdom and same experts. Seems to me though that by now I have a track record people should take into account.

18. **Marty**
February 8, 2024

    Peter,

    Well, I hope you aren't interpreting my words as meaning people should not take your ideas seriously until they've been vetted by the sort of people who criticized you in the past for not publishing in the field you criticize. That would be very much at odds with what I was trying to say.

    In fact, back in the bad old "string wars" days I always thought arguments by your critics were bogus when they claimed you weren't qualified to assess or criticize string theory, simply because you weren't a "string theorist" or "active researcher," even though it was obvious from the specificity of your comments that you had spent significant time and effort to learn about what you were criticizing.

    My "criticism," if you want to call it that, is solely about the choice of medium for discussing your ideas. Since popular science media also have a vested interest in creating a level of buzz, I imagine it can sometimes work against the best interests of an interviewee…

Anyway, I ‘m glad you have found a direction to pursue seriously. Now you just need a grant so you can hire a postdoc/researcher or two to help you make faster progress. 🙂

19. **Hazelnut**
February 9, 2024

Okay I'll be blunt – only 'publishing' your ideas in preprints and blogs makes you look like a crank, using your position (as a Columbia professor, notable author, high profile blogger) to promote these unproven ideas in popular media makes you look like a hypocrite. Accusing people who are mildly critiquing you of having "no interest in science" is the kind of thing people used to say to you.

For the record I don't think you are a crank, I have read your preprint, understand the gist if not the fine details and my reaction to it was 'huh'. When you have actually worked out some physical prediction or interesting consequences of your idea that might be interesting. It is your job to convince the wider scientific community not vice versa.

20. **John**
February 9, 2024

Our local public library has the New Scientist magazine on its magazine rack.

https://coqlibrary.chilifresh.com/r1/polaris/search/title.aspx?ctx=1.1033.0.0.1&pos=1&cn=126950

The current issue on display is the Jan 20, 2024 issue so it will probably be a couple of weeks before the issue with this article appears in the library. So others interested in reading this article might want to check their local library to see if they have the magazine in their catalogue.

21. **Dom**
February 9, 2024

Having read this Blog for many years it seems to me that one of the default put-downs aimed at Peter from the string establishment is "Well why can't he come up with an alternative idea?'
It seems odd to then attack him for saying "well actually I am working on one" which is all I can see that he has done.
If the attack then becomes "it's so unfair that he uses his blog to publicise it" then his obvious response should be:
"Why don't you start your own blog then?"

22. **Felix**
February 9, 2024

The pearl-clutching about Peter talking to a popular science magazine is completely over the top. If a journalist asks to talk to you about a subject you're known to be interested in, and you say 'I'm working on something I think is extremely promising, nothing concrete yet, and who knows, it might be nothing', what is morally objectionable about that? Comparing this to decades of string theory hype or the 'black holes in the lab' scandal is bizarre. Can anyone name a single string theorist who has said anything close to 'Maybe I've just gotten old and just lost my way' about their research interests?

23. **RichardT**
February 9, 2024

I think there is nothing wrong in discussing in-progress new ideas in any forum. If Peter gets to a point where he wants to publish something more, then of course he can.

Criticising a decades old, well-entrenched set of ideas such as string theory is very different from attacking new and emerging ideas. I don't see Peter doing the latter, which is why I don't see any hypocrisy here.

24. **jack morava**
February 9, 2024

What Felix said.

25. **Peter Shor**
February 9, 2024

Peter, you say:

> Now I'm hearing that people don't want to read a five page paper or take seriously my claims about a solid new idea until it's been vetted by the same sort of conventional wisdom and same experts. Seems to me though that by now I have a track record people should take into account.

It's not just your track record that people should be taking into account; they should also be taking the track record of these "experts" into account.

26. **Peter Woit**
February 9, 2024

A serious question about journals, hope to hear from those who have thought more about this and know much more:

Why publish a theoretical physics paper in a journal? Note this is not about mathematics papers, where there is a very good argument that this is the right way to get proofs checked, crucial to having as reliable a literature as possible.

I can think of several arguments against journal publication:

1. Everyone reads new physics papers on the arXiv, not in a journal. The only exception to this I can think of was the wormhole publicity stunt paper, published in Nature, not available on the arXiv (still to this day I think).

2. Publication of a theoretical physics paper in a journal gives minimal information about its worth or reliability. See the example in 1, or look up the published works of the Bogdanov brothers.

3. By publishing a paper in a journal, you are handing over rights to the content (yes, I know, exactly which rights is a complicated story) to some organization, often a profit-making one that has its own interests which are not yours and not those of the community.

As for the arguments pro:

1. Journal publication is a standard credential used by funding agencies to decide about grants, universities to decide about hiring, promotion, pay raises, etc. In my particular case none of these things are relevant to my situation.

2. Feedback from referees can be useful in many ways.

3. Publication in a small number of high profile journals is good for PR. See the Nature story above. PRL encourages people to have their institutions put out press releases when a PRL paper comes out.

When I wrote the "Spacetime is right-handed" paper last fall, the main goal was to write something as short and as readable as possible that got the main technical idea across and explained why it was important and opened up a new way of thinking about unification. I did though have in the back of my mind the idea of submitting it to PRL, for reasons 2 and 3. Given some of the accusations in the comments above that I'm doing PR instead of submitting papers to journals, the funny thing is that the only case I can think of in recent years when I've done something motivated by PR was exactly this case of submitting that paper to that journal. It seemed likely that this PR move wouldn't work, that the paper would not be accepted, but I honestly think it contains original and important ideas that fit precisely what PRL says it is looking for and trying to publish.

There was the secondary motivation of hoping for useful feedback. There were two referee reports, one with nothing useful, the other with some detailed comments about the exposition which were helpful. Neither referee found anything wrong with the paper or argued that the idea was already in the literature. The reports both pretty much argued that the implications of the idea in the paper remain to be developed, so instead I should write a longer paper and further develop the ideas. I can't argue with that, plan to do so.

While that's what I'm working on, when done I'm not seeing a decisive argument in favor of submitting the preprint to a journal. It will be much too long for a PRL announcement, so 2. is inapplicable as well as 1. Yes, there might be helpful feedback from referees, but I've found that there are experts in this field I know who have been willing to look at a paper and provide such feedback before I submit the paper to the arXiv as a preprint.

Another part of the argument against submitting to a journal is that I unfortunately know very little about them. As mentioned above, I don't look at them when they come out and see what they publish. I also don't know their copyright and open access policies, or the exact nature of the organization behind them (how predatory on a scale of 0-100?). I'd have to do a bunch of research to gather information. Or, maybe a helpful commenter can point to the best possible option.

27. **Hazelnut**
February 9, 2024

I am sure all the other people who produce 1 preprint a year and refuse to even attempt to publish their work after a single rejection will soon have write ups in the New Scientist.

Peter has made his career out of clutching pearls whenever some string theory booster makes a public statement. You know all the string guys are also genuinely excited about their own ideas, just as Peter is? And while attacking these entrenched ideas what did he suggest instead? High among the advice was a call for rigour and for physics to take some lessons from math. I wasn't aware that mathematicians refuse to publish their work in reputable journals or go to conferences.

If this was someone you were not a fan of, what would you think of this attitude?Peter's reputation is as a critic not a researcher, so he cannot really lean on that here.

And yes, you can and should say no to journalists sometimes. I have done it myself.

28. **Chris**
February 9, 2024

Peter, I think what you are doing is great. The workings of science and the iterative and generative process of coming up with ideas is something that should be shown to people (all people, not just a select few self-anointed ones). People like Hazelnut and Marty seem to be fine with the old ivory tower approach to things. It's such an antiquated mindset.

Keep doing what you are doing!

29. **B. Malpani**
February 9, 2024

Hazelnut wrote:
You know all the string guys are also genuinely excited about their own ideas, just as Peter is?

No, I don't know that at all. And at this point in time, I can't believe it at all. I think that they are perfectly aware of their colossal failure: how could anyone think otherwise?

There's a reason why David Green came up with the idea that we won't be able to judge string theory for another 80 years – he wants to be sure that none of the string theorists are forced into that confrontation with their failure, or that their current critics can feel that they've been vindicated.

Speaking strictly for myself, petty attempts to impugn Woit for his completely unobjectionable interview in New Scientist just serve to reinforce my extremely low opinion of the probity of string theorists, and underscore their desperation to avoid being confronted with their decades of failure.

The intellectual and monetary capital, and careers, that have been squandered on string theory will remain squandered. Attacking Woit is not going to transform string theory from a scientific dead end into a success, sorry.

30. **JJ**
February 9, 2024

Peter has always allowed that string theory ideas are worth pursuing. His main point for decades has been that those ideas shouldn't be allowed to crowd out all other foundational ideas, in the field or the surrounding public discussion. He has always addressed himself to both audiences. Now he lets it be known to specialists and the interested public that he's got what he thinks is a promising idea. He doesn't say it's the only game in town, he's not looking to replace one variety of hype with another, he's not moving goalposts, he's just putting a new idea in precisely the places he has always said there should be lots of them. What's the problem again?

31. **Peter Woit**
February 9, 2024

All,
Please, enough about the tedious subject of string theory. As far as I know, Hazelnut/Marty aren't string theorists.

32. **Scott Aaronson**

February 9, 2024

FWIW, I've faced a similar problem: because of my role as a blogger and public commentator on quantum computing (and now also AI safety), I talk to journalists a lot, and often if they hear that I'm working on something new, they want to interview me about it, even if it's still half-baked, and even if it doesn't particularly deserve more attention than five dozen other things that my colleagues are working on. So then, should I refuse to talk?

I decided on the following compromise policy:

Don't specifically SEEK OUT "unfair advantages," which would give my research undue attention for non-research-related reasons.

BUT: explaining whatever you're currently excited about, with anyone who seems genuinely interested in it, is like 70% of the joy of science. So don't abstain from that joy. If people ask what I'm working on, I should just tell them, along with my honest assessment of how solid or important or worth writing about it is.

33. **Mitchell Porter**
February 9, 2024

Peter: How close are you, to writing a lagrangian for standard model fields coupled to gravity, in your right-handed Euclidean space?

34. **Peter Woit**
February 9, 2024

Mitchell Porter,
The problem isn't so much writing down the Lagrangian, which will just be usual one for the Standard Model + GR. The real question is whether the use of chiral variables opens up a way of constraining the usual SM, explaining something new. The main problems here are that to get something new you probably need a new idea about the geometry of the Higgs, and I'm trying various things there. On the GR side, you have the usual problem that you are doing Euclidean quantum gravity, how do you understand analytic continuation?

There's lots of possibilities to think about, but my time for this is limited for the next couple months as I try to focus on the course and the notes for that (some of which involve working out background material useful for trying out some new ideas involving the chiral geometry).

35. **S**
February 9, 2024

From the article:

"It isn't that Woit believes he necessarily has the answers. But, he says, it is good to know that, despite the long search for a theory of everything, there are still new possibilities opening up."

I see this as perfectly consistent with a dedication to rigor and a desire to avoid hyping things that may not be true. How many of the string theory articles that Peter complained about over the years had any such disclaimer? From what I can remember, extremely few, if any. Rigor is one thing; we also need new ideas to be rigorous about. When they come, there's nothing wrong with talking about them, even in public. I'll join in the accusations of hypocrisy if we're imminently treated to glossy hardcover books or magazine articles where Peter breathlessly explains to a lay audience what his ideas imply about the meaning of their lives, or we're treated to weekly posts promising experimental evidence in six months over a years-long timeframe.

Till then, all I see is a physicist who has a well-deserved platform being asked what he's excited about, and answering the question. Good for him for being excited about physics after everything he's seen.

36. **NoGo**
February 10, 2024

Hazelnut calls Peter Woit hypocritical. As fat as I know, this word means doing something yourself that you criticize others for.

As a reader of his book and this blog, I don't need a physics degree to tell that the gist of what Peter criticizes String theorists for is misrepresenting the state of their theories. Refusing to admit failure, claiming connection with experiment, insisting on "no other game in town", pretending they have a coherent well-defined theory etc. etc. all boil down to misrepresentation.

I don't see any evidence that Peter misrepresents his work in the interview with New Scientist. He is quite clear about this being an idea he likes which may yet turn wrong and which is not yet fully developed and is not endorsed by physics community.

I don't recall Peter ever criticizing String theorists just for talking to the "secular press" or the fact they promote their work, his beef is with _what_ they tell the press and _how_ they promote their work.

I find the accusation of hypocrisy completely bogus.

37. **Filip Hrdlicka**
February 10, 2024

It is a pity that the comment section focuses on just Peter's part of the article and not on other mentioned ideas like Aastrup/Grimstrup ideas.

38. **Robert A. Wilson**
February 10, 2024

Peter,
Can I ask you a mathematical/physical question about your model? I am sure your readers would prefer this to yet more amateur sociology.
The algebraic construction of twistors relies on a Clifford algebra for Spin(4,2), which can be either Cl(4,2) or Cl(2,4). I have heard your two talks and I have read your two preprints, and I still cannot figure out which one you use. So that is my question.
It is not a frivolous or irrelevant question, because the corresponding question for spinors is whether you use Cl(3,1) or Cl(1,3). The former gives you real (Majorana) spinors and the latter gives you pseudoreal/complex (Dirac) spinors. The Standard Model is completely clear that the latter describes physical matter, and the former does not. It is therefore an important question as to whether your twistors are real or pseudoreal, and I am looking forward to your answer.

39. **Doug McDonald**
February 10, 2024

A question for Peter that I don't fully understand (not just the answer, the question):

is the “right-handed” in your theory purely a mathematical definition, or is it anchored to the real world through the weak interaction and how your theory fits into the rest of the standard model?

40. **Peter Woit**
February 10, 2024

About those upset that I’m talking to the press about spinors instead of following the rules and talking only to physicists in carefully vetted venues (invited conference talks and refereed publications in the right journals). I realized that this is very familiar, it’s exactly the reaction I got nearly 20 years ago when I started getting quoted in the press about the problems of string theory. What I was saying then I think turned out to be quite accurate. We’ll see what the future holds for the ideas I’m talking about now, but I’m optimistic about their prospects.

41. **Peter Woit**
February 10, 2024

Robert A. Wilson,

Short answer is I don’t know. One difference with Clifford algebras is that the twistor story is very chirally asymmetric. One is making a choice of convention: points are right-handed spinors. Changing convention, what’s space-time and what’s internal geometry interchange.

That the different choice of convention (metric signature or def. of Clifford algebra) changes the nature of spinors and twistors is something mysterious. If what is going on gets properly understood, perhaps the two different things one sees here will both appear, playing different roles.

42. **Peter Woit**
February 10, 2024

Doug McDonald,
It’s a mathematical fact that spinors in 4d come in two kinds, a convention to call them “right” and “left”. What I’m proposing is very much related to the real world, basically that you can describe what appears in Minkowski spacetime as spacetime geometry just using one kind (“right” by convention), that the other kind are essentially the spinors of weak isospin.

43. **Robert A. Wilson**
February 10, 2024

Peter,
Chiral asymmetry is to do with what happens when you restrict to the even part of the Clifford algebra. One can of course change conventions as to which half of the splitting is left-handed and which is right-handed, and which half you use for spacetime and which half you use for internal symmetry. But that isn’t what I’m talking about. What is going on in the Dirac/Majorana spinor question is perfectly well understood, apart from some residual questions about neutrinos. I do not think it is in the least mysterious. Dirac spinors describe observed physics, and Majorana spinors do not. The same seems to be true for twistors, as far as I can see – pseudoreal twistors describe observed physics (three generations of massive fermions), and real twistors do not. If you disagree, then I would like to know why you disagree, because you probably have a deeper insight into the physics here than I do.

44. **Peter Woit**
February 10, 2024

Robert A. Wilson,
Again, I really don’t understand the possible physical significance of this issue. The place in physics it might be significant is in the story of right-handed neutrinos and neutrino mass terms. What I’m trying to understand is the relation between different real forms. In terms of the Clifford algebra you’re getting two possible different real forms to associate to Minkowski space-time. Maybe they both play a different role, but that is pure speculation.

45. **Eleni Petrakou**
February 11, 2024

For what continuing the “amateur sociology” discussion is worth,
Previous comments showed in detail why Peter’s behaviour has nothing to do with either hypocrisy or unfair advantages. But as a science journalist I’d feel like clarifying a couple of points to any interested earnest critics, assuming those exist in here.
For one, informing people of ongoing, potentially interesting, work on open questions is among the top objectives of a physics journalist. Everyone that knows about science knows that almost all of this work will lead to nothing, and this has nothing to do with reporting on it. What has to do with integrity, however, is presenting ongoing work as something else, usually a lot more successful.
Also, on a more practical side, journalists working on a topic will search for people involved in it. If word of mouth or a google search or prior knowledge provides names then, yes, we’ll go for them. If needs be we’ll look beyond them, but talking to the already known experts is in no way immoral.
Having to spell this out pains me, but reporting unresolved opinions is totally fine; and it has nothing to do with monopolizing grants because of having very resolved and failed opinions.

46. **Robert A. Wilson**
February 11, 2024

Yes, indeed, my question is about real forms, specifically whether you are working in SL(8,R) or SL(4,H) to describe the chirality of twistors. I understand that you don’t yet have an answer to that, but that you are looking at real forms of SU(4), where the corresponding question is to distinguish between SL(4,R)=Spin(3,3) acting on a Majorana spinor, and SL(2,H)=Spin(5,1) acting on a Dirac spinor. But then I can’t reconcile this question with properties of twistors acted on by Spin(4,2)=SU(2,2), or with your embedding of U(1) x SU(3) which requires real form SU(4) or SU(3,1).
So you will surely eventually have to address the question of SL(8,R) or SL(4,H), and when you do, it may be useful to note that SL(4,H) contains SU(2) x U(3), but SL(8,R) does not.

47. **Alex**
February 11, 2024

I wasn’t able to read the article because of the paywall, but it seems there’s no mention of Connes’ Spectral SM?

It really baffles me how little attention it gets. People would be very surprised if they knew how well developed and understood it is by now. Whenever anyone asks me about the unification problem, I always mention this approach as the best we have at this moment in time. In my opinion, of course…

48. **Bruys**
February 13, 2024

I don't understand the criticism of Peter for allowing someone to write about his ideas in New Scientist. What a boring world it would be if no-one discussed their ideas!

Peter has been critical of people making unreasonable claims for String Theory, not for discussing String Theory ideas – there is no hypocrisy being practised here.

49. **zzz**
February 14, 2024

Hnut:
"I have read your preprint, understand the gist if not the fine details and my reaction to it was 'huh'. When you have actually worked out some physical prediction or interesting consequences of your idea that might be interesting. "

you are all over the place here, is this an interested "huh"? or not ?
because (again) you are immediately contradicting your criticism,

50. **Peter Woit**
February 14, 2024

zzz,
I think "huh?" is a pretty universal reaction from physicists to that paper. The argument for a different relation between vector and spinor geometry is hard to comprehend if you haven't thought a lot about the usual version of this. I tried to write something short and as comprehensible as possible, but don't think that succeeded very well. Next there will be a much longer version, we'll see if that helps.

In the paper I try and point out how this different relation opens up possibilities for a new way to do unification. To me, these seem very promising and something that no one has looked at before, but time will tell. It's perfectly sensible for people to decide they want to ignore this until it's further developed, but I'm still seeing no argument for why I shouldn't keep trying to explain these ideas to anyone who will listen.

Two Items

February 14, 2024
Categories: This Week's Hype

If I'm going to point to something about string theory and say the same things as always about it, seems best to first start with the opposite, an item about something really worth reading.

- This spring I've been teaching a graduate course aimed at getting to an explanation of the Standard Model aimed at mathematicians. The first few weeks have been about quantization and quantum mechanics, today I'm starting on quantum field theory, starting with developing the framework of non-relativistic QFT. While trying to figure out how best to pass from QM to QFT, I've kept coming across various aspects of this that I've always found confusing, never seen a good explanation of. Today I ran across a wonderful article by Thanu Padmanabhan, who I knew about just because of his very good introductory book on QFT, Quantum Field Theory: The why, what and how. The article is called "Obtaining the Non-relativistic Quantum Mechanics from Quantum Field Theory: Issues, Folklores and Facts" and subtitled "What happens to the anti-particles when you take the non-relativistic limit of QFT?" It contains a lot of very clear discussion of issues that come up when you try and think about the QM/QFT relationship, a sort of thing I haven't seen anywhere else.

  Looking for more of Padmanabhan's writings, I was sad to find out that he passed away in 2021 at a relatively young age, which is a great loss. For more about him, there's a collection of essays by those who knew him available here.

- For something I can't recommend paying more attention to, New Scientist has an article labeled How to Test String Theory, which is mostly an interview with Joseph Conlon. Conlon's goal is to make the case for string theory, in its original form as a unified theory with compactified extra dimensions. On the issue of testability there's nothing new, just the usual unfalsifiable story that among all of the extra stuff (moduli fields, axions, extra dimension, extended structures) that appears in string theory and that string theorists have to go to great trouble to make non-observable, it's in principle conceivable that somebody might observe one of these things someday. But, that's not really what people mean when they ask for a test. For details of the sort of thing he's talking about in the New Scientist article, see here.

  I strongly disagree with Conlon about some of what he's saying, but the situation is very much like it has always been with many string theorists since way back to nearly forty years ago. We don't disagree about the facts, it's just that I've always looked at these facts and interpreted them as showing string theory unification ideas to be unpromising, whereas string theorists like Conlon somehow find reasons for optimism, or at least for believing there's no better thing to do with their time. Last time I was in Oxford, Conlon invited me to lunch at his College and I enjoyed our conversation. I think we agreed on many topics, even about what is going on in string theory, but it looks like we're always going to have diametrically opposed views on this particular question. For more from him, as far as popular books by string theorists go, his Why String Theory? book is about the best there is, see more about this here.

Update: A couple more.

- Curt Jaimungal has a conversation with Lee Smolin.
- Andy Strominger is giving talks on Celestial Holography at the KITP "What is String Theory?" program, first one is here. Lots of questions from the audience. One thing he makes clear is that this is not leading to a theory of quantum gravity. Stringking is back, his comments on this:

  > KITP program on what is string theory such a joke this week. Strominger shilling his celestial vaporware.

Comments

1. **Anonyrat**
   February 15, 2024

   I was in high school, just learning calculus, and T. Padmanabhan was doing his Master's at University College in Thiruvanantapuram, and one summer he organized with a co-student or two, an after hours class for interested students, where he taught the Calculus of Variations, Lagrangian and Hamiltonian mechanics and made it all intelligible to me – an amazing teacher!

   I wish that I had kept contact; but that one summer is a memory I cherish.

2. **tulpoeid**
   February 15, 2024

   I realized it's Padmanabhan who's written the mesmerizing textbook "Sleeping Beauties in Theoretical Physics"… such a loss…

3. **Diogenes**
   February 16, 2024

   A lot of this seems to be an embedding of "personal Bayesianism" into the scientific project. So people start with different personal "creedences" of some idea (perhaps highly correlated to their involvement in it) and update more or less frequently with new evidence according to their personal estimate of the value of the evidence, conditional probabilities, etc. So it's not really surprising to see different estimates of say [10%, 90%] creedences on theories based on some empirical "my truth" basis like this. Especially in some cases where there is no real evidence to update on, or priors to estimate.

   What seems a bit different here is the idea of "expected future personal Bayesianism", meaning personal forecasts of future progress getting rolled into current credeences with very high probability. If the progress was that automatic it would already have happened. So very high "expected future personal Bayesianism" creedences based on very little evidence or substance seem to be the cause of the sociological argument here.

   Sean Carroll's long podcast on the state of Physics kind of outlines the case for this, but while the first half of the podcast is very good, when he veers into the defence of "expected future personal Bayesianism" and insider hiring practices in academia it is less impressive, although I think very honest. Believing in the serial correlation of past individual scientist's successes with future successs over very long time horizons is counter to quite a bit of evidence.

   The question is what is the proposed alternative to insider "expected future personal Bayesiansm?" I suspect it would look something like the rich guy funding models of Perimeter and Simons, run like a venture capital fund, with the expected return of each investment near zero, but high overall (societal) returns to a diversified enough portfolio of ideas and individuals. But more funding to entrenched incumbents supported by "look these guys are really smart, and they almost did something incredibly cool 20 years ago" probably has a very average rate of return, especially if the pitch-deck (in the form of popular science books) is a bit cooked.

   An even bigger problem is whether these theories of Planck-scale physics make sense to attempt, given they can't be directly proven or evaluated. But although I see no evidence of this, my "expected future personal Bayesianism" gives me hope that they can.

4. **Michael Arthur Stringer**
February 17, 2024

Joseph Conlon is a very nice guy with a passion for both the mathematics and physics(?) found in String Theory. However, in the New Scientist interview his role as a defendant for the continuing relevance of String Theory (rather than a degenerate research program) falls pretty flat – he comes over more as a 'Witness for the Prosecution'.

5. **Joseph Conlon**
February 17, 2024

Thanks, Peter. I also enjoyed our lunch in Oxford. No personal quarrel; but I am as mystified by your views as you seem to be about mine.

If one (a) accepts that there is an awful lot we don't know about our current universe and (b) think that research on these questions is worthwhile (and my impression is we agree on both points) then I cannot really understand the hostility to string theory as a subject, especially when compared to the alternatives, although I could understand some allergic reaction to some of the bad PR done in the name of string theory.

Likewise, I can't really grok why you seem hostile to ideas if they have the label `string theory' attached, but indifferent if the same ideas appear without that label. For example, the physics part of the interview concerns ideas for physics in the epoch between inflation and BBN (e.g. moduli domination), which you seem quite scathing about above.

We really know essentially nothing, observationally, about this epoch. Nil, zip, dada. And it could cover up to a factor of 10^30 in time. So surely all theorists in the particle theory / cosmology zone with at least some interest in pheno should care about ideas for what could be in this epoch and how we could test them? This is up to half the lifetime of the universe on a log scale! Of course we should think about what happened them and how we might observe them.

I don't recall any posts by you criticising cosmologists who write papers about this era as unfalsifiable, etc — but many of the same/similar ideas (early matter domination/trackers/quintessence/kination etc) become 'not even wrong' when in a string context: and I cannot really understand why.

I can 'get' hostility to string theory as a subject from those who think that we should all work on climate physics, AI or quantum computing. I can get allergic reactions to bad PR. But I can't really understand intellectual hostility from anyone with a broad-minded interest in particle theory.

6. **Peter Woit**
February 18, 2024

Joe,
In this particular case the hostility is to claims that effects of moduli fields are a "test of string theory", which is misleading (a more accurate description of the implications of such fields would be as serious evidence against string theory).

In general I don't spend my time criticizing cosmologists or anyone else for working on whatever they find interesting, however unpromising or misguided it looks to me. The focus on string theory is because the way it has been pursued and hyped to the public and other scientists over the last 40 years has done a lot of damage to the kind of research I care about. This first drew almost all resources in the field to one speculative idea, which was bad enough. Now after decades of this idea not working out, it has discredited all research on unified theories.

I do try and spend my time on more positive pursuits, but the hype campaign won't stop and actually just gets more disturbing (see the wormhole fiasco, or the recent Brian Greene panel). About the only other person criticizing this is Sabine Hossenfelder, and my point of view is very different than hers on the problem (no, it's not "Lost in Math").

7. **Joseph Conlon**
February 18, 2024

Those aren't my words though. In what I say, I try and be super-careful about any expression like 'test of string theory'. As you know, if you talk to journalists (which generally scientists should do if asked) you don't control the blurb and you don't control the title: and likely something will be picked that you would never choose yourself.

So you either have to live with headlines you would rather were different, or not say anything at all: and I choose the former.

8. **Art**
February 24, 2024

It looks like some chapters have been recalled in your latest qftmath notes version. I was wondering if Padmanabhan's article had influenced your treatment.

9. **Peter Woit**
February 24, 2024

Art,
I've just this afternoon uploaded the latest version of the notes, see
https://www.math.columbia.edu/~woit/QFT/qftmath.pdf

The material I've been lecturing on the last week or two and have now finished (chapter 7) has been about non-relativistic qft, which is generally considered too simple to make it into most QFT books, which start with the relativistic theory. But it seems to me best to first understand the non-relativistic theory, where anti-particles decouple, making the whole story much more straightforward.

The earlier version I had posted had a partial chapter 7, including something I'd started writing on propagators. When I started adding more and gave a lecture, I realized that I was doing things in a confused and overly complicated way. Normally I figure this out while preparing a lecture, this time I didn't realize it until I was actually in the middle of the lecture (and realized that an argument had gone in a circle and come back to essentially the same starting point…). Apologies to the students for putting them through that, but others I hope will benefit because the experience made it possible to write up much clearer notes.

So, no, Padmanbhan not responsible, but preparing and delivering a lecture was, as always in teaching, very educational for me.

10. **Art**
February 24, 2024

Got it, thanks. I'm looking forward to the reappearance of Chapters 9 and 10 in a future version.

11. **Peter Woit**

February 25, 2024

Art,
Forgot to include those in this latest version. Will be getting to that part of the course later in the week and be rewriting them, new version should appear in a week or two.

12. **Michael Weiss**
February 27, 2024

Peter, you have previously commented on exciting-sounding analogies between bench-top experiments and black holes, including the information-loss paradox. Yet Nature Reviews Physics is again highlighting these analogies as sources of profound insights; see https://www.nature.com/articles/s42254-023-00630-y.epdf?sharing_token=zj4iqWa8yEwZ-i4Fl6fAitRgN0jAjWel9jnR3ZoTv0Nz0uC7Et1O9sYRTMTUg9QS9YGeXjxcQPTc-Ho86x7uS-7F0WJfvtsbRyG4MuSBzadIgdFFCqIuydBu_jceodTM88QhNAtDbDJSby0DN9GCTpPIuYpnXNwxYECfp0qBwBg%3D. Is this work significant because new insights are obtained into otherwise intractable systems, or is it because the analogies simply sound cool? Sorry for what may be naive questions.

13. **Peter Woit**
February 27, 2024

Michael Weiss,
This sort of thing has never made any sense to me. There's something obviously absurd on its face about claiming "I'm going to study motion of a fluid in a lab, and learn about quantized space-time degrees of freedom." I don't see how it's any different than me saying "I'm going to test my quantum gravity theory in which some variable satisfies a quadratic equation with solution a parabola by going outside and throwing a ball whose trajectory should follow the same parabola."

This Nature paper is somewhat less nonsensical than the Nature wormhole fiasco paper, and at least these authors didn't hold a press conference and convince Quanta to make a video about it.

Three Items

February 27, 2024
Categories: Uncategorized

Kind of like the last posting, but this time you get two worthwhile items to make up for one that's not.

- Dan Garisto has a very good article here examining the present state of high energy experimental particle physics and phenomenology. He also summarizes current thoughts about the future. The CERN FCC-ee proposal is still in feasibility study mode, with the big problem its high cost. Numbers like \$15 – \$20 billion have shown up in press reports, and Garisto has "tens of billions". The feasibility study is supposed to be finished late next year, and presumably a big part of it is people at CERN crunching numbers trying to figure out some plausible way this could work financially.
- There's a very good article at Quanta about efforts to put together version 3 of the very influential "Kirby List" of open problems in topology. For version 1, see here, version 2 here, and as far as I can tell, version 3 still not finished (but discussed here).
- Brian Keating has a video asking "What would It take for String Theory to move beyond the realm of pure math, Into verifiable territory"? The answer obviously is a conventional substantive scientific prediction of anything. By describing the problem with string theory as being that it is now in "the realm of pure math", I think Keating is missing the point. The problem with "string theory" is not that it's pure math, but that it's not a theory. "String theory" is now a 50 year old set of failed hopes and dreams that a theory might exist, see for instance Theorists Without a Theory. Every so often I try to figure out what people still pursuing this are up to, most recently today taking a quick look at KITP talks by Liam McAllister here and here.

  The problem shows up clearly at 10:23 of the first talk where he's talking about his goal, which gives up on studying all or even representative string theory solutions and tries just to find any "valid solutions". But what is a "valid solution"?

  > And by valid solutions, we should say what equations are we trying to solve? And, it's not the case that we can currently think about finding cosmological solutions of the exact theory in any non-perturbative sense.

  McAllister artfully avoids saying what everyone at the talk knows (after all, the talk is part of a program entitled "What is String Theory?"): you can't look for solutions to the theory because there is no theory. More specifically, no "exact" theory, just a long list of possible theories that one hopes might be in some sense approximations to a real theory. He then goes on to specify the extremely complex approximate theory he wants to work in, chosen by the "look under the lamppost" method as something you could actually imagine calculating. Whenever I look at things of this kind I'm completely mystified why anyone thinks it make sense to embark on insanely complicated calculations like these with essentially zero credible scientific motivation. Somehow though, he has a whole group of people doing this. By the end of the second talk he's giving his vision of the future, which features an old photo of a room of hundreds of men in suits and ties calculating with pencil, paper and slide rules.

  I was mystified twenty years ago why anyone thought this was a good idea, and the whole thing has just gotten stranger and stranger…

Comments

1. **Sabine**
   February 28, 2024

   The FCC cost estimate numbers I have seen or heard is something like USD 12 billion for the first stage, USD 20 billion for the first & second, and the "tens of billions" that includes the operation cost which is (conservatively) another billion per year. Even if these numbers are somewhat off, I think it's realistic that in total it'll be $40 billion at least.

2. **Sabine**
   February 28, 2024

   I find it interesting how graphic designers can't seem to resist the temptation to arrange the standard model particles in some sort of symmetrical configuration even if that doesn't make any sense. The infographic in the MIT Tech Review article is another example of that. If you Google it, you'll find many more examples. All with symmetries that have nothing to do with the physics.

3. **Sabine**
   February 28, 2024

   Everyone who thinks that SUSY "explains" the Higgs mass misunderstands what it means to "explain" something in scientific terms. The Higgs mass is a free parameter with and without SUSY. It's about time this naturalness nonsense stops.

4. **suomynona**
   February 28, 2024

   @Sabine:

   If you want a visualization of the Standard Model particles that makes an attempt to group things according to their actual physical properties, see this one:
   https://www.quantamagazine.org/a-new-map-of-the-standard-model-of-particle-physics-20201022/

5. **Mitchell Porter**
   February 28, 2024

   Peter, I assume you're aware of the recent use of machine learning to estimate physical yukawa couplings in various string compactifications, using simpler ones for which analytical results exist, as a way to benchmark the AI estimates? e.g. https://arxiv.org/abs/2402.01615

6. **Peter Woit**
   February 28, 2024

   Mitchell Porter,
   Doesn't matter how you do these calculations, they're still meaningless.
   Since people are throwing their money at AI, I assume this is both a great way to attract funding, as well as generate papers with minimal effort.

7. **Sabine**
   February 28, 2024

@suomynona sorry I don't know what you mean, the ones I see on that page make as little sense as all others I have seen

8. **David Yager**
February 28, 2024

Hi Peter,
Any plans for the eclipse next month? Going to this one won't involve an exotic trip around the world – although some parts of Ohio may seem like a third world country when traveling from Columbia.

9. **Peter Woit**
February 28, 2024

David Yager,
Will definitely go to somewhere on the eclipse track. I'm canceling my class for that day, and a couple days before will head up to Boston first then Burlington area day of eclipse if weather there looks good. Otherwise will head west looking for clearer skies. My 93 year old mother is very enthusiastic about coming along.

10. **maxstroke**
February 28, 2024

@Sabine: Are there any good infographics out there, to your mind? Or is the point that there is no "natural" way of grouping the standard model particles in a visual representation? If that's the case, then it seems any arbitrary viz would be as good (or bad) as any other… Blindfolded people touching the elephant and all that…

11. **Peter Woit**
February 28, 2024

If people are going to discuss this, I'd like to advertise the graphic for SM fermions from my book, see
https://www.math.columbia.edu/~woit/fermions.pdf

12. **Zachary Yezek**
February 28, 2024

Is anybody even still trying to turn the conjectured M-Theory (or its successors) into an actual concrete theory with specific principles & equations?

To use General Relativity as an analogy, if string theorists don't have the Einstein tensor or Field Equations yet do they at least know that the equation they're looking for will relate matter & energy distributions to warped space-time geometries? Do they at least know they need a tensor equation, or that it must satisfy the strong equivalence principle?

I ask because it isn't clear that even the "string" theorists are still working that problem. About the closest thing to it that I'm aware of is that "Swampland" project trying to find non-trivial consistency conditions that all the 'string vacua' must honor. Sort of meta-conditions on any such equation and its solution space. But even that effort appears to have produced little of substance, beyond the vaguest possibility that a positive cosmological constant is incompatible with string theory.

13. **Sabine**
February 29, 2024

@maxstroke I've never seen one that made sense. I thought about this a lot for my first book and came up with something that made sense (at least it's what I thought) but it was so complicated I realized it wouldn't do any good. I have my own infographic (it's the one I keep using in my videos) but it's omitting a lot of information about the gauge groups. Though at least I do have 8 gluons.

Just to give you an idea it was kind of similar to this:

https://static.scientificamerican.com/blogs/cache/file/65C0B45B-606B-44AF-83F80189256EB5D6_source.jpg?w=590&h=800&29A6937B-1463-45E9-823B3D940BC2F532

Kinda messy, but I think it's actually a pretty good summary of the SM Lagrangian. (Leaving aside that it has only 1 gluon…)

My point is just that humans seem to have a tendency to want things to be nicely symmetric and sorted and fit into easily understandable categories, and the standard model just isn't to their liking. I understand of course why graphic designers want pretty graphics, but I'm not at all sure that the message these graphics convey is helpful.

14. **Peter Woit**
February 29, 2024

Zachary Yezek,
As far as I can tell, no one has ever had a viable idea about M-theory of this kind. In particular, if you look at Witten's papers from the 90s, this is something he was very much looking for. But at some point he seems to have given up.

One goal of the KITP "What is String Theory?" program seemed to be to attract interest to this problem, but looking at the talks, I see no one even trying to address it.

15. **tulpoeid**
February 29, 2024

Twenty years ago I attended a theory summer school where a very personable professor would make remarks such as (while arriving at the solution of a long example on the whiteboard) "and now we'll do what string theorists have not been able to do for twenty years, we'll write down the lagrangian".
I wonder if there has been any progress with that.

16. **Peter Woit**
February 29, 2024

tulpoeid,
No.

17. **anon**
February 29, 2024

The thing I like most about the Association for Mathematical Research, the new politically-neutral alternative to the American Mathematical Society, is that it has the most

comprehensive list of problem lists I have ever seen:
https://amathr.org/problems/

18. **David Roberts**
February 29, 2024

@Zachary

I don't follow the research field actively, but given the proximity of the work of my one-time coauthor Urs Schreiber to my own interests in geometry, I watch what he is doing with Hisham Sati. They are slowly chipping away at a very principled approach to finding core principles of M-theory using contemporary mathematical tools and showing how scattered observations derived in special cases are consequences of them. It's not throwing up ones hands and blaming the swampland, but trying to get to a point of rigorously proving things posited in the 90s (like, for example, Witten's idea that brane charges are quantised in K-theory) from a central underlying principle.

I'm not sold on string/M-theory as The One True Theory, but from the point of view of mathematical physics it's much better than all the alternatives I see Peter pointing to. The fact it requires heavy formalism from mathematics developed in the past 20 years and even the past 5-10 years means that I suspect a lot of people in the physics world prefer to stick to claiming an mathematical model of a quantum system on a chip using linear algebra is really telling us about real-world cosmological wormholes, since it's a lot less effort to understand and explain, especially to the popular press.

19. **Peter Woit**
March 1, 2024

David Roberts,
The problem with Sati/Schreiber is that the answer to "what is M-theory" that they are pursuing has no connection to actual physics. The string theorists gathered at the KITP to discuss "what is string theory?" don't think of what Sati/Schreiber are doing as relevant to the question they are asking. For most physicists, the math apparatus Sati/Schreiber are using is a barrier to them getting interested, but there are physicists (Witten most notably) who can follow this and they show no signs of interest, exactly because there's no connection to physics.

This kind of thing has always been to me the main problem with string theory, more than the lack of connection to experiment. When string theory research finds a direction that is mathematically fruitful (take mirror symmetry as an example), it is a direction orthogonal to any connection to physics. When string theory research finds a direction that tries to connect to physics (any "string phenomenology"), it is mathematically hideous, orthogonal to interesting mathematics. This has always seemed to me conclusive evidence that whatever "string theory" is, it's a wrong idea about unification, that a right idea will not be orthogonal to good mathematics.

20. **Maximillian**
March 6, 2024

I can't get over the picture of hundreds of people in suits and ties in a room calculating with slide rules. I laughed so hard I cried.

21. **David Roberts**
March 7, 2024

@Peter

apologies for the slow reply, but what I posted was in response to the question by Zachary

> Is anybody even still trying to turn the conjectured M-Theory (or its successors) into an actual concrete theory with specific principles & equations?

Regardless if one thinks that M-Theory is even a theory with connection to physics or not, one can attempt to build a more principled theory that is based on some specific principles, as opposed to a bunch of ad-hoc conjectures and suppositions. It is a stretch to my imagination deny that Schreiber and Sati are trying to "turn the conjectured M-Theory into an actual concrete theory with specific principles". This is their literal stated goal. Whether these principles are physical or not is a separate question. They are certainly building up a mathematical theory and proving it gives rise to effects conjectured in the literature.

I repeat also: I'm not sold on it being a physical theory either (with the caveat that I'm not a physicist), but I certainly admire the intention to sort out the mathematics that lies behind a bunch of things in the M-theory literature.

(All this comes of course with the usual disclosures that I know Urs reasonably well, and I admire the mathematics he works on.)

A New Approach to Modularity

February 28, 2024
Categories: Langlands

I was assuming that Peter Scholze's [Emmy Noether lectures] at the IAS would be the big news about advances in the Langlands program this coming week, but an anonymous correspondent just sent me [this link]. Tomorrow Andrew Wiles will be giving a talk in Oxford on "A New Approach to Modularity", with abstract:

> In the 1960's Langlands proposed a generalisation of Class Field Theory. I will review this and describe a new approach using the trace formua as well as some analytic arguments reminiscent of those used in the classical case. In more concrete terms the problem is to prove general modularity theorems, and I will explain the progress I have made on this problem.

I'm curious to hear from anyone who knows what this is about or can report tomorrow after the talk. Wiles does have a certain track record of unveiling unexpected huge progress in a talk like this…

Update: Well, the talk should be over now. Sure someone who was there can let us know what happened?

Update: There's a [tweet with some photos].

Update: The [first of Scholze's talks] is available at the IAS youtube channel.

Comments

1. **GG**
   February 29, 2024

   I was at the seminar but I am reluctant to comment as I am not a number theorist. To my understanding, Wiles showed that proving the 2006 Michel-Venketash mixing conjecture would imply modularity. I can provide the photographs of the whiteboard if interested.

2. **Peter Woit**
   February 29, 2024

   GG,
   Thanks! That's consistent with third-hand reports I've heard from another source, that this is about new cases of modularity, but conditional on cases of the mixing conjecture. Better I not try and provide a garbled fourth-hand version, I hope someone else who was there can provide more details, ideally a set of notes. Not clear to me if my hosting photographs of a talk would be a good idea if the speaker/sponsoring institution don't approve.

3. **David Roberts**
   February 29, 2024

   FWIW, the comment on the first photo in the Twitter post saying "proved by" is I think referring to the Annals paper [*Joint equidistribution of CM points*] by Ilya Khayutin. This paper proves a particular special case of the Mixing Conjecture over the rationals.

4. **Z Y**
   March 4, 2024

   Isn't the mixing conjecture already proved if we assume GRH? That would make for a very interesting turn of events

Spring Course Notes

March 3, 2024
Categories: Uncategorized

This spring I've been teaching a course aimed at math graduate students, starting with quantum mechanics and trying to get to an explanation of the Standard Model by the end of the semester. Course notes for the first half of the course are available here, but still quite preliminary, in particular I need to do a lot of work on section 9.4 and add material to chapter 10. Hoping to get to this tomorrow.

There won't be much progress on the notes for the next couple weeks. This coming week I'm hoping to spend some time trying to understand Peter Scholze's IAS lectures, will go down to the IAS on Tuesday. On Thursday I'm heading out on a spring break vacation to the Arizona-Utah desert.

Perhaps a good way to think about these notes is that they're both aimed more at mathematicians than physicists (although I hope accessible to many physicists) and also designed more to supplement than to replace the discussions in the standard physics texts. So, a lot of the standard material is not there, since it's well-covered elsewhere, but there are a lot of topics covered that usually aren't.

One unusual aspect of the notes is that I spend a lot of time trying to explain non-relativistic quantum field theory, since that seems to me to be a better starting point than immediately diving into the relativistic case. I'd be curious to know if anyone can point me to a good discussion of the path integral formalism for non-relativistic quantum field theory, which is something I haven't found. This is one reason it's taking a while to finish writing up my own version.

Also original here I think is a careful discussion of the real forms of spinors and twistors. This in some sense is background for the new ideas about "spacetime is right-handed" which I've been working on. Nothing in the notes now about the new ideas, but I hope the explanation of the conventional story in these notes is useful.

   March 4, 2024

   Hey Peter,

   From the Physics side of things, there are some recommended texts that discuss the path-integral for non-relativistic QFT. In my experience, they are usually associated with advanced statistical mechanics and condensed matter. Not sure if this is what you are looking for, but a couple of standard choices are:

   – QFT in Condensed Matter Physics, Naoto Nagaosa
   – Quantum Many-Particle Systems, John W. Negele and Henri Orland

   All the best

2. **Adam**
   March 4, 2024

   The path integral for non-relativistic quantum fields (the so-called coherent state path integral) is everywhere in condensed matter theory. Two few textbooks, just off the top of my mind:
   Altland and Simons, "Condensed Matter Field Theory", Chapter 4
   Dupuis, "Field Theory of Condensed Matter and Ultracold Gases", Chapter 1 (that chapter is accessible for free here
   https://www.worldscientific.com/doi/epdf/10.1142/9781800613911_0001)

   This kind of path integrals can be generalized to many Lie algebras (su(2), su(1,1), etc), see e.g. Perelomov "Generalized coherent states and their applications".

3. **David Brown**

4. **Peter Woit**
   March 4, 2024

   Thanks for the references!

   Closest to what I've been looking for are section 2.2 of Nagaosa and section 1.4 of Dupuis. These give an imaginary time path integral of the right sort, but do it for finite imaginary time, to do a finite temperature calculation. Not seeing a discussion of zero temperature and the relation via analytic continuation to the real time Wightman function.

   Yes, one can think of these as "coherent state path integrals", as well as "phase space path integrals". I wrote something very long ago about the problems with these, see https://www.math.columbia.edu/~woit/tqtandrepthy.pdf
   At the time I got interested in this when thinking about the Chern-Simons path integral. If you look at something very simple with the same structure (path integral over paths on a sphere as phase space) you see that there are very serious problems making any sense of such things. A fundamental aspect of quantization is that you can't just go directly from a symplectic manifold to a quantum system, preserving the symplectic invariance (the infinite-dimensional group of symplectomorphisms). There's something fundamentally conceptually wrong with the phase space/coherent state path integral, because it appears to do this. For the thing to make sense you need somewhere to smuggle in a polarization or somehow break the symplectic invariance.

   When your integral is just a Gaussian, then you can formally do the exact integral and get something sensible, at least in imaginary time. There's something interesting going on here which I don't fully understand. The formal "derivations" of a coherent state path integral though aren't really helpful, since they have obvious problems (you're "integrating" over "paths" with no continuity property, with formulas involving their derivatives).

5. **Adam**

March 4, 2024

Peter,

It is possible to do some calculations (in imaginary time) even if the action is not Gaussian. In the case of a quartic term, one can use a Hubbard-Stratonoich (HS) transformation to render the integral gaussian, integrate out the field, and then HS field. Because, as you remark, neither the original field nor the HS field are continuous, one needs to be extra careful. However, using insight from Ito calculus (the HS field is effectively a weight noise), one can recover the exact result, see Sec. II of https://arxiv.org/abs/1906.02571.

I've become interested in this problem when trying to understand how to (properly) perform non-linear change of variables in such integrals. Contrary to standard Feynman path integrals, here it is much more subtle because the field is not continuous (in the Feynman case, it is continuous but not differentiable, which allows for controlling the derivatives of new variables, however with the introduction of new "quantum potential" terms). No such luck here however. As far as I know, it is still an open problem.

6. **Peter Woit**
March 4, 2024

Adam,
Thanks for the comment and reference. These seem to be consistent with my understanding, that for configuration space path integrals you have continuity and if careful can do transformations on the the fields with results consistent with usual quantization. But for phase space or coherent state path integrals, no continuity, and (beyond linear transformations), the "integral" doesn't at all have sensible properties under change of variables.

7. **Adam**
March 4, 2024

Peter,
Are you saying that such non-linear changes of variables would be completely impossible? Would you have a reference that would substantiate that?
If it is in the reference you gave in a comment above, could you explain the argument for someone not really knowledgeable in CS TFT?

8. **Peter Woit**
March 4, 2024

Adam,
I haven't thought much about this in a very long time, and even then, I was focused on a different problem: how do you make sense of path integrals over paths in G/T (G compact, T maximal torus) and recover the usual quantization story there, where it's the representation theory of G?

There is a no-go theorem, the Groenewold-van Hove theorem. Because of that theorem, something must go wrong if you do non-linear symplectic transformations on the variables, in the sense that such transformations can't correspond to unitary transformations on the states. A different aspect of this is that, in addition to a phase space you need a polarization on that phase space to get a quantization, and the quantization depends subtly on the polarization. What I'm wondering about phase space path integrals is where the polarization choice comes in.

Again, a problem for me here is that I haven't thought seriously about this in a long time.

9. **Hansi**
March 4, 2024

For the path integral, i would suggest
https://link.springer.com/book/10.1007/978-3-540-76956-9

Mathematical Theory of Feynman Path Integrals
An Introduction
Authors: Sergio A. Albeverio , Raphael J. Høegh-Krohn , Sonia Mazzucchi
Part of the book series: Lecture Notes in Mathematics (LNM, volume 523)

That is what a math student would go for. It starts with non-relativistic path integrals and then goes over to quantum field theory, but all in theorem proof style. Some of the authors work at Bonn university.

10. **Micha**
March 5, 2024

Hi Peter,

there are some path integral books by Kleinert. I'm not so sure how close it is to what you are looking for. Here some version from his homepage.
https://hagenkleinert.de/documents/pi/HagenKleinert_PathIntegrals.pdf

11. **Arnold Neumaier**
March 6, 2024

Peter,
you wrote, "There's something fundamentally conceptually wrong with the phase space/coherent state path integral, because it appears to do this. For the thing to make sense you need somewhere to smuggle in a polarization or somehow break the symplectic invariance."

But you dind't notice that this is already smuggled in in the coherent state integral, since (as especially John Klauder emphasized repreatedly) a coherent state provides not only a symplectic structure but also a compatible metric structure, which is just a way to define the required polartization.

12. **Peter Woit**
March 6, 2024

Arnold Neumaier,
When you naively write down the coherent state path integral, looking at the measure and action, only difference with the phase space integral is the boundary conditions. Like in the phase space path integral, choice of polarization appears just in the boundary conditions.

It's been a long time since I looked at Klauder's attempts to define coherent state path integrals. I guess you can try and use the Kahler structure polarization to do this. But after spending a lot of time looking at this kind of thing years ago, I never found anything that seemed convincing.

13. **Anon**
March 6, 2024

I'm just a student, but I like the following books on path integrals:
1)G.Roepstorff- Path Integral Approach to Quantum Physics (Grad level mathematical physics book);
2)L.S. Schulman- Techniques and Applications of Path Integration (Undergrad-Grad level theoretical physics book)

14. **Peter Woit**
March 7, 2024

Anon,
Nothing in the Roepstorff book about phase space/coherent state path integrals, but it has an excellent detailed treatment of Euclidean quantum fields. The Schulman book near the end has a chapter on the phase space path integral, carefully explaining the problems with it.

15. **PS**
March 8, 2024

Hi Peter,

you might find a series of papers by Hashimoto et al useful, for example "Borel-Weil theory and Feynman path integrals on flag manifolds" (https://projecteuclid.org/journals/hiroshima-mathematical-journal/volume-23/issue-2/Borel-Weil-theory-and-Feynman-path-integrals-on-flag-manifolds/10.32917/hmj/1206128252.full) or "The Borel-Weil theorem and the Feynman path integral" (https://mathweb.tifr.res.in/sites/default/files/publications/studies/SM_13-Geometry-and-Analysis.pdf#page=325). Building on earlier work of Alekseev, Fadeev, and Shatashvili, they describe how to perform path integral quantization of coadjoint orbits the form G/T and, for the linear Hamiltonians corresponding to Lie group generators, how to regularize the path integral to obtain the usual representation theory of G. (I will admit I haven't fully gone through these papers, so I'm not sure how correct they are.)

16. **Peter Woit**
March 10, 2024

PS,
I've looked a lot at this kind of thing, but I don't think they're really "path integrals" in any useful sense. They depend crucially on exactly how you've chosen to discretize the "path" (which is an infinite set of points in a space, with no continuity properties). If you can't change variables, is this really an integral in any coordinate-invariant sense?

17. **PS**
March 11, 2024

I see. So your issue is with the phase space path integral in general. I guess from geometric quantization, it's not a surprise that one can only give a simple definition of the phase space path integral for classical observables whose flow preserves the polarization, and perhaps has to resort to a BKS-type construction for more general observables. The fact that the coordinate space path integral is invariant under general coordinate transformations would correspond to the fact that the cotangent lift of such transformations preserve the vertical polarization. But I have to admit, I've never given it much thought (I don't use path integrals much).

I've found one paper that discusses this: "Symplectic structures, BKS kernels and path integrals of BRST bosonic strings" (https://link.springer.com/article/10.1007/BF01550943).

18. **Arnold Neumaier**
March 12, 2024

Peter,

"It's been a long time since I looked at Klauder's attempts to define coherent state path integrals"

20 Years of Not Even Wrong

March 18, 2024
Categories: Uncategorized

The first entry on this blog was 20 years ago yesterday, first substantive one was 20 years ago tomorrow (first one that drew attacks on me as an incompetent was two days later). Back when I started this up, blogging was all the rage, and lots of other blogs about fundamental physics were starting around the same time. Almost all of these have gone dormant, with Sabine Hossenfelder's Backreaction one notable exception. She and some others (like Sean Carroll) have largely moved to video, which seems to be the thing to do to communicate with as many people as possible. There are people who do "micro-blogging" on Twitter, with the descendant of Lubos Motl's blog StringKing42069 on Twitter. I remain mystified why anyone thinks it's a good idea to discuss complex issues of theoretical physics in the Twitter format, flooded with all sorts of random stupidity.

Looking back on what I was writing 20 years ago it seems to me to have held up well, and there is very little that I would change. The LHC experiments have told us that the Standard Model Higgs is there, and that supersymmetry is not, but these were always seen as the most likely results.

My point of view on things has changed since then, especially in recent years. When I started the blog I was 20 years past my Ph.D., in the middle of some sort of an odd career. Today I'm 66, 40 years past the Ph.D., much closer to the end of a career and a life than to a beginning. In 2004 I was looking at nearly twenty years of domination of fundamental theory by a speculative idea that to me had never looked promising and by then was clearly a failure. 20 years later this story has become highly disturbing. The refusal to admit failure and move on has to a large degree killed off the field as a serious science.

The technical difficulties involved in reaching higher energy scales at this point makes it all too likely that I'm not going to see any significant new data about what the world looks like above the TeV scale during my lifetime. Without experiment to keep it honest, fundamental theory has seriously gone off the rails in a way which looks to me irreparable. With the Standard Model so extremely successful and no hints from experiment about how to improve it, it's now been about 50 years that this has been a subject in which it is very difficult to make progress. I've always been an admitted elitist: in the face of a really hard problem, only a very talented person trained as well as possible and surrounded by the right intellectual environment is likely to be able to get somewhere.

My background has been at the elite institutions that are supposed to be providing this kind of training and working environment. Harvard and Princeton gave me this sort of training in 1975-1984 and I think did a good job of it at the time, but from what I can tell things are now quite different. 40 years of training generations of students in a failed research program has taken its toll on the subject. I remember well what it was like to be an ambitious student at these places, determined to get as quickly as possible to the frontiers of knowledge, which in those times meant learning gauge field theory. These days it unfortunately means putting a lot of effort into reading Polchinski, and becoming expert in the technology of failed ideas.

One recent incident that destroyed my remaining hopes for the institutions I had always still had some faith in was the program discussed here, which made me physically ill. It made it completely clear that the leaders of this subject will never admit what has happened, no matter how bad it gets. Also having a lot of impact on me was the Wormhole Publicity Stunt, which showed that the problem is not just refusing to face up to the past, but willingness to sign onto an awful view of the future, as long as it brings in funding and can be sold as vindication of the past. Watching the director of the IAS explain that this was comparable to the 1919 experimental evidence for GR surely made more than a few of those in attendance at least queasy. This particular stunt may have jumped the shark, but what's likely coming next looks no better (replace quantum computing with AI).

The strange thing is that while the wider world and the subject I care most about have been descending into an ever more depressing environment of tribalistic behavior and intellectual collapse, on a personal level things are going very well. In particular I'm ever more optimistic about some new ideas and enjoying trying to make progress with them, seeing several promising directions. Whatever years I have available to think about these things are looking like they should be intellectually rewarding ones. Locally, I'm looking forward to what the next twenty years will bring (if I make it through them…), while on a larger scale I'm dreading seeing what will happen.

Update: For a place with extensive comments about this blog posting, see Hacker News.

Comments

   March 18, 2024

   Hi Peter,

   Enormous Congratulations on the 20th Anniversary!
   I've enjoyed the ride tremendously and looking for what's new in NEW is always a highlight of the day.
   Maybe I should stop harassing you to write about Lean… 🙂

   Best wishes for 20 more, or as long as you want!

2. **John Horgan**
   March 18, 2024

   Peter, I'm glad you've hung in there, you're invaluable for calling out hype and bullshit, as with the wormhole-in-a-quantum-computer story. And I'm glad you've found meaning in your own work, even if the world seems to be falling apart. Good luck with it.

3. **John SIrois**
   March 18, 2024

   Thank you Peter. I've been reading for all 20 years and I appreciate that you've kept the format, content and tone consistent over all this time. I learn alot here.

4. **Douglas Natelson**
   March 18, 2024

   Congratulations on 20 years! It's been enjoyable to read your writing over the years, and it's been an inspiration to continue my own blog, even though we're in some post-blogging era now. (Writing on medium or substack may represent some resurgence of long-form blogging, but both platforms have issues.)

5. **Ryan Snyder**
   March 18, 2024

   Thank you for your work, Peter. I only learned about you a couple years ago after wondering what the physics world was up to after having left it behind when I earned my Ph.D. I'm glad there are people like you out there. You've taught me a lot. Please keep writing.

6. **S**
March 19, 2024

Happy twentieth anniversary, Peter! You've created one of the most important blogs in physics, and even in mathematics (surprisingly enough). Your staying resolutely on-point through vast waves of criticism has surely contributed to the important things this blog has achieved — which it certainly has. Thank you for your work, and may it prosper through many more years!

7. **B. Malpani**
March 19, 2024

Congrats on the milestone! Although it is indeed regrettable that such a blog is still necessary.

"[Sabine Hossenfelder] and some others (like Sean Carroll) have largely moved to video, which seems to be the thing to do to communicate with as many people as possible."

Well, that's an example of the world getting worse, imo: a long time ago, the web used to be full of things to read. It's become a place of things to watch but for many things videos can never replace the written word.

8. **Aswin Mannepalli**
March 19, 2024

Dear Peter,

I don't meant to be melodramatic but your blog was one of the constants in my life. Ever since I did a physics summer program for high school students at Princeton, we little "rebels" would read your blog. When Nova was hawking d-branes, you kept us grounded. When people were fighting pointless wars over black holes, we turned to you for truth.

Thank you so much.

One last request – can you write a book about your human journey? Perhaps less technical than your last, but I would find it a beautiful testament to the life you lived – and the hope you give to others.

9. **Evgenii Rudnyi**
March 19, 2024

Thank you for your blog and your book. I have read it after Green's The Elegant Universe. It was very good for me at that time to read your book.

Good luck!

10. **Tom WEIDIG**
March 19, 2024

Congratulations from Luxembourg!

But StringKing is not Lubos, or is he?

I actually miss Lubos' blog… it was never dull and always interesting in some way.

11. **Anonymous**
March 19, 2024

Hello and congratulations on these 20 years!

I am not a physicist, I can assure you that the conversations around string theory outside the circle of fundamental physics have changed greatly in the last 20 years.

Nowadays in the world of science, everyone knows, more or less, that string theory has never given anything concrete (and is not at all close to doing so) and, although it is intellectually an interesting construction, it is not a physical theory and I hardly know any scientist who takes it seriously. This is even more visible with the younger generations.

12. **Sabine**
March 19, 2024

Happy anniversary! Your blog is one of the few I am still reading. Also Scott Aaronson is still around.

Google hasn't updated the blogger interface for a decade or so. They'll either have to entirely revamp it or phase it out at some point in the not-so-far future. This is why I have moved my written content to substack, in case anyone is interested https://sciencewtg.substack.com/

(Though I have someone else making the Substack posts on my behalf, the content comes from me.)

13. **Handle**
March 19, 2024

Congratulations and thanks! I've learned a tremendous amount from you over the years, and I'm grateful for it. Keep it up!

14. **Jian**
March 19, 2024

Congratulations on 20 years! I have learned a lot from your blogs.

March 19, 2024

Nice reminder of how old I am, Dr. Woit.

It's shocking to realize how long I've been reading this blog. Almost as remarkable is how consistently well written and interesting it has been throughout its 20 years of existence.

Thank you, keep up the excellent work, and congratulations!

LMMI

16. **Jens**
March 19, 2024

Congratulations and thank you for all these years of thoughtful commentary!!! Your blog has been one of the best sources on the state of high energy physics, and I've enjoyed it very much. Your willingness to engage constructively with your critics is impressive and a great example of how intellectual discourse should be conducted.

17. **Scott Locklin**
March 19, 2024

Congrats on your anniversary, and thanks for saving all those kids from the noodle theory meat grinder. It was a child who pointed out the Emperor's clothes; that sort of childlike stating of the obvious (the true spirit of science) is a rare quality among adults these days. Being the first man to stand up and duke it out with all those "wicked smaht' yoyos shows great character.

18. **Chris Oakley**
March 19, 2024

Often controversial, but always well written and always worth reading. Congratulations on 20(+) years of service to the scientific community!

19. **QM**
March 19, 2024

Thank you for all of your efforts to hold a mirror up to science. It's only good if it passes close scrutiny.

20. **Matt Grayson**
March 19, 2024

Congratulations! It's been wonderful to see you stick to your rational perspective while so many imposing minds seem to have lost theirs. It's even better to see your research program showing promise and yielding interesting results.

May you have another successful twenty years!

21. **J**
March 19, 2024

Thank you for keeping this blog going for 20 years. I have always enjoyed reading it. The coverage of both theoretical physics and mathematics is great.

22. **AcademicLurker**
March 19, 2024

I discovered your blog some time in 2005 and have been a regular reader ever since. Congratulations on 20 years!

23. **Mark Hillery**
March 19, 2024

Hi Peter,

Congratulations on your 20th anniversary. I don't remember when I started reading your blog, but I found it an interesting window, with a strong point of view, into what was going on in high energy theory. This is a field I had some contact with in graduate school, but lost touch with after that. After reading the blog for a few years I actually ran into you at a New Year's Eve party in Brooklyn. Thanks for the public interest talk you gave at Hunter College, which led my English department colleague, Rebecca Connor, to describe the LHC as "the great white whale of physics," an amusing description that would never have occurred to me. A caution about elitism, though; not all things that are interesting come out of Harvard and Princeton.

24. **Steve Huntsman**
March 19, 2024

You convinced me to leave my two volumes of Green, Schwarz, and Witten (in my defense, acquired in 1996) on the shelf at my last job when I left in 2020. It was a pleasure to meet you about a decade before that and to read this blog since at least 2005. Thanks!

25. **theoreticalminimum**
March 19, 2024

Thank you so much for all that you've offered through your blog. You have done a tremendous service to the community of people out there paying attention (in ways technical and not so) to what you've shared, and I for one am very grateful. Thank you again.

26. **Nilay Kumar**
March 19, 2024

Hey Peter, huge congrats on the 20th! I've always appreciated your principled stance. Here's to many more!

Incidentally, I was going through some files on my old hard drive this weekend and ended up reading notes about linking numbers via Chern-Simons theory that I wrote for your course. Great stuff — hope that course is still going strong!

27. **Steve Esser**
March 19, 2024

Congrats on a great blog from a 20 year reader.

28. **Peter Woit**

March 19, 2024

Mark Hillery,

Thanks!

No intention to imply that Harvard/Princeton (or a small list of similar institutions) are the only place that interesting ideas come from. Such institutions though do have outside influence since many people look to them for leadership, they attract outsize amounts of funding and numbers of talented ambitious young people. At the moment they have outsize responsibility for the sad state of the field.

Thinking of cases where new ideas came from outside such institutions, one local example that came to mind is Lenny Susskind's co-discovery of string theory. His undergrad degree was City College and he did the string theory work while at Yeshiva.
But, maybe that's not the most convincing example…

29. **FA**
March 19, 2024

Congratulations! I have been following your blog since my undergrad days (also almost 20 years ago now).

30. **Ali**
March 19, 2024

Hi Peter,
Congrats on twenty years of chasing your own great white whale! I've been avidly following since the beginning and fondly remember our few conversations when I was an undergrad at Columbia in the 90's. I should have picked your ear more back then in retrospect. I distinctly remember you being much more positive about careers in math than physics. That was of course the right advice…too bad I didn't take it. To me it was clear that something was amiss with string theory back then and was not something I thought worth pursuing (especially as a grad student at Princeton at the tail end of the 90's). Still shocking how so few have spoken out about the abysmal situation over the years. What a shame for the great legacy of theoretical physics, now so badly tarnished. Wishing you another twenty years of blogging and even deeper inquiry.

31. **Wyrd Smythe**
March 19, 2024

Congratulations on 20 years of worthwhile posts! I've been following you for, I think, about 15 of them, and have enjoyed them immensely (bought and very much enjoyed your book, too). I'm an interested amateur fascinated by fundamental physics, and much of it has been over my head, but the learning experience has been wonderful (small steps over time will still get one someplace). Here's to 20 more!

I've noticed a general indulgence in fantasy (science fiction, at best, outright fiction at worst) in our society for many years now. Tragically, it seems even to have infected science: string theory, SUSY, and any multi-dimensional theory are just some examples. Physics seems lost in fantastical musings and wonderings. I'm so weary of "science" articles that center around "maybe", "might", and "could". That's not science to me, that's speculation.

And I regret the decline-to-near-vanishing of long-form blogging. Videos have their place, but the written word, I believe, is vastly superior. Much easier to take the time to chew on a single paragraph or to go back and check a part. And many video editors seem compelled to include lots of barely (or not even) relevant stock footage to illustrate and make the video "more interesting" (read: more distracting and annoying).

But I rant when I should instead just raise a glass to your accomplishments! Congrats again!

(BTW: It was fascinating to go back and read your first posts. The comments were *especially* fascinating!)

32. **Barak Shoshany**
March 19, 2024

Congratulations on the 20th anniversary, Peter! I've been reading your blog for many years, since around 2012, when I was an undergrad. I think it wouldn't be an exaggeration to say that you played a significant role (along with Lee Smolin, Sabine Hossenfelder, and others who put an effort into demystifying string theory) in shaping the direction of my physics career, as well as the way I explain physics to the general public.

33. **Eric Weinstein**
March 19, 2024

Congratulations on the Blog Anniversary Peter.

One thing you did not mention in your post is three developments that are due to you.

First and foremost, the appearance of your book "Quantum Theory, Groups and Representations" was an incredible event. That book joins books like "Geometric Quantization" and "Einstein Manfifolds" and "Spin Geometry" as one of the great works of modern scientific exposition of a topic that had previously been scattered in the literature and all but impossible for most to extract. That book also should have silenced any 'colleagues' who, in desperation, made attacks about your level of knowledge or understanding (no need to name names).

The next two things are the appearance of two of your own ideas about the origin of our fundamental theories. In one you appear to start with SU(4) as a primative input, quotient out by SU(3) x U(1) to get a world with electro-strong field content and then make arguments about Wick rotating between Euclidean and Lorentzian 4-submanifolds hoping to pick up an extra Weak Isospin SU(2) from the Spin(4) structure. While I don't personally think that is right, it does immediately provide a concrete world in which to build natural models and explore their consequences.

The next idea about Space-Time being chiral (which I admit I did not realize was a separate program until we talked) was to think about the oddity of how the Weak force is not only chiral but 'maximally chiral' in that it is not only a question of a complex representation not being equivalent to its conjugate representation, but SU(2) weak isospin being either 'on' or 'off' depending on the spinor being either Left or Right and the fields in question being either 'Matter' or 'Anti-Matter'. And here again you were exploring this spinorial idea based on the sui generis nature of our home dimension n=4 being the only one in which Spin(n) is semi-simple. I believe in a version of this, but that is not relevant here. The point is that you are trying to turn the weak assymmetry into a naturally geometric third 'on-off switch' after Handedness and Matter/Anti-Matter.

I bring these up in their own right, but since this is 'Not Even Wrong' I want to close with how these positive attempts to do new physics interact with the implosion of particle theory.

When you and Smolin wrote your books, I noticed that you were attacked for two different and incompatible reasons. Smolin was misportrayed as writing a self-promotional book to take a cheap shot at the successful community in an attempt to boost his pet theory. You on the other hand were attacked for the opposite reason! “Woit doesn’t have any alternate proposals, so why should he be complaining that there is something wrong?” was the grumbling I heard.

We now know the answer. It doesn’t matter whether you have a theory or do not have a theory of your own. String Theory/M-Theory is, to its faithful DEFINITIONALLY the ‘Only Game In Town’. This is part of a monotheistic religion which insists that there are no other ideas and no critical colleagues. There are ‘only words’ and ‘charlatans, populists and grifters’.

While I don’t agree with your models (yet at least), they are clever and not stupid, and I’m pleased to see you evolve into a colleauge who has proven himself now as a master expositor, and a theorist with your own research program, providing 1-2 other ‘games in town’.

Let me just close by saying that for years, the first place I check when I come back from a trip abroad is this clunky old ‘blog’. Just in case, physics came back to life. Thanks for doing this.

Eric

34. **MKT**
March 19, 2024

Love this comment by Oglop in the Hacker News discussion Peter linked to:

“This blog changed my life. I was on a path of going into research in physics, and I remember somehow finding this blog as an undergrad. It was like I was a soviet reading western news. After another year of courses where I began to notice exactly what the author mentioned, string theorists controlling purse strings and research directions, I gave up and left.”

It was like I was a soviet reading western news…wow.

35. **David Muldowney**
March 19, 2024

Congratulations Peter, a fantastic achievement.
Have been following your blog for 5 years or so with great interest.
Alway love to see a new entry – bizarrely it was one of the things that kept me going during those awful Covid lockdowns!
Had an instinctive allergy to String theory in my postgrad days back in the mid-90s.
To find someone (along with Smolin) who gave such eloquent voice to these doubts has been a great discovery

36. **Scott Aaronson**
March 19, 2024

Happy anniversary, Peter!!

FWIW, your blog was one of the central inspirations for me to start mine, and in particular, to use it to criticize wild quantum computing claims. Thank you.

Whether I share your perspective, have quibbles, or simply don’t know enough to say, I always find you refreshingly honest and well worth reading. Here’s to many more years, and hopefully new discoveries in physics that surprise everyone and render many old debates irrelevant.

37. **Severin Pappadeux**
March 19, 2024

Thank you!

38. **flippiefanus**
March 19, 2024

Congratulations Peter. Thank you for maintaining a blog in this crazy field where sanity prevails. I’ve never been a fan of string theory and it is great to read the perspectives of a somebody closer to the fire than I am.

I remind myself that Newton’s theory of light prevailed for a hundred years before it was replaced by a better description. String theory has not been around for a hundred years yet. I do believe it will eventually be replaced. However, Newton’s theory was replaced by something better. So the way to attack string theory is by doing what you are doing: develop a better theory.

39. **Lei**
March 20, 2024

Congratulation ! and Thanks a lot.

I read your article, subscribed your blog when I was an undergraduate. Now, I become a faculty in university.
Really hope your texts never disappear in its way as it was.

40. **Bruce Bartlett**
March 20, 2024

Congratulations Peter on twenty years of this blog! The blog has been wonderful, and Not Even Wrong (the book) was also a wonderful intellectual contribution. Besides the main feature of your book (holding a critical mirror), the math chapters on topological field theories were extremely well written and I learnt a lot from them.

41. **Mike**
March 20, 2024

I’ve been reading your blog for about 14 years. I really appreciate you sticking your neck out time and again. As someone outside of academia who does not personally know any physicists or mathematicians, this blog is one of the few places that I can learn about current developments (or the lack thereof). Heres to another 20+years of blogging! And lets hope the next 20 years will bring a totally unexpected left field (pun?) discovery that will revitalise fuadamental physics.

42. **Robin Whitty**
March 20, 2024

What are people's highlights from this outstanding 20-year endeavour? One of mine: https://www.math.columbia.edu/~woit/wordpress/?p=11709
Not even string theory: April 2020, Not Even Wrong hosts the heavyweights of arithmeatic geometry sparring over the ABC conjecture proof controversy.

43. **Peter Woit**
March 20, 2024

Robin Whitty,

Yes, on the mathematics side, that was a high point. Thanks go to Peter Scholze for being willing to engage publicly in a detailed technical debate using the comment section here. That was taking place at the height of the Covid lockdown, so it was a bit challenging to moderate that discussion without my usual advantage of having experts down the hall to consult with.

On the physics side, I'd like to point out that the first announcement of the Higgs discovery was not July 4, 2012, but on this blog June 17, 2012, see https://www.math.columbia.edu/~woit/wordpress/?p=4772
In that case, there are also several experts to thank, but they will remain anonymous.

Both cases show that a main reason for some of the best content that appears here is not my writing, but that a large number of expert physicists and mathematicians appreciate what I've been doing over the years and are willing to contribute their own knowledge and expertise to provide material of high-quality.

44. **Christoph**
March 20, 2024

Peter,

thank you for your example. You live in the way that every human should live: honestly and true to yourself.

All the best for your future.
Christoph

45. **Cédric Bardot**
March 20, 2024

Bravo Peter pour votre endurance à maintenir avec rigueur et constance cette chronique personnelle sur la recherche mathématique contemporaine et en particulier sur la physique des interactions fondamentales !
Merci également pour la convivialité et la qualité des échanges de vue dans votre espace des commentaires, fruit des efforts consacrés à le modérer.
Longue vie encore à ce blog et du bonheur pour son auteur.

> Il serait seulement à souhaiter que les géomètres n'eussent pas quelquefois abusé de la facilité qu'ils avaient d'appliquer le calcul à certaines hypothèses. C'est souvent le désir de pouvoir faire usage du calcul, qui les détermine dans le choix des principes ; au lieu qu'ils devraient examiner d'abord les principes en eux-mêmes, sans songer d'avance à les plier de force au calcul. La géométrie, qui ne doit qu'obéir à la physique quand elle se réunit avec elle, lui commande quelquefois. S'il arrive que la question qu'on veut examiner soit trop composée, pour que tous les éléments puissent entrer dans la comparaison analytique qu'on en veut faire, on sépare les plus incommodes, on leur en substitue d'autres, moins gênants, mais aussi moins réels, et l'on est surpris de n'arriver après un travail pénible qu'à un résultat contredit par la nature ; comme si après l'avoir déguisée, tronquée ou altérée, une combinaison purement mécanique pouvait nous la rendre.

Jean Le Rond d'Alembert

46. **Earl DuCaine**
March 20, 2024

Congratulations on 20 years! In its way your post was as important as Hilbert's problems, which outlined a set of mathematical problems he felt were of fundamental importance. Although a few turned out to not be real problems, and a few had solutions that turned out not to be very interesting, the best of them lead to revolutionary changes (arguably the last revolutionary charges so far) in the fundamentals of mathematics and its philosophy.

To stake out the unequivocal claim that string theory will lead to no necessary changes to the standard model and will continue to be nothing but a pernicious intellectual influence on its practitioners a bold, breathtaking pronouncement at the time. It was seminal and points to the grave situation we're in today — that it's surprisingly easy for academic institutions to be captured by an ideology which is 'not even wrong' and it's extraordinarily difficult for them to recover from not-even-wrongness.

47. **Paolo Bertozzini**
March 20, 2024

Dear Peter, my congratulations for the 20 years of "Not Even Wrong" 🙂 This blog, that I have been following from its inception, has been a constant source of critical thoughts on the current developments (and degeneration) in theoretical high energy physics, with inspiring posts on mathematical physics and much more. I would also like to stress not only the "critical" side of the content of the blog, but also the "conceptual" importance of the recent proposals for alternative roads (twistor unification, Euclidean QFT, spinorial geometry) that I find deeply interesting (also in view of some of my current lines of work). I am looking forward to even more exciting developments! Congratulations again 🙂 Paolo

48. **Stephane**
March 21, 2024

Congratulations Peter for the 20 years of your Blog.
What I like best is your effort to be pedagogical and informative.
I learned a lot from your blog.

PS: Michel Talagrand awarded the 2024 Abel Prize – https://abelprize.no/article/2024/michel-talagrand-awarded-2024-abel-prize

https://www.math.columbia.edu/~woit/wordpress/?p=12819

49. **Paul Titze**
March 21, 2024

Hi Peter,

Congratulations in keeping up NEW for so long, I always look forward to reading your posts, keep up the good work.

Cheers, Paul Titze.

50. **Shantanu**
March 21, 2024

Peter, congrats on 20 years of blog.
Once again, you have forgot to mention about neutrino mass which is evidence for Physics beyond standard model.

51. **Joseph Conlon**
March 21, 2024

Congratulations Peter on the anniversary. I have always thought you wrong on substance, but wrong for the best of reasons, i.e. caring about the subject.

52. **Michael Gogins**
March 21, 2024

Thank you for this blog which I have been reading for almost the whole 20 years.

I am not a scientist and I do not have a mathematical education, but I am deeply interested in the physics and associated philosophical implications. Also, the sociological side is also very interesting, perhaps more so, and I think I understand it better.

I'm not qualified to evaluate your own theoretical ideas, but I greatly respect you for insisting on contributing to the discussion, in an even-tempered way, in spite of often being labelled an "outsider" or "not an expert." That says more about your critics than it does about you.

I wish there were more blogs of this kind.

To me, the huge issue here is, who is going to preserve us from highly placed liars?

53. **Art**
March 21, 2024

Let me add my congratulations to the pile. While I treasure your blog and course notes publications, I can't help wondering if they're the best use of your time, now that you have a significant new idea to develop. What balance do you think is optimum?

54. **Alessandro Strumia**
March 22, 2024

Congratulations. Yours is the best physics blog, after that Lubos closed his own. Because you said some truth that nobody wanted to hear about strings, and Lubos did the same about wider academia problems.

55. **Cormac McGuinness**
March 22, 2024

Congratulations Peter on 20 years!

Still very much an avid and constant reader of NEW, having first read your American Scientist article in 2002 (https://doi.org/10.1511/2002.10.110). It has been a thorough and continuing education into the status within the world of HEP of experiment and theory and the ways in which the development of the latter has, in part stalled, due to the concentration on specific speculative theories. This has been of extreme interest to someone far from this field of physics. However shocked or disheartened by the program discussed and linked to above, I think you have reached and continued to inform a generation of physicists about asking the right questions about the approaches that are being followed.

On a lighter, or a darker note if you will!, there is always the total eclipse to look forwards to. I presume you will be visiting some point on the path of totality !? Will it be a shorter road trip for you than 2017 ? (certainly shorter than 2006).

I am sure we will all look forward to hearing about it and any other elements of physics or mathematics that you choose to highlight!

Best wishes for the future and regards from Ireland
Cormac (Mc)

56. **Peter Woit**
March 22, 2024

Art,
Writing posts for the blog doesn't actually take a lot of time. Where I have historically wasted a lot of time is by trying to follow exactly what is going on in string theory and things that have emerged from it. It's clear to me now that any minute spent trying to understand things like what "swampland program" research is, is a minute completely wasted, so I plan to do less of that.

57. **Peter Woit**
March 22, 2024

Cormac McGuinness,

Thanks! Definitely planning to try and see the eclipse soon, bringing along my 93 year old mother. Exact location to be determined only a day or two before the eclipse, based on what the cloud cover projections look like.

58. **Uair01**
March 22, 2024

Thank you very much! I'm just an engineer, but I've followed your blog since your book came out. I can't assess the mathematics, but I think you're right, based on the sociology. I'm afraid that this is the case here: "The market can remain irrational longer than you can remain solvent." But then translated to physics …

59. **John Baez**

March 22, 2024

Sorry to be late to the party. Congratulations on 20 years of your blog, Peter! I'm glad you've been persistently exposing the shortcomings of string theory – a much needed corrective to the hype. I think it really has had an effect. The triumphalism never ends, alas, but it's taken less and less seriously by outsiders.

The really sad part is how little progress we've made on fundamental physics since the 1980s. For anyone out there who wants to see evidence, check out my timeline here , along with the definition of "fundamental physics" that I'm using. Once I realized that this stagnation wasn't going to end anytime soon, I quit fundamental physics (or more precisely, relegated it to the status of a hobby). It really hurt: the dream dies hard, especially after one has spent decades on it. But it hurts more to keep banging ones head on the same old wall! I am not optimistic about any of the new theories of fundamental physics that I see. Thus I'm really glad your blog has expanded to cover more lively and promising endeavors, like the Langlands program.

60. **PeterP**
March 22, 2024

Congratulations, Peter, for this lifetime achievement and keep standing tall under the tremendous pressure from we all know who. Ironically, your name and blog are now forever attached to the string theory. However, we all believe you are on the right side of history here.

On a side note (or not so), I think folks still do not fully understand or grasp your idea and where it could lead that space-time and matter have opposite chiralities. If I may, you might keep elaborating and adding detailed calculations that would follow from it.

61. **Peter Woit**
March 22, 2024

PeterP,
Thanks! I'm working on exactly this now, hope to have something detailed written down by the end of the summer. In the meantime, my latest posting at least points exactly to where I think the missed possibility is in the standard discussion of the Standard Model.

62. **Santo D'Agostino**
March 22, 2024

Congratulations on twenty years of very valuable and appreciated service to the mathematics and physics communities! I have been reading your blog since the early days, and have learned a lot from it.

Continued best wishes!

63. **Andrew Thomas**
March 24, 2024

Congratulations on 20 years of blogging!

I remember fundamental physics seemed so exciting 20 years ago, with all the great blogs and – yes – even the string wars arguments. I don't understand quite why you're still so angry about string theory now as it seems to have faded away. The Strings conference seems to be on its last legs. In fact, everything seems so quiet now – I don't understand it. Where are all the new physics books? We used to get something big every few weeks, now nothing. It was more fun in the old days!

I hope Lubos is OK. I know he was your sworn enemy (well, most people's sworn enemy) but it seems rather sad that he's not around anymore.

64. **Peter Woit**
March 24, 2024

Andrew Thomas,
Unfortunately I don't think fundamental physics was truthfully exciting 20 years ago. It was already in a very bad way, with a huge amount of outrageous hype to the public about "exciting" ideas like the multiverse. Now the hype level has died down and the public is more aware of the problems with string theory, but the situation of actual fundamental theory research is significantly worse than 20 years ago.

What am I angry about? I'm looking back at a 40+ year career that started when the field was very healthy, and watched it be essentially destroyed and killed off. That the people who did this are holding public events assigning themselves grades of "A+++" is just disgraceful, and specifically aimed at making impossible any acknowledgement of what happened and any drawing of lessons for the future.

I also hope Lubos is OK, but I'm pretty sure stopping doing the kind of blogging he was doing was good for him.

65. **Anonymous**
March 24, 2024

"I also hope Lubos is OK,"

I was also concerned about whether Lubos is OK, and checked a little while ago to see if he was doing anything visible on the Internet. He seems to have a quora account that currently seems to be active:

https://www.quora.com/profile/Lubo%C5%A1-Motl

66. **Jim**
March 24, 2024

I was reading Not Even Wrong the book when I was a graduate physics (HEP-TH) student; the university librarian had gotten it surprisingly. 6 years later I left the field with 2 MSc (in my country and the US). I left the field halfway through my PhD after realising what the job prospects were about, what was demanded from me (commitment & huge risk Vs the monetary component) and started doing quantitative analysis and later machine learning.

It's been 9 years now that I do data science, a very rewarding career which also allowed me in my free time to research and publish (in A&A) an article regarding a method that uses ML on GAIA data.

I miss the days when I was innocent (in a sense) and naive (in a good way I'd like to believe) and wanted to pursue String Theory after QFT (my undergraduate thesis was an intro to QFT, later I did 4 grad courses on the subject). I was looking at the standard treatments of ST, charming as they were, but there was still an itch. Coming from you, Lee Smolin and Roger Penrose. I want to thank you since I was affected so much by your writings.

Plot twist now:
That being said, in an ideal world if financials were not an issue back then, I would still pursue these ideas, including LQG and twistors. As much time as needed. Just being at the forefront of knowledge without worrying about job prospects would have been the holy grail for me personally. I wouldn't mind if there was only remote connection to physical reality by some of TOE candidates, that's the idea frankly; understanding the concepts is rewarding on its own.

67. **DrDave**
March 25, 2024

Many have followed your blog, and you have made a difference. I am hopeful for the future as geniuses pop up every now and then.

68. **Paddy**
March 25, 2024

Congrats. But boy don't we grow old too fast. At least some consolation knowing that our justifiable anger at certain things were there even when we were young.

69. **Marty**
March 26, 2024

Hi Peter,

I am one of your longer-term regular readers of your blog. I continue to enjoy your articles whenever they appear, although they seem to appear at a somewhat reduced average rate compared to the early years.

I found out about your blog in March 2004, about one week after you started it, thanks to this posting in Physics Forums by the user "selfAdjoint". I had read prior posts of yours in Physics Forums, and because (unlike most string theory skeptics at the time) your posts seemed to be written by someone who had made real effort to understand string theory in the technical sense, I promptly headed over to your new blog!

Without a doubt, your blog played a key role in cementing my prior skepticism about string theory. I had applied to several doctoral programs for entry the coming Fall, and (like so many who are interested in theoretical physics) wanted to pursue high energy theory. Your writings were very helpful in making clear, ahead of time, how important it was for future academic job prospects to work in a trendy area. Your writings also made it clear that the general approach of string theory was at least partly orthogonal to the approach I wanted to pursue (an approach that was unpopular then, and is still unpopular now), which was to work on models for *constructing* quantum fields in an emergent sense from a single underlying, fundamental non-quantum (but also non-classical) field. So when it came time to look for a PhD advisor, it was neither a surprise nor disappointment that there was zero interest by any of the theorists in supervising non-mainstream work that I wanted to do. Staying with particle theory would have required working on either particle phenomenology (which at UCSC meant supersymmetry) or string theory. I ended up focusing on cosmology.

Interestingly but unfortunately, the only other physics grad student I knew at UCSC who also read your blog decided to go ahead with string theory anyway (I urged him to reconsider, but he believed going with the trend was best…). He worked with a well known string theorist, but unfortunately it didn't go as hoped — the approach he pursued at the urging of his advisor didn't work out, and he ended up not getting a postdoc. I think his advisor felt bad about how things worked out for him.

Anyway, this is just one bit of anecdotal evidence that you have provided a real service to others through this blog. Hopefully you continue to find blogging a worthwhile use of your time. I miss the time when you posted more frequently — sometimes posts now are weeks or even more than a month apart — but understandably it takes your time and energy, especially when you don't find much of personal interest to discuss.

I think your moderation style has worked well on the whole, for instance keeping pointless discussions from becoming even more pointless (especially during the string wars). There have been times I wished you would let a discussion run longer, but at least you made clear when you didn't feel you had the expertise or interest to moderate a wandering discussion.

70. **Z Y**
April 1, 2024

Congratulations on the 20 years. I'm curious if you still consider
"Why does the vacuum state break electroweak gauge symmetry?"
As the The Holy Grail of Physics nowadays

71. **Peter Woit**
April 2, 2024

ZY,
Yes, that's still the "Holy Grail". Since I wrote the posting 20 years ago, there has been the major development of the discovery of the Higgs. At that time it was possible that the LHC would tell us about something else than the Higgs, but that did not happen. So, we have nothing new from experiment to guide us on this question.

72. **JE**
April 3, 2024

Hi Peter,

Congratulations for your bravery, resolution and patience during these 20 years!

In the early days of this blog ("The Thin Line of Theory" thread, back in Jan. 2005) –at the height of the Quantoken-Lubos/ST-LQG wars– I commented that string theory might turn out to be nothing more and nothing less than a highly sophisticated human invention enabling many theoretical physicists to keep busy while another physicist came out with a sound theory of quantum gravity in which they could work.

I added that it was a well-devised survival tool that would end up being a marginal subject at math departments only when a simpler theory could unify GR and QFT, and that the LHC would make no difference (because it is NEW) even though no superpartners would be found across its energy range.

The latter happened to be true. The former has not yet happened.

Back then, much like Marty and other commenters, I was discouraged from pursing my own ideas by potential PhD advisors instead of going mainstream with them. As I was more interested in pursuing these ideas than in engaging with them in string theory or noncommutative QFT to get a PhD (partly thanks to this blog), I left academia and kept working on my stuff in my spare time.

As to what has not yet happened, experimental confirmation of any future new insights in particle physics will probably involve matching precision measurements in HEP and cosmological observations, because they will likely have cosmological effects that should fit with these observations. No need to reach higher energy scales in particle colliders, imho.

73. **Giovanni Ronchi**
April 9, 2024

Dear Prof. Woit,

I am a math high school teacher in Milan who got his Master's degree three years ago with a thesis on the homotopy theory of differential graded categories, and an avid reader of your blog

My initial interests to study math were motivated by physics. I later discovered the wonders of algebra and wanted to deepen my understanding of category theory, algebraic topology and algebraic geometry

Part of the motivation for the study of those areas has been the use of categories and homotopy theory in the works of Schreiber, Fiorenza et al. (which I couldn't and can't understand, tbh)

From your blog I understood that:
a) Speculative ideas in physics papers can be vary far from verifiable and/or in accord with our current data
b) String theory is not as promising as Greene and Kaku present it
c) The math I focused on is not as important for physics as I thought reading the n-Lab (my mistake, not nLab's)
d) Fundamental theoretical physics is not making fast progress eventhough hype is ever-present in scientific headlines
e) The link between representation theory and fundamental physics is greater than I expected (I have just started reading your book)

For these and many more ideas you shared I thank you and wish you other 20 years of happy blog- and non blog- life

Giovanni

Abel Prize to Michel Talagrand

March 21, 2024
Categories: Uncategorized

I was very pleased to hear yesterday that this year's Abel Prize has been awarded to Michel Talagrand. For more about Talagrand and his mathematics, see the Abel site, Quanta, NYT, Nature and elsewhere. Also, see lots of reactions on Twitter like this one.

Almost exactly ten years ago I got an email from someone whose name I didn't recognize, expressing interest in the notes I had made available online which would turn into the book on quantum mechanics. He was reading the notes and had some comments which he included, saying he thought they were trivial but maybe I would want to take a look. Some of them were of the type "I don't quite understand the argument on page X". Figuring that I'd help out an earnest reader with a weak background by explaining the argument a bit better, I took a look at the argument on page X. After a while I realized that what I had written was nonsense, a very different argument was needed. "I don't quite understand" was his way of politely telling me "you have this completely wrong."

I soon ran into Yannis Karatzas and asked him if he knew anything about this "Michel Talagrand". He told me "of course! He's amazing, almost got a Fields Medal". Over the next year or two I benefited tremendously from Michel continuing to read carefully through my notes and send me detailed comments. He was very much responsible for improving a lot the quality and accuracy of what I was writing. He had begun his own project of trying to understand quantum field theory by writing a book about it. The result is available as What Is a Quantum Field Theory?, which is a wonderful resource for anyone interested in a precise and accurate account of much of the basics of the subject. If you've seen Gerald Folland's excellent Quantum Field Theory: A Tourist Guide for Mathematicians, you can think of Talagrand's book as a much expanded version, giving the full story that Folland only sketched.

During many of my trips to Paris since that time I've gotten together with Michel and his wife Wansoo, and have also seen them here in New York. It has been a great pleasure to get to know Michel in person, he is a wonderful human being as well as a truly great mathematician.

Comments

1. **Peter Shor**
   March 21, 2024

   I've known Michel Talagrand for many years, since I solved a problem (for my graduate thesis) that he solved independently. He is a truly remarkable mathematician, and is a great choice for the prize.

2. **Ray**
   March 25, 2024

   There is also an interesting interview of Talagrand discussing his research on spin glasses here: https://caphes.ens.fr/history-of-replica-symmetry-breaking-in-physics/ The entire collection is actually quite interesting.

3. **Jonathan Baxter**
   March 28, 2024

   "What Is a Quantum Field Theory?" is an excellent book. I wish he had addressed path integrals though. Very curious as to any insights he may have had.

4. **Daniel**
   March 28, 2024

   Cute detail from Le Monde article:

   Il y a aussi le hasard romantique qui lui a fait rencontrer son épouse dans une petite ville de l'Ohio, aux Etats-Unis. Un concours de circonstances: à la suite d'un séjour professionnel au Canada, il rend visite à un collègue dans le pays voisin, dont la porte de bureau s'ouvre sur une étudiante coréenne, qui deviendra sa femme. Et dont le nom, Wansoo Rhee, sera associé à un futur prix de mathématiques (en probabilité, analyse fonctionnelle, informatique théorique ou combinatoire), décerné par une fondation qu'il a créée et qui est dotée des montants des prix qu'il a reçus. Il sera attribué tous les deux ans, à partir de 2032 – «soit lorsque j'aurais 80 ans, ou un an après mon décès si je meurs plus tôt», précise-t-il.

   https://www.lemonde.fr/sciences/article/2024/03/22/michel-talagrand-un-improbable-mathematicien-j-ai-voulu-prendre-des-risques_6223545_1650684.html

5. **Giovanni Ronchi**
   April 1, 2024

   A translation of Daniel's comment via Google Translate:

   "There is also the romantic chance that made him meet his wife in a small town in Ohio, in the United States. A combination of circumstances: following a professional stay in Canada, he visits a colleague in the neighboring country, whose office door opens to reveal a Korean student, who will become his wife. And whose name, Wansoo Rhee, will be associated with a future mathematics prize (in probability, functional analysis, theoretical or combinatorial computer science), awarded by a foundation that he created and which is endowed with the amounts of the prizes that he received. It will be awarded every two years, starting in 2032 – "either when I am 80 years old, or one year after my death if I die earlier," he specifies."

6. **Peter Shor**
   April 1, 2024

   @Giovanni Ronchi: Google Translate messed up slightly — it should read *theoretical computer science or combinatorics,* not *theoretical or combinatorial computer science*. Both interpretations of the French are possible, but I don't believe that combinatorial computer science is a recognized field of mathematics, either in English or in French.

7. **Auke Jongbloed**
   April 2, 2024

   @Peter Shor: DeepL is doing much better, it also correctly translates "deviendra sa femme" into "was to become his wife" instead of "will become his wife". Here's the translation of DeepL: "There's also the romantic chance that led him to meet his wife in a small town in Ohio, USA. A combination of circumstances: following a professional stay in Canada, he visited a colleague in the neighboring country, whose office door opened on a Korean student, who was to become his wife. And whose name, Wansoo Rhee, will be associated with a future mathematics prize (in probability, functional analysis, theoretical computer science or combinatorics), awarded by a foundation he has set up and which is endowed with the amounts of the prizes he has received. It will be awarded every two years, starting in 2032 – "when I'm 80, or a year after I die if I die earlier", he explains."

8. **Anonyrat**
   April 27, 2024

   I recently received my copy of ""What Is a Quantum Field Theory?" and after a quick scanning of its pages, I realized that my training as a physicist blinded me to the sloppy physicist's mathematics of Quantum Field Theory, and how much of a problem that it poses to mathematicians.

   Can/will QFT ever be put on a sound mathematical basis? Is it a worthwhile effort in that it will advance mathematics and physics?

9. **Peter Woit**
   April 27, 2024

   Anonyrat,

   The thing is that there are at least two different categories of sloppy use of mathematics by physicists in QFT, with very different significance.

   1. Writing things that are fundamentally correct, but in a way that makes it a struggle for someone to figure out exactly what you are saying and why it is true. The writer may or may not themselves understand exactly what the correct statement is and why it is true. Talagrand does a great job in his book of taking the usual problems of this kind in a QFT book and fixing them.

   2. Writing about a topic as if it is understood when it isn't. There are various places in QFT where understanding what is going on is an open problem. Mathematicians rarely if ever will make the mistake of writing about something like this without being aware of and addressing the problem. Physicists on the other hand, will happily write about something ignoring significant problems, assuming they are "just a technicality". Maybe the problem is just a technicality, maybe not, there are examples where we really don't know (e.g. non-perturbative definition of chiral gauge theory).

David Tong: Lectures on the Standard Model

March 22, 2024
Categories: Euclidean Twistor Unification, Uncategorized

David Tong has produced a series of very high quality lectures on theoretical physics over the years, available at his website here. Recently a new set of lectures has appeared, on the topic of the Standard Model. Skimming through these, they look quite good, with explanations that are significantly more clear than found elsewhere.

Besides recommending these for their clarity, I can't help pointing out that there is one place early on where the discussion is confusing, at exactly the same point as in most textbooks, and exactly at the point that I've been arguing that something interesting is going on. On page 7 of the notes we're told

> We can, however, find two mutually commuting $\mathfrak{su}(2)$ algebras sitting inside $\mathfrak{so}(1, 3)$.

but this is true only if you complexify these real Lie algebras. What's really true is
$$\mathfrak{so}(1, 3)\otimes \mathbf C = (\mathfrak{su}(2)\otimes \mathbf C) + (\mathfrak{su}(2)\otimes \mathbf C)$$
Note that
$$\mathfrak{su}(2)\otimes \mathbf C=\mathfrak{sl}(2,\mathbf C)$$

Tong is aware of this, writing on page 8:

> The Lie algebra $\mathfrak{so}(1, 3)$ does not contain two, mutually commuting copies of the real Lie algebra $\mathfrak{su}(2)$, but only after a suitable complexification. This means that certain complex linear combinations of the Lie algebra $su(2)\times su(2)$ are isomorphic to $so(1, 3)$. To highlight this, the relationship between the two is sometimes written as
> $$\mathfrak{so}(1, 3) \equiv \mathfrak{su}(2) \times \mathfrak{su}(2)^*$$

This is a rather confusing formula. What it is trying to say is that the real Lie algebra $\mathfrak{so}(3,1)$ is the conjugation invariant subspace of its complexification
$$(\mathfrak{su}(2)\otimes \mathbf C) + (\mathfrak{su}(2)\otimes \mathbf C)$$
where the conjugation interchanges the two factors. Tong goes on to use this to identify conjugating an $\mathfrak{so}(3,1)$ representation with interchanging its properties as representations of the two $\mathfrak{su}(2)\otimes \mathbf C=\mathfrak{sl}(2,\mathbf C)$ factors.

For a very detailed explanation of the general story here, involving not just the Lorentz real form of the complexification of $\mathfrak{so}(3,1)$, but also the other (Euclidean and split signature) real forms, see chapter 10 of the notes here. My "spacetime is right-handed" proposal is that instead of identifying the physical Lorentz Lie algebra in the above manner as the "anti-diagonal" sub-algebra of the complexification, one should identify it instead with one of the two $\mathfrak{sl}(2,\mathbf C)$ factors (calling it the "right-handed" one). Conjugation on representations is then just the usual conjugation of representations of the right-handed $\mathfrak{sl}(2,\mathbf C)$ factor.

Comments

1. **S**
   March 22, 2024

   Forgive my asking what I know you've almost surely addressed before on the blog, but am I right in remembering that this is also related to the highly confusing fact that the Spin groups in signature (1,3) and (3,1) are not isomorphic?

2. **Peter Woit**
   March 22, 2024

   S.

   (First, should note that Spin(1,3)=Spin(3,1), the problem is not there, but with the Clifford algebras, or pinors. Pin(1,3) is not equal to Pin(3,1) and one of the Clifford algebras is 4 by 4 real matrices, the other is 2 by 2 quaternionic matrices).

   No obvious relation to that (at least not that I understand).

   But in the picture I'm proposing there's a fundamental right-left asymmetry, unlike the usual Clifford algebra/space-time story. So, the issue you are mentioning, which shows up for pinors, not spinors, may show up somehow.

   Update: Moderating out further discussion of this issue as off-topic.

3. **Marvin**
   March 23, 2024

   Hi Peter,

   Thanks for having brough forward this link. I read some pages here and there, and I agree that it really look as a very clear and good tutorial on the Standard model.

4. **Chris Oakley**
   March 25, 2024

   I learned the Poincaré group from the ancestor of Tong's lecture notes at Cambridge DAMTP in 1980 and they were similarly careless about combining generators of rotations and boosts with complex coefficients, this being an undefined operation in the context of the group theory used up to that point. Interestingly, our scratchy lecture notes on Lie groups were all we had as there did not seem to be any text books worth the mention on the subject at the time. Maybe Peter's book fills this void. When I have time, when I retire, if I am ever able to, I will check it out properly!

5. **Robert A. Wilson**
   March 25, 2024

   I've never found anyone who can explain this careless mixing of complex combinations of rotations and boosts convincingly. It happens all the time, and is usually mathematical nonsense. I assume they must be trying to describe some real physics, but I can't see the connection between the physics and the mathematics. Tong, for example, follows convention in putting a scalar i into the definition of the Lie bracket, which unfortunately makes it impossible to talk about symplectic Lie algebras in any reasonable way, and makes it almost impossible to distinguish different real forms of the same complex Lie algebra. If you think, as I do, that the distinction between so(3,1) and so(4) is of utmost importance for quantum mechanics, then this is a rather serious issue.

6. **Peter Woit**
   March 25, 2024

   Robert A. Wilson,

   I think there is a straightforward mathematical version of what Tong and everyone else is trying to say in their textbooks, but to state it you need to distinguish between a real Lie algebra and its complexification, and distinguish between different real forms. I don't know of any textbook that does this (would be curious to hear if anyone else does know of such a thing). Some say as little as possible to avoid writing down nonsense, others do write down something that makes no sense. Behind this I think are various combinations of the author not understanding what is really going on, and the author understanding what is going, but deciding that keeping track of the necessary distinctions is too much trouble for this kind of textbook.

7. **Robert A. Wilson**
   March 25, 2024

   On page 26 of Tong's notes, he basically says that the physicists' version with Hermitian matrices generating unitary Lie algebras is equivalent to the mathematicians' version with anti-Hermitian matrices, but this isn't true for real (orthogonal) Lie algebras or quaternionic (symplectic) Lie algebras, only for complex (unitary) Lie algebras. In the real case there are more Hermitian than anti-Hermitian matrices, and in the quaternionic case it is the other way round. The quaternionic case does arise even in classical physics, for example in the symplectic gauge group of phase space, and it is quite tricky to handle this example using complex Hermitian matrices, rather than the natural anti-Hermitian (split) quaternionic matrices. This can lead to error, for example to using the 21 independent symmetric 6×6 real matrices instead of the 21 independent anti-Hermitian 3×3 quaternionic matrices, and thereby generating the wrong Lie algebra.

8. **maxstroke**
   March 25, 2024

   Not sure if this is directly on point, but Richard Behiel just a few days ago put out an amazing youtube titled "the mystery of spinors". For a layperson, it is helping me get the most tenuous foothold on some of the notation and concepts that folks here know in their bones. https://www.youtube.com/watch?v=b7OIbMCIfs4&t=1374s

9. **Arnold Neumaier**
   March 26, 2024

   Peter,

   "you need to distinguish between a real Lie algebra and its complexification, and distinguish between different real forms. I don't know of any textbook that does this (would be curious to hear if anyone else does know of such a thing). "

   Try Section 2.7 and Section 11.6 of v2 of the Lecture Notes
   'Classical and Quantum Mechanics via Lie algebras'
   by A. Neumaier and D. Westra,
   https://arxiv.org/abs/0810.1019

10. **Peter Woit**
    March 26, 2024

    Arnold Neumaier,
    What I had more specifically in mind was the case of the Lorentz group and its finite dimensional representations, where I don't know of a physics textbook that distinguishes between the real Lie algebra and its complexification, as well as between the other real forms of that complexification.

11. **Fadde'ev-Popov ghosts**
    March 29, 2024

    Woit, perhaps you do not consider these to be physics textbooks; however, they are quite accessible for hep-th:

    Miller, Symmetry Groups and Their Applications
    Lounesto, Clifford Algebras and Spinors

12. **Peter Woit**
    March 29, 2024

    Fadde'ev-Popov ghosts,
    I don't have a copy of the Miller book, but from what I remember it was a general group theory book aimed at physical applications, unlikely it had the specific facts about spinors and real forms that I'm referrring to.

    The Lounesto book is not the kind of book explaining relativistic quantum mechanics or quantum field theory that I had in mind. It does have a great deal of detail about the Clifford algebra in Minkowski signature, but what I'm referring to is not that, but the complexified and real form stories of the Lorentz and rotation groups in 4d, which I don't see there (although I didn't look closely, it possibly is there in some form).

13. **Arnold Neumaier**
    March 29, 2024

    There may be something in one of the following books, but I don't own them and cannot check:

    A. Barut and R. Raczka, Theory of group representations and applications. World Scientific 1986.

    B.C. Hall, Lie Groups, Lie Algebras, and Representations: An Elementary Introduction, Springer 2003,

    A.W. Knapp, Representation theory of semisimple groups. An overview based on examples, Princeton University Press 2001.

    B.G. Wybourne, Classical groups for physicists, Wiley 1974.

A Report From Mochizuki

March 25, 2024
Categories: abc Conjecture

I don't really have time to write seriously about this, and there's a very good argument that this is a topic anyone with any sense should be ignoring, but I just can't resist linking to the latest in the abc saga, the REPORT ON THE RECENT SERIES OF PREPRINTS BY K. JOSHI posted yesterday by Mochizuki.

To summarize the situation before yesterday, virtually all experts in this subject have long ago given up on the idea that Mochizuki's IUT theory has any hope of proving the abc conjecture. Back in 2018, after a trip to Kyoto to discuss in depth with Mochizuki, Scholze and Stix wrote up a document explaining why the IUT proof strategy was flawed. Scholze later defended this argument in detail and as far as I know has not changed his mind. Taking a look at these two documents and at Mochizuki's continually updated attempt to refute them, anyone who wants to try and decide for themselves can make up their own minds. All experts I've talked to agree that Scholze/Stix are making a credible argument, Mochizuki's seriously lacks credibility.

The one hope for an IUT-based proof of abc has been the ongoing work of Kirti Joshi, who recently posted the last in a series of preprints purporting to give a proof of abc, starting off with "This paper completes (in Theorem 7.1.1) the remarkable proof of the abc-conjecture announced by Shinichi Mochizuki…". My understanding is that Scholze and other experts are so far unconvinced by the new Joshi proof, although I don't know of anyone who has gone through it carefully in detail. Given this situation, an IUT optimist might hope that the Joshi proof might work and vindicate IUT.

Mochizuki's new report destroys any such hope, simultaneously taking a blow-torch to his own credibility. He starts off with

> .. it is *conspicuously obvious* to any reader of these preprints who is equipped with a solid, rigorous understanding of the actual mathematical content of inter-universal Teichmüller theory that the author of this series of preprints is **profoundly ignorant** *of the actual mathematical content of inter-universal Teichmüller theory*, and, in particular, that this series of preprints **does not contain**, at least from the point of view of the mathematics surrounding inter-universal Teichmüller theory, **any meaningful mathematical content whatsoever**.

and it gets worse from there.

Update: A commenter points to a response from Joshi here.

Update: Scholze has a comment on MathOverflow indicating precisely where Joshi's attempted proof runs into trouble.

Update: Mochizuki and those around him award themselves \$100,000 (this is the IUT Innovator Prize described here).

Comments

1. **Jeff Berkowitz**
   March 25, 2024

   Do I understand this correctly? Joshi worked hard in an attempt to patch up the perceived deficiencies in Mochizuki's proof, and Mochizuki shot him down? I guess because … in Mochizuki's eyes there are no "perceived deficiencies"?

2. **Peter Woit**
   March 25, 2024

   Yes, that's about it. He's basically, in a very unprofessional manner, attacking as an incompetent the one person outside his circle who believes his IUT methods are worth pursuing.

3. **Low Math, Meely Interacting**
   March 25, 2024

   A while ago I attempted to comprehend the plain English content in an earlier such communication. I forgot how much an onslaught of italics and bolding could make my eyes throb.

4. **NoGo**
   March 25, 2024

   Among other weirdnesses in this report one thing sticks out to me: in this report as in his previous ones Mochizuki steadfastly refuses to call Scholze and Stix by name, always using euphemisms like "RCS" or "redundant copies school". I cannot but notice a strange similarity to Vladimir Putin's steadfast refusal to ever mention by name his political opponent Alexey Navalny, until the latter's death.

   And speaking of unprofessional manner, I think Mochizuki hits the new lows. He basically tells that to him the papers of Joshi look like they were produced by ChatGPT, although he graciously gives the poor guy the benefit of the doubt!

   Well, calling Scholze (not by name) an ignoramus that makes bad undergrad-like mistakes sounds positively like a compliment by comparison…

   I hope the experts will tell us if there is any meaningful mathematical content in this report, but given his tone, and the hard-to-read style that Mochizuki adopts, I am not holding my breath.

5. **Eric Lehman**
   March 25, 2024

   Joshi has a Theorem 9.11.1 in one of his papers. Mochizuki comments:

   "[where we note that it is not clear whether or not the number "9.11…" assigned by the author to these key results in [CnstIII] was purely coincidental or a consequence of some sort of sense of rhetoric or humor that lies beyond my understanding]."

   I don't know whether Mochizuki is connecting Joshi's theorem numbering to the September 11 terrorist attack, the 911 emergency number in the US, or something else. In any case, I fear that more than anger may be at work in Mochizuki's mind.

6. **Sabine**
March 26, 2024

Next time I really want to insult someone I'll call them "ignorant of inter-universal Teichmüller theory" and that will certainly do the job.

7. **S**
March 26, 2024

This is painful to look at. It does not seem to me that Prof. Mochizuki is well.

8. **Mike**
March 26, 2024

Perhaps Mochizuki was also irked by Joshi's papers because he wants all the glory for an abc proof.

Besides a consensus that the proof doesn't exist, do experts consider that there is any interesting or useful mathematics in the IUT papers? If so, one sign of hope is that I think there's a real possibility that this could be settled via a formalisation effort within, say, 10 years. If the proof doesn't compile as Lean code, Mochizuki will have to argue that computer CPU's are incompetent at mindless elementary computational steps.

9. **Low Math, Meekly Interacting**
March 26, 2024

My admittedly cheap shot about formatting was kind of hinting at that suspicion: This does not read like the product of an entirely well mind. At minimum, a dearth of independent editorial feedback to moderate the tone (and the font) has allowed a tendency toward self-sabotage to run amok.

10. **Giant Toad**
March 26, 2024

@Mike: The expert consensus is that there is essentially nothing of interest in any of the IUTT papers. This is well-reflected in the discussion hosted on this blog back in April 2020.

It is also clear that there is zero chance of settling all of this by a computer formalization of Mochizuki's work, since at the heart of things (i.e. in the proof of Corollary 3.12) there is nothing actually there to feed into the computer. Something which is not already well-understood by humans cannot be formalized!!

11. **categoricalequivalent**
March 26, 2024

It seems that there are fewer mathematicians thinking this includes useful ideas. I think they, who insist that the theorem was proved and want that it is accepted by mathematicians, should deal with computerization by themselves. Although it was unrealistic a little ago, it is prospering more and more these days. Well, if it doesn't work well, then they can't avoid conceding the fact that the proof is incomplete, so they will hesitate to do it.

12. **Arpex**
March 26, 2024

The growing weirdness in Mochizuki's rebuttals, his peculiar sentence construction, his obsession with identifying non-existent hostile patterns in the criticized texts, and even his polarization between the Western and Eastern mathematical communities are probably not indicatives of arrogance and single mindedness, but rather of some form of cognitive decline, not much different from what happened to several prominent mathematicians (needless to say which one comes to mind first). In this case, this might not be the appropriate forum to discuss the situation or criticize a once prolific mathematician, who apparently is not able anymore to defend himself and his work in an articulate and objective manner.

13. **Jj**
March 26, 2024

Right or wrong, Joshi's work be judged on its merits and not be intermingled with the circus that surrounds Mochizuki..

14. **momerathe**
March 26, 2024

As a very gentle admonition: I feel it is bad form to speculate about someone's mental health, and such comments may be hurtful to those struggling with mental health issues and to their loved ones. Let's try to be kind.

15. **Peter Woit**
March 26, 2024

Arpex/momerathe,
I agree that such speculations are not a good idea, but recognition that there is a problem is important. Those surrounding Mochizuki in Kyoto should be doing something about this, not enabling his behavior but staging an intervention. Even if they believe he's completely right about the mathematics, why isn't anyone telling him that writing documents like this is destructive to his own interests?

16. **Anupras**
March 26, 2024

Although IUT has potential, Mochizuki is extremely arrogant (with his refusal to attend proposed conferences on IUT and with regards to clarification of the theory to non-experts, and that could be one of the reasons why most mathematicians have given up on it.

17. **Millstone beside bath**
March 26, 2024

Prior to the Comments against Joshi and his paper, from what Prof. Mochizuki wrote in his blog in Japanese this January, I have had serious concerns, not about the IUTT itself: https://plaza.rakuten.co.jp/shinichi0329/diary/202401020000/

I would never recommend using a translation tool with the expectation that meaningful content would be written. Only the translation of the title of the post here: Deification, Ethnocentrism, and Suppression of Rationality of the West based on Christianity and Judaism

The problem is already out of mathematics. I believe we should not help it get any worse.

18. **fwiw**
March 27, 2024

Peter,

> why isn't anyone telling him that writing documents like this is destructive to his own interests?

Well,

> 'In light of the blatant obviousness underlying (Reac1), many consultees were not interested in investing the time and effort necessary to discuss Joshi's series of preprints in detail and indeed strongly encouraged me to simply ignore them as well'

19. **martibal**
March 27, 2024

This is a kind of crash-test on how the maths community is healthier than the hep-th one. Although Mochizuki is a well recognised mathematician (as far as I understood), when he speaks no sense, then some prominent mathematicians say so. At the end of the day, only Mochizuki's pride is wounded.
When recognised physicists speak non sense in high energy theoretical physics, the all field is ruined…

20. **finitelocallyfreegroup**
March 27, 2024

I'm convinced that Scholze and Stix's objection to Mochizuki's Corollary 3.12 is valid, as Mochizuki hasn't been able to defend himself by spelling out all the details in all those years after the objection was made. Assuming the objection is valid, then nothing would save IUT, including any attempt to make IUT even fancier by incorporating perfectoid fields, because nothing prevents the real numbers to have nontrival automorphismes as ordered abelian groups.
But in any case Mochizuki's response to Joshi's hard work is unacceptable. In doing mathematics we pursuit the ultimate consensus that is unaffected by any personal status, political power or even the law of physics. Nobody is entitled to shut another mathematician up by personal attack or political hints.

21. **Peter Woit**
March 27, 2024

Millstone beside bath,
That's another document that would argue for an intervention from those close to Mochizuki.

fwiw,
The right advice to Mochizuki would have been not to ignore Joshi's work, but to respond professionally to the mathematical content.

22. **A. Wolf**
March 27, 2024

Peter, I feel your "right advice" to Mochizuki presupposes he has the ability to respond professionally to mathematical critique, which seems an unrealistic expectation at this point. The people who work with him surely realize he cannot respond in a professional manner, so telling him not to respond at all is probably the best advice they can offer.

I don't see an intervention forthcoming. If they're willing to publish his papers in Kyoto then they are very unlikely to back down on support, not only due to this action demonstrating an unwillingness to challenge him when they should, but also due to the escalation of commitment. Admitting he needs an intervention would be tantamount to an admission that the IUTT publications are evidence of a serious systemic error. This entire phenomenon is about saving face and the longer it persists the more entrenched the actors become.

23. **Peter Woit**
March 27, 2024

A. Wolf,
I fear that you are right. Concerning Martibal's comment above, I think the difference between this and the string theory case is that here the problem has remained localized in Kyoto, while in physics it spread through the entire community.

24. **Darren Untoward**
March 27, 2024

A response by Kirti Joshi to Shinichi Mochizuki's recent comments on his papers are here: https://mathoverflow.net/questions/435110/consequences-of-kirti-joshis-new-preprint-about-p-adic-teichm%c3%bcller-theory-on-th/467851#467851

25. **prefertobeanonymous**
March 27, 2024

Stix and Scholze ultimately did read Mochizuki's mathematical content and pointed out the first thing they thought wasn't correct (3.12).

It would be very nice if someone could do the same for Joshi's work. Mochizuki's document appears to be mostly disparaging and (I need to review it again) but he doesn't seem to say something like "I follow Joshi's work until paper ___ page ___ proposition ___" which Scholze and Stix HAD done for Mochizuki.

26. **Giant Toad**
March 27, 2024

Amused that Mochizuki insists on writing "Fontaine-Fargues curve", while the universally accepted name is Fargues-Fontaine curve. It's a small detail, but coming from someone who insists so forcefully on accuracy and carefulness etc., it is rather ironic.

27. **Enraged number theorist**
March 27, 2024

By the way did anybody manage to make any sense out of the Oberwolfach report
of Mochizuki?

It reminds me of the hallucination of ChatGPT (ops).

More seriously, I might be missing something, but that report aims to give a completely elementary description of his “main idea”.

Perhaps I am limited, but by reading it, there seems to be no fucking way he has a proof of abc. It seems more or less accurate that he has gone senile from that report.

If not, how is it possible that such an institution as Oberwolfach has accepted to lower their standard to the point of accepting this trash in their reports? Isn’t it enough that RIMS has already decided to trash its name for good? Shall we have this guy sabotage the prestige of other important mathematical institutions too?

I would love if some person involved with that publication could step in here and justify this choice, by making some explanation for this. To me this document makes no fucking sense!

28. **B. Malpani**
March 28, 2024

Some might think that this is a trivial detail, but keep in mind that Mochizuki is 54 years old; i.e. not a senile old man exhibiting what has been labeled “cognitive decline”.

Recall that he maintains a “Safety Confirmation Information for Shinichi Mochizuki” webpage; Internet Archive has crawled it as early as 01 April 2012. (Sorry but the date is what it is.) He seems to update this page often but not daily. (Weekly, perhaps?) I hope that the impulse that lead to such a webpage doesn’t further develop.

Current developments are, simultaneously, surprising, and somehow, not surprising.

Very sad.

29. **Peter Woit**
March 28, 2024

Enraged Number Theorist,
I assume you’re referring to
this

This was just one contribution to this workshop
https://ahgt.math.cnrs.fr/activities/workshops/MFO-RIMS23/
organized as part of this

https://ahgt.math.cnrs.fr/

There’s supposedly an eight-member committee supervising that, and Benjamin Collas seems to be the main person responsible for promoting IUT this way. He and that committee might want to discuss what they should do about the situation Mochizuki has created.

30. **The Cohomologist**
March 28, 2024

Hey Peter,

Noticed this odd comment on page 7 of Mochizuki’s report:

>>[where we note that it is not clear whether or not the number “9.11…” assigned by Joshi to these key results in [CnstIII] was purely coincidental or a consequence of some sort of sense of rhetoric or humor that lies beyond my understanding].

Any idea what this means? Is this a 9/11 reference?

31. **Enraged numer theorist**
March 28, 2024

Dear Peter,

Yes, exactly that report, indeed. Thanks for pointing out the name of the responsible person.

I hope Oberwolfach, he and the other organizers are aware that the number theory community is watching this, and nobody is amused, to put it mildly.

Given the public attention that this guy is drawing with his inflammatory bullying with the mathematical community at large, and given how little sense that report makes (and how much at stakes there is with these claims!), it is clear to many in the community that Oberwolfach and the organizers should do something to distance themselves from this person.

Accepting that nonsense as a report is a terrible testament of low standards of academic quality. And for an institutions like Oberwolfach, where reputation is pretty much everything, that’s a very dangerous move.

I trust somebody will do something about this!

32. **David Roberts**
March 28, 2024

@Enraged number theorist

that example of his in section 3.2 (the Riemann sphere being the gluing together of two affine complex charts), feels to me like either linguistic sophistry or a total unwillingness to learn what people mean when they talk about colimits like this.

I went through the process of calculating this colimit in an elementary way from the definition, in a pdf linked this blog post. And showed that doing the kind of apparently wicked identification Mochizuki condemns really doesn’t matter. It’s the kind of conceptual mistake you might expect an undergrad to make when learning about category theory.

Or for that matter, physicists 100+ years ago worrying about the “hole paradox” because they are sufficiently mathematically sophisticated to think about diffeomorphisms of manifolds and charts and whatnot correctly.

One can even do this gluing together of P^1 in a skeleton of the category of complex manifolds, or complex varieties or whatever, where you don't have the freedom to find a new, distinct copy of the affine line.

The affine line itself can be literally unique (not even up to isomorphism, but the only representative of its isomorphism class), but there are two different embeddings into the projective line, and hence we can still distinguish the coordinates on the two charts.

I really don't understand why this particular example is so important to Mochizuki, when it really portrays an unfamiliarity with how people speak in modern geometry.

33. **Enraged number theorist**
March 28, 2024

Dear David,

Thanks for the thoughtful reply.

What now brings particular gravity to the situation is that such futile discussions on his side are implied to be the "main idea" behind the proof of such a deep statement as ABC. As a report of an institute like Oberwolfach and to top it up now, from somebody that twice has shown extremely bullying behaviour with other professionals, drawing a lot of attentions from the larger public, which must be thinking something particularly clownish is going on with the number theory community: hard to refute that!

What is particularly sad about this, is that it might give to the outsiders the misleading idea that whether somebody has proved ABC or not could really rest on such futile discussions as the one of his report. That's really a sad unfortunate turn of events, since Diophantine Geometry is that one subject where the biggest gems (which are logically weaker results than ABC) have all came with tour-de-forces of absolute brilliance, from masters like Siegel, Bombieri, Faltings and Vojta (to name a few), with no empty trivialities, but one difficult idea after the next.

It is of the utmost importance that as a community we distance ourselves from this crank. Personally anybody can use their time as they wish (and I hope that as a community we will be able to address Joshi's investment and its intellectual value on its own ground). But as a community it is of utmost importance that this clown/bully does not anymore have a space in our most revered institutions.

I am pretty sure the German tax payers wouldn't be amused to know on what kind of farse Oberwolfach is wasting their time on. This sounds like a joke or an exaggeration. It is not:

As a community the bare minimum we can do to keep our credibility from a society that invests in our intellectual pursuits, is to keep such clowns at bay.

34. **GeoMan**
March 28, 2024

Like everybody, I've found Mochizuki's work and behavior on this baffling. But I've also found the Scholze/Stix reply uncompelling–it is, at best, a sketch of what's wrong with the IUT program. In a way this is not surprising; if the target of your objection is indeterminate, your objection will be too. So when Peter says that "all experts [he's] talked to agree that Scholze/Stix are making a credible argument", that is exactly correct: it's a credible argument, not a compelling one, and certainly not a disproof of IUT ABC.

In contrast, Joshi and Dupuy have attacked this problem the right way: comprehensively and with full rigor. Whether there are better things they could be doing with their time is another story . . .

35. **marksym**
March 29, 2024

On MO there's a question about a purely mathematical claim of Mochizuki stated in the note Peter links to, but apparently nobody knows either what it means or how to prove/refute it https://mathoverflow.net/questions/467696/global-character-of-abc-szpiro-inequalities

36. **Clarification needed**
March 29, 2024

What does it mean to "sum up local inequalities at each prime number of a number field"?

I surely don't know how to prove a statement when I don't even know what exactly is the statement!

Can somebody please clarify the precise meaning of this claim? I believe the MO's question does not do any job in making this precise.

This might be actually helpful. If Joshi is indeed "summing up local inequalities" (whatever that means) and if one can show that this can never give a proof of ABC through those triples as Mochizuki suggests, then at least we can get a cheap verification that Joshi's "proof" is (also) flawed/inexistent (like Mochizuki's one) and avoid waste time in empty discussions for 12 more years.

37. **Peter**
March 29, 2024

Peter Scholze is participating in the discussion on MO.

38. **Héhéhé**
March 30, 2024

@GeoMan

I think Scholze has better things to do than spend his time responding to a person who insults him (and others) and who is incapable of producing an understandable mathematical text, let alone a credible counterargument to his objections.

It is not up to Scholze to disproof IUT ABC. He has already done his part. It is up to Mochizuki to produce an irrefutable and clear proof. But, given the last 12 years, that probably won't happen.

If Joshi's demonstration proves incorrect, it's time to move on and leave Mochizuki alone in his delusions.

39. **TS**

March 31, 2024

It is interesting to see that the disproof of Joshi's proof that Mochizuki added in his revision is actually readable and has a fairly standard layout, at least relative to the surrounding text. I think there are several ways in which this is humorous, but let me just point out that the part where he seems the most like a normal, functioning mathematician is exactly the part which he says an AI could write.

40. **Darren Untoward**
April 1, 2024

Kirti Joshi has briefly responded to Peter Scholze's concerns about his proof in this MathOverflow response: https://mathoverflow.net/a/468180/472518 . Joshi mainly states that he is working on a full response to the points that Scholze raised, and thanks Scholze for his comments.

There are several linked MathOverflow responses on this topic now, they might be interesting reading.

41. **Curious observer**
April 2, 2024

A fuller response to various questions has been posted by Joshi on MO and his site https://mathoverflow.net/a/468180/472518

https://www.math.arizona.edu/~kirti/qa.pdf

42. **NoGo**
April 4, 2024

Apparently Mochizuki &Co awarded themselves $100,000 every year for 10 years: "The IUT Innovator Prize will be awarded annually for 10 years"

The same page states that "The IUT Challenger Prize of $1,000,000 will be awarded to the first mathematician to write a paper on the IUT theory that shows an inherent flaw in the theory". Why do I have a feeling that Scholze and Stix won't get it even if they publish their findings in a journal?..

43. **AO**
April 4, 2024

Leaving aside the non-mathematical part of the discussion, is it fair to say that Mochizuki's mathematical objection to Joshi's paper is now seen by other experts as fundamentally correct?

44. **martibal**
April 5, 2024

Where do they got this money from ? Did they manage to convince some rich guy to spend money on that (like the breakthrough prize) or did they mage to convince the japanese governement that this question was worth $1.000.000 ? In both case it is a bot worrying for the health of the math community.

45. **Adam Treat**
April 5, 2024

@Curious Observer

It seems Joshi has not yet responded to Scholze's objection restating Mochizuki's objection, but promises to do so in the future. From what I can tell the pdf you linked does not address this objection at all. Yet.

@AO

I have the same question, but from reading the comments on MO it certainly does seem like Scholze agrees with the specific mathematical objection that Mochizuki makes of Joshi.

46. **Soyoko**
April 30, 2024

New responses from Joshi to Mochizuki and Scholze.

https://www.math.arizona.edu/%7Ekirti/local-global-issue.pdf

https://www.math.arizona.edu/%7Ekirti/response-to-Mochizuki.pdf

47. **Unfollow**
May 2, 2024

Will Sawin has already pointed out a flaw in Joshi's response, here https://mathoverflow.net/questions/467696/global-character-of-abc-szpiro-inequalities#:~:text=I%20believe%20the%20claim,dealing%20with%22%20is%20wrong.

48. **Darren Untoward**
May 6, 2024

@Unfollow Joshi has very slightly updated his response on May 2: see https://www.math.arizona.edu/%7Ekirti/local-global-issue.pdf ; pages 3 and 6 inserted a line or two that arguably can be taken to be a response to the concerns about locality raised by Scholze and Sawin.

How I fell out of love with academia

April 5, 2024
Categories: Uncategorized

Sabine Hossenfelder today posted a new video on youtube which everyone in theoretical physics should watch and think seriously about. She tells honestly in detail the story of her career and experiences in academia, explaining very clearly exactly what the problems are with the conventional system for funding research and for training postdocs.

After a string of postdocs requiring moving and living far from her husband, she decided she needed to move back to Germany and applied for a grant to fund her research (I believe for this project). This is how she describes the situation:

> At this point I'd figured out what you need to put into a grant proposal to get the money. And that's what I did. I applied for grants on research projects because it was a way to make money, not because I thought it would leave an impact in the history of science. It's not that what I did was somehow wrong. It was, and still is, totally state of the art. I did what I said I'd do in the proposal, I did the calculation, I wrote the paper, I wrote my reports, and the reports were approved. Normal academic procedure.
>
> But I knew it was bullshit just as most of the work in that area is currently bullshit and just as most of academic research that your taxes pay for is almost certainly bullshit. The real problem I had, I think, is that I was bad at lying to myself. Of course, I'd try to tell myself and anyone who was willing to listen that at least unofficially on the side I would do the research that I thought was worth my time but that I couldn't get money for because it was too far off the mainstream. But that research never got done because I had to do the other stuff that I actually got paid for.

As that grant ended, she decided to try instead applying for grants to work on research that she found to be more promising and not bullshit, but those grant proposals were not successful. Since then, she has left the academic research system and concentrated on trying to make a career oriented around high-quality Youtube videos about scientific research.

It seems to me that Hossenfelder correctly analyzes the source of her difficulties: "The real problem I had, I think, is that I was bad at lying to myself." Those more successful in the academic system sometimes criticize her as someone just not as talented as themselves at recognizing and doing good research work. But I see quite the opposite in her story. Many of those successfully pursuing a research career in this area differ from her in either not being smart enough to recognize bullshit, or not being honest enough to do anything about it when they do recognize bullshit.

Comments

1. **Branislav Raskovic**
   April 5, 2024

   Re: "most of academic research that your taxes pay for is almost certainly bullshit. "

   Although some research may be BS, "most" is a gross exaggeration. The pursuit of most forms of intellectual investigation needs to be fostered and encouraged …. Even if no proximate utility. Her personal issues with her career should not taint the environment others are working in by making such gross exaggerations.

   I enjoy reading all your posts, and in general agree with most of your commentary, but this post of yours does much dis-service to many.

2. **Peter Woit**
   April 5, 2024

   Branislav Raskovic,
   I personally wouldn't make global statements about all academic research. But, in the field of fundamental theoretical physics, she is quite right that most academic research is now bullshit. This is not about "Her personal issues", or about intellectual investigation being attacked, or about criticism of research as lacking proximate utility. It's about the continuing disaster of overwhelming bullshit that has afflicted a field, for reasons that she explains.

3. **Garald**
   April 5, 2024

   Oh come on. You can write a grant proposal that you know will likely be accepted (all the while believing, rightly or wrongly, that it's interesting and perhaps doable) and then you can start working on things that are related, more interesting and more doable (by you). Then you just need to convince the grant committee that they are closely related, and that's subjective enough that you don't have to lie.

4. **Peter Woit**
   April 5, 2024

   All,

   I'm now deleting most of the comments that are coming in. Everyone wants to argue about how science/academia/etc works in general, but I don't think that kind of very general discussion is worthwhile (and I don't want to moderate it).

   Hossenfelder had some very important specific things to say, based on her specific experiences, which she has described with a very rare openness and honesty. This is an important challenge to others in the field, and I'd like to hear from those who have a serious response to that.

5. **David Brown**
   April 5, 2024

   I think it is worth emphasizing Hossenfelder's remarks about her exposure to the writing of textbooks. "The next problem was: the head of the institute made a lot of money selling textbooks. He wrote very little of these textbooks himself. Rather, he gave assignments for parts of the books to students and postdocs — which is why, in case you've ever wondered, these textbooks are so discontinuous and partly repetitive."

6. **Peter Woit**
   April 5, 2024

   David Brown,

Besides what she had to say about postdocs and grants, the stories about the textbooks (Greiner-Reinhardt) and funding for women were interesting, but perhaps specifically problems of that particular institution and that particular time.

7. **Eric Weinstein**
   April 5, 2024

   As we all know exactly what she is talking about, it will be curious to see who pretends otherwise this time.

8. **The Cohomologist**
   April 6, 2024

   I believe you've discussed this on your blog before, but perhaps it bears repeating—how much of the experience Sabine describes carries over to academic mathematics? Treatment of postdocs and grad students, etc.?

9. **Alessandro Strumia**
   April 6, 2024

   Theorists disappear because of two main problems: a) not being hired; b) being hired. In some countries some theorists get hired permanently (often after over-working on mainstream arguments for a few year), next they can do whatever they want. And many stop doing research. Sabine got problem a) probably because she openly criticised the field. Professional theorists always pretend being excited and never criticise colleagues, fearing getting them as referees. Then boring wrong stuff spreads. A possible fix would be allowing anonymous comments below each arXiv paper.

10. **martibal**
    April 6, 2024

    What Peter think about anonymous comments ? Who would moderate this (it is not difficult to imagine many situations of conflict of interest, personal revenge etc).

11. **Peter Woit**
    April 6, 2024

    Eric Weinstein,
    Though a theorist, here Hossenfelder carried out an important experiment, showing the same person can get a grant to write the 25,000th paper about ads/cft, but not be able to get a grant to write papers about other less popular topics.

    The Cohomologist,

    The situation in math is different and significantly better. For one thing, at least in the US, math "postdocs" are funded mostly not by grant money but by teaching and in general grants are smaller and much less significant.

    martibal,
    There would be problems with anonymous comments. In any case, the problem she is discussing is really the job situation, not the literature, which is a different issue. Also, given that the arXiv censors (see the trackback saga) people for posting non-anonymous critical comments on papers by influential theorists, they're unlikely to start allowing anonymous critical comments.

12. **Max Lein**
    April 6, 2024

    @Peter Woit
    I think you are painting with a broad brush here, particle physics and the theory of gravity (as in alternatives to/extensions of/modifications of GR) are not representative of theoretical physics at large. The theory of topological insulators was an important development in condensed matter physics and the theory of classical waves. Some of the techniques that were used in the systematic classification of hermitian/selfadjoint and especially non-hermitian systems came from particle physics. Improvements in manufacture (e. g. 3d printing) made many of these claims accessible to experimental verification.

    @The Cohomologist
    I'm a mathematical physicist by trade who works with both sides of the aisle, although in most jobs I was considered a mathematician. In my experience (which covers Canada, Japan and Europe), some of the pressures and problems are quite similar. Some obscure (and I mean this with love) fields only have a handful of people in it, and personal tiffs or perceived slights can certainly impact one's academic career.

13. **an old guy**
    April 6, 2024

    In 1990 I made the most difficult decision in my life to that point – exiting my graduate physics program @ a top-3 school (whatever top 3 means). It was to be the last time in my life that I felt like an utter failure. There were two years where the idealistic future I had envisioned had no ready replacement; everything felt like a submission to the hedonistic treadmill, the polar opposite of what motivated me to physics.

    What was Physics' offense?

    It was a factory of marginal thought, a vortex of group-think, and a bizarre form of Ponzi-scheme that felt sure to crash. I couldn't look away from this impression. I tried. I passed my qual, convincing myself that I just had to find the right group. I networked and probed. I volunteered my time. And nothing resonated, or when a group working a semi interesting topic would be critically probed, the reflexive defensiveness was palpable and void of humility. Eventually, the behavior and group-think took on an ugliness I could not ignore.

    I had to jump.

    I didn't have anywhere to land.

    As I've watched Dr. Hossenfelder over the years, in addition to feeling a sense of admiration and respect, a lighthearted reprieve due to her humor, a familiar sense of simpatico in probing the world and what structures lay beneath… I also see a haunting specter of what I could have become. It's chilling. I would have struggled to fight a hollowing bitterness that accompanies compromise.

    And it's not just Dr. H.

    As I've followed Dr. Weinstein, I've periodically attempted to square his career path with my brother-in-law's who did their graduate work at Harvard at the same time (some 30+ years ago). To be blunt: the exercise saddens me. I don't mean this glibly or arrogantly (though, that is likely how it will come across), but mine is the sadness of being right. Of forecasting correctly. Put another way, had I “stuck it out” within academia, the probability of residing within Thoreau’s disquieting aphorism–The mass of men lead lives of quiet desperation–was terrifying likely.

In short (apologies for the sililoquy), the dynamic Peter calls out, as do Dr. H & W, had a genesis decades ago. Decades ago! That little to nothing has changed is unconscionable; a poster-child of institutional rot. It is shameful condition for a profession so grand.

Then again, fast forward to now, there are those I admire that remain engaged or adjacent to the academic realm. I view them as representing the best of what I could have become, had I decided differently three+ decades ago.

Someone like Peter, who courageously and continuously calls out the perils of HEP group-think, while contributing to his field.

Or, someone like Dr. W who stubbornly develops his views outside of the sanctified realm, while living life rather well.

Or, most compellingly, someone like the indomitable soul of Dr. H. Bless her.

Adieu –

14. **Sabine**
April 7, 2024

Hi Peter, thanks for the link. Yes, that was the first of those projects, lots of buzzwords about AdS/CFT and quantum simulations and strange metals and so on. Worked like a charm!

Just one correction. I haven’t left academia, I am affiliated with the University of Munich (the Center for Mathematical Philosophy), it’s just that I’m not employed by them (partly because I don’t live in Munich and have no intention of moving there). I haven’t entirely abandoned the idea to apply for another grant again in the future — mostly because I’d like to have a team to work with — but at the moment I’m rather sick of it.

15. **gentzen**
April 7, 2024

> martibal,
> There would be problems with anonymous comments. In any case, the problem she is discussing is really the job situation, not the literature, which is a different issue. Also, given that the arXiv censors (see the trackback saga) people for posting non-anonymous critical comments on papers by influential theorists, they’re unlikely to start allowing anonymous critical comments.

Your best chance to comment on arXiv papers and get actual feedback is probably
https://scirate.com/
There are more platforms (i.e. I wrote in December 2017: “In addition to SciRate, also other options came up. The two most recent were openreview.net and fermatslibrary.com”), but I doubt that any of those alternatives is as “open to everyone”, accepted by scientific communities, and simple to use as SciRate. However, SciRate is non-anonymous, plain real world name. No idea whether or how that is enforced.

That Peter Woit is denied arXiv trackbacks is simply ridiculous. But those trackbacks failed to achieve their purpose anyway. And that me or you won’t get trackbacks makes perfect sense to me, because otherwise arXiv would risk spam attacks. Platforms like SciRate can handle spam, because they are less anonymous.

16. **Stacy McGaugh**
April 7, 2024

In addition to all the valid scientific issues mentioned above, it seems worth also considering the enormous constraints imposed on academic careers by personal constraints – the two body problem, wishing to have but not frequently uproot children, and even just having a geographic preference to live in a particular region (like where you’re from). The demands of an ambitious career path rather aggressively select against these normal human desires, skewing the ranks of the academy.

17. **BM**
April 7, 2024

Earlier this evening I decided to re-read an article in Inference Review by Emanuel Derman about option-pricing theory that I had stored in my bookmarks. Unfortunately it appears that the entire website has been taken offline; I thought you might like to know given your previous posts about this quite peculiar online journal.

This is obviously off topic but I’m afraid that comments on the older, related posts have been disabled; please feel free to delete as you see fit, Peter.

18. **Max Lein**
April 8, 2024

@Sabine
Munich is a great place for people working at the intersection of physics and philosophy. Apart from Harald Lesch, Detlef Dürr used to be very active.

@Stacy McGaugh
Yes, the lack of permanent positions is a huge problem, and scientists getting tenure later and later in their career (if at all). I got a tenured position at the tender age of 43. My lack of stability really had an impact on my personal life, e. g. we had children much later than we hoped for.

19. **martin**
April 8, 2024

I don’t understand why she couldn’t get a job at an university, where one can teach and do research. Having a salary makes you independent of grants, and for theoretical physics you can still do research even if you don’t always get a grant.

20. **ateixeira**
April 8, 2024

So the coments about the book writting are on Greiner’s books? That’s a pitty because I really liked all of his (actually not his books)…

21. **Peter Woit**
April 8, 2024

BM,

Inference lost its funding a while back, stopped commissioning articles. I hope the problem with the website is only temporary.

martin,
Permanent faculty positions in this kind of theory are very hard to get (likely impossible if you're someone not getting grants). And it you were lucky enough to get one, almost surely you would have to move to somewhere far from where your spouse, family, etc. are.

22. **Peter Woit**
April 8, 2024

By the way, skies very clear here in Maine. Later today will be in Jackman to see the eclipse.

23. **Amateur Physicist**
April 8, 2024

I had pretty similar experiences in my academic career. My solution was simply to leave academia and take up a teaching job, where I teach maths and physics for engineers. My salary is about twice I got in the University, the work is nice, and I have lots of time for my own research. I can study whatever I want, and so I am truly independent. Actually, most of my papers have been published since I left academia. So, leaving the academia does not necessarily mean an end of a research career.

24. **Andrew**
April 8, 2024

The evolutionary biologist Jerry Coyne has some thoughts on this here: https://whyevolutionistrue.com/2024/04/08/sabine-hossenfelder-hangs-it-up-and-some-personal-thoughts/

25. **Z Y**
April 8, 2024

Peter,

After the sad state of affairs that this comments thread reflects upon, it brings a smile to my face that an eclipse still excites physicists, enough to travel to a spot within the totality path.

26. **DrDave**
April 8, 2024

We should all support Sabine for telling her story. Also, not all of us can live on our YouTube earnings. She has put a ton of quality work into her channel.

27. **JE**
April 9, 2024

@Garald,

Re: "You can write a grant proposal that you know will likely be accepted (all the while believing, rightly or wrongly, that it's interesting and perhaps doable) and then you can start working on things that are related, more interesting and more doable (by you). Then you just need to convince the grant committee that they are closely related, and that's subjective enough that you don't have to lie."

Well, convincing some grant committee that your groundbreaking research project on e.g. new compactification methods for Calabi-Yau manifolds deserves a grant (based on academic achievements, published research, and so on) is very likely much easier than getting a grant for some 'promising' non-mainstream project of yours still these days. Convincing the committee that the former has anything to do with your more interesting and doable non-superstringy project may be tougher.

Several generations of theoretical physicists, like S.H., have suffered this 'bias' for the last 40-50-60 years. The problem does not seem to lie in that they have not been –or are not– creative enough to cheat a little bit on grant committees. The problem seems more related to the question of why string theory has (for so long) been and (still) is considered a mainstream research subject in HEP by grant committees, mass media, journals/referees and leading figures in the field.

28. **Daniel Shawcross Wilkerson**
April 9, 2024

Frankly, Sabine is exactly correct. I am a computer engineer and computer scientist and the situation in computing is the same. *Many* computing people leave academia for exactly this reason. I have heard a friend say something like all people are doing in computing is taking an idea from 20 years ago and publishing it again under a different name. That might not be 100% true, but it is certainly much of what gets funded.

Another way to put what Sabine is saying is that research funding is limited at the imagination of the people in the funding agencies. And that's being nice about it and not considering the possibility of a lot of cliquishness where people just fund their friends.

Further, Sabine is omitting the fact that people get funding based on publications and the "high status" people in academia sometimes use outright plagiarism to get said publications. Even when proved, the "high status" are above the law and therefore allowed to do so by the committees that are supposed to punish it. This is not a theoretical assertion: I and others have witnessed this first-hand at the highest levels (most famous people and universities).

For those who are not experienced with academia, if you listen, you can hear the ring of truth in Sabine's whole story, whether you want to admit it or not. We need people who are not researchers (that is, most people) to recognize that the funding system set up by the legislatures creates corruption. Only then can the situation be fixed. I have seen people instead reflexively take emotional umbrage at criticisms of the system, clinging to a notion of the purity of the ivory tower. Please stop: your willful blindness is just making the situation worse. For those of us who are researchers, you are making our lives intolerable. We are the ones discovering and inventing things for you and we could really use your help. Please listen.

29. **Jason Tyler**
April 9, 2024

Was just able to watch Sabine's video. Not too surprised about her revelations. Thank you for sharing and it is nice to see the fantastic support she is receiving here and on her channel. Academia needs someone like her desperately, to clear the fog and smooth things out. Follow your dreams and blow us all away.

30. **jj**
April 11, 2024

I'm long-term faculty at a mid-tier US college. My students are mostly good, occasionally very good. I enjoy wide discretion in my choice of courses and research. I have great colleagues. I work hard. I've developed some ideas that I believe in and that I'm proud to publish. With luck, some will be real contributions. I've received a few grants and fellowships, although my winning percentage is modest. I've served on national peer review committees. I support innovative work as I'm able. There are many people like me in academia. Getting a job like mine requires not only hard work but luck. That said, in my experience, people with talent and training comparable to mine who don't get a job like mine end up doing other things that they enjoy instead, often make more money than me, and mostly don't express serious regrets. For this reason, some of the comments here surprise me. Broad charges of "corruption", "outright plagiarism", "above the law", "willful blindness", etc. are not borne out by my experience. "We all know exactly what she is talking about" (Eric Weinstein) strikes me as sophistical. What we know is what SH said. What she's "talking about", especially when held against some of EW's more eye-raising public allegations, is another matter. What Stacy McGaugh observes — that the "demands of an ambitious career path rather aggressively select against these normal human desires" — could be said equally of the law, finance, entertainment, sport, or any other sector where conditions are right for the development of a "star system". In short, I see the problems with HEP that PW has been shedding light on for decades, and I feel his pain, but I'm not sure I see good reason for wholesale deprecation of "the system".

31. **RetiredGuy**
    April 11, 2024

    The situation with National Labs is not much prettier, although there is a much more job security than an untenured academic position, and much less than tenured one. But you still can only work on projects that can be "sold" to the sponsors even if it is "bullshit"; reasoning otherwise is severely discouraged.

32. **Peter Woit**
    April 11, 2024

    jj,
    There have been large numbers of comments coming in about problems of the academic research system in general and in lots of different areas. I've deleted almost all of them because I don't think this kind of general denunciation is helpful. I also though don't think the "everything is fine for me" counter-position is helpful. People really should try to respond specifically to the facts that Hossenfelder was presenting in an unusually honest manner.

    About the "star system" thing. The problem is that academic research is not like "law, finance, entertainment, sport", because in those fields people become stars by bringing in a lot of money, selling a lot of tickets, scoring a lot of goals, a very different situation. In particle theory in particular, for decades now people have been becoming "stars" and collecting \$3 million prizes on the basis of failed ideas.

    The remarkable thing in Hossenfelder's story is her experience with grants, showing that the same person who can get a research grant by spouting the conventional hype about the same topic everyone else is working on cannot get funding to work on ideas they find much more promising. This situation has been going on for decades and is one of the main reasons why this particular field is a disaster area right now.

    I've been thinking about my own early career experiences, back when I was a postdoc at Stony Brook 1984-1988. During those years, string theory completely dominated the subject of trying to use more mathematics to make progress in fundamental physics. I guess I was aware that the correct career move for someone with my interests was to find a hot string theory topic using some of the mathematics I had been learning and start working on that. But I didn't think string theory was at all promising as a fundamental theory, was arrogant enough to believe that my own ideas about what was promising (spinor geometry…) were better. I just couldn't see myself heading down a road of competing for grants/jobs etc. by working on things I didn't really believe in. Seemed a better idea to do what one thought best until the money ran out and you were forced to do something else. This ended up working out fine, although it involved a large amount of luck. I know lots and lots of good physicists of my generation who left the usual path for similar reasons, ended up but working not on different ideas about fundamental theory, but on completely different topics.

33. **jj**
    April 12, 2024

    Peter, things might be getting a little mixed up. My basic point isn't that everything is fine for me, it's that many people in academia, in my experience the vast majority, are neither crooks nor victims. One might get a different idea from some of the comments here. To be sure, writing successful grant applications isn't the same thing as doing worthwhile work, and I've seen people get much better at the former than they are at the latter. But again the number of such people isn't huge, and those who are uninterested in applying for grants (like me, usually) can often get by without them. Those who dislike the whole game for whatever reason or don't land a TT job mostly still have decent alternatives, so we're not talking about an all-or-nothing spin of the wheel. I'd be sad if your important complaints about HEP got mixed up with more questionable resentments. It's reassuring to hear that you're filtering the more egregious stuff.

What is String Theory?

April 11, 2024
Categories: Uncategorized

This semester the KITP has been running a program asking What is String Theory?, which is winding up next week, and was promising to "arrive at a deeper answer to the question in the title." It seems though that this effort has gone nowhere, with this report from the scene:

> Went to a string theory conference with many of the top researchers in the field centered around tackling the question "what is string theory" and the consensus after the conference was that nobody knows lmao

For an answer to the question from someone with a lot more experience, I recently noticed that Lubos Motl is very active on Quora, giving thousands of sensible answers to a range of questions, especially having to do with Central Europe. He explains the relation of string theory and M-theory (disagreeing with Wikipedia), and defines string theory as

> the name of the consistent theory of quantum gravity which covers all the vacua found in the context of critical string theory and M-theory.

I had trouble getting my head around the concept of an undefined theory known to be consistent when I first heard about it nearly 30 years ago, but it seems to still be a thing.

Comments

   April 11, 2024

   Unrelated but I thought I would mention that Peter Higgs died earlier this week, 8th April

2. **Peter Woit**
   April 11, 2024

   Dom,
   I didn't write a posting about this simply because I know nothing about him personally and nothing about his life's work beyond having looked briefly at his two famous papers. Better that people get information about him and his life and discuss that at a better venue.

   When I looked at the papers it was in the context of trying to carefully sort out the 1962-64 history, see
   https://www.math.columbia.edu/~woit/wordpress/?p=3282

3. **S**
   April 12, 2024

   Lubos's posts on quora are quite fascinating. Thank you for sharing that.

4. **David Brown**
   April 12, 2024

   In the link https://www.math.columbia.edu/~woit/wordpress/?p=3282 in the Update at the bottom of the entry for "The Anderson-Higgs Mechanism", the 1st "here" link goes to the American Journal of Physics website, but does not yield an expository article. Is something wrong with my browser, or is it the 1st "here" link?

5. **Interested Amateur**
   April 12, 2024

   One thing I've been very impressed with over the past twenty years is how Peter still doesn't bear a grudge against those within the String community that were outrageously abusive towards him on their blogs. I used to have a blind admiration towards the intellectual talents of one String theorist in particular; but this was quickly eroded over the years by his bizarre views on identity politics in general and his belief in 2014 that the results of BICEP would be proven correct over those of the 'jealous' Planck collaboration.

6. **Anon**
   April 12, 2024

   Do you find the recent DESI results hinting at decaying dark energy instead of a cosmological constant to be any vindication of the string theory swampland problem, if the results hold up? Before I remember you posting that if de Sitter is in the swampland then the straightforward interpretation is string theory is wrong since the universe is asymptotically de Sitter. The new results suggest there could be gaps in this argument.

7. **Peter Woit**
   April 13, 2024

   David Brown,
   I've updated that link so that it works again (although the article is now behind a paywall).

8. **Peter Woit**
   April 13, 2024

   Interested Amateur,
   The string theory story makes clear that the smartest people in the world can be wrong about something and tenaciously hold fast to a wrong idea against all evidence. I've never held a grudge against Lubos (although on some days I have been rather angry that the senior people around him that he looked up to weren't willing to explain to him that those who thought string theory was not the language in which God wrote the world had serious arguments and might be correct).

9. **Peter Woit**
   April 13, 2024

   Anon,
   The fact that no one knows what string theory is makes clear the nature of the "swampland program". When people make a "swampland conjecture", they are conjecturing

behavior of an unknown theory. If experiment conflicts with this, you can't use that to say the theory is wrong, since you don't know what the theory is. All you can do is say that the experiment has told you something about the unknown theory. Vafa is quite explicit about this, that in his program new experimental evidence can never tell you that your fundamental theory is wrong, since you don't know what it is. This isn't a normal kind of science in which you have a notion of testing a theory that could be wrong. Here the "theory" is unknown, so can't be wrong (so, one could say, "not even wrong"….).

10. **David Brown**
April 13, 2024

@Peter Woit, a pdf for "A Question of Mass" by Jeremy Bernstein, 2010
can be found at a website at the Fluminense Federal University (Universidade Federal Fluminense) in Brazil:
http://profs.if.uff.br/tro/lib/exe/fetch.php?media=ajp000025.pdf

11. **Peter Woit**
April 13, 2024

All,
Please, enough discussion of the Lubos Motl story, which is not the topic of this posting.

12. **NoGo**
April 14, 2024

Peter,

>I had trouble getting my head around the concept of an undefined theory known to be consistent

But maybe the consistency is a part of definition, not a property of the theory! As in (to paraphrase Nathan Seiberg) "if we find a consistent theory of quantum gravity, we will call it String Theory".

13. **Shantanu**
April 15, 2024

Peter, there is also a recent course on string theory at Perimeter institute (!)

14. **Peter Woit**
April 15, 2024

Shantanu,
The Perimeter Institute long ago changed from its initial emphasis on research outside the dominant string theory-based ideology. The lectures on string theory this year by Gaiotto are likely much the same as ones he has been giving there since 2014. At this point the director of Perimeter is a string theorist, and they hosted the 2023 Strings conference. I guess one can argue that they are following their initial contrarian model, going all in on string theory during the years that most of the rest of the physics community has given up on it.

Having a graduate course on string theory is very common. I see two problems with these courses, and quickly looking at Gaiotto's first lecture, his course likely will be an example:

1. The background and motivation given to the students is the same failed ideology that has killed the subject over the last 40 years. The students are not told any of the serious problems with this, why it doesn't work.

2. The technical material is most of the time a detailed immersion in Polchinski's string theory book. It may be the best string theory textbook, but it contains nothing about the problems with string theory, and it is a very challenging task for anyone to absorb the technical material it presents. The early graduate school years are crucial in training theorists, and if they spend one or more of these years immersed in the details of the quantization of the string, those are years in which they are not learning much more important things.

It could be worse though, Perimeter could be one of those institutions that teaches string theory at the undergraduate level….

15. **martibal**
April 15, 2024

But for sure there is also a course on loop gravity, noncommutative geometry, dynamical triangulation and all alternatives to string theory, right ?

16. **Alessandro Strumia**
April 16, 2024

Regge : QCD = string : quantum gravity

17. **Davide**
April 16, 2024

Peter,
I do my best to keep my course factual and hype-free. If you can pinpoint any inaccurate or deceptive statements, please let me know.
The main technical tools the students acquire during the course are the quantization of free fields in 2d, the definition of composite operators in free field theories and associated anomalies, some basic aspects of BRST quantization, the definition of disorder operators and boundary conditions in 2d free theories and rudiments of 2d CFT. Depending on the time availability, I may also sketch the 't Hooft expansion and the relation between bosonic and fermionic 2d QFTs (aka GSO projection).
Many of these tools are of general applicability in Theoretical Physics. I hope they will serve the students well independently of their final specialization.

18. **Peter Woit**
April 16, 2024

Davide,
Thanks for your comment.
From what I understand you're planning mostly a course on 2d qft, specifically CFT. That's fine and some of the techniques are of more general use. My problem is really with the whole conception and framework of such a course.

If you were teaching condensed matter physicists and saying that the point of the whole thing was to study certain classes of condensed matter phenomena in 2d, that would be fine. But students are coming into this believing what Polchinski's book and a 40 year old publicity campaign tell them, that the point of all this technology is a specific theory (the 10d critical superstring, defined by considering a CFT and doing very difficult integrations over moduli spaces of super Riemann surfaces). No one is telling them that the idea of doing this and getting QG + the SM by compactifying on a Calabi-Yau just doesn't work.

Looking at your first lecture, you're doing the standard thing of telling the students to think of a QFT as an integral over paths with complicated rules for how paths split and recombine. String theory is then motivated as going to an integral over surfaces.

But this isn't what the standard model QFT is. It's an integral over fields, with the fields having very specific and subtle geometrical significance (connections, spinors) and the action also having very specific and subtle geometrical significance (curvature, Dirac operator). The message the students get in most string theory courses is that the more advanced, deeper way of thinking about fundamental physics is to throw out all those structures and think about Riemann surfaces and 2d conformal symmetry.

In your first lecture you're not talking about CFT or the QG/unification motivation, but about the "paths to surfaces" motivation and other motivations, leading up to drawing the usual M-theory conjectural diagram. Back in 1995 this was an interesting conjecture, but nearly 30 years later I think anyone trying to sell it to students needs to at the same time clearly explain that looking for such a new kind of fundamental theory has gone nowhere and essentially everyone has given up on it. I guess related to what you were trying to explain is the idea of relating string theory to a large N expansion of QCD, which would be a good motivation.

Maybe my fundamental problem these days is that calling a course "string theory" at a time when experts no longer mean anything in particular by the words "string theory" comes with the need to make clear to the students exactly what you mean by "string theory" and exactly what the motivation is for studying this specific thing. If you don't do that, they're going to think what you mean is the definition and motivation given in the textbook you assigned, which at this point have all sorts of serious problems no one is telling them about.

19. **Simone Speziale**
April 17, 2024

@ martibal, I'm currently visiting, I gave my small contribution to that balance you are mentioning 😉 It was however just an evening lecture to the master students on semiclassical spin networks, Regge geometries and spinors.

There used to be a course on loop quantum gravity (I taught it once myself but that was almost 20 year ago and for UW students, PSI didn't even exist back then!), I dont know if it continues.

There is a LQG group here (of remarkably broad interests), a few students and postdocs working on LQG and on asymptotic safety, Renate Loll is a regular visitor for the CDT side, so fortunately `other games in town' are still represented, and it is possible for the master students to get some exposure to them and broaden their perspectives.

20. **martibal**
April 19, 2024

Noncommutative geometry seems to have disappeared after having been well (but shortly) represented by M. Marcolli. A bit scary to see how a place which was highly advertised as its beginning as a paradise for original thinkers has been (at least partly) swallowed by string and AdS/ CFT (according to the master program visible on the website). It was not enough to be dominant in Princeton, ENS and other famous places, one had to be sure that no place dealing with high energy theoretical physics was spared from string,

21. **Matthew Foster**
April 19, 2024

2D CFT remains a very useful framework for nonperturbative calculations in condensed matter physics. The calculation by Cardy and Calabrese of entanglement entropy using twist operators is a masterful example, whereby one only uses the Schwarzian derivative to get the transformation of the stress tensor from a cut plane (representing the division into subsystems A and B) to the whole plane, and combine that with the conformal Ward identity for the 3-point function of the stress tensor and the two twist ops. It's very hard to get the result even for free fields by elementary (constrained path integral) means–I've tried and failed!

Abelian and nonabelian bosonization remain useful for edge modes of topological liquids, spin chains, and 2D fractal surface-state wave functions of bulk topological superconductors. Also anyon statistics are ultimately traced back to monodromy properties of conformal blocks, although I get the impression that most workers in topological quantum computation bypass this.

On the other hand, though, the rate of new significant results is quite slow and there remains a steep learning curve to get through chapters 5-9 in the big yellow book, plus the prerequisite Lie algebra representation theory for WZNW models/nonabelian bosonization. Hence I don't teach this stuff to grad students in a course, and I'm generally loathe to recommend it for self-study either–it's just very hard to find good applications, for me at least. It's a pity though because the material is some of the most "beautiful" in statistical physics.

22. **Paolo Bertozzini**
April 21, 2024

@ Martibal

"Non-commutative Geometry" has not only been disappearing from the list of research areas represented in Perimeter … it has been almost completely disappearing from the panorama of research in fundamental physics and quantum gravity in particular. Practical first example: at the recent International Society for Quantum Gravity conference in Nijmegen Quantum Gravity 2023, where almost all areas of research in quantum gravity were significantly represented, there was not a single talk specifically dedicated to non-commutative geometry and the topic was barely mentioned in a few cases by researchers in other fields. Second example: in the recently published Handbook of Quantum Gravity there is not even a section properly dedicated to this subject. There might be many (and complex) reasons for such a "retreat" that are too long to be elaborated here.

23. **Andreas Karch**
April 24, 2024

As someone ALSO currently teaching a graduate level course on string theory out of Polchinski's book, I have to take exception. The original goal of string theory (getting quantum gravity in our world plus the standard model) has significant obstacles to overcome that no one currently knows how to tackle, this is fair enough. But still, at lesat in 10d superstrings give us a theory of quantum gravity in which graviton scattering order by order in perturbation theory is finite. That's amazing. Nothing else like it is known to mankind. Future theorists should learn it as a proof of concept ast least. The fact that the tools and tricks one needs to understand on the way are useful beyond that is an added bonus. As graduate chair here at UT I am unfortunately responsible for cutting our string sequence down from 2 semesters to 1. I find it hard to justify why string theory should get more time than cosmology, particle physics or advanced GR (all of which we teach as 1 semester courses). But that one semester I'll defned tooth and nail.

24. **Peter Woit**
April 24, 2024

Andreas Karch,
We'll just have to disagree about quantizing the 10d superstring and understanding the extremely complex story of how one is supposed to get amplitudes that have nothing to with the 4d world out of hopefully finite integrations over supermoduli spaces of super-Riemann surfaces.

On the list of things physicists have come up with that are amazing and worth teaching to students, I still think this topic is very, very far from the top.

Science Outreach News

April 16, 2024
Categories: Uncategorized, Wormhole Publicity Stunts

A few items on the science outreach front:

- The Oscars of Science were held Saturday night in Hollywood, with a long list of A-listers in attendance, led by Kim Kardashian. More here, here and here.

  You'll be able to watch the whole thing on Youtube starting April 21.

- The World Science Festival will have some live programs here in New York May 30 – June 2. One of the programs will feature the physicists responsible for the Wormhole Publicity Stunt explaining how

  > we may be able to create wormholes—tunnels through spacetime—in the laboratory.

- Stringking42069 is back on Twitter with his outreach efforts for the string theory community.

Comments

1. **Mike**
   April 16, 2024

   To state the obvious anyone who thinks Kim Kardashian adds to the glamour of science doesn't understand the psychology of why science is exciting to scientists. It's vomit inducing. Rather than celebrating science the superficial appeal to celebrity taints it.

2. **Z Y**
   April 16, 2024

   @Mike I could replace the KK name by any of the royals that give prizes and the meaning of your sentence wouldnt change muc, but i dont see many people complaining of that 🙂

3. **Interested Amateur**
   April 16, 2024

   I find the science awards ceremony to be patronizing and cringe: the good looking Chads and Stacies give out prizes to the not-so-good looking nerdy introverts. Growing up as a kid interested in science and maths, my hero was Spock and not captain Kirk.

4. **tulpoeid**
   April 16, 2024

   @ Z Y
   Let's keep some standards. I also don't like monarchy, but you can't equate any prize-giving royal, and actually most of the celebrities that attended this show, to Kim Kardashian. Not everyone is as bad as everyone else. Even swamps have a bottom. Let's keep the level of our proverbial bar in mind.

5. **ateixeira**
   April 17, 2024

   ZY you are totally right. Also the presenters and A-list celebrities present are not there for the scientists. They are there for the masses. The rationale apparently is that the masses will see the A-list celebrities getting along with the scientists and will be more attracted and conscientious of science.

6. **David Roberts**
   April 17, 2024

   If the King of Sweden is the one physically shaking the Nobel laureates' hands, I view the process as really one run by the various academic societies. The Breakthrough Prizes seem more to me to be like a explicit stunt by Yuri Milner to try to attach Hollywood glam to scientists and mathematicians. No one talks about the King of Sweden as somehow making the Nobel Prize more socially desirable and "cool", or pretends that's the case.

7. **Steve Huntsman**
   April 17, 2024

   God, how awful. Where's Perelman when you need him?

8. **Z Y**
   April 17, 2024

   @David Roberts About your last sentence, I dont think the Breakthrought Prize is considered by the public at large more socially desirable or cool that the other prizes just because all those celebs are at the ceremony. However I do have seen references in the general public that a royal giving a prize adds to the importance of that prize and you can really see all the panache that is devoted to the royals presence at those ceremonies, even in some of the winners speeches you hear paying respects to them. Having said that, I do have a high regard for the Nobel's committee and winners (nothing is perfect) but Milner's prize is not that bad, it does bring awareness to some of the recent discoveries of science at large that the Nobel cannot afford to recognize

9. **Peter Shor**
   April 17, 2024

   The celebrities do not determine who wins the Breakthrough Prizes — a committee of scientists including many of the previous prizewinners do. The unfortunate thing for the Physics prize is that many of the first prizewinners were string theorists, but I don't think you can blame this on the non-scientists involved.

10. **Diogenes**
    April 17, 2024

I am pleased to note that I don't think I recognize any of these names winning the Breakthrough Prize. That is some progress in directing the funds where they may start to be useful.

11. **Douglas Natelson**
April 17, 2024

The idea of the World Science Festival is great, and while I question the overall emphasis, if the topics rotate over the years through different disciplines, that's fine. The claim about actually producing wormholes in the lab (by using a quantum computer) is still anger-inducing, though.

12. **Gavin**
April 17, 2024

Glad to see you're pointing people to StringKing again so they can find content like this:

https://twitter.com/stringking42069/status/1780127988224282904

More seriously, I want to object again to you giving this troll any visibility on your platform.

13. **smitchmor**
April 17, 2024

Unfortunately, the full World Science festival format seems to be one of the casualties of the pandemic.

In years past the festival was centered around NYC's Washington Square Park. There was a science themed street fair (ideally coinciding with a beautiful spring day) with most events held at nearby NYU facilities.

A wide range of academic disciplines were represented; always had it's share of WOO! physics, but didn't dominate.

Speaking of celebrity, one annually recurring event was called the Flame Challenge, hosted by Alan Alda. The challenge involved encouraging clear cogent communication on seemingly simple questions such as "What is flame?… is color?… is sound?" to grade school students. It was a clinic in encouraging genuine interest in physical science, sans hype. Likely that health issues will prevent a repeat, but his genuine enthusiasm will be missed.

I can honestly say that I looked forward to the festival each spring and hope they it can be built back to something resembling it's previous incarnation.

14. **Rainy Sunday Afternoon Theoretical Physicist Drop Out**
April 18, 2024

This is a total off-topic, but reading that the Perimeter Institute is now directed by a string theorist makes me weep.

Is this the institute that Les Smolin "created" in Toronto, to work on alternative theories in fundamental physics/unification, excluding string theory and other mainstream approaches?

The sense of defeat is… (I don't have the right word).

P.S. Now, I have an image: it makes me think of the ending of the 1978 version of The Invasion of the Body Snatchers.

15. **Amitabh Lath**
April 20, 2024

I am a little uncomfortable with the Kim Kardashian bashing. I probably share your general distaste for the lifestyle but what are we saying to young people? That you cannot be someone that follows the Kardashians and hope to be accepted in the physics and math world? Now look around your departments and note the homogeneity and wonder where it comes from.

KK herself does seem to have an innate understanding of the highly complex system that is American Celebrity culture. She also navigated a marriage (with kids) to an apparently neurodivergent man with increasingly erratic behaviors. I do not believe she is dumb. I know we would all have preferred say, Michelle Obama, but if KK is bringing her millions of followers, let's not stick our noses in the air and shoo them away.

16. **Peter Woit**
April 20, 2024

Amitabh Lath,
I agree that criticizing Kim Kardashian personally isn't a great idea, and it's completely besides the point. The little that I know about her is confirmed by Wikipedia, that she's "famous for being famous".

From the beginning, Milner explained clearly that he felt a big problem with science was that it was not enough part of the celebrity culture and he wanted to do something about that. For him (and many other people), the problem with science is that scientists do not get the attention and respect that people like Kim Kardashian get. If this is what you believe, funding a Hollywood "Oscars of Science" and having Kim Kardashian show up to applaud scientists accepting multi-million dollar prizes makes perfectly good sense.

For myself, the problems with science I see are very different, and in the particular case of fundamental particle theory, more celebrity culture will make the problems worse, not better.

17. **Mike**
April 20, 2024

For what it's worth I wasn't bashing Kim Kardashian in my initial comment, just lamenting what I regard as the misguided idea that science should be made more "cool" by association with celebrities. It would be nice if people thought that figuring out the fundamental laws of physics, proving langlands conjectures, understanding how biological cells work and creating more efficient solar cells is awesome without the need for celebrity endorsement. But of course that wish is hopelessly naive and idealistic.

18. **Peter Woit**
April 20, 2024

Mike,

I don’t know about “cool”, but I don’t understand at all the belief that scientists are not respected, even less the idea that the way to deal with this is endorsement from reality tv stars. According to this
https://www.forbes.com/sites/tracybrower/2022/05/30/new-data-the-most-respected-jobs-and-5-ways-to-gain-respect-no-matter-what-your-work/
the profession of scientist is at the top of the list. What’s at the bottom? Reality TV star.

According to this data, associating scientists with Kim Kardashian is the single most effective thing you could do to make them less respected by the public.

19. **Mike**
April 21, 2024

Peter, I’m overreaching myself with regards to actual knowledge here but my conjecture is that a decent percentage of people acknowledge that being a scientist is a noble calling (even if the practical reality is often somewhat corrupted by the usual social/economic phenomena) while being a “celebrity” a la Kim Kardashian is far less honerable. So its not so much an issue of respect for the scientific professions (although the dumb commentary around climate change, Covid etc do seem to have increased anti-science sentiment). However, in practice most people are far more interested in the personal lives of celebrities, both those with meaningful accomplishments and those without, than they are about the actual content of science textbooks, research papers etc. I’d guess that this is approximately the reasoning behind the inclusion of celebrities into the promotion of the prizes: if people respect the scientific profession and are fascinated by the lives of these celebrities, if we bring them together maybe they’ll get more into the science? I’m not at all convinced.

20. **Amitabh Lath**
April 21, 2024

Mike and Peter, about a million kids who would not have paid any attention to science happened to catch a glimpse, however brief, because of Kim Kardashian. I do not care about her, but I do want to attract the 0.5% of those kids whose interest might be piqued by physics and math. They will help us expand and diversify (and man do we need it). One good way to get these kids to go rushing towards engineering or computer science rather than physics is to indicate that their love of pop/celebrity culture is somehow loathsome; you must be lovers of classical music and opera and jazz to succeed in our rarefied world.

21. **Amitabh Lath**
April 21, 2024

Look, let me give you a concrete example. We are just finishing up our application round for our summer physics program for high school students (Quarknet). They discover cosmic rays, measure muon lifetimes, analyze data from neutrino and collider experiments, have informal chats with graduate students, lab visits, it’s a blast. We try desperately to get a broad range of students in terms of gender, background, socioeconomic status, etc. Now some of these students, mostly female, POC, might be Kardashian fans. If we instructors come in with the sort of disdain you exhibit we will lose these students. They will clam up and not engage.

22. **Mike**
April 21, 2024

Amitabh Lath,
I want more diversity in science, I hope the breakthrough prize gambit works, and if it does I’ll be the first to celebrate.

I take your point though, it’s probably not productive for me to complain about the methodology on the internet, kids are impressionable and if its effective that’s the most important thing. However, as touchingly naive as it may be, I’d just rather live in a world where the science speaks for itself.
Best of luck with the summer program, sounds epic.

23. **David Roberts**
April 21, 2024

@Peter Shor

I’m under no illusion that the celebrities pick the winners. But with eg the Nobel or the Abel, it’s not the previous winners that pick the prize, but the independent and long-running academic bodies, which lends the weight to the prize.

I’d much rather see some really, really good science communicators (of which there are plenty on YouTube) be given decent space at the Breakthrough Prizes along with the Hollywood glitterati, say even equal billing. I tried watching the show live, once, when I happened to be in the US at the time. It was awkward. Actors can act, but they do not usually act as ‘talking science’ that well. Morgan Freeman reading off an autocue about mathematics and physics is much less enjoyable than someone who can speak extemporaneously and enthusiastically on the same topic, at least to me (of course, Freeman’s voice is wonderful to listen to, in any case).

But all of this is my own bias, and, as others have intimated, people like Tom Crawford or Ayliean or Tai-Danae Bradley that connect with the public in a way I sure never can, are good for the field; they show that maths isn’t just about stuffy old white men with beards (I resemble some of those adjectives, at least, and probably on the way to the others at some point).

24. **S**
April 22, 2024

Mike,

You say that people are far more interested in the personal lives of celebrities than the writings of scientists, notwithstanding the difference in respect accorded each. That may be true, but it seems to me that this kind of thing is *at most* likely to get the public interested in the personal lives of scientists as well — still not their writings. That would seem no kind of improvement

25. **Peter Shor**
April 24, 2024

@David Roberts says:

> But with eg the Nobel or the Abel, it’s not the previous winners that pick the prize, but the independent and long-running academic bodies, which lends the weight to the prize.

The Dirac Medal, which I assume is chosen the standard way, is still giving prizes to string theorists, while the Breakthrough Awards (at least for this year) seem to have stopped this practice.

26. **David Roberts**
April 25, 2024

@Peter Shor there's probably something to be said about sufficient and/or necessary conditions, here. Let us see how the Breakthrough prizes turn out after a few decades. 🙂

27. **That correlation has a high p-value**
April 30, 2024

I don't follow the argumet that KK, or similar actors, may increase, on net, the diversity of the math community. As a members of a minority group, fleeing away a shallow mass culture was a great apeal towards an intellectual life. To be sure, I am not arguing the merits of KK, just that her presence probably have zero net effect on diversity. My reading is that Milner just likes to hang out with scientists and mass culture actors (god knows why). The younger me would see KK and the string theory guys and secide to go work on avant garde movies instead, with its cooler and more diverse crowd that look down on KK.

This Week’s Hype

April 23, 2024
Categories: This Week's Hype

Until about a year and a half ago, the way to get funding in physics was to somehow associate yourself to the hot trend of quantum computing and quantum information theory. Large parts of the string theory and quantum gravity communities did what they could to take advantage of this. On November 30, 2022, this all of a sudden changed as two things happened on the same day:

- Quanta magazine, Nature and various other places were taken in by a publicity stunt, putting out that day videos and articles about how “Physicists Create a Wormhole Using a Quantum Computer”. The IAS director compared the event to “Eddington’s 1919 eclipse observations providing the evidence for general relativity.” Within a few days though, people looking at the actual calculation realized that these claims were absurd. The subject had jumped the shark and started becoming a joke among serious theorists. That quantum computers more generally were not living up to their hype didn’t help.
- OpenAI released ChatGPT, very quickly overwhelming everyone with evidence of how advanced machine learning-based AI had become.

If you’re a theorist interested in getting funding, obviously the thing to do was to pivot quickly from quantum computing to machine learning and AI, and get to work on the people at Quanta to provide suitable PR. Today Quanta features an article explaining how “Using machine learning, string theorists are finally showing how microscopic configurations of extra dimensions translate into sets of elementary particles.”

Looking at these new neural network calculations, what’s remarkable is that they’re essentially a return to a failed project of nearly 40 years ago. In 1985 the exciting new idea was that maybe compactifying a 10d superstring on a Calabi-Yau would give the Standard Model. It quickly became clear that this wasn’t going to work. A minor problem was that there were quite a few classes of Calabi-Yaus, but the really big problem was that the Calabi-Yaus in each class were parametrized by a large dimensional moduli space. One needed some method of “moduli stabilization” that would pick out specific moduli parameters. Without that, the moduli parameters became massless fields, introducing a huge host of unobserved new long-range interactions. The state of the art 20 years later is that endless arguments rage over whether Rube Goldberg-like constructions such as KKLT can consistently stabilize moduli (if they do, you get the “landscape” and can’t calculate anything anyway, since these constructions give exponentially large numbers of possibilities).

If you pay attention to these arguments, you soon realize that the underlying problem is that no one knows what the non-perturbative theory governing moduli stabilization might be. This is the “What Is String Theory?” problem that a consensus of theorists agrees is neither solved nor on its way to solution.

The new neural network twist on the old story is to be able to possibly compute some details of explicit Calabi-Yau metrics, allowing you to compute some numbers that it was clear back in the late 1980s weren’t really relevant to anything since they were meaningless unless you had solved the moduli stabilization program. Quanta advertises this new paper and this one (which “opens the door to precision string phenomenology”) as well a different sort of calculation which used genetic algorithms to show that “the size of the string landscape is no longer a major impediment in the way of constructing realistic string models of Particle Physics.”

I’ll end with a quote from the article, in which Nima Arkani-Hamed calls this work “garbage” in the nicest possible way:

> “String theory is spectacular. Many string theorists are wonderful. But the track record for qualitatively correct statements about the universe is really garbage,” said Nima Arkani-Hamed, a theoretical physicist at the Institute for Advanced Study in Princeton, New Jersey.

A question for Quanta: why are you covering “garbage”?

Update: String theorist Marcos Mariño on twitter:

> In my view, using today’s AI to calculate the details of string compactifications is such a waste of time that I fear that a future Terminator will come to our present to take revenge for the merciless, useless exploitation of its grandparents.

Update: More string theory AI hype here.

Comments

1. **Low Math, Meely Interacting**
   April 23, 2024

   But isn’t it amazing it took this long? It’s the sort of problem the AI hype machine was practically created for.

2. **Peter Woit**
   April 23, 2024

   LMMI,
   Actually people have been getting grants to use AI to supposedly study the string theory landscape for quite a few years now. Before the AI hype boom, this was part of the Big Data hype boom.

   What’s new is that Quanta finally got around to promoting this stuff. Unclear why that took so long, and why they waited until they had Arkani-Hamed on record describing it as garbage.

3. **clueless_postdoc**
   April 23, 2024

   This is purely a layman perspective. I read your post, then I read the quanta article. Never mind if what they’re doing is science, let alone good science, but if at some point people could write down a particular Calabi-Yau 3 fold, and say well if you compactify using this particular Calabi-Yau, you get the standard model. That would be pretty interesting, no? From reading your blog and various popsci books, it seems previously this failed because people simply did not have the computing power, but now it seems they do?

   Remark: “never mind if this is science….it would be pretty interesting?” – perhaps the reason I’m paid by a (poor) math department instead of a physics one.

4. **Peter Woit**
   April 23, 2024

   clueless postdoc,

The problem is that Calabi-Yaus come with a large number (say order 100) parameters. These are going to give you 100 new long-range gravitational strength forces. This looks nothing like physics, it's what Arkani-Hamed is referring to when he says "the track record for qualitatively correct statements about the universe is really garbage". This has nothing to do with any computational difficulty. The reason people gave up on this in 80s was not that the calculations were difficult, but that they were meaningless.

If you decide you're going to assume that you have some mechanism that dynamically fixes the moduli parameters to specific values, you can try and calculate standard model parameters for the effective 4d theory with those fixed parameters. But the result would depend on 100 parameters, and not be based on any underlying theory, again Arkani-Hamed's "garbage".

5. **Dan Winslow**
April 24, 2024

Well…sure, classical computing AIs for this are probably worthless. That's pretty obvious! However, one should think of the current effort as kind of a tune-up. When they start using AIs from QUANTUM computing, then maximum buzzword density will have been achieved and the whole argument will collapse into a single point of infinitely dense grant money.

6. **clueless_postdoc**
April 24, 2024

Hi Peter,

Thanks for the reply!
Again I am very much a layman. I agree the first option is probably not physics. But take the second option, suppose you manually take 100 or so parameters, fix them, and if my reading of the situation is correct, you get some extension of standard model that includes gravity, in a reasonably consistent way? Never mind if this destroys any way of getting it out of a simple fundamental theory, my impression is that we don't currently have any other way to do this (no other competing theory can go this far)?

My uninformed opinion, from a rather humble vantage point, is that having a Rube-Goldberg machine that does at least something is better than having nothing at all. (Never mind how much hype is or would be generated from this)

7. **Peter Woit**
April 24, 2024

clueless postdoc,
The problem is that if you fix the moduli, by hand or by the KKLT Rube Goldberg mechanism, you don't have a consistent theory. You do have an essentially infinite number of things you can calculate, so you can try and keep calculating, trying to make more and more complicated choices to get results that are not in obvious disagreement with observation, but this can't lead to anything meaningful.

I recommend that everyone interested in this follow the Twitter discussion with Marcus Mariño at
https://twitter.com/marino_beiras/status/1783042977922699457
Mariño is a string theorist expert on the subject of Calabi-Yaus, so very well equipped to know whether the calculations being advertised in Quanta are meaningful or garbage.

8. **john**
April 24, 2024

This Dirac Medal and Prize Award Ceremony might be of interest.

https://www.youtube.com/watch?v=tvyIkqqAQw8

They mention string theory in some of the work that was awarded prizes.

9. **zzz**
April 24, 2024

i like that Quanta magazine's graphic for AI-string theory excitement uses an image of an overhead projector. a classroom device that was used for ~20 years starting about 30 years ago.

10. **Peter Woit**
April 24, 2024

zzz,
From what I remember, overhead projectors are significantly older than that, but I guess the technology died right around the same time (late 80s) as the idea in the graphic that one could go from a Calabi-Yau to physics.

11. **Sabine**
April 24, 2024

Imagine how much worse this is going to get once we have widely available neural nets that can reliably be trusted to do maths. Theoretical physicists have created a research standard where maths being correct (more or less) is basically the only criterion for having a "scientific" theory and a publishable paper. Soon they'll be able to generate "theories" automatically and try to publish them.

Hey, GPT! Please come up with 5 new dark matter candidates that evade all existing bounds on direct and indirect detection but will show up in a muon collider at 500 GeV. Format for PRL.

Come to think of it, this might finally make them realize that this isn't how science works.

12. **Xirtam Esrevni**
April 24, 2024

"If you're a theorist interested in getting funding, obviously the thing to do was to pivot quickly from quantum computing to machine learning and AI, and get to work on the people at Quanta to provide suitable PR"

It wasn't just theorist, many software quantum computing companies did just this! Perfect example is Zapata Computing (https://zapata.ai) which pivoted to AI and then went public (ZPTA) this month; thankfully there stock has crumbled since the IPO.

The issue is you have both government and venture capital are so willing to through money at quantum computing and AI regardless of the use case or application.

13. **Mark Raugas**
April 24, 2024

Peter — we last saw each other when I came around to Columbia to talk about AI and math research my group was doing. It turns out I was at a recent Aspen workshop on this topic, with some of the people named in the article, so I thought I would share some thoughts.

I think in general, solving PDE using neural networks instead of traditional linear algebra solvers is interesting in a wide variety of areas in applied mathematics. The trained network becomes a numerical approximation to a solution to the PDE. This is typically called "Physics Informed Machine Learning" and has been around for some time.

I thought it was fun that the strings researchers were using these solvers to try to solve for Ricci flat metrics, purely from a mathematical standpoint, but I don't think it will solve the landscape problem, help define M theory, etc. Even if you could solve for all the classical complete intersection examples (they mention in the article that CY with large h_1,1 or h_2,1 they can't handle), you are very correct to point out the broader moduli space stabilization issues. But say one did have a library of these metrics, numerically evaluated, available as an oracle function. I wonder if that moduli problems somehow might become more tractable. It could be that a diffusion model could then find paths from one network to another (each representing a CY metric). A big problem would be in that case that a network has many more parameters than the input (like an image) and might be very expensive to train. Sampling from such a trained network, even if you could construct it, would yield candidate metrics on moduli space that would somehow have to be checked. I also wonder if you would not learn anything interesting. Say you train only on complete intersection CY examples, would you ever find a non-geometric example? I wonder if going down those trains of thought could be a distraction, ultimately.

Regarding AI, a person at the workshop asked "Why don't you just use a numerical PDE solver?" and the quick response was "That's too hard."

The speaker could dive into numerical PDE solvers if they had time, but it does point to a question regarding the democratization of technology. If the Python packages for contemporary machine learning are relatively easy to use, like Mathematica, and the older Fortran/C++ linear algebra solvers are hard to use, sociologically you will see people adapting themselves towards tools that are easier to use in their studies. That is an indirect product of hype — general hype around AI causes there to be economic investment in related infrastructure, and then the barrier to using related tools falls to the point where it is accessible outside the machine learning community. So people get herded into using those types of tools or approaches. This is not new.

14. **ab**
April 24, 2024

> I think in general, solving PDE using neural networks instead of traditional linear algebra solvers is interesting in a wide variety of areas in applied mathematics. The trained network becomes a numerical approximation to a solution to the PDE. This is typically called "Physics Informed Machine Learning" and has been around for some time.

Are there any rigorous results on the accuracy of these solutions? How do you know they're not just hallucinating?

15. **Magnatolia**
April 24, 2024

Has it been so common for physicists to pivot to AI in the last few years? I don't know any except Max Tegmark and Michael Douglas

16. **Alex**
April 24, 2024

New Witten interview here: https://youtu.be/PZ_qnBwSejE?si=K3HuWjpT2Bx33my8

Apparently, he wants to go back to the good old days of string theory in the 80s… which seems in line with this current hype about CY manifolds…

17. **Michael Weiss**
April 25, 2024

Returning to the past use of overhead projectors in teaching physics, the most creative example I experienced was due to the late Nobelist E.M. Purcell: he gave an entire lecture on an envelope, writing on the envelope, which was projected on the big screen. The subject of the class was "back of the envelope" calculations. I remember many Harvard freshmen laughing when Purcell set e =1 and pi = 1; Ed looked up in earnest dismay, stating that until one is prepared to due such approximate calculations, one is not ready to do physics. Perhaps the string theorists erred in not taking this maxim to heart?

18. **Eitan Bachmat**
April 27, 2024

ab,
There are sometimes, though not often, rigorous results, I would look at the work of Weinan from Princeton, a numerical analyst who now works on AI for solving differential equations, he has a talk at the recent ICM. In the direction of optimization and rigorous results, there are 2 NSF-Simons collaborations called MoDL (math of deep learning), I qould look mostly at the Berkeley centered one, led by Peter Bartlett. Usually results are on relatively simple models, but they are increasingly providing interesting insights. I would also consider the worka of Sanjeev Arora.

19. **Syksy Räsänen**
April 27, 2024

Magnatolia:

In cosmology alone, the latest conference on machine learning had over 400 participants: https://indico.iap.fr/event/1/

This talk by Guilhem Lavaux gives an overview of the kind of things machine learning is used for in cosmology: https://cloud.aquila-consortium.org/s/ELxwdMx43zXnNSz

20. **Magnatolia**
April 28, 2024

Syksy Räsänen, those kinds of applications make sense to me, but I was wondering more about physicists who have made a complete 180 like Tegmark, whose public profile is now based entirely on AI in the Silicon Valley style and whose papers are all like https://arxiv.org/abs/2209.11178. (Some of his AI papers are purportedly based in physics ideas, but as far as I can tell it's only advertising)

21. **Eitan Bachmat**
April 29, 2024

Magnatolia
Neural networks were studied by physicists as brain models and for optimization from the beginning, mainly in the statistical physics community and this continues tobl this day, some names are Hopfield, Amit, Sompolinski, Tishby, Zecchina, Montanari and there are many more. These researchers though are more on the academic side, trying to model the behavior of networks using a variety of techniques, out of equilibrium, bifurcation, spin glasses…
Those on the more commercial side usually would be found on wall street or silicon valley. Then, as pointed out, AI for exploring physics is becoming huge, with most applications, not in HEP, though analyzing CERN data would make a lot of sense.

Various and Sundry

April 28, 2024
Categories: Euclidean Twistor Unification, Langlands

The semester here is coming to a close. I'm way behind writing up notes for the lectures I've been giving, which are ending with covering the details of the Standard Model. This summer I'll try to finish the notes and will be working on writing out explicitly the details of how the Standard Model works in the "right-handed" picture of the spinor geometry of spacetime that I outlined here.

At this point I need a vacation, heading soon to France for a couple weeks, then will return here and get back to work. There may be little to no blogging here for a while.

On the Langland's front, Laurent Fargues is turning his Eilenberg lectures here last fall into a book, available here. In Bonn, Peter Scholze is running a seminar on Real local Langlands as geometric Langlands on the twistor-P1

Update: One more item. Videos of talks from a conference on arithmetic geometry in honor of Helene Esnault at the IHES last week are now available. Dustin Clausen's talk covers one of my favorite topics (the Cartan model for equivariant cohomology), making use of the new formalism for handling he has developed with Scholze for handling C-infinity manifolds in a more algebraic way.

Update: Now back from vacation. While I was away, Quanta made up for its nonsense like this with a very nice article about "Weil's Rosetta Stone" and what it has to do with geometric Langlands. In the comments people have pointed to the proof of geometric Langlands that has finally been finished, and New Scientist has an article (or see Edward Frenkel on Twitter here).

Comments

1. **Bernard l'Amateur**
   April 29, 2024

   Peter,

   I'm curious to know if there is a particular reason for which you're always coming to France for vacation during the summer. Are other European countries, like Germany, Switzerland, Spain, Italy, or even Britain or Australia not interesting to you? Is it always Paris your destination here in France? Is there a math or physics conference you wish to attend here in France? Also, don't you teach in the summer at your university? Do you have 3 months of vacation since the Fall semester there starts in September?

   Best,
   Bernard

2. **Peter Woit**
   April 29, 2024

   Bernard l'Amateur,

   I do travel a fair amount, for conferences or other reasons, have been to all the countries you mention in recent years, except Australia (have never been there, would very much like to go sometime). Paris is a favorite place to spend time in, for many reasons, including the fact that I partly grew up there. I usually don't go there during the summer, since that's when it's hot, full of tourists and all the actual Parisians have left town. This year in particular there's a very good reason not to be in Paris in the middle of the summer. This trip is not for a conference.

   I don't teach during the summer, but usually spend almost all of it in New York, which I enjoy, despite some periods when the heat/humidity is a bit much. It's not vacation, I work on some combination of my own research or writing projects and dealing with tasks associated with the department computer system that I'm responsible for. Also, lots of long bike rides.

3. **Marvin**
   April 30, 2024

   Hi Peter,

   Your are saying: "…including the fact that I partly grew up there". So are you fluent in french?

4. **Mark**
   April 30, 2024

   An update on the abc conjecture:

   Kirti Joshi has posted two responses to Peter Scholze and Shinichi Mochizuki about their criticisms of Joshi's proof of the abc conjecture:
   https://mathoverflow.net/a/470293

   The documents can be found directly here:

   https://www.math.arizona.edu/%7Ekirti/response-to-Mochizuki.pdf

   https://www.math.arizona.edu/%7Ekirti/local-global-issue.pdf

   The first document is directly addressed to Mochizuki himself, while the second document seems to be addressed to the general mathematical population.

   Section 0.3 of the second document looks crucial in my eyes, since it highlights what Joshi thinks the flaw is exactly in the proof of Mochizuki's original Corollary 3.12, and also in Joshi's proof of Theorem 9.11.1, which is his version of Corollary 3.12. According to Joshi, Mochizuki's proof of his Corollary 3.12 in IUT3 is incomplete because it relies upon Mochizuki's Corollary 2.2 in IUT4 being proven first, but Mochizuki never proved Corollary 2.2 in IUT4 before proving Corollary 3.12 in IUT3 in his set of papers.

   And as Joshi admits in the same section, he organized his Constructions papers in the same way that Mochizuki did, so that the two sets of abc papers can be compared. As a result, Joshi's Theorem 9.11.1 in Constructions 3 relies on Theorem 5.7.1 in Constructions 4 to be proven first, but he put Theorem 5.7.1 after Theorem 9.11.1, so there is a gap in Joshi's proof of Theorem 9.11.1.

What I'm not currently sure of is whether Joshi's proof of Theorem 5.7.1 in Constructions 4 also relies on Theorem 9.11.1 in Constructions 3 (and similarly if Mochizuki's Corollary 2.2 in IUT4 also relies on Corollary 3.12 in IUT3). If so, then there is a circular dependency which invalidates Joshi's proof and Mochizuki's original proof of the abc conjecture. If not, then Joshi should have valued logical correctness and logical completeness above following Mochizuki's evidently poor organization of Mochizuki's own proof outline, and put his proof of [Joshi's] Theorem 5.7.1 in Constructions 4 before his Theorem 9.11.1 in Constructions 3, so as to bridge the gap that is currently in his proof of Theorem 9.11.1 in Constructions 3.

5. **Alessandro Strumia**

The first of a series of five papers claiming to prove geometric Langlands is on the arxiv.

9. **Samuel**
May 9, 2024

Any reaction to the new proof of the geometric Langlands conjecture?

https://people.mpim-bonn.mpg.de/gaitsgde/GLC/

10. **kitchin**
May 9, 2024

Sam Raskin gave two talks available on Youtube outlining the proof, which is many hundreds of pages. The papers include clarifications of folklore, and the precise setting for previous results, so it should be a great contribution both in content and in documentation. He says the Betti analog is more beautiful, if I recall, and that there is room for more understanding in the general case. The abstracts of the four draft papers are fun to read, with the middle paper still under re-organization (five papers total).

* Harvard CMSA, on April 9
* IAS, on May 6, announcing the actual proof

They are similar talks.

11. **Jim Holt**
May 11, 2024

Peter, now that James Simons has died, would you consider writing up a brief blog entry on Chern-Simons theory and its potential role in quantizing gravity? This is, after all, JS's greatest achievement–much greater than out-investing Buffet and Soros. Yet it's almost impossible to explain. All the obits of Simons–like the ones today (5/11/24) on the front pages of the NY Times and the Wall St. Journal–allude to Chern-Simons in passing without further comment. I myself have a nugatory understanding of the theory, despite working through much of Baez & Muniain's book on gauge fields, knots, and gravity. Please enlighten us!

12. **Peter Woit**
May 11, 2024

Jim Holt,
On vacation without a keyboard so unable to do justice to Simons or Chern-Simons. Greetings from Montpellier!

13. **Jim Holt**
May 22, 2024

I enthusiastically second Edward Frenkel's suggestion (which might seem self-serving!) that a great place to learn how the Langlands program works is Frenkel's own book "Love and Math." His exposition of it there–especially geometric Langlands–is lively and quite beautiful.

14. **Cédric Bardot**
June 1, 2024

Incidentally here is a short inquiry to provide one reason why Paris looks like a paradise for mathematic(ian)s
This is a list of cities with the largest number of winners of the Fields medal:

Paris, France – 12 winners
Princeton, United States – 7 winners
Moscow, Russia – 6 winners
Cambridge, United Kingdom – 5 winners
Zurich, Switzerland – 4 winners
Berkeley, United States – 3 winners

Göttingen, Germany – 3 winners
Harvard, United States – 3 laureates
Kyoto, Japan – 3 winners
Stanford, United States – 2 winners
Warning:
I asked Chat Mistral AI to make the list. E “counted the number of Fields Medal winners who were affiliated with an institution in each city at the time of their award. It is possible that errors or omissions were slipped”.
Data source: https://www.mathunion.org/imu-awards/fields-medal/laureates.

Wormholes, Part Deux

May 27, 2024
Categories: Wormhole Publicity Stunts

I had thought that the universally negative reaction to the fall 2022 wormhole publicity stunt meant that we'd never hear more about this, with even the editors of Quanta magazine having understood that they'd been had. While away on vacation though, I learned from Dulwich Quantum Computing that all the authors of the original stunt are back, now claiming not just wormhole teleportation, but Long-range wormhole teleportation.

I'd also thought that no one at this point could possibly think it was a good idea to help these authors go to the public with their claims about creating wormholes in a lab. It seems though that this coming weekend if you're here in NYC you can buy tickets to listen to some of them explain in person

> the mind-bending speculation that we may be able to create wormholes—tunnels through spacetime—in the laboratory.

Comments

1. **Klaus**
   May 27, 2024

   Peter, is one or several of the authors Michio Kaku writing under a pseudonym?

2. **Peter Woit**
   May 27, 2024

   Klaus,
   I suppose Kaku might have decided that his credibility would be compromised if he claimed to have actually created a wormhole, so decided to write under a pseudonym, but that's "mind-bending speculation".

3. **B.Malpani**
   June 3, 2024

   Peter: just wondering: has there really been only one comment and your reply; or have there been additional comments that you've, uh, moderated?

   Just curious if this kind of hoax has, perhaps, been normalized.

4. **Peter Woit**
   June 4, 2024

   B. Malpani,
   Lots of moderated comments, basically people making worse jokes than the first one, or insulting the authors as morons (or me as a moron for mentioning their work).

   No substantive comments moderated out. Besides the authors likely no one out there is reading their work or willing to argue for it. Most physicists think this is nonsense, and not worth talking about (probably they're right…).

   I would be quite interested to hear from anyone who went to last weekend's event and could report on what happened there.

Strings 2024

June 4, 2024
Categories: Strings 2XXX

There's been very little blogging here the past month or so. For part of the time I was on vacation, but another reason is that there just hasn't been very much to write about. Today I thought I'd start looking at the talks from this week's Strings 2024 conference.

The weird thing about this version of Strings 20XX is that it's a complete reversal of the trend of recent years to have few if any talks about strings at the Strings conference. I started off looking at the first talk, which was about something never talked about at these conferences in recent years: how to compactify string theory and get real world physics. It starts off with some amusing self-awareness, noting that this subject was several years old (and not going anywhere…) before the speaker was even born. It rapidly though becomes unfunny and depressing, with slides and slides full of endless complicated constructions, with no mention of the fact that these don't look anything like the real world, recalling Nima Arkani Hamed's recent quote:

> "String theory is spectacular. Many string theorists are wonderful. But the track record for qualitatively correct statements about the universe is really garbage"

The next day started off with Maldacena on the BFSS conjecture. This was a perfectly nice talk about an idea from 25-30 years ago about what M-theory might be that never worked out as hoped.

Coming up tomorrow is Jared Kaplan explaining:

> why it's plausible that AI systems will be better than humans at theoretical physics research by the end of the decade.

I'm generally of the opinion that AI won't be able to do really creative work in a subject like this, but have to agree that likely it will soon be able to do the kind of thing the Strings 2024 speakers are talking about better than they can.

The conference will end on Friday with Strominger and Ooguri on *The Future of String Theory*. As at all string theory conferences, they surely will explain how string theorists deserve an A+++, great progress is being made, the future is bright, etc. They have put together a list of 100 open questions. Number 83 asks what will happen now that the founders of string theory are retiring and dying off, suggesting that AI is the answer:

> train an LLM with the very best papers written by the founding members, so that it can continue to set the trend of the community.

That's all I can stand of this kind of thing for now without getting hopelessly depressed about the future. I'll try in coming weeks to write more about very different topics, and stop wasting time on the sad state of affairs of a field that long ago entered intellectual collapse.

Update: The slides for the AI talk are here. The speaker is Jared Kaplan, a Johns Hopkins theorist who is a co-founder of Anthropic and on leave working as its Chief Science Officer. His talk has a lot of generalities about AI and its very fast progress, little specifically about AI doing theoretical physics.

Comments

1. **David Roberts**
   June 4, 2024

   > train an LLM with the very best papers written by the founding members, so that it can continue to set the trend of the community.

   Did anyone who consented to this being made public know anything about LLMs??

2. **Fred J**
   June 5, 2024

   As with many AI afficionados, these guys seem to have forgotten or, (more cynically) ignored the fact that even here, the "Garbage In, Garbage Out" principle still applies.

3. **Alessandro Strumia**
   June 5, 2024

   The first talk, by Montero, addresses the key issue but its conclusions look scientifically unserious: «There's constantly new stuff going on. It's extremely exciting… We can chart the String Landscape and find where we are in it» should be replaced with «If the string landscape has ≈ 10^500 vacua we have no idea how to find if we are in it, we got stuck, it's extremely frustrating».

4. **hrdlifil**
   June 5, 2024

   It is not true that there has been nothing to blog about. I would be extremely interested in a post about the recent proof of geometric Langlands.

5. **Felix**
   June 5, 2024

   Almost as depressing as the LLM bit is the idea that the 'founding members' should have anything to do with guiding the future direction of the field. I can't think of any other subject where you could say something like that with a straight face.

6. **Peter Woit**
   June 5, 2024

   hrdlifil,
   The problem with writing about the geometric Langlands proof is that I don't know much about it, and lack the time/energy it would take to learn enough to write something useful. Here is where I need guest bloggers…

7. **Peter Woit**
   June 5, 2024

Fred J.,
What's remarkable about the string theory community is that they seem quite happy with the subject's turn to producing what Arkani-Hamed identifies as garbage, to the point of finding an automated system for producing greater amounts of garbage an attractive vision for the future.

Felix,
The idea seems to be to find someway to get around Planck's insight into scientific progress ("one funeral at a time").

8. **jim**
June 5, 2024

training LLMs and then ask them to theorize about strictily quantitative aspects is not going to lead anywhere. LLMs are pretty bad in quantitative reasoning, at least not as good as in text-related queries.

For the matter at hand, string theory and more purely theoretical subjects with deep math background, it's completely hopeless to do so. And I am sure that some people have already attempted that, feeding pdfs massively about a subject and ask questions about it. At least I did.

Also check this Nature paper:
https://www.nature.com/articles/s42254-023-00581-4
(Science in the age of large language models)

9. **PeterO**
June 5, 2024

"train an LLM with the very best papers written by the founding members, so that it can continue to set the trend of the community"

I echo the sentiment of David Roberts.

I do not understand physics enough to judge or criticise string theory. I do know about LLMs. I am in shock at the stupidity of that statement. My secondary reaction is: oh, how I'm feeling now is maybe how it has felt for you all for the past 20+ years.

10. **Cobi**
June 5, 2024

Note that Yuji Tachikawa, who is behind the question and, presumably, also the corresponding hint " Train an LLM …" has a penchant for humorous paper titles and/or acknowledgements (see e.g. 1508.06679 or the acknowledgements in 1312.2684 and 2203.16689). I am pretty sure that the suggestion to train a language model on some papers was really just a joke.

11. **David Roberts**
June 5, 2024

@Cobi

that's what I hope. It undermines what I guess is the point of the document, and given that other people are talking, in total sincerity, about AI exploring the Landscape as a way to move forward, a worrying thought that people might take it seriously.

The work I respect the most on the mathematics underlying the hypothetical M-theory (divorced from any judgement about its relation to our universe), has been such that it could not have been extrapolated from "the very best papers written by the founding members, so that it can continue to set the trend of the community."

12. **Alessandro Strumia**
June 6, 2024

Cobi, surely the Tachikawa question is just a joke, but organisers wrote "100 questions… all of them very interesting" instead of selecting really interesting questions. That's the problem.

13. **Douglas Natelson**
June 6, 2024

I don't understand how anyone can claim that LLMs as they are currently implemented can really lead to serious progress in something like theoretical physics when they manifestly are incapable of even elementary quantitative understanding. Show me a single LLM that correctly answers the question "Which weighs more, one pound of feathers or two pounds of hammers?". The latest enterprise-level ChatGPT (along with every other one I've tried) says that they weigh the same, because that question is *almost* the same wording as a famous "trick" question. When LLMs can't reliably produce the accurate statement that two is greater than one, forgive me for not having much faith that they will produce deep insights into quantum gravity.

14. **Cobi**
June 6, 2024

I didn't mean to suggest that Yuji's question was a joke, just the corresponding hint. Whether the questions should have been further curated by the organisers is i guess a matter of taste. If the purpose was to have an open brainstorming session, then not making a preselection is kind of the point.

15. **Meng**
June 6, 2024

@Douglas GPT4 answered it correctly: "Two pounds of hammers weigh more than one pound of feathers. Two pounds is always heavier than one pound, regardless of what the items are."

16. **Peter Woit**
June 6, 2024

Douglas Natelson,

I don't think the question is whether LLMs will produce deep insights into quantum gravity, but whether they can do what current string theorists are doing as well or better. "Insights into quantum gravity" is not what we're getting from current string theory research, take a look at the talks at Strings 2024 to see what we are getting.

String theorists are already claiming to use LLMs to do original string theory research, in particular setting them to work on calculating things involving huge numbers of constructions of supposed string vacua and approximations to Calabi-Yau metrics. Kaplan's talk would have been more interesting if he looked at this sort of thing and where it is going. Such calculations are part of Arkani-Hamed's "garbage", and LLMs are already happily doing them. That they will soon (if not already) be able to do them better and faster than human string theorists is quite plausible. LLMs should also be able to use the corpus of tens of thousands of worthless string theory papers to get as good as humans at generating and publishing papers, at writing grant proposals and getting them funded.

In addition, there's a huge amount of money out there looking for "AI" projects to fund, and a huge appetite from science journalists like those at Quanta for stories about the wonders of how AI will lead to great research progress.

I wish Kaplan had been talking about these topics rather than the more generic topics he chose.

17. **Peter Woit**
June 6, 2024

About the Tachikawa question, see this exchange on twitter

https://x.com/AlessandroStru4/status/1798631213168840956

I think Tachikawa is (seriously) motivated by a very real problem for string theory that Strumia points to. The generation of the "First Superstring Revolution" was trained in real physics and did their formative research in QFT, but those trained from 1984 on often skipped lightly over this and their formative years were spent mastering technical issues in string theory. I've become increasingly pessimistic that theorists who start their career with that kind of training will ever do anything other than keep working down the blind alley they were sent down at the beginning of their career.

Worse than this is that the past 20 years or more of string theorists should have been well aware that this was a dead or dying field that hadn't worked out, but decided to devote their lives to it anyway. The whole subject has gone from attracting smart intellectually ambitious young people with the talent to work on promising new ideas to attracting instead intellectually ambitious young people unable to see the difference between a promising new idea and a failed one.

18. **Douglas Natelson**
June 6, 2024

@Meng, google's Gemini got it right, after I posted. Mea culpa. GPT via enterprise-level Bing Copilot got it wrong as of this morning. Perplexity got it wrong last night and gets it correct this morning. Interesting.

@Peter, I have no doubt that certain rote-like calculations (keep grinding through order by order diagrams, where there are patterns in what is being done) could be automated well. LLMs are already quite good at spitting out python code for common tasks based on what they've scraped from github. Still, fundamental lack of math literacy has to be a showstopper for many points of interest to physicists. Anyway, enough out of me.

19. **Erich Weiss**
June 6, 2024

The explosion of new data and observation in cosmology, and theory papers resulting from it seems very promising and interesting. The work on the cosmological constant, candidates for dark matter, gravity from entanglement, etc seems quite interesting.
Much more interesting than the dead horse named String Theory.

20. **Brett Smolenski**
June 6, 2024

The notion of training current LLM architectures on theoretical physics papers and expecting anything serious to emerge is laughable; however, the notion of using an approach similar to what was done with AlphaFold, but to search for 'compactifications of string theory to get real world physics', doesn't seem unreasonable. IF such a search could be made exhaustive and came up empty, wouldn't this falsify string theory? At least it seems it would be much better to have a machine spinning its wheels doing this than physicists.

21. **Peter Woit**
June 6, 2024

Brett Smolenski,

You don't need AI to investigate the question of whether string theory makes any predictions about the real world. Just ask any of the experts working in the field. This experiment has now often been done, with the result that the honest answer is simply no. The people working on this know there are no predictions, they just believe that there's still some hope of a breakthrough which would lead to predictions.

You will sometimes find people claiming that there are predictions. In all cases though either the people doing this don't know what they're talking about, or are using a non-standard meaning for "prediction". Vafa for example these days often claims that string theory makes "predictions", but he also says that if the "prediction" turns out to be wrong it doesn't mean that there's anything wrong with string theory.

22. **Anon**
June 7, 2024

Hi Peter,

Just want to say thank you. I was an advanced theoretical physics undergrad a few years ago hoping to do string theory as research (spurred on by Brian Greene's highly irresponsible book). Your blog (and your book) made me realise the sad state of affairs in the string theory community (as exemplified in Strings 2024) and I switched to math. Now, every time that I see the status of string theory now, I want to thank you.

23. **bitboy**
June 7, 2024

Researcher in over-hyped, speculative physics pivots to researcher in over-hyped subset of AI and now claims that the latter will magically help with the former! You can't make this stuff up.

24. **Bob Y**
June 7, 2024

"LLMs should also be able to use the corpus of tens of thousands of worthless string theory papers." This statement includes a serious threat to advancement of scientific knowledge unless existing policies of citation of copyrighted materials are enforced.

LLMs do not credit original sources for learning materials that are protected by copyrights. The citation of previous work provides three benefits: 1. Potential verification or indictment of the validity of source material; 2. Credit for prior work to scholars who depend upon such credit for general reputation enhancement including promotions and grants. 3. Credit to professional societies and publishers for providing outlets for the original research work.

25. **Eric Weinstein**
June 7, 2024

Not to worry. I asked ChatGPT to speak in what it takes to be the voices of Susskind, Witten, Kaku, Motl and others regarding String Theorists' past pronouncements on the advantages of String Theory over all other approaches.

Here are the results:

———————-

ChatGPT:

"Your approach to quantum gravity is so outdated, it belongs in a history book, not a physics journal."

"Comparing your theory to String Theory is like comparing a horse-drawn carriage to a spaceship—quaint, but hopelessly obsolete."

"If your theory had any less predictive power, it would be a random number generator."

"You know, your work might have merit—in an alternate universe where String Theory doesn't dominate."

"Your calculations are charmingly quaint, like a child's attempt to explain the cosmos with crayons."

"String Theory has elegance, beauty, and predictive power. Your theory has… well, it exists, I suppose."

"I haven't seen this many dead ends since the last maze I solved. Have you considered taking up puzzles instead of physics?"

"Your attempts at a unified theory are like a high school science project compared to the grandeur of M-Theory."

"In the realm of theoretical physics, String Theory is a symphony. Your work, I'm afraid, is just background noise."

"M-Theory is the only game in town, and it looks like you're still trying to figure out the rules of checkers."

———-

Well, while I may prefer the originals, by November, this should be much closer. And, it's not that far off now of what we have to show for 41 years of String Theoretic leadership in fundamental physics.

26. **tulpoeid**
June 8, 2024

@ Bob Y,

We humans also don't cite the textbooks and papers we've read to become proficient in a field. There is nothing wrong with this.

27. **Peter Woit**
June 8, 2024

See Scott Aaronson's blog for a link to another argument that we're just a very few years away from AI going "superintelligent". Thinking again about Brett Smolenski's comment, maybe the way things will work out is that superintelligent AI will not crank out more garbage research, but quickly reach the conclusion that string theory is a failed research program not worth pursuing. If that happens, what will be the reaction of the (human) physics research community?

Before that happens, AI should be able to resolve some simpler questions about part of the string theory research program, such as
1. Is the string theory landscape just pseudoscience?
2. Does the "Swampland Program" make any sense at all?

From the last bit of Strings 2024, it seems the situation is that there will be a Strings 2025 in January in Abu Dhabi, but no one yet has stepped up to organize a Strings 2026. Maybe it won't be necessary?

28. **Stipe Galić**
June 9, 2024

Reading this Woits piece, I had a flashback to the famous Bogdanov affair, where a PhD thesis on quantum gravity of questionable quality was approved and defended. An advisor who approved the thesis topic said: 'All these were ideas that could possibly make sense. It showed some originality and some familiarity with the jargon. That's all I ask.' LLMs are excellent at 'familiarity with the jargon'. Feeding AI hype into the string machine? Sounds like a lot of funding.

29. **John Baez**
June 10, 2024

Sadly that person was Roman Jackiw. I imagine he was back-pedalling furiously.

30. **bob**
June 17, 2024

@Smolensky: "an approach similar to what was done with AlphaFold, but to search for 'compactifications of string theory to get real world physics', doesn't seem unreasonable."

But you can test (in vitro/cristallography/ect) the results of AlphaFold.
And the fortune of AlphaFold (now AlphaFold3) is that is very very close to wetlab results.

31. **zzz**
June 17, 2024

alphafold and the protein structure problem is different , there are many thousands of solved proteins to learn from. in string theory there is nothing like that.

The Mystery of Spin

June 13, 2024
Categories: Uncategorized

The following makes no claims to originality or any physical significance on its own. For a better explanation of some of the math and the physical significance of the use of quaternions here, see this lecture by John Baez.

I've been spending a lot of time thinking about spinors and vectors in four dimensions, where I do think there is some important physical significance to the kind of issue discussed here. See chapter 10 here for something about four dimensions. A project for the rest of the semester is to write a lot more about this four-dimensional story.

Until recently I was very fond of the following argument: in three dimensions the relation between spinors and vectors is very simple, with spinors the more fundamental objects. If one uses the double cover $SU(2)=Spin(3)$ of the rotation group $SO(3)$, the spinor (S) and vector (V) representations satisfy
$$ S\otimes S = \mathbf 1 \oplus V$$
which is just the fact well-known to physicists that if you take the tensor product of two spinor representations, you get a scalar and a vector. The spinors are more fundamental, since you can construct V using S, but not the other way around.

I still think spinor geometry is more fundamental than geometry based on vectors. But it's become increasingly clear to me that there is something quite subtle going on here. The spinor representation is on $S=\mathbf C^2$, but one wants the vector representation to be on $V_{\mathbf R}=\mathbf R^3$, not on its complexification $V=\mathbf C^3$, which is what one gets by taking the tensor product of spinors.

To get a $V_{\mathbf R}$ from V, one needs an extra piece of structure: a real conjugation on V. This is a map
$$\sigma:V\rightarrow V$$
which

- commutes with the $SU(2)$ action
- is antilinear
$$ \sigma(\lambda v)=\overline{\lambda}\sigma(v)$$
- satisfies $\sigma^2=\mathbf 1$

$V_{\mathbf R}$ is then the conjugation-invariant subset of V.

If we were interested not in usual 3d Euclidean geometry and $Spin(3)$, but in the geometry of $\mathbf R^3$ with an inner product of $(2,1)$ signature, then the rotation group would be the time-orientation preserving subgroup $SO^+(2,1)\subset SO(2,1)$, with double cover $SL(2,\mathbf R)$. In this case the usual complex conjugations on $\mathbf C^2$ and $\mathbf C^3$ provide real conjugation maps that pick out real spinor ($S_{\mathbf R}=\mathbf R^2\subset S$) and vector $(V_{\mathbf R}=\mathbf R^3\subset V=S\otimes S)$ representations.

For the case of Euclidean geometry and $Spin(3)$, there is no possible real conjugation map σ on S, and while there is a real conjugation map on V, it is not complex conjugation. To better understand what is going on, one can introduce the quaternions $\mathbf H$, and understand the spin representation in terms of them. The spin group $Spin(3)=SU(2)$ is the group $Sp(1)$ of unit-length quaternions and the spin representation on $S=\mathbf H$ is just the action on $s\in S$ of a unit quaternion q by left multiplication
$$s\rightarrow qs$$
(we could instead define things using right multiplication).

There is an action of $\mathbf H$ on S commuting with the spin representation, the right action on S by elements $x\in \mathbf H$ according to
$$s\rightarrow s\overline{q}$$
(this is a right action since $\overline {q_1q_2}=\overline q_2\ \overline q_1$).

This quaternionic version of the spin representation is a complex representation of the spin group, since the right action by the quaternion $\mathbf i$ provides a complex structure on $S=\mathbf H$. While there are no real conjugation maps σ on the spin representation S, there is instead a quaternionic conjugation map, meaning an anti-linear map τ commuting with the spin representation and satisfying $\tau^2=-\mathbf 1$. An example is given by right multiplication by $\mathbf j$
$$\tau (q)=q\mathbf j$$
Note that in the above we could have replaced $\mathbf i$ by any unit-length purely imaginary quaternion and $\mathbf j$ by any other unit-length purely imaginary quaternion anticommuting with the first.

In general, a representation of a group G on a complex vector space V is called

- A real representation if there is a real conjugation σ. In this case the group acts on the σ-invariant subspace $V_\mathbf R\subset V$ and V is the complexification of $V_\mathbf R$.
- A quaternionic representation if there is a quaternionic conjugation τ. In this case τ makes V a quaternionic vector space, in a way that commutes with the group action.

Returning to our original situation of the relation $S\otimes S= 1 \oplus V$ between complex representations, S is a quaternionic representation, with a quaternionic conjugation τ. Applying τ to both terms of the tensor product the minus signs cancel and one gets a real conjugation σ on V.

What's a bit mysterious is not the above, but the fact that when we do quantum mechanics, we have to work with complex numbers, not quaternions. We then have to find a consistent way to replace quaternions by complex two by two matrices when they are rotations and and complex column vectors when they are spinors (so $S=\mathbf C^2$ rather than $\mathbf H$).

In my book on QM and representation theory I use a standard sort of choice that identifies $\mathbf i,\mathbf j,\mathbf k$ with corresponding Pauli matrices (up to a factor of i):
$$1\leftrightarrow \mathbf 1=\begin{pmatrix}1&0\\0&1\end{pmatrix},\ \ \mathbf i\leftrightarrow -i\sigma_1=\begin{pmatrix}0&-i\\ -i&0\end{pmatrix},\ \ \mathbf j\leftrightarrow -i\sigma_2=\begin{pmatrix}0&-1\\ 1&0\end{pmatrix}$$
$$\mathbf k\leftrightarrow -i\sigma_3=\begin{pmatrix}-i&0\\ 0&i\end{pmatrix}$$
or equivalently identifies
$$q=q_0 +q_1\mathbf i +q_2\mathbf j + q_3\mathbf k \leftrightarrow \begin{pmatrix}q_0-iq_3&-q_2-iq_1\\q_2-iq_1 &q_0 +iq_3\end{pmatrix}$$

Note that this particular choice incorporates the physicist's traditional convention distinguishing the 3-direction as the one for which the spin matrix is diagonalized.

The subtle problem here is the same one discussed above. Just as the vector representation is complex with a non-obvious real conjugation, here complex matrices give not $\mathbf H$ but its complexification
$$M(2,\mathbf C)=\mathbf H\otimes_{\mathbf R}\mathbf C$$

Note added: complexified quaternions are often called "biquaternions"
The real conjugation is not complex conjugation, but the non-obvious map
$$\sigma (\begin{pmatrix}\alpha&\beta \\ \gamma & \delta\end{pmatrix})= \begin{pmatrix}\overline\delta &-\overline\gamma \\ -\overline\beta & \overline\alpha \end{pmatrix}$$

Among mathematicians (see for example Keith Conrad's Quaternion Algebras), a standard way to consistently identify $\mathbf H$ with a subset of complex matrices as well as with $\mathbf C^2$, (giving the spinor representation) is the following:

- Identify $\mathbf C\subset \mathbf H$ as
$$z=x+iy\in \mathbf C \leftrightarrow x+\mathbf i y \in \mathbf H$$
- Identify $\mathbf H$ as a complex vector space with $\mathbf C^2$ by
$$q=z +\mathbf j w \leftrightarrow \begin{pmatrix}z\\ w\end{pmatrix}$$
Note that one needs to be careful about the order of multiplication when writing quaternions this way (where multiplication by a complex number is on the right), since
$$z+w\mathbf j= z+\mathbf j\overline w$$
- Identify $\mathbf H$ as a subset of $M(2,\mathbf C)$ by
$$q=z +\mathbf jw \leftrightarrow \begin{pmatrix}z&-\overline{w}\\ w& \overline z\end{pmatrix}$$

  This is determined by requiring that multiplication of quaternions in the spinor story correspond correctly to multiplication of an element of $\mathbf C^2$ by a matrix.

  With this identification
$$\mathbf i\leftrightarrow \begin{pmatrix}i&0\\ 0&-i\end{pmatrix},\ \ \mathbf j\leftrightarrow \begin{pmatrix}0&-1\\ 1&0\end{pmatrix},\ \ \mathbf k\leftrightarrow \begin{pmatrix} 0&-i\\ -i&0\end{pmatrix}$$

  This is a bit different than the Pauli matrix version above, but shares the same real conjugation map identifying $\mathbf H$ as a subset of $M(2,\mathbf C)$.

Update: There's a very new video here, where Keith Conrad discusses quaternions, especially the case of quaternion algebras over $\mathbf Q$ and their relation to quadratic reciprocity.

   June 13, 2024

   I have been following this series called "Spinors for Beginners" and they are up to video 20 in the series which covers the Lorentz Group. It's good background information to help me understand the spinor topics in your blog posts.

   https://www.youtube.com/watch?v=tztQrSRF_Ds&list=PLJHszsWbB6hoOo_wMb0b6T44KM_ABZtBs&index=21

2. **peter cameron**
   June 13, 2024

   Peter – You open your remarks with
   "…the fact well-known to physicists that if you take the tensor product of two spinor representations, you get a scalar and a vector. The spinors are more fundamental, since you can construct V using S but not the other way around."

   In geometric representation of Clifford algebra, wavefunction interactions can be modeled by the Clifford product, sum of dimension-reducing dot and dimension-increasing wedge products. So product of two vectors is scalar plus bivector, where bivector is what i think you are calling a spinor. This seems to be the inverse of what you say.

   In geometric representation of Clifford algebra, product of two bivector spinors is scalar plus quadvector. No one-dimensional vector there.

   Please can you explain to me how our perspectives seem inverted in this?

3. **Garrett Lisi**
   June 14, 2024

   The dance between spinors and biquaternions makes an appearance in a recent short paper I wrote, "C, P, T, and Triality." I would send you the hep-th arXiv link but the paper has been "on hold" for five weeks now. This is especially annoying since I don't think there's anything technically wrong with the paper. I strongly suspect one or more arXiv moderators just doesn't like me or my work so I'm getting special treatment.

4. **David Roberts**
   June 14, 2024

   @Garrett

   why not also host it elsewhere until then so people can see it?

5. **Garrett Lisi**
   June 14, 2024

   The arXiv is where it belongs, and the most reasonable place people would see it and possibly cite it. If they reject it, which I see no good reason for, maybe I'll retract all my papers in disgust.

6. **Peter Woit**
   June 14, 2024

   Garrett,

   Sorry to hear that. I hope anyone reading this who is in the good graces of the arXiv moderators will contact them to ask them to fix this.

   I'll also add to the posting what I should have originally had there, that "biquaternions" is a standard name for the complexification of the quaternions.

7. **Peter Woit**
June 14, 2024

Peter Cameron,
A bivector is not a spinor.
What I'm writing about in this posting is specific to 3d, but there's a very general story explaining what you bring up, simplest in even dimensions.

In dimension d=2n, the Clifford algebra (which includes vectors, your bivectors, etc), when complexified (allow complex coefficients) is isomorphic to the matrix algebra $M(2^n,\mathbf C)$. Spinors are column vectors $\mathbf C^n$ that these matrices act on. More invariantly, the Clifford algebra is the algebra of linear transformations of the spinor space S.

What you can build out of vectors is not spinors, but linear transformations of spinors. Since the linear maps on S are isomorphic to the tensor product $S\otimes S^*$, the general story is that (in even dimensions) the spinors are not something you can build out of vectors, but a "square root" of what you can build out of vectors (the complexified Clifford algebra).

8. **David Roberts**
June 14, 2024

@Garrett

I'm not saying don't keep pushing to get it on the arXiv, I'm saying pop it on your own website for now (or somewhere, anywhere, public), so that people can judge for themselves the content of the paper, now that you've just advertised it on a widely-read blog…. By doing nothing you're giving the arXiv moderation process the power to keep the paper out of sight.

9. **Garrett Lisi**
June 14, 2024

@David
Very well, I've made it available here:
https://deferentialgeometry.org/works/CPTaT.pdf

10. **flippiefanus**
June 15, 2024

"I still think spinor geometry is more fundamental than geometry based on vectors."
There is a subtlety with this notion that has frustrated me for a long time. It is the fact that the formulation of geometry in terms of vectors allows shift invariance (because there is nothing physically special about the choice of the origin), while the formulation in terms of spinors does not seem to make shift invariance so apparent. The choice of origin is somehow encoded into the associated spinors that cannot be so easily accessed. Perhaps you know of a way around this problem.

11. **Peter Woit**
June 15, 2024

flippiefanus,

Yes, vectors are essentially the same as shifts, they generate translations (momentum is a vector). If you define vectors in terms of spinors, nothing changes about translations. But if you express your vectors in terms of spinors (e.g. as matrices), you have some new things. In particular you have the Dirac operator, which is a vector, but acts on spinors.

In the usual discussion, the Dirac operator is written $D=\gamma^\mu \frac{\partial}{\partial x_\mu}$ which looks like it is a scalar. It really is a vector though…

12. **Robert Wilson**
June 16, 2024

To a mathematician, a spinor is not an element of C^2, but an element of H. Then you have absolutely no problem getting a real vector out of the square of the spinor, because you take the quaternionic tensor product of two 1-dimensional quaternion representations, which is automatically a 4-dimensional real representation.

13. **Robert A. Wilson**
June 16, 2024

The main problem, I think, with regarding a spinor as living in C^2 rather than H, is that it picks out a particular direction of spin as being somehow special. The question then is, which direction is it? This is not an easy question to answer. But it is an important question to ask. So I don't understand why physicists try to insist that it isn't a question.

14. **Peter Woit**
June 16, 2024

Robert A. Wilson,
If you're doing QM with spin, you need to have a complex state space. In particular, if you want to couple to EM, you need a distinguished choice of how the complex numbers act. I do suspect there's a mystery there.

15. **Robert A. Wilson**
June 16, 2024

Yes, I agree there is a bit of a mystery there – why does the mathematical symmetry of the quaternions need to be broken to C^2 to describe observed physics? There is no doubt that it does need to be broken, but why? And how?

16. **GS**
June 18, 2024

I think there are typos in your definition of "antilinear". I think it should be
\sigma (\lambda v) = \bar{\lambda} \sigma (v)

17. **Peter Woit**
June 19, 2024

GS,
Thanks! fixed.

18. **Peter Woit**
June 19, 2024

    testing

19. **akhmeteli**
June 30, 2024

    Peter Woit,

    "A bivector is not a spinor."

    For what it's worth, according to E. Cartan, The Theory of Spinors (Dover, 1981), Section 154, in the space of special relativity, "the semi-spinor is, then, the polarised bivector". See also E.T. Whittaker, On the relations of the tensor-calculus to the spinor-calculus. Proc. Roy. Soc. A 158, 38–46 (1937).

20. **Peter Woit**
June 30, 2024

    akhmeteli,
    The Whittaker reference makes clear that this is about the Klein correspondence, which is at the basis of the idea of twistors.
    What's going on is you can identify the Grassmannian of complex two planes (the half-spinor space at a point) in complex four dimensions (twistor space) with the space of two-forms satisfying a particular equation. So, yes, you can relate spinors to certain two form ("bivectors"). But, spinors are not bivectors, this is about special complex bivectors, and is very special to four dimensions.

Latest Breakthrough From String Theory

June 19, 2024
Categories: This Week's Hype

PRL has just published this paper (preprint here), with associated press release here. The press release explains that the authors have discovered how to use string theory to provide "an easier way to extract pi from calculations involved in deciphering processes like the quantum scattering of high-energy particles."

The press release has led to stories here, here and here, as well as commentary from Sabine Hossenfelder.

As for applications of this, the press release refers to Positron Emission Tomography, while one of the stories linked above gives the more modest explanation of what this is good for:

> The series found by IISc researchers combines specific parameters in such a way that scientists can rapidly arrive at the value of pi, which can then be incorporated in calculations, like those involved in deciphering scattering of high-energy particles, the release said.

Update: This just gets more and more idiotic as the press stories multiply. India Today now has Indian physicists untangle new pi series that could change maths forever. It would be helpful if the people who issued this press release had some sense of shame and had it withdrawn.

Comments

1. **PHL**
   June 19, 2024

   "The series found by IISc researchers combines specific parameters in such a way that scientists can rapidly arrive at the value of pi, which can then be incorporated in calculations".

   Is this serious? A new series for pi is interesting, especially if it converges significantly faster than any other series already known for pi. But, the comment above is ridiculous.

2. **Peter Woit**
   June 19, 2024

   PHL,
   There's no claim this converges faster than any other known series. I suspect these series are not something really new, they are not being published in a math journal where relevant experts would have looked at such a claim.

3. **HJM**
   June 19, 2024

   I think it does not converge faster than the Chudnovsky algorithm.
   To get 10 decimals of pi:
   – Chudnovsky series: 1 term
   – Series from the string theory paper: roughly 10 terms

4. **David Roberts**
   June 19, 2024

   That's painful.

5. **SM**
   June 20, 2024

   The precise claim made in the preprint (p. 9) is that the new series converges faster than the Madhava series for pi. Nowhere in the paper has it been claimed that it converges faster than all known algorithms.

   https://en.wikipedia.org/wiki/Leibniz_formula_for_%CF%80

6. **NoGo**
   June 20, 2024

   From one of the stories:

   "He added that there have been many derivations of formulae over time. The formula the team has found is close to what was found by Indian mathematician Sangamagrama Madhava, which was written in the 15th century, in a poetic language."

   So what exactly that team discovered? (Apart from a 15-century poem). What they broke through?

7. **clueless_postdoc**
   June 20, 2024

   It seems the calculation of \pi is just something they fed to the press story to attract the public's attention to this work, and many statements written by the press seem quite silly. Would anyone from the field mind commenting on the significance of the paper (and why it's accepted by PRL – presumably not because they managed to calculate \pi)

8. **Peter Woit**
   June 20, 2024

   clueless_postdoc,

   An excellent question, I was wondering the same. Seems mystifying why this was accepted by PRL, ignoring the pi nonsense.

Another question about PRL. They encourage people to issue press releases when a paper is published, but do they ever do anything when authors issue press releases misrepresenting what PRL published?

9. **Will Orrick**
June 21, 2024

The press coverage is cringeworthy, but ridiculing the work without looking at isn't terribly informative. The authors seem to have series for zeta(2) and pi that contain a free complex parameter. In other words, within the radius of convergence the values of the series are independent of the parameter. When the parameter is specialized to a particular value, each series reduces to a classical form: in the case of zeta(2) taking the parameter to zero gives the series of the Basel problem; for pi taking the parameter to infinity gives the Madhava series (a specialization of the series expansion of the arctan function). The classical series are extremely slow to converge. For other values of the parameter convergence can be vastly faster, but still, apparently, very slow relative to the state of the art. Whatever the significance of these series may be, it's probably not going to be in numerical analysis.

I find it very hard to tell with these kinds of things whether the result is new, but it very well could be. Every person listed in the paper's acknowledgments section appears to be a physicist, so it's not clear whether the authors reached out to any mathematicians prior to publishing.

10. **Peter Woit**
June 21, 2024

Will Orrick,
I did read the paper, and it's ridiculous. The fact that they have written down a series for zeta(2) depending on a complex parameter is not in itself anything interesting. There's zero evidence this series is any kind of advance in analytic number theory (much less one that "could change maths forever"), since there's zero evidence that they bothered to consult with anyone who knows anything about analytic number theory.

11. **Concerned Indian mathematician**
June 21, 2024

India at the moment is hyper-nationalistic, so such exaggerated news coverages aren't uncommon (in fact they are extremely common). So this coverage by Indian media is mostly a stance towards exaggerating Indian contributions to science (in the sense that the scientists are Hindus working at an Indian university rather than a foreign one.)
This is not to say that there aren't other legitimate contributions by Indians to the Sciences, but India Today is well know to be biased twards the hypernationalism mentioned above.

12. **Martin**
June 22, 2024

They say that they can deduce the identity for zeta(2), but they don't show how they did it. They also say that for lambda=0 the expression becomes the usual series for zeta(2), but it seems undefined for lambda=0.

13. **AnotherMartin**
June 23, 2024

I don't see what the problem with this is. It doesn't appear to me that they are claiming that this finding will revolutionize anything. If you think that it belongs to a hallway chat rather than an online publication, then I agree. But perhaps the same goes for this mockery of their work?

14. **kodlu**
June 26, 2024

Good followup on mathoverflow

https://mathoverflow.net/questions/473931/possible-new-series-for-pi

and mathstackexchange

https://math.stackexchange.com/questions/4937730/is-the-new-series-for-a-big-or-even-medium-deal

15. **Timothy Chow**
June 26, 2024

I was the one who posted on MathOverflow, asking if the series is new. It's a little soon to say for sure, but Jesús Guillera is one of the people I would think would recognize the series if it were known, and he didn't recognize it. I agree with Will Orrick's sentiment. There's no reason to react either positively or negatively to the hype; one should just ignore that, and evaluate the mathematical result on its own merits. The formula is not particularly suited for computation, but it could be interesting for other reasons that remain to be discovered.

By the way, "analytic number theory" is probably not quite the right keyword for this type of thing. "Transcendental number theory" is closer, but the experts who are most likely to recognize such a formula are those with an interest in experimental mathematics, high-precision computation, and infinite series. Or possibly special functions.

16. **Protomon**
June 27, 2024

Concerned Indian mathematician, is there reason to think there's a particular 'Hindutva' angle behind this and that it's not just the usual failing of the scientific press? I know Hindutva has successfully pushed many ahistorical narratives on math and science history into schools and popular thought, but in general I thought contemporary research is very under-emphasized by the Hindutva movement/current Indian government.

17. **Peter Woit**
June 28, 2024

All,
I've deleted most of the incoming comments that want to argue about the current situation in India, probably should have deleted anything referring to this at all, will do so in the future.

18. **Anonymous**
July 3, 2024

Some discussion here as well –

https://youtu.be/rGd7Db52w1Q?si=rs7kP1WuHSMt40FU

19. **Timothy Chow**
July 19, 2024

The YouTube channel Numberphile has just posted an interview with Sinha and Saha.

https://www.youtube.com/watch?v=2lvTjEZ-bbw

In light of some of the discussion here, it's worth pointing out that starting at 8:35, they mention that they consulted various mathematicians prior to publication, including Terence Tao.

20. **Peter Woit**
July 19, 2024

Timothy Chow,

What they actually say is that they consulted one mathematician, a friend of theirs (he supposedly consulted others, including Terry Tao), and he hadn't seen the formula. Also evidently they put a question on math stack exchange (after the paper had been submitted for publication) which no one responded to, see https://math.stackexchange.com/questions/4876995/parametric-representation-of-the-euler-beta-function-zeta-functions-and-pi

They also admit that a lot of the press coverage was nonsense, but take no responsibility at all for the misleading press release that was issued in their name and the nonsense that was in it (they say the press release was the idea of their dean, not theirs).

21. **Timothy Chow**
July 22, 2024

Peter, what exactly in the press release itself (as opposed to subsequent stories that were written based on the press release) do you consider to be nonsense? I see you mention PET, but PET is mentioned only as an example of an application of some theoretical ideas by Dirac that he did not expect to have applications. There is no claim that their own work has practical applications, to PET or anything else; quite the opposite. I don't see anything in the press release (at least regarding pi) that I consider to be "nonsense," and I feel confident that Sinha and Saha stand behind it (in contrast to your claim that they "take no responsibility at all" for it). Also you made a comment that you suspect that the series is not new, but the evidence so far (from MathOverflow) seems to be that it is new. Finally, you said that there's "zero evidence" that they consulted with anyone, which may have been true at the time you made the comment, but we now know that they did consult with at least one person who then consulted with others.

22. **Peter Woit**
July 22, 2024

Timothy Chow,
About what is nonsense, I addressed that already in the posting:
1. "an easier way to extract pi from calculations involved in deciphering processes like the quantum scattering of high-energy particles."
Besides being confusing, the "easier way to extract pi" claim is simply nonsense intended to mislead the reader.
2. Bringing positron emission tomography into it is complete nonsense, again, intended to mislead.

Another example:
3. "The series that Sinha and Saha have stumbled upon combines specific parameters in such a way that scientists can rapidly arrive at the value of pi, which can then be incorporated in calculations, like those involved in deciphering scattering of high-energy particles."
This is complete nonsense: the signficance of a a new series for pi is that you can calculate pi more quickly which helps your scattering amplitude calculations????
Whoever wrote it had no understanding of what they were writing. It reappears in lots of the press stories.

As for whether the series is "new", I can take any known series for pi, do a random transformation of variables and get a "new" series for pi. The question is whether it's "new" in an interesting way. I'm guessing also that the question of whether the series is interesting is more relevant for the series they write down for the zeta function, where the reason for interest in such a series is clearer (very unclear why a series for pi is interesting, other than the technical reason of faster convergence, which isn't a reason here).

The "zero evidence" they consulted anyone statement was accurate. Now a more accurate statement would be that they only consulted one person (Apoorva Khare), who had no expertise on such series expansions. Note that they thanked a lot of people in the acknowledgements, not including Khare. I'm guessing they only asked him about this after the paper was submitted (like the question on stack exchange).

I don't know what evidence you have that these two "stand behind" the press release. In the video here's their explanation of how it happened
"When the paper got published we sent it to our divisional chairman and director, both of whom are mathematicians. Both of them had good things to say, especially our divisional chairman. He said that we should actually make a press release focusing on pi so that's how this story centered around pi originated. I don't think it would have actually occurred to either of us to actually try to sell to the lay person that "look, we found a new formula for pi"."
He's very explicitly saying "this kind of publicity seeking is not something I would do, I did it because my divisional chairman told me to". There's also a lot of discussion about how much of the press coverage was misinformation. The obvious question of why that happened isn't addressed in the interview. The obvious answer is that the press coverage was misinformation because the press release was misinformation.

23. **Timothy Chow**
July 22, 2024

Peter,

It seems obvious to me that Sinha and Saha stand behind their press release, because in the interview they had ample opportunity to disavow or repudiate it, but they didn't. (It seems you agree with me that they didn't repudiate the press release, since their non-repudiation is one of your complaints.) True, the press release wasn't their idea in the first place, and they had mixed feelings about the reaction, but they never retracted anything they said, or said they wish they hadn't done it. But I won't continue to debate the point; if we really care, we could contact Sinha and Saha directly and ask them whether they stand behind their press release.

The things you call "nonsense" seem to me to be par for the course when it comes to science journalism. Perhaps I'm just more tolerant than most scientists on this score. In the long run, I find that the hyper-critical attitude toward science journalism that is so common in the scientific community amounts to shooting ourselves in the foot. For example, I disagree that "bringing positron emission tomography into it is complete nonsense." It's no more nonsense than saying, in response to whether a new theorem in number theory has practical applications, that there are currently no known applications, but that G. H. Hardy once boasted that number theory has no applications and yet much number theory has found applications in cryptography. Bringing up G. H. Hardy and cryptography is cliched, but it's not nonsense.

As for the series for pi itself, I take the attitude that much of mathematics amounts to the search for hidden structure. Any new identity involving a fundamental constant is potentially the tip of some iceberg, a small hint that some large undiscovered structure lies hidden beneath the surface. Chasing down such hints doesn't always work out, of course, but it's a pretty good heuristic. As an analogy, my Ph.D. thesis advisor Richard Stanley once wrote a survey paper on log-concave and unimodal sequences in algebra, combinatorics, and geometry. I used to be puzzled why people would invest so much effort into studying, and trying to prove, unimodality. What's so interesting about a unimodal sequence? It was only later that I understood that unimodality is usually interesting not so much for its own sake, but because it is so often a sign of interesting structure that lies hidden beneath the surface. Stanley doesn't make this "iceberg" claim explicitly in his paper, but if you read his survey with this thought in mind, then the examples he discusses provide ample evidence for icebergs.

Returning to identities for pi, there are boatloads of identities for pi that have been discovered empirically, and I think one would have to be a diehard skeptic not to believe that there must be some underlying theory that explains why these identities exist. In many cases, the identities are either unproved or the only known proof is a "mechanical" proof using the WZ method. These identities may not be so interesting for their own sake, but they are begging for an explanation (note that "explanation" and "proof" are not synonymous). A big reason why Ramanujan has had such an enduring legacy is that so many of his discoveries (including formulas involving pi) have pointed the way to previously unsuspected mathematical structures.

The Sinha-Saha identity was surprising to several of the experts who saw it on MathOverflow. I therefore take it as a working assumption that there is an iceberg, until someone shows otherwise.

Physical Intuition vs. “Math”

June 29, 2024
Categories: Uncategorized

A common theme in discussions online of the problems of fundamental theoretical physics is that the subject has gotten “lost in math”, losing touch with “physical intuition”. In such discussions, when people refer to “math” it’s hard to figure out what they mean by this. In the case of Sabine Hossenfelder’s “Lost in Math” you can read her book and get some idea of what specifically she is referring to, but usually the references to “math” don’t come with any way of finding out what the person using the term means by it. Here I’ll mostly leave “math” in quotation marks, since the interesting issue of what this means is not being addressed.

“Physical intuition” is also a term whose meaning is not so clear. Sometimes I see it used in an obviously naive way, referring to our understanding of the physical world that comes from our everyday interaction with it and the feeling this gives us for how classical mechanics, electromagnetism, thermodynamics work. Some people are quite devoted to the idea that this is the way to understand fundamental physics, sometimes taking this as far as skepticism about subjects like quantum mechanics.

Usually though, the term is not being used in this naive sense, but as meaning something more like “the sort of understanding of physical phenomena someone has who has spent a great deal of time working out many examples of how to apply physics theory, so can use this to see patterns and guess how some new example will work out”. This is contrasted to the person lacking such intuition, who will have to fall back on “math”, in this situation meaning writing down the general textbook equations and mathematically manipulating them to produce an answer appropriate for the given example, without any intuitive understanding of the result of the calculation. This is what we expect to see in students who are just learning a new subject, haven’t yet worked out enough examples to have the right intuition.

If the question though is not how to apply well understood fundamental theory to a new example, but how to come up with a better fundamental theory, I’d like to make the provocative claim that “physical intuition” is not going to be that helpful. New breakthroughs in fundamental theory have the characteristic of being unexpectedly different than earlier theory. The best way to come up with such breakthroughs is from new experimental results that conflict with the standard theory and point to a better one. But, what if you don’t have such results? It seems to me that in that case your best hope is “math”.

Here’s a list of the great breakthroughs of fundamental physics in the 20th century, with some comments on the role of “physical intuition” and “math”.

- **Special relativity**: According to physical intuition, if I’m emitting a light ray and speed up in its direction, so will the the speed of the light ray. The crucial input was from experiment (Michelson-Morley), which showed that light always travels at the same speed. Finding a sensible theory of mechanics with this property was largely “math”.
- **General relativity**: There’s a long argument about the role of “math” here, but I think the only way to develop “physical intuition” about curved spacetime is to start by learning Riemannian geometry (which Einstein did).
- **Quantum mechanics**: Here again, a crucial role was played by experimental results, those on atomic spectra. A large part of the development of the subject was applying “math” to the mysterious spectra for which there was zero “physical intuition”. Later on, a better understanding of the theory and better calculational methods involved bringing in a large amount of new “math” to physics, especially the theory of unitary representations of groups.
- **Yang-Mills theory**: This was pretty much pure “math”: replacing a U(1) gauge theory by an SU(2) gauge theory.
- G**ell-Mann’s eight-fold way**: Pure “math”.
- **The Anderson-Higgs mechanism**: The funny thing here is that Anderson did get this out of “physical intuition”, based on what he knew from superconductivity. Particle theorists ignored him (especially when it came time for a Nobel Prize), and their papers about this were often mainly “math”, more specifically argumentation about how the mathematics of gauge symmetry could give a loophole to a theorem (the Goldstone theorem).
- **The unified electroweak theory**: Looks to me more like “math” than “physical intuition”.
- **QCD and asymptotic freedom**: David Gross famously had the “physical intuition” that the effective coupling grows in the ultraviolet for all QFTs, based on experience with a wide range of examples. He set a mathematical problem for his student (Frank Wilczek), and when the “mathematics” was finally sorted out, they realized the usual physical intuition for QFTs had to be replaced by something completely different.

Making a list instead of the great disasters of 20th century theoretical physics, there’s

- **Supersymmetry**: OK, this one is “math”. I suspect though that the problem here is that the “math” is not quite right, but missing some other needed new ideas.
- **String theory**: As we’re told in countless books and TV programs, this starts with a new “physical intuition”: instead of taking point particles as primitive objects, take the vibrational modes of a vibrating string. Developing the implications of this certainly involves a lot of “math”, but the new fundamental idea is a physical one (and it’s wrong, but that’s a different story…).

Comments

1. **lun**
   June 29, 2024

   Let’s expand some of these a little bit though:
   Special relativity–>Logic shows that relativity (the Galilean kind) is in conflict with electromagnetism and Galilei’s transformations, intuition shows the third must go and be substituted by something that respects the first two, math was used to derive that.

   General Relativity–>Logic shows gravity must be updated to take special relativity into account and the most naive implementation will break the equivalence principle, intuition says the equivalence principle is fundamental and one must find a way to preserve it, logic and some thought experiments (Ehrenfests’s paradox) say that because of time dilation this inevitably involves Riemannian geometry, maths follows

   Quantum mechanics—>Experiment gives funny results, intuition shows that to explain them one needs some seemingly counter-intuitive ansatze (Bohr’s momentum quantization, the photoelectric effect), which are then progressively systematized using more and more sophisticated maths.

   Yang Mills/Gell-mann/Electroweak theory—>Intuition shows that perhaps it is worth to extent the techniques we used to classify spin to systems where there seem to be approximate degeneracies analogous to spin (isospin/strangeness), group theory follows.
   Intuition also guided the analogy between strong and weak isospin

   Asymptotic freedom—->Before Gross there was the parton model, with a mix of intuition and phenomenological maths by Feynman,Bjorken etc showing that “partons” weakly coupled at high Q^2 exhibit the sort of scaling seen experimentally.

   Higgs—>The necessity of renormalizability follows the deeply intuitive work of Wilson, through there is quite a lot of sophisticated maths to connect this to Gauge symmetry.
   The result that a theory broken by the Higgs mechanism is still renormalizeable is intuitive (the Higgs is in the IR, gauge symmetry needs to operate in the UV) but needs a lot of sophisticated maths to prove.

   In each case intuition has a crucial role in selecting what math to pick. The set of consistent mathematical systems is almost certainly infinitely larger than the set of consistent mathematical systems relevant to physics. So it is an interplay between the two.

2. **Anonyrat**
June 29, 2024

The path integral, Feynman diagrams, the Parton model are more physical intuition than math.

Rohrlich, F. The unreasonable effectiveness of physical intuition: Success while ignoring objections. Found Phys 26, 1617–1626 (1996).
https://doi.org/10.1007/BF02282125

Abstract

The process of theory development in physics is a very complex one. The best scientists sometimes proceed on the basis of their physical intuition, ignoring serious conceptual or mathematical objections well known to them at the time.The results soon justify their actions: but the removal of these objections is often not possible for a very long time. Four examples are presented: Newton, Schrödinger, Dirac, Dyson. Some thoughts on this “unreasonableness≓ are offered.

4. **anon**
June 29, 2024

Why are you acting like these are mutually exclusive? It’s clear to me that new ideas always come from a combination of qualitative and quantitative reasoning, in support of each other.

Einstein had the qualitative ideas that led to General Relativity in mind long before he learned Riemannian geometry. He also said that “every true theorist is a kind of tamed metaphysicist.” The taming here is the translation of qualitative insight (“physical intuition”) into quantitative form (“math”).

June 30, 2024

“Steven Weinberg, who was awarded a Nobel Prize for unifying the electromagnetic and weak interaction, likes to make an analogy with horse breeding: “[The horse breeder] looks at a horse and says “That’s a beautiful horse.” While he or she may be expressing a purely aesthetic emotion, I think there’s more to it than that. The horse breeder has seen lots of horses, and from experience with horses knows that that’s the kind of horse that wins races.”

But like experience with horses doesn’t help when building a racing car, experience with last century’s theories might not be of much help conceiving better ones. ”

That’s a quote from my book “Lost in Math” to say I agree with you.

6. **flippiefanus**
June 30, 2024

This is a topic close to my heart. It can be called “physics vs formalism”. In my view, there has never been a successful *unguided* venture into theory space (like string theory) . None of the successful examples that you discussed were unguided. Their advent took place within the context of observed problems revealed by experiments, often amidst several competing theories at the time. Even with general relativity: Einstein spent a long time pondering the problem, considering everyday examples (like a man falling from a window) to build up his “physical intuition,” until he came up with the equivalence principle. Only then did he venture into math, guided by this principle.

7. **Jim Baggott**
June 30, 2024

“Math” v “physical intuition” is surely about choosing a strategy when confronted with a challenging problem in theoretical physics. The choice obviously depends on the background and experiences of the chooser, and history shows that there is no ‘best’ choice. The real issue is the potential (or lack thereof) for a proper interplay between theory and experiment. All the examples of successful theoretical developments, no matter what strategy was adopted, involve experiment, because experiment in physics is the arbiter of ‘success’. In the cases of supersymmetry and string theory, these are unsuccessful either because these approaches make no contact with experiment, or because the ‘predictions’ they have made have simply not be upheld by experiment. The more substantial issue then arises from theorists justifying their continued commitment to an unsuccessful theory by seeking to change the definition of ‘success’.

8. **Nikita**
June 30, 2024

Doesn’t the canonical history of general relativity involve a rather “naive” form of physical intuition? “I am falling in an elevator”, “I am moving on a rotating disk”, etc.

9. **Paddy**
June 30, 2024

Pardon me for being facetious but many years ago I decided that “intuition” is just a word one uses for a body of knowledge learned so deeply and so many years ago that one doesn’t recall not knowing it. E.g., much of at least non-rel. QM seems superficially to be intuitive to me–which is patently ridiculous.

10. **Erin**
June 30, 2024

This is a fascinating topic but I come down on the other side. Quantum mechanics, SR and GR were all driven by physical observation and intuition. “Math” was the available tool to be used. If math was dominant, Hilbert would have figured out GR.

11. **Peter Woit**
June 30, 2024

Nikita,
Yes, it somehow has become “canonical history” that “math” wasn’t important, that Einstein figured out general relativity by using his physical intuition to think through what happens when you fall in an elevator. Enough of this kind of dubious argument about GR. If someone wants to point to a serious discussion of the topic, that fine. Otherwise, enough of that.

12. **Scott Aaronson**

June 30, 2024

After years of talking with physicists, I concluded with some amusement that when they said “physical intuition,” they just meant “guesses of which math to use for physics problems, whenever the guesses turn out to be correct.” 😀

13. **Peter+Shor**
June 30, 2024

To talk about a somewhat different field, statistical mechanics, Giorgio Parisi won the Nobel Prize in part for inventing the replica method. This is a case where it seems to me that the math is completely broken, but the physical intuition works anyway. But there’s not “no math”. There’s lots of equations, but none of them can be justified rigorously.

It seems to me that papers with few equations, but lots of hand-waving about physical intuition, are likely to be completely wrong.

14. **Eric+Weinstein**
June 30, 2024

This is a great idea for a post Peter.

I worry that the term ‘math’ is being used for two very different things: Geometric vs Analytic thinking.

Likely the term ‘Physical intuition” is also being bound to two very different ideas: Constructing Lagrangians vs Unpacking Lagrangians.

And, oddly I think these two subdivisions are mirroring each other. A mathematician trained in Geometry is often much closer to a Field Theorist trying to develop new Lagrangians than (s)he is to most hard core analysts. There are very things that separate mathematical from physical intuition in such cases but there are a few. In particular the concept of what is geometrically natural is slightly different to what is physicalliy natural in a Lagrangian. The “Mexican Hat Potential” quartic potential is obviously geometrically awkward as is the Yukawa Coupling as are the CKM/PMNS matrices. They come from experiment, but they don’t correspond to natural fiber bundle theory that mathematicians would stumble upon. Yet they are natural enough to a field theorist who might not see why the Yang-Mills term is incredibly more geometrically natural because the field theorist may believe that renormalizability is the proxy for naturality.

Conversely, the mathematical analyst might be more focused on keeping control of infinities in mathematical work while the perturbation/regularization/renormalization concerns mirror those in analysis need to keep infinities from spoiling everthing. Yet this is often about unpacking Lagrangians rather than constructing them.

This leads to two related but distinct concepts of elegance and beauty. I have never understood the argument that String Theory is beautiful…but at least I’d like to think I know WHY I don’t understand it. It is because it is largely based on a mathematics problem that doesn’t strike me as the way forward: “How do we treat the metric so that it doesn’t blow up or misbehave when added to the field content to be quantized?” That is really an analysis question to my mind which drags in a lot of geometry kicking and screaming. So you end up with beautiful geometric objects like Calabi-Yau manifolds but for very weird and often ugly reasons.

Ultimately, I think that what we are struggling with here is four quadrants: geometry, model building and phenomenology, QFT, and hardcore analysis on manifolds. We are looking for beautiful geometry to become a compelling natural Lagrangian. That is two quadrants. Then it will need to be unpacked by QFT types to discern what degrees of freedom would be observed at our effective energy scales. And that in turn would need to be made into rigorous analysis to be fully satisfactory. What I don’t understand is why those of us who base oursevels in one of these quadrants or the other too often try to discount those in the other three. It just seems totally self-defeating. One man’s opinion.

15. **Robert James Parkinson**
June 30, 2024

Perhaps a slight aside, but as far as I can tell “the math” means anything one does not have a really good intuition about.

And it’s not just physicists who talk this way either. Ask any (well-educated) person on the street what an average is and they’ll explain it in plain English with clarity and precision. Ask them about standard deviation and you’ll get a slightly muddier answer.

Ask them about the third moment of a random variable, and they’ll tell you that for something like that you gotta do the math.

So “math” seems to be the psychological state where one starts manipulating equations with pen and paper and knowledge in the hands begins to take over from knowledge in the mind.

Just my theory.

16. **Peter Woit**
June 30, 2024

Robert James Parkinson,
I put “math” in quotation marks because I think different people mean different things by it. That it is often getting used by non-mathematicians to mean “stuff I don’t really understand” sounds right.

I like a lot Scott Aaronson’s observation that “physical intuition” often doesn’t mean a non-mathematical understanding of a problem but does mean knowing what the right mathematical understanding of the problem is. To me the big problem of finding a way forward in fundamental theory is exactly that of finding the right mathematics. Mathematics is a set of languages and tools for using these languages, we need to identify which of these is needed to make progress. Eric Weinstein’s comment is along similar lines, with a specific proposal, mine would be different.

17. **Gavin**
June 30, 2024

Wow this is a wildly out of touch point of view of how physics is done.

To a physicist, “the math” means doing a formal calculation from first principles. There’s often an implication that the calculation is being done with a high degree of generality.

Working physicists often think it’s not a good idea to only use “the math” when doing real world problems. There’s a famous quote by Wheeler: “Never make a calculation before you know the answer.” There are a variety of *heuristic techniques* that physicists use to get a feel for the answer, including:
* Dimensional analysis
* Knowledge of relevant experimental results

* Experience with related calculations
* Knowing that the calculation must reproduce some known result as a special case
* Toy models

In fact, I don't think this heuristic mode that physicists use is particularly different from what mathematicians use; I think it is quite analogous to what Terry Tao refers to as the "post rigorous" stage of mathematics: https://terrytao.wordpress.com/career-advice/theres-more-to-mathematics-than-rigour-and-proofs/

Trying to find "a general solution" to some equation without a *physical question* motivating the endeavor is a classic path to getting lost in equations and not deriving insight from them.

In terms of finding new theories, I think all of your examples can be reframed in terms of a physical motivation. For example, Einstein's paper on special relativity starts by talking about how it is strange the current produced in a coil of wire moving relative to a magnet has two apparently different explanations in two different reference frames. This motivated him to take equations discovered earlier by Poincaire and others (whether or not he was actually aware that they were previously discovered) and *interpret* them physically in terms of various thought experiments, making them manifestly relevant for physics. Of course math still has a role, especially when it expands our conceptual understanding — like when Minkowski reinterpreted the Poincaire transformations in terms of spacetime geometry. But even then, the benefit of Minkowski's work was not blindly applying a formalism, but developing new ideas that allowed us to reinterpret existing results in a new framework where different intuition can be applied.

In reality, research is messy, and I think all tools and points of view are needed. But I think the way your article is framed that all discoveries in the 20th century are based on "math" and string theory is based on "physical intuition" is unabashedly political and not a serious attempt to understand the philosophy of science.

18. **Peter Woit**
June 30, 2024

Gavin Storm,
I think you're missing the point of my posting. It was specifically an intentionally provocative argument against the idea that, in a situation where current theory doesn't apply and you don't have any experimental guidance, the way forward is "physical intuition", not "math". I often hear this in discussions of the current lack of progress in fundamental physics ("the problem is that the string theorists are doing math, not using physical intuition"), and I think it's completely wrong-headed.

You're arguing about something completely different, about whether one should start trying to solve a problem with heuristic methods or with a rigorous formal calculation. Of course both mathematicians and physicists generally start with the first, later move on to the second.

My argument is about what heuristic method you should use. Should you look to the mathematical tools you have successfully used in the past (your built up "physical intuition") or should you look for new tools? The best example of the ones I gave in the posting might be the Gell-Mann one. He and everyone else stared a long time at the patterns of strongly interacting states they were seeing, not recognizing any pattern they were used to or anything that fit the mathematical tools they had in hand. He finally got around to talking to a mathematician who told him about the representations of SU(3), giving him a new mathematical tool that explained the patterns.

In the context of string theory, some people argue that it failed because, seduced by Witten, string theorists went out and adopted all sorts of new mathematical tools not previously useful in physics. I think it failed for a different reason: it was a completely wrong heuristic idea based on picking a wrong physical system (the vibrating string) as starting point.

19. **Bob Y**
July 1, 2024

I started my career as a theoretical high energy physicist and am now an experimental biological physicist. I have published in major refereed journals in both fields. I find Jim Baggot's comment above to be especially relevant and cogent. A simple question is always "What are the experimental data?" that either do or do not validate any "conclusion(s)" coming from math or physical intuition. Experiment is always the final arbiter in science although math, physical intuition as well as experiment can interact along the way to a final determination. Peter your last entry gives some very cogent examples relevant to both Baggot's comment and what I try to express.

20. **Peter Woit**
July 1, 2024

Bob Y,
The question I'm interested in is that of research in areas where there is no experimental evidence to interact with. Should theoretical quantum gravity research, for instance, be described as "not physics" because there is no experiment to interact with?

21. **Kirk**
July 2, 2024

The thing that really bugs me is people acting as if mathematics has nothing to do with intuition, therefore if there is any intuition at all, it must be physical intuition.

I've thought about this often, mostly in bafflement before I realized other people were defining 'math' very differently from me. To me, mathematics is just being incredibly careful and precise with your logical relationships (as even 'true/false' can be mapped to 0/1, partially true to some other number or a tensor, etc), so that even if you use different definitions from other people they'll still be able to follow your steps *because you defined your terms*; like how 'field' can mean two different technical things, the mathematical kind and the physics kind.

Intuitions about geometry are inherently intuitions also about math, they're not two separate things. The problem is the space of possible geometries in math is much wider than in physics, so usually, some guidance from the real world is useful.

However, this will break down in domains where we cannot even in principle do an experiment. From there, we will need mathematics: specifically, metamathematics of how different axiom systems relate to each other and why one might get 'picked out' as the more 'inertial' or 'equality preserving' of the two. But what I say here by 'mathematics' and what someone else hears when I say it may be two different things, and lead to an ugly and ultimately pointless argument: if you think mathematics is only calculations, you are not going to be thinking about all the work (axioms) that has to go in before you ever get to calculations so much.

22. **Peter+Shor**
July 3, 2024

If theoretical quantum gravity research is "not physics", it's hard to see what else it could be. It certainly isn't rigorous enough to be called "mathematics". I suppose a case could be made for it being "nonsense", but I think this is much too pessimistic (although it's true for some current theoretical quantum gravity research).

23. **Robert Cochrane**
July 4, 2024

Thank you for promoting and sympathetically moderating such an interesting and wide ranging discussion, as you previously did on Sabine Hossenfelder's piece about academic life.

First, intuition. I see this as a subconscious, unwritten and often unverbalised collection of prior knowledge which can be called on when action is needed and there is no specific data and no time to collect data. The more specialised the individual and the more typical for him or her the problem, the more reliable it becomes.

It is not reliable in new situations, merely a guide to a possible starting point. But in research situations it may save a lot of time by suggesting a first line of attack (e.g. an appropriate mathematical framework) based directly or subconsciously on previous experience. The analysis and calculations still need to be done and the approach may be unsuccessful. In this sense, it applies to math as well as physics – there are many famous conjectures which have been disproven.

On your examples, first, special relativity. Einstein's original 1905 paper on special relativity was entitled (in translation) "On the electrodynamics of moving bodies". Einstein's father ran an electrical business and the young Albert was fascinated by Maxwell's Equations, later saying that his predecessor was not Newton but Maxwell. His intention was to resolve a problem of asymmetry in the application of the equations. Special Relativity is just Part I of the paper.

He also refers but only in passing to the failure of experiment to show "motion of the earth relative to the light medium". He later said he knew of the M&M experiments but had not read the paper. As to math, there is nothing in his paper beyond the reach of a high school math graduate and the basic calculations are simple.

Next, general relativity. This is far more complex story and impossible to summarise briefly and accurately. The first steps taken by Einstein and others were the extension of special relativity to include special cases of accelerating frames and objects which do not require general relativity. Einstein wished to extend it to arbitrary accelerating frames and gravity and proposed using the principle of general covariance, which extends invariance of physical laws to arbitrary differentiable coordinate transformations and is in many ways was a natural extension of SR.

He did not have the mathematical knowledge to do this and sought help from an earlier classmate and friend, Grossmann, who pointed him towards tensors and the Ricci tensor in particular and assisted him with the math. But Grossmann believed, in error, in 1913 that the resulting mathematical framework for general relativity did not lead asymptotically to Newtonian gravity and they went round in circles for two years before returning to the 1913 tensor approach in 1915.

The basic mathematical framework needed was already in existence, but Einstein needed Grossmann to point it out, and even then, there were major difficulties in its application and finding solutions in practical circumstances, with initially erroneous predictions for key tests.

Leaving aside quantum mechanics and particle physics, your final question is whether research should be described as "not physics" if there is no experimental evidence. My view is quite conventional – research should be either explanatory of existing phenomena (i.e. based on data, even if only qualitative) or should lead to testable predictions. Its mathematical basis should as far as possible be well founded; this is usually the case, the problem is finding the right structure and adapting it to the application. Both special and general relativity did just that.

24. **Per Östborn**
July 14, 2024

Peter,

Referring to your exchange with "Nikita", I don't see why the involvement of a naïve form of physical intuition in the history of general relativity would imply that math wasn't important.

In this context, the essential thing to me is to identify the spark that inspires the pursuit of a theory. It may very well be naïve physical intuition even though the formulation of the theory itself requires a lot of math, possibly even novel mathematical ideas.

I don't know if the following counts as pointing to a serious discussion of the topic, as you requested, but I'll give it a try. Sparks of inspiration are personal, so we have to listen to the physicists themselves.

Einstein described in a lecture in Kyoto in 1922 how "the luckiest thought" of his life came to him in 1907 (Physics Today 35(8) pp. 45-47, 1982):

"The breakthrough came suddenly one day. I was sitting on a chair in my patent office in Bern. Suddenly a thought struck me: If a man falls freely, he would not feel his weight. I was taken aback. This simple thought experiment made a deep impression on me. This led to the theory of gravity."

Similarly, special relativity had been brewing in Einstein's mind since his teenage years (Autobiographical notes, Open Court, 1949):

"After ten years of reflection such a principle resulted from a paradox upon which I had already hit at the age of sixteen: if I pursue a beam of light with the velocity c (velocity of light in a vacuum), I should observe such a beam of light as a spatially oscillatory electromagnetic field at rest. However, there seems to be no such thing, whether on the basis of experience or according to Maxwell's equations. From the very beginning it appeared to me intuitively clear that, judged from the standpoint of such an observer, everything would have to happen according to the same laws as for an observer who, relative to the earth, was at rest. For how, otherwise, should the first observer know, i.e., be able to determine, that he is in a state of fast uniform motion? One sees that in this paradox the germ of the special relativity theory is already contained."

When it comes to the development of new fundamental theory, I would say that such sparks or general ideas are necessary. It is not enough to search for a mathematical framework that can accommodate new experimental results, it seems to me.

Michelson and Morely did their experiments in the 1880s, and mathematical efforts to account for the lack of aether drag began immediately, via Fitzgerald contractions and the like. However, Einstein's relativity postulate was necessary to jump from ad hoc theories to a new mechanics based on general principles that allowed the derivation of a lot of other, seemingly unrelated results.

I would say that the history of quantum mechanics is similar. Decades of experimental results that deviated from the predictions of classical physics were accounted for in an array of phenomenological mathematical models. However, it was not until the work of Heisenberg and Schrödinger that a single, coherent theory emerged that could be used to derive a lot of new predictions. And Heisenberg and Schrödinger both seem to have been inspired by simple, general ideas.

The abstract of Heisenberg's groundbreaking paper from 1925 reads in its entirety (Über quantentheoretische Umdeutung kinematischer und mechanischer Beziehungen, Zeitschrift für Physik 33(1) pp. 879–893, 1925):

"The present paper seeks to establish a basis for theoretical quantum mechanics founded exclusively upon relationships between quantities which in principle are observable."

He goes on to write:

"It is well known that the formal rules which are used in quantum theory for calculating observable quantities such as the energy of the hydrogen atom may be seriously criticized on the grounds that they contain, as basic element, relationships between quantities that are apparently unobservable in principle, e.g., position and period of revolution of the electron."

Schrödinger had a different angle of attack. He was inspired by de Broglie's matter waves and seems to have fallen in love with the idea that continuously interacting waves is the substrate for the entire physical world. In the last paper before those that define wave mechanics, Schrödinger wrote (On Einstein's gas theory, Physikalische Zeitschrift 27 pp. 95–101, 1925):

"This means nothing other than to be serious about the De Broglie–Einstein wave theory of moving particles according to which these are nothing but a kind of 'foam crest' on a fundamental radiation wave."

The relativity postulate is a metaphysical principle that goes deeper than the apparent constancy of the speed of light. Heisenberg's strict epistemic ansatz in his 1925 paper predicates and goes beyond the choice to express mechanics by means of non-commuting matrices. Schrödinger's (presumed) idea that 'everything is waves' is more far reaching than the Schrödinger equation.

I think new such general ideas are needed to spark further development of fundamental physics. They don't have to be entirely correct to be fruitful. Whether Heisenberg's epistemic approach is appropriate is a matter of philosophical taste. Schrödinger's vision of waves was clearly insufficient. Newton's idea that space and time are absolute is wrong, but it was nevertheless immensely fruitful, of course, since it allowed the expression of the relations between all objects by means of their individual coordinates, the evolution of which could be expressed with differential equations.

Could the same be said about string theory? Could there be something to its mathematical structure even though the basic physical intuition about the "vibrational modes of a vibrating string" is misguided? If so, could the theory have been developed without this idea?

Sorry for the length of this comment, and for repeating lots of standard material. I guess my point is to defend "physical intuition". However, I would like to rephrase it as "metaphysical intuition", meaning intuition about which general principles describing the physical world are fruitful guides in the formulation of fundamental physics.

"Metamathematical intuition" is surely also needed, understood as intuition about which mathematical structures and requirements are fruitful for the same purpose. Dirac's equation seems to have been the result of such intuition, for example.

25. **Sebastian**
July 17, 2024

All theories in physics, including those mentioned in the post, are based on intuition, almost by definition. It is not possible to develop a correct and entirely new physical theory purely through rigorous formal derivation without incorporating one's perception of the phenomenon in question. Importantly, this perception pertains to one's understanding of the phenomenon rather than the phenomenon itself. When developing a new hypothesis, one's understanding cannot be guided by the not-yet-existing theory and, therefore, must be intuitive.

I (respectfully) believe that the examples provided by the author are misinterpreted and treated in an ahistorical manner. The most striking example is that of special relativity. The Lorentz transformation and related mathematical formalism were indeed derived years before Einstein's article through symmetry-based considerations of Maxwell's theory. However, it was Einstein's understanding of the important (non-mathematical) principle of relativity, particularly his intuition of time and distance as measured with clocks and rulers, that constituted the actual breakthrough. This breakthrough (a) changed our conceptual understanding of reality and (b) inspired further development of vast mathematical formalism beyond the Lorentz transformation. Notably, Einstein's discovery did not rely on the Michelson-Morley experiment, as the validity of the principle of relativity was not dependent on the existence of aether.

I believe the greatest breakthrough in our understanding of nature came from a physicist who had limited knowledge of and mistrusted mathematics: Sir Michael Faraday. Faraday introduced the concept of a "field" purely through intuition, departing from the idea of action-at-a-distance along straight lines (Newton's description of physics with ordinary differential equations) and instead proposing a "medium" and curved "force lines." This led to Maxwell representing physics with partial differential equations. Theorists often overlook that field theory, the foundation of our understanding of fundamental forces, was introduced by Faraday through his meticulously conducted and brilliant experiments on electromagnetism. Faraday's discovery process contradicts the author's statement: "The best way to come up with such breakthroughs is from new experimental results that conflict with the standard theory and point to a better one." Faraday did not have a "standard" theory to compare to, nor did he attempt to understand existing mathematical theories. Instead, he built a consistent conceptual framework of electric and magnetic force by formulating hypotheses about reality and testing them experimentally. He was able to extrapolate his non-mathematical ideas to make claims about the electromagnetic nature of light without experimental methods to prove it or any mathematical formalism. Learning about Faraday's story could teach many theorists a valuable lesson in humility and help prevent unsound philosophical claims about the connections between mathematics and reality.

There is no reason to believe that a story similar to Faraday's can not happen again in the XXI, XXII, or XXIII century, despite "big science" and "mathematics" being widely considered the only way of ensuring scientific progress.

26. **Peter Woit**
July 18, 2024

Sebastian,
This is exactly the point of view that I am arguing against. Given the conceptual and mathematical sophistication of our theories of modern physics, there is zero chance that they are going to be improved by a a new Faraday as you suggest.

A Few Items

July 2, 2024
Categories: abc Conjecture, Langlands

A few items, all involving Peter Scholze in one way or another:

- A seminar in Bonn on Scholze's geometrization of real local Langlands is finishing up next week. This is working out details of ideas that Scholze presented at the IAS Emmy Noether lectures back in March. Until recently video of those lectures was all that was available (see here, here and here), but since April there's also this overview of the Bonn Seminar, and now Scholze has made available a draft version of a paper on the subject.
- In three weeks there will be a conference in Bonn in honor of Faltings' 70th birthday. Scholze's planned talk is entitled "Are the real numbers perfectoid?", with abstract

  > Rodriguez Camargo's analytic de Rham stacks play a key role in the geometrization of "locally analytic" local Langlands both over the real and p-adic numbers. In both settings, one also uses a notion of perfectoid algebras, with the critical property being that "perfectoidization is adjoint to passing to analytic de Rham stacks". This suggests a "global" definition of perfectoid rings. We will explain this definition, and present some partial results on the relation to the established p-adic notion. Two natural open questions are whether tilting works in this setting; and what perfectoid algebras over the real numbers look like.

- On the abc conjecture front, Kirti Joshi has a new document explaining his view of The status of the Scholze-Stix Report and an analysis of the Mochizuki-Scholze-Stix Controversy. To some extent what's at issue is what was discussed by Scholze and others on my blog back in April 2020 (see here). Joshi is trying to make an argument that there is a way around the problem being discussed there, but I don't think he has so far managed to convince others of his argument (Mochizuki refuses to even discuss with him). He ends with the following:

  > Meanwhile, Scholze and I are having a respectful and professional conversation (on going) as I work to clarify his questions; while I continue to wait for Mochizuki's response to my emails.

  He also clarifies that he has not yet finished a water-tight proof of abc along Mochizuki's lines:

  > My position on whether or not Mochizuki has proved the abc-conjecture is still open (as my preprint still remains under consideration). In other words, I'm currently neutral on the matter of the abc-conjecture. However, I continue to work on to tie up all the loose ends.

Update: In the comments someone points to this conference at MIT next week, which will start off with a talk by Faltings on *Mordell past and present*. That conference will be followed by this one the following week.

Update: Erica Klareich at Quanta has a very nice article about the recent proof of Geometric Langlands. About the implications of this work, there's a nice quote from Peter Scholze:

> "I'm definitely one of the people who are now trying to translate all this geometric Langlands stuff," Scholze said. With the rising sea having spilled over into thousands of pages of text, that is no easy matter. "I'm currently a few papers behind," Scholze said, "trying to read what they did in around 2010."

He's not the only one struggling to understand what was known before this proof, and daunted at the prospect of trying to read the 800 pages of five papers (see here) that make up the full proof.

   July 3, 2024

   Boris,
   I fear that topic is one that I know very little about, and certainly couldn't improve on Tao's explanation. He points to talks at the Sarnak conference, for which videos should now be available.

6. **Peter Woit**
   July 3, 2024

   Anon,

   I'll try to say something, but hoping one or more of my readers is willing to do a better job…

Real local langlands classifies representations of real Lie groups. For the simplest example, think of SL(2,R) and its discrete and principal series representations. This is done in terms of "Langlands parameters", for which Scholze provides a new geometric interpretation, in terms of geometric Langlands, on the twistor P1.

This is the same classification of representations as before, but a new geometric point of view. Most dramatically, this is done with new methods replacing the usual geometry and analysis, methods that have developed out of work on the p-adic case. This provides some very new and different ways of looking at the real case, and a unified perspective on what is happening at the p-adic and real places. A speculative possibility is that this will lead to new global results (i.e. for Q, not Q_p and R), with Scholze's upcoming talk suggesting "a "global" definition of perfectoid rings."

7. **Will Sawin**
July 3, 2024

Indeed, one can see the videos at https://www.youtube.com/watch?v=dIe5hqTuB4k and https://www.youtube.com/watch?v=diASDVdMaN0

The first talk (by James Maynard) goes over the statement of the result, prior work, applications, and a brief summary of the proof. The second talk (by Larry Guth) explains the ideas behind the proof. I would encourage everyone who hears that description and thinks they will understand the first talk but not the second to try watching it – it's a masterpiece of finding the key ideas of a complicated proof and explaining them in simple terms.

8. **Anon**
July 16, 2024

There's something weird in the poster of "conference in Bonn in honor of Faltings' 70th birthday". I see Peter Sarnak name as one of the speakers, but he's not listed as the speaker in the abstract of the conference

9. **Peter Woit**
July 16, 2024

Anon,
A likely explanation is that he was planning to attend the conference, so on the poster, but at some point changed plans and won't be there, so, not on the program.

10. **Oisin McGuinness**
July 18, 2024

The conference for Faltings' 70th birthday has updated their streaming policy, see main page at https://www.mpim-bonn.mpg.de/faltings70

"Due to the great interest in this conference, we will stream most of the talks live via Zoom. The program indicates which talks will be streamed. The Zoom link will follow shortly before the conference. The talks will not be uploaded on the website later."

Excellent!

By the way, the Mordell Conference https://mordell.org site has been updated with slides of the talks, including that of Faltings (1st talk), and a talk on possible formalization by Michael Stoll (last talk), both fascinating in different ways.

Also see the photo of the participants, Faltings is near the top right….

11. **David+Roberts**
July 18, 2024

@Oisin McGuinness

actually, not posting the videos afterwards is less good than just live-streaming. Far fewer people will get the watch the talks as a result.

12. **Oisin McGuinness**
July 19, 2024

@David+Roberts

"Far fewer people will get the watch the talks as a result."

Agreed, but when I asked the organizers initially, some weeks back, they were not going to have anything, so what they are doing is an improvement.

It is a big shame (similarly for the recent Mordell Conjecture Conference) that recording is not standard anymore for many of these conferences. Some talks are clearly of possible historic import. Some foundational support is needed to support more recording! By contrast the IAS does a great job.

Are you listening Simons Foundation???

13. **Sandeep**
July 21, 2024

I might have missed, but was there a post on the proof of Geometric Langlands? I just read the Quanta article.

14. **Peter Woit**
July 22, 2024

Sandeep,

I haven't written about the Gaitsgory/Raskin et al proof, haven't followed the technicalities. Thanks for mentioning the Quanta article, I just read it and it's quite good. I'll add a link to that.

The Harvard Swampland Initiative

July 12, 2024
Categories: Swampland

The past few years I've been noticing more and more claims like this one, supposedly finding a way to "connect string theory to experiment". When you look into such claims you don't find anything at all like a conventional experiment/theory connection of the usual scientific method, giving testable predictions and a way to move science forward. As for what you do find, for many years I tried writing about this in detail (see here and here), but that's clearly a waste of time.

One thing that mystifies me about such claims is that I find it very hard to believe that most theorists take them seriously, always assumed that the great majority was with Nima Arkani-Hamed, who recently characterized the track record of this kind of thing as "really garbage". But if most theorists think this is garbage, why am I seeing more and more of it? A hint of an answer comes from the paper with the supposed connection, which describes the Harvard Swampland Initiative as the place the work initiated.

I hadn't been aware there was a Harvard Swampland Initiative, but it is a Research Center at Harvard, running an "immersive program" in which "participants collectively navigate the Swampland". More importantly, it has no less than ten associated postdoc positions. On the scale of different ways of having influence on a field, being able to hand out ten postdoc positions at Harvard is right up there. This goes a long way towards explaining to me what I've been seeing in recent years. It also makes me quite depressed: when I started my career in that department in the late seventies, the idea that fifty years later this is what it would come to is something beyond any one's worst nightmare at the time.

Update: In case anyone has any doubt about what the main goal of the Swampland program is, see here:

> Recently, physicists have started a new program called Swampland to overcome the criticism of string theory that arose in the 2000s.

"Recently" seems to refer to 2005, when this started.

Comments

1. **DKepler**
   July 13, 2024

   One aspect that is also becoming increasingly obvious is the intent of getting such works through in a prestigious journal such as PRL (arxiv format of the present one suggests the same for this work as well). Quote some numbers, throw in some data analysis, make some vague references to experiments, put in big names in Acknowledgements, and PRL is usually happy to accept. If you see timelines of some recently accepted PRL papers, you will see a few stringy ones that had merely 2-3 weeks between submission and publication!

2. **Sabine**
   July 13, 2024

   In a few years from now, one of them postdocs will fall off the bandwagon and draw attention to themselves as a critic of string theory. Someone will set up a blog. Someone will write a book.

   "The word is about, there's something evolving,
   Whatever may come, the world keeps revolving,
   They say the next big thing is here,
   That the revolution's near,
   But to me it seems quite clear
   That's it's all just a little bit of history repeating."

3. **fwiw**
   July 13, 2024

   > Quote some numbers, throw in some data analysis, make some vague references to experiments, put in big names in Acknowledgements, and PRL is usually happy to accept.

   That's just nonsense. PRL remains extremely selective and demanding. About half of all submissions to PRL are desk rejected in a few working days. Go ahead and try.

4. **Peter Woit**
   July 13, 2024

   fwiw,

   About PRL's extremely selective and demanding standards for string theory papers, I'll just point to
   https://www.math.columbia.edu/~woit/wordpress/?p=14001

   Enough about PRL, the real question here is why anyone thinks this is science or why any journal would publish it.

5. **fwiw**
   July 14, 2024

   hang on, is the harvard swampland initiative definitely a research center as opposed to an initiative to create seminar series, visitors, discussions etc on swampland? aren't the participants just harvard researchers who are joining in those activities, cf. ten post-doc positions handed out by the swampland research center, all hired by funding from the harvard swampland 'research center' for swampland

6. **Peter Woit**
   July 14, 2024

   fwiw,

   https://www.physics.harvard.edu/research-centers

7. **Some guy idk**
July 14, 2024

I'm a bit confused. The Swampland is broader than the string theory landscape, and I'd think much of the work being done there would have nothing to do with strings. Isn't that exactly what you've been advocating for? Quantum gravity and other steps towards unification outside of string theory?

8. **Peter Woit**
July 14, 2024

Some guy idk,
The swampland is Vafa's program, and in different places he emphasizes different aspects of it. He is certainly not setting it up as an alternative to string theory. For what he has in mind, look at his original 2005 swampland paper
https://arxiv.org/abs/hep-th/0509212
and for something more recent, lecture notes from two Harvard courses
https://arxiv.org/abs/2212.06187

In both places he makes very clear what the motivation for the program is: to fight the argument that "string theory predicts nothing" because you can get any low energy physics you want with an appropriate choice of "string vacuum". The origins back in 2005 were in the context of arguments over Susskind's "landscape", see
https://arxiv.org/abs/hep-th/0302219
Susskind essentially argued that you could get just about anything out of string theory, then anthropic arguments would determine where we were in the landscape. Vafa realized this was disastrous for string theory, and that at least one blogger was doing a lot of damage to string theory by pointing this out.

So, his motivation from the beginning has been to try to fight the "string theory makes no predictions" argument, sometimes by arguing "string theory gives a consistent quantum theory of gravity coupled to matter and maybe we can find generic consistency conditions for such things, so these would be string theory predictions".

I think if you listen to what he says about the swampland and string theory, you'll see that the whole point is to mount a defense of string theory and of the study of "string theory vacua". String theory is taken as an assumption that cannot be challenged. When asked if he would abandon string theory if the "predictions" he finds are disconfirmed, he says that no, he wouldn't. Such disconfirmation would just mean that one needed to modify one's understanding of "string vacua".

If you don't believe me that a main motivation here is responding to all too effective criticism that string theory can't predict anything, see here
https://www.math.columbia.edu/~woit/wordpress/?p=10486

9. **Some guy idk**
July 14, 2024

Thanks for responding!

What about "swampland conjectures" like the completeness of spectrum hypothesis (satisfied by string theory but not necessarily motivated by it) and weak gravity conjecture (has little or nothing to do with strings)? These things, as I understand, try to establish a network of conditions for a future complete theory of quantum gravity, and I would think that's worthy research that anyone could get behind.

10. **Mitchell Porter**
July 15, 2024

In "The Swampland: Introduction and Review" (arXiv:1903.06239), Eran Palti writes:

"One approach towards providing evidence for a Swampland conjecture is by utilising known vacua of string theory as a type of experimental data…

"Another approach that is commonly adopted to study Swampland criteria is utilising quantum gravity arguments directly in the low-energy effective theory. There are low-energy aspects of quantum gravity that are expected to be universal, in particular relating to black holes and to the holographic nature of gravity. Relative to [the first approach], this approach has the advantage of broader generality. On the other hand, the arguments often lack the explicit details and concreteness of string theory based evidence."

So there is a part of the Swampland program which is logically independent of string theory. It would be useful for this discussion, to know how extensive it is.

11. **Peter Woit**
July 15, 2024

Some guy idk/Mitchell Porter,
I just don't see any point to these string-inspired conjectures about which low energy physics is compatible with string-inspired general ideas about gravity. If your conjecture says that the SM is compatible with gravity, you've learned nothing. Whatever the correct explanation of gravity is, it has to be compatible with the SM at low energies because that is the way the world is. If your conjecture says that the SM is not compatible with gravity you've also learned nothing (beyond that your conjecture is wrong).

The main motivation for all this activity is to justify continuing doing meaningless calculations about "string vacua", partly in order to be able to make bogus claims about "connecting string theory with experiment", partly in order to not have to admit you've wasted 40 years on a wrong idea.

12. **David Brown**
July 18, 2024

The article by Rocci & Van Riet is available on arxiv.org .

What is the "Not Even Wrong" perspective on the following?
"Swamplandish Unification of the Dark Sector" by Cumrun Vafa, 2024
https://arxiv.org/abs/2402.00981

14. **Peter Woit**
July 19, 2024

David,
The most amazing collection of misuses of the term “prediction” in any abstract of a paper, ever.

Same old, same old: hideously ugly unmotivated introduction of huge numbers of new degrees of freedom, followed by elaborate effort to explain why they’ve never been seen by pushing them to regions inaccessible to experiment. Then, claim that this leads to a “prediction”.

Various and Sundry

July 31, 2024
Categories: Uncategorized

A few items of different kinds:

- The Harvard Math department website has a wonderful profile of Dick Gross.
- The second International Congress of Basic Science ended a few days ago in Beijing. A huge number of interesting talks, video and slides available here. My Columbia colleague Richard Hamilton was one of the winners of a Basic Science Lifetime Award, unclear how much wealthier this makes him and his fellow awardees.
- Alphaxiv is a new website allowing for research discussion of arXiv papers.
- The Gates Foundation evidently is no longer going to pay publishing costs for open access journals. The problem is that this kind of funding incentivizes some sorts of bad publishing practices. They refer to

> unsavory publishing practices by poor actors (paper mills, questionable quality review, unchecked pricing)

- The Perimeter Institute last week had a summer school on Celestial Holography. This panel discussion explains some of what the people involved are trying to do.
- Curt Jaimungal has been planning a series of programs on *Rethinking the Foundations of Physics*, with the topic "What is Unification?". For the first program, featuring Neil Turok, see here. I'll record something on Friday, part of the plan evidently is a lot of questions. If you have one, you can try leaving it as a comment and I'll try and get some of them to Curt.

2. **Low+Math,+Meely+Interacting**
   August 2, 2024

   Enjoyed the Turok discussion, and following Q&A. Thanks for the pointer!

   Celestial holography and the related amplitudes and "modern S matrix" efforts appear to lean heavily on twistors, and attempt to find analogous connections between quantum gravity and a conformal field theory in flat spacetimes as is seen in AdS/CFT.

   Turok, et al.'s theory is conformally invariant, makes use of Twistor Theory to formulate that, and equates (if I understood correctly) breaking of this conformal invariance with electroweak symmetry breaking.

   Your own twistorial approach also seems quite different, with instead the breaking of spin group symmetry associated with the Higgs mechanism.

   Unless I've badly misunderstood, Twistor Theory is not a model of quantum gravity, but a different way of describing space-time that might be more fundamental and better suited to theories of quantum gravity. In that regard, these three and other approaches utilizing twistors might have little otherwise to do with one another.

   Then again, there might be deep connections between them. What do you think?

3. **Peter Woit**
   August 2, 2024

   LMMI,
   Twistors encode beautifully 4d spinors and 4d conformal symmetry and give a remarkable different way of thinking about space-time. A space-time point is by definition the spinor space at the point. This is going to appear naturally if you try and do anything with 4d conformal symmetry. So, not surprising the celestial holography people and Turok find twistor variables useful.

   Since the beginning, the hope of people working on twistors has been that these are the right variables for quantum gravity. This works in a sense for a chiral version of gravity, not for the usual gravity which is thought of as parity invariant.

   I'm pursuing a somewhat different version of this story, emphasizing the idea of looking not just at Minkowski spacetime twistors and Euclidean spacetime ones. Whether this has anything to do with these other programs, I don't know, it's not something I'm seeing indications of at the moment.

4. **Mark Hillery**
   August 3, 2024

   As a former journal associate editor, I found the announcement by the Gates Foundation that they would no longer pay APC's (article processing charges) very interesting. I hope this is a trend. I think it is time to admit that gold open access has not worked. Its proponents, who were initially idealistic scientists but soon came to include government bureaucrats, claimed wonderful things for it. Among these were the claim that anyone could read the scientific papers for free thereby improving access (true) and that this would somehow decrease the amount of money going to large publishers (false). The money to pay the APC's was supposed to come from the money institutions would save on subscriptions (at a cash-starved institution like CUNY this hope was laughable) and research grants. In regard to grants, not everyone has them, and the money that goes to pay APC's is money that is not used to pay things like graduate student salaries. What happened is that you got bureaucrats mandating that papers be published in gold open access journals (see the EU's Plan S), publishers adapting very nicely (the APC to publish in Nature is $12,290) and increasing the amount of money they made, and predatory journals sprouting up like mushrooms. It is time to go back to the drawing board, and refusing to fund APC's is a step in the right direction.

5. **SRP**
   August 4, 2024

   Way back in 1978 I took calculus from Dick Gross. Even as a young assistant professor he was an excellent and engaging instructor, very good at adding historical motivations to his lucid explanations and letting his sense of humor come through.

6. **David+Roberts**
   August 4, 2024

   The people who took the lead on gold OA (that is, paying a journal to make the article open access in the journal itself) where biologists who were **already paying $3000 in page charges per paper** for publishing closed access papers (colour figures etc. This was early 2000s, mind). This was merely a 'cost of doing business', which was small change in light of the huge expense of actually running an experimental lab. A quick search found a Reddit discussion about lab costs, and one respondent gave an estimate of $300k/year, outside salaries, it seems)
   They figured they could instead set up journals charge that amount but make them open access, so literally a net zero change in cost to themselves. Also, by not publishing physical journals they could cut costs, but also still pay for journal infrastructure. This multi-thousand dollar figure was latched onto by the established publishers, when it really should be less for them by economies of scale. And it completely pulled one over the rest of academia where people just don't have that cashflow, and of course you got the predatory publisher relishing this new norm.

7. **Z Y**
   August 7, 2024

   The ICBS does a good job in putting together an impressive number of mathematicians across all disciplines and regions of the world, akin to an ICM but every year. I wonder if there is something of this magnitude or bigger in the physics side of things. They have considerably expanded the number of laureates. Still I refuse to like the choosing of the words: Basic Science in the name, if there is not experimental biology at all. Are there experimental physicists showing their results in there? if not, maybe International Congress of Theoretical Science would be more apt.

Zombie Wormhole Publicity Stunt

August 2, 2024
Categories: Fake Physics, Wormhole Publicity Stunts

I had thought that the Wormhole Publicity Stunt could now be safely ignored, with almost everyone in the physics community agreeing that this was an embarrassing disaster that was dead and buried. Even the people at Quanta had realized that they had been misled into helping promote something that wasn't at all what it claimed to be. The Quanta promotional video that was a big part of the publicity stunt is still on Youtube, but they've added this text:

> UPDATE: In February 2023, an independent team of physicists presented evidence that the research described in this video did not create any wormholes, holographic or otherwise.

Today though, the World Science Festival put out a Zombie revival of the publicity stunt, under the bizarre title Did Einstein Crack the Biggest Problem in Physics…and Not Know It? It starts off with Brian Greene explaining that this may be the "Holy Grail" connecting string theory/quantum gravity to experiment, with such experiments not needing an expensive collider or space telescope, just a Google quantum computer.

Brought in for the discussion are the three architects of the publicity stunt, Daniel Jafferis, Joe Lykken, and Maria Spiropulu. At a couple points there is a mention that something might be "controversial", but there's zero explanation of what the "controversy" might be. After starting out with some background about wormholes and entanglement, the rest of the program is basically outrageous and misleading hype, without a hint of why anyone might be skeptical about it.

I've now wasted too much of my life trying to debunk bogus claims of this kind, with the wormhole nonsense just the latest and most egregious example. One learns over the years that it's impossible to stop this kind of thing, there's no way to kill off the Test of String Theory/Fake Physics enterprise. Even if you think something has been completely debunked, its proponents will always find some way to emerge from the grave and keep going. If anyone is aware of a source for the right kind of silver bullet to stop this, let me know.

Comments

1. **Jean-Pierre Laflamme**
   August 2, 2024

   On the web, the means to destroy zombie invasions may not be appropriate for the discussion that needs to be had here :).
   Jokes aside, perhaps we should target the sources of funding for this research which is going round in circles, possibly hampering the funding of other potentially more promising research.

2. **Sabine**
   August 3, 2024

   Fwiw, I think the hype has much decreased in the past decade, and I think that's to no small part b/c of your blog, so thanks for all the fish etc & don't give up

   As someone once told me, academia is like a big tanker ship, inertia is huge. Even if you stop the engines it'll keep going for a few miles and I think that's what we're seeing here.

3. **Eleni**
   August 3, 2024

   https://3quarksdaily.com/3quarksdaily/2024/07/the-wormhole-fiasco.html

4. **John Baez**
   August 3, 2024

   Maybe start spreading the word that these people are just… weird.

5. **Rainy Sunday Afternoon Theoretical Physicist Drop Out**
   August 3, 2024

   I just watched the video with Brian Greene…

   And honestly, it is a mix of half-baked "common-man" examples of quantum mechanics systems using spin, which would embarrass a part-time contract lecturer were he to listen to his students talking this way in the coffee place near college after a few beers.

   Also with overtones of a Monty Python sketch.

   And these are the guys that got where I could never make it?

   I don't know whether to feel depressed… or proud…

   Regards

6. **Alessandro+Strumia**
   August 3, 2024

   It's your fault. Your criticism prompted string theorists to try doing something testable.

7. **Peter Woit**
   August 3, 2024

   Jean-Pierre Laflamme,
   It looks like the DOE grant that funded this is still active. I'm curious to know if these people will try to get another one to fund doing this, would hope that they would run into trouble with that.

Two problems though are:
1. To some extent this was funded by Google, and good publicity but bad science is probably fine with them, so they may keep funding it.
2. IAS faculty in this case seem to have convinced the IAS director that this was earth-shattering work on a par with the 1919 verification of GR predictions. I don't know that they're going to stop doing this kind of thing and they have a lot of influence.

8. **Patrick Moylan**
   August 3, 2024

   The title is another example of countless and unjustified Einstein hagiography (Did Einstein Crack the Biggest Problem in Physics…and Not Know It?).

9. **David+Roberts**
   August 4, 2024

   People just walk into Betteridge's law, it's astounding. Or else the person who was tasked with coming up with a headline knew what they were doing, and more or less trolled the people doing the stunt.

10. **Jean-Pierre Laflamme**
    August 4, 2024

    I do not claim to be a great expert in the field, but I think that the drifts we see come from the difficulty, or even the impossibility, of testing the different theories put forward. Previously, we could relatively easily disprove or confirm a theory, but today, laboratories or observatories are worth billions of dollars (CERN, FCC, JWST). Although they are very useful for the advancement of knowledge, they arrive, as we see currently, that they bring more questions than answers. Speculative physics can therefore take the lead if it brings theories that make us dream like wormholes, superluminal speeds or even teleportation. The solution would perhaps involve a multidisciplinary committee of wise persons who would come to moderate all this before it gets out of hand.

11. **Peter Woit**
    August 4, 2024

    Jean-Pierre Laflamme,
    Yes, that's the problem, but it has long ago gotten out of hand. And it has been the kind of "wise persons" one would appoint to the kind of committee you suggest who have often been the ones who have gotten us here. Quanta magazine and the IAS director consulted with such before joining the publicity stunt.

12. **Jean-Pierre Laflamme**
    August 5, 2024

    Peter,
    This is an interesting discussion. It is certain that for such a committee of wise to be effective, it would be necessary, as much as possible, for people who have a conflict of interest in the research subject to withdraw from it. But human nature being what it is, this is perhaps easier said than done.
    Note : I use the terms "Comittee of wise" as a traduction of "Comité de sages" in french, but I am not sure if the traduction is entirely good for english speaking persons.

13. **Peter Woit**
    August 5, 2024

    Jean-Pierre Laflamme,
    The translation is fine. The problem with this kind of proposal is that string theory is an extremely complicated and poorly understood subject, with string theorists themselves often not understanding parts of the subject. String theorists argue that anyone who is not a string theorist is incompetent to evaluate the state of the subject.

14. **Jean-Pierre Laflamme**
    August 5, 2024

    Peter,
    Keep up your blog like this. Your contributions surely contribute to keeping this unbridled research, I would say, in string theory, under relative control. In any case, in any field, and without falling into fake news, the right to constructive criticism remains essential in the search for truth.

Susskind: String Theory is Not the Theory of the Real World

August 7, 2024
Categories: Uncategorized

Lawrence Krauss has just put up a long interview with Lenny Susskind. I was listening to it while doing something else, found myself shocked when the discussion got to the current state of string theory to find that I mostly agreed with what Susskind has to say. Here's some of it (around 1:23):

> I can tell you with absolute certainty String theory is not the theory of the real world, I can tell you that 100%…. My strong feelings are exactly that String theory is definitely not the theory of the real world.

Here he's referring to "String theory" (with a capital S) as the superstring theory which has a known definition, at least perturbatively. He goes on to explain that he thinks it possible that some very different generalized or "string-inspired" theory might have something to do with the real world but that:

> we don't know and we don't know if String theory will help us find those things…. We are still uncertain about whether whatever it is: "generalized", "boundaries pushed", "string-inspired theories". We don't know and I think that's the bottom line now.

As for the idea that we just need to understand how to break the superstring supersymmetry to get the real world:

> People will say oh all you have to do is spontaneously break supersymmetry, blah blah well it's been 25 30 40 years by now that nobody's figured out how to do that.

On the "failure" description, he thinks String theory has not been a failure in the sense of showing gravitation and QM can coexist, but, as for particle theory:

> Whether it's been a failure in producing a theory of Elementary particles I would guess remains to be seen but String theory (with a capital S) is not the right theory.

On the wormhole publicity stunt (1:38):

> Not a very good experiment… the experimental implementation of it left more than a little bit to be desired. That got much too much hype, yeah.

Krauss brings up the the string theory hype problem, with

> we owe it to the public I think to be careful in what we say. I understand we get excited and it's fine for physicists to get excited with each other but we have to be careful of what we say we can do because if we don't it'll come down and bite us in the butt.

Susskind's response is:

> I completely agree with that, but on the other hand there is a tension between that and the importance of keeping excited and letting the public know why we're excited.

I'd have liked to hear Susskind's thoughts on what should be done when a bunch of theorists write popular books hyping ideas that don't work. Whose job is it to explain to the public that they were misled by overenthusiastic scientists? If he's not going to do that, would he at least be publicly supportive of those who do this job?

Another question I'd have liked to ask him would be: given that he agrees that the idea of using string theory to understand particle physics hasn't worked and we don't know that "string-inspired" is the right direction to go, what next? If "string-inspired" is not the way to go, should we just give up on going beyond the SM? If not, how would he encourage young people to work on non-"string-inspired" ideas about unification that might take us beyond the SM?

Comments

1. **John Horgan**
   August 7, 2024

   Susskind pushed really hard for landscape theory, which is a consequence of string theory, in his pop book The Cosmic Landscape. And as I recall he said on The Edge website that if you reject landscape theory you're probably a creationist. So now he's telling us that he takes it all back?

2. **Z Y**
   August 7, 2024

   This is awesome, he is the first high profile string theorist that I know that is publicly recognizing the things are they really are, it may start something… or not..

3. **Peter Woit**
   August 7, 2024

   John,
   I was thinking of writing more in this blog post, about the last part of the conversation with Krauss, where he talks about the landscape. There he's much more careful in his argument, no nonsense about rejecting the landscape anthropic argument as being akin to creationism, or rejecting the theory of evolution.

   He's much more careful there than in his popular book. His argument now is that if you had a unified theory and then knew "The equations" governing the world, you could look at the solutions to these equations. He acknowledges that maybe if we find "The equations", they will have only one, or a few solutions. Then any multiverse created by bubbling baby universe would have the same laws everywhere, no role for anthropics possible.

   But, he argues, if you have "The equations" and they have a vast number of solutions, then the multiverse picture with our universe a randomly chosen anthropically allowed solution is a consistent possibility. He tries to argue that no one has any other viable theory for the size of the CC, so this deserves some sort of status as best known explanation.

   The problem of course is that we don't know "The equations". My problem with what he was doing in the past was always that he and others were trying to argue that this was somehow evidence for string theory, or at least explained why string theory can't predict anything. What struck me about his current argument is that he no longer is doing this. Instead of arguing that the equations of the String theory-based KKLT construction were "The equations", now he's saying that String theory doesn't work as a unified theory, that we don't at all know what "The equations" are.

   So, now his anthropic landscape argument is just an abstract argument about an unknown theory with conjectured properties, no longer an argument based on string theory.

To pin him down, Krauss should have asked him specifically what he now thinks about KKLT as an explanation of the string vacuum and a unified theory. I'm guessing he might now take the correct position: you can't tell whether KKLT vacua make sense since you don't know "The equations" that they are supposed to solve.

4. **Peter Woit**
August 7, 2024

Z Y,
I think what he's saying here is what most prominent string theorists have been thinking for a long time. In private, I've found they often agree that known string theory is useless to do particle theory, say only reason to work on it is as a model of quantum gravity.

The question then is why the hype about string theory and unification is still getting heavily promoted by many people, with no push-back from those who know it is nonsense. It's one thing to justify hype from scientists overly enthusiastic about a new idea they are working on, but I don't think there's any way to justify hype from scientists trying to evade acknowledgement that their ideas from 20-30-40 years ago haven't worked out.

5. **Sabine**
August 7, 2024

amazing, thanks for digging up

6. **hrdlifil**
August 8, 2024

Of course String theory is not a theory of the real world, it is not a theory of anything. The real STRING THEORY – M-Theory cannot be built upon shaky handwaving grounds.

We first need to understand what is a full non-rational 2-dimensional σ-model conformal field theory, then what is full non-perturbative YM and finally then we can have the true rigorous non-perturbative M-Theory.

Yes this might be a 10 000 year problem, but every problem needs to start somewhere and there is no other game in town other than String theory which serves as a good starting point.

7. **Jim+Eadon**
August 8, 2024

"Krauss brings up the the string theory hype problem"
Dear Prof Woit, do you think that the laughable Quantum Wormhole hype is inadvertently crippling the String Theory bandwagon, by exposing the hype machine?
It would be ironic if the downfall of hype-driven String Theory is catalysed by hype itself, in this case, by non-ST (wormhole) hype.

8. **Peter Woit**
August 8, 2024

Jim Eadon,
The wormhole hype was so bad that even the string theorists recognized it and some got annoyed. Susskind though here seems to me to be taking the position that
1. This was "much too much hype".
2. But it is understandable that people do this kind of thing, it's not something worth doing anything to stop.

For some context, Susskind himself has a lot of responsibility for what happened. He was one of very few people the hypesters chose to let in on the planned hype campaign before it started. As part of this, he and a collaborator wrote the article in Nature accompanying the hype announcement. When I told the people at Quanta that they had been had, I was told that I was wrong, that they had consulted four experts while writing their article and producing their video. One of the four was Susskind.

9. **Adam+Treat**
August 8, 2024

Seems Susskind still hasn't grappled with Sabine's point that it is not possible to specify a probability distribution over possible universes even if we had 'the equations.' Good for him for divorcing the anthropic nonsense from "String theory" landscape, but still would be better if he grappled with the deeper point.

10. **Peter Woit**
August 9, 2024

Adam Treat,

I can imagine versions of "The equations" which would give dynamics of a big bang and baby universe creation which would imply a probability distribution. I can also image versions that wouldn't. The basic fact is that we know nothing at all about this, are ignorant not just of "The equations" but of what variables they are in.

One can entertain oneself by arguing about the properties of completely unknown equations, but this isn't science in any sense. You might as well argue about the Gods and what they are up to when they create universes.

11. **Peter**
August 9, 2024

I studied physics. It was a long time ago, and I never really practiced it, but the debate about string theory has reached the point that I don't even understand anymore what the expression "the equations" is supposed to mean in this context.
Does anyone have an idea what these equations should look like, other than being able to describe 10^500 (or whatever) universes, of which our universe might be one?

12. **Peter Woit**
August 9, 2024

Peter,
What Susskind is saying is:

1. For String theory, with a capital S, meaning the theory we know the equations for, there is no possible connection to the real world.

2. For some unknown better theory that does describe the real world, “string-inspired” or not, there will be “The Equations” which define it. We have no idea what these are. He wants to go on and make an argument for the anthropic explanation of the CC, based on assuming certain properties of the these unknown equations.

13. **Mitchell Porter**
August 13, 2024

There are many papers on supersymmetry breaking in string theory, as well as on non-supersymmetric string theories, so I don’t know what Susskind is talking about. Does anyone know what he’s talking about?

14. **Peter Woit**
August 13, 2024

Mitchell Porter,
Anyone who has actually been looking at those thousands of papers on supersymmetry breaking knows what Susskind is talking about: they don’t solve the problem. As Susskind explains, people have been trying for 40 years without success.

You can claim supersymmetry as a good idea because it has new symmetry generators so makes new predictions (equal mass superpartners with specific properties) if unbroken. The predictions are wrong, so you have to break SUSY (explicitly or dynamically). The problem is that any known way of doing this complicates the theory while either making new wrong predictions, or just allowing you to move the new predictions somewhere unobservable, predicting nothing at all observable. This has been the problem with SUSY, in QFT or string theory, since the beginning.

15. **Mitchell Porter**
August 14, 2024

Peter,
Perhaps I can explain myself by analogy with KKLT. The 2000s debate over KKLT was on matters like, is this really how reality works, is this still science, and so on. But the 2020s debate over KKLT is on matters like, is this how *string theory* works, or do nonperturbative effects actually collapse the whole construction.

What I can’t tell, is if Susskind is calling stringy models of SUSY breaking into doubt *as rigorous string theory* (analogous to KKLT 2020s debate), or if he’s just saying that they are all empirically unsatisfactory.

16. **Peter Woit**
August 14, 2024

Mitchell Porter,
The debate over whether non-perturbative effects stabilize moduli goes way back, KKLT itself was just part of that ongoing debate. In the 2000s leading figures in the field were debating this, the debate over whether this turned the subject into pseudo-science was a follow-on. Yes there are still people debating whether KKLT works now, but no one of any significance is paying attention any more.

It became clear early on in this debate that when you don’t have a non-perturbative theory, arguing over the technicalities of non-perturbative effects doesn’t really make sense. Susskind now I think is just following the mainstream opinion that, as currently understood, String theory with a capital S can’t answer this kind of question.

Whether he’d put some specific string theory model of SUSY breaking in the capital S category or not I don’t know, you’d have to ask him. But I think it’s clear he now realizes this is irrelevant: the ones that you could argue for don’t say anything about the real world anyway. From what he says, for a connection to the real world he’s not looking for some minor improvement on what is known, but for some different theory (his interest in ER=EPR indicates something very different than capital S string theory).

17. **Dr. Udai S Singh**
August 17, 2024

I just want to thank all of you people, and especially the progenitor of this blog, Dr. Peter Woit. It took me forever to finally find a sensible, scientific, nuanced rebuttal to all the String Theory crap I have been deluged with for decades. Now I can at least hold reasonable and logical conversations with amateur science enthusiasts who are being misled by this huge crowd of people like Kaku.

18. **Michael Naray**
August 18, 2024

This is no surprise, surely? If you watch Susskind’s lectures that have since been turned into the ‘Theoretical Minimum’ series of books, he unequivocally states to the students that ‘string theory is not a theory of the real world. It doesn’t work, it doesn’t match observations. It just doesn’t.’ And that was recorded over 10 years ago!

19. **Mitchell Porter**
August 21, 2024

Michael Naray – I have found where he says that: at 1:17:45 here

https://www.youtube.com/watch?v=NZ-ElsvYKyo

(at theoreticalminimum.com, this lecture is listed under “Supplemental Courses” as “String theory wrap-up”).

20. **B. Malpani**
September 11, 2024

…[i]the importance of keeping excited and letting the public know why we’re excited.[/i]

He can be as excited as he wants, but what is important is that he produce theories that make testable predictions. That, in reality, is what he’s paid to do, but he and his cohorts seem to have kinda given up on that. “Letting the public know why he’s excited” is *not* part of his job description; it seems to have become a license to lie for the sake of pressuring bureaucrats to continue to fund his failures.

Quick Links

August 9, 2024
Categories: Uncategorized

Starting to write a longer, more technical posting, but for now, a few quick links:

- The film *Particle Fever* (for more about this, see here) may get made into a musical. With a little luck they'll skip the nonsense about the multiverse that blemished the film.
- Tommaso Dorigo performs an experiment that the airline industry probably doesn't want publicized.
- My big problem with discussions of climate change has always been that I'm not able to evaluate the science myself, so when told to "Trust the Science", I get queasy, all too aware that in some parts of science I can evaluate, "Trust the Science" is a really bad idea. Luckily, there is someone with a track record I can trust, Sabine Hossenfelder, who has a new video about trusting scientists and climate change. She has carefully looked into this, and explains her conclusions: here you can trust the science, the problem is very real.

  If you want to argue about climate change though, you're going to have to find some place else.

Comments

1. **Phil HALPER**
   August 13, 2024

   Sabine does great video but please watch this example where she makes basic physics errors and is guilty of the overhyping of bad results she accuses others of: https://www.youtube.com/watch?v=foq4nVAwEao

2. **Peter Woit**
   August 13, 2024

   Phil Halper,
   I don't think Sabine is infallible. She has a clear inclination and agenda to try and take challenges to conventional wisdom seriously, looking into them carefully rather than just dismissing them. This can get her into trouble, but it's exactly what gives her a lot of credibility in this case, where she's siding with conventional wisdom.

3. **Davide Castelvecchi**
   August 14, 2024

   I feel like we keep going in circles. There's a long tradition of physicists who say they don't trust the science until they look into it for themselves: a decade ago, it was Richard Muller … https://www.nytimes.com/2012/07/30/opinion/the-conversion-of-a-climate-change-skeptic.html

4. **John Baez**
   August 14, 2024

   If you haven't watched all of Sabine's video, you might mistakenly guess she thinks climate scientists are
   *over*estimating the severity of the climate crisis.

5. **John Baez**
   August 14, 2024

   In case I wasn't clear enough: she thinks climate scientists tend to *understate* the severity of the climate crisis, at least in their public pronouncements, and she gives a list of reasons for why they would.

6. **martibal**
   August 14, 2024

   I really wonder why the reliability of climate change science needs to be discussed continuously ? Of course it is good to discuss scientific results, and string theory sadly shows that "trust the scientist" is not a sufficient argument, but I doubt many theoretical physicist have studied in great details the data analysis that lead to the discovery of – say – the Higgs boson. I guess many physicist just blindly trust the colleagues from CERN. So why is climate change science always put in doubt ?

7. **Peter Woit**
   August 14, 2024

   All,
   Please, no more comments about climate science. The only point of my posting was
   1. I personally have neither the time nor competence to evaluate the reliability of different climate models projecting the future climate.
   2. "Just trust the mainstream science establishment" doesn't work for me based on long experience in a different scientific field.
   3. I'm grateful that in Sabine Hossenfelder we have a science communicator who doesn't just tell us "trust scientists" and recommend the linked video.

8. **Tommaso Dorigo**
   August 18, 2024

   Hello Peter,
   thanks for the link! About radiation levels high up – I think that indeed for some of us a not insignificant part of our radiation dose comes from international flights. E.g. Gordon Watts just made the 2M miles mark with United, so presumably he's been up for 3M counting other companies. This is about 5000 hours at high altitude, where a x20 radiation level makes it about as much of a dose as one gets in 25 years on the ground. Gordon flies a lot, but there is people who flies much more (apart from airline pilots and hostesses, of course)… And now with the "all you can fly" programs (e.g. wizzair) this can only worsen.
   But I was indeed more concerned by observing the leaks from airport scanners!
   Cheers,
   T.

9. **David+Roberts**
   August 19, 2024

Bear McCreary is a phenomenal composer. If nothing else, the score to that musical will be well worth a listen.

Two More

August 13, 2024
Categories: Langlands, Uncategorized

Two more items:

- I can't recommend strongly enough that you watch the new Curt Jaimungal podcast with Edward Frenkel. The nominal topic is the recent proof of the geometric Langlands conjecture, but this is introductory material, with geometric Langlands and the proof to be covered in a part 2 of the conversation.

  Before getting into the story of the Langlands program at a very introductory level, Frenkel covers a wide range of topics about unification in math and physics and the difference between these two subjects. While there's a lot about mathematics, Frenkel also gives the most lucid explanation I've ever heard of exactly what string theory is, what its relation to mathematics is, and what its problems are as a theory of the real world. He has been intimately involved for a long time in research in this field, playing a major role in the geometric Langlands program and working together with both Langlands and Witten.

- Nordita this month is hosting a program on quantum gravity, aimed at covering a diversity of approaches. Videos of the talks are appearing here. The program includes an unusually large number of panel discussions about the state of the subject. One of these is a discussion of the Status of the string paradigm which has the unusual feature that two string theory skeptics (Damiano Anselmi and Neil Turok, who have worked on string theory) have been allowed to participate in the six member panel.

  The response to the failures over the last forty years seems to be that current researchers should not be held accountable for ways in which the string theory paradigm of the past has not worked out. Things are fine now that they have moved on to the Swampland program, have realized that progress on string theory will have a 500 year time-scale, and know that string theory is better than the Standard Model since it has a finite or countable number of ground states.

Comments

1. **Bertie**
   August 14, 2024

   What a marvellous podcast with Edward Frenkel! I think the host was getting frustrated that Frenken stayed at an elementary level in his explanation, but what a blessing this was for non-mathematicians like me. His introductory digression into string theory was also amazing (with hilarious reference made to Archimedes – yes jump out of the bath and run around naked, but not for 40 years).

2. **Some guy idk**
   August 15, 2024

   Would you say that the connection between geometric Langlands and S-duality is a curiosity or that it hints at something larger and of greater use?

3. **Peter Woit**
   August 15, 2024

   Some guy idk,
   Definitely this is a reflection of something deep about math and physics that we don't fully understand. For what is understood, Frenkel is a great source, I also recommend looking at David Ben-Zvi's talks and lecture courses on the subject.

4. **Karl Young**
   August 15, 2024

   Though I find Jaimungal a bit overbearing at times (e.g. the occasional melodramatic background music) I also find great value in what he does, particularly for retired generalist geezers like me who no longer keep up with the cutting edge of research in any area. And I have to agree that the interview with Frenkel was a total revelation. Frenkel's depth of knowledge and philosophically cogent views re. Mathematics, Physics, and Mathematical Physics, combined with his humor and common sense are a truly rare gift. I found it amazing that in that relatively short presentation I finally attained some insight into why proving Taniyama-Shimura-Weil in turn proved Fermat's Theorem as well as things like what's so important about N=4 supersymetry (maximally consistent extension of the Poincaré group). I wait with bated breath for the geometric Langlands conclusion !

5. **C**
   August 16, 2024

   They proved geometric Langlands. They soaked the metaphorical nut to the maximum. Now we must apply their technologies and hammer and chisel away at arithmetic Langlands until nothing is left.

6. **David in Tokyo**
   August 16, 2024

   Karl Young writes:
   "Though I find Jaimungal a bit overbearing at times"

   Maybe. But Frenkel would get stuck on a point and not move on, and Jaimungal would pull him back on track. Sure, I found myself disagreeing occassionally, but overall, he did a great job.

   "particularly for retired generalist geezers like me"

   Exactly. The magic of Frenkel is that he shows us non-specialists what we need to be looking into to get one step deeper into the material.

   This is the opposite of a common complaint I have with Quanta math articles: it'll say "a bit is a thing that can take on one of two values" and then jump into bleeding-edge-level math without showing you how to get there.

7. **Will Sawin**
   August 17, 2024

   @C

It's important to note that they only proved unramified geometric Langlands. The unramified geometric Langlands conjecture is often called the geometric Langlands conjecture because the ramified version is harder to state, and most work has been in the unramified case, but I would still guess that proving ramified geometric Langlands is easier than proving the function field Langlands conjecture, which is easier than proving the reciprocity conjecture for representations algebraic at infinity in the number field case, which is easier than proving the full Langlands conjectures over number fields.

8. **Ellie Kesselman**
   August 18, 2024

   I'm probably a first-time commenter here, but a long-time reader. Unlike the rest of the comments prior to mine, I wanted to thank you for sharing details of the Nordita program. I began with Status of the String as you recommended. I found the panel contributions of the two former string theorists (Damiano Anselmi and Neil Turok) to be the most informative and accessible. Anselmi presented first; too bad he was halved and even quartered in the video, all the way to the left of the screen. Turok didn't mince words, nor was he sarcastic! Both did good Q&As.

   Slightly off-topic: In the Wikipedia entry for Not Even Wrong, a few outgroup editors–myself included–have been trying to include mention of this blog. Not Even a single sentence has been allowed. Amusingly, the same editors who are the most anti-theist (their recent Wikipedia initiative was to categorize all Hindu deities, the Christian trinity, and G-d and the prophets of Judaism as "in-world characters") are also the most ardent supporters of unprovable physics.

9. **Low+Math,+Meely+Interacting**
   August 19, 2024

   Frenkel must be a lot of fun to interview. I've really enjoyed hearing his thoughts on these and other subjects that are now available online.

   It's tough to not get a bit discouraged, despite his jovial attitude. Insuperably large numbers of Calabi-Yau manifolds and the moduli stabilization problem are literally decades-old issues. It's nice to have it summarized so succinctly, but he could have provided exactly the same assessment 20 years ago, as others did, and have been doing. Yet today we have the Swampland Conjectures, one of which flatly denies our universe is what precision cosmology (which today is a fair term) tells us.

   The basic fact is that String Theory (with a capital S, I suppose) has been in violent disagreement with observation from the beginning, which is an astonishingly long time for anything remotely resembling science to be allowed to persist. That really is the bottom line, and philosophical arguments about beauty and the validity of anthropic reasoning, etc., etc. ad nauseam, should really have been minor asides to the basic, glaring fact of the matter: These ideas are just incredibly empirically wrong. They always have been, and there's precisely zero justifiable reason to think by now they won't always be.

   Occasionally this lands again on my brain like a physical blow, and I'm just bewildered again. You'd think by now I'd be inured to the disillusionment, especially given the state of the world at large, but afraid I'm not there yet.

10. **Peter Woit**
    August 19, 2024

    LMMI,
    What's discouraging are the many influential people in this subject who, forty years later, still promote the same hype. The interviews with Susskind and Frenkel are encouraging in that more and more people who understand this subject are willing to speak up and acknowledge that things haven't worked out.

11. **Low+Math,+Meely+Interacting**
    August 19, 2024

    Almost on cue, Quanta comes out with an article suggesting the putative DESI anomaly is support for the Swampland program. Ambulance chasing with a heap of grossly exaggerated relevance. My disillusionment continues unabated.

12. **Paolo Bertozzini**
    August 20, 2024

    Dear Peter, thanks for the interesting and useful links (as always).

    Let me start with a consideration on the quantum gravity program in Nordita: "(non-commutative) geometry" was essentially absent from the panorama of the many approaches to quantum gravity covered there. This is not surprising at all: (as I already mentioned here in comments to previous posts) it is already several years that approaches based on "geometry" somehow disappeared from the current trends in QG where, across all the several lines of research, there is a uniform substantial agreement on the fact that "geometry" is only *emergent* and the fundamental degrees of freedom are quantum *pre-geometric*. The main trouble for researchers that try to dedicate time and energy on the study of *geometry of QFT* in view of applications to QG (including spinorial/twistorial geometry in 4-d), is not so much now the hype due to string theory, holography or quantum information, but this kind of wide consensus that deprives general relativity (and geometry) from a role in a fundamental theory. This, in my opinion, is deeply related to the historical evolution of QFT "post-renormalization", with its ideological reliance on "effective field theory", reductionism and "emergence".

    Among the speakers/moderators invited in the several panel discussions in Nordita, I found particularly interesting N.Turok (with His intriguing alternative "mirror-cosmology") and (in view of my personal lines of research in algebraic QFT in QG) the point of view of S.Giddings on the encoding of geometry via the net of observables algebras on Hilbert space … something that in algebraic quantum field theory goes back to R.Haag and U.Bannier (and was further developed, in view of reconstruction of Minkowski space-time, by D.Buchholz and S.Summers).

    The podcast from Frenkel is for sure very pleasant: I do appreciate His great ability to simplify a very complicated topic in a way that still allows to grasp some fundamental ideas. Still, I suspect that "oversimplification" in the discussion about the relation between mathematics and physics is deeply misleading: it might serve as a naive explanation/justification for the huge past and present interest of some mathematicians in mathematical topics related to, or inspired by, string theory, but nothing more than that. The interplay between the notions of "mathematical truth" and "physical reality" is way more complex than the mere statement that physical reality is a singleton in a landscape of mathematical truths (that btw seems to suggest that mathematicians are living in a "delusion of imaginary landscapes"). Furthermore mathematics is not completely immune to the social pathologies created by hype and powerful influences that have been so evident in certain areas of theoretical physics: the role of "standard proofs" or "computer simulations" in mathematics is very similar to that of "reproducible experimental evidence" in physics and hence similar issues are going to be found when reliance on such pillars is shaking or just changing (see "theoretical-mathematics" as in Jaffe-Quinn or the current discussions on "automated theorems checking and AI" as exposed in the recent Scientific American interview to T.Tao or in M.Harris' blog).

    Best Regards 🙂

    August 20, 2024

    Reading the program on Quantum Gravity : the title of the second week *Workshop on **Formal Aspects and Consistency of Quantum Gravity Approaches*** reminds me of the following quote of Pierre Cartier (who died a few days ago*)

> To conclude, I would like to offer some remarks about the word “formal”. For the mathematician, it usually means “according to the standard of formal rigor, of formal logic”. For the physicists, it is more or less synonymous with “heuristic” as opposed to “rigorous”. It is very often a source of misunderstanding between these two groups of scientists.

source: https://www.emis.de/journals/SLC/wpapers/s44cartier1.pdf
His death is a loss for the mathematical community I think from my narrow perspective as he was a bridge between mathematicians and mathematical physicists if not theoretical physicists and mathemagicians.
It might be worth noting *his dream of a cosmic Galois group* is still alive and a kicking example of hopes and dangers or subtleties in conjectures illustrated for instance by Francis Brown work on multizetas or Elliott Gesteau last preprint on the factorization paradox.

*https://www.lemonde.fr/disparitions/article/2024/08/19/pierre-cartier-mathematicien-francais-est-mort_6286756_3382.html

The Elegant Universe: 25th Anniversary Edition

August 20, 2024
Categories: Book Reviews

Brian Greene's The Elegant Universe is being reissued today, in a 25th anniversary edition. It's the same text as the original, with the addition of a 5 page preface and a 36 page epilogue.

The initial excitement among some theorists in late 1984 and 1985 that string theory would provide a successful unified theory had died down by the early 1990s, as it had become clear that this was not working out. This didn't stop the theory from continuing to be sold to the public in hype-heavy books such as Michio Kaku's 1995 Hyperspace. Interest in string theory among theorists was revived in the mid-nineties by the advent of branes/dualities/M-theory. The publication of the *The Elegant Universe* in 1999 brought to the public the same hyped story about unification, together with the news of the new "M-theory". The book was wildly successful, selling something like 2 million copies worldwide. A 3-hour PBS special based on the book reached an even larger audience.

From the beginning in 1984 I was dubious about string theory unification, and by the late 1990s could not understand why this was dominating physics departments and popular science outlets, with no acknowledgement of the serious problems and failures of the theory. From talking privately to physicists, it became clear that the field of particle theory had for quite a while become disturbingly tribal. There was a string theory tribe, seeing itself as embattled and fighting less intelligent other tribes for scarce resources. Those within the tribe wouldn't say anything publicly critical of the theory, since that would not only hurt their own interests, but possibly get them kicked out of the tribe. Those outside the tribe also were very leery of saying anything, partly because they felt they lacked the expertise to do so, partly because they feared retribution from powerful figures in the string theory tribe.

At some point I decided that someone should do something about this, and if no one else was going to say anything, maybe I needed to be the one to do so. My unusual position in a math department pretty well insulated me from the pressures that kept others quiet. I've told the story of the article I wrote starting at the end of 2000 here. It was put on the arXiv in early 2001 and ultimately published in American Scientist. Looking at it again after all these years, I think the argument made there stands up extremely well. While there was no direct reference to the Greene and Kaku books, there was:

> String theorists often attempt to make an aesthetic argument, a claim that the theory is strikingly "elegant" or "beautiful". Since there is no well-defined theory, it's hard to know what to make of these claims, and one is reminded of another quote from Pauli. Annoyed by Heisenberg's claims that modulo some details he had a wonderful unified theory (he didn't), Pauli sent his friends a postcard containing a blank rectangle and the text "This is to show the world I can paint like Titian. Only technical details are missing." Since no one knows what "M-theory" is, its beauty is that of Pauli's painting. Even if a consistent M-theory can be found, it may very well be a theory of great complexity and ugliness.

The subject of string theory and the state of fundamental physics was complicated and interesting enough that I thought it deserved a book length treatment, which I started writing in 2002 (the story of that is here). The book I wrote was not a direct response to T*he Elegant Universe*, but was an alternative take on the history and current state of the subject, trying to provide a different and more fact-based point of view.

During this time, Kaku came out with his own M-theory book, Parallel Worlds, published in 2004. Also in 2004, Greene published a follow-up to T*he Elegant Universe*, entitled *The Fabric of the Cosmos*, which was the basis several years later of a four-hour Nova special.
Over the last twenty-years there's been no let up, with Kaku's latest The God Equation, yet another hype-filled rehash of the usual string theory material. Greene regularly uses his World Science Foundation to do more string theory promotion, most recently putting out "The State of String Theory", where we learn the subject deserves an A+++.

In recent years I've often heard from string theorists who feel that their research is getting a bad name because of the nature of the Greene/Kaku material. They see this hype as something that happened long ago, back before they got into the subject, so ask why they should be held accountable for it. When asked why they won't do anything about the ongoing hype problem, it becomes clear that string theory tribalism is still a potent force.

Turning to the new material in this new edition of the book, much of it is the usual over-the-top hype, although often in a rather defensive mode:

> the past twenty-five years have been such an astonishingly productive period that exploring progress fully could easily fill an entire book on its own… The fact is, the past twenty-five years have been jam-packed with discoveries in which string theorists have scaled towering problems and dug deeply into long-standing mysteries… the decades of rich development in string theory carried out by some of the most creative, skeptical and discerning minds on the planet is the most readily apparent measure of the field's vitality. Scientists vote with their most precious commodity — their time. By that measure, and correspondingly, the measure of vibrant new ideas that have opened stunning vistas of discovery, string theory continues to be a source of inspiration, insight, and rapid progress.

While some scientists have left the field

> others, indeed so many others that string theory has been berated by for attracting too many of the highest-caliber scientists, have found that the pace of new theoretical discoveries and novel physical insights is so rapid and thrilling that they are propelled onward with vigor and excitement.

The epilogue mostly deals with three topics. The first is the failure to find SUSY at the LHC, which Greene explains is perfectly compatible with string theory, and that, even before the LHC turned on:

> there were theorists at that time who emphasized that string theory seems to favor superheavy superpartners, far too massive for the Large Hadron Collider or even any remotely realistic next-generations colliders to produce.

He acknowledges that at the present time string theory predicts nothing at all about anything, that even if we had a Planck scale collider:

> We would still need to understand the theory with greater depth to make detailed comparisons between calculations and data, but in that imagined setting experiment would guide theorizing much as it has across a significant stretch of the history of physics.

The second topic is the string theory landscape and the anthropic multiverse "prediction" of the CC, with about ten pages devoted to explaining that

> the dark energy has its measured value because if its value had been significantly different, we would not be here to measure it.

The final topic, taking up twelve pages, is AdS/CFT. The conclusion is that:

> *We now have powerful evidence that — shockingly — string theory and quantum field theory are actually different languages for expressing one and the same physics*. In consequence, the experimental luster of quantum field theory casts a newfound experimental glow on string theory.

No more "what is M-theory?", instead we're told that the question "What is the fundamental principle underlying string theory?" gets answered by:

> the new lesson seems to be that quantum mechanics already has gravity imprinted into its deep structure. The power of string theory is that its vibrating filiaments allows us to more easily see this connection.

The last section is "A Final Assessment." No A+++, but:

> In the arena of unification, both in terms of showing that gravity and quantum mechanics can be united as well as demonstrating that such a union can embrace non-gravitational forces and matter particles too, I give string theory an A. String theory surmounts the difficult mathematical hurdles that afflicted earlier work on unification and so, at least on paper, establishes that we have a framework in which the dream of unification can be realized.
> In the arena of experimental or observational confirmation, I give string theory an incomplete.

One thing I was looking for in the new material was Greene's response to the detailed criticisms of string theory that have been made by me and others such as Lee Smolin and Sabine Hossenfelder over the last 25 years. It's there, and here it is, in full:

> There is a small but vocal group of string theory detractors who, with a straight face, say things like "A long time ago you string theorists promised to have the fundamental laws of quantum gravity all wrapped up, so why aren't you done?" or "You string theorists are now going in directions you never expected," to which I respond, in reverse order "Well, yes, the excitement of searching into the unknown is to discover new directions" and "You must be kidding."

As one of the "small but vocal group" I'll just point out that this is an absurd and highly offensive straw-man argument. The arguments in quotation marks are not ones being made by string theory detractors, and the fact that he makes up this nonsense and refuses to engage with the real arguments speaks volumes.

Note: after tomorrow I'll be on a short vacation for a while in San Francisco and dealing with blog comments might take longer than usual.

   August 20, 2024

   You said Green's sold two millions. Just to have an idea of the impact of the critics versus hype, how much did you sell with your book ?

2. **Peter Woit**
   August 20, 2024

   martibal,
   I didn't pay much attention to that number, and almost all the sales were long ago (the book now sells only a small number of copies/year). I think the right order of magnitude was significantly more than 10,000, significantly less than 100,000.

3. **thphys**
   August 20, 2024

   I was one in a generation of physicists motivated to study string theory in graduate school in large part due to The Elegant Universe (I was in high school when it was first published). My entering graduate class at Stanford almost 20 years ago started with about a dozen students who initially wanted to study string theory, but nearly all moved on to other realms of theoretical physics after taking a course or two on string theory as first years. I think among many students then it became very obvious very quickly that the purported beauty of string theory was at most skin deep.

   It's a rather disappointing irony that with this re-release of The Elegant Universe, Greene seems to have leaned in to the content of the second half of the book, which was by far weaker than the first half (even with no skin in the string theory game). At the time anyway, from my naive student perspective, there were very few titles on the market that made the oddities and confusions of quantum mechanics and relativity so accessible and engaging as the first half of The Elegant Universe. With major results and Nobel prizes in both of these fields since its initial publication, it seems rather a shame that he has just doubled down on string theory. Though I guess that is at least consistent with the World String Festival that he hosts.

4. **Felix**
   August 20, 2024

   I read The Elegant Universe just before starting my undergraduate degree and was totally convinced by it that string theory was going to solve all of physics. It took a few months of studying in a physics department full of actual particle physicists to realise none of them took it seriously, and most of them thought it was embarrassing. I tried to watch the 'The State of String Theory' panel discussion but gave up very quickly once it turned into an uncritical string theory love-in. Michio Kaku has a lot to answer for, but I think Brian Greene is up there for guilt in terms of misinformation.

5. **Mark**
   August 21, 2024

   I did an undergraduate degree in theoretical physics thanks to books by Kaku and Greene. Thankfully an experimental particle physicist convinced me I would be better off switching to experimental work for my PhD.

6. **Peter Woit**
   August 21, 2024

   It's interesting to see that the comments back up an argument I've often heard from physicists when I criticize books like this. They tell me "sure, the material in that book about string theory is nonsense and misleading the public, but it's getting young people excited about physics and interested in becoming physicists. Once they do become physicists they'll realize this is nonsense and go on to do some real physics."

7. **Jan-Magnus Økland**
   August 21, 2024

   I believe that, in that book, Greene told the story of my once PhD advisor, the late Stein Arild Strømme and Geir Ellingsrud finding the wrong number of twisted cubics on the general quintic threefold, only to be corrected by a new string theory way of coming up not only with the corrected number but a recursive formula for degree d rational curves on there. Stein Arild quickly found the coding error and gave string theorists a win. That complex quintic threefolds are real six dimensional spaces with flat metric that could curl up in every space time point making ten dimensions and rational curves being important in that theory and giving candidates for a model of our world suddenly was all the rage. If I recall correctly there were too many candidates. However the count of 317206375 still stands. Not even wrong, being a fitting phrase for it.

8. **Paul**
   August 21, 2024

   thphys, that sounds like the incoming class of 2007. I was there and can confirm. I remember during graduate school orientation when a string theorist told the incoming particle theorists, "We don't have room for all of you, so you'll have to switch to something else." That's right after they admitted us knowing our intentions, and we accepted.

It's an interesting phenomenon of unintentional bait and switch. Physics departments love the extra attention, publicity, and enrollment figures, but not everyone likes the field that is doing the recruitment.

9. **Doug+McDonald**
August 21, 2024

In 1967 I was a Chemistry grad student (doing scattering experiments and their theory) and took an advanced QM course in Chemistry and sat in on Glashow's second-level physics course. One big thing at the time was (the tail end of) S-matrix theory and Regge Trajectories.

Today I was looking in Wikipedia and found, in an article on Quantum Chromodynamics the following:
"The relation between the short-distance particle limit and the confining long-distance limit is one of the topics recently explored using string theory, the modern form of S-matrix theory."

To me that seems to be very damning.

10. **Peter Woit**
August 21, 2024

Doug McDonald,
It's more the amplitudes program that is the modern form of S-matrix theory. String theory is something much worse….

That sentence is complete nonsense, and the quoted papers don't correspond to the claim. The idea that QCD in some other variables is some sort of string theory has been around for a very long time, I spent a lot of time thinking about that in grad school. The problem is exactly the opposite of what the sentence says: no one has any idea how to get the asymptotic freedom of QCD out of string theory.

To help Wikipedia out I deleted that sentence.

11. **Doug+McDonald**
August 21, 2024

Thanks for correcting Wikipedia.

12. **Eric+Weinstein**
August 21, 2024

I am not aware of anyone holding so much as a single multi-day conference on physics forcing a re-examination of whether this is "Academic Capture" by string theorists where the leaders of the failed string generation were forced into head to head contact with String Theory's critics.

By my estimation, it would cost the same ammount in 2024 dollars for a string of 3 conferences like Shelter Island, Oldstone and Poccono cost in the 1940 when Fundamental Physics ended its 19 year stagnation. Surely I am not the only one to have noticed this. Yet everyone treats this as if it were madness. Odd no?

Is there ever a point when this is too long, failed and insane to be a mistake, fad or accident? Would that be 50 years? 100 years? 200 years?

I don't think in 2024, this is gauranteed to be a bug. I think it must be considered at this point that we may be looking at a feature. String theory, unlike real physics, is safe and has that as an actual major advantage over say the Spinorial/Twistor approaches. Further it only acknowledges one rival that it has chosen itself (LQG) and only aggrees to contests it, itself judges by String standards.

Real physics remains the most dangerous subject known to man, as we know from WWII, Castle Bravo and the Atomic Energy Acts of 1946 and 1954. Imagine what the next theory might bring. It could be arbitrarily powerful and much easier to deploy.

String theory doesn't confer military advantage. It's harmless. You can do it with your friends. You can do it with your rivals. It's totally harmless and safe. What it does is simple to state: it kills funding, interest, morale and opportunity in vital rival theories of physics while stagnating the field, far better than any known alternative. It's a near perfect sterility program.

But, of course, that is madness to suggest that $500,000 dollars (or less!) could be used to figure out whether this is the only game in town as claimed by people who refuse to constructively and collegially engage their colleagues. After all, our String Theorists are far too busy succeeding and winning to consider wasting their precious time on alternatives…IYKYK. 😉

13. **Carl Feinberg**
August 22, 2024

I attended the "State of String Theory". Although Andy Strominger gave it an A+ (as opposed to an A+++, David Gross gave it a B+ and Ed Witten declined to give it a letter grade. Cumrun Vafa was a no show on the panel due to Covid.

14. **Diogenes**
August 24, 2024

Those of us who know, know. But if you were at Harvard in 1985 you know very smart people were pretty dubious about string theory but said "Hey let Ed go with it, he's unbelievably smart." I was there when Schwartz came to Jefferson Hall and spoke about the cancellations. It was interesting. There was still a lot of scepticism even then. It is sad to see what has become of Brian Greene. Not much else has worked out either.

15. **Bernhard**
August 24, 2024

The only string theorist I can recall who actually engaged in responding at least a few of the arguments made by you and Smolin was the late Polshinski, at least in the beginning. Since then, it has always been straw-man attacks.

16. **NS**
August 26, 2024

@Carl Feinberg. Strominger gives an A++ earlier in the discussion (at 43:00). Without any irony, he adds that otherwise he wouldn't be working in it.

17. **Redeemed string theorist**
August 30, 2024

This book is notorious for being solely responsible in making a bunch of millennial string theorists who now have no choice but to do string theory if they want an academic job.

The Terrifying Power of Mathematics

August 29, 2024
Categories: Uncategorized

Ted Jacobson has put on the arXiv a transcription of a 1947 Feynman letter about his efforts to better understand the Dirac equation, in order to find a path integral formulation of it. The letter also contains some fascinating comments by Feynman about mathematics and its relation to "understanding". In particular I like this one:

> the terrifying power of math. to make us say things which we don't understand but are true.

In some other places in the text he elaborates:

> The power of mathematics is terrifying – and too many physicists finding they have the correct equations without understanding them have been so terrified they give up trying to understand them. I want to go back & try to understand them. What do I mean by understanding? Nothing deep or accurate — just to be able to see some of the qualitative consequences of the equations by some method other than solving them in detail.

The Dirac equation is something wondrous and mystifying. If one tries, like Feynman, to find a simple understanding of it in conventional geometric terms, one is doomed to failure. It is expressing something about not the conventional geometry of vectors, but the deeper and much more poorly understood geometry of spinors.

In terms of Feynman's goal of finding a path integral formulation, the best answer to this problem I know of is the supersymmetric path integral. For one place to read about this, see David Tong's notes, in particular section 3.3.1. In this paper, Atiyah gives a closely related interpretation of the Dirac operator in terms of an integral over the loop space of a manifold, using a formal argument in terms of differential forms on the loop space. I don't think either of these though are what Feynman was looking for.

In any case, what one really cares about is not a single-particle theory, but the quantum field theory of fields satisfying the Dirac equation. Here there's a standard apparatus of how to calculate given in every quantum field theory textbook. These standard calculations involving Dirac gamma-matrices fit well with Feynman's "physicists finding they have the correct equations without understanding them have been so terrified they give up trying to understand them".

Comments

1. **John Horgan**
   August 31, 2024

   What Feynman calls "terrifying" is what Wigner calls "unreasonable." Why does math work so well, and what does it actually tell us about the world? Good questions, with no definitive answers.

2. **aldo6**
   August 31, 2024

   Interesting, thanks for the link.

   Unrelatedly: there's a piece in the Giardian about Grothendieck. https://www.theguardian.com/science/article/2024/aug/31/alexander-grothendieck-huawei-ai-artificial-intelligence

3. **aldo7**
   September 1, 2024

   Apparently there was a 5 part podcast about Grothendieck on Radio France last month https://www.radiofrance.fr/franceculture/podcasts/serie-alexandre-grothendieck-legende-rebelle-des-mathematiques

   And there's a conference on Topos next week https://ctta.igrothendieck.org/

4. **tulpoeid**
   September 3, 2024

   I'd be really interested in a longer explanation of what the last sentence of this post means to say.

5. **Peter Woit**
   September 3, 2024

   tulpoeid,
   I'm working on understanding details of how Wick rotation works for spinors, and one striking thing is how hard it is to find a clear, coordinate-invariant geometric description of how spinor fields work, even in Minkowski space. The geometry of spinors and the Clifford algebra is subtle, but the standard treatments in a QFT book don't even try to use this, instead just write down formulas and show that they work.

6. **Anon X**
   September 5, 2024

   Peter,
   I'm not sure this is what you're looking for, but the lovely book by Gregori L.Naber " The Geometry of Minkowski Spacetime-2nd edition" has a sizeable amount of material regarding spinors on Minkowski…

7. **Peter Woit**
   September 5, 2024

   Anon X,
   That's about spinors in Minkowski space-time, there's lots of places where this is done. Also lots of places where spinors in Euclidean space-time are discussed, which is a significantly different story. What's not well-known and much more subtle is the relation between these two (e.g. how does Wick rotation work for spinors?).

Podcast on Unification

September 2, 2024
Categories: Euclidean Twistor Unification

I recently did another podcast with Curt Jaimungal, on the topic of unification, which is now available here. As part of this I prepared some slides, which are available here.

The main goal of the slides is to explain the failure of the general paradigm of unification that we have now lived with for 50 years, which involves adding a large number of extra degrees of freedom to the Standard Model. All examples of this paradigm fail due to two factors:

- The lack of any experimental evidence for these new degrees of freedom.
- Whatever you get from new symmetries carried by the extra degrees of freedom is lost by the fact that you have to introduce new ad hoc structure to explain why you don't see them.

There's also a bit about the new ideas I've been working on, but that's a separate topic. Over the summer I've been making some progress on this, still in the middle of trying to understand exactly what is going on and write it up in a readable way. I'll try and write one or more blog entries giving some more details of this in the near future.

Comments

1. **Bryan**
   September 3, 2024

   I just watched the interview, and from my layman pov I thought it was great. Definitely the clearest explanation I've seen of your new ideas! My question is: in the presentation you talk about some of the questions unified theories have tried and failed to answer, so how does this approach of explaining wick rotation with imaginary time in Euclidean geometry help to answer these outstanding questions? Is it mainly about the ability to do certain lattice calculations that you alluded to? Or is it that formalizing the wick rotation like this might lead to other unknown future insights and predictions?

2. **Peter Woit**
   September 3, 2024

   Bryan,
   I'm afraid I didn't really explain this here, to explain the ideas carefully is another whole talk. Working out details still in progress, but the basic claim is that when you Wick rotate spinors from Euclidean spacetime to Minkowski, one of the two SU(2)s that makes up rotations in 4d Euclidean space-time becomes the internal SU(2) symmetry of the standard model (NOT the usually expected Minkowski space-time transformations). This gives an explanation of the SU(2) in the SM, and a new avenue for unifying things.

3. **Bryan**
   September 3, 2024

   Peter, thanks for the explanation. During the lecture I didn't know what you meant by "internal symmetries" but now it makes sense. Thanks!

4. **Gavin**
   September 4, 2024

   This is a genuine question, not meant as a challenge.

   If you identify one of the SU(2)'s going from Euclidean to Lorentzian signature with an internal symmetry, where does fermions of the other handedness come from? In other words, your Wick rotation will generate (say) right-handed fermions. If I understand correctly (and maybe I don't), instead of generating fermions that transform in a left-handed spinor representation, the Wick rotation will generate fermions that transform in the SU(2) weak gauge group. But we observe states which transform with a left-handed spinor representation (for example, the electron has a mass so it has both left and right handed spinor components). Where do those left-handed states come from in this picture?

5. **Peter Woit**
   September 4, 2024

   Gavin,
   Still working on writing up the details of this that would completely answer your question, but here are some things to keep in mind (note, here "right" and "left" are being used to label chirality, not discussing helicity).

   1. The way chirality (left vs. right) works is quite different in Euclidean and Minkowski signature. In Euclidean spacetime, there are independent SU(2) groups for each chirality. In Minkowski spacetime there is just one SL(2,C) group.

   2. The way chirality works in Minkowski spacetime is that the standard spinor representation of the SL(2,C) group is one chirality, the complex conjugate representation the other chirality. If a particle is right chirality, its antiparticle is left chirality. It's well-known that when you write the SM in terms of fundamental Weyl fields, you can take the fundamental fields to be all one chirality (say, right, to go with my "spacetime is right-handed" slogan). The left chirality particles are anti-particles of these fundamental fields.

   There's a lot more to say about this, again, exactly how the reconstruction of the Minkowski spacetime spinor fields from the Euclidean spacetime spinor fields works, and what happens to chirality as you do this, is something I'm still sorting out.

6. **Nigel B**
   September 4, 2024

   Presumably, Peter, your approach circumvents the theorems of Lochlainn O'Raifeartaigh and Coleman-Mandula relating to the impossibility of combining internal symmetries with relativistic symmetries.

7. **Peter Woit**
   September 4, 2024

   Nigel B.,

Those theorems say that in Minkowski spacetime you can only extend spacetime symmetries by symmetries that commute with spacetime symmetries ("internal"). If you extend by symmetries that don't commute with spacetime symmetries, you will get a trivial theory.

What I'm doing doesn't violate this, since the Euclidean left SU(2), after Wick rotation, commutes with Minkowski space-time symmetries.

This should be clear from the point of view of my last paper, where, from the complex point of view, encompassing both Euclidean and Minkowski, space-time symmetry is purely right-handed, commuting with the left-handed factor.

8. **Gavin**
   September 4, 2024

   Thanks! Looking forward to seeing the details!

9. **Mitchell Porter**
   September 4, 2024

   Regarding evidence in favor of conventional unification, one could mention the near-unification of the gauge couplings when extrapolated to high energies, and the fact that the generations form SU(5) or SO(10) multiplets. (I sometimes wonder to what extent anomaly cancellation alone, favors ensembles of fields that look like GUT multiplets.)

10. **Peter Woit**
    September 5, 2024

    Mitchell Porter,
    That a generation fits nicely into the spin representation of SO(10) may very well be some kind of hint about unification. But the SO(10) symmetry is very badly broken, and this embodies exactly the problem I'm pointing to: whatever positive you get from the new symmetry is overwhelmed by the huge negative of having to introduce all sorts of ad hoc new structures and parameters, just to break the new symmetry down to the SM symmetry, carefully hiding all observable effects of the new symmetry.

    On coupling constant unification, same problem. There you have the additional problem of needing a SUSY theory, so you get all the extra negatives of having to do SUSY breaking.

    Georgi and Glashow were right to give up on this a long time ago, even though it was their baby. Since that time, things have just gotten worse and worse for this idea every year, as limits on SUSY masses and the proton lifetime get pushed higher and higher.

11. **arno**
    September 6, 2024

    Dear Peter,

    I am a "chiral" theoretical physicist (studying quark matter) and I do not understand physically your statement: "The left chirality particles are anti-particles of these fundamental fields".

    For massive Weyl fermions, the mass mixes chirality and it is not a good quantum number. Very simply put, a left handed fermion for an observer is right handed for another inertial observer if he has the correct speed and this is possible because the fermion does not go at the speed of light. Hence the chirality is not a good quantum number because it is not observer independant. I do not see how your statement about the left chirality of particles being anti-particles is compatible with this physical explanation.

    But I am not a mathematician so may be the misunderstanding is purely a matter of physical interpretation of mathematical statement.

    Best,

    Arno

12. **Peter Woit**
    September 6, 2024

    Arno,
    I think there are various problems of terminology here. For me Weyl fermions are massless, so I'm not talking about mass terms, or SM Yukawas. For massive particles helicity is not chirality, have to distinguish the two.

    I don't want to get into this anyway, because what I'm talking about is just exactly the same story that is in every textbook if you just look at it in Minkowski space-time. For what I'm interested in, you have to think about Euclidean space-time spinors. Part of the story is that the way chirality works is quite different in the two cases. In Euclidean space time right and left chirality Weyl spinors are completely independent, while in Minkowski spacetime they are conjugates of each other.

13. **Bertie**
    September 6, 2024

    One question for Peter, have you used any mathematical construction so far that wasn't already published before 1973? In the optimistic scenario that you are on to something remarkable, how sad it would be if it could have all been done 5 decades earlier, just imagine the progress that might have been possible in the intervening period, compared to what we got.

14. **Peter Woit**
    September 7, 2024

    Bertie,

    Most of what I'm looking at involves results in math and physics not necessarily pre-1973, but from the 70s and early 80s, before the field reoriented around string theory in 1984-5. In particular, the main work on twistors in Euclidean signature and the relation of this self-dual Yang-Mills began in 1977-78.

    One thing I've been spending a lot of time looking at is the standard reference about wick rotation of spinor fields, an Osterwalder-Schrader paper from 1973.

15. **issa**
    September 7, 2024

peter:

i greatly enjoyed both the recap and the new ideas. i'm not well versed in these areas but i'm trying! 🙂

to ask a vaguely curt-like question and to tie the second half of your talk back to the first a little bit, would it be fair to summarize your approach (as manifested, not necessarily as conceived) as something akin to: "why are we off inventing new things (structures, dofs) which don't describe the universe when we haven't actually nailed down what we think we are sure on? and look, when i really try to nail down some of these existing technicalities everyone is hand waving (in this case spinors under wick rotation), things start to happen that seem like exactly what we were missing?"

16. **Peter Woit**
September 7, 2024

issa,
Yes, that's a pretty good summary.

17. **Mathieu**
September 7, 2024

Dear Peter,
On the unification topic, is there something like a yearly progress review that would summarize the successes and failures of the most studied currents, and present the promising new ideas ? (Sorry for the somehow naïve question)

18. **Peter Woit**
September 8, 2024

Mathieu,
Unfortunately a yearly progress review of the kind you are asking for would just say that their have been no successes, and no one is interested in discussing the failures. As for promising new ideas, lots of people with often dubious claims of them, but none that have gotten any wide acceptance.

19. **lun**
September 9, 2024

So any idea how SU(3) (QCD) and U(1) (the "rest" of the electroweak theory) emerge? Why is SU(2) "special"?

20. **Peter Woit**
September 10, 2024

lun,
Some related ideas about SU(3) and U(1) are in the "Twistor Unification" paper I wrote and talks about that. It is is the SU(2) and its chiral nature that has an explanation just from trying to understand Wick rotation for spinors, without getting into the twistor story.

21. **David Roberts**
September 10, 2024

I can't say anything about physics, but su(2) is pretty special from a mathematical point of view, since it is small, but mighty, and turns up everywhere. ^_^

(PS Peter— I don't know what happened with commenters' names all getting a + instead of spaces, but I finally remembered to edit to take it out)

Podcast About String Theory, Other Items

September 8, 2024
Categories: Uncategorized

A few weeks ago I recorded a podcast with Robinson Erhardt, which has now appeared as String Theory and the Crisis in Physics. We mainly talk about the current situation of string theory in physics and the history of how things have gotten to this point, topics familiar to readers of this blog.

Some other items:

- A Frequently Asked Question from students is for a good place to learn about the geometry used in gauge theory, i.e. the theory of connections and curvature for principal and vector bundles. Applied to the case of the frame bundle, this also gives a way of understanding the geometry of general relativity. One reference I'm aware of is *Gauge Fields, Knots and Gravity*, by John Baez and Javier P. Muniain, but I'd love to hear other suggestions. These could be more mathematical, but in a form physicists have a fighting chance at reading, or more from the physics point of view.
- For new material from mathematicians lecturing about quantum field theory, see Pavel Etingof's course notes, and Graeme Segal's four lectures at the ICMS (available in this youtube playlist).
- If you want to understand the mindset of the young string theory true believer these days, stringking42069 is back.
- There's something called "Plectics Laboratories" which has been hosting mainly historical talks from leading physicists and mathematicians. For past talks, see their youtube channel. For a series upcoming September 23-27, see here.
- The IAS is hosting an ongoing Workshop on Quantum Information and Physics. One topic is prospects for future wormhole publicity stunts based on quantum computer calculations, see here. At the end of the talk, Maldacena raises the publicity stunt question (he calls it a "philosophical question") of whether you can get away with claiming that you have created a black hole when you do a quantum computer simulation of one of the models he discussed.
- Ananyo Bhattacharya at Nautilus has an article on the role of physics in creating new math. While there is a lot there to point to, recent years have not seen the same kind of breakthroughs Witten and Atiyah were involved in during the 1980s and 90s. I'm hoping for some progress the other way, that new ideas from mathematics will somehow help fundamental theoretical physics out of its doldrums.

2. **Jack**
   September 9, 2024

   Peter,

   In addition to Baez and Muniain, I have enjoyed "Differential Geometry, Gauge Theories and Gravity" by Göckeler and Schücker, as well as the classic "Geometrical Methods of Mathematical Physics" by Schutz.

   The Eguchi, Gilkey and Hanson review is also very readable.

   Kind Regards

3. **Kartik Prabhu**
   September 9, 2024

   I did a quick review in https://arxiv.org/abs/1511.00388v3

   Some more physics-oriented ones:
   Y. Choquet-Bruhat, C. Dewitt-Morette, and M. Dillard-Bleick, Analysis, Manifolds and
   Physics, Part I: Basics.

   Y. Choquet-Bruhat and C. Dewitt-Morette, Analysis, Manifolds and Physics. Part II: 92
   Applications.

   Some more mathematical ones:
   S. Kobayashi and K. Nomizu, Foundations of Differential Geometry. Volume I. Interscience Tracts in Pure and Applied Mathematics.

   S. Kobayashi and K. Nomizu, Foundations of Differential Geometry. Volume II. Interscience Tracts in Pure and Applied Mathematics.

4. **La Rosa**
   September 9, 2024

   Concerning the first point, I would suggest Hamilton's Mathematical Gauge Theory.

5. **Arnold+Neumaier**
   September 9, 2024

   Geometry of Physics by Frankel has somewhat higher mathematical standards.

6. **Phil Harmsworth**
   September 9, 2024

   The Eguchi, Gilkey and Hanson review mentioned above refers to T. Eguchi, P.B. Gilkey and A. J. Hanson, "Gravitation, Gauge Theories and Differential Geometry", Physics Reports 66 (6) (1980) pp. 213-393.

Chris Isham's book, Modern Differential Geometry for Physicists, World Scientific 1991 is very approachable.

Robert Hermann's book, Gauge Fields and Cartan-Ehresmann Connections, Math Sci Press 1975 is a good summary once you've mastered the material in the first two items.

7. **Andrzej+Daszkiewicz**
   September 9, 2024

   Two books by Gregory Naber, "Topology, Geometry and Gauge fields: Foundations" and "Topology, Geometry and Gauge fields: Interactions" keep a quite elementary approach, but go quite far and will be a good foundation for a more advanced reading.

8. **Garrett+Lisi**
   September 9, 2024

   I'm seeing lots of great suggestions above for covering the geometry of gauge theory. Over the years I've compiled some of my notes covering this and other topics into a personal wiki. People who enjoy a casual but mathematical wiki format may find it helpful. Here are three notes in it, of increasing sophistication:
   https://deferentialgeometry.org/#connection%20%5B%5BClifford%20vector%20bundle%5D%5D%20%5B%5BEhresmann%20principal%20bundle%20connection%5D%

9. **Cynicism**
   September 9, 2024

   Humble request: Could you stop giving air to Twitter?

   When you share a link to a tweet and you don't have an account, you can only see that tweet. Maybe. More often than not you just see a screen that says "Something went wrong. Retry?" It won't work if you retry.

   You might well say, "Well then go get an account." I used to have one but I deleted it when the terms of service got much more invasive. I have felt better about that decision since the list of owners came out.

   Moreover, Twitter is already inaccessible from Brazil. Surely there will be other countries. There is a great tradition of physics in Brazil: Bohm, Lattes, et al. Do you really want to cut them out from what you want to say about physics?

10. **Peter Woit**
    September 9, 2024

    Cynicism,
    Twitter is pretty much just a sewer of idiocy. Almost always when I link to something there it's to point to some kind of exceptional idiocy from string theorists. If you're a big fan of this kind of thing, maybe it would justify getting a twitter account, maybe not.

    Another reason for me to look at Twitter is that there are a few accounts that sometimes provide links to something interesting I didn't know about. In those cases what I put on the blog is not the Twitter source but the link.

11. **zzz**
    September 9, 2024

    i second that twitter request. i got an error or login request or some bs.

12. **Peter Woit**
    September 9, 2024

    zzz,
    Sorry, but if you want to experience the stringking phenomenon, you have to take the plunge into the Twitter sewer. I'm pointing to it rather than ignoring it because it gives some weird sort of insight into what is going on among some string theorists as they face the collapse of their subject.

    The whole thing reminds me a bit of a Hunter Thompson saying: "when the going gets weird, the weird turn pro."

13. **John Baez**
    September 9, 2024

    There is no such thing as Twitter.

14. **Peter Woit**
    September 9, 2024

    John Baez,
    Just because billionaires change names of things doesn't mean I have to use their new name. I'm boycotting using not only "X", but "Alphabet", "Meta" and "SLMath".

15. **Simone Speziale**
    September 9, 2024

    Dear Peter,

    indeed it would be nice if you would consider strengthening your boycott of using the name X to a complete boycott of linking to Twitter/X altogether… even if a sewage, I would think that linking to it still gives it relevance and encourages people to use it, which ultimately legitimizes Musk's take on it. And too bad if this makes us miss interesting sociological phenomena like stringking.

    Back to the question about references: on top of the many excellent ones already given, and for the specifics of the frame bundle approach to GR: the first few chapters of Chandra's mathematical theory of black holes are very nice and pedagogical.

16. **Johan**
    September 10, 2024

    Quite mathematical, but always keeping physics in sight, is

Shlomo Sternberg, Curvature in Mathematics and Physics, Dover, 2012.

17. **Karl Young**
September 10, 2024

Re. the podcast (and the one with Jaimungal) I have to say that it was nice getting a somewhat nuanced view of your take on the current state of physics (much of which rings true for me). As on old retired geezer who happily surfed the nonlinear dynamics fad and was able to parlay that into a happy, bottom feeding career in applied mathematical physics I have no skin in the game, but nonetheless found how pervasive the internal political influence of the string theorists, a little surprising. When I was in grad school in the late eighties, taking GR and QFT classes things seemed a little more wide open (though part of that may have been the result of a pretty strong crossover between cosmologists and high energy theorists in my department). Anyway that's all a rather long winded way of asking if there's a lot in Not Even Wrong that wasn't covered in these podcasts. I'm a pretty slow reader so at this age have to pick wisely, and though I'm sure I'd enjoy Not Even Wrong, if there's not much more than you expressed in the podcasts, it sounds like maybe I should go get up to speed on spinors instead (and any recommendations there are welcome).

18. **Peter Woit**
September 10, 2024

Karl Young,

As far as the string theory controversy goes, the two recent podcasts give a pretty good idea of my side of that, so if that's all you care about, you can live without reading the book. There is however, much material on other topics there, in particular a lot about the relation of math and physics, nothing to do with string theory.

Not much in the book about spinors, I'd agree that learning about those is a more fruitful pursuit than thinking about string theory. Hard to find good readable references on the topic. I've written some blog entries, should find time to write more and should create a category here so people could find them.

19. **lll**
September 11, 2024

Below I will put my two cents (literally!) on good references for learning the basics of (geometric) Gauge Theory:

i) before embarking on the project resulting in his monumental "Foundations of differential geometry" with Kobayashi, Nomizu wrote a booklet entitled "Lie groups and differential geometry", which I still find the best (mathematically oriented) introduction to principal bundles, connections, holonomy, etc;

ii) to those who have mastered Nomizu's little gem, I recommend reading Bleecker's "Gauge theory and variational principles", a slightly thicker and (essentially) self-contained account of the fundamentals of gauge theory, with emphasis on its variational aspects and including elegant discussions on spinors and on the unification of gauge fields and gravitation usually associated to Kaluza and Klein. Despite being too mathematically oriented on the whole, this jewel is filled here and there with insightful comments on the emergency of gauge invariance a more physically inclined reader may find fruitful.

20. **Scott Caveny**
September 11, 2024

Physics students wanting to understand more about the geometry of gauge theories might find the following texts useful:

1. 2004 A Course in Modern Mathematical Physics: Groups, Hilbert Space and Differential Geometry by Peter Szekeres

2. 2013 Mathematical Physics: A Modern Introduction to Its Foundations by Sadri Hassani

3. 2017 Differential Geometry and Mathematical Physics: Part I. Manifolds, Lie Groups and Hamiltonian Systems by Gerd Rudolph and Matthias Schmidt

4. 2017 Differential Geometry and Mathematical Physics: Part 2. Fibre Bundles, Topology and Gauge Fields by Gerd Rudolph and Matthias Schmidt

Physics students prepared to read mathematics literature (at the level of Choquet-Bruhat & Dewitt-Morett) may find useful content in

1. 1991 Modern Geometry: Part I: The Geometry of Surfaces, Transformation Groups, and Fields by B. A. Dubrovin, A. T. Foment, and S. P. Novikov

2. 1985 Modern Geometry: Part II: The Geometry and Topology of Manifolds by B. A. Dubrovin, A. T. Foment, and S. P. Novikov

3. 2017 Riemannian Geometry and Geometric Analysis Seventh Edition Jurgen Jost

21. **Aaron Cofer**
September 12, 2024

Thanks for posting the Etingof notes. It looks like a very interesting take on the subject (algebraic combinatorics view?), but that could be a reflection of my ignorance.

Do you know of any similar books/notes that take a more elementary approach along these lines?

22. **Anon X**
September 14, 2024

I think "Differential Geometry: Connections, Curvature, and Characteristic Classes" by Loring W. Tu is quite accessible. It's the sequel to his much liked "An Introduction to Manifolds".

23. **Hansi**
September 14, 2024

That one here,

Helga Baum, Eichfeldtheorie (Gauge field theory)
is in german but mathematically sound and rather simple:

https://www.amazon.de/Eichfeldtheorie-Differentialgeometrie-Faserb%C3%BCndeln-Springer-Lehrbuch-Masterclass/dp/3642385389

some of it is here on this pdf

https://www.mathematik.hu-berlin.de/~baum/Skript/KompaktkursHFB-05.pdf

For those who want a simple book on gauge theory that is easy to read, from a typical german math department which is not as high profile like Bonn….

This Week’s Hype

September 16, 2024
Categories: This Week's Hype

Today’s Washington Post has an opinion piece from Brian Greene, running under the demonstrably false title Decades later, string theory continues its march toward Einstein’s dream.

In the piece, the argument of string theory critics is given as:

> Critics argue that the situation is untenable, noting, “If you can’t test a theory, it’s not scientific.” Adherents counter, “String theory is a work in progress; it’s simply too early to pass judgment.” The critics retort, “Forty years is too early?” To which the adherents respond, “We’re developing what could be the most profound physical theory of all time — you can’t seriously cross your arms, tap your foot and suggest that time’s up.”

The problem with the results of forty years of research into string theory is not that progress has been too slow but that it has been dramatically negative. To see this, one can just compare the text of chapter 9 of Greene’s 1999 *The Elegant Universe*, which has an extensive discussion of prospects for testing string theory by finding superpartners, fractionally charged particles, or cosmic strings. Twenty-five years later, the results of experimental searches are in: no cosmic strings, no fractionally charged particles, and most definitively no evidence of superpartners of any kind from the LHC.

The other sorts of predictions advertised in that chapter are based on the idea that string theorists would better understand the theory and be able to make testable predictions about neutrino masses, proton decay, axions or new long range forces, the nature of dark matter, and the value of the cosmological constant. Instead of progress towards any of these, things have gone in the opposite direction: all evidence from better understanding of string theory is that it either naturally predicts things in violent disagreement with experiment (wrong dimension of space time, huge number of new long-range forces, …) or predicts nothing at all. 25 years later, Greene now goes with the latter:

> The challenge for string theory is that it has yet to produce *any* definitive, testable predictions.

The article goes on to make a different case for string theory:

> … string theory continues to captivate seasoned researchers and aspiring students alike because of the remarkable progress that has been made in developing its mathematical framework. This progress has yielded provocative insights into long-standing mysteries and introduced radically new ways of describing physical reality.
>
> For instance, string theory has provided unmatched insights into the surface of black holes, unraveling puzzles that have consumed some of the greatest minds, including Stephen Hawking. It has offered a novel, though controversial, explanation for the observed speedup of the universe’s expansion, proposing that our universe might be just one of many within a larger reality than conventional science ever imagined.

The problem here is that these supposed advances aren’t from advances in string theory. If you follow the link above that justifies “string theory has provided unmatched insights into the surface of black holes”, you’ll find the text:

> Most physicists have long assumed it would; that was the upshot of string theory, their leading candidate for a unified theory of nature. But the new calculations, though inspired by string theory, stand on their own, with nary a string in sight. Information gets out through the workings of gravity itself — just ordinary gravity with a single layer of quantum effects.

The string theory “explanation” for the value of the CC is just the “anthropic” explanation, which besides not really being a scientific explanation, has nothing to do with string theory.

The piece ends with something highly speculative and ill-defined (ER=EPR) that has nothing to do with string theory:

> Roughly, it’s as if particles are tiny black holes, and the entanglement between two of them is nothing but a connecting wormhole.
>
> If this realization holds up, we will need to shift our thinking about the unification of physics. We have long sought to bring general relativity and quantum mechanics together through a shotgun wedding, fusing the mathematics of the large and the small to yield a formalism that embraces both. But the duality between Einstein’s two 1935 papers would suggest that quantum mechanics and general relativity are already deeply connected — no need for them to marry — so our challenge will be to fully grasp their intrinsic relationship.
>
> Which would mean that Einstein, without realizing it, may have had the key to unification nearly a century ago.

Where string theory research is after 40 years is not on a continuing march forward towards “Einstein’s dream”, but in a state of intellectual collapse with no prospects of any connection to the real world, just more hype about vague hopes for something different, something for which there is no actual theory.

Update: I recommend checking out Sabine Hossenfelder’s latest youtube piece, which is mostly devoted to the Brian Greene wormhole publicity event stunt discussed earlier here. Near the end of the video, she tells a story that explains a lot about why this kind of thing keeps going on (see here). She had been writing a regular column for Quanta Magazine, but they stopped publishing her after she wrote a column in which she argued that physicists should not be misleading the public by claiming that the “black holes” supposedly on the other side of a duality from a given quantum system were actual physical black holes.

What she was warning about in 2019 is an essential part of the wormhole publicity stunt, and of other similar continuing efforts that have been going on for years. One impetus behind this nonsense has always been clear: there’s attention to be gotten, and money to be made. Another factor though is the one Hossenfelder explains here. Press outlets devoted to science want to publish positive news about scientific advances, want nothing to do with authors who explain that this positive news is nothing but hype.

Comments

1. **Paddy**
   September 16, 2024

   Read this WaPo “column” about 5am local time today. Been waiting for your response. Thank you. Was upset that they allowed such without a reasoned rebuttal.

2. **Bob Zannelli**
   September 16, 2024

   EPR=ER seems to be the latest rage but as Bob Wald has aptly said all these ideas to save quantum unitary in black hole evolution have a price tag of modifying quantum theory to the point of nonrecognition. (not his exact words) EPR=ER seem to me to be one of ugliest and ad hoc solutions to a problem it's not really clear there needs to be a solution for. Much more sensible in my opinion are the viewpoints of Wald, Unruh and Thorne and the late James Hartle who argue(d) that the black hole information problem isn't a real problem at all. What is the real problem are all the ad hoc theories trying to solve this problem.

3. **martibal**
September 16, 2024

What is the duality in Einstein two papers of 1935 that he is talking about ?

4. **Peter Woit**
September 16, 2024

martibal,
Einstein Rosen paper on wormholes versus EPR paradox paper.

5. **Diogenes**
September 16, 2024

The problem with string theory is not just that it doesn't predict anything per se (which it doesn't) but that in addition it doesn't make any existing theories more parsimonious or useful. For all kinds of technical reasons the unification part has failed. You are left with the quantum gravity part, which probably has worked better than any other approach, but still not that well at all. If moving away from point particles will always cause this much trouble it would be interesting to reflect upon why that is ..

6. **Peter**
September 16, 2024

I find the "we just need more time" argument particularly hard to understand.

There were roughly 50 years between the discovery of QM by Heisenberg and Schrödinger, and 't Hooft and Veltman. In those 50 years QM led to many interesting things: the Dirac equation, anti-particles, the neutrino, QED, the development of gauge theories, the description of the Higgs mechanism, the standard model … not to mention the Mössbauer effect, Raman spectroscopy, lasers, developments in solid state physics and so on. The standard model is a success, but it is far from the only success of QM.

It's now 40 years since the first superstring revolution. Physics' finest worked on it, uninterrupted by world wars. And as far as I understand, absolutely nothing comparable happened in string theory. In those circumstances, you have to have seriously strong guts to claim that you just need more time and everything will be fine.

7. **David**
September 16, 2024

I am a retired biophysics professor. This behavior just astounds me. I grew up in an environment where you went overboard to be careful that what you said was either true or you had to carefully qualify it. If I said something in a lecture or paper that turned out to not be quite right, I was mortified. If, for example, I had made the easily checked misstatement about the black hole link that you discuss, I don't think I could ever live it down. What is happening? Has there been a dramatic change in the academic scientific ethos, or is there something about this field that attracts this kind of behavior.

8. **Scott Aaronson**
September 16, 2024

I *think* I've been following this for long enough that I could simulate the next couple steps of the argument. Greene could say, for example, that the anthropic "explanation" for the CC isn't completely unrelated to string theory, since string theory gives you a context within which the dimensionless constants of the SM could vary in eternal inflation. He could also say that ER=EPR and the recent progress on the black hole information problem came from the string community, and plausibly wouldn't have emerged without that path (even if, at the end, the strings can be removed like scaffolds). You, in turn, could reply that it's nonsense to talk about a "string theory mechanism" for varying constants without a nonperturbative definition of the theory, and also, string theorists said 30 years ago that their goal involved unification of the forces and predictions confirmed by experiment, so why do they get to change the goal midgame to "quantum gravity insights from which the strings can be removed like scaffolding"?

9. **Peter+Shor**
September 16, 2024

I'm not convinced that the recent "progress" on the black hole information paradox holds water. Does anybody other than the authors really understand it?

If you know the results that you want to come up with, and you do enough non-rigorous manipulations of vaguely related quantities, you can almost always come up with the desired results. How sure are we that this isn't where these results came from?

10. **Philippe David**
September 16, 2024

Do you think the Washington Post would accept a countering opinion piece?

11. **Peter Woit**
September 16, 2024

Bob Zanelli,
My problem with ER=EPR is not that it's ugly and ad hoc, but that I don't see any actual calculation of anything that corresponds to what the Washington Post is advertising as the discovery that "particles are tiny black holes, and the entanglement between two of them is nothing but a connecting wormhole."
As far as I can tell, the problem is not that the theorists doing this have a theory that is ad hoc, but that they have no theory that is supposed to correspond to the real world.

12. **Peter Woit**
September 16, 2024

Peter,
I agree, but want to again emphasize that there has been progress in our understanding, but it's been in the opposite direction of that indicated by the Washington Post headline, which much more accurately should have been

"Decades later, string theory continues its march away from Einstein's dream."

13. **Peter Woit**
September 16, 2024

David,

I'm also astounded by what is going on here. 25 years ago I understood what Greene and others were doing as understandable enthusiasm for some specific ideas about physics (even though I had my doubts about them). Considering everything that has happened since then, I just don't understand at all why anyone involved in this would think it's a good idea to now go to the public claiming all is well and doubling down with even much more outrageous hype than that of 25 years ago.

14. **Peter Woit**
September 16, 2024

Scott Aaronson,

Yes, you qualify as a pro at this. That's exactly right.

15. **Peter Woit**
September 16, 2024

Philippe David,
I have no idea if the Washington Post would be interested in publishing such a piece. I do know that I feel I've done more than my part trying to deal with this kind of hype, so I'm not interested in being the one to work on arranging for and writing something. Among the many others who know enough about the subject to know what is seriously wrong here, I'd hope there are some who care enough about this to try and do something about it.

16. **Jean-Pierre Laflamme**
September 16, 2024

It seems increasingly clear that the very foundation of the theory, that fundamental particles are actually made of strings, is wrong or biased from the start. And this would be the reason why this theory is full of oddities or leads nowhere despite all the efforts made.
When you have taken a wrong turn from the start, you must have the humility to retrace your steps and start again in a more promising direction.

17. **wormholes**
September 16, 2024

When you plug simple numbers in ER=EPR, you see that it cannot work https://arxiv.org/pdf/2002.08178 . A wormhole connecting two entangled electrons would have a mass of 10^27 eV (in order to explain the entanglement entropy). Already grossly excluded with simple experiments.

18. **Alex**
September 16, 2024

Scott says,

"…why do they get to change the goal midgame to "quantum gravity insights from which the strings can be removed like scaffolding"?"

"Peter's" above hypothetical critique would already indeed be a valid one. But now let me add mine: why are we even granting that these are actual "quantum gravity insights" in the first place? When the hypotheses are so wildly speculative and poorly justified, the actual concrete models so far from anything resembling reality, the derivations so full of hand-waving, then, I think, we are more than allowed to be skeptic of even that basic point.

There may be something of interest from the quantum computing and quantum complexity point of view (I don't know, you tell me), but from the quantum gravity one (the hard problems are well known, are decades old), I see very little substance, as per usual.

We need to start to put the bar much more higher to what we call "quantum gravity" these days, otherwise almost anything is now passing for it. Of course, since there's no accepted theory or even accepted direction, that's difficult. My two cents are: let's stick to the basic and well known issues that appear when you try to apply the current QFT formalism to GR and build from that. What I see now is that people invent their grandiose theories or approaches, with very little justification for their hypotheses and then try to apply those the the mentioned issues; they then proceed to sell this as insights into quantum gravity. Problem with this is that there as many ways of doing that as grandiose theories or approaches the human mind can conceive (let's not throw LLMs into that mix, please!) Even the black hole information issue (one of the main motivations behind many of these proposals) needs a lot more understanding at the QFT in (classical) curved spacetimes regime before clearing things enough to see if we can even get "QG insights" about it. Bob Wald's (and also Unruh's) objections to its status as a supposed paradox that is unresolvable in standard QFT in curved spacetimes deserve more attention, in my opinion. I'm not saying he's right, but his takes on this are much more technically naunced and well informed than Susskind's ones, which have been much more influential in some communities in theoretical physics (particularly, the commnunity that gave rise to the subject being discussesed in this blog entry)…

19. **Shantanu**
September 16, 2024

Peter or someone else, how is fractionally charged particles evidence for string theory?

20. **yaron kedem**
September 17, 2024

A side note: It feels like this "40 years" time span has been with us for quite a while. The first revolution was 40 years ago but people have been talking about string theories for at least 10 years by then.

21. **anon**
September 17, 2024

I find the objections to this article slightly unreasonable. The argument of Greene's article is 1) string theory has made no experimental predictions 2) it has made deep and serious mathematical advances 3) one such, still conjectural and not understood even mathematically, are the concepts of duality 4) here is an example of such, which if physically applicable will have physical implications.

As a pure mathematician I can get behind all of those statements, and their consequence — string theory is not nonsense. It has failed, so far, at explaining anything about the physical world. But the many serious physical intuitions that have informed it — intuitions that are (were?) unavailable to pure mathematicians — have produced surprising and deep progress, with consequences in algebraic geometry and representation theory.

It is likely that any description of the physical world that involves mathematics will use these consequences – algebraic geometry (equations) and representation theory (symmetry) are very basic. That is not to say that string theory will be the foundation of any physical understanding, a statement about which I am at best agnostic.

You may find argument (4) overhyped by Greene, but I hope you do not differ in the rest of this assessment.

22. **Peter Woit**
September 17, 2024

anon,
You're making a different argument than the one in article, which is that string theory is making progress towards "Einstein's Dream" (which was not to do math). My post here is responding to the argument actually made.

I am ignoring the claims in the article about mathematics (which are overhyped) since the relation of string theory and mathematics is a complicated and separate subject.

As far as I can tell, there is no significant new mathematics involved in "ER=EPR", whatever that is.

Looking at the situation locally at Columbia, there was a period during the 1990s when there was significant joint activity between math and physics here, much of it organized by Brian. That stopped a long time ago, as his interests moved away from mathematics to purely physics issues.

Shantanu,
The idea that string theory models naturally give fractionally charged states goes back to this Wen-Witten paper from the very early days (May 1985) of the string theory unification via Calabi-Yau story, see
https://doi.org/10.1016/0370-2693(92)91557-P

It was prominently featured in The Elegant Universe, but I've never seen anyone else in recent decades promoting this as a "prediction" or "test" of string theory.

25. **anon**
September 17, 2024

The WP has a "Today's Opinions" summary of its op-eds, written by Drew Goins, which described Greene's editorial as follows:

Frontiers in physics
Math and physics professor Brian Greene's op-ed isn't rocket science. At least you can test rocket science.

No, Greene is writing about string theory, the most fantastical and unprovable frontiers of science. As he explains for the uninitiated masses, string theory entirely holds up on its internal mathematics, but to actually test whether the outcomes it predicts are true, experimenters would need to re-create the conditions at the heart of black holes or at the moment of the Big Bang.

Does string theory being untestable mean that string theory is unusable? Absolutely not, Greene writes. Of course, if some flaw were to appear within the theory, or some experiment actually came along to debunk it, Greene would abandon it posthaste: "I'm an advocate for truth, not string theory."

But, until that moment, string theory is still unlocking fabulous maybe-truths about the universe. Let Greene's words wash over you: wormholes and black holes, "holographic duality," quantum-entangled particles that behave the same no matter the distance between them. Even if you don't fully understand them, they might still inspire awe … and buy-in.

26. **Peter Woit**
September 17, 2024

anon,
That this piece is not science but advertising trying to get "buy-in" is right. A good question for the Washington Post is why they are publishing advertising masquerading as science.

27. **Adam+Treat**
September 18, 2024

Scott,

"He could also say that ER=EPR and the recent progress on the black hole information problem came from the string community, and plausibly wouldn't have emerged without that path (even if, at the end, the strings can be removed like scaffolds)."

Imagine in 40 years time, Gil Kalai is proven right and QC is still not feasible. This would be like some other member of the QC community rebutting Gil Kalai by saying, "Well, Scott Aaronson's work on fingerprinting AI outputs is instrumental in AI safety and that came from the QC community and plausibly wouldn't have emerged without that path (even if, at the end, quantum computing could be removed like scaffolds." In other words, I give you the non-sequitur.

PS: I'm old enough to remember when ER=EPR was introduced as fanciful big conjecture / brainstorming and even Susskind seemed sheepish in putting it forward given all the handwaving. Now it is treated like a big breakthrough??

28. **Jonathan**
September 18, 2024

@Bob Zanelli, @Alex:

“He could also say that Newtons gravitation came from the epicycle community, and plausibly wouldn’t have emerged without that path (even if, at the end, epicycles can be removed like scaffolds).”

30. **Brathmore**
September 18, 2024

Always keep in mind that Editors of Newspapers and Magazines can alter an author’s submitted article. We don’t always know precisely how the sausage was made.

31. **Peter Woit**
September 18, 2024

Brathmore,
The points made in the article are substantially the same as the material in the new edition of The Elegant Universe that was just published, see
https://www.math.columbia.edu/~woit/wordpress/?p=14092

A logical guess as to why this piece is being published now in the Washington Post is that it’s a byproduct of the publisher’s effort to promote the new book.

32. **Bob**
September 18, 2024

An analogy to the wormhole story I have been thinking lately: a lot of integrable systems can be described in terms of vector bundles on twistor space. If I create something in the lab in a setup where it becomes well-approximated by one of these integrable systems, did I just create twistor space in the lab? That would be a good headline: “Physicists create twistor space, a six (real) dimensional space, in the lab.”

33. **Supermembrane**
September 18, 2024

One could plausibly say that knot theory came from Kelvin’s vortex model of the atom, which was an attempt at a theory of everything from the 19th-century perspective, unifying electromagnetism, atomic physics, and possibly gravity, in terms of the dynamics of the ether. Ultimately, it failed as a theory of physics, made obsolete by relativity and quantum mechanics. Only knot theory remained after. Maybe string theory will meet a similar fate, in the end.

34. **Robert James Parkinson**
September 18, 2024

I could be wrong, but I get the impression that Mr. Greene is trying to protect physics from public backlash. I don’t really know, but it seems like the Physicists are trying to pivot away from string theory without saying so. Break the news to the public that they’ve been BSing you slowly and gently.

Maybe that is for the best. But going forward scientists should be much more cautious in their “science communication” and let the politicians campaign for funding.

35. **Peter Woit**
September 18, 2024

Bob,
I don’t think you can create twistor space in the lab. On the other hand I do think we actually live in twistor space and experience it directly (space-time points are indirectly observed quantities, when you open an eye you’re experiencing directly a CP1 in twistor space…).

36. **Peter Woit**
September 18, 2024

Robert James Parkinson,

Protection against public backlash is a big goal here, but I don’t think it’s physics in general that he’s trying to protect.

37. **Sabine**
September 19, 2024

Hi Peter, thanks for the link. I can’t believe we’ve been going on about this for almost 20 years!

38. **Scott+Aaronson**
September 22, 2024

Adam Treat: People, including me, HAVE made the argument that quantum computing research can partly be justified by the new things it’s led to in classical theoretical computer science. Watermarking of AI outputs is a terrible example, since that has nothing to do with quantum computing except for the involvement of a couple of the same people (e.g. me), but, say, lower bounds for triangle counting and locally decodable codes, lattice-based cryptosystems, new characterizations of counting classes, advances in lower bounds by polynomials, speedups for classical optimization problems via Quantum Monte Carlo running on classical computers, and much more have come from QC. But I’ve also been very clear that none of this can substitute for the big enchilada, the actual building of a scalable QC and its use to get some benefit over a classical computer for some problem that people care about.

39. **Scott+Aaronson**
September 22, 2024

Alex: One could take the position that, e.g., the black-hole information paradox isn’t worth discussing at all without a detailed theory of quantum gravity in which to do calculations. But if one *does* treat it as worth discussing, then I think it’s inarguable that AdS/CFT and “It from Qubit” have now completely changed the terms of discussion. E.g. we now know that the same Euclidean path-integral hocus-pocus that led to the prediction of Hawking radiation in the first place, also leads to the prediction that the radiation encodes the infalling information (even though it doesn’t provide a microscopic description of how). More generally, there’s now a toy setting where (1) spacetime is emergent from a more fundamental description and (2) black holes are understood in the conventional framework of QM.

40. **David Roberts**

September 23, 2024

There’s a difference between praising something that acted as a catalyst to discover other things that ultimately don’t depend on the catalyst, and praising the catalyst as a success *on its own terms*, when the other discoveries ultimately aren’t contributing to the continuing unsolved problem the catalyst was supposed to solve. A constant argument people make in grant applications here in Australia is for the whole “well, it contributes indirectly to blah blah blah, unforseen consequences etc”. But try telling the ARC that your grant money was deserved because you didn’t achieve anything your research application said you would address, but someone else has later borrowed some techniques and solved some other problem. Research inspiring other research that solved other problems is a basic given. If your research is so insular it can *only* somehow address one single problem and never connect to anything else, then that is a really risky situation. So praising a program for basically having a bare minimum feature every productive scientific or mathematical theory has, feels like pretty poor change to me.

41. **Peter Woit**
September 23, 2024

David Roberts,
In addition, in many cases the supposed new progress is as much or worse hype than the original string theory hype, promoted by the same people. The most egregious example would be the wormhole publicity stunt, promoted as “quantum gravity in the lab”, inspired by ads/cft/string theory. With no consequences for the original string theory hype, there’s now sometimes a doubling down on even more outrageous hype.

42. **Alex**
September 23, 2024

Some kind of consequence is the low number of faculty positions in hep-th. This looks like the worst job market in a long time:
https://particle.physics.ucdavis.edu/rumor/doku.php?id=current

Of course this predominantly affects young people. But most departments don’t want to hire in this field anymore (and haven’t for a while).

43. **Peter Woit**
September 23, 2024

Alex,
Unfortunately I think that’s right. You can get the public to continue to buy books by doubling down on the hype, but there is then a blowback effect that you lose credibility in your wider academic field, with people being unwilling to hire in your area.

I’m quite serious when I say that I see this subject as now being in a state of intellectual collapse. One is seeing much fewer significant new ideas than at any time in the past. String theorists over the years have often said “you can see the field is healthy because it is attracting talented young people”. But if there are no jobs and nothing is happening, these talented people move on to something else.

44. **Thomas Corrigan**
September 23, 2024

I just found the WPO article (FB showed it to me a week late), and as soon as I saw who had written it, I knew what to expect. Your blog is where I went to find some sanity, and did. Along with, of course, Sabine’s video. Just want to say “thank you”, from a retired theoretical nuclear physicist (Iowa State, then JHU/APL).

45. **Martin G**
September 26, 2024

Have you tried asking Quanta for the reasons why they stopped publishing Sabine, or will you simply take her assumptions and word for it?

46. **Peter Woit**
September 26, 2024

Martin G,
I don’t think it’s hard to figure out what Quanta’s point of view is on this, and I don’t see any reason to doubt what Sabine says. If you look at what they do and what she does, they are quite different things. She’s also not the compromising sort who would change what she does to fit with what they want to do.

Their big new project about quantum gravity is a very good example of how different what they do is from what she does. I’ll try and write something about that soon.

47. **Karl Young**
September 26, 2024

Interesting that Quanta is taking sides in the string wars. I still consider what they do extremely valuable in terms of providing access to information about current research for those who aren’t trying to read all the latest journal articles. But if they get too selective it seems that they run the risk of providing a skewed picture of what the research community regards as important. And they also seem to be getting a little sloppy, e.g. a recent, otherwise well written piece on the development of group theory and it’s use in physics, contained the statement “At high energies, group theory can be used to show that electromagnetism and the forces that hold atomic nuclei together and cause radioactivity are all manifestations of a single underlying force.“ It’s a bit ironic that after your nice non-technical description of the experimental failure of GUTs re. the recent podcasts, that they’d be so sloppy. Maybe I’m nit picking but for a publication that aims to provide good information on current developments in science that statement felt problematic.

48. **Peter Woit**
September 26, 2024

Karl Young,
That Quanta quote was from someone writing about math, not very well informed about physics. You could probably find similar examples of people writing about physics, saying not very well informed things about math.

Like the Simons Foundation, they’re focused on certain elite institutions, so for instance tend to reflect the point of view of people in Princeton at the IAS, and want to make the scientific community look good. So, rather different than Sabine Hossenfelder.

I wouldn’t describe Quanta at this point as “taking sides in the string wars”. In their latest series of articles about quantum gravity, they more or less ignore string theory. This fits well with what’s going on at places like the IAS, where quantum gravity research has long ago moved away from string theory (even if it’s hard to get them to admit it…).

Is Spacetime Unraveling?

September 26, 2024
Categories: Uncategorized

Quanta magazine has just put out an impressive package of material under the title The Unraveling of Space-Time. Much of it is promoting the "Spacetime is doomed" point of view that influential theorists have been pushing for decades now. A few quick comments about the articles:

- String theory is barely even mentioned.
- There is one article giving voice to an opposing point of view, that spacetime may not be doomed, an interview with Latham Boyle.
- The big problem with the supposedly now conventional view that spacetime needs to be replaced by something more fundamental that is completely different is of course: "replaced with what?". A lot of attention is given to two general ideas. One is "holography", the other Arkani-Hamed's amplitudes program. But these are now very old ideas that show no signs of working as hoped.

  Thirty years ago Lenny Susskind was writing about The World as a Hologram. The idea wasn't new then and seems to be going nowhere now. It was 17 years ago that Arkani-Hamed started re-orienting his research around the hope that new ways to compute scattering amplitudes would show new foundations for fundamental physics that would replace spacetime. Years of research since then by hundreds of theorists pursuing this have led to lots of new techniques for computing amplitudes (twistors, the amplituhedron, the associahedron, now surfaceology), but none of this shows any signs of giving the hoped for new foundations that would replace spacetime.

Instead of saying any more about this, it seems a good idea to try and lay out a very different point of view which I think has a lot more evidence for it. This point of view starts by noting that our current best fundamental theory has been absurdly successful. There are questions it doesn't answer so we'd like to do better, but the idea that this is going to happen by throwing the whole thing out and looking for something completely different seems to me completely implausible.

One lesson of the development of our best fundamental theory is that the new ideas that went into it were much the same ideas that mathematicians had been discovering as they worked at things from an independent direction. Our currently fundamental classical notion of spacetime is based on Riemannian geometry, which mathematicians first discovered decades before physicists found out the significance for physics of this geometry. If the new idea is that the concept of a "space" needs to be replaced by something deeper, mathematicians have by now a long history of investigating more and more sophisticated ways of thinking about what a "space" is. That theorists are on the road to a better replacement for "space" would be more plausible if they were going down one of the directions mathematicians have found fruitful, but I don't see that happening at all.

To get more specific, the basic mathematical constructions that go into the Standard Model (connections, curvature, spinors, the Dirac operator, quantization) involve some of the deepest and most powerful concepts in modern mathematics. Progress should more likely come from a deeper understanding of these than from throwing them all out and starting with crude arguments about holograms, tensor networks, or some such.

To get very specific, we should be looking not at the geometry of arbitrary dimensions, but at the four dimensions that have worked so well, thinking of them in terms of the spinor geometry which is both more fundamental mathematically, and at the center of our successful theory of the world (all matter particles are described by spinors). One should take the success of the formalism of connections and curvature on principal bundles at describing fundamental forces as indicating that this is the right set of fundamental variables for describing the gravitational force. Taking spin into account, the right language for describing four-dimensional geometry is the principal bundle of spin-frames with its spin-connection and vierbein dynamical variables (one should probably think of vectors as the tensor product of more fundamental spinor variables).

What I'm suggesting here isn't a new point of view, it has motivated a lot of work in the past (e.g. Ashtekar variables). I'm hoping that some new ideas I'm looking into about the relation between the theory in Euclidean and Minkowski signature will help overcome previous roadblocks. Whether this will work as I hope is to be seen, but I think it's a much more plausible vision than that of any of the doomers.

Update: John Horgan has some commentary here, taking the point of view that discussions of "Beyond Space-time" are fine, as long as you realize what you're doing is "ironic science" not science.

Comments

1. **Dan Winslow**
   September 26, 2024

   As a side note, I have to say that was some pretty impressive presentation work on the part of whoever is doing the web ui for that article. Really very nice and kind of cutting edge as far as I am aware. You can see the evolution towards a more magazine-style "i'm turning these glossy pages" kind of experience.

2. **NoGo**
   September 26, 2024

   Dan Winslow: To the contrary, I find this style of presentation pretty much unreadable/un-navigable. Luckily, it seems the articles themselves are accessible from the normal landing page in the normal way.

3. **Georgi Ivanov**
   September 26, 2024

   One of the linked articles in the main one that I found more interesting was about the 'Long-forgotten math' of von Neumann's algebras. The mathematician who rigorously grounded the third type, namely Alain Connes, has been the primary architect of noncommutative geometry. In that setting, spinors are the elements of the Hilbert space on which the Dirac operator acts. I wonder if you have found anything useful from this spectral formalism.

4. **Peter Woit**
   September 26, 2024

   Georgi Ivanov,
   My interest generally has been in very specific examples, hoping to get a deeper understanding of the Standard Model. Using the general theory of operator algebras is kind of at the other end of things, useful to say things independent of any specific theory (which is why theorists without a theory doing quantum gravity find it useful).

   Non-commutative geometry a la Connes is a different story, pretty much off-topic.

5. **Paolo Bertozzini**
   September 27, 2024

   Dear Peter (thanks for this extremely interesting post, mentioning Boyle's interview) and Georgi Ivanov (thanks for touching on the “operator algebra point”),

The problem with the now standard view that “space-time is only emergent”, and hence not fundamental, is huge: (as I already mentioned in previous messages here) essentially all of the main current approaches to quantum gravity are in agreement on this!
It is a big pleasure to see some dissenting voices like Boyle and Peter 🙂

There is a significant difference between “emergent” and “derived”: space-time can very well have a role and existence at the fundamental quantum level, without invoking “macroscopic emergence”, and still be “derived” (for example in a spectral way) from operationally defined quantum degrees of freedom (for example quantum fields and their operator algebras).

If Peter allows me just one very short excursion into the “off-topic” direction (operator algebras and non-commutative geometry): the interplay between von Neumann algebras (of quantum fields with their Tomita modular theory) and non-commutative geometry (including Connes’ non-commutative standard model features) is still a work in progress and could be much deeper (and interesting for 4-dimensional geometry) … I can assure that there some researchers currently still working on it 😉

Best regards (and sorry for the little “off-topic”) 🙂
Paolo

6. **Jim+Eadon**
September 27, 2024

I also noticed virtually mention of String Theory; wormholes made inside computers malarky, and that.
Does this mean that Quanta has finally got the message on those topics? Or do you think it that the string lobbyists are generally giving up?

7. **Peter Woit**
September 27, 2024

Jim Eadon,
I think the people at Quanta ultimately realized there are various problems with the wormhole claims and that these are not supported by most theorists in the field.

Those theorists interested in continuing to make way overhyped claims about string theory or wormholes are now not getting a sympathetic hearing from either their colleagues or most science journalists. They can now only do this without pushback at certain venues like Brian Greene’s panel discussions.

8. **Peter Woit**
September 27, 2024

I see that right now you can ask the Quanta journalists questions yourself, at
https://www.reddit.com/r/IAmA/comments/1fqogti/were_physics_journalists_who_have_spent_years/

9. **Garrett+Lisi**
September 27, 2024

This was not encouraging:

chevalierbayard
Is String Theory a dead end?

Natalie_Wolchover
I’ve done a lot of reporting and writing about string theory over the past couple of years for my forthcoming book, and it does not at all strike me as a dead end. There’s a huge amount of vitriol about it among certain science communicators, but in my view, they mislead the public on this. Among working theoretical physicists, string theory is a tool for studying quantum gravity and a conceptual framework that’s mathematically consistent, and which is related to quantum field theory – the language of the Standard Model of particle physics. Exactly how or whether string theory is related to reality remains unclear. But it’s part of a web of mathematical languages that is trying to tell physicists something and they aren’t going to stop studying it.

Charlie’s new article, Physicists Reveal a Quantum Geometry That Exists Outside Space and Time, covers fascinating new research that has an interesting tie-in to string theory: https://www.quantamagazine.org/physicists-reveal-a-quantum-geometry-that-exists-outside-of-space-and-time-20240925/

Charlie_Wood42
+1 to what Natalie said. I’ll also add that many theorists consider string theory to be the best working example of what a theory of quantum gravity might look like. It does some impressive and hard to do things like nailing exactly the entropy of a black hole, down to the multiplicative constant. That doesn’t make it right, but it does make it interesting. It also makes it a top contender until someone comes up with a more complete, or more testable framework. Lots of people definitely want that and are working on alternatives, but I don’t think anything has obviously dethroned it yet.

10. **Peter Woit**
September 28, 2024

Garrett Lisi,
Yes, that’s the Quanta editors at their worst. No one is arguing that physicists should stop studying string theory, just that string theorists and journalists who listen to them should stop the forty years of often outrageous hype and instead provide an accurate account of the state of the theory. I’m also not a fan of denouncing unnamed “unnamed science communicators” for unspecified statements.

It’s also amazing how successful the hype for the Strominger-Vafa calculation from nearly 30 years ago has been (it got them a 3 million dollar prize). There’s zero chance that Charlie Wood understands that calculation (for example, that it’s not actually a black hole…), but he’s sure about it impressively “nailing exactly the entropy of a black hole, down to the multiplicative constant.” There’s a generic problem with the Quanta coverage of string theory/quantum gravity that that they’re way too credulous about claims made by certain prominent people in this field, with the wormhole fiasco the most egregious example.

11. **Armin**
September 28, 2024

“No one is arguing that physicists should stop studying string theory, just that string theorists and journalists who listen to them should stop the forty years of often outrageous hype and instead provide an accurate account of the state of the theory.”

I completely agree with the point about stopping the hype, but, at least for that fraction of string theorists who went into it because they saw it as the key to finding the "holy grail of physics", doesn't assessing it realistically imply precisely that they should stop studying string theory?

Also, in the absence of a credible alternative, it might be too difficult to just stop a research program, as a matter of human psychology. It seems to me that as long as people can fall back on justifying what they are doing via "other benefits", they would rather stay with the familiar, even if it does not work, than venture into the unfamiliar which might not work and doesn't even provide a fallback.

What would you tell a person in that situation, Peter?

12. **Peter Woit**
September 28, 2024

Armin,
I'm just not understanding why anyone would want to spend their life studying an idea that doesn't work. If your job doesn't require this why do it? If it does, why not find another one? If you think your string-theory related research program is working, no reason you shouldn't keep at it. But, it is important though that people not deceive themselves and not be deceived by others about what works and what doesn't. Here there are a bunch of prominent string theorists (and journalists at Quanta…) who have something to answer for.

13. **Peter**
September 28, 2024

I studied physics, but for some weird reason spent most of my time in "the media". In the late 1980s, early 1990s, I did some (modest) science journalism. Back then, even if you weren't a specialist, you could have a certain "feeling" for new results. And if you didn't, there often was link between the result and a feasible or already performed experiment to check if the results were going in the right direction.

A simple example is cold fusion. As a physicist (or a chemist) you'd expect that chemical reactions are typically in the eV range. So where the hell does the energy for cold fusion comes from? In labs across the world, experiments were done that didn't show fusion at all. So, if you wanted to report about cold fusion, you had a starting point.

The arrival of string theory changed that dramatically. The subject is so complicated that you had to take the experts' word for it. There were no experiments to keep them honest. The space for the "independent judgment" of a reporter – always a delicate thing in science journalism – was reduced to zero.

So what do you do as a science reporter? I've been in the media long enough to know the answer: you cover you ass. You create a situation in which you can always say "I was was just reporting what the experts were saying. You got a problem with that? Go and tell the experts."

It's also an ideal situation for a herd mentality. You don't want to be summoned to the chief editor's desk to be asked "Hey, what the f!ck? Everybody else is writing that this result of string theory is the greatest thing since sliced bread, and you are skeptical? Who the f!ck are you? It was in a press release by goddamn Harvard! Goddamn idiot, next time we can forget about an exclusive!"

Herd mentalities are strange things, though. It's perfectly possible that somewhere in 2030 the herd will be marching in the opposite direction. "50 years of string theory and you have nothing to show?" And everybody in the herd will be screaming that they already knew in 2024 that string theory was a dead end, physically speaking.

14. **Mark Hillery**
September 29, 2024

I really wish Quanta would not write so much about the extremely speculative and totally-divorced-from-experiment parts of physics. It misrepresents what most physicists do. I don't know how someone who doesn't work in physics regards this stuff, but as someone who does, I have, for the most part, stopped reading it. As far as their latest cluster of articles on spacetime is concerned, I read the one about Wheeler, because I met him a few times and heard one of his talks. His style was oracular and the talk was quite cryptic. The only other article I looked at was the one that talked about von Neumann algebras, because my thesis advisor worked in algebraic quantum field theory (I never did, but I picked up a little knowledge of the subject). No mention of algebraic quantum field theory in the article, just that these algebras are now interesting because some people in quantum gravity are using them. The other articles in the cluster and the video – well I have better things to do. Some of their physics articles that are not about quantum gravity are very good, and I would like to see more of those.

15. **Mathias**
October 3, 2024

Hello Peter,

Saying that it's too early to seek for emergent theories of space-time because (among other things) 4d space-time geometry as we know it has still things to teach us concerning unification issues beforehand (a statement which is arguably sound) is not incompatible with the fact that ultimately space-time will turn out to be an emergent structure from some deeper degrees of freedom of the fundamental laws of physics.

Best,

16. **Bertie**
October 4, 2024

I read Professor Woit's Nov 2023 paper, which was reprised in a recent podcast. I find this work so tantalizing and would like to ask if there is likely very long to wait until a new paper outlining any new developments might appear? Thanks.

17. **Peter Woit**
October 4, 2024

Bertie,
I was planning a longer and more detailed paper after that, but as writing it realized that the fundamental technical issue of how you wick rotate spinor field theories from Euclidean to Minkowski is something I really need to get carefully sorted out. This is taking a while, with slow progress. Even for charged scalar fields what happens is tricky, spinor fields even more so.

18. **Marty**
October 5, 2024

Apologies for this off-topic comment, but…

I just watched Sabine's latest video, where you are mentioned by name at the end. I followed her blog during its entire active existence and have viewed a number of her videos since, and generally agree with most of her views and diatribes. But I can't remember ever feeling revulsion over her commentary like I did with her new video.

Not only was the title very misleading (conflating a narrow area of physics with physics in general), she decided to accuse certain physicists of intellectual dishonesty by name, without obvious provocation.

Even you were not spared — she sort-of complimented you, but immediately followed with a dismissive comment, one that a listener who is unfamiliar with your lengthy history as a skeptic would likely interpret as a suggestion that your underlying motivation is a desire to "sell" your own theory. (Seriously, Sabine? What theory? Do you mean Peter's limited writings on an idea he is excited about and actively exploring? Where is he suggesting he has a theory?)

Overall, I find the video disgusting for her careless denigration of some individuals' character, and of progress in physics overall, even if the actual physics content has merit.

19. **Peter Woit**
October 5, 2024

Marty,
For those wondering what this is about, see
https://www.youtube.com/watch?v=cBIvSGLkwJY

I'm much more sympathetic than you to the rant, since I feel exactly like that some days. Like for Sabine, seeing this argument reappear brought back bad memories of twenty years ago, and depressive thoughts about how the field is dead, people are going to just go on repeating the same arguments about failed theories for the rest of my life and beyond.

The problem with such rants, from me or from her, has always been the question "yes, but why don't you do something more positive than just get outraged about this?" For many years I didn't have an answer to that. There were general ideas that I would write about that seemed to me worth pursuing, but nothing specific that I could point to as highly promising. A few years ago when I started realizing that a set of ideas I'd given up on could actually work and started writing about them, criticism then shifted from "you should be ignored because you don't have an alternative" to "you should be ignored because all you are doing is pushing your own speculative alternative".

Enough time-wasting on this for today, back to trying to figure out exactly what is going on when you Wick rotate spinors…

Richard S. Hamilton 1943-2024

September 29, 2024
Categories: Obituaries

I heard this morning that Richard Hamilton passed away ~~yesterday~~ early this morning. He was a renowned figure in geometric analysis, and a faculty member here at Columbia since 1998. In terms of mortality, the last year or two at the Columbia math department have been grim ones, as we've lost five senior faculty at relatively young ages: Igor Krichever at age 72, Henry Pinkham at age 74, Lars Nielsen at age 70, Walter Neumann just last week at age 78, and now Hamilton at age 81.

Richard wrote a short autobiographical piece about himself at the time he was awarded the Shaw Prize in 2011, available here. There's an interview conducted by his Columbia colleague John Morgan here. Just a couple months ago, Richard was award the Basic Science Lifetime award in Mathematics. You can watch his lecture given in Beijing at the time here.

Richard shared with my four other colleagues that have recently passed away a truly generous outlook on life and other people, very much the opposite of some negative stereotypes of academics as narrow and competitive, hostile to their colleagues and institution. I'll miss him, as I miss the others we have recently lost.

Update: Frank Calegari has some memories of Walter Neumann here.

Comments

   September 30, 2024

   Thank you for posting your recollections of Richard Hamilton. I only know of him through his groundbreaking work on Ricci flow, but now I must dig a bit deeper to understand his great contributions.

2. **Jason Starr**
   September 30, 2024

   I remember Richard Hamilton and S. – T. Yau working on Ricci flow all weekend long, every weekend in the Harvard math department when I was a beginning graduate student. It is a terrible loss. I regularly refer to Hamilton's thesis for a more prosaic result: irreducibility of Hurwitz schemes of covers of higher genus curves (Hurwitz proved irreducibility in genus zero).

3. **Jason Starr**
   October 1, 2024

   By the way, I learned of this part of Hamilton's thesis through Walter Neumann (another sad loss). This part of his thesis was never published, although the same result does also appear in an article of Gabai — Kazez and in Joan Birman's "Braids" volume.

4. **Matt Grayson**
   October 1, 2024

   Richard was generous with his time and talents. Any new idea made his eyes light up and he'd approach the blackboard with a smile, a spring in his step, and a "let's see if it works!" He will be missed.

5. **James Allen Isenberg**
   October 1, 2024

   I have known Richard Hamilton for over 40 years. Just a year or so ago, we held a conference at the Simons center in honor of the 40th anniversary of his epic work on Ricci flow. He was his usual very animated, very insightful, and very fun-loving self. I will miss him very much.

6. **David Ross**
   October 2, 2024

   It is in large part thanks to Hamilton's work on Ricci, that Perelman was able to vanquish the Poincare Conjecture. Perelman would have been the first to say as much, but since he's not in these comments we'll have to say it for him.
   RIP.

All Langlands, all the time

October 3, 2024
Categories: Langlands

Trying to keep track of everything happening in the Langlands program area of mathematics is somewhat of a losing battle, as new ideas and results keep appearing faster than anyone could be expected to follow. Here are various items:

- Dennis Gaitsgory was here at Columbia yesterday (at Yale the day before). I don't think either lecture was recorded. Attending his lecture here was quite helpful for me in getting an overview of the results recently proved by him and collaborators and announced as a general proof of the unramified geometric Langlands conjecture. For details, see the papers here, which add up in length to nearly 1000 pages.

  For a popular discussion, see this article at Quanta.

  To put things in a wider context, one might want to take a look at the "What is not done in this paper?" section of the last paper of the five giving the proof. It gives a list of what is still not understood:

  Geometric Langlands with Iwahori ramification.
  Quantum geometric Langlands.
  Local geometric Langlands with wild ramification.
  Global geometric Langlands with wild ramification.
  Restricted geometric Langlands for ℓ-adic sheaves (for curves in positive characteristic).
  Geometric Langlands for Fargues-Fontaine curves.

  Only the last of these touches on the original number field case of Langlands, which is a much larger subject than geometric Langlands.

- Highly recommended for a general audience are the Curt Jaimungal – Edward Frenkel videos about the Langlands story. The first is here, the second has just appeared here, and there's a third part in the works. One scary thing about all this is that Frenkel and collaborators are working on an elaboration of geometric Langlands in another direction ("analytic geometric Langlands"), which is yet again something different than what's in the thousand-page paper.
- Here at Columbia, Avi Zeff is working his way through the Scholze proposal for a version of real local Langlands as geometric Langlands on the twistor P^1, using newly developed techniques involving analytic stacks developed by Clausen and Scholze. This is an archimedean version of the Fargues-Scholze work on local Langlands at non-archimedean primes which uses ideas of geometric Langlands, but on the Fargues-Fontaine curve. Together these provide a geometric Langlands version of the local number field Langlands program, with no corresponding geometric global picture yet known.
- Keeping up with all of this looks daunting. To make things worse, Scholze just keeps coming up with new ideas that cover wider and wider ground. This semester in Bonn, he's running a seminar on Berkovich Motives, and Motivic Geometrization of Local Langlands, promising two new papers ("Berkovich motives" and "Geometrization of local Langlands, motivically"), in preparation.

  As a sideline, he's been working on the "Habiro ring" of a number field, finding there power series that came up in the study of complex Chern-Simons theory and the volume conjecture. According to Scholze:

  > My hope was always that this q-deformation of de Rham cohomology should form a bridge between the period rings of p-adic Hodge theory and the period rings of complex Hodge theory. The power series of Garoufalidis–Zagier do have miraculous properties both p-adically and over the complex numbers, seemingly related to the expected geometry in both cases (the Fargues–Fontaine curve, resp. the twistor-P^1), and one goal in this course is to understand better what's going on.

- Finally, if you want to keep up with the latest, Ahkil Mathew has a Youtube channel of videos of talks run out of Chicago.

   October 3, 2024

   Actually, geometric Langlands for Fargues-Fontaine curves is being dealt with – see my lectures on Akhil's channel for a detailed discussion of the current status of things.

2. **Quasiparticular**
   October 4, 2024

   "Keeping up with all of this looks daunting."

   And gosh, you've been writing about the Langlands program for two decades! At this time is there any component of the Langlands shockwave that pulls focus on physics? (I assume Langlands/QFT is a topic still dear to you)

3. **Peter Woit**
   October 4, 2024

   Quasiparticular,

   First of all, several people wrote in, outraged about how mathematical physics has become. This post was purely about developments in mathematics research by mathematicians, not about physics. Physicists are not involved at all in this.

   I've always been intrigued by tantalizing connections of this field to physics, but these recent developments don't seem to go in that direction. From its beginnings, there have been relations between geometric Langlands on a Riemann surface and 2d conformal QFT. Witten found a great deal of material relating geometric Langlands to a specific 4d QFT. David Ben-Zvi has written a lot about how the topological QFT point of view illuminates the larger structure of this subject. That the twistor P1 shows up here as the description of an archimedean point and in physics as the twistor description of a space-time point continues to fascinate me (but, may be meaningless..)

   So, nothing really new that I'm aware of on the relation to physics front, but, as pure mathematics, a great deal is happening here.

4. **kitchin**
   October 6, 2024

(Math) people might be interested in a conference in Copenhagen last summer, consisting of lecture series by Clausen, Efimov and Nikolaus. "Continuous K-theory, dualizable and rigid categories." Videos as well as good notes: https://www.math.ku.dk/english/calendar/events/masterclass-continuous-k-theory/ . I've only dipped into to the Clausen talks so far, joint work with Scholze. More analytic structure built into complex manifolds.

The second Curt Jaimungal – Edward Frenkel video Peter mentions contains a nice summary of three different Langlands'es, starting with the only one Robert Langlands endorses for the use of his name (the number theory one)! It goes from about the 1:40 mark to the end of the video. I don't recall it laid out so concisely in his book Love & Math. Somewhere else in the video Frenkel recounts his conversations with Langlands, which is charming. (And informative, are far as leading to making abstract things more like functional analysis, as far as I understand it.)

Two hundred year old number theory problems are a good validation of math, in a sense applied math. Since group theory started there, it makes some sense the algebra would grow to almost incomprehensible levels. As long as it solves problems.

5. **Jim+Eadon**
   October 7, 2024

   Dear Peter, Is the latest research by Scholze et al involving the Twister P1 have any impact on your own research, and, even, vice versa?

6. **Peter Woit**
   October 9, 2024

   Jim Eadon,
   So far I fear the impact on my own research has been negative, since I've spent a fair amount of time trying to understand it (which has been rewarding in its own way), but don't see any particular way to connect the way the twistor P1 appears there and in my own research.

7. **toto**
   October 30, 2024

   Seems like the lectures on the Habiro ring are online : https://archive.mpim-bonn.mpg.de/id/eprint/5132/

Various Items

October 24, 2024
Categories: Uncategorized

A few items that may be of interest:

- Edward Frenkel has a new Youtube show/podcast, entitled AfterMath. I gather that part of the concept here is a follow-on to his book Love and Math, but in this different format. He's always thought-provoking and well-worth listening to on almost any topic, I'm looking forward to seeing what he does with this.
- Also in the Bay area, Michael Peskin recently gave a talk on How Should We Think about 10 TeV pCM Colliders?. Much of it is a very sobering look at the possible known ways to build a collider capable of colliding elementary particles at 10 TeV in the center of mass. The technical challenges are daunting and if this is going to get done it's going to take quite a while and be very expensive.

  Besides the technological and financial problems, he faces up to the main problem of justifying such a project:

  > Are the secrets of electroweak symmetry breaking and the Higgs field to be found at 10 TeV ? If we believe in this, we must still find arguments to convince our skeptical scientific colleagues. If we don't believe in it, we are believing that there is no point in making the next step in collider physics.
  >
  > We cannot imagine the future of particle physics without grappling with this question.

  More specifically, he sees the challenge as

  > to get the money to build such a collider, we would need
  >
  > **definitive proof of violation of the Standard Model from HL-LHC or Higgs factories**
  >
  > or
  >
  > **a clear and compelling model to be tested** (as the MSSM was for LHC).
  >
  > In my opinion, this puts a large burden on the theory community
  >
  > 1. To be sure that an e+e- Higgs factory actually is built
  > 2. To put forward simple and attractive models of EWSB with a "little hierarchy"

  Unfortunately I don't see any evidence of any attractive ideas about 2., and the sad history of the hype about SUSY and naturalness means that people are going to be looking a lot more skeptically at any claims by theorists to have such a thing.

- Speaking of Peskin, if you're looking for an alternative to Peskin and Schroeder, there's a recent new QFT book that I've seen which appears to be quite good: Introduction to Quantum Field Theory, by Anthony Williams. It doesn't go as far as Peskin and Schroeder and other textbooks that get seriously into Standard Model physics, but it has a lot more detailed and careful explanations of the basics of relativistic quantum field theory. As such it should be significantly more readable by advanced undergraduates and beginning graduate students.
- Finally, two questions I'm wondering about, curious if anyone reading this knows the answer:

  Whatever happened about the bet between Ken Lane and David Gross over SUSY? Did Gross pay up?

  What's going on with the 2025 Breakthrough Prizes? In past years, these things have been announced in September, Hollywood "Oscars of Science" ceremony in the spring. This year, nothing in September, and October is almost over, so wondering if the Breakthrough Prize people have a new concept for the prizes for the coming year.

- One more thing: I just noticed that the SMF has recently published a 1963 text of Grothendieck's, his notes for a fall 1963 seminar at Harvard on duality theorems in algebraic geometry. Hartshorne ran the seminar and later wrote up notes, which were published as LNM 20, Residues and Duality.

Update: I've confirmed with Ken Lane that it seems David Gross won't admit that SUSY has been a failure and he's given up on Gross ever paying off on the bet. For more about the reaction of Gross and others to losing SUSY bets, see here
https://www.math.columbia.edu/~woit/wordpress/?p=8708
For documentation of the 1994 Gross/Lane bet, see page 62 of
https://indico.cern.ch/event/527162/contributions/2159007/attachments/1298122/1936489/deroeck_SUGRA_2016_v4.pdf

Update: Thanks to commenters who have answered both of my questions. Besides finding out what happened with the Gross/Lane bet, this comment explains that the new plan for the Breakthrough Prize is to announce it at the same time it is awarded at the Hollywood "Oscars of Science" event in April (so, 2025 prizes announced and awarded April 2025).

Comments

1. **Andrzej Daszkiewicz**
   October 24, 2024

   Thanks for the tip about the Williams' book.
   BTW, do you plan to add chapters 12-16 to your notes on QFT? I'm about to start reading them.

2. **James Lai**
   October 25, 2024

   Off topic: Hi Prof. Woit, I am eagerly looking forward to your QFT notes as I am half way through your book

3. **David Brown**
   October 25, 2024

   Did Gross pay his SUSY bet to Lane?
   According to a Physics Forum entry, Lane did enjoy an expensive restaurant meal at Gross's expense (in 2016? or 2017?).
   https://www.physicsforums.com/threads/interesting-anecdotes-in-the-history-of-physics.1059261/page-4

4. **Peter**
October 25, 2024

Give us your take on this year's physics Nobel Prize! Is it physics? Is it worth of a Nobel Prize? Is it an indictment of physics research? Has the Nobel committee jumped on a bandwagon?

5. **Peter Woit**
October 25, 2024

Andrzej Daszkiewicz/James Lai

Sorry, but I haven't found the time to work on that project. I've been working out the details of how Wick rotation works for chiral spinors. As part of that, I understand much better how Euclidean QFT/path integrals are related to the Minkowski QFT/operator formalism. Whenever I get to writing more about QFT I want to incorporate this material.

6. **Peter Woit**
October 25, 2024

David Brown,
I'm not sure that physics forum entry reflects anything other than that by 2017 there was sufficient LHC luminosity that Gross had lost by the precise terms of the bet. Did Lane really get his dinner?
While Gross over many years heavily promoted (as a "prediction" of string theory) the claim that the LHC would see superpartners, I'm not aware of any place where he ever admitted that this didn't work and that he had lost the bet.

7. **Peter Woit**
October 25, 2024

Peter,
I thought of writing about the Nobel Prize, didn't do so because it seemed that everyone likely could guess what I thought. Also, the reaction I was seeing online was lots of outraged physicists, so better to let them be the ones to complain about this, instead of more complaints from me.

In case you can't guess what I think about this, it reflects the ongoing problem the physics Nobel committee has, that large parts of fundamental physics have basically been dead for quite a while, so they have to find new areas to give the prize to. On the AI aspects, the last thing the world needs now is more rewards and attention given to AI research. While Hopfield has claims to be a physicist and one could make a reasonable case that the work he did counts as physics, the choice to reward Geoffrey Hinton with a physics prize is really hard to understand.

8. **David Brown**
October 25, 2024

In reply to an email inquiry, Professor Lane kindly sent the following response:
"No, Gross never paid. I think he never will. He is what is called a "welsher" — an unfortunate term; it has nothing to do with people of Wales, who are maligned by this term."

9. **Peter Woit**
October 25, 2024

For documentation of the Gross/Lane bet, see page 62 of these slides:
https://indico.cern.ch/event/527162/contributions/2159007/attachments/1298122/1936489/deroeck_SUGRA_2016_v4.pdf

10. **James**
October 25, 2024

Years ago one of Ken Lane's former students relayed the tale of Ken giving a talk to a group people involved in giving out funding. At the end, one of the questions was what will he do if his theory (technicolor) doesn't work out, and his response was something like "I guess I'll fall on my sword and retire." We had a good laugh about that, but now after reading this blog for a few years it's clear that such behavior is not universal.

11. **Mathematician**
October 28, 2024

From the Breakthrough Prize: The foundation will announce the next prize laureates in April 2025 coinciding with the annual ceremony. Moving forward, the yearly schedule will be altered with the nomination portal open from April to July (specific dates to be announced), with again the prize laureates being announced in April.

12. **Andrew**
October 29, 2024

Talking of introductory books on QFT, I wondered if you'd looked "A Prelude to Quantum Field Theory" by Donoghue and Sorbo?. It seems like it should be a good once over lightly for tourists who just want a bit more detail than, for example, Zee or Carroll's recent pop physics books on the subject, but I've seen comments that it goes a bit too far in the direction of terseness.

13. **Pasquale Di Cesare**
October 31, 2024

Peter Woit
Instead, I feel you should and hope you write more in depth about the recent Nobel. I guessed your reaction but more insight would shed light on progress in physics and epistemology. As long as Hopfied is concerned, it looks to me his RNN is a spin glass. Parisi's shared Nobel in 2021 was, in particular, also for resolving SK model of spin glass. He interestingly wrote: "I think that the Nobel prize in physics should continue to spread into more regions of physics knowledge," … "Physics is becoming wider and wider, and it contains many areas of knowledge that did not exist in the past, or were not part of physics." But I agree on the AI hype wagon, unfortunately.

14. **Peter Woit**
October 31, 2024

Pasquale Di Cesare,
I'm afraid it does look like the parts of physics I care most about are dying off (or dead already…). Funding and attention is moving towards other topics, ones I know little about and have no interest in taking the time to learn more. So, for topics like neural networks, seems best for me to not write about them, whether people want to

call them “biology” or “physics” or whatever.

15. **Stephane Dubedat**
November 4, 2024

> Are the secrets of electroweak symmetry breaking and the Higgs field to be found at 10 TeV ? If we believe in this, we must still find arguments to convince our skeptical scientific colleagues. If we don’t believe in it, we are believing that there is no point in making the next step in collider physics.

I have just recently started reading your amazing blog so I still don’t know for sure your opinions on the matter of the future of particle physics experiments.
It seems to be a popular trope that particle physics makes no new discoveries and only confirms prior knowledge (the standard model) and therefore that theoretical particle physics (string theory, GUTs, sterile neutrinos, glueballs, etc) is “dead”.
This trope is false and stems from the fact far too few people are aware of the experimental anomalies.
Moreover it also is a result of not considering wether current colliders are “underpowered” in order to constrain the existence e.g. of a new particle.
I invite the reader to see figure 3 page 11
https://arxiv.org/abs/2309.03870

The paper shows that there are actually many major anomalies in particle physics, moreover most importantly it shows there are anomalies at every order of magnitude of energy, from 0.1GEV to 1TEV.
The paper is very far from exhaustive as new anomalies are discovered each year in hep ex, even more if you take into account the interellated cosmological anomalies (such as the galactic center gamma ray excess or the photon count excess).

As such, particle physics (and cosmology) are, which is extremely misunderstood, in their golden age.
The other trope is that to discover new physics we need higher energy colliders..
As seen, spanning 5 order of magnitude of energy, there are anomalies at every level. Therefore it seems likely new anomalies will keep being discovered beyond 1 TEV, especially considering the known anomalies in ultra high energy cosmic rays.
Moreover there are particles that are best observed at 10TEV. The higher energy also increase the statistical power, allowing to move known anomalies beyond 5 sigmas.
However, while a 10TEV collider would be useful, especially via resurrecting the already dug desertron, in terms of cost versus reward, there is the extreme low hanging fruit of making low energy and 1TEV energy colliders with higher accuracy, as yes, there are more new physics to be found in the 0.1Gev to 1tev range than in the 10tev range. Much more important that raw energy, is the accuracy of the collider, which is the product of its luminosity (as shown by the tremendous success of belle II) and by its paradigm (electron collider, LINAC, muon collider), which is what is needed to once and for all confirm the myriad of known anomalies as scientific discoveries.
And this crucially lack funding despite being moderate cost…
While some major specific particle factories are being delayed.. the salvation and revolution in particle physics is coming very soon, via the arrival of two new higher than LHC precision colliders: NICA https://arxiv.org/abs/2401.12893
and FAIR https://arxiv.org/abs/1808.09550
Those two projects, will change particle physics forever as being the first colliders to not be underpowered, not regarding energy, but regarding precision, the signal to noise ratio (of which belle II has shown the path). And are operational in 1-2 years not the decades..
Another advance parallel and as useful as colliders, are experiments that sets new limits of the electric dipole moment and lacks funding.
Among the known anomalies, the one that should be confirmed the soonest (1-2 years) should be the lowest energy anomaly: the X17 particle.
Now in terms of “novel” ideas in particle physics that are actually original, there is one considerably underknown, which is the extreme prospect of resurrecting the Sakata model, which works very surprisingly well.
https://www.semanticscholar.org/paper/Sakata-Model-Revisited%3A-Hadrons%2C-Nuclei-and-Stefanovich/2b49b07cd8a0b82bbbfff2e5bbeb134721b3a9df

Of note is that the best empirical fit no longer is the standard higgs but a higgs triplet https://arxiv.org/abs/2404.14492

The Crisis in String Theory is Worse Than You Think…

October 31, 2024
Categories: Uncategorized

Curt Jaimungal has a piece out, an interview with Lenny Susskind, with the title The Crisis in String Theory is Worse Than You Think…. Some of what Susskind has to say is the same as in his recent podcast with Lawrence Krauss (discussed here). These days, Susskind sometimes sounds like Peter Woit:

> We live in the wrong kind of world to be described by string theory. No physicist has ever won a big prize for string theory. I can tell you with absolute certainty that it is not the real world that we live in. So we need to start over.

(interesting that Susskind seems to think the "Breakthrough Prize" is not a "big prize", maybe because he's one of the few well-known string theorists who hasn't gotten one).

Susskind says he himself is working on trying to extend string theory to something different which will work in dS space, not just AdS, but he agrees with my claim that this is something the field has essentially given up on:

> I actually don't know anybody who is working, striving to try to expand the theory into either de Sitter space, which is not supersymmetric, or just more generally into an expanded version of the theory. Older people worked on it in the past. They worked on something called spontaneous breaking of supersymmetry. Don't worry about what it means. It just means the theory wouldn't be supersymmetric, and they failed. Now, that's not a criticism of them. I worked on it, and I failed. That's not a criticism of anybody, but it's a fact that there is no precise theory which is not supersymmetric.
>
> That is intolerable, in a sense. It can't stay that way. We have to describe our world. That's our purpose, and as I said, I don't know anybody who's actually working on that. If you were to send out a message to all the world's theoretical physicists, anybody working on a generalization of string theory, you'd probably find some yeses, probably mostly among older people, and somehow we have to change this.

I'd argue the field has given up on it because, after decades of work, it's clear this goes nowhere, and sooner or later Susskind will realize this.

At one point Susskind starts making an odd argument, hard to reconcile with the current state of the subject:

> Look, there are still people who believe in the flat Earth, for God's sakes. There's people who believe all kinds of weird stuff. Don't think about individuals. Think about the consensus of the largest fraction of physicists working on these things, and you'll probably be right. The overall consensus of the field tends to be right. Peculiar individuals, no matter how famous they are, no matter how brilliant they are, if they're off that consensus, and they've been off that consensus for a long time, they're probably wrong. That doesn't mean for sure that they're wrong. Don't look for the weirdos. Look for what the consensus of the majority of well-respected, highly accomplished physicists believe. And you'll probably be right. There's no guarantee of it. There are very few cases where the consensus has gone wrong for a long period of time, just where some offbeat idea of some particular individual suddenly changes everything. I'm not saying it doesn't happen, but rarely. Penrose, what can I say? He believes all kinds of things that I wouldn't subscribe to. But more than that, things that the consensus wouldn't subscribe to.

Besides the weirdo Roger Penrose, he's no fan of the ideas of another weirdo:

> What is Peter Woit? If you look on the Internet, if you look on the archive, he has a small number of papers which are bad. They're bad mathematics and bad physics. They're just bad. I probably shouldn't say that. I probably shouldn't, but I'm going to say it anyway. He has nothing to offer at all. I assure you that if he had something that was compelling and interesting and that solved some problem, the physics community would notice him. I looked at his papers. I was unimpressed,

I guess his reaction is fair, partly since my own criticism of his work on the landscape is much the same (I have on the other hand had nice things to say about his textbooks, some of which appears as a blurb on the French edition of one of them).
In any case, if you start with the assumption that anything too far off the consensus is going to be unpromising, you don't need to spend much time looking at my work to confidently evaluate it as having nothing to offer.

Jaimungal does get Susskind to realize that the "if it's not close to the consensus, it's probably bad" argument is a dubious one, especially at a time when the consensus research program has clearly failed:

> But you're perfectly right. We should certainly be on the lookout for ideas which are not the consensus. We should be watching for them and not immediately dismiss them because they're not exactly the same as the ideas that we've been pursuing. For sure, we should be doing that. So I would agree with you about that. And maybe we haven't been diligent enough with some of these ideas…
>
> Most of the people I know, and that might even include myself to some extent, are derisive about a lot of these ideas. And they're correct that there is a very strong skepticism about them, and maybe to some extent, unfounded. We all know that. There's nothing hidden about that. The answer is I've looked at them, and I don't find anything compelling about them. If you call that derision, yeah, I am a little bit derisive. However, I would say maybe there are elements in those theories which will come back, come back in some different form, which will connect better with the things which I think are right. And that's a possibility, which I suspect most of my friends don't entertain.

Who knows, some day Susskind may come around to the idea that one of the SU(2)s in the 4d Euclidean rotation group being an internal symmetry is not complete nonsense. Once I finish writing up a more detailed version of what I've been working on I'll send him a copy. Maybe I'll even finally figure out a way to use this to do something new with Kogut-Susskind/Kähler-Dirac versions of fermions, and he'll be pleased that in 1977 he was on the right track…

Update: Somewhat related to the posting is this new rant from Sabine Hossenfelder. It's motivated by this from "Professor Dave", who has 3.4 million Youtube followers and is upset that she is hurting the credibility of scientists by criticizing what has happened in fundamental physics over the past 50 years (a topic he seems to know nothing about). While I disagree with her about some things, I strongly identify with:

> Why the fuck is it my fault that cranks think I'm their best friend because I'm pointing out that there's no progress in the foundations of physics? It's a fact. We haven't made progress in theory development for 50 years.

To connect explicitly to the topic of this posting, a big reason for the lack of progress is the way Susskind and other leaders of the field see things. In their minds it's not possible that the consensus (i.e. groupthink) of GUTs/SUSY/strings of the past 50 years could be wrong. Anyone who argues otherwise is a "weirdo" who doesn't understand the arguments behind the consensus and can't possibly have any useful ideas about an alternative.

Anonymous,
Thanks, changed to that one.

3. **Alvaro Ledesma**
October 31, 2024

After this declaration, why does nobody mention Edwar Witten and its role in keeping consensus in this dead-end route? Great work in mathematics, sure. Genius. Not so much on keeping string theory in life support instead of taking the much more difficult decision of unplugging it.

4. **Robert Smart**
October 31, 2024

Prof Alexander Hamilton from Colorado has wandered into this area. In the abstract of an upcoming (1-Nov) talk (https://gaupdate.wordpress.com/2024/10/29/osmu-2024-lect-a-hamilton-string-theo-unif-geom-alg-01-nov-2024-online/) he writes "chief arguments against bosonic string theory without any supersymmetry are, first, that it does not admit fermions, and second, that its ground state is tachyonic, therefore unstable. But D-branes, discovered by Polchinski in 1995, are surfaces upon which open bosonic strings can end, and those D-branes can carry fermions.".

October 31, 2024

Just want to acknowledge what seems to me as a mature, reasonably humble, and constructive reply to a public criticism. That's not easy.

6. **Felix**
October 31, 2024

Being accused of doing bad physics by the person who wrote 'Dear Qubitzers, GR=QM' (1708.03040) has to be some sort of badge of honour

7. **DrDave**
October 31, 2024

It's so tragically sad that halfway (!) to a moment of realization that could genuinely help the field, Susskind devolves into ad hominem attacks. So many follow this route…. If he found something in Peter's or Penrose's work that he disagreed with, why not engage in ideas, through a letter, or in a journal? You're a scientist; do science.

8. **Sabine**
November 1, 2024

Trouble is, if you search Inspire for papers on the topic string theory the paper production isn't tapering off. It's just that we don't hear about it much anymore. Swampland is tapering off. Wormholes are still going strong. And quantum simulations are at all all time high.

9. **tbgb303**
November 1, 2024

Hm, read Not Even Wrong when it came out – only just discovered your blog! (Yup, I'm a bit slow, but we get there in the end)

Just to repeat the previous poster, it is admirable to see ad hominem attacks politely brushed aside after finally being accepted as correct about String Theory's limitations and cultural stagnation. It's only taken nearly 20 years – hats off!

10. **Jim+Eadon**
November 1, 2024

"Susskind says [he] is trying to extend string theory to something different which will work in dS space"
So, Suskind is trying to formulate a superstring DeSitter holographic duality? I would have thought many have tried to do that: do you know of such a research program? Are there serious blockers?

11. **David Brown**
November 1, 2024

Please give us an umlaut: Kähler <— Kahler.

12. **Yorg**
November 1, 2024

The part where he said that he still believes in GUT despite no observed proton decay was also interesting.

13. **Low+Math,+Meely+Interacting**
November 1, 2024

Consensus? Well, once there was one about phlogiston. The luminiferous aether had a period of reasonably broad acceptance. Observation contributed significantly to changing the consensus.

In the present, with little hope of observation as a correction for the frontiers of high energy physics, consensus seems a rather dubious lodestone. Seemingly one now just has to muddle about, with the hopes that many people doing the same on some different tack will eventually lead to someone having a breakthrough, hopefully with observable consequences. Very difficult. Extremely risky. Thousands of theorists working, most or all of them doomed to failure. I fail to see how modern academic consensus could possibly support such a diversified endeavor. Major structural change would be needed, and it seems entirely unlikely to materialize. What a prison consensus has turned out to be.

14. **Peter Woit**

November 1, 2024

Dr. Dave,
Actually I much prefer the straightforwardness from Susskind to the usual tactic of string theorists who disagree with me, which is to do everything possible not say my name and pretend I don't exists, acting like it would be beneath them to engage with anything I do.

This was different partly because Jaimungal went out of his way to ask repeatedly and specifically about me, partly because Susskind in general makes a point of not mincing words and saying exactly what he thinks.

The way he went on about the "consensus" was fascinating. It is exactly the way most people in this field think, although they don't say so out loud. Because this is the way almost everyone behaves, nothing is going to change here until the day the "consensus" changes. This interview is fascinating, showing Susskind trying to reconcile two contradictory things: "the consensus is always right" and "the consensus is stuck".

15. **Peter Woit**
November 1, 2024

Sabine,
Yes, that's really strange. I'm serious when I say this is a subject that has intellectually collapsed and died, but that doesn't mean people have stopped writing papers. It really has become kind of a zombie situation.

16. **Peter Woit**
November 1, 2024

Jim Eadon,
Susskind's comments about other people not trying do dS holography are pretty odd. Obvious places where the string program got stuck and doesn't do what you want (M-theory, holography with non-negative curvature, etc) have been well-known for decades. People don't work on these because there's no promising idea, all evidence is that these are speculative ideas which don't work.

17. **Pauline**
November 1, 2024

Sting Theory will never end until this blog ends, as this blog has talked more about string theory than any other blog/youtube channel/media outlet over the past three decades.

The sooner Peter retires, the sooner physics can move on.

18. **clueless_postdoc**
November 1, 2024

"Actually I much prefer the straightforwardness from Susskind to the usual tactic of string theorists who disagree with me"

Having seen conflicts in other fields outside of physics, I tend to agree with this. The one thing more rude than having heated discussion is ignoring the person you disagree with and hoping/persuading others do the same. I've seen people ignore disagreements with others under the name of diplomacy, but IMO this behaviour is doing much more damage to the field.

(though on a more realistic note maybe it's sometimes not practical to always argue, protracted arguments are expensive time and energy wise and you never know if the person you argue with will behave reasonably)

19. **Peter Woit**
November 1, 2024

Pauline,
Maybe that's the explanation for why people are still writing over a thousand meaningless papers about string theory each year: they're doing it just to piss off Sabine and me, if we stopped, they'd stop.

20. **Ryan**
November 1, 2024

Maybe I'm being overly generous to Susskind, but I read his comments as saying that theories outside of the consensus are usually (implying not always) wrong. And that's correct – most theories that go against consensus turn out to be incorrect.

However, contrary to Susskind's admitted derision of non-consensus theories, a willingness to buck consensus should be applauded even if the effort ultimately fails, especially when consensus is stuck. It's that 1 theory out of 100 that actually works and upends consensus that makes the 99 failures all worthwhile.

21. **Yoh Tanimoto**
November 1, 2024

This is the first time I leave a reply here but I have been a long-time reader of your blog and appreciate very much your critical comments. I am also curious about your recent papers as I work on the Osterwalder-Schrader axioms and await enthusiastically your further developments.

Apart from the interesting admission of Susskind about the failure of the string theory as a theory for the real physics, I would like to know what he means when he says "(the String theory) is a very very precise mathematical structure, it exists, it's well-defined". It is well-defined in which sense? Do I understand correctly that even the perturbation series for the S-matrix is not proven to be finite even on the flat 10-dimensional spacetime?

22. **Peter Woit**
November 1, 2024

Yoh Tanimoto,
When physicists like Susskind say things like what you quote, you need to take into account that they are spending most of their time doing things like "ER=EPR" which are completely ill-defined. The minute they have any actual equations, then they have a "precise mathematical structure". If they can compute a one-loop term, then it's "very, very precise" and the theory is well-defined.

Possible problems with the superstring perturbation expansion in flat 10-d spacetime are not really the point. The problem is that to leading order this looks nothing like the real world. "Compactification" schemes to make it look like the real world quickly get you deep into ill-defined territory. Or, more accurately, anything well-defined doesn't look like the real world, you need to head off into regions where there is no well-defined theory to avoid falsification of your idea. This is what happens when you start with a wrong idea, except that normally people give up (or don't wait 40 years to do so).

23. **Bernhard**
November 1, 2024

Susskind's unprofessional behavior and continuous ad-hominem attacks are probably one of (but certainly not only) the reasons nobody (but string theorists) take string theory seriously anymore. Obviously none of us can shout it at a conference because we fear funding repercussions, but we all say it privately during coffee breaks. It is fine to criticize and even trash a paper – it is not fine to use the argument "who is X" to make a point.

24. **Arnold Neumaier**
November 1, 2024

Ryan,

"It's that 1 theory out of 100 that actually works and upends consensus that makes the 99 failures all worthwhile."

No. The good theories replacing more limited theories were always due to better insight, not due to trying all possibilities. Only those few failures that increase the insight in a significant way are worthwhile. It does not help to search under 99 or 9999 lamp posts when the key was lost where there was less light.

25. **Yoh Tanimoto**
November 1, 2024

I see… so, for mathematicians, it is not well-defined even in the flat 10d spacetime.

Well, I understand your point that the passage to 4d is much more problematic. I think I would still appreciate if something (quantum) were really well-defined even in 10d, but I'm afraid I won't see it as no one is working on it.

26. **Peter Woit**
November 1, 2024

Yoh Tanimoto,
I think the "consensus" view on 10 d superstring theory in flat space time is:
1. How to define the perturbation expansion for all terms in higher genus is a very technical problem, conjecturally all such terms will be finite.
2. The perturbation expansion is just an asymptotic expansion, and will not converge for non-zero coupling.

My interpretation of this has always been that, as far as mathematicians are concerned, this is not, even conjecturally, a truly well-definied theory. Susskind is using a different definition.

27. **Erich+Weiss**
November 1, 2024

Is Susskind claiming that string theory is "the consensus"? Among whom?
People he talks to? Most physicists I talk to have decided long ago that string theory is just failed physics. What on earth does he mean?

28. **Peter Woit**
November 1, 2024

Erich Weiss,
Who he talks to is theoretical physics faculty at Stanford, Harvard, IAS/Princeton and a few other places. While their colleagues in other fields of physics are realizing this is a failed project, they're sticking to the "consensus" that string theory is "the only game in town". For them, those in other fields who don't agree are just basically ill-informed about the complexities of string theory and its great achievements, and not as bright as they are. Those in the same field who disagree are "weirdos".

29. **Douglas Bundy**
November 1, 2024

Many years ago, I pointed Peter to a talk by the late, great Sir Michael Atiya, given at David Gross' group in California. I remember that he expressed his bewilderment at the baroque nature of string theory, and the amazing fact that QM depends upon the ad hoc invention of man, the square root of -1. He said, if string theory turned out to be true, he would find it entirely bizarre that nature was constructed that way. Maybe, Susskind's recommendation to "start over" should begin there. Just saying.

30. **Peter Woit**
November 1, 2024

Douglas Bundy,
I'd forgotten about that. For those interested, see
https://online.kitp.ucsb.edu/online/plecture/atiyah/

31. **Mitchell Porter**
November 2, 2024

Since his conversation with Lawrence Krauss, I have been puzzling over Susskind's remarks regarding supersymmetry. I still don't really get why he's so negative about the prospects for supersymmetry breaking within string theory. But maybe the real reason why he wants a non-supersymmetric generalization of string theory, is that his top priority is to understand quantum gravity in De Sitter space. That would make sense to me.

32. **Alex**
November 2, 2024

Just pointing out that it should be obvious that there's a difference between the usual consensus that happens in heatlhy science (which is an essential part to drive progress), which is strongly backed by empirical findings, and its degenerate, cancerous growth relative, the group think. Of course, what Susskind sees as the former in his field, most of the rest of the community has finally reached, or is reaching, a consensus (oh, the irony! haha) that it's actually the second thing, a tumor that has to be removed before it kills the patient.

33. **Juraj**
November 2, 2024

What Susskind calls “consensus” is nothing more than a groupthink. The change will not come from those that comfortably live from the current situation.

34. **Eric+Weinstein**
November 3, 2024

After listening to this carefully, I am of the opinion that something extraordinary happened during the interview, and it is due to the host that things got really interesting.

As I understand it, Lenny is trying to say something radical within the established frameworks, but without losing those paradigms and questioning them. It’s like saying “We need to challenge all our assumptions and go back to square one…within String Theory.” The host then does something that I have never seen. He respectfully lets Susskind go on, but points out the contradiction that no one has been able to get at for 40 years: how can all of these theorists say with certainty that String Theory is the “Only Game in Town” when they clearly have no idea if there is anything going on outside of String Theory?

What is unique about Jaimungal as host is that he has far more information than a non-physicist like Dennis Overbye or KC Cole. But as a non-physicist, he can push back on the interviewee for the first time. When the guest says something wrong, Jaimungal is right there pointing out that the claims being made are actually wrong. This has never happened before. Either you get interviewers like S. Carroll and NDGT who are not String Theorists (but can seem like marketers for Strings), or you get people who have to take what is claimed on faith. I think what just happened is that we saw our first earthquake interview of this type. Respectful. In depth. But not Public Relations for String Theory.

The result was that Susskind actually changed his position DURING the interview. He went from saying “Follow the consensus and avoid the weirdos almost always.” at the beginning, to “You should ignore what I have to say about other researchers and other games in town. I don’t know them. I don’t know those people so I shouldn’t say. Maybe they are doing things. We don’t know. We tend to be very derisive in String Theory. This is not exactly a secret. It’s entirely possible the answer is with someone who is outside.” I have never seen this before.

35. **Dawood Kothawala**
November 3, 2024

Alex: Over the past year, I am hearing more and more string theorists pompously claiming that information paradox has been solved using wormholes-entanglement connection of Susskind. And I am talking here about well known string theory researchers!

36. **Low+Math,+Meely+Interacting**
November 3, 2024

Having watched the entire interview, I found it a generally laudable discussion all around. My two main quibbles are the paradoxical advice to young theorists and the terse dismissals of “bad” physics. For the latter, I should point out I greatly appreciated Susskind’s concise summary of the difficulties of the Many World’s interpretation of QM. I’ve seen all of them before, but I think Susskind has a talent for rendering a pithy verdict. So it’s disappointing, if he’s actually put in the time to read a paper (which seems to be the case) to hear it simply dismissed as “bad”. I would have genuinely been interested in his reasons for thinking so. Apparently he couldn’t be bothered.

As for advising new generations of physicists to strike out on their own, he seems to be saying they should be willing to commit career suicide en masse for the good of the discipline. That doesn’t seem to me to be very helpful. Rather, I would have liked for him implore folks with tenure to give talented young mavericks a living, and provide them the opportunity to at least fail well. It likely does really come down to the incentive structure, and high-minded exhortations to follow Truth will never be enough.

37. **Marvin**
November 3, 2024

Eric+Weinstein

From the interview: “We tend to be very derisive in String Theory. This is not exactly a secret. It’s entirely possible the answer is with someone who is outside.”

Again, he can’t close the box definitively,by not saying that a completely new theory will come from outside, but instead pretending that an answer to String problems will come from outside. It is Zombieland and the Outsider.

38. **SDR**
November 3, 2024

That is almost as devastating as things could possibly be for string theory as a physical theory of nature. And his ad hominem attack is disappointing in somebody of his stature: it makes him look small-minded and vindictive.

39. **Peter Woit**
November 3, 2024

While Susskind does acknowledge the possibility that outsiders/weirdos might do something important, it’s in the context that they might come up with an idea that will build upon the consensus research program and vindicate it. I don’t hear him anywhere acknowledging that the whole program might be a mistake. For him and the others at Stanford/IAS/Princeton/Harvard/etc. who have been doing this for forty years, it seems to be completely inconceivable that the whole thing could be wrong.

40. **Matthew Foster**
November 4, 2024

String theory has always been a deeply weird program. Obviously many technical developments “along the way” were amazing and useful (2D CFT e.g.), but the original 30 years of worldsheet theory building is one of the strangest developments I can think of in theoretical physics: trying to build a many-particle theory of everything from the vantage point of a single string, splitting and merging into a few others, operating in an ambient fixed background spacetime.

And I still don’t get why the branching polymer result due to Froehlich et al wasn’t a big alarm bell for the field back in 1984. Ivan Kostov claimed to me that the problem doesn’t resolve in the critical dimension either. If the bosonic string doesn’t exist because summing the configurations of a liquid membrane always gives you singular branching surfaces, how can one be sure the same affliction doesn’t obliterate superstrings?

41. **Scott Caveny**
November 5, 2024

The production of approximately 1000 papers per year for the last 30 years is definitely worrisome: Search on \`String Theory\` at INSPIRE shows the 1984 \`first revolution\` with persistent production around 1000 papers per year since about 1996 (the \`second revolution\`)

https://inspirehep.net/literature?sort=mostrecent&size=25&page=1&q=String%20Theory

In an attempt to understand more about this persistence I came across Barry Bradlyn's analysis from 2009 (not sure if it was ever discussed on this blog as it seems relevant to the conversation)

https://web.mit.edu/demoscience/StringTheory/

Unfortunately, Bradlyn's analysis is now 15 years old. It might be interesting to learn what an update of that analysis demonstrates.

But assuming that a career is about 40 – 45 years, the persistence of this intensity of production over 30 years suggests the possibility that the field of String Theory research escapes Thomas Kuhn's mechanism of paradigms shifting as workers literally die off . The generation `born` in 1984 should be retiring now. If ST is a Kuhnian paradigm, then production should be dying off as the first generation retires. But that is not what seems to be happening.

`Echo chamber` effects tend to produce persistence but more practically funding produces root cause persistence. The feedback loop between funding and echo chamber effects is then a possible mechanism for the escape of ST from the natural history of a scientific paradigm.

42. **Mitchell Porter**
November 10, 2024

Matthew Foster,

I tried to find the result that you're talking about. These two 1985 papers by Ambjorn et al are still being cited:

https://inspirehep.net/literature/212827

https://inspirehep.net/literature/221042

In the second paper they explore what they call a regularization of the Polyakov action, which may avoid being dominated by the branched polymers for dimensions between 2 and 30.

I can't say if this work ultimately converged with nonperturbative studies of string path integrals within string theory; most of its current citations are in topics like "2D Liouville quantum gravity".

43. **Matthew Foster**
November 10, 2024

Hi Mitchell

The status is also reviewed here,
https://arxiv.org/abs/1310.8552

I actually became aware of this stuff as a cm theorist, due to applications of Liouville CFT to various condensed matter problems (although no results were directly obtained from LCFT as far as I can tell, and instead extracted from mappings to simplified glass-transition models).

I haven't dug too deeply here but spent some time discussing with Ivan Kostov at a conference. He said that many attempts had been made to tame the branching polymer solution (by adding higher-order terms to the N-G action), but these "irrelevant" operators failed to tame the IR behavior. It's a quite interesting statistical mechanics result, that the attempt to sum over "liquid" membranes becomes dominated by singular polymer configurations.

I can imagine various ways around this for the usual string program–these aren't superstrings, Minkowski vs Euclidean, etc. Maybe AdS/CFT allows one to somehow claim that these problems go away in the non-perturbative limit, since the corresponding boundary SUSY CFT is weakly coupled and one can do calculations.

Then maybe it's just dS vs AdS all over again?

44. **Andy Colombo**
November 20, 2024

Susskind is eighty-four, has a solid reputation and position, so my perception is that he can afford to say the "truth" on record, eventually. However, he chose his words very carefully, so as not to admit that an actual change of framework is needed. «We live in the wrong kind of world to be described by string theory» is, in my view, a masterpiece of linguistic manipulation, where string theory does not get to be associated with the adjective "wrong": the world itself does. «We need to start over» sounds more like "di Lampedusa strategy" to me: keep working on the same things, while pretending that an actual self-correction has taken place. Kudos to Curt Jaimungal for pointing out that the "consensus" is biased, for showing that the leaders of the "consensus" do not actually know what the colleagues outside of said framework are working on, and for respectfully keeping the whole interview on track: that was no small feat.

Living in a Post-truth World

November 6, 2024
Categories: Uncategorized

I grew up in the 1960s and 70s, at a time when fundamental physics was making huge dramatic progress and Western democracies were changing in equally dramatic ways, mostly for the better. It truly did seem that the Age of Aquarius was upon us, and that human societies were on a consistent route to progress, however uneven. By the late 1970s and early 1980s things had started to change, but that humanity and my chosen field of science were sooner or later moving forward still seemed self-evident.

By the late 1990s the situation started getting more disturbing. The likes of Newt Gingrich started taking over the Republican party, with a highly successful propaganda arm called Fox News running 24 hours a day, pushing lies about the Democrats, especially the Clintons (remember Whitewater?). For some mysterious reason, even the New York Times joined in. In theoretical physics, proponents of a failed theory dominated the subject, putting out endless propaganda to the public such as Michio Kaku's Hyperspace.

Around this time I started spending a lot of time trying to understand how these things could be happening. If someone is saying obviously untrue things, logically there are only two possibilities: they're ignorant and believe what they're saying, or they're dishonest, know very well that they are lying. Watching this kind of thing for many years, I started to realize that a better way of thinking about what was going on is that for many people (mathematicians being somewhat of an exception) the issue of truth just isn't very relevant. Newt Gingrich and Michio Kaku likely weren't thinking at all about whether what they were saying was true, they were thinking about what would get votes, sell books, or otherwise further their goals in life. Gingrich was doing what he was doing to save the republic, Kaku to pursue the dreams of Einstein, but both had enthusiastically entered a post-truth environment.

Over the last decade or two, things have gotten much, much worse. Those with a lot of influence in fundamental theoretical physics have driven the field to intellectual collapse by continuing to heavily promote failed ideas. The scientific method is based on abandoning failed ideas and moving on to better ones. As an undergraduate at Harvard I watched Glashow, Coleman, Weinberg, Witten and others quickly abandoning that which didn't work and moving on to impressive new ideas, with more of the same at Princeton during my graduate years. These days Harvard Physics features a group of people devoted mainly to propping up the failed string theory program (Vafa with the "swampland", Strominger with "A+++" and Jafferis with the wormhole publicity stunt). The situation at the IAS/Princeton isn't a lot better.

On the American democracy front, the Trump phenomenon embodies post-truth in its purest form, with the full triumph now of a movement devoted to saying whatever will get them to power, with less than no interest in whether any of it is true. I've spent a lot of time trying to understand why voters in the US voted the way they did in this latest and recent elections. Taking a look at last night's exit polling, the answer is pretty simple. Rich and poor voted much the same way, but those with the least education voted for Trump by a 28% margin, those with the most education voted for Harris by a 21% margin. The polite term for the first group seems to be "low information voters", but what's going on is that education is exactly what gives you the tools to look for the truth and not get taken in by lies.

The situation has gotten dramatically worse in recent years, as people get their information from social media, with the rise of powerful algorithms designed to generate outrage and "engagement" (sometimes designed and funded by bad actors). These send even some of the smartest people around deep into rabbit holes of lies.

So, given all this, how does one live a fulfilling life in a post-truth world? I'm 67 years old, now see little chance I'll be around to see a return to the sort of world I once knew where what was true mattered. On the citizen in a democracy front, over the last few days I've adopted a new policy. When I'm reading anything, at the word "Trump" I stop and move on to something else. Other terms will get added to that algorithm as needed. What's going on is all too clear, there's nothing I can do about it, and I need to stop wasting time and energy thinking about it more. I've deleted the Twitter account I was using (@peterwoit, not the @notevenwrong blog post announcement account) and won't anymore waste time in that sewer. I'll miss stringking42069, but one has to make sacrifices.

On the theoretical physics front, I'll give up wasting time paying attention to what string theorists are up to, and try to concentrate on more worthwhile intellectual activities. The blog will continue though, since it's one of the main positive things I can do to make a small dent in the post-truth information environment. I've always benefited greatly from the many readers who write to me to tell me about things I may not have seen. Keep those cards and letters coming, especially since I'll be spending less time looking for something new on the physics side of many of the usual topics I've covered.

Due to massive increases in the volume and sophistication of trolling, blog comments are now all moderated. If you want to argue that it's all the Democrats fault (yes, I know that they have their own post-truth problem with identity politics), or that theoretical physics is doing just fine, please go away. If you have an insightful and constructive suggestion about how to live in the post-truth world, I'm willing to listen.

Update: Violated my own new policy by reading the following two analyses of where we are, which are better informed than my own:

https://newrepublic.com/post/188197/trump-media-information-landscape-fox
https://www.inquirer.com/opinion/commentary/trust-mainstream-media-2024-election-20241110.html

   November 6, 2024

   It is like being in open water with no land in sight.

   I think your book on symmetry and quantum theory is one of the best things to happen in this world you describe. I look forward to recommending it to, and buying it for, my son.

   I don't fully agree with your conclusions here, but I understand them, and I respect them. Something began vanishing when we were young men (I am 8 years younger than you). Not Even Wrong is almost always the first thing I check when I reach the internet. Don't abandon it. It is a sandbar to many. Courage, my friend.

2. **John Hessler**
   November 6, 2024

   Peter—all I can say is we love you— always a commentary that goes to the core.

3. **Peter Woit**
   November 6, 2024

   Hi Eric,
   Thanks, although one problem with teaching the course that book is based on again this semester is that I'm very aware of problems with it and how it could be improved,

more so each time I teach the course. One more positive project I should work on is a rewrite.

4. **Anonyrat**
   November 6, 2024

   In “Microbe Hunters”, Paul De Kruif has these words from Louis Pasteur:

   “…..Do not let yourselves be tainted by a deprecating and barren skepticism, do not let yourselves be discouraged by the sadness of certain hours which pass over nations. Live in the serene peace of laboratories and libraries. Say to yourselves first: What have I done for my instruction? and as you gradually advance, What have I done for my country? until the time comes when you may have the immense happiness of thinking that you have contributed in some way to the progress and good of humanity….”

   If that seems far-fetched, I quote you Vaclav Havel:

   “Hope is definitely not the same thing as optimism. It is not the conviction that something will turn out well, but certainty that something makes sense regardless of how it turns out.”

   I interpret this as doing the right thing is always meaningful no matter how futile it may seem.

   IMO, you’re doing the right things.

5. **CWJ**
   November 6, 2024

   Amen, brother.

   I would like to point out that there is plenty of theoretical physics outside of particle physics–condensed matter, nuclear physics (my own field), astrophysics, biophysics… I love this blog, but am disappointed when physics is so narrowed to a single subfield.

   And recently I was at a nuclear physics conference, the fall APS conference, which was full of excited and energized young people, talking about their research and their schooling and networking with each other. There was a lot of positive and productive energy there, and it gave me considerable hope for the future.

   (Though I do worry terribly about the prospects for science funding in the immediate future.)

6. **Marty**
   November 6, 2024

   I completely agree with you — preserving sanity increasingly requires significant filtering. But too much filtering can mean losing touch with the world as it is, so where does one draw the line?

   FWIW (probably not a whole lot, given the current state of things), these are a few of the things I’ve done.

   1. We already have enough societal division, and I don’t want to contribute to it. I’ve found most people who I suspect strongly disagree with me on important political matters (e.g., whether Trump is mentally or dispositionally suitable for the Presidency) can be quite pleasant, humorous and even reasonable outside of politics. So I try to stay away from hot-topic political discussions unless I know them well, and regardless, I try not to define people by their political views (no matter how much I disagree). It’s sometimes really tough to do.

   2. I try to keep in mind that reasonable people can disagree on important issues, even after a lot of though and with the same background information, when they start out with different premises. And since one’s premises are not entirely objective — they are influenced by environment while growing up and “coming of age,” what we have been exposed to (or sheltered from), etc. — I don’t think it is fair or even morally justified to judge people because of their views if their views are honestly held and not purely self-serving. Some people just think some things are more important than other things; I know I do.

   3. I also try to remember that a lot of people just aren’t well equipped to think critically about what they hear, especially when it would require disagreeing with their friends and family and risk being pushed “outside” their social group. How much of that is their fault; to what degree are they responsible for their gullibility and willingness to embrace lies when they support what they want to believe? The answer isn’t clear to me; a lot of it seems like human nature combined with inadequate training in critical thinking. Are these flaws of human nature that will make non-authoritarian governments ultimately fail, or at least the variety of them that allows equal participation by all? I sure hope not.

   4. I stay away from social media content and news sources that are strongly biased in either direction, and *especially* avoid commenting on them. If someone sends me a link to an analysis that doesn’t look well thought out, I won’t read it. And in my experience it’s almost always (but not literally always) pointless to try to change a person’s views when they already have things All Figured Out. But you already know that much, much better than me I’m sure.

   That’s probably an already-too-long enough list from me.

   A sad part of the whole exercise we have just witnessed is that all the economy-related things people are angry about — inflation, interest rates, debt, etc. — will almost certainly become somewhat worse under a Trump administration than a Harris one. That on top of indifference to climate change and power vacuum/instability in the world that authoritarians can freely exploit…

7. **Peter Woit**
   November 6, 2024

   Marty.
   My problem isn’t knowing how to deal with people who think Trump is not a liar. They’re few and far between where I live and work. Problem is, how to live comfortably in a society where truth doesn’t matter, one that is becoming more and more degraded with each passing year?

8. **Paolo Bertozzini**
   November 6, 2024

   Dear Peter,

   yes, something has been going very wrong at some point in the ’70s-’80s, although the roots of the problem probably predate its visibility (also in theoretical physics).

   I do understand and share the disillusionment … often I even wonder if there has ever been a meaning for those “values” of the ’60s that we see now so irremediably compromised, or if it was all just propaganda as well. Paying less attention to the “annoying material” is for sure of great help (and I am using this strategy too) … but even more effective is to increase the communication with those few (?) that still have some constructive attitude and understand the current dysfunctional situation.

Your blog is of extreme relevance as a point of reference and information exactly for this kind of researchers in mathematical physics … and personally I am always looking to see further activity here … especially about the important ideas on Euclidean unification that I follow with great interest … hence my strongest encouragement to continue the good work here.

9. **Diogenes**
November 6, 2024

The same pathologies in academia that enabled string theory to survive have also enabled a set of campus born political ideas to survive for about the same length of time that are now seriously outdated. What you saw last night was a rejection of many of those ideas, mixed up with a lot of other toxic noise. Given your insights on the sociology of string theory survival perhaps use those insights to analyze that political phenomena as well.

10. **Garrett Lisi**
November 6, 2024

Truth always wins in science — that's pretty much tautological — it just often takes a distressingly long time, with much wasted time and anguish before it arrives. This blog has been a bright beacon of sanity above a turbulent sea of misguided high-energy physics ideas and publicity. I deeply hope you will not only get to continue to document the fall of string theory, but get to describe the multitude of ideas that come next — maybe even one that turns out to be true.

11. **Sabine**
November 7, 2024

I think there are many people who share your feelings and I guess you won't be surprised that I have had similar thoughts. You probably don't hear much about what is going on in Europe but the major difference, it seems, is that the Europeans aren't as loud, not that they are any better.

I think we could be more deliberate about community building. I know there are some communities among readers of some blogs or other outlets/newsletters which are doing well in the sense of rational discourse, but it would be worth collecting them. And, yes, I mean that as an exclusive community because, as we have all noticed I guess, everything else gets overrun by trolls eventually.

I have talked about this many times before with other people and nothing ever came out of it, so I'm not holding my breath, but maybe an academic underground of sorts is what the world needs at this point.

12. **Enno**
November 7, 2024

Isn't this a conquest of postmodernism, Foucault (power replacing truth), Derrida (applying this to language), Butler (to sex), … to dispense with the rather Christian concept of a universal truth? Then formal (school and academic) education, forms your mind rather to the worldview of the ruling class. Here we are.

13. **Ahania**
November 7, 2024

Book recommendation re this topic: Doctor Faustus by Thomas Mann.

14. **Paul Stevenson**
November 7, 2024

A lot in your post resonates, and I ditched Twitter earlier this year too and miss parts of it. Glad to read, though, that the blog wil continue

15. **Robert Smart**
November 7, 2024

Humans love to form groups, and one of our favourites is "We are the group that believes X". Think about it: this really works best when X is something that no reasonable person could believe. If X were actually verifiably true then you'd get all sorts of riff raff claiming to be in your group.
See the first minute of https://youtu.be/0tQTqOar7yc?si=GnE88cY5FwxoTKmR where Ren Zhengfei, the founder of Huawei, explains how self criticism is America's secret strength. Most scientists and mathematicians are so polite that we never find out who they think is wrong, let alone who they think are frauds. The world needs more like you and Sabine Hossenfelder. To get more scientists involved in the struggle for truth we need some mechanism which maintains anonymity until critiques are blessed by a significant group. Which doesn't mean such groups will always be right, but at least the conflict will be out in the open.

16. **Joseph Conlon**
November 7, 2024

I'm just going to throw in some historical perspective.

Isaac Newton was born at the start of the English civil war, the king was executed when he was 6 years old, and the country was extraordinarily turbulent politically until his 20s.

The generation who discovered quantum mechanics grew up during the first World War, then had the German civil war (Heisenberg had to sneak through the lines at night to get food for his family).

High levels of political turbulence is not uncorrelated with throwing up scientists and science of the absolute highest quality.

17. **Peter Woit**
November 7, 2024

Diogenes/Enno,
My reference to post-truth problems on the left was largely to excesses at universities that those who work there are well aware of. But, those have nothing to do with the post-truth problems in physics or American democracy. The identity politics excesses were much worse in 2020, when Biden narrowly won. Foucault might have something interesting to say about the triumph of post-truth politics, but it's not his fault.

Sorry, no more about this. It's another waste of time.

18. **Alex**
November 7, 2024

I really enjoy seeing someone talk about the amount of disinformation out there, and why people are willing to believe whatever comes their way as long as it suits them. I am a young graduate student in theoretical physics at the moment and I want to comment that I would conjecture that many of us who even think about studying string theory is because we want a good post-doc position somewhere.

Admittedly, I took a string theory course, and I can tell you I only took it to prepare myself, if I must be put into a position, to do research in strings. I doubt anyone in that course thought what we were studying was a deep fundamental truth, and that we were all just trying to either (a) prepare for research in strings (sadly for a post-doc) or (b) pretend we were mathematicians. Of course, there were those also who wanted to simply learn what was string theory (in which typing that out sounds ironic to me), and then never wanted to look at it again.

19. **Attendee**
November 7, 2024

You are being a bit too quick in believing that education would somehow help people get to the truth. After all, our string theory colleagues are some of the most educated people in the planet and they have no problem following whatever comes out of Harvard and Princeton. Indeed, if Physics PhDs can look you in the eye and say that they really believe that wormholes form when you entangle spins simply because Maldacena and Susskind say so, why should you be so surprised that people get taken in by demagogues?

At the end of the day, people are tribal – it is far easier to simply follow rather than to question. Very few people do what you do – which is to publicly air criticism. This is because people then worry about having to spend time defending the criticism and then dealing with the potential blowback. They secretly hope that the nonsense they are criticizing will die on its own. But, String Theory, Trumpism and Left-wing Identity Politics all show that this is not the case – bullshit doesn't die without a fight. It grows. The only way to end it is to actively fight it and I am doing it in my own way.

I have personally learned a lot from your blog – largely in terms of keeping me current on various physics news and updates on mathematics. So, thank you!

20. **Matt+Grayson**
November 7, 2024

When Congress changed the rules on foreign ownership of news organizations – opening the door for Murdoch & Co, the writing was on the wall. As you said, post-truth gained a huge vector (the infection kind) in FOX. Citizens United ended the chance of meaningful opposition.

I've asked historians for examples of cultures who have come back from our current state – a major power in thrall to a demagogue – without massive bloodshed, and I've yet to hear of one. In 2016, I felt that the only thing that will matter is, when the tanks surround the White House, will the guns be pointing in or out. In 2020, the Joint Chiefs supported an orderly transition of power. Next time? Who knows…

21. **Patrick M OKeefe**
November 7, 2024

"Watching this kind of thing for many years, I started to realize that a better way of thinking about what was going on is that for many people (mathematicians being somewhat of an exception) the issue of truth just isn't very relevant. Newt Gingrich and Michio Kaku likely weren't thinking at all about whether what they were saying was true, they were think"ing about what would get votes, sell books, or otherwise further their goals in life."
"On Bullshit" (2005) by the Princeton philosopher Harry G. Frankfurt is a witty and insightful exploration of this theme.

22. **Ulysses**
November 7, 2024

I have one sad data point to add towards the claim that level of education does not matter in how one's brain can be reorganized to operate within a post-truth framework, which seems to be strongly correlated with exposure to the social media brain virus. Both my siblings are also highly educated (PhDs + postdocs in a hard science + scientific careers). Both have disappeared in deep rabbit holes of lies and are of one mind. The inability to have a basic reasoned discourse with them is shocking to me.

The question that I really would like to have an answer to is: What makes me and others apparently immune? Presumably a similar level of exposure to the virus did not lead to the same outcome in me. Is there something that makes one's brain naturally resistant? Can such an ability be cultivated? Or is it innate? I am not a psychologist, but I suspect there must be a correlation with traits that are found in addictive personalities and brain changes that result from drug addiction (or religious conviction, which I consider being basically the same thing). There is no other way that I can explain the seemingly unbreakable attachment that manifests.

23. **Andreas Eder**
November 7, 2024

I'm 62 and I also have the feeling that things gradually started to go wrong over the last 30 years. Maybe it is a sign of age, but I certainly lost the positive outlook on the future.

@Enno: truth certainly is not a christian concept, that would rather be universal belief. I think it owes much more to the ancient greeks.

24. **Steven Bratman**
November 7, 2024

I have followed you for years, and appreciated your scientific perspective greatly. But I would like to offer a humanistic perspective: Humans only sometimes value truth as a virtue in itself. It comes and goes. We are not entering a post-truth world because we were never in a world profoundly devoted to truth. It's a constant struggle. Like ice age glaciers, there are simultaneous advances and retreats in different places. Optimism is at root an attitude, not a response to particular events. It is especially important in adverse circumstances, which occur frequently in human life. Despair is an indulgence, a humanly understandable one, but not useful to dwell in more than briefly. Others have faced and are facing great challenges, and so can we.

25. **Andrew M**
November 7, 2024

I'm not willing to throw in the towel on truth yet.

I think this pervading feeling of "post-truth" is part of the reason so many people are attracted to the "abc conjecture" story. How can we arrive at truth, when ultimately, for practical reasons of time and ability, we have to rely on consensus at times? How do we recognize if we are stuck in a Kyoto bubble? It really says something when a field rooted in logic itself struggled with the straying from embedded norms for discussing work. It just really struck a chord.

"Appeal to authority" is not a correct way to search truth, but without using consensus as a proxy, it would be near impossible to usefully share knowledge and progress individually or as a group / field / society. It seems, as usual, the answer is not at either end of the spectrum, but in messy nuanced moderation.

Returning to the topic at hand, yes, we probably should not waste as much time engaging with things we cannot individually change. But if none of us ever engage, nothing will ever change. Moderation is sadly almost always the answer.

26. **Peter Shor**
November 7, 2024

Attendee:

You say:

> Indeed, if Physics PhDs can look you in the eye and say that they really believe that wormholes form when you entangle spins simply because Maldacena and Susskind say so, why should you be so surprised that people get taken in by demagogues?

Do you know whether they actually believe this, or whether they're just saying this so that their job prospects aren't torpedoed by Maldacena, Susskind, and their buddies? Either way, it's a very sad state of affairs.

27. **Michael Gogins**
November 7, 2024

Thank you for this post.

In history, people who had to live in, shall we say, a-truthful societies have resorted to various strategies, among them:

(1) Monasteries such as Lindisfarne or St. Gall's.

(2) Friendships of private conversations, where friends were sometimes entrusted with manuscripts that have to be preserved from the secret police, well known now from the Stalinist USSR.

(3) Where officially supported jobs are not to be had, working on one's own time.

(4) Identifying those in power who are secretly sympathetic to a search for truth.

(5) Living and working far from the centers of power.

(6) Propagating real ideas in the form of satires and amusements.

(7) Being officially employed in one capacity, but actually doing one's most important work in another capacity — does this describe you?

28. **Peter Woit**
November 7, 2024

Michael Gogins,
The problem isn't that telling the truth is suppressed or that truth-tellers such as myself experience terrible retribution. I'm doing just fine. My non-tenure track faculty position nicely encompasses multiple duties, some of which are closely related to my research work (teaching advanced courses has been very helpful). The people suffering under the post-truth regime in physics are the theorists forced to think about the swampland. Who knows what will happen with our new post-truth government run by cronies of a deranged New York City real estate developer, but I'm betting that those who will suffer will not be well-off New Yorkers with graduate degrees but the people he scammed into voting for him.

The problem I'm dealing with is a different one, having to change the story I've always told myself about the importance of trying to understand the latest theoretical physics research and understand what is going on in our society, in order to participate in the progress of humankind. Now that those things have turned to post-truth and humanity seems to be reversing gears to ever more stupidity and ever more tribalism, I need to find a different story.

29. **Attendee**
November 7, 2024

Peter Shor,

I think some of them know that it is all nonsense but simply play along to get academic positions. But my sense is that a significant number of them genuinely believe it's true – they mumble a bunch of "algebra" about gravitational path integrals and believe that the result has been mathematically established. The "algebra" is a joke since all they do is write down a bunch of ill defined expressions and pick terms that they want. Astonishingly, it does not occur to them that the sheer ridiculous nature of the result should make them question the "algebra".

What can I say – this episode certainly made me question academia in general. In physics, experiment has provided a wonderful way to robustly establish the truth. We have now empirically seen a branch of physics go down a rabbit hole since this branch is explicitly uninterested in any kind of experiment. This has been lead by the so called "elite" institutions. Given this, what am I supposed to make of academic claims from other disciplines where experiments are practically hard to do?

30. **Anonyrat**
November 7, 2024

Whether or not Trump won, the American public would still have a huge proportion of post-truth people to contend with, between 40% to 50%. This problem was not going away with a Democratic win. This problem is beyond the scope of an individual and IMO, beyond the scope of this blog. It is like the seawaters lapping at your doorstep due to the sea rise from climate change.

Nothing happened on November 5th that suddenly shifted the situation in science or academia. You've been doing the right things, so keep fighting the good fight. We still don't have Lysenkoism, and these institutions still can recover, and maybe even be a bastion in the problem that I have deemed to be out-of-scope.

31. **B'Rat**
November 7, 2024

Italy has the dubious honor of leading by example when it comes to terrible statesmen: Mussolini inspired Hitler, and Trump is, in many ways, a repackaged Silvio Berlusconi. As an Italian, I think I can offer my 2 cents on why not engaging with Trump might actually be the right decision—and possibly even a solution.

From his debut on the right in 1994 to the crisis of 2012, the entrepreneur-turned-politician Berlusconi dominated the Italian scene, whether in power or not (and most of the time, he was). He was more con man than political leader—crass, populist, and self-serving. His promises were often blatant nonsense, and, as the owner of a large portion of Italy's media, he turned it into a propaganda machine. He made short work of his opponents, except for one timid, center-left economics professor, Romano Prodi, who beat him… **TWICE**. Thoughtful, meticulous, and unshakably calm, Prodi projected quiet integrity and consistency. His lack of charisma was legendary: he was so reliably dull that even Berlusconi's exemplary skill at painting opponents as dangerous communists couldn't stick. While others on the left kept their megaphones blaring denouncing Berlusconi as a fascist autocrat (and thus often committed themselves to obvious or perceived exaggerations), Prodi didn't take the bait. Politely outlasting everyone's theatrics with a warm smile and a stack of carefully prepared notes, he patiently explained the finer points of his proposals and appealed to reason, earning a reputation as a competent and reliable alternative to his flashy rival—a reputation his anti-Berlusconi colleagues struggled to achieve. (For the record, both of Prodi's terms ended when he was backstabbed by the usual coalition infighting on the left, which never capitalized on his strengths and is mostly still repeating the same mistakes with the current crop of politicians on the right.)

The moral of the story? I think that even at a personal level we shouldn't tunnel-vision ourselves in opposing the worst of the "other side." Instead, we should apply ourselves to building and proposing another model.

32. **D.H.**
November 8, 2024

I think it's essential to take note of the "education by race" statistics along with the plain education ones. It's specifically white non-college graduates who went hard for Trump. Non-white voters went overwhelmingly Democratic with virtually no difference between education levels. White college graduates, while decisively Democratic, landed at essentially a midpoint between the aforementioned groups.

Another thing perhaps worth mentioning: a friend of mine doorknocked for Harris in Minnesota, speaking with (in his estimation) 150+ people, specifically union member households. Among other things, he found it notable that in his experience pretty much 0% of people–nobody, not even strong Trump supporters–actually believed any specific claims Trump makes. Basically, they know he speaks in meaningless word salad, but nonetheless believe that he/the MAGA movement are nebulously, somehow, going to return them to a world that felt more normal and comfortable for them. Obviously education still bears upon this to some degree, but perhaps not along the particular lines that we might instinctively expect.

With no disrespect intended, I'd tentatively suggest that a perspective from within academia may naturally tend to overemphasize the intellectual element of our political situation and its "post-truth" ideological manifestation (as well as encouraging a rather skewed view on "identity politics" through the demented and hypocritical version that has taken strong root in the soil of university administration). More specifically, I strongly believe–and I think this exit polling generally evidences–that the fundamental problems are to be found in this society's as-yet unresolved stew of white supremacist, sexist, and otherwise bigoted attitudes which can be exploited to compel ideological allegiance to an obviously-doddering freak whose words you don't even believe.

As to how to live in this catastrophically post-truth world, I personally believe that for those in relatively stable positions within academia or government bureaucracies in America (I work in one of the latter), the immediate imperative is to think seriously about our colleagues–particularly our junior colleagues and/or students, and particularly those who are most likely at risk from any rapid changes in federal policies come January (e.g., immigrants/temporary residents, anyone who's "out" as transgender, etc.)–and consider how we might create countervailing or insulating structures/expectations within our own institutions, and how we might offer meaningful material support to those who might, regrettably, come to need it. This may seem different from what you're actually asking about here, but I'd argue that it's of primary and overriding importance in the near term if we want any chance of defending and growing institutions/communities committed to free and rigorous inquiry.

33. **Giovanni Ronchi**
November 8, 2024

Dear Professor Woit,

Thank you for your work on this blog, your books and your interviews elsewhere, it's really appreciated.
I hope you'll continue with the same energy as before

34. **John Horgan**
November 8, 2024

Peter, thanks for this. Your thoughtfulness and decency make me feel better. I still believe truth will prevail, as will justice, haltingly, messily. I still cling to my crazy belief that war will end in my lifetime! But yeah, for now, I'm going to focus on doing what I love, with people for whom I care. I have no time for anger or despair. John

35. **Steven**
November 8, 2024

Please check out the polling that shows Republican voters were *far* more wrong on factual questions than Democratic voters. This is relevant.

36. **Peter Shor**
November 8, 2024

Attendee:

I think a similar phenomenon may have occurred in artificial intelligence. There have been a number of experiments showing that the models of neurons used in neural nets are much too simplistic to actually be how the brain works. And yet computer scientists studying neural nets completely ignored these experiments and proceeded with their research undeterred.

However, using these neural nets seems to have experimentally produced machines with remarkable capabilities, so maybe there are enough similarities between the brain and the neural net model for the machines to work anyway. Or maybe the brain and neural nets work in completely different ways, but neural nets still work to produce useful programs.

The difference between neural nets and string theory may be that the AI researchers could test whether their neural nets were doing interesting things, and eventually figured out how to train them to produce remarkable results. As far as I can tell, the string theory and the It-from-Qubit people don't have *anything* to ground their research in, and thus are straying farther and farther from reality.

37. **Peter Woit**
November 8, 2024

D.H.
I don't think this has to do with racism/sexism/etc. A lot of the same people now voting for Trump voted for Obama and elected him. A majority of white women have consistently voted for Trump. Even more of them voted for him this year (versus 2020) when he was running against a woman. If you look at the election results by county from North Carolina, rural heavily white counties voted overwhelmingly for the Black gubernatorial candidate.

The tribalism at work here is not so much racial or gender based. It is strongly rural versus urban. Yes, most US voters now are just like the string theorists who have entered a post-truth state where they are not interested in what is actually true or not and just go by tribe, following what they hear from the "leaders". They neither know nor care about any relevant facts. Listening to string theorists justify what they are doing, it's generally the same untrue talking points, most of what I've heard from Trump voters asked to explain their vote, it's all Republican party talking points distributed by Fox News and other right-wing outlets.

38. **Alessandro Strumia**
November 8, 2024

Saying that now is post-truth is not true. You can freely write. If you are depressed, you can go walk at the beach. This was not allowed in the old world you miss, when Eastern Europe was under Soviet occupation, and only mainstream media existed. Now is a better world, despite residual problems.

39. **Ryan**
November 8, 2024

Coming from the UK I have no skin in this game, at least not directly yet. It seems like the US is having its Brexit moment. When the UK population voted to leave the EU there was a very similar reaction that everyone who had voted for it was either stupid, uneducated, racist or had been duped by propaganda. While that is certainly the case for some, it certainly wasn't the case for all. Also, similar to what D.H. said, most people didn't really vote for what the campaigners on the leave side were saying but they believed that leaving was the right thing to do.

From the outside, it appears that no one on the democrat side has ever really tried to engage with those who had voted for Trump in the past, they just assumed that they wouldn't be so "stupid" this time. This left them with no real choice but to vote for Trump again. In the end; if people are offered more of the same or a change, they'll sometimes pick change even if it's not necessarily the change they want.

I applaud your decision Peter to focus on what is important to you rather than waste time on that which isn't. If nothing else, something good has come out of what is a bad situation for you.

40. **Attendee**
November 8, 2024

Peter Shor,

I attended an It-from-Qubit conference at Stanford once to see what the fuss was about. They gave out delicious biscuits. I consumed a few and likely gained some weight. That is the only bit that I can say has quantifiably come from this collaboration.

I would say that the senior string theorists are a dejected lot these days. I have been in the field for a while and I can say that their body language visibly lacks the confidence of the past. The brash confidence of we-are-the-smarties-and-the-rest-of-you-are-dumb has been replaced with a sort of sad and dejected look. Thus Susskind's recent meltdown about the state of string theory doesn't surprise me.

But, none of this stops them from publicly lying about the progress in the field and so they continue brainwashing young people into joining it. I was raised Catholic and I have seen that defeated look in an old priest who has figured out that perhaps there isn't an almighty after all but if he admits to it, he loses his job and has to find a new line of work. So they continue preaching – and that system has lasted nearly 2000 years.

41. **Peter Woit**
November 8, 2024

Hi Alessandro,

One of the sadder things to see on Twitter in recent years has been your obsessive defense of the indefensible, as long as it was "anti-woke". You, Bret Weinstein and some others I know clearly joined the post-truth brigade because of mistreatment at the hands of the woke. Hopefully, now you'll feel much better, and your obsessive campaign to deal with the excesses of the woke by turning control of the world over to Trump and Putin ends better than I expect.

42. **Georg**
November 8, 2024

Alessandro Strumia,
Your characterization of traditional media of all flavors and political tendencies as „mainstream", suggesting that they all follow a uniform and presumably „woke" narrative, is a particular embarrassing contribution to the post-truth stream. Equating traditional media of the western world with the Soviet regime is a gross denunciation, especially when your hero is a big fan of the latter's dictatorial successor.

43. **Low Math, Meekly Interacting**
November 8, 2024

My knowledge of history isn't what it should be. However, it does seem roughly accurate to characterize the brief stretch of time from the Enlightenment to now as highly anomalous. Only quite recently has value in "truth" as we humanistically define it been widespread, especially by those in positions of power. It's not implausible that there could inevitably be a regression to the historical mean.

Around last Halloween I heard a summary of a study in some podcast, speculating on why people would choose to watch horror movies. Perhaps they help us cope with the real life horrors we may encounter. Like any form of play, jump-scares serve not only to amuse, but also to prepare.

Dystopian speculative fiction is nothing new, but there seems to be more of it around. When I was young we escaped into Narnia and Middle Earth. My daughter and all her friends love the Hunger Games. They stopped wanting to dress up like Hermione Grainger years ago. Now they want to be Harley Quinn. I think they're getting prepared.

It's hard for us who have lived long enough to witness the decline of the Enlightened West to imagine how such a thing could happen. But it's nothing short of a miracle we were born in a time in which we could grow up to take truth for granted. It was nice while it lasted.

44. **Peter**
November 8, 2024

Alessandro Strumia,

"Now is a better world, despite residual problems."

Not in all respects, and you know it. I studied physics and got my master's in 1983. If you would have told me then what the state of HEP theory would be in 2024, I would have thought you were nuts.

I once interviewed Jean Bricmont (from Sokal & Bricmont fame) and he explained why he thought truth was important: "Because truth is the only thing the poor and oppressed have." In the 1980s you still could voice those sentiments without being laughed out of court as a naive idiot. So yes, it was better then.

Being rather old now, I have the strange feeling that I'm living in a world where truth simply doesn't matter any more. Perhaps civilization has reach that stage in which, in many domains, we don't have to question anymore if statements are true. We can make up things as we wish, and a mythical thing called the "marketplace of ideas" will tell us who is right. Or who gets the money.

Is that a better world? I don't think so.

45. **Rich Townsend**
November 8, 2024

Populists like Trump need an unhappy and alienated population and they then exploit them in a few basic ways. This is not new and I think the periods when debate has been based on truth have actually been in a minority through history, even recent history.

The first way is to tell people what they want to hear even if it's completely impossible. People will believe it, or at least, give it a chance.

The second is to blame outsiders and demonise opponents. Trump's pronouncements on immigrants have been similar to those used by various dictators and racist regimes in the recent past. People, particularly if they have a sense of lost status, and particularly if they lean towards conservatism, are very willing to blame out-groups for society's ills. Likewise, accusing democrats off all kinds of nefarious and untrue activities.

The third, which very much ties in with this, is to present simple solutions to complex problems.

The fourth is to legitimise dark-side thoughts and actions. This can be thrilling – wow, I can say or do these previously forbidden things, I can treat those people as less than human.

It's amazing and horrific to look at some of the worst regimes in the 20th century, on left and right, and see how far people are willing to go when they buy into this stuff. Those regimes have been expert in the use of propaganda and lies, just as Trump and MAGA are.

What's different now is that the propaganda is also being spread peer-to-peer rather than just top-down. But the messages are nothing new.

Naively, when the internet was taking off, I though it would be a way for people to spread the truth and undermine despotic regimes. Sadly it's turning out differently.

46. **John Pohl**
November 8, 2024

Please feel for us working in the field of medicine. The anti-vax movement seems to have done nothing but intensify in a post-truth society. It is absolutely tragic.

47. **Ashley**
November 9, 2024

Dear Professor Woit,

I would add a comment from a cognitive behavioural perspective, even though I've retired and left the profession, the profession is still in me.

As a therapist, I always accepted that what my clients told me was true. The question of therapy then became how to get the client to explore why their truth didn't seem to work?

I'd like to say that all my clients came through with a better understanding of what was true, but the truth is that at best it was 50% of them. Homo sapiens are subject to seeing the world as they are, not the world as it is. We can rationalize this as the Dunning-Kruger effect, with a side-order of Gell-Mann amnesia , or as Robert A Heinlein said, "Man is not a rational animal; he is a rationalizing animal."

So, what I know is that refuting falseness takes work, and then the outcome is subject to confounding variables that psychology and neuroscience has yet to control.

48. **Philip**
November 9, 2024

One of the things I really like about this blog is the engagement of other scientists in the comments. I get a lot of value from multiple other practitioners going back and forth on ideas.

I used to get a lot of this benefit from edge.org comments, and their organized public debates — e.g. the back and forth between Susskind and Smolin on the anthropic principle. Does anyone know why edge ceased being that place that Sabine calls "academic underground"? Are there good alternatives, beyond blogs such as this?

PS I resonate with Peter's thoughts on twitter. In fact, I don't know how people engage in debates on Twitter in the first place. I tried. I couldn't. It's like trying to drink water by putting your head under the Niagara falls.

49. **Peter Woit**
November 9, 2024

Philip,

A big part of the explanation of why US democracy is in a post-truth environment is clearly that most people are now getting their news not from sources optimized for truth, but from sources optimized either for the interest of electing right-wing candidates (Fox News, etc.), or for "engagement" (Twitter, TikTok, etc.). About this, I'm no expert and if you want to discuss the problem, you should find someone knowledgeable.

I'm much more knowledgeable about sources of information about theoretical physics. The trend in the last decade or so seems to have been for there to be fewer blogs on the subject, for reasons I don't completely understand. Some blogs run by string theorists (e.g. Jacques Distler, Clifford Johnson, Lubos Motl…) have gone dormant or rarely used simply because the field is dead so there's nothing to write about. Some theorist blogs have moved to youtube, which is where you need to be now to get a large audience. Why virtually no young theorists are trying to blog about what they find interesting is somewhat of a mystery to me. If people can suggest examples of such, that would be great to know about.

About edge.org. What happened to it is far off-topic and I don't want to start a discussion of it here, but for those unaware, see
https://www.buzzfeednews.com/article/peteraldhous/jeffrey-epstein-john-brockman-edge-foundation

50. **clueless_postdoc**
November 9, 2024

Thanks for writing this. It is indeed very interesting how phenomena found broadly in society (i.e. entering a post-truth world) also manifests itself in the sciences. People like to pretend science happens in a vacuum outside of societal forces, but that simply isn't true. How attitudes in society influence the behaviour in the sciences is no doubt very interesting, and deserves much closer inspection (probably worth half a dozen sociology PhDs).

As for why people start to generate hype, my guess would be that it works. Compared to a group that doesn't generate hype, the one that generates hype gets an added advantage, then eventually everyone starts doing it out of necessity. I would imagine a reasonable portion of the people heavily promoting their works are in private sincere and genuine individuals, but do it because they think everyone is doing it and they need to do it to survive. (this applies to young people, I'd imagine if you do this for 10-20 years you forget what it means to be sincere and genuine anymore).

A way to combat this, I imagine, is when large portions of the community reaches consensus that this kind of hype generation is harmful. Without this consensus, you have nothing to lose by generating hype: at worst some raised eyebrows, but if people buy in you get to win big (plus, if enough talent gets draw in the field may take on a life of its own living solely off of the talent of the young people). With such consensus there is an added social cost/penalty for raising hype, so I'd imagine you'd only do it if you think is worth it.

51. **Quasiparticular**
November 10, 2024

Hi Dr. Woit,

Longtime reader: found the blog in undergrad with your article on 'The Principle,' that pro-geocentrism movie. I was a budding scientific skeptic and your blog was a sort of anchor to reality. It helped prepare me for the road ahead. Poetic that a mathematician is responsible for this: I'll let G.H. Hardy's writing from 'A Mathematician's Apology' explain:

'When the world is mad, a mathematician may find in mathematics an incomparable anodyne. For mathematics is, of all the arts and sciences, the most austere and the most remote, and a mathematician should be of all men the one who can most easily take refuge where, as Bertrand Russell says, "one at least of our nobler impulses can best escape from the dreary exile of the actual world."'

52. **Alessandro+Strumia**
November 10, 2024

Hi Peter and Georg,

Yes, I am happy that, as expected, "the indefensible" was preferred by the majority. Because I think that the woke problem is way bigger than the disinformation problem. Actually, disinformation can spread because "sources optimized for truth" (I think Peter means media and academic institutions) failed and lost the trust of common-sense people, by promoting political nonsense. So toxic that best people from the political side you prefer had to move to the opposite side, leading to the current situation.

What you call post-truth is the rejection of a top-down authoritarian attempt of replacing the old liberalism with a new consensus. In the chaotic rejection process, some unscientific beliefs circulate. That's not optimal, but it's needed.

As next needed step, political power will try fixing the shame of academic institutions that went political and started cancelling science. Your future president announced that universities engaging in censorship will face cuts to their federal funding.

I privately warned about these issues years before I decided that being mistreated is better than keeping silently accepting the forced consensus. The official institutional position of HEP is doubly wrong: everything is perfect and adding quotas will make it better.

53. **Peter Woit**
November 10, 2024

Alessandro,
I think your point of view that having the US overrun by disinformation is worth it to deal with the excesses of the woke in science is a serious mistake. It's the same serious mistake Cumrun Vafa has made in deciding that having fundamental theoretical physics overrun by non-science like the Swampland program is worth it as a tactic in his battle with anti-string forces.

In both cases, signing up for post-truth is a short-term tactic with dangerous long-term consequences. In Vafa's case, the collateral damage to physics and science in general from what he is doing will overwhelm anything helpful to string theory.

In the case of the excesses at universities, from what I see in the US, that situation was already getting better, but for the last year we've already been in a new environment where power has moved from the woke uninterested in the truth to Elise Stefanik and the like, who are even less interested. The new world led by Trump/Putin/Xi will be less woke, but it will be a place profoundly hostile to truths incompatible with their interests.

While you're worrying about a "top-down authoritarian attempt of replacing the old liberalism" with a new woke ideology, I think you should also be concerned about top-down authoritarian attempts to replace the old liberalism with the old fascism. Instead of signing up for that with Trump, why not stick to defending both truth and the old liberalism?

54. **Marshall Eubanks**
November 10, 2024

Here is a suggestion:

Experience and history suggests that you should make sure your affairs are in order, while we are still in the ancien regime. For example, if you need to renew your passport, do it now.

55. **Peter Orland**
November 10, 2024

Peter, I understand if you don't want to engage in argument with the comment-
"As next needed step, political power will try fixing the shame of academic institutions that went political and started cancelling science. Your future president announced that universities engaging in censorship will face cuts to their federal funding." – but this calls out for a response.

This provocative statement is typical of authoritarians. It assumes things not in evidence. Whatever cancelling and censorship is done by the "woke", it is laughably tiny in comparison to that of dictators and oligarchs. In evidence, I offer the enormous damage done to science in 20th Century Italy, Germany, the Soviet Union and other countries by repressive regimes. Once these regimes were fully established, the quality of science in their countries – except for that of a few insulated bright minds – took a nosedive.

Our emerging overlords in the US could not care less about the quality of science – or anything else. They want loyalty, not facts.

56. **GS**
November 10, 2024

I'm not sure that I understand the argument that wokism is so toxic that widespread disinformation and fascism is an acceptable alternative. Even in the most extreme "woke" system, what is the state of the world? Scientific progress is hampered slightly by quota systems that prioritize social equality over merit? A few people lose their jobs or are denied tenure because they speak out against the politics of academia? A handful of trans athletes gain an unfair advantage in sports? How many people's lives would truly be made worse by the injustices of this extreme version of wokeness?

It seems like lunacy to claim that those injustices are so great that they justify deporting/interring millions, using the military to eliminate/silence political opponents, stripping women of their bodily autonomy, abandoning Ukraine and Gaza, gutting public healthcare, rolling back environmental protections, and deregulating crypto/banking markets and tech companies in a manner that will certainly increase wealth inequality.

Because I fear that I have gone off topic from the original post and because I don't want my comment to be condemned to the aether, I'll suggest that the way to live in a post-truth world is to spend more time talking in-person with your neighbors. Have a beer, watch some sports, play a game of chess. Share your point of view and listen to theirs. You won't always agree, and it's almost certain that they won't understand your complaints about the state of theoretical physics, but maybe you'll just care about each other and enjoy being in each other's company. In the end, that's all we can really hope for.

57. **Alessandro Strumia**
November 11, 2024

Peter: as you mix swamp and woke, let me tell a story and next its moral. This year I wanted to present a good paper at a small workshop about modular invariance. Despite that the situation got better, workshops still need a gender quota, who happened to be a US DEI coordinator, who did not allow me, and no physicist dared to defend scientific standards. So I went instead to a big conference where the organisers could write: «this is a purely academic event. It does not promote any political opinion». At this big excellent multidisciplinary conference in China, Vafa gave an interesting talk about swampland. He also said that the universe is about to end and dark matter must be a 5th dimension. Many good string theorist were in the audience, but nobody said that this "conjecture" has obvious exceptions.

The moral is that Woits and Trumps who dare to question the consensus are needed. But they don't need to be fully right, because more free speech allows to correct the correction. We don't need to cancel Woit because he spreads immoral stringphobic disinformation. It's enough to keep free speech. That's why the woke are an important problem.

Peter Orland writes that political power fixing academia is authoritarian. No, it's democracy: the woke annoyed so many people that enough approve politicians acting on how public money is used by academia. This is unusual, because the goal of academia used to be truth, so better not be managed by politicians with different goals. But now part of academia abandoned its mission.

GS: the main reason why the woke problem needs to be fixed is that false academic scholarship lead to bad mayor political decisions. Better avoiding entering in the issues. To hear them, follow Elon Musk. He understands the issues as well as he lands innovative rockets. Unlike progressives lost in resentment, he shows that real progress can be achieved. Monuments can be built instead of vandalised.

58. **Peter Woit**
November 11, 2024

All,
I'm shutting off comments here after this. For one thing, it's too often interfering with my plan of trying to concentrate on productive activity.

Alessandro,
What you write just makes it clear to me that you are looking at everything through the lens of the DEI/woke issue in science. While this explains why you became an obsessive supporter of the much worse awfulness we now live with, I don't think this situation is of general interest, since the fraction of the electorate that cares even slightly about this is vanishingly small.

Why Sabine Hossenfelder is Just Wrong

November 11, 2024
Categories: Quantum Mechanics

Sabine Hossenfelder's latest video argues

1. There's no reason for nature to be pretty (5:00)
2. Working on a theory of everything is a mistake because we don't understand quantum mechanics (8:00).

These are just wrong: nature is both pretty and described by deep mathematics. Furthermore, quantum mechanics can be readily understood in this way.

Actually, the title and first paragraph above are basically just clickbait. Inspired by the class I'm teaching, I wanted to write something to advertise a certain point of view about quantum mechanics, but I figured no one would read it. Picking a fight with her and her 1.5 million subscribers seems like a promising way to deal with that problem. After a while, I'll change the title to something more appropriate like "Representations of Lie algebras and Quantization".

To begin with, it's not often emphasized how classical mechanics (in its Hamiltonian form) is a story about an infinite dimensional Lie algebra. The functions on a phase space $\mathbf R^{2n}$ form a Lie algebra, with Lie bracket the Poisson bracket $\{\cdot,\cdot \}$, which is clearly antisymmetric and satisfies the Jacobi identity. Dirac realized that quantization is just going from the Lie algebra to a unitary representation of it, something that can be done uniquely (Stone-von Neumann) on the nose for the Lie subalgebra of polynomial functions of degree less than or equal to two, but only up to ordering ambiguities for higher degree.

This is both beautiful and easy to understand. As Sabine would say "Read my book" (see chapters 13, 14, and 17 here).

This is canonical quantization, but there's a beautiful general relation between Lie algebras, phase spaces and quantization. For any Lie algebra $\mathfrak g$, take as your phase space the dual of the Lie algebra $\mathfrak g^*$. Functions on this have a Poisson structure, which comes tautologically from defining it on linear functions as just the Lie bracket of the Lie algebra itself (a linear function on $\mathfrak g^*$ is an element of $\mathfrak g$). This is "classical", quantization is given by taking the universal enveloping algebra $U(\mathfrak g)$. So, this much more general story is also beautiful and easy to understand. Lie algebras are generalizations of classical phase spaces, with a corresponding non-commutative algebra as their quantization.

The problem with this is that these have a Poisson structure, but one wants something satisfying a non-degeneracy condition, a symplectic structure. Also, the universal enveloping algebra only becomes an algebra of operators on a complex vector space (the state space) when you choose a representation. The answer to both problems is the orbit method. You pick elements of $\mathfrak g^*$ and look at their orbits ("co-adjoint orbits") under the action of a group G with Lie algebra $\mathfrak g$. On these orbits you have a symplectic structure, so each orbit is a sensible generalized phase space. By the orbit philosophy, these orbits are supposed to each correspond to an irreducible representation under "quantization". Exactly how this works gets very interesting, and, OK, is not at all a simple story.

Comments

1. **Skewered Cigar**
   November 11, 2024

   Can you say exactly what is needed to quantize a given theory? I was told by a physicist that you can never quantize with the Lagrangian alone, which surprised me. I would have assumed that with the Lagrangian alone, one can compute the phase space and then proceed from there.
   In other words, what is the smallest list of ingredients from which the rest of the ingredients and then the quantized theory can be cooked up?

2. **Peter Woit**
   November 11, 2024

   Skewered Cigar,
   Given a Lagrangian, you can get classical equations of motion (Euler-Lagrange), but you can't for every Lagrangian construct a quantum theory. If you try to use canonical methods, you first have to construct a phase space, but in general the Legendre transform won't have the properties you need. In addition, even if you do get that to work, you'll then have a Hamiltonian function that you don't know how to quantize (operator-ordering ambiguities, no sensible state space, etc.)

   Telling students that all you have to do is pick any Lagrangian and use it to define a quantum theory by a path integral is extremely misleading. That doesn't actually work except in special cases.

3. **Sabine**
   November 12, 2024

   Well played, Peter, certainly got me to click.

   I am sure you know this, but just so that no one else gets confused.

   My argument is not that nature is not beautiful. My argument is that there is no reason for nature to conform to any preconceived notions of beauty that humans have. This is very different from saying that nature is not beautiful. Indeed the argument in my book is that we learn what beauty even means from nature. (And there are several historical examples for how this happened in physics.) Problems arise if we do it the other way round: try to find natural laws using a certain notion of (mathematical) beauty.

4. **Kartik Prabhu**
   November 12, 2024

   @Skewered Cigar @Peter Woit

   You can construct a phase space from the Lagrangian. You start with the Lagrangian and vary it (as usual), but don't throw away the boundary term (not as usual). This boundary term is a (pre)symplectic potential, and a second variation gives a conserved (pre)symplectic form on the space of solutions of the theory. You can try this with usual quantum mechanics viewed as a field in 1-dimensions

   The whole "pre" stuff is about whether this symplectic form is degenerate or not; in any gauge theory it will have degenerate directions. However, you can take functions on the phase space which are constant along the degenerate directions, and define a Poisson bracket on such functions. Quantization then be done is the usual way, along with the usual issues of operator ordering for nonlinear functions, e.g. any Hamiltonian of interest.

Of course, all of this is much easier said than done, but in principle the Lagrangian gives you, at least, all the classical structure needed for quantization.

5. **S**
November 12, 2024

"have have" is a repeated word in your post.

Since this is extremely pedantic, I'll also add a relevant question: is "the orbit method" the same thing as the Mackey machine?

6. **Peter Woit**
November 12, 2024

All,
Sorry, the reference to Sabine Hossenfelder's views on beauty was just to get you to click on the post and hope you would read the interesting content here. I'm not about to host a discussion of this topic here now.

7. **Peter Woit**
November 12, 2024

S,
Thanks, fixed.

I don't think there's much relation between the two. I've mainly encountered the "Mackey machine" as a way to understand representations of semi-direct products, don't know if there's an analog in terms of behavior of orbits.

The orbit method was originally developed for nilpotent and solvable Lie groups, where it works well, and there are relations to Mackey's work on induced representations. For the much more challenging issue of semi-simple groups, I don't know of much relation to Mackey.

8. **Peter Woit**
November 12, 2024

Kartik Prabhu,
What you're describing ends up requiring something like the Dirac method of quantization of constrained Hamiltonian dynamics, with all sorts of trouble in consistently imposing constraints.

In any case, what one is doing when one does this is trying to get to exactly the Hamiltonian context I'm writing about, finding a physical phase space identified with R^2n with the standard symplectic structure and a Hamiltonian function on it. At all stages of this, the fact that you can't consistently find operators for all functions on phase space is a significant problem.

9. **Peter Woit**
November 12, 2024

Kartik Prabhu,
Another point to emphasize is that when you go through the constrained dynamics process you often will end up with a physical phase space which is not R^{2n} and cannot be quantized by canonical methods. This happens for some of the simplest interesting QFTs. A good example is Chern-Simons theory in 3d on a Riemann surface. The Lagrangians is very simple but the degeneracy problem means that your physical state space is going to be the space of gauge equivalence classes of flat connections on the Riemann surface. Quantizing this is a completely different story than canonical quantization and requires very different methods.

Trying to instead make sense of the path integral leads to a host of other issues.

10. **Arturo López**
November 12, 2024

I wonder why, if QM is understood, 't Hooft is trying to substitute it with deterministic calculations; why Penrose insists in the unresolved problem of the quantum measurement or why even Steven Weinberg published in his last years some papers introducing non-standard randomness in the wave function. It seems to me that great physicists (I mentioned three Nobel laureates) confess in the end they are not confortable with the current understanding of QM but they dare to speak honestly only when they are old and so respected they are beyond any suspect or reprisals.

11. **Peter Woit**
November 12, 2024

Arturo Lopez,

I've written extensively about this on the blog in the past, see for instance
https://www.math.columbia.edu/~woit/wordpress/?p=10533

I agree that there is a measurement problem, but I see it as the problem of how the classical description of the world emerges out of the quantum description. The quantum formalism in terms of representation theory is simple, beautiful, deep and very very powerful. The idea that you're going to replace that with something much more naive and completely different doesn't seem plausible to me (the Nobel Prize winners who have tried this don't seem to me to have gotten anywhere at all with it, Weinberg I think admitted as much).

I don't want to host another discussion of the measurement problem, happy to discuss the ideas about the relation between QM and representation theory in the posting.

12. **anon**
November 12, 2024

Hi Peter,

Some other comments on quantization which I think fit nicely with the orbit method but are not often discussed.

There is a sense in which the "points" of the "symplectic category" are Lagrangian submanifolds. I learned this from an essay by Alan Weinstein. The idea is that one considers a category in which the objects are symplectic manifolds, and the morphisms between a pair of such manifolds, M and N say, are Lagrangian submanifolds of the product M x N. (This is a reasonable notion of morphism because the graph of a symplectomorphim from M to itself is the same thing as a Lagrangian submanifold in M x M.) In this category, a "point" in M should mean a morphism pt -> M, or equivalently a Lagrangian submanifold in pt x M ~ M.

Now imagine you are a classical physicist and you arrive at this idea that the “points” in a symplectic manifold are really the Lagrangian submanifolds. You might decide that it really isn’t right to consider functions f(p,q) on phase space, but rather that one should choose a foliation by Lagrangian submanifolds and only study things like f(p) or f(q) which are constant on Lagrangian submanifolds. You can almost imagine how following this philosophy could lead a classical physicist to “discover” geometric quantization.

13. **Arnold Neumaier**
November 13, 2024

Peter Woit said:

Kartik Prabhu,
What you’re describing ends up requiring something like the Dirac method of quantization of constrained Hamiltonian dynamics, with all sorts of trouble in consistently imposing constraints.

One can get from a general presymplectic form = closed 2-form (no matter what its origin, in particular, the Lagrangian 2-form works) a Poisson algebra on the associalted Hamiltonian vector fields – except that now the latter do not include all vector fields. See Section 13.2 of my recent book

A. Neumaier and D. Westra, Algebraic Quantum Physics, Vol. 1: Quantum mechanics via Lie algebras, de Gruyter, Berlin 2024.

(or Section 18.1 of my free online lecture notes https://arxiv.org/pdf/0810.1019v2 from 2011). Fixing all Casimirs gives a symplectic manifold, and for certain values of the Casimirs these can be extended by geometric quantization.

Dirac’s method is only needed when one wants to have a more explicit description of the reduced symplectic manifold – since one then has to construct a complete set of generating Casimirs.

14. **Josh**
November 13, 2024

Hi Anon,

Would you expound on this a bit? I believe that the orbit method uses Kahler-polarizations, which don’t fit into the foliaiton context you described. Also, while states are (sometimes) constant along the leaves of a Lagrangian foliation, observables aren’t, so I find the idea that a classical physicist would discover quantization this way to be a reach. I think quantization is much easier to motivate by making the observation (which is never mentioned) that the quantum mechanics of projective space agrees with the classical mechanics of projective space, ie. the quantum and classical equations of motion agree on quantum observables.

15. **anon**
November 13, 2024

Hi Josh,

I realized after reading your comment that I am bit confused about the point you are making so take what I write now with a grain of salt. Akshay Venkatesh has a nice set of lecture notes on geometric quantization and the orbit method. In the last section, he explains the quantization of coadjoint orbits. It can be described using Lagrangian submanifolds, but they are Lagrangians of the complexified tangent bundle of the orbit, not of the orbit itself, as the story I sketched in my earlier comment would suggest. So as you point out, my earlier comment was too simple. That comment was really only aimed at canonical phase spaces. Why in the orbit method do we need to use Lagrangians in the complexified tangent bundle and not the orbit itself? Here is where I get confused but I think the point is that there is a G-action in the orbit story and a foliation by Lagrangians of the orbit itself would not be G-equivariant. I think my earlier comment needs a disclaimer: “if there is a G-action on the symplectic manifolds, you need to do everything in a G-equivariant way and the constructions are more complicated.” Maybe someone who understands this better than me can chime in.

16. **Peter Woit**
November 14, 2024

Josh/anon,

The Venkatesh lecture notes anon refers to are here

https://math.berkeley.edu/~fengt/249C_2017.pdf

This doesn’t address the orbit method in general, for that a place to start is Kirillov’s book
https://bookstore.ams.org/gsm-64/

For the case of semi-simple groups, the story becomes quite intricate, precisely because the representation theory of these groups (in the non-compact case) is similarly intricate, in a way that matches, but not quite. For this, see Vogan’s
https://math.mit.edu/~dav/PCorb.pdf
and a posting here with a link to some of his slides
https://www.math.columbia.edu/~woit/wordpress/?p=631

The relation between the general idea about Lagrangian submanifolds that anon is pointing to and quantization is explained by Segal in lecture 4 of these notes

https://web.math.ucsb.edu/~drm/conferences/ITP99/segal/segal2_n.pdf

This isn’t about the orbit method, it’s about trying to quantize general symplectic manifolds (without the G symmetry of a co-adjoint orbit). It’s not well-known as it should be that there really isn’t a viable way of doing this in general. For the case of cotangent bundles, Segal explains the relation between Lagrangian submanifolds and quantizing by using pseudo-differential operators.

17. **Curious Fish**
November 19, 2024

Are there good references on the Poisson geometry approach to classical mechanics? I am aware of pure math references on this topic, but not of references written for physicists. In particular, are there situations, or families of problems, where the Poisson approach makes a mechanical systems easier to study?

18. **Peter Woit**
November 19, 2024

Curious Fish,

For some answers to your question, see here
https://mathoverflow.net/questions/28532/classical-mechanics-motivation-for-poisson-manifolds

19. **Arnold Neumaier**
November 20, 2024

    Curious Fish,,
    ”are there situations, or families of problems, where the Poisson approach makes a mechanical systems easier to study?”
    Hydromechanics can be put into a Hamiltonian framework on Lie-Poisson algebras, but not on symplectic manifolds. See, e.g.,
    P.J. Morrison, Hamiltonian description of the ideal fluid. Rev. Modern Phys. 70 (1998), 467.

The Impossible Man

November 15, 2024
Categories: Book Reviews

There's a new book out this week, a biography of Roger Penrose by Patchen Barss, with the title The Impossible Man: Roger Penrose and the cost of genius. Penrose is one of the greatest figures in physics and mathematical physics of the second half of the twentieth century, arguably the dominant theorist in the field of general relativity. His work on twistors is the most important new idea about space-time geometry post-Einstein, and I believe it will be studied long after string theory has been finally consigned to the oblivion of failed ideas. His 2004 book The Road to Reality is an unparalleled comprehensive summary of the geometric point of view on fundamental physics, a huge work of genius written to try and convey the deepest ideas around to as many people as possible.

The new biography provides a lot of detail about Penrose's life and work, well beyond what I'd learned over the years from reading his writings and those of others who worked with him. It does a good job of explaining to a wide audience some areas of his work, and how the background he grew up in helped make some of his great achievements possible. From an early age, Penrose was fascinated by geometry, and he became our greatest master at visualizing four dimensional space-time, generating deep insights into the subject. While one can motivate twistor theory in several very different ways, it came to him through such visualization.

Another thing I learned from the book was more of the story of the singularity theorems for which he was awarded the Nobel Prize in 2020. While Hawking often gets more attention for this, it seems that there's a good case that the creative ideas there were more Penrose's, with Hawking much better at getting attention for his work. That, despite having read a great deal about this story over the years, I'd never heard that Penrose saw things this way until reading this book is much to his credit.

In later parts of the book, the author handles well the issue of some of Penrose's more problematic later projects. Experts on cosmology are highly skeptical of his conformal cyclic cosmology ideas, and pretty much everyone thinks his involvement with Stuart Hameroff around questions having to do with consciousness has been misguided.

Penrose played an important role in my life, by suggesting to his publisher that they publish *Not Even Wrong* (for the story of that, see here). While, I haven't been in contact with him for many years, and only have met him in person briefly twice, he seemed to me unassuming and more likely to be friendly and helpful to others than your average academic.

Unfortunately, the book pairs a largely very good discussion of Penrose's scientific career with a very extensive and rather unsympathetic discussion of his personal life. If you read reviews such as the one today in the Wall Street Journal, you'll be told that Penrose's personal story "fits the template" of the genius as "deeply weird", with the book showing that "the cost of genius" is personal sacrifices by those around him.

The huge amount of material included in the book about Penrose's parents, his two long marriages and his relationships with his four children seems to me to paint a picture completely typical of his generation. That an upper-class British man growing up in the 1930s and 1940s would have an emotionally withholding father is not very notable. That a male academic of this period would have a marriage that failed after 20 years is not unusual, nor is having a wife with very valid complaints about giving up her own career and interests to follow her husband around to different positions. None of this has anything to do with Penrose's genius or great accomplishments, beyond the common phenomenon of successful people being too busy and preoccupied to provide enough attention and care to those around them.

The central part of the book is derived from a collection of 1971-76 letters between Penrose and Judith Daniels, a younger woman who had been a childhood friend of his sister. Penrose was unhappy in his marriage, very much in love with Daniels, and saw her as his muse, someone who could appreciate his work. Unfortunately for him, she had a boyfriend and no interest in a sexual relationship or marriage with him. The book goes on for pages and pages quoting these letters and explaining the details of exactly what happened. It's no more interesting than one would expect. One could argue that Penrose did do something rather objectionable to her, trying to get her to read the manuscript of his two volume joint work with Wolfgang Rindler, *Spinors and Space-time*.

The four chapters devoted to this story unfortunately are also the ones covering the time of his great work on twistor theory, which gets somewhat buried amidst the not very dramatic unrequited love drama. This section of the book ends with a dubious attempt to connect the two together:

> He couldn't let go of twistor theory, and he couldn't let go of Judith. In a single letter, he both lamented the impossibility of recreating the magic they once shared and attempted to do exactly that. He wouldn't take no for an answer — from her or from the universe.

For the years 1971-76, this book provides all the detail you could ever want about why Roger Penrose wanted to sleep with Judith Daniels and why she wasn't interested. For the details of the story of one of the great breakthroughs in understanding the geometry of the physical world, we're going to have wait for another book.

Comments

1. **CWJ**
   November 15, 2024

   Thanks for this thoughtful and illuminating review. I had read one other (non-scientist) review and was intrigued. Admittedly, now I am much less interested.

   I heard Penrose speak a couple of times (like 30 or 35 years ago), though that was firmly in the Emperor's New Mind era, which struck me as being based upon very poor argumentation. Even today with students I use it as an example of how someone can be clearly quite brilliant and make enormous contributions, but still be wrong about other things.

2. **Christopher Oakley**
   November 15, 2024

   Peter, you are now making me feel guilty about having enjoyed James Gleick's book about Feynman's private life. Maybe if had known Feynman personally, as I do Penrose*, I would have just felt that his private life was none of his damned business and that he should just leave it alone!
   * = not very well, but well enough to know that he's a nice, polite man.

3. **Peter Woit**
   November 15, 2024

   Hi Chris,
   Thing is, I normally greatly enjoy scientific biographies which include details of the subject's private life, the more outrageous the better. If a biographer wants to tell us that Feynman and Hawking were regulars at strip clubs, that's fine with me. Actually I thought the recent Hawking biography that had a lot about his private life was quite good, see
   https://www.math.columbia.edu/~woit/wordpress/?p=12235

   What I don't like about this particular treatment of Penrose's private life is

1. It appears to me to be a moralistic hit job, making out Penrose to be an unusually flawed human being (rather than the usually flawed kind).
2. It's boring (there's a whole chapter about the big moment when he and Judith both went to Trieste, stayed in the same hotel. She told him she was not interested in a romantic involvement with him and they went sightseeing).

4. **Diogenes**
   November 15, 2024

   The thing that makes great geniuses interesting and their stories signifcantly different from lots of other people is almost never their personal romantic lives. Their upbringings on the other hand are frequently very interesting, and probably relevant.

5. **Christopher Oakley**
   November 15, 2024

   Hi Peter, I know Penrose a bit better than you, but not by much. The main connection is that I am friends with one of his protégés and have spoken to him a few times at this person's parties. Yes, Feynman and Hawking loved the idea that they were the Wild Ones and would have wanted you to know all about their visits to Titty Bars, etc., but Penrose is definitely not that kind of person, and will not relish anyone dredging through his past. Maybe the author thinks that him being a Nobel Laureate, and all, makes him fair game, but I don't think so, and nor do I think it has much bearing on his work in mathematics.
   As an Oxford man myself, I might add to your analysis the fact that Oxford has held Penrose in the highest regard as long as I can remember, and the fact that Twistor Theory has had limited (so far) impact on physics is not held against him. Bear in mind that Theology, Philosophy and Classics are the high status subjects around these parts.

6. **Peter Woit**
   November 15, 2024

   Diogenes,
   This is certainly true in Penrose's case. He grew up in an unusual family, providing him an unusually rich intellectual background while growing up. This is described well in the book.

7. **AUT**
   November 15, 2024

   I think the parts of the book on Penrose's relationship with Daniels and the dissolution of his relationship with his wife are actually very important. They show very clearly how entwined his professional and personal life were and how even someone like Penrose can have a great (for lack of a better word) insecurity over his work. In a better world this kind of material would be completely frivolous, but in reality, when people think about great scientists like Penrose, they come in with a whole set of deeply ingrained ideas about what such a person must be like.

   For example, Penrose going on the Joe Rogan podcast was reported by Barss as a key episode in the ending of his relationship with his second wife. Taken in and of itself, that's completely uninteresting, but I think it's important to understand that when Penrose goes on the Joe Rogan podcast, he's getting as much out of it as Rogan, and arguably more – a massive audience and an open platform for ideas which he thinks have been unfairly dismissed. This kind of dynamic is usually pretty much invisible to (if not outright rejected by) the general public, so I think it's important to have such an open display of it. If even someone like Penrose can have such a gross craving for a certain kind of recognition, I think this can strongly inform how we see much lesser 'pop' scientists who are still often given every benefit of the doubt.

   On the other hand, of course I would love to see greater focus on technical biography and the research development of many parts of his work! Hopefully someone else will write a truly 'scientific' biography of Penrose.

8. **Peter Woit**
   November 15, 2024

   AUT,
   After reading the book, I just don't see how the failure of Penrose's first marriage was much different than the typical way half of such marriages fail. Like many people, he seems to have decided soon after the marriage that it was a mistake, but stayed in it hoping things would change. It's the biographer who seems to be claiming that there was something distinctive about the nature of genius responsible for this, but I'm not seeing it.

   Later in life Penrose became a public figure very much in demand, even if not quite on the Hawking scale. From then on, he had the usual temptations of celebrity to deal with, and one can question his choices (maybe a bad one was agreeing to open his life to this biographer…). I'm not sure what this set of problems has to do with being a genius.

9. **AUT**
   November 15, 2024

   I think that if there's a thesis statement for that part of the book, it's in this paragraph:

   "Joan, Judith, Salley, and Vanessa, each in her own way, made Roger's career possible. They managed his everyday life, freeing him to journey into black holes and tinker with conformal geometry. Beyond offering the praise and encouragement he considered essential to his creative process, they were variously sounding boards and editors, career counsellors, confidantes, and muses, willing or not. Some sacrificed their own careers and put his needs ahead of their own. They offered intellectual, logistical, and emotional support. Joan, whom Lionel treated as a blight on the Penrose mystique, served a crucial role in developing Roger's belief in his own exceptional talents. He used their unhappy marriage as justification for fully embracing the work that established his career and won him the Nobel."

   Aside from whether or not this kind of content is valuable as biography (and I think it is), I think it's very different from saying that there's something about genius which is responsible for various life conditions. If anything it's something more like the converse, that for some people the ability to creatively prosper is built on having a certain kind of environment and a certain kind of psychological and/or material (dis)comfort. It also reminds me of Shing-Tung Yau's autobiography, where I found it very striking that his wife was for some years raising their young children alone on the opposite side of the country, during some of the most productive years of his career.

   I think it's very valuable to understand that such tremendously productive and creative workers – call it genius if you like – often don't exist in a vacuum. It might already be plainly obvious to many of us, but to the broader public I think it's definitely not.

10. **Peter Woit**
    November 16, 2024

    AUT,
    Yes, that's a clear thesis statement. The problem is with the accusation that Penrose achieved what he did by treating the women in his life (and his children) unusually badly. Everyone is reliant upon those close to them for support. Most marriages of Penrose's generation involved a wife willing to forgo having her own career, move because of her husband's job, stay home to raise children and support her husband's career.

It’s fine for a biographer to point out that Penrose, like most men of his generation, was able to succeed because of such an arrangement. What I don’t see is any evidence from the book that there was anything even slightly unusual about Penrose’s story in this regard.

11. **Hubble constant**
November 16, 2024

Interesting, and there is now a NYT review of the book.

Penrose was doubtless one of the great original thinkers at his prime (which spanned decades), and I too found his semi-popular book The Road to Reality impressive. He has had many great hits, some of which Peter mentions above. However his later/recent efforts in cosmology were embarrassing. He nevertheless continued to push his theory (conformal cyclic cosmology), and even “find” evidence of it in the cosmic microwave background (with a collaborator who evidently agreed to do so) despite being told by cosmologists that his theory, and certainly the “finding” in the data, is basically nonsense. I guess in that regard he’s no different from other greats who could not be stopped from doing and claiming such things in later years (e.g. Michael Atiyah claiming he solved the Riemann Hypothesis, which may have been discussed on this blog).

12. **Peter Woit**
November 16, 2024

Hubble constant,

The Atiyah situation was different. In the last few years of his life he was suffering from a mild form of dementia, unable to follow complex arguments or understand what was a valid proof. I didn’t write about it on the blog, it seemed obviously best if everyone would just politely ignore his claims about proofs. It was too bad that some people publicly spread his claims about the Riemann hypothesis.

Penrose is different. Plenty of people with their faculties intact have dubious theories about cosmology and make unsupported claims about them (string cosmology anyone?). He’s been fond of contrarian ideas for a long time. Despite some effort, I never was able to completely understand how CCC was supposed to work.

13. **Andrew Thomas**
November 17, 2024

I briefly met Roger last year. I know that not only is he a brilliant physicist, he’s also a great guy, absolute gold. He told me the Road to Reality was the most difficult book he ever wrote, and he almost didn’t finish it.

I’m actually going to defend some of his work on consciousness, which I think gets a raw deal. Before he met Stuart Hameroff, he wrote The Emperor’s New Mind which remains a brilliant book (got me interested in physics). He was one of the first leading physicists to take an interest in consciousness, which was a brave move at the time.

At the core of the book, he expressed something that we maybe all feel but no major scientist had really said before – that there really is something fundamentally different between how our brains feel – how it feels to be conscious – and the very basic operation of a computer which might superficially be appearing to be doing the same thing as our brain, but is almost certainly not conscious. There’s something there which needs explaining, and Roger was the first major scientist to express that.

14. **CWJ**
November 17, 2024

Andrew Thomas,

I’m afraid I had the exact opposite reaction to The Emperor’s New Mind. First of all, lots of scientists have investigated the phenomenon and problem of consciousness, for a long time. Even just casually, I took an elective course on States of Consciousness in the early 1980s. And already back then people were investigating neural networks as working very differently from standard computers. To claim that Penrose was ‘the first major scientist’ to express that brains work differently from computers is wrong. (I don’t know how you are defining ‘first major scientist’. Brain biologists have know this for a very long time, and even John von Neumann seems to have realized this as far back as 1958.) Penrose seemed to have not bothered in the least to look up any research on consciousness. This doesn’t take away from his brilliant work in mathematical physics. But in the science of consciousness, he was not groundbreaking in the least.

15. **Andrew Thomas**
November 18, 2024

Hi CWJ,
There has of course been plenty of interest in consciousness from philosophers and psychologists for centuries, going back to Descartes. But there was no interest from what we might call the hard scientists until the work of neuroscientist Christof Koch in the early 90s, and others such as Stanislas Dehaene who basically created the modern field. I know the history of this field pretty well. Penrose’s 1989 work predates them. I actually suspect he might have influenced their work and – if so – we should consider him the father of the modern field of consciousness studies.

I don’t know why you mention neural nets – yes, they don’t work like computers but that has nothing to do with consciousness. I was also working with neural nets in the early 90s – my PhD is in that area. There was never the slightest mention of consciousness. Yes, I know that he was obviously not the first to suggest that “brains work differently from computers”, but we’re not talking about structure, we’re talking about consciousness. As far as I am aware, Penrose was the first to consider if computers were conscious (Turing had earlier wondered if they were “intelligent” in the Turing test).

I believe Penrose was a genuine pioneer in this area, and we should give him credit.

16. **Mitchell Porter**
November 18, 2024

Andrew Thomas,

Penrose was hardly the first skeptic of computer consciousness, or of fashionable reductionist theories of mind. He wasn’t even the first physicist to suggest a quantum theory of mind – though his specific ideas are highly original – and I think his theory achieved maximum potency only once he teamed up with the anesthesiologist Stuart Hameroff, who gave it biological concreteness by associating it with microtubules. But no doubt he opened quite a few minds, and gave skeptics of computationalism a new champion.

17. **Peter Woit**
November 18, 2024

All,
Enough about Penrose and consciousness. I don’t want to moderate a discussion of that since I know nothing about it and also don’t want to learn more.

18. **Luca Signorelli**
November 18, 2024

I have a semi-direct connection to RP through a "common friend" (I'm being deliberately vague here), and I'm relatively sure this book's reason for being is both problematic and highly unhelpful in trying to understand Roger's character and personality. I'll try to be as polite as I can – let's say that as far as I know, Roger is not your token gutter press cannon fodder, and so it's not anyone whose life story can be transformed into an instant hit job, the kind of stuff people love to read about a scientist (in case you don't know, people is interested in scientists life only when they're alleged victims, alleged loonies or alleged sleaze – try writing about a scientist whose life is remotely normal without "spicing it up" and any publisher will reject your book proposal in a millisecond.

So, I think the author tried to spice up Roger's life as much as possible. This is relatively commonplace in the world of celebrity biographies. Still, my understanding (and I'm being very cautious here) is that, well, being Roger now quite old, the circumstances surrounding the author's access to Roger's life details bear further scrutiny. I'm not implying anything illegal or such; it's just that Roger may have mistaken the book's scope when he did agree to talk with the author.

So, to sum it up, take the whole "Roger Penrose personal life story" part of the book with a massive pinch of salt. Or at least, that's my understanding.

19. **Peter Woit**
November 19, 2024

Luca Signorelli,
From the author's own description, Penrose (who is 93) has severe vision problems, and lives alone, without anyone to watch out for his interests. It appears to me that in this situation the author took advantage of a vulnerable elderly person.

20. **Low+Math,+Meekly+Interacting**
November 19, 2024

The details could be 100% accurate, and it would still be a disturbing and unseemly choice to publish this book, at least while the subject is still alive. I also find the whole account rather dreary and mundane, and entirely unhelpful in understanding anything of value about what makes Penrose interesting.

I do blame the fascination with people like Feynman for incentivizing such "humanizations" and I have, to some degree, been guilty of contributing my fair share of cash to keeping that cult alive. If Feynman is remembered as a narcissistic, sexist pig along with being a great physicist, well, he contributed as much as anyone in his autobiographical accounts to that cultivated persona. What did Penrose do to encourage dredging up petty embarrassments a half-century old? He's no Feynman, and this book just makes me sad.

21. **Peter Woit**
November 19, 2024

LMMI,
I don't think the character assassination here becomes less problematic once the target passes away.

The last thing I want to do is to get involved in the "Richard Feynman, misogynist who should be canceled or not?" debate. I'm not a fan of moralistic attacks on people's characters, especially not the version where one invokes present day moral values to attack people for how they lived in eras with different moral values.

While there's nothing wrong with a Penrose biographer explaining why his first marriage was an unhappy one, the reasons this was unhappy seem to me generic ones afflicting late 1950s marriages.

it seems to me that he's trying to make Penrose look bad for having a garden-variety late-1950s unhappy marriage. He's turning having a standard problem common in one's time into a moral failure

22. **Phil H**
November 20, 2024

Re: the singularity theorems, I'm not so sure that the "creative ideas there were more Penrose's, with Hawking much better at getting attention for his work".

Remember that Hawking and Ellis published "The large scale structure of space-time" in 1973. This book was for many years the standard reference for the application of global techniques in general relativity, i.e. it provided a useful resource for researchers in the field rather than being a publicity stunt. (Penrose might be referring to the Hawking personality cult that resulted from the publication of "A Brief History of Time" in 1988, but as Jane Hawking explained in her book "Travelling to Infinity: My Life with Stephen", that latter book arose from financial necessity rather than any need for attention or publicity.)

On twistors: it appears that much of the 20th century research was circulated via the twistor newsletter, and continued to be so for many years. A fellow PhD student was very interested in this material, so while on a visit to England in the early 1980s, I asked Penrose for copies. He refused to provide anything at all. So not "more likely to be friendly and helpful to others than your average academic" IMHO.

23. **Robert Cochrane**
November 20, 2024

Peter Woit and Phil H

The Twistor Newsletter was originally partly handwritten when mathematical typesetting was very difficult and was mimeographed (manually rotary stencilled) for circulation. It included work by a range of mathematicians, was not intended to replace publication and could be speculative. The editions even up to the early 1980s ran to hundreds of paper pages. To me, with memories of circulating newsletters in those days, It is not surprising that even a man of Roger Penrose' well known generosity rejected a request for copies of previous editions made on behalf of a third party.

On a more positive note, the entire archive is now freely available online thanks to the Oxford Mathematical Institute and its staff and contributors at:

https://people.maths.ox.ac.uk/lmason/Tn/

24. **Alex V**
November 20, 2024

"While Hawking often gets more attention for this, it seems that there's a good case that the creative ideas there were more Penrose's, "

After reading both papers, I was definitely left with the impression that the ideas used to prove the singularity theorems are Penrose's, while Hawking seems to have only applied those techniques to the case of a cosmological singularity.

Also, does anyone know if there has been a rebuttal to Roy Kerr's claim that the singularity theorems do not prove the existence of actual singularities?

25. **Andrzej Daszkiewicz**
November 20, 2024

Alex:
there is a video at the Phil Halper YT channel https://www.youtube.com/watch?v=foq4nVAwEao where some people, including Senovilla, Ashtekar, Warner and Penrose himself point to a crucial error Kerr made in his paper. I am not an expert, but they all seem to make a good point. Warner even plans to make it a homework problem in his future courses on GR: find the error in Kerr's argument.

26. **Scott Caveny**
November 20, 2024

Re: the singularity theorems, I'm not so sure that the "creative ideas there were more Penrose's, with Hawking much better at getting attention for his work".

In their chapter on global techniques and singularity theorems, MTW's Gravitation described in 1973 Penrose's `pioneering theorem on singularities` of 1965 as `the birth of global techniques` (employed by the primary workers in the field Geroch, Ellis, Hawking, etc).

27. **John Baez**
November 21, 2024

Kerr's argument is wrong. See this answer on Physics Stack Exchange:

https://physics.stackexchange.com/a/791566/112768

28. **Peter Woit**
November 21, 2024

All,
Sorry, but I'm not going to allow more comments debating the Kerr claims. This is a technical issue that has nothing to do with the book. From the limited amount I've done of looking into this, if there's anything there, it's a not very interesting issue about exactly what you mean by "singularity".

29. **Matthias**
November 22, 2024

On another physicist, Cambridge University Press has just released the online version of Steven Weinberg: A Life in Physics. Available here:
https://www.cambridge.org/core/books/steven-weinberg-a-life-in-physics/BB818FF83303ED57F5B1894A7CF5C178#

Recent talk at the Isaac Newton Institute by Penrose, "From the Origins of Twistor Theory to Bi-Twistors and Curved Space-Times" – https://youtu.be/wWRBX_UtIu8?si=YiySvD73D0MxAgQ1.

Brings the history up to date.

31. **Cormac O'Raifeartaigh**
November 24, 2024

I met RP once at a GR centenary conference in King's college, couldn't get over how gentle and unassuming he was. We had a lovely quiet lunch together where he asked a lot about Dias and my late father. I met him again a few days later at another historical conference in Berlin, whereupon he treated me like an old friend!

32. **Thomas**
November 24, 2024

By the way: Weinberg's memoir, just published by Cambridge press, is very interesting.

This Week’s Hype

November 22, 2024
Categories: This Week's Hype

If a post-truth field of science is going to keep going, it needs to convince funders and the public that progress is being made, so there’s a continual need for people uninterested in truth and willing to produce appropriate propaganda. This is the 142nd edition of This Week’s Hype, which has been documenting this phenomenon for the past twenty years.

Such a post-truth project requires cooperation from institutions responsible for communicating science to the public. One such is the Royal Institution which sponsored a program of pure propaganda for string theory, now available on Youtube. From the transcript:

> I’m not in propaganda mode here, and we shall avoid propaganda mode… As you see, I’m trying not to go into propaganda mode… Once again I’m in no propaganda mode, but we are fairly sure…

If a speaker four times in a talk assures you that what he’s saying is not propaganda, one thing you can be sure of is that it is propaganda.

Another part of maintaining a post-truth scientific field is that you need people willing to write propaganda “scientific” articles, institutions willing to publish such articles and venues to promote them. A good example of this is The Standard Model from String Theory: What Have We Learned? now published in The Annual Review of Nuclear and Particle Science.

The publisher of Annual Reviews has a publication called Knowable Magazine, tasked with promoting their articles, and they’ve hired Tom Siegfried to write about this one under the title String theory is not dead. By the way, if somebody is hiring journalists to write propaganda pieces entitled “Field X is not dead”, you can be sure that field X truly is dead. Siegfried has had a very long career in the string theory propaganda business, going back nearly 30 years. See for instance this posting, which has some background on Siegfried.

In his very hostile review of *Not Even Wrong* for the New York Time, Siegfried explains that I’m completely wrong about string theory’s lack of predictions:

> …string theory **does** make predictions — the existence of new supersymmetry particles, for instance, and extra dimensions of space beyond the familiar three of ordinary experience. These predictions are testable: evidence for both could be produced at the Large Hadron Collider, which is scheduled to begin operating next year near Geneva.

Like all of those in the post-truth business, having one’s “predictions” turn out to not work doesn’t have any impact at all on one’s willingness to keep the propaganda campaign going.

A good giveaway that something is propaganda is a title that indicates that you’re not going to get just information about something, but also a sales job. Today the Higgs Centre in Edinburgh has a talk scheduled with the title What is string theory and why you should care?. The idea that people at a theoretical physics center would not know what string theory is after the past forty years is pretty laughable, so clearly the point of this talk is not the first part of the title, but the “you should care” part.

Update: Video of the Higgs Centre talk by string theorist Sašo Grozdanov is now available here. As usual in such things, lots of discussion of the quantization of the single-quantized theory of a bosonic string, which connects not at all to physics. No discussion of why the much more complicated things you would need to do to try and make this look like physics simply don’t work. Grozdanov’s acknowledges criticism of string theory, but claims that it’s just “sociological”, coming from people who are too impatient. According to him (and he says he’s embodying the consensus of the field):

- “It’s the only way forward”
- “We have nothing else”
- “It’s the only thing that works”

He acknowledges there’s no connection to the real world, interprets this though as only indicating that “we’re missing something” (since alternatives are not conceivable).

   Dear Peter,

   Specifically regarding the hype on IA applications to quantum gravity/unification/theoretical physics I think this is about to go on steroids and as evidence there is this recent interview with Nobel Laureate Demis Hassabis

   https://www.youtube.com/watch?v=pZybROKrj2Q

   in the section of peer into the mysteries of the universe.

   If I remember correctly, he hopes to be able to apply it in the next 10-20 years and mentions wormholes and string theory. Luckly at least he mentions he dislikes the Multiverse….

   Leo,
   String theory hype is bad enough, last thing I want to do is get involved trying to do anything about AI hype. Took a quick listen to the Hassabis comments about the how AI and the end of all resource limit will allow us to operate at the Planck scale. Presumably the next generation DeepMind will explain to him at some point that he’s a fool.

   All, please don’t take this as an invitation to start discussing AI, the world is depressing enough as it is.

   Looking at the mostly negative comments under the video, we can see that even the general public no longer believes in string theory in recent years.

Don’t worry Woit, string theory is dying, slowly but surely

Velvet,
Yes, and this kind of thing hastens the process. A typical reaction to a “String theory is not dead” headline likely is something like “Oh, that’s interesting, I hadn’t known that the consensus is that string theory is dead.”

Peter, are you happy or unhappy with the Siegfried piece? I thought it was great – one of finest pieces of “damning with faint praise” I’ve seen in recent months.
You write that Annual Review wanted to “promote” an article with the Siegfried piece. Well, it works, but probably not as they intended. The only reason why I wanted to read their article was because of a very perverse curiosity. How do you stay a True Believer when – as Siegfried writes – basically nothing works out as planned?
It’s also telling that the title, “String theory is not dead”, is nowhere to be found in Siegfried’s piece. It feels like the work of some sub-editor who, after a desperate search, couldn’t find anything better to say about the subject.

Peter,
A good point that the title may not have been chosen by Siegfried.

Siegfried always struck me as what the string theorists might describe as a “useful idiot”, someone who had no understanding of what he was writing about, but could be relied upon to try and say something positive. That has become increasingly more difficult, so even a Siegfried at this point can only come up with praise that is rather faint.

He’s trying to portray the situation as:
” Success remains elusive, but real progress has been made. Questions plaguing physicists about not only the smallest bits of matter but also the properties of the entire universe may yet yield to string theorists’ efforts.”
where an accurate statement would be that no progress has been made, rather things have continued to go in the wrong direction.

Near the end there’s a section title “Tests are possible” which is the same dishonest bullshit that was in his NYT review of my book. Since it’s a section title, not in the main text, again this may be written by an editor, not him.
